"In Bipp treatment fewer dressings and less attention to the wound between dressings are required. Eusol is very cheap, whereas Bipp is expensive, but more dressing materials and apparatus are necessary for Carrel treatment. Bipp gives the more rapid results in most cases." Observations on the chemotherapy of bacterial infections, with special reference to experimental pneumococcus infection, C. H. BROWNING and R. GUL-BRANSEN (Jour. Path. and Bact., 22 (1919), No. 3-4, pp. 265-269).—Experimental proof is given that virulent organisms within the tissues—in the present case pneumococci introduced into the peritoneal cavity of mice—can be effectively dealt with by means of antiseptics, and that the result is obtained, not by killing the organisms through the sole agency of the antiseptic, but through some form of cooperation of the antiseptic and the tissues.

The immunizing action of sodium chlorid against the anaphylactic injection (metatrophic therapy), C. RICHET, P. BRODIN, and F. SAINT-GIRONS (*Compt. Rend. Acad. Sci.* [*Paris*], 169 (1919), No. 1, pp. 9–11).—The authors state that, while severe anaphylactic symptoms are produced in a dog by an injection of 50 cc. of horse plasma three weeks after a sensitizing injection of the same plasma, such symptoms are entirely absent if, instead of using the pure plasma for the second injection, the same quantity of the same plasma be used after dilution with nine times its volume of an isotonic solution of sodium chlorid. If an injection of the salt solution is made before the injection of the pure plasma, the amount of salt must be greatly increased owing to the extreme rapidity of the elimination of the injected salt.

The theory is advanced that the sodium chlorid impregnates the nerve cells and immunizes them against the anaphylactic poison, and the possibility is suggested of utilizing this phenomenon for the prevention of anaphylactic shock.

On the cultural characters of certain anaerobic bacteria isolated from war wounds, R. S. ADAMSON (Jour. Path. and Bact., 22 (1919), No. 3-4, pp. 345-400, pls. 5).—This paper, which forms the first part of a general investigation of the bacteriology of wounds, deals solely with the cultural characteristics of strictly anaerobic bacteria isolated from wound material, garden and pasture soil, human and horse feces, and putrefying meat.

Fifteen anaerobic organisms are described, of which 13 are spore-bearing bacilli, one a bacillus without spores, and one an anaerobic diplococcus. The spore-bearing bacilli have been classified in three groups based on their cultural reactions. The first or proteolytic group consists of *Bacillus ædematis maligni*, *B. bifermentans sporogenes*, and *B. tetanoides*. The second or saccharolytic group comprises *B. ærogenes capsulatus*, *B. butyricus*, *Vibrion septique*, *B. von Hibler IX*, and Bacillus E. The third group, possessing neither proteolytic nor saccharolytic powers, consists of *B. tetanoides* (A), Bacillus L, Bacillus S, and MacIntosh's bacillus Type III (C).

In addition to detailed descriptions of these organisms, the paper includes a table of their cultural features, a list of 39 literature references, and several plates including colored representations and photo-micrographs of some of the cultures.

Contributions to the biochemistry of pathogenic anaerobes, VI-VII, C. G. L. Wolf (*Jour. Path. and Bact.*, 22 (1919), No. 3-4, pp. 270-307).—Two papers are presented in continuation of the investigation previously noted (E. S. R., 40, p. 577).

VI. The proteolytic action of Bacillus sporogenes (Metchnikoff) and B. welchii (pp. 265–288).—In this paper the fermentation changes which take place in a cooked-meat medium inoculated with B. welchii and B. sporogenes are reported.

In a medium consisting solely of sterilized muscle and water both organisms grew with great rapidity, forming large quantities of gas consisting of carbon dioxid and hydrogen. The amount of gas formed per liter of medium was about the same with both organisms. With *B. sporogenes* from 70 to 75 per
The proteolytic power of *B. sporogenes* was much greater than that of *B. welchii.* There was also a notable difference in their volatile acid production. *B. welchii,* which forms large quantities of volatile acids in carbohydratecontaining media, did not form any considerable quantity of acid with muscle tissue while *B. sporogenes* formed large quantities of acids in both media.

VII. The biochemistry of B. proteus (pp. 289-307).—This paper includes a review of the literature on B. proteus and reports of a study of the growth of several strains of the organism on different media, the results of which are summarized as follows:

"B. proteus grown upon various media does not exhibit any of the qualities of a putrefactive organism. It is a moderate gas former, the largest amount of gas being obtained in cultures of cooked meat. Compared with putrefactive organisms such as B. sporogenes and B. histolyticus, its proteolytic activities are not great. The two strains examined attacked lactose. The analytical result gives a lactose consumption of 6.9 gm. per liter. The volatile acid production is very small. In none of the experiments was any putrefactive smell noticeable, and no indol was produced under the most favorable circumstances for its development. B. proteus contains a powerful urea-splitting ferment, being capable of transforming 45 per cent of the total nitrogen of urine into ammonia."

Some experiments dealing with the question whether lipoids can act as antigens, CHUNG YIK WANG (*Jour. Path. and Bact., 22 (1919), No. 3-4, pp. 224-228).*—Lipoidal extracts of egg white, horse serum, and ox corpuscles were made by successive two-hour extractions of the material in a shaking machine with chloroform and ether alternately. The extract after drying and immediately before use was saponified with a few drops of N/10 caustic soda and finally emulsified in saline. Tests with the lipoidal extract and with an emulsion of the residue were performed with rabbits, using the complement deviation method.

Negative results as to antigenic properties were obtained with the lipoidal extracts of egg white and horse serum, and positive results with the lipoidal extract of ox-blood corpuscles. The crude residue after the extraction of lipoids in the latter case was found to be less potent in antigenic power than the extract but to retain still some of this power. The results with the different lipoidal extracts are considered by the author to be due possibly to varying degrees of stability of union of the protein's with the lipoidal elements.

The loss of complementing power in guinea-pig serum at various temperatures, J. W. BIGGER (*Jour. Path. and Bact.*, 22 (1919), No. 3-4, pp. 323-344, figs. 10).—This paper reports the results of an investigation of the rate at which guinea-pig sera, freed from clot and cells and kept in vitro at various temperatures, lose their complementing power.

At low temperatures the rate of disappearance of complement was much slower than at higher temperatures. A 75 per cent loss occurred at  $50^{\circ}$  C. in from one-half hour to one hour, at  $30^{\circ}$  in 47.5 hours, at  $20^{\circ}$  in 87 hours, at  $9^{\circ}$  in 165 hours, and at  $1.5^{\circ}$  in 920 hours. The rate of loss of complement was more rapid in the earlier than in the later stages and at temperatures between 9 and  $50^{\circ}$  appeared to be regular.

The value of the new complement deviation method for the serodiagnosis of glanders, O. WALDMANN (Arch. Wiss. u. Prakt. Tierheilk., 42 (1916), No. 2-3, pp. 194-222).—A review is given of the literature on the complement deviation and conglutination methods for the diagnosis of glanders, followed by a report of results obtained by the authors in the Pathological Institute of the Veterinary

School (Berlin). The author is of the opinion that the complement deviation method is superior to others for the serological detection of the disease.

Note on the rapid production of serum against rinderpest and its utilization in infected regions, M. CURASSON (*Rec. Méd. Vét.*, 95 (1919), *No. 11, pp.* 323-327).—Methods employed by the author for immunization against rinderpest are described in detail.

Animals which have recently recovered from the disease are chosen for hyperimmunization, and animals at different stages of the disease are used to furnish the virulent blood. In place of a single massive injection, two inoculations of virulent blood are employed for immunization, the first coming from an animal at the end of the first stage of the disease and the second, after an interval of 3 or 4 days, from an animal at the second or third period. Each inoculation of 3 or 4 liters is in itself sufficient to produce hyperimmunity.

The blood for immunization is drawn into a sodium citrate solution in sterile bottles. The immunizing blood is drawn four times, first on the tenth day following the second virulent injection and then at intervals of four days. From 3 to 5 liters are taken each time, the blood being received in sterile bottles containing 2 gm. of potassium oxalate and 0.25 gm. of phenol dissolved in 50 or 60 cc. of water. In place of oxalated blood, blood serum to which phenol is added in the proportion of 0.25 gm. to a liter of the serum may be employed. Both blood and serum are kept cool until used.

As a preventive measure, the oxalated blood is injected in doses of 40 cc. for adults and from 20 to 30 cc. for young animals. Virus in the form of virulent blood, kept liquid by defribination or by the addition of sodium citrate, is injected at the same time in 0.25 cc. doses. If immune serum is used in place of the oxalated blood the doses should be diminished by one-half.

As a curative measure the immune blood or serum is said to be of only limited value, acting with certainty only during the first stage of the disease.

Swamp fever in Wyoming.—Economic importance, general characteristics, and control, J. W. Scorr (*Wyoming Sta. Bul. 121 (1919)*, pp. 91–140, figs. 36).— This bulletin was prepared for the purpose of bringing facts relating to the nature of swamp fever, its economic importance, how it may be recognized, and how controlled to the attention of ranchmen and farmers of the State. The author calls attention to the fact that the experiments previously noted (E. S. R., 39, p. 162) have conclusively demonstrated that the disease may be transmitted by certain biting flies, a detailed report of which work will be presented in a later paper.

Diagnosis of tuberculosis by the complement deviation method, CHUNG YIK WANG and J. CROCKET (*Brit. Med. Jour., No. 3053 (1919), pp. 7–9*).—An improvement in the method of preparation of tubercle antigen for the diagnosis of tuberculosis by complement deviation is reported which, together with certain precautions in technique, is said to have rendered the method much more reliable as a diagnostic procedure. The nonspecific reaction which other observers have obtained is attributed by the authors to the presence of lipoids in the antigens employed and to an insufficient heating of the tested serums. To obviate these difficulties the tubercle bacilli employed as antigens in the present study were freed from lipoids by 5 extractions alternately with chloroform and ether, and the serums were heated for at least two full hours at 55° C. The final technique employed and classification of results were similar to those of the Wassermann test.

The findings of the cases investigated by this method were positive in 75 per cent of the 104 tuberculosis subjects tested, and none of the controls reacted positively to the test after differentiation of Wassermann serums from tuberculosis by a chloroform differential method devised by the authors. It is,

478

therefore, considered justifiable to regard the test as specific, and to conclude in case of a positive reaction not only that the disease is present but that the lesion is in an active condition. A negative result, as in the Wassermann test, is considered significant though inconclusive.

Instructions concerning the work of the Tuberculosis Eradication Division (U. S. Dept. Agr., Bur. Anim. Indus., 1919, pp. 20).—This manual of instructions includes an outline of the three projects of the division—the eradication of tuberculosis from pure-bred cattle, from circumscribed areas, and from swine; brief descriptions of tuberculin testing by the subcutaneous, intradermal, ophthalmic, and combined methods, with an explanation of the nature of tuberculin; and directions for the identification of animals after testing, disinfection of stables, care of hypodermic syringes and clinical thermometers, ordering of supplies, etc. A list is included of the tuberculosis-eradication field offices and inspectors in charge of the same.

Contribution to the study of ulcerous lymphangitis (*Rev. Gén. Méd. Vét.*, 28 (1919), No. 329, pp. 233-243).—This is the report of a series of studies on the nature of ulcerous lymphangitis and its mode of transmission, therapy, and diagnosis. Evidence is furnished that the bacillus of Preisz-Nocard is the specific cause of the disease, and that it is possible to reproduce it experimentally by local inoculation of very small doses of a young culture of the organism, associated preferably with an inert substance such as powered charcoal. The true symptoms of the disease do not appear until about a month after the virulent injection.

The therapeutic agents studied included toxins such as mallein, tuberculin, rivoltin, etc., specific vaccines, chemical substances, serums, and surgical methods. In no case were entirely satisfactory results obtained. The various methods of treatment apparently hastened the cure of light attacks, but had little effect on extended lesions.

While the injection into the conjunctival tissue of a glycerin extract of a pure culture of the bacilli of Preisz-Nocard produced a reaction in animals afflicted with the disease, such a reaction is not considered specific as an edema was also produced at the point of inoculation in healthy animals.

Abortion disease of cattle, W. E. COTTON (*Jour. Amer. Vet. Med. Assoc.*, 55 (1919), No. 5, pp. 504-528).—This paper, delivered before the veterinarians of Indiana, summarizes the present status of knowledge of contagious abortion of cattle.

Infectious abortion and sterility in cattle, E. T. HALLMAN (*Michigan Sta. Circ. 40 (1919)*, *pp. 3-7*).—This is a popular summary of information.

A new nematode causing parasitic gastritis in calves, A. L. SHEATHER (Agr. Research Inst. Pusa Bul. 86 (1919), pp. 5, pls. 5).—A discussion and description of an undescribed nematode, found in immense numbers in the fourth stomach of several calves which had died showing all the symptoms associated with parasitic gastritis.

The results of investigations of hemorrhagic septicemia in sheep in Colorado, I. E. NEWSOM (*Amer. Jour. Vet. Med.*, 14 (1919), No. 7, pp. 371-377).— The author gives an account of several of the 24 outbreaks of this disease investigated.

Tick eradication laws, R. C. KNOX (*Arkansas Sta. Bul. 160 (1919)*, *pp. 16*).— A compilation of Arkansas laws relating to tick eradication, together with the regulations of the board of control, with notes on these laws and regulations prepared by R. M. Gow.

Parasitic diseases, S. HADWEN (Jour. Amer. Vet. Med. Assoc., 54 (1919), No. 6, pp. 639-642, figs. 3).—Following reference to the article on ixodic lymphan-

gitis by Jarvis, previously noted (E. S. R., 38, p. 785), the author presents data to show that ticks, particularly *Dermacentor albipictus* and possibly also *D. venustus*, play an important part in the production of fistulous withers among unbroken range horses in sections of British Columbia.

Investigations on the pathological anatomy of infectious anemia of the horse, I. KANI and K. KIKUCHI (Bul. Imp. Col. Agr. and Forestry, Japan, No. 3, (1917), pp. 34, pls. 6).—This report includes a detailed account of 5 cases studied.

The etiology of an epidemic among horses (meningo-encephalitis enzootica; Borna disease), R. KRAUS, G. FISCHER, and L. KANTOR (*Rev. Inst. Bact.* [*Argentina*], 2 (1919), No. 1, pp. 114–118, pls. 6, fig. 1).—The authors show for the first time that Borna disease occurs in Argentina. The lesions in the brain and the cultures correspond to the descriptions given by Joest and Degen (E. S. R., 26, p. 786) and Johne.

Observations with regard to the etiology of joint-ill in foals, J. M'FADYEAN and J. T. Edwards (*Jour. Compar. Path. and Ther.*, 32 (1919), No. 1, pp. 42-71).—In continuation of the investigations previously noted (E. S. R., 39, p. 891) the authors report upon 37 cases at some length.

The bacteria encountered in the cases described fall into four groups, namely, strepticocci, *Bacillus nephritidis equi*, *B. abortivo-equinus*, and coliform bacilli. In 20 of the 37 cases examined the indications are that streptococci was the cause of the lesions, since they were more or less abundantly present in the diseased joints, and occurred there in a state of purity or accompanied only by an inconsiderable number of other bacteria whose presence could reasonably be regarded as accidental. *B. nephritidis equi* was apparently by itself in causing the disease in four cases and was present in three others. *B. abortivo-equinus* was the cause of the disease in two of the cases. *B. coli communis*, or organisms closely resembling it, was probably the cause of the disease in four cases, and possibly in a fifth.

Studies on anthelmintics.—I, Experiments with repeated doses of oil of chenopodium, M. C. HALL (Jour. Amer. Vet. Med. Assoc., 55 (1919), No. 4, pp. 416-423).—Experiments are reported which were conducted with a view to determining the method in which chenopodium can be successfully employed against the hookworm in the dog and to secure further data on its anthelmintic action.

The results indicate that chenopodium in repeated doses of 5 minims daily for 12 doses is rather efficacious against ascarids, whipworms, and probably hookworms. It has no equal as a drug for the removal of ascarids, since it will in a great majority of cases remove 100 per cent of the worms present in the dog and is apparently about as effective under proper conditions of administration against ascarids of man and swine.

Studies on anthelmintics.—II, The anthelmintic and insecticidal value of carbon bisulphid against gastrointestinal parasites of the horse, M. C. HALL, M. J. SMEAD, and C. F. WOLF (Jour. Amer. Vet. Med. Assoc., 55 (1919), No. 5, pp. 543-549).—The authors present data that lead to the conclusion that carbon bisulphid was 100 per cent effective against bots and ascarids, namely, Gastrophilus nasalis, G. hamorrhoidalis, and Ascaris equorum (A. megalocephala). "In our experiments, it was uniformly 100 per cent effective against bots, removing all of 690 bots from the 6 infested animals, and usually 95 to 100 per cent effective against ascarids, removing (approximately) 91 of 94 worms from the 8 infested animals, or almost 97 per cent.

"Carbon bisulphid gives as good results in 1 6-dram dose as in 2 4-dram doses or 3 3-dram doses, and it is likely that the smaller sum total of drug in the one dose is to be preferred to the greater total in several doses, especially as the gastric lesions seem less pronounced with the 1 dose. It is quite possible that further experiment will show that a single dose even smaller than 6 drams will be adequate."

A mycosis of turkeys, R. G. ARCHIBALD (Jour. Compar. Path. and Ther., 31 (1918), No. 4, pp. 257-260, figs. 4).—This report relates to a disease in a flock of young turkeys in Nyasaland. The affection, in which lumps appeared on the heads and necks and occasionally on the knee joints, had a predilection for young birds, usually attacking those between 6 days and 7 months old, with a case mortality of 75 to 85 per cent, while older birds rarely acquired the disease. Macroscopically and histopathologically the lesions showed a striking similarity to epithelioma contagiosum avium.

# RURAL ENGINEERING.

**Operation and maintenance of irrigation systems,** S. T. HARDING (New York: McGraw-Hill Book Co., Inc., 1917, pp. XII+271, pls. 12; figs. 28).—This is a practical treatise on the operation and maintenance of irrigation systems, based on data derived from such practice in the Western States. The general features of maintenance are first discussed. The maintenance of irrigation structures is next taken up in some detail, together with the important features in the organization for operation and maintenance. Considerable space is devoted to methods of delivering irrigation water and measurement of irrigation water. Final chapters cover rules and regulations for operation and cost accounting.

**Reclaiming** the arid West, G. W. JAMES (*New York: Dodd, Mead & Co.,* 1917, pp. XXII+411, pls. 48).—This is a popular treatise on the work of the founders, organizers, and present workers of the U. S. Reclamation Service, and includes descriptions of the main reclamation projects.

Irrigation opportunities in Russia are great, V. V. TCHIKOFF (*Engin. News. Rec.*, 82 (1919), No. 4, pp. 190–192, fig. 1).—The author reviews the irrigation situation in Russia, stating that the chances for both public and private enterprises are good. Cotton is the principal crop of arid Russia, and agriculture is conducted on the steppes by dry farming methods. Irrigation in Russia is confined mostly to the southern part, which is arid and semiarid. About 10,000,000 acres are irrigated in the arid region. Pumping plants are operated here and there, but more than 99 per cent of the irrigation is from gravity canals. In the semiarid regions it is stated that the proper storage of water, an increase in the use of underground water, and the use of economical irrigation methods are necessary for future success.

Measurement of irrigation water (*Washington: Dept. Int., U. S. Reclam. Serv., 1918, pp. 53*).—This pamphlet contains tables showing discharge through weirs and orifices and acre-feet equivalents to a given number of second feet of flow.

Pumping for irrigation, J. B. MARCELLUS (Kans. Agr. Col. Ext. Bul. 17 (1918),  $p\dot{p}$ . 16, figs. 2).—This bulletin gives popular advice on the selection and installation of an irrigation pumping plant, based on observations from the various pumping experiments conducted in the Arkansas River Valley.

Electrically driven high-lift centrifugal pumps supply water for irrigation, B. P. FLEMING (*Engin. News-Rec.*, 82 (1919), No. 2, pp. 74–79, figs. 4).—This article describes the design and construction c. 2 new high-lift irrigation pumping plant with steel manifold and reinforced concrete force main, and reports efficiency tests. The amount of water necessary to be supplied by pumping was estimated at 10,000 acre ft., to be supplied within a period of 50 days. A plant of 4 horizontal centrifugal units of 25 sec. ft. capacity each was selected. Each unit was attached by flexible coupling to a 350 hp., 3 phase, 60 cycle induction motor using current at 440 volts. In the tests it was found that all the units exceeded the required efficiency of 81 per cent at 90 ft. head.

"As a whole the efficiency tests of this plant illustrate the recent very remarkable advance in centrifugal pump design from the standpoint of efficiency, and give reason to believe that it is not too much to expect that in the case of large units, working under reasonably high heads, 85 per cent efficiency may be obtained where the character of the installation is such as to warrant the extra expense of a pump designed for the special conditions under which it is to operate. Such efficiency can only be obtained by the use of small running clearances in the impeller at the wearing ring, which prevent leakage from the discharge back to suction; and the water seal preventing air leakage into the suction passage around the shaft must be perfectly air-tight. Wear is to be expected in the course of time in the wearing rings, and the glands can not be maintained in perfect condition after a long period of use, so that to maintain the high efficiency found when the installation is new it will be necessary to renew from time to time the wearing rings and the bronze sleeves on the shaft."

**Transforming canal losses in terms of depth to quantity**, P. A. CUPPER (*Engin. News-Rec.*, 81 (1918), No. 5, p. 220, fig. 1).—Graphic data are given showing the seepage loss in irrigation canals in second feet per thousand feet length of canal for wetted perimeters from 0 to 100 ft. for a loss of 1 ft. in depth over the wetted canal area in 24 hours.

Computing the lateral pressure of saturated earth, A. G. HUSTED (Engin. News-Rec., 81 (1918), No. 10), pp. 441, 442, figs. 2).—The author proposes a method of computing the lateral pressure of saturated earth which is based on the usual dry earth formula but takes account of the separation of hydrostatic from earth pressure and allows full hydrostatic pressure. Thus, the vertical earth pressure is obtained by adding the total weight of earth above the plane of saturation to the net weight of earth below the plane of saturation; the lateral earth pressure is obtained by multiplying this vertical pressure by tan<sup>2</sup>  $(45^{\circ} - \frac{1}{2} \phi_2)$  in which  $\phi_2$  = the angle of repose of earth under water; and the total lateral pressure is obtained by adding the hydrostatic pressure to this lateral earth pressure.

Inexpensive cypress lath subirrigation plan (Okla. Agr. Col., Ext. Div. Circ. 72 (1918), pp. 4, figs. 5).—This circular gives brief instructions for the use of cypress lath in the construction of subirrigation laterals.

Agricultural drainage, T. J. EVANS (Florence, Ala.: Author, 1918, pp. 35, figs. 2).—This pamphlet is a prospectus of a more elaborate work on the subject to be issued later. Its purpose is to secure the opinions of professional men and to interest those contemplating drainage projects.

Synopses of drainage laws, J. S. SMITH ET AL. (*Columbia, Mo.: E. W. Stephens Pub. Co., 1918, pp. 365*).—This handbook contains a brief outline of the drainage laws of each of 24 States.

Farm drainage (Ann. Rpt. Dept. Agr. Prince Edward Island, 1917, pp. 35–48, pls. 3).—This report deals with the underdrainage of agricultural lands with special reference to conditions on Prince Edward Island. It is estimated that there are 200,000 acres on the island that could be profitably drained. Under average conditions it is estimated that drainage costs about \$30 per acre. Features of drain construction are discussed.

Use of dynamite in antimalarial drainage operations, J. K. HOSKINS and W. E. HARDENBURG (*Pub. Health Rpts.* [U. S.], 33 (1918), No. 47, pp. 2052, 2053).—It was found that in antimalarial drainage work with dynamite the best results were obtained in mucky areas where the mud was so deep and soft that hand excavation became slow and difficult. An analysis of the costs of two adjacent ditches in a large swamp, one excavated with dynamite and the other with hand labor, is given. The yardage of the dynamited ditch was 4,151 and of the hand dug ditch 1,956. The cost per cubic yard of the dynamited ditch was 39 cts. as against 45 cts. per cubic yard for the hand dug ditch. The method of using the dynamite is described.

Segment blocks have advantages on larger size drains; D. L. YARNELL (*Engin. News-Rec.*, 82 (1919), No. 14, pp. 663, 664).—An investigation of the use of segment block for large size drains, made by the Bureau of Public Roads of the U. S. Department of Agriculture is reported from which it is concluded that owing to their cost, lightness, and convenience of handling, and structural advantages over tile their use for large size drains should increase.

Progressive erosion in a dredged drainage channel, C. E. RAMSER (Engin. News-Rec., 82 (1919), No. 18, pp. 876, 877, figs. 6).—Observations on enlargement and effect on capacity due to erosion in the North Fork Deer River drainage channel, made by the Office of Public Roads of the U. S. Department of Agriculture, are reported. Measurements of six cross sections of a portion of the channel constructed in May, 1915, were made along a course of 700 ft. in April, 1916, and in January, 1917. A comparison of the plotted cross section showed that after a certain amount of erosion had taken place in the channel erosion did not tend to increase the irregularity of the channel.

"Between April, 1916, and January, 1917, the average cross-sectional area of the channel increased from 331 to 409 sq. ft. The values of n in Kutter's formula obtained for high stage during the years of 1916 and 1917 were 0.0271 and 0.267, respectively, from which it is seen that the roughness coefficient was practically the same before and after the erosion occurred."

"The mean velocities in the channel were about 4.5 ft. per second, and the discharge capacities for 1916 and 1917 were 1,473 and 1,881 sec.-ft., which represents an increase of 27.7 per cent for the period from April, 1916, to January, 1917. The increase in cross-sectional area was 23.5 per cent, which is less than the percentage of increase in capacity."

It is noted that in the design of this channel no provision was made for **a** run-off rate to give satisfactory drainage at the beginning, the probable effect of erosion being foreseen and a considerable financial saving being effected thereby.

Inspection of drainage ditch cross-sections after contract dredging, E. S. BLAINE (*Engin. News-Rec.*, 82 (1919), No. 21, pp. 1019–1022, figs. 7).—This article describes and explains the development of methods for examination of cross sections of drainage ditches after contract dredging. Soundings at first made by level rod gave way to lead and line following along a tape, the boat in use by the sounding man being pulled across the ditch by means of the tape.

The water supply of Egypt, 1913–14, B. F. E. KEELING (*Trans. 3. Internat. Cong. Trop. Agr. 1914, vol. 2, pp. 370–380, figs. 5*).—The hydrography of the Nile and methods of water supply for irrigation are discussed and attention drawn to the abnormal dearth of water during 1913–14. Data are submitted to show that under such conditions the rice crop must be sacrificed in favor of the cotton crop.

Drinking water (*Rpt. Min. Agr. Prov. Quebec, 1917, pp. 100–102*).—Sanitary analyses of 13 samples of water from domestic drinking supplies are reported and briefly discussed. Eleven of the samples were found to be contaminated and one was considered doubtful. Details on the bacterial flora of three of the samples are reported, from which it is concluded that "such waters could only disseminate disease and multiply the consumer's liabilities."

Water purification, J. W. ELLMS (New York: McGraw-Hill Book Co., Inc., 1917, pp. X+485, pls. 6, figs. 168).—It is the purpose of this book to provide the

reader with as nearly as possible a complete account of the development of the art of water purification. Consideration is first given to the physical, chemical, and biological properties and characteristics of various classes of water. The relation of polluted public water supplies to water-borne diseases is given special attention. The various steps in purification processes such as plain sedimentation, coagulation, filtration, and disinfection are described in considerable detail. Special chapters are devoted to water softening and to the removal of iron and manganese from ground water supplies.

Water systems for farm homes, F. C. FENTON (Univ. Missouri, Agr. Ext. Serv. Circ. 49 (1918), pp. 16, figs. 13).—This is a brief popular bulletin on the subject, prepared with special reference to Missouri conditions. In addition to the pneumatic system of water supply the so-called autopneumatic system, the value of which has been much under discussion, is described as having been in actual operation and having been found practical. It is stated, however, that "many such systems have been in operation for years and are giving excellent satisfaction, while others have given considerable trouble. Taking everything into consideration, it can not be considered as reliable as some of the other systems."

The relation of the shrinkage and strength properties of wood to its specific gravity, J. A. NEWLIN and T. R. C. WILSON (U. S. Dept. Agr. Bul. 676 (1919), pp. 35, pls. 5, figs. 16).—This bulletin reports data on the relations of the strength properties of woods to their specific gravity in such form as to render them easily useful (1) for estimating the properties of any particular timber, (2) for selecting timber for any given purpose, (3) for comparing the various species, and (4) for determining to what uses different species are best adapted.

Analyses of over 200,000 tests, made at the Forest Products Laboratory at Madison, Wis., indicated a fairly constant relation between specific gravity and strength.

It was found in plotting the strength values in different tests to a natural scale that in practically every case a curve was formed corresponding to the general equation  $f=p \ G^n$ , in which f is the strength value, G the specific gravity, and p and n are constants. Curves, equations, and data are given for shrinkage, static bending, impact bending, compression, hardness, shearing, and tension for both green and air-dry wood.

The table on the opposite page gives equations for shrinkage and for each of the strength properties of green and dry wood in terms of specific gravity.

"In comparing different timbers or species, in estimating their various properties, and in finding species with exceptional strength in some properties which may render them valuable for special uses, a knowledge of the specific gravity strength relations is a valuable aid. . . . Such equations can never take the place of tests of species whose properties are unknown. If any particular mechanical property is known, the specific gravity may be approximated and the other properties estimated; even the properties of woods upon which no test data are available can be estimated with a fair degree of accuracy from the results of specific gravity determinations. Nevertheless, it is apparent from a study of the table and diagrams that no one kind of test can replace a complete series of tests."

Wear-resisting values of various aggregates for concrete roads indicated, H. S. MATTIMORE (*Engin. News-Rec., 80 (1918), No. 18, pp. 861–863, figs. 12).*— An impact testing machine designed to measure the resistance to impact of different materials and mixes entering into the construction of concrete roads is described and illustrated, and tests conducted by the New York State Highway Commission on the impact resistance of several hundred different aggregates and mixes are summarized.

	Condition of wood,		Green.	dry.

Equations for shrinkage and for each of the strength properties of green and air-dry wood in terms of specific gravity.

It is concluded that "(1) crushed stone remains intact and resists impact better than gravel. (2) Large size stone and gravel are more durable than the small sizes. (3) The resistance to impact depends upon the quality of both the mortar and the coarse aggregate and, although a good matrix has a tendency to support a weak coarse aggregate, the use of a good quality of the latter will make a more durable pavement. (4) A coarse-grained sand mortar resists impact better than a mortar made with finer-grained sand. (5) No relation has been observed between compressive strength and resistance to impact... An increase of cement content increases resistance to wear, but with a proper selection of aggregates of excellent quality a 1:2:4 mix can be made which will offer a better resistance to impact than a poorer quality of aggregate mixed 1:1.5:3."

Effect of tractive resistance in terms of gasoline consumption (*Engin. and* Contract., 51 (1919), No. 19, p. 482, figs. 3).—Three charts are given showing the relation between tractive resistance of road surface, annual cost of roadbed, and grade on gasoline consumption for motor vehicles.

An economic study of the gas tractor in Pennsylvania, D. S. Fox (*Pennsylvania Sta. Bul. 158* (1919), pp. 3-20, figs. 5).—This bulletin reports data derived from detailed records secured from 54 farms in central and southeastern Pennsylvania, on which gas tractors were operated during the year ended in the spring of 1918. Tractors were used chiefly on the larger farms, 123 acres of crops per farm being the average. The average purchase price was \$959, and the average estimated life of the tractor was 8.1 years. Kerosene at 12 cts. per gallon was a cheaper fuel than gasoline at 25 cts. The cost per 10-hour day was \$2.06 for kerosene and \$3.32 for gasoline, and per horsepower hour 2.2 and 3.1 cts., respectively.

The average tractor did 50.6 days' work. There was an average of 12.8 days of plowing, 9.3 days of harrowing, and 19.6 days of belt work. The average tractor used a little over 1 gal. of cylinder oil worth 45 cts. for each 10-hour day. The average cost of operation including operator's labor was \$622.12 for 50.6 days, or an average of \$12.30 per day. The cost excluding the operator's labor was \$495.62, or \$9.80 per day. The size of farm was increased in only two cases, and more intensive crops were grown on only 7 farms of the 52 that were operated before the purchase of the tractor.

The most important factor affecting the cost of operation was days of work done per tractor. Tractors working 30 days or less, or an average of 24.3 days, cost \$19.97 per day, while tractors working over 70 days, or an average of 84.9 days, cost only \$9.85 per day. In the second case the overhead cost was distributed over more days of work.

The average tractor cost of plowing was \$2.33 per acre. The plow cost was 71 cts, per acre, making a total of \$3.04. The tractor cost for harrowing and disking was 69 cts. per acre for once over the ground, and excluding the cost of tillage implements used.

The farmer's son was the most efficient operator. The average cost per day was as follows: Son \$10.75, owner \$12.16, and hired man \$12.82. An average of 1.8 horses were disposed of on 48 farms. The cost of operation, less the operating labor, was \$275.34 for each horse displaced.

There was a change in layout on only two farms. The fields on most farms, however, should be rearranged for efficient tractor operation.

Tractor test on the university farm, J. A. HOWENSTINE (Agr. Student, 24 (1918), No. 9, pp. 542, 543, fig. 1).—A test was conducted on a 12–20 h. p. tractor plowing 8 in. deep on heavy black clay soil at the Ohio State University. Kerosene was used for fuel, gasoline being required only for starting and priming. A three-bottom gang plow and a harrow were used. The average speed was

1.66 miles per hour, and 0.401 acres were plowed per hour. The fuel consumption per acre was 3.71 gal. of kerosene, and the cost per acre plowed and harrowed was 70.9 cts.

Demonstrations of tractors and plows (*Trans. Highland and Agr. Soc. Scot.*, 5. ser., 30 (1918), pp. 295-358, figs. 29).—This is a report of tests of 29 different tractors with a number of types of plow on stubble and grass land, consisting in one case of a deep free loam with occasional earth-fast stones and in another of a free loam overlying a clay subsoil. The stiffest grade encountered was 1 in 5.2. Of the 29 machines which took part in the demonstration 15 ran on four wheels, 6 on three wheels, 4 on caterpillar tracks, and 4 were single unit machines. Twenty-five machines were driven by paraffin, 3 by petrol, and 1 by steam. The weights varied from less than 3,000 lbs. to over 8,000 lbs. The depth of plowing required varied at the different points from 6 to 8 in. for grass land and from 7 to 9 in. for stubble. The general conclusions derived from the results of this test are as follows:

The weight of the tractor should not exceed 3,000 lbs., and the horsepower should not be less than 20-brake horsepower. Caterpillar tracks did not show any advantage in gripping power over the best type of wheels. Well designed spuds appeared preferable to either spikes or bars on wheels. Exposed gear drives on wheel tractors and excessive wear on caterpillar tracks tended to impair durability. Spring attachments between tractor and plow, with a release device in case of severe shocks, appeared desirable. It was found that the point of attachment should be variable vertically and horizontally. Speeds of  $2\frac{1}{2}$  and 4 miles per hour forward, with reverse, appeared to be most generally useful. Complete vaporization of paraffin was not generally obtained, and it is thought probable that the use of petrol will be more satisfactory under normal conditions. Handling and turning did not usually prove difficult. Single unit machines had the advantage that the implement operated was directly under the observation of the driver. Lighter tractors and single unit machines occupied less time and space in turning. It was found that plows must be adjustable to varying widths as well as to varying depths. Where the tractor and plow were separate an automatic lift was found desirable. Α guide wheel to regulate width of leading furrow was also found desirable. It is concluded further that under the conditions of the test the price of a tractor should not exceed £300 (less than \$1,500).

Homemade header attachment, F. E. FULLER (Mont. Col. Agr. Ext. Serv. [Pub.], No. 27 (1918), pp. 4, figs. 2).—A homemade header attachment for the ordinary binder is briefly described and illustrated.

Potato planting machinery in New York, E. V. HARDENBURG (Cornell Countryman, 16 (1919), No. 2, pp. 75, 76, fig. 1).—It is stated that approximately 75 per cent of the acreage in the four principal potato areas of New York is planted by machine planters.

A study of comparative costs of machine and hand planting on 360 potato farms showed that machine planting was more economical on farms producing 5 acres or more of potatoes. A study on 635 farms of the potato yields obtained from the use of one and two-man planters showed, with one exception, that the yields per acre were higher where two-man planters were used.

Farm mechanics, H. A. SHEARER (*Chicago: Frederick J. Drake & Co., 1918, pp. 250, figs. 239*).—This is a popular treatise on machinery and its use in the saving of labor on the farm, and includes sections on tools, shopwork, driving and driven machines, farm waterworks, and sewage disposal, and care and repair of farm implements. It is obvious that considerable of the information has been compiled from somewhat out-of-date publications.

140363°-19-7

The farmer his own builder, H. A. ROBERTS (*Philadelphia: David McKay*, 1918, pp. 302, pls. 11, figs. 171).—This is a popular reference book describing methods and presenting suggestions, details, formulas, and rules for estimating labor and materials for the construction of dwellings, barns, and other farm buildings, together with their accessories, with special reference to concreta and carpentry.

The homemade stave silo, L. S. CORBETT and E. W. MORTON (Univ. Maine Ext. Bul. 118 (1918), pp. 13, pl. 1).—This bulletin discusses silo construction with special reference to Maine conditions, and describes and illustrates a type which it is stated may be constructed in the State with farm labor and at low cost.

Pit silos for New Mexico, J. E. WATT (N. Mex. Col. Agr., Ext. Serv. Circ. 30 (1918), pp. 16, figs. 8).—General information on the construction and cost of pit silos is given with special reference to New Mexico conditions,

The silo, F. W. IVES (Agr. Col. Ext. Bul. [Ohio State Univ.], 14 (1918–19), No. 4, pp. 24, figs. 22).—This bulletin gives general information on the construction and cost of silos with special reference to Ohio conditions.

A silo for every farm, E. L. WESTOVER (*Oreg. Agr. Col., Ext. Bul.* 297 (1918), *pp.* 15, *figs.* 16).—This bulletin gives general information on silo construction with special reference to Oregon conditions, and describes and illustrates the wooden-hoop and re-saw types of silo. It is stated that either type should not cost more than \$1.50 per ton capacity in the State.

Suggestions for selecting and building a silo, S. I. BECHDEL (*Penn. State*, *Col. Ext. Circ.* 72 (1918), pp. 32, figs. 21).—General information on silo construction is given with special reference to Pennsylvania conditions.

Silos: Types, relative costs, ensilage crops, machinery for ensilage crops, silage facts and factors (*Wyo. Farm. Bul.*, 8 (1919), *No. 10-12, pp. 32, figs. 24*).—This bulletin deals with silos and their construction with special reference to Wyoming conditions, and gives information regarding silage cutting, silo filling, etc.

How to cure hams, bacons, and other pork products, L. Foot (Col. Agr. Univ. Ark., Ext. Circ. 52 (1918), pp. 40, figs. 12).—This is a handbook of instructions for ice plants, cold storage, meat markets, and other plants having refrigerating facilities.

Bill of materials and building plans for the Clemson sweet potato storage house, G. P. HOFFMANN and G. E. PRINCE (*Clemson Agr. Col. S. C., Ext. Circs.* 10-11 (1918), pp. 2 each, pl. 1).—Detailed drawings, specifications, and a bill of materials for sweet-potato storage houses of approximate capacities of 1,000 and 2,000 bu, are given.

The self-feeder for pork production, L. R. HIGHFILL (Univ. Fla. Div. Agr. Ext. Bul. 20 (1919), pp. 8, figs. 7).—This bulletin describes and illustrates self-feeders for hogs. These consist mainly of a hopper for holding the feed, below which is a trough into which the feed flows from an adjustable opening.

The farm poultry house, C. E. SEITZ and N. E. B. TALCOTT (Va. Polytech. Inst. Ext. Bul. 37 (1918), pp. 14, pls. 3, figs. 10).—This bulletin enumerates the essential features of poultry house construction with special reference to Virginia conditions, and describes and illustrates the combination roof poultry house, the shed roof poultry house, and the colony house.

Housing farm help, R. S. WHITING (Nat. Lumber Manfrs. Assoc. [Pub.], Gen. Ser. No. 76 (1918), pp. 24, figs. 23).—This pamphlet describes and illustrates and gives plans of farm dwelling houses. It is based largely on work done by the agricultural engineering divisions of the State colleges and the Rural Engineering Division of the U. S. Department of Agriculture. Farm sewage disposal for Idaho conditions, J. C. WOOLEY (Univ. Idaho Ext. Bul. 20 (1918), pp. 12, figs. 10).—This is a very brief description of the construction of sewage disposal systems which presumably are considered adequate to meet all rural conditions in the State of Idaho.

A portable privy for use in field service, T. H. D. GRIFFITTS (*Pub. Health Rpts.* [U. S.], 33 (1918), No. 30, pp. 1225, 1226, pls. 2).—A portable privy is described and illustrated which is designed for the use of laborers employed at work and required to move from place to place.

Electricity on the farm, M. CREESE (*Md. Col. Agr. Ext. Serv. Bul. 9* (1917), *pp. 145–176, figs. 22*).—The purpose of this bulletin is to show the possibilities of the use of electricity on the average Maryland farm and to illustrate the applications of electricity for light and power. Lighting plans for the farm house and barn are also given.

# RURAL ECONOMICS.

The place of agriculture in reconstruction, J. B. MORMAN (New York: E. P. Dutton & Co., 1919, pp. IX+374).—Soldier land settlement policies of ancient Rome and the encouragement given to the matter by Great Britain, France, and Canada are the subjects of earlier chapters. Sources of information for analysis of the latter situations are respectively the program of the British Labor Party and the British Government plan of small holdings and profit-sharing as administered by the Board of Agriculture and Fisheries; the text of the French law of April 9, 1918, and subsequent decrees and a pamphlet of instructions concerning it; and the provisions of the Canadian Land Settlement Act and the plan for vocational training under direction of the Department of Soldiers' Civil Reestablishment.

The policy of the Secretary of Interior, land settlement acts proposed for the United States, and propositions by farmers' organizations are described in detail. The author urges a national policy of agriculture and land settlement for the United States which shall provide for the employment of returned soldiers, insure production on the unused acres in order to meet the needs of the entire Nation, furnish mortgage and personal credit, facilitate land purchase, and train farm laborers.

The land and the soldier, F. C. Howe (*New York: Charles Scribner's Sons*, 1919, pp. XI+196).—The principles of Government promotion of farm colonies and its practicability, as illustrated by the Durham State Land Settlement in California and by similar projects in foreign countries, Australia, Denmark, Ireland, Germany, and Russia, are discussed. The author points out what he considers to be the advantages of such socialized farming in establishing returned soldiers, spreading efficient agricultural practice, and offering remedies for the evils of usury, land monopoly, and farm tenancy. He sets forth in detail matters of selection of sites, plans of the communities, and means of financing and securivg credit to the colonists.

Information regarding progress under the Land Settlement Act of the State of California and about the plans for soldier settlement in the future (Sacramento: State Land Settlement Bd., 1919, pp. 43, figs. 12).—This gives a detailed description of the Durham State land settlement from the passage of the State Land Settlement Act, and of progress up to May 30, 1919. See also a previous note (E. S. R., 40, p. 591.)

The place of agriculture in modern industrial society, I-II, E. G. NOURSE (Jour. Polit. Econ., 27 (1919), Nos. 6, pp. 466-497; 7, pp. 561-577).—From a discussion of two philosophies, termed the extravagantly agrarian and the strictly mercantilist, the author approaches the theory of the conciliation of agriculture

[Vol. 41

He shows in turn that France has been compelled to adopt a harmonious adjustment of her agriculture and commerce; that England has pursued a commercial policy involving the sacrifice of her agriculture; and that Germany has followed the course of State intervention to insure a balance between agriculture and industry for military expediency. He claims that the tendency in the United States has been to avoid any conscious policy, with the result that agriculture was approaching a position subservient to industry at the beginning of the war, and he advocates stabilizing our agriculture by guarantying to it equal favor with industry in education, capital, and organization.

Food production in the United Kingdom (War Cabinet [Gt. Brit.] Rpt. 1917, pp. 156-165).—This chapter contains the report of the British War Cabinet as regards increased agricultural production, and the main problems that confronted the Boards of Agriculture in carrying out the program for production.

Food production and its problems for the consumer (Min. Reconstr. [Gt. Brit.], Reconstr. Prob. [No.] 14 (1919), pp. 22).—Statistics are given to show that the number of the population fed from products of the soil of the United Kingdom has been growing continually smaller since the first complete census in 1801. The fact that a smaller number of persons is fed from the cultivated land of the United Kingdom than from that of Germany is explained by the greater proportion of land under grass in the United Kingdom. The author maintains that, if the home-grown food supply is to be increased, the farmer must be assured of a settled policy in regard to education, credit, and insurance against the risks incurred in arable farming.

Rural industries (Min. Reconstr. [Gt. Brit.], Reconstr. Prob. [No.] 13 (1919). pp. 13).—Certain trades are described as rural industries and as means of providing alternative occupations and increased income for agriculturists. Assistance for this development through propagandist societies and a certain amount of State aid is recommended for Great Britain.

Rural economy of France, H. M. CONACHER (Scot. Jour. Agr., 1 (1918), No. 4, pp. 442-450; 2 (1919), Nos. 1, pp. 49-59; 2, pp. 203-212).—This article relates to the conditions of the rural economy of France in the nineteenth century and the effects of the French Revolution upon agricultural practices, this information being derived mainly from the Rural Economy of France since 1789, by De Lavergne. It reviews, also, characteristics of the later agriculture, especially of the systems of landholding by various departments, as exhibited in La Petite Propriété Rurale en France, previously noted (E. S. R., 22, p. 395), and the land tenure and principal agricultural industries of the Seine-Marne Basin.

[German agriculture after the war], STIEGER (Jahrb. Deut. Landw. Gesell., 31 (1916), pp. 134–149).—Discussing methods of increasing the supply of agricultural labor in Germany, the author advocates piecework for the permanent workers; utilization by industrialized farms during the busy seasons of the labor bands of transients leaving their own small holdings in search of temporary labor, also of children of school age when not in attendance at school, and of students, teachers, and artisans when on vacation; the adaptation of now useless war machinery for use in agriculture; and other remedies.

A practical scheme of agricultural organization and rural reconstruction in Bengal, G. S. DUTT (Bengal, Bihar, and Orissa Coop. Jour., 4 (1919), No. 6, pp. 440-459).—This contains extracts from an address in which branch agricultural associations of the agricultural association of the district of Birbhum in the Province of Bengal are described as propagandist and organizing bodies for the purchase and dissemination of seeds and fertilizers, for supplying credit to members, and for advancing practical agricultural education. The 1919]

author urges support for the cooperative movement and a central organization for these associations along the plan of central agricultural societies in Japan and Denmark.

The consolidation of agricultural holdings in the United Provinces, H. S. JEVONS (Agr. Jour. India, 13 (1918), No. 2, pp. 222-230; 14 (1919), Nos. 1, pp. 49-64; 2, pp. 331-349, pl. 1, figs. 2).—The author outlines the necessity of a regrouping of the land holdings in India to increase the supply of agricultural products. He maintains that there should be established demonstrations of improved agricultural methods to be continued for a period of years, and that the increase of agricultural products and the resulting permanently higher standard of living. He discusses the custom of cultivating scattered holdings as a stage of the evolution of primitive society; describes the enclosure movement in England; and then sketches the advantages and procedure in developing in India a new type of rural village, enlarging and consolidating holdings, providing for surplus population, replanning of roads, and the cost of reorganization.

Organization of the village, D. NEWTON (Jour, Bd. Agr. [London], 26 (1919), No. 3, pp. 247-254).—In a résumé of a paper read before the Agricultural Club, the author reviews provisions in the Land Settlement (Facilities) Bill for advancement of communal life in the villages, discusses critically some proposals of the Agricultural Policy Subcommittee for rural development and village organization, and outlines alternative proposals as to methods of procedure and essential and desirable requirements.

Function of the departmental agricultural labor bureaus, A. DUMONT (*Vie* Agr. et Rurale, 9 (1919), No. 12, pp. 211, 212).—The purpose, constitution, resources, functions, and sources of the labor supply handled by the departmental agricultural labor bureau in France are briefly described.

Cooperative credit operations under the Rural Credits Act, E. A. WEIR (Agr. Gaz. Canada, 6 (1919), No. 1, pp. 43-46).—A report of money loaned and for what purpose, methods, and achievements up to November 1, 1918, of ten societies in Manitoba.

Cooperation in agriculture in Italy, A. TARLI ( $L^{2}Egypte$  Contemporaine, 10 (1919), No. 46, pp. 349–373).—The People's Banks of Italy, on the general plan of the Schulze-Delitzsch banks of Germany, and the cooperative savings banks of rural districts, are described in detail to show the growth and importance of cooperation in Italy. Other societies included in the discussion as being evolved out of requirements of agriculturists are establishments for manufacture of chemical fertilizers and societies, limited or not, for collective farming, buying and selling, hiring machinery, insuring live stock, etc. A brief summary is given of Italian legislation favoring cooperation.

Report of the Irish Agricultural Organization Society, Ltd. (*Rpt. Irish Agr. Organ. Soc., 1918, pp. 115*).—This report is based on the work of 677 societies for the year ended March 31, 1918, the statistics appended continuing information previously noted (E. S. R., 39. p. 796).

The farmer and the patent system, E. J. PRINDLE (Sci. Amer., 80 (1899), No. 11, pp. 162, 163; also in 121 (1919), No. 2, pp. 36, 48).—This is an estimate of the benefit to the farmer of the patent system and the encouragement and protection of invention.

The Japanese farmers in California (San Francisco: Japanese Agr. Assoc., [1919], pp. 32, pls. 5).—A collection of reprints, chiefly from San Francisco newspapers, and of extracts by officials of Japanese organizations giving popular information as to agricultural achievements and war activities of Japanese in America.

The woman on the farm, H. C. BULLOCK (Syracuse: Syracuse Univ., 1917, pp. 26).—A bibliography of books and magazine articles in Syracuse, N. Y., libraries covering the social condition of the farm woman, women as farmers, women on ranches, and aids for farm women.

Wealth for the woman farmer, C. ARNOULD (Fortune de la Fermière. Paris: Libr. Delagrave, 1918, pp. 213, figs. 56).—A handbook of methods in certain dairying, live stock, and gardening industries.

Regulations of the Secretary of Agriculture under section 5 of the United States Cotton Futures Act as amended March 4, 1919 (U. S. Dept. Agr., Off. Sec. Circ. 137 (1919), pp. 26).—This supplements information previously noted (E. S. R., 35, p. 693), by giving the text of 12 regulations under section 5 of the act as amended March 4, 1919.

Farmers' Market Bulletin (North Carolina Sta., Farmers' Market Bul., 6 (1919), No. 27, pp. 24).—This contains the usual list of products which farmers have for sale and brief notes by W. R. Camp on Low Price Soy Beans for Soil Improvement, and Market Prospects; and by C. S. Jones on Pure-bred Live Stock for Sale.

Monthly Crop Reporter (U. S. Dept. Agr., Mo. Crop Rptr., 5 (1919), No. 7, pp. 61-72).—In this number are included the usual estimates of crop conditions July 1, 1919, with comparisons, estimated farm value of important products June 15, average prices received by producers of the United States, and range of prices of agricultural products at important markets, also the United States crop summary for July 1. Special commercial reports for July, 1919, on peaches and pears, and a regional apple crop report, cotton report for July, and a Florida and California crop report are made. Other items noted relate to sugar cane acreage; cotton and cottonseed prices to producers; acreage and production of truck crops in 1918 and 1919, United States; Sea Island and Egyptian cotton acreage and forecast; acreage and production, 1919, of beans, hops, broom corn, and Kafir corn; tobacco estimates by types and districts; sugar beet acreage planted, 1919; and honey yields and prospects.

**Price Current-Grain Reporter Year Book 1919, E.** G. OSMAN (*Price Current-Grain Rptr. Year Book 1919, pp. 112*).—This number continues information previously noted (E. S. R., 40, p. 294) by adding statistics for the year ended May 1, 1919.

[Agricultural statistics of the United States] (U. S. Dept. Com., Bur. Foreign and Dom. Com., Statis. Abs. U. S., 39 (1916), pp. 127-168; 40 (1917), pp. 129-170; 41 (1918), pp. 139-183).—Data previously noted (E. S. R., 36, p. 594) are continued for the later years.

[Agriculture in Guatemala] (*Mem. Sec. Fomento* [*Guatemala*], 1916, pp. 4–8).—A brief report of the production of grains, live stock, and fruits in 1916 for Guatemala and its departments or counties.

Observations on agriculture in Hawaii, P. J. WESTER (*Philippine Agr. Rev.* [*English Ed.*], 12 (1919), No. 1, pp. 8-30, pls. 6).—This article describes some methods of cultivation, climatic and other conditions affecting agriculture, and the production and export trade from Hawaii of sugar cane, pineapple, coffee, and rubber.

Agricultural statistics of Ireland (*Dept. Agr. and Tech. Instr. Ireland, Agr. Statis., 1916, pp. 111*).—This report continues data previously noted (E. S. R., 38, p. 295).

[Agricultural industry of Holland] (*Rpt. Rotterdam Chamber Com. 1918, pp. 146-214*).—In these pages of an abridged translation of a report of the Rotterdam Chamber of Commerce for the year 1918 is given an account, with current and comparative figures, of imports into Holland of merchandise, principally grain and other foodstuffs and textiles; also of the home trade in vegetables and other agricultural products.

Agricultural statistics of Portugal (*Estatis*, *Agr. Portugal*, 1916, *pp.* 170).— Data relating to the production and stocks of the principal crops and of olive oil are given for the year 1916.

Agricultural returns for the crop year 1915–16 (Dir. Geral Estatis., Repartiçao Estatis. Agr. [Portugal], Ano Colheita 1915–16, pp. 74).—This gives the area sown, returns of principal crops, comparisons of the respective areas sown to crops, seed sown per acre, and other comparative figures for the agriculture of Portugal; also a summary of crop statistics for foreign countries.

Agriculture [in Algeria], JONNART (In Exposé de la Situation Générale de l'Algérie en 1918. Algiers: Govt., 1919, pp. 392-398, 446-457).—These pages report returns of a few principal crops in recent years, status of agricultural organizations for encouragement of agriculture, and the expenditure for and accomplishments in the way of colonization.

Study of some Egyptian farms, BARIOS (Compt. Rend. Acad. Agr. France, 4 (1918), No. 13, pp. 417-427; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 9 (1918), No. 8, pp. 982-984; Agr. Gaz. Canada, 6 (1919), No. 1, p. 109).—The author described before the Academy of Agriculture of France, April 10, 1919, five capitalist farms in Egypt in order to point out the advantages of investment of French capital in colonial agricultural enterprises. Data are derived from official reports of stock companies, the minister of public works, and other official administrators of these farms.

[Agriculture in Japan], S. SATO (Japan Year Book, 1917, pp. 522-541; 1918, pp. 522-541).—Information previously noted (E. S. R., 36, p. 690) is continued for the later years.

[Agricultural statistics of Australia], G. H. KNIBBS (Off. Year Book Aust., 11 (1901-1917), pp. 248-409).—These pages continue information previously noted (E. S. R., 39, p. 192).

Production [in New Zealand] (Statis. Dominion New Zeal., 3 (1917), pp. 1-120).—Data previously noted (E. S. R., 39, p. 690) are continued for 1917.

# AGRICULTURAL EDUCATION.

The education (Scotland) act, 1918, in relation to agriculture (Scot. Jour. Agr., 2 (1919), No. 1, pp. 37-41).—The provisions of this act most vitally affecting agriculture are those limiting the conditions of part-time employment of children of school age, and those requiring boys and girls between 15 and 18 years of age to attend continuation classes.

The scheme makes full provision for those practically concerned with agriculture to take part in its administration, either as members of education authorities and school management committees, or as members of the proposed advisory industrial committees. This is expected to insure that the schemes of instruction will meet the requirements of the various districts of the country, both in their scope and in the arrangement of times and seasons.

The number of boys and girls under 18 engaged in agricultural work in normal times is estimated at one-sixth of the whole number of persons so engaged. The period of attendance at classes is to be not less than 320 hours.

Eighteenth annual general report of the Department of Agriculture and Technical Instruction for Ireland, 1917–18 (Dept. Agr. and Tech. Instr. Ireland, Ann. Gen. Rpt., 18 (1917–18), pp. VI+250).—This is the usual annual report of the department's administration and funds and details of operations during the year 1917–18, including agricultural and technical instruction. Agricultural yearbook for 1919, edited by H. M. KNUDSEN (Landökonom. Aarbog [Copenhagen], 20 (1919), pp. 146).—This is the annual directory of public institutions and associations for the advancement of Danish agriculture in its various branches. A list of periodicals published in Denmark is appended.

Georgia State plan for vocational education under the Smith-Hughes law, 1918 (Ga. State Vocat. Bd. [Bul.] 4 (1918), pp. 47).—This is an outline of the plan for vocational education in Georgia for 1918–19. It is proposed to use 50 per cent of the funds available for training teachers for agricultural subjects, 20 per cent for home economics subjects, and 30 per cent for trade and industrial subjects. The length of the course for the training of white teachers of agriculture is four years, or 144 semester hours, and of colored teachers, one year. An outline is given of the 4-year agricultural course. Apprentice teaching of at least 12 weeks will be done in congressional district agricultural schools and rural county high schools or departments of agriculture in rural high schools.

Home economics education: Organization and administration, J. T. BERRY and A. E. RICHARDSON (*Fed. Bd. Vocat. Ed. Bul. 28 (1919)*, *pp. 64*).—This bulletin discusses (1) the general provisions of the vocational education act with reference to the distribution of funds and administrative machinery, and their relation to home economics education; (2) special provisions relating to home economics education in all-day schools and part-time and evening schools or classes; (3) the training of teachers of vocational home economics under the Smith-Hughes Act.

A table showing the sequence of courses and the relationship of art and science subjects to home economics subjects; outlines of a suggested type of courses for all-day classes, including a 2-year course in which half of the day, or 15 hours a week, is devoted to home economics subjects and the other half to related and nonvocational subjects; 4-year courses for 6-hour and 5-hour school days, respectively, in which one-half of the time is devoted to home economics and related art and science; a suggested course in the use and preparation of food for part-time classes; a suggested course in clothing for the family for evening classes; and a tabular approximation of the time and distribution of subjects in a 4-year teacher-training course in vocational home economics of 120 semester hours, are included.

Home making.—Lessons for the seventh and eighth grades in the rural schools of Indiana (Ind. State Dept. Pub. Instr. Bul. 31 (1918), Ser. I, pp. 14; J, pp. 14; K, pp. 11; L, pp. 8; M, pp. 15; N, pp. 13; O, pp. 14; P, pp. 12).—This is a continuation of this series of monthly lessons previously noted (E. S. R., 39, p. 498). The subjects dealt with are Care of the Family in Health, Care of the Family in Sickness, Selection of Clothing, House Decoration, House Furnishing, Care of the House, Home Management, and How to Live.

Suggestive lesson plans for teaching the budget, H. C. GOODSPEED (Madison, Wis.: State Dept. Pub. Instr., 1918, pp. 11).—The material in this pamphlet comprises two lesson plans for children's budget and personal accounts and the household budget and accounts, respectively, a suggestive form for household accounts, and a dramatic exercise for 11 girls, entitled Our Budget. The lesson plans set forth the teacher's aim, points to be taught, and the method of presentation.

Syllabus for nature study, humaneness, elementary agriculture, and homemaking (Univ. State N. Y. Bul. 675 (1918), pp. 52).—This syllabus is designed to indicate the general scope and character of instruction to be given in nature study and humaneness in grades 1 to 6, and in agriculture and home making, taught by means of junior home projects, in grades 7 and 8 of the public schools of the State of New York. Supervised home project and club work (*Ind. State Bd. Ed., Ed. Bul. 32* (1918), pp. 44, figs. 27).—This bulletin deals with the organization and present status of home project work in Indiana, which is now on a permanent basis, and with factors that make project work successful. Notes on the work of Indiana club leaders are included.

Prizes for boys' and girls' competitions (Agr. Gaz. Canada, 6 (1919), No. 3, pp. 265–274).—This is a series of articles, prepared with a view to standardizing on a basis of experience the wide variation of information and practice with regard to prizes offered for boys' and girls' agricultural competitions. The articles present the views of responsible officials in Prince Edward Island, Nova Scotia, New Brunswick, Ontario, Manitoba, Saskatchewan, and Alberta, and of various live-stock associations.

School fairs in 1918 (*Agr. Gaz. Canada*, 6 (1919), *No. 1*, *pp. 60–77*, *figs. 13*).— This is a series of brief reports by agricultural education officials on school fair activities in 1918 in the Provinces of Prince Edward Island, Nova Scotia, New Brunswick, Ontario, Manitoba, Saskatchewan, and Alberta.

Rural community center movement (Agr. Gaz. Canada, 6 (1919), No. 9, pp. 809-815).—Brief statements are made of the present status of this movement in the Provinces of Nova Scotia, Quebec, Ontario, Manitoba, and Alberta.

In Nova Scotia the traveling rural science teachers have made a beginning through the medium of school exhibitions, plays by the school children, debates, clubs, etc. The clergy are also assisting in bringing the church and the school together in a social way. In Quebec, where the movement began about 10 years ago, the factors that are believed to have played a large part in arousing an interest in this movement are the clergy and the county demonstrators, the homemakers' club, and Macdonald College, which, in August, 1918, held a two weeks' summer school for rural improvement which was attended by nearly 70 persons, chiefly country ministers. The movement received an impetus in Ontario with the passing of a bill and the voting of money for the establishment of community halls and athletic fields in rural districts. The text of the regulations passed under this act are given, also an outline of a course of lectures on rural conditions and problems offered by the University of Toronto in its department of social science. The movement in Manitoba is under the direction of the Social Service Council, a federation representing 24 provincial bodies. Its activities are indicated by the following five standing committees, viz, the public forum, better business, young people, public health, and recreation. Community halls are briefly discussed as valuable assets of the movement in Alberta.

# MISCELLANEOUS.

Thirty-second Annual Report of Nebraska Station, 1918 (*Nebraska Sta. Rpt. 1918, pp. 44*).—This contains the organization list, a report of the work of the year, a report of the extension service of the college of agriculture, and a financial statement for the fiscal year ended June 30, 1918. The experimental work reported is for the most part abstracted elsewhere in this issue.

Monthly bulletin of the Western Washington Substation (*Washington Sta.*, West. Wash. Sta. Mo. Bul., 7 (1919), No. 4, pp. 53-64, fig. 1).—This number contains brief articles on the following subjects: Sheep for Farm Flocks, and Control of Canadian Thistles, both by W. A. Linklater; Summer Garden Practices, and Summer Pruning, both by J. L. Stahl; Summer v. Winter Feeding of Poultry, by Mr. and Mrs. G. R. Shoup; and Some Common Fruit Diseases, by A. Frank.

# NOTES.

California University.—A group of 96 soldiers of the Australian Expeditionary Forces has been enrolled by their Government at the Farm School at Davis for agricultural training, with special emphasis on irrigation as applied to intensive agriculture. About 70 per cent of these men have requested a twelve months' course of training and the remainder, a six months' course. They were chosen from about 1,000 applicants and 37 already owned their own farms, while the remainder have agreed to purchase lands in irrigated districts.

The university student enrollment now numbers nearly 9,000, necessitating 60 appointments to the faculty. Among these are A. H. Hoffman as assistant professor of agricultural engineering, Thomas Batchelder and A. M. Burton as instructors in animal husbandry and agricultural extension, respectively; and Miss Mary Van Camp as assistant in agricultural extension. C. B. Lipman, professor of soil chemistry and bacteriology, W. F. Gericke, assistant professor of soil chemistry, and A. M. Hendrickson, assistant professor of pomology, have been granted leaves of absence.

**Connecticut State Station.**—C. B. Morison, assistant in chemistry, has resigned to accept a position with the American Institute of Baking.

Georgia Station.—Dr. B. B. Higgins has returned from overseas service and resumed his duties as botanist and plant pathologist October 1. T. S. Buie has been appointed assistant agronomist, beginning December 1.

**Purdue University and Station.**—The largest freshman class in the history of the university is reported. The School of Agriculture has the largest enrollment of any of the schools in the university.

H. E. Allen has resigned to accept a position with the American Hereford Cattle Breeders' Association, and has been succeeded as assistant professor of animal husbandry by B. E. Pontius of the Massachusetts College. P. S. Lucas, assistant professor of dairy manufactures at the Oregon College has been appointed associate professor of dairy husbandry and assistant professor of dairying, and E. H. Leiendecker, assistant in dairying. W. O. Mills has resigned as assistant in dairy extension work to engage in farming.

W. B. Crooks, in charge of boys' and girls' calf club work, has been appointed assistant professor of animal husbandry to take charge of horse work. The new horse barn is nearing completion and it is planned to enlarge the pure-bred stud considerably.

Other recent appointments include J. B. Kendrick, George B. Newman, R. J. Plaster, and W. W. Radspinner as assistants, respectively, in vegetable pathology, entomology, extension work, and pomology; Thomas Jahne and R. R. Mulvey as assistants in soils; C. C. Barkdell, L. H. Crudden, and A. S. Eldredge as deputy inspectors in the office of the State chemist; and E. C. Rowe and William F. Ricketts as inspectors in the creamery license division.

Iowa College.—F. B. Paddock, State entomologist of Texas, has accepted a position as State apiarist of Iowa and associate professor of zoology and ento-

mology in the college, vice F. Eric Miller, resigned to assume charge of apicultural work in the Ontario College July 1.

Kansas College and Station.—The entering class numbered nearly 900, a much larger number than in any previous year. The total enrollment, including short courses, is expected to reach at least 3,500, breaking all previous records.

The new swine building, for which the legislature appropriated \$10,000, has been completed. The building is of the monitor type, 132 ft. long and 32 ft. wide, with a two-story center section 32 ft. wide and 40 ft. long. It contains pens for 45 brood sows, a herdsman's room, an office, ample storage space for feed, scales, a shower bath, and other modern features. A portion of the floor space is provided with facilities for conducting investigations on various types of floors.

In cooperation with the State Crop Improvement Association the department of agronomy has completed an inspection of 25,000 acres of Kanred wheat, grown by 572 members of the association. This is a part of the campaign to encourage the substitution of Kanred for other varieties in the hard wheat belt. The results of the inspection have been published by the association for the benefit of farmers wishing to buy the wheat for seed. About 50,000 acres of the new variety were grown in the State this year.

George S. Knapp has resigned as superintendent of the Garden City substation to become State irrigation commissioner, and has been succeeded by F. A. Wagner of the Bureau of Plant Industry of the U. S. Department of Agriculture. Plans are being made for material extensions in the irrigation investigations at Garden City following an appropriation from the last legislature for new electrical pumping equipment.

Dr. Theodore Macklin, professor of agricultural economics, has resigned to become associate professor of agricultural economics at the University of Wisconsin. Dr. R. K. Nabours, professor of zoology, is making an extended study of Karakul sheep in Asia.

Herbert F. Roberts, head of the department of botany, has resigned to accept an appointment in the department of botany of the University of Manitoba. A department of botany and plant pathology has been established in charge of L. E. Melchers. Other appointments include Dr. William E. Muldoon, associate professor of comparative medicine in the New York State Veterinary College, as associate professor of comparative medicine; Dr. H. F. Lienhardt as assistant professor of pathology; F. L. Thomsen as assistant professor of agricultural economics; Dr. L. Jean Bogert as head of the department of food; Miss Hildegarde Kneeland as professor of household economics; Miss Martha E. Pittman as assistant professor of the department of food economics and nutrition; Miss Clara Higgins as research assistant in poultry husbandry; Dr. F. C. Gates as assistant professor of botany; F. L. Hisaw, jr., as assistant professor of zoology and mammologist; B. C. Zimmerman as instructor in animal husbandry; Herschel Scott as instructor in agronomy; C. F. Huffman as assistant in dairy husbandry; and Charles H. Kitselman as assistant in animal abortion investigations. F. E. Colburn, photographer at the Iowa College, has been appointed head of the newly authorized department of illustrations, which will include the photographic and illustrative work of the college and station.

Kentucky University and Station.—The new judging pavilion, seating 600 people and with two additional classrooms, is nearing completion.

Misses Elizabeth H. and Marguerite J. Perry have resigned as seed analysts. Recent appointments include the following: Dr. W. D. Valleau, research assistant at the Minnesota Station, as plant pathologist; J. B. Kelley of the Iowa College as professor of agricultural engineering; G. W. Forster as instructor in farm management and agricultural economics; Dr. A. J. Steiner as assistant veterinarian; J. R. Dawson as extension dairy specialist; E. M. Prewitt as assistant extension dairy specialist; Miss Marietta Eichelberger as instructor in nutrition; Miss Mabelle Cornell as instructor in textiles and clothing; Miss Marie Boterf as instructor in practice teaching in home economics; Miss Gertrude M. McCheyne of the Utah College, in charge of home demonstration agents; and Miss Dora Sonnenday, as extension specialist in cooking.

Louisiana University and Stations.—Dean and Director W. R. Dodson has tended his resignation after twenty-five years' service, effective January 1, 1920. E. C. Freeland, assistant research chemist, and J. H. Jolly, assistant chemist, have resigned to accept commercial positions with sugar factories in British Guiana and Havana, Cuba, respectively. Dr. F. V. Emerson, geologist for the station and in charge of soil survey work for the station, died October 11. E. A. Meier, a 1919 graduate of the university, has been appointed farm manager for the State Station at Baton Rouge.

Massachusetts College and Station.—John D. Willard, in charge of the extension work in marketing, has been appointed director of the extension service, beginning about January 1, 1920.

Mrs. Maria E. Fernald, collaborator in entomological work with her husband, Dr. C. H. Fernald, and author of A Catalog of the Coccidæ of the World, died October 6 at the age of eighty years.

Mississippi College.—Daniel Scoates, professor of rural engineering, has been appointed professor of agricultural engineering at the Texas College vice R. A. Andree, resigned, and has entered upon his duties.

Missouri University and Station.—Theodore Sexauer has been appointed professor of agricultural education. Other appointments include, as instructors, Mack M. Jones in agricultural engineering, Ray E. Miller and Donald W. Chittenden in animal husbandry, Percy Werner, jr., in dairy husbandry, and George W. Hervey in poultry husbandry; and as assistant, Charles W. Turner in dairy husbandry. Ralph Loomis has been appointed specialist in rural marketing; Ralph L. Mason, extension instructor in poultry husbandry; and Mark H. Kenny, extension assistant professor of dairy husbandry. The resignation is noted of W. B. Combs, assistant professor of dairy husbandry.

Nebraska University and Station.—Miss Alice Loomis, head of the department of home economics, has resigned to become director of home economics work for the Nebraska Board of Vocational Education, beginning September 1, and has been succeeded by Miss Margaret Fedde. J. W. Hendrickson has been appointed assistant professor of dairy husbandry and assistant dairy husbandman, vice W. B. Nevens, who resigned September 1 to take up post graduate work in the University of Illinois.

Other appointments include C. K. Shedd of the Iowa College and Station as professor of agricultural engineering and in charge of tractor testing for the State; C. C. Wiggans, research horticulturist of the Delaware Station, as associate professor of horticulture; William H. Savin as assistant professor of animal husbandry and assistant animal husbandman; and J. C. Russel as assistant professor of agronomy.

New Jersey College and Stations.—J. M. Hunter has resigned as professor of animal husbandry and animal husbandman to become manager of a large cattle farm in the State. L. E. Hazen resigned September 1 to become professor of farm engineering in the Oklahoma College. Robert Poultney has resigned as assistant extension specialist in dairying. Robert P. Armstrong has been appointed assistant professor of horticulture and assistant pomologist; M. S. Klink assistant professor of rural engineering; Charles B. Gentry assistant professor of agricultural education; and George W. Martin assistant professor of botany. Arthur L. Prince has been appointed assistant chemist vice H. C. McLean, resigned; Robert F. Poole research assistant in plant pathology; and Lindley G. Cook assistant to the director. F. G. Helyar, director of short courses, has also been appointed professor of animal husbandry and animal husbandman.

New Hampshire College and Station.—Dr. H. R. Kraybill, assistant physiologist of the Division of Horticulture and Pomology of the U. S. Department of Agriculture, has been appointed professor of agricultural chemistry and head of the chemistry department of the station.

**Cornell University and Station.**—The College of Agriculture announces that it will award a limited number of free tuition scholarships to students from the devastated regions of France and Belgium. Holders of these scholarships may enter at any time before the close of the academic year 1922–23.

The department of rural economy has recently added several works of reference in economic history, particularly in the grain and provision trades. These include complete sets of a number of periodical price lists for over fifty years. These acquisitions and other promised gifts, when added to the material already in the university library, are expected to place the university in possession of an unusual amount of fundamental material for the study of economic history, prices, and the marketing of the great agricultural staples of the country.

At the New York State Fair, held at Syracuse, September 8 to 13, the College of Agriculture, as part of its work in rural social organization, presented several one-act plays in a "little country theater", to demonstrate the value of rural dramatics as a form of recreation to bring countryside communities together. It was also the aim to show how easily the plays could be presented.

Clark L. Thayer, instructor in floriculture, resigned October 1 to become associate professor of floriculture at the Massachusetts College. E. L. Worthen has been appointed extension professor of soil technology for the year 1919–20 vice E. O. Fippen, who has received a year's leave of absence.

North Dakota College.—Lieut. Horace A. Holaday of the Sanitary Corps, nutrition officer at Newport News, Va., and formerly professor of chemistry at the University of Idaho, has been appointed professor of physiological chemistry and head of the division of foods and physiological chemistry.

**Ohio State University.**—Clark S. Wheeler has resigned as director of the agricultural extension service, effective November 1, to engage in commercial work.

Oklahoma College.—W. T. Magee has been appointed associate professor of animal husbandry.

Pennsylvania College and Station.—Recent resignations include E. L. Worthen, associate professor of agronomy; George S. Bulkley, assistant professor of dairy husbandry; Dr. J. F. Olney, station bacteriologist; instructors W. W. Wood in agricultural extension, A. F. Yeager in pomology, and L. E. Yocum in botany; and assistants E. V. Bearer, agricultural education, C. G. Ferrari in agricultural chemistry, F. W. Knipe in farm mechanics, H. C. Yerger, jr., in dairy manufactures, and C. W. McDonald in animal husbandry. W. G. Edwards, J. W. Miller, Fred Hultz, and A. L. Beam have returned from military service. Among the new appointments are the following: As assistant professors, Walter B. Nissley in vegetable gardening extension and R. R. Welch in dairy husbandry extension; as instructors, G. M. Foulkrod in farm mechanics, John R. Eyer in economic entomology, Martin H. Knutsen in bacteriology, P. Thomas Ziegler in poultry husbandry, Harold B. Pierce in chemical agriculture, F. B. Lincoln in pomology, J. Stanley Cobb in agronomy, Lloyd W. Steelman in poultry husbandry extension, and J. Stanley Owens in agronomy extension; and as assistants, Carl G. Degen in agronomy, Miss Esther S. Mixer in chemical agriculture, Russell M. Love in dairy husbandry extension, D. H. Stewart in agricultural extension, and Ellis M. Christen in animal husbandry.

Tennessee University.—L. R. Hesler, assistant professor of plant pathology at Cornell University, has been appointed professor and head of the department of botany.

Texas College and Station.-J. W. Luker has been appointed superintendent of the feeding and breeding substation vice J. W. Jennings, resigned to engage in farming. Ross M. Sherwood has been appointed poultryman vice W. L. Mayer, resigned to engage in teaching, and J. B. McNulty has been appointed dairyman, beginning September 1: R. G. Brewer has been appointed assistant animal husbandman in sheep and goat investigations vice C. M. Hubbard, resigned to accept an appointment with the Washington College. Dr. M. C. Tanquary, associate professor of entomology and assistant in staple crop investigations at the Kansas College and Station, has been appointed chief of the division of entomology and State entomologist, beginning January 31, 1920, vice F. B. Paddock, whose appointment in the Iowa College and Station is noted on page 496. P. V. Ewing, animal husbandman in charge of swine investigations, W. E. Jackson, assistant entomologist, and Wellington T. Brink, executive assistant in charge of library and publication, have resigned to go into commercial work, effective September 30, December 1, and August 21, respectively.

Utah College and Station.—A new live-stock building has recently been completed at a cost of approximately \$90,000, which will house the college and station departments of animal husbandry, dairy husbandry, poultry husbandry, range management, and veterinary science. The basement of the building will contain a modern commercial dairy.

B. L. Richards, Ph. D., has been appointed associate professor of botany. Vermont University and Station.—Recent appointments include A. H. Gilbert as assistant professor of plant pathology and assistant pathologist in the station, and J. A. Newlander as instructor in animal husbandry.

Virginia Truck Station.—G. S. Watts resigned July 15 to become assistant horticulturist at the Massachusetts College and was succeeded August 15 by Floyd H. Keister.

Washington Station.—Two barns and a 120-ton tile silo are to be built at the Western Washington Substation at Puyallup at an estimated cost of \$24,000. A tract of 60 acres of nearby land has recently been purchased. It is planned to improve the dairy herd, retaining the best of the Jerseys on hand and adding a group of Holstein-Friesians.

West Virginia University.—Dr. John L. Sheldon, in charge of work in botany and bacteriology the last 16 years, has resigned.

**Philippine College of Agriculture.**—The College of Veterinary Science has been transferred to Los Banos. This brings it in contact with the remaining work of the institution. A new entomology and plant pathology building has been completed.

# CONTENTS OF VOL. 41, No. 6.

	Page.
Recent work in agricultural science	501
Notes	599

#### SUBJECT LIST OF ABSTRACTS.

#### AGRICULTURAL CHEMISTRY-AGROTECHNY.

Agricultural chemistry, Gain	501
Industrial and agricultural chemistry in British Guiana, Browne	501
Bulletin from the analytical food laboratories in Surinam, Sack	501
International catalogue of scientific literature. D.—Chemistry	501
The volatile oils, Gildemeister and Hoffmann	501
American tomato seed oil, Jamieson and Bailey	502
Contribution to study of ash-constituents of plants, L. and D. Leroux	502
Composition of the ash of crab grass as affected by the soil, Buckner	502
Physical and chemical properties of hydrocyanic acid, Gray and Hulbrit_	502
An adiabatic bomb calorimeter, Holland, Reed, and Buckley	503
Electrical apparatus for use in electrometric titration, Roberts	-503
Indicator test papers, Kolthoff	503
Determination of hydrogen-ion concentrations in bacterial cultures, Jones_	503
A sensitive reaction of manganese salts, Caron and Raquet	504
Specific colored reaction of oxalates, Caron and Raquet	504
Iodometric studies, Kolthoff	504
Determining nitrogen by Kjeldahl process, Villiers and Moreau-Talon	504
Notes on potash determination, Steuerwald	504
Sulphates in electrolyte and sulphur in foods, Krieble and Mangum	505
Determination of lactose and of albuminoids in preserved milk, Defrance_	505
On the estimation of sugar in blood, Maclean	505

CONTENTS.

	Page.
Picric acid method for the estimation of sugar in blood, De Wesselow	- 506
Notes on the determination of water solubles in leather, Frey and Clarke_	506
The industries of the farm, Larbaletrier	506
Methods of preservation of fruits and vegetables, Manaresi	506
Preserving in cold without sugar, alcohol, or antiseptics, Bertrand	506
The mechanism of the preservation of fruits in cold water, Bertrand	506
Composition and calorific value of sirups and molasses, Browne	507
Deterioration of manufactured cane sugar by molds, N. and L. Kopeloff_	507
Production of glycerin from sugar by fermentation, Eoff et al	507
Mannose yeast, Mezzadroli	508
Conference on recent developments in the fermentation industries	508
Potash from kelp: Preliminary paper, Turrentine and Shoaff	508
Hemlock bark as a source of tannin, Edwardes	509

#### METEOROLOGY.

Climatological data for the United States by sections	509
Observations at Massachusetts Experiment Station, Ostrander and Smith_	509
Meteorology, Trivett	509
The mild winter of 1918–19, Brooks	509
Some characteristics of the rainfall of the United States, Ward	510
Rainfall régimes in Mexico, López	510
The relation of rainfall to configuration, Salter	510
Fertilizing value of rain and snow, Shutt	510
The period between blooming and ripening, Hegyfoky	510

# SOILS-FERTILIZERS.

Classification of humus-free and humus-poor soils of Sweden, Atterberg	510
Classification of soils high in humus of Sweden, Atterberg and Johansson_	511
Soil survey of the Los Angeles area, Cal., Nelson et al	511
Analyses of soils of Terrell County [Ga.], Worsham, jr., et al	512
Report on geology of east central Minnesota, Harder and Johnston	512
Rate and extent of solubility of soils under treatment, Bouyoucos	512
Moisture content of subsoil to hygroscopic coefficient, Alway et al	514
Relation of soil moisture to orchard irrigation practice. Fortier	515
Sterilization of soils and influence of protozoa on fertility, Truffaut	515
Soils, Davis	515
Investigational work with fertilizers, Shutt	516
The synthesis of ammonia at high temperatures, III, Maxted	516
Sodammonium sulphate. Niter cake in fixation of ammonia, Dawson	516
Availability of the nitrogen in garbage tankage, Bear and Walley	517
Study of nitrification of leather and oil cake, Guillin	517
The peat deposits of Minnesota, Soper	517
Peat, Guieu	518
Reconnaissance of Uinta Mountains regarding phosphate, Schultz	518
The fertilizing action of bone meal phosphate, Beger	518
Our natural resources of potash, Brown	518
Nature of recombined potash in cement mill dust, Merz and Ross	518
German potash industry during the war, Edwards	519
Tests with potash on lowland moor soils, I–II, Werth	519
Injurious effects of potash and sodium salts upon soil structure, Hager	519
Comparative value of various forms of limestone, Stewart and Wyatt	520
Results of liming experiments by Finland Moor Culture Society, Rindell_	520
The ammonia-fixing capacity of calcium sulphate, Bear and Workman	521
The effect of manganese on the growth of wheat, McHargue	521

# AGRICULTURAL BOTANY.

Plant succession in relation to range management, Sampson	521
Botanical survey [in India], Carter	522
Agricultural botany [in India], Howard	522
Forest botany [in India], Hole	522
Evolution through normal diversity, Cook	522
The symbiomorphoses; recent studies on asexual hybridization, Daniel	522
Underground runners, Warming	522
Natural grafting of branches and roots, Dallimore	522

	Page.
Cross-inoculation of legumes, Koch and Butler	523
Potassium requirements of bacteria, Koch	523
Occurrence, behavior, and origin of smooth-stemmed foxglove, Saunders_	523
The purple hyacinth bean, Freeman	023
The effect of certain organic substances on seed germination, Fred	523
Action of radium on green plants with and without light, Packard	523
On the dynamics of photosynthesis, Osterhout and Haas	523
A method of studying respiration, Osterhout	524
An indicator method of measuring the consumption of oxygen, Osterhout_	524
Comparative studies on respiration, I-V	524
Analytic and synthetic studies on chlorophyll, Mary	525
Growth rates in plants. Debatin	525
Abnormal stem growth of soy beans in sand cultures. McCall et al	52
Osmotic pressure in plants on mountains. Arrhenius and Soderberg	525
Materials in san in different parts of stalk of cane Kuijper (Kuyner)	525
Turgescent tissue in sugar solutions and toxic substances. Those	525
Quantity of reproduction in stem of <i>Dryconbullum</i> aluginum I cob	506
Quality of regeneration in stem of <i>Bryophytham catychium</i> , Loep	520
Consideration of pathologic conditions in Amorosia tripiaa, Stewart	520
The nature of charred wood, Boodle	026

# FIELD CROPS.

American husbandry, a much overlooked publication, Carrier	527
[Report of field crops work in Florida, 1918]. Scott et al.	527
[Report of State and cooperative experiment farms in Wyoming]	528
Field crops work at Canada stations and farms, 1917]. Grisdale et al	528
Beport of field crops work in St. Vincent, 1917–181. Watts	528
[Report of field crops work in British Guiana 1917] Harrison	528
[Report of field drops work in Union of South Africa 1918] Smith et al	528
[Report of field grops work in Burma 1918] English	528
Field groups in Durma 1. Adomson	520
[Field crops in Burlina], Automotion	520
[Field crops in Ceylon], Molegoue et al.	529
[The progress of crop investigations in findia, 1917–16]	529
[Report of field crops work in South Australia, 1918–19], Spanoro	529
Constructive rotations: Fertility, crops, drainage, and farm labor, Barker_	529
The temporary ley, Stapledon	529
The grasses and grasslands of South Africa, Bews	529
[Grasses for paper making in the Union of South Africa], Juritz	529
Methods of selection applied to the cereals, Beauverie	529
Twinning in alfalfa, Southworth	530
Variety tests with two-row barley, 1913–1916, Iversen	530
[Observations on beer barleys in Argentina], DGirola	530
[The castor oil plant in Brazil], d'Utra	530
Red clover, Findlay	530
Variety tests of corn [in North Carolina], Garren	530
Some curious freaks of corn, Jones	530
Description of supposed fossil species of maize from Peru, Knowlton	530
A fossil ear of maize, Collins	530
Inheritance of immunity to leaf blister mite in cotton, Harland	530
Improvement of yield of Sea Island cotton in West Indies, Harland	531
Improved type of cotton for southern Maratha [India], Kottur	531
Problems following introduction of American cotton in Punjab. Roberts	531
Egyptian cottons: Deterioration and means of remedying it. Mosseri	531
Cotton, Bigwood	531
The early history of cotton in Bombay, Mackenna	531
Work of Imperial Institute in connection with British cotton cultivation	531
Cottonseed by-products	532
Fiber plant investigations [in South Africa], Holmes-Smith	532
Production of flax fiber and seed flax in Canada Robertson	532
Tests with flar variaties Gordon	532
The flax industry (in Victorial Bobiliard	522
Lalang grass as a naner material Eaton	522
Official grain standards of the United States for oats Houston	529
Handbook official grain standards for oats	529
The spraving of Irish notatoes Leiby	520
Report on the composition of notatoes grown in the United Vingdom	599
report on the composition of polatoes grown in the United Kingdom	033

# CONTENTS.

	Pag
Rice [in Argentina], Ito	5
Preliminary notes on rice selection work at Saigon, Carle	5
The transplanting of rice in Egypt. Mosséri	5
Utilization of rice and its by-products	5
A forage plant from the Solanaceæ family, Hunnicutt	5
Fertilizer experiments with sugar cane [at Tucumán]. Cross	5
Experiments on stripping [sugar] cane. Cross	5
Costs of production in the sugar industry	5
Germination of tobacco seedIII, Light and darkness, Goodspeed	5
Nomenclature of wheats grown in South Africa	5
Kota, a rust resisting variety of spring wheat. Waldron and Clark	5
Results of wheat variety and manurial trials, season 1918–19, I–II	5
Irrigation and protein content of wheat, Jones, Colver, and Fishburn	5
Official field crop inspection. Bollev	5
The size of seed, Findlay	5
Seed Reporter	5
Weeds in relation to forage: Determination of fruit and seed. Naumann	5
Tests of chemical means for the control of weeds. Grav	5
The use of chemical sprays for combating weeds. Adams	5
Eradication of weeds by sprays and manures. Brenchley	5

### HORTICULTURE.

Practical vegetable gardening, Böttner	538
Grow your own vegetables, Johnson	538
The garden frame for food and flowers, Rowles	538
[Report on horticultural work, 1918], Macoun et al	538
The carob in California, Condit	538
Notes on the dasheen and chayote, Youngken	538
Hardy fruit culture, Lawrance	538
The fruit growers' yearbook and market gardeners' guide, 1918	538
Decade records in Ohio apple orchards, Nos. 2 and 3, Gossard	538
Using an apple sizing machine, Lewis	539
Experiments with citrus trees, Floyd	539
Report of assistant plant physiologist, Nothnagel	539
Citrus experiment grove, Collison	540
Citrus growing in South Africa.—Oranges, lemons, naartjes, etc., Davis	540
Culture, selection, and manuring of coconuts, McRae and Anstead	540
The coconut in Cochin China, Morange	540

#### FORESTRY.

Forest management, Recknagel and Bentley, jr	540
A National Forest policy, Graves	540
Natural afforestation in a New Zealand mountain area, Morrison	541
The Douglas fir, a tree giving large returns, Manvilli	541
The collection and some uses of the oleoresin of Douglas fir, Mahood	541
The Hawaiian genus kokia.—A relative of the cotton, Rock	541
The true mahoganies, Rolfe	541
Mahogany, recognition of kinds by microscopic characteristics, Dixon	541
A. Field tests with Hevea.—B. Germination trials with Hevea, Maas	541
Structure of cell elements in bark of <i>Hevea brasiliensis</i> , Bobilioff	541
Variability in plantation rubber, de Vries and Spoon	542
Relation of specific gravity of latex to rubber content, de Vries	542
Tapping experiments on <i>Hevea brasiliensis</i> , de Jong	542
The application of preservatives to renewing bark of rubber, Petch	542

# DISEASES OF PLANTS.

Report of associate plant pathologist, Sherbakoff	542
Report of the acting Dominion botanist, Grisdale	543
Mycology and plant pathology, Butler	543
Plant diseases, Hutchinson	543
Diseases and animal pests of cultivated plants in East Indies, van Hall	544
Biologic specialization in the genus Septoria, Beach	544
Wheat diseases in Java, Palm	544
The control of rust [in Manitoba], Jackson	544

-0

	Page.
Disease of flax due to Colletotrichum, Pethybridge and Lafferty	544
Curtailing potato diseases, Orton	545
Cooperative spraying [of potatoes for late blight] in Vermont, Lutman	545
Is crown gall injurious to apple nursery stock? Fracker	545
Avocádo scab, Stevens	545
Report of plant pathologist, Stevens	545
A bacterial disease of citrus	546
Ustulina zonata on Hevea brasiliensis, Sharples	546
European poplar canker in the vicinity of Philadelphia, Pa., Primm	546
Daldinia vernicosa, a pyroxylophilous fungus, Rhoads	546
Dalainia vernicosa, a pyroxylophilous fungus, Rhoads	546

# ECONOMIC ZOOLOGY-ENTOMOLOGY.

Tropical wild life in British Gulana, Beebe, Hartley, and Howes	546
Birds of field, forest, and park, Gilmore	547
The birds of North and Middle America, Ridgway	547
Notes on North American birds, VIII, Oberholser	547
The migration of North American birds, IX, Oberholser	547
Birds of a Washington city dooryard, Oberholser	547
Another purple martin roost in the City of Washington, Oberholser	547
Range, migration, and economic value of bobolink, McAtee	547
Eumyias v. Stoporala, Oberholser	547
The status of the subfamily name Fuligulinæ, Oberholser	547
The geographic races of <i>Hedymeles melanocephalus</i> , Oberholser	547
A revision of the subspecies of <i>Passerculus rostratus</i> , Oberholser	547
Passerherbulus leconteii becomes Passerherbulus caudacutus, Oberholser_	547
Proper orthography of generic name Phoethornis Swainson, Oberholser	547
Descriptions of nine new North American pikas, Howell	547
The family name of the American wood warblers, Oberholser	548
A dangerous snail introduced in California, Gorton	548
Report of entomologist, Watson	548
Unusual nursery insects, Weiss	549
Insects of the season	549
Report of the entomologist, Fullaway	549
Insect and arachnid pests of 1917, Macdougall	549
Division of entomology, annual report, 1916–17, Lounsbury	549
Economic entomology, Tryon	549
Common insects and diseases of the apple, Chase	549
More important insect enemies of the rose mallow in New Jersey, Weiss_	549
Insect pests of stored grains and mill products, Lathrop	549
Insecticides and fungicides, Shutt	549
Adulteration of insect powder with daisy flowers, Roark and Keenan	550
Fumigation with liquid hydrocyanic acid, Quayle	550
Liquid hydrocyanic gas for fumigation	551
The treatment of cloth to prevent mildew, Morrill and Yothers	551
The care of spraying machinery, Yothers	551
Two new genera and thirteen new species of Thysanoptera, Hood	551
Some plant bugs that infest citrus trees, Froggatt	551
The genuis Phatnoma, Gibson	551
The genera Corythaica Stal and Dolichocysta Champion, Gibson	551
Notes on the North American species of Corizus, Gibson	551
Cicadula sexnotata, injurious to wheat, oats, and barley, Ellinger	551
Third contribution to the knowledge of Italian Coccidæ, Leonardi	551
An interesting reaction to louse bites, Moore	551
Clinical studies on effects of louse bites, Hirschfelder and Moore	551
The biology of <i>Pediculus humanus</i> , Nuttall	552
Report on typhus conditions in native dwellings, Brain	552
Notes on the tussock moth in British Columbia, Anderson	552
The European corn borer, Houser	552
The history of the codling moth in British Columbia, Treherne	552
Differences in pink bollworm and Pyroderces simplex, Averna-Sacca	552
Physiological and parasitological studies of Lepidoptera, Gautier	552
Coccopacini parasites of the caterpillar of <i>Pieris brassica</i> , Paillot	552
Argentine fruit fly (Anastrepha fraterculus), Caride Massini and Bréthes_	552
Black ng ny and its parasites in Sorrento peninsula, Italy, Savastano	552
The maize leaf miner ( <i>Phytomyza</i> sp.), Knowles	553
Lonchaa aristella, injurious to capring and fig, Silvestri	503

CONTENTS.

	Page.
Susceptibility of anophelines to malarial infections, Swellengrebel et al	553
Cost of malaria.—Loss of Anderson-Cottonwood district, Cal., Gray	553
Mosquito control about cantonments and shipyards, Le Prince	553
The mosquito problem in Britain, Parsons and Brook	553
A few general directions with regard to destroying mosquitoes, Gorgas	553
Fishes in relation to mosquito control in ponds, Hildebrand	553
Comparison of culicifuges under laboratory conditions, Bacot and Talbot_	554
The tobacco flea-beetle, Metcalf and Underhill	554
Controlling asparagus beetles, Guyton	555
The passion vine longicorn beetle (Monohammus fistulator, French, jr	555
Life history of Brachys ovatus and B. grosus, Weiss and Nicolay	555
The native lime tree borer ( <i>Citriphaga mixta</i> ), Froggatt	555
The wood borer and its control, Cockayne	555
Contribution to the knowledge of <i>Coeliodes ruber</i> in Italy, Silvestri	555
Catalogue of species of Curculionidae of Cholina group, da Costa Lima	556
Report of the apiarist. Sladen	556
Trial of a system of keeping two queens in a hive. Sladen	556
How the female Blastophaga works. Condit	556
, other and the second s	

# FOODS-HUMAN NUTRITION.

A selective bibliography on dehydrated foods, Greenman 557
An aerobic spore-forming bacillus in canned salmon, Hunter and Thom 557
The nutritive value and cost of some important vegetables. Rubner 557
Nutritive value of the carob bean, Jaffa and Albro
Pumpkin as flour substitute, Alpers558
Beports of storage holdings of certain food products during 1918, Bell
Swiss food book 558
Dependence of protein needs on mineral metabolism, Röse and Berg 558
Factors of growth and equilibrium: Vitamins: auximones. Schaeffer 558
A lecture on the practical importance of vitamins, Hopkins, 558
Vitamins and fungi, Linossier558
The lipoids as indispensable constituents of food. Stepp 559
Researches on fat-soluble accessory substance, I-II, Drummond 559
Note on rôle of antiscorbutic factor in nutrition, Drummond 560
Antiscorbutic property of fruits.—I, Orange juice, Givens and McClugage_ 560
The antiscorbutic properties of green malt, McClendon and Cole 561
Studies of infant feeding.—XI. Bosworth and Bowditch 561
Effect of alkali and malt on retention of calcium in infancy. Sato 561
Hospital diets with relation to treatment of diseases. McCullough 561
The etiology of sprue, pellagra, and scurvy, Nicholls 562
The scurvy of guinea nigs. III, Hess and Unger 562
Remarks on nathogenesis of deficiency diseases and on pellagra, Rondoni_ 562
Dietetic helps in diabetes, Donk562
Analysis of normal Filipino urine, Concepcion 562
Metabolism and cooling power, Hill and Hargood-Ash 565
Energy exchange in man, Krogh568

# ANIMAL PRODUCTION.

[Food Control Officials Sixth seventh and eighth meetings]	563
[Feed Control Onicials.—Sixth, seventh, and eight integral	564
[Feed Control Officials.—Ninth and tenth annual meetings]	FOA
Commercial feeding stuffs, Proulx et al	564
Inspection of commercial feeds, Wessels	564
Texas feed control law.—Advice to dealers and distributors, Fuller	564
Farm feeds: Grains, mill feeds, and concentrates, Shutt	564
Bran and shorts under Canada Food Board, Shutt and Dorrance	565
Range management on the National Forests, Jardine and Anderson	565
Fattening steers on summer pasture in the South, Ward, Gray, and Lloyd	565
Cattle feeding experiments, Scott	566
Corn silage for beef production, Wilson and Thompson	567
[Steer feeding experiments in Canada]	567
Raising calves on farms where whole milk is sold, Swett	567
Sheep on irrigated farms in the Northwest, Jayne	568
Does it pay to feed corn to fattening lambs on pasture? Hammond	568
Feeding experiments [with hogs], Scott	568
Economical substitutes in swine feeding, Rothwell	569
# CONTENTS.

	Page.
[Swine feeding experiments in Canada]	569
Hogging down rye, Robison	569
Citrus fruit rinds as a hog feed, Allen	570
[Feed records of Canadian horses]	570
Feeding experiments with Leghorns, Philips	570
Poultry feeding experiments, Thompson	571
Influence of age of hens on egg production, Dvorachek and Stout	571
Illumination of poultry houses to increase egg production, Aubry	572
How to prevent loss in market eggs, Pound	572

# DAIRY FARMING-DAIRYING.

Experimental feeding [of dairy stock], Langelier	572
Calf-feeding experiments at Kilmarnock, 1916 and 1917, Paterson	572
The escutcheons of dairy cows, Hooper	572
Composite samples, their value to the dairy plant, Mojonnier	573
Varying bacteriological results from different laboratories, Kilbourne	573
A new method for scoring dairies, Judkins	573
The Chicago milk inquiry, Duncan	573
Report of Chicago Milk Commission	574

# VETERINARY MEDICINE.

Effect of nutrition on agglutinins, complement, and amboceptor, Zilva	574
Growth accessory substances for bacteria in animal tissues, Kligler	574
Studies on the biology of streptococcus.—I, Dochez et al	575
The antigenic properties of proteoses, Fink	575
Is hemoglobin antigenic? Schmidt and Bennett	-576
Prophylactic and curative value of serums and vaccines, Izcara	576
Gas gangrene.—Protection by antiserum and antiserum mixture, Nevin	577
Bactericidal action of whole blood of rabbits, Heist and Solis-Cohen	577
Bacterial flora of milk with high counts from normal udder, Cooledge	578
Contagious abortion in cattle, McGilvray	578
The cattle tick pest	578
The pathology and epizootiology of louping ill, Stockman	578
Chronic pox-like infection in goats and its treatment, Stone and Fisher	578
Dissemination of hog cholera by insects, Dorset et al	578
A new strongylid from the hog, Railliet, Henry, and Bauche	579
The blood pressure of the horse, Schilling	579
Epizootic lymphangitis of solipeds, Boquet, Nègre, and Roig	579
Contribution to study of ulcerative lymphangitis of horse, Mullie	579
Report on ulcerative lymphangitis in the A. E. F., Leibold	579
The streptococci of equines, Jones	580
Scrapie, M'Gowan	580
Sarcosporidia as the cause of scrapie, M'Fadyean	580
Traumatic action of Strongylus equinus, Parodi and Widakovich	580
Differentiation and distribution of paratyphoid group.—VI, Mulsow	580
Lead poisoning in waterfowl, Wetmore	581
The loco-weed disease, Marsh	582

# RURAL ENGINEERING.

Tests to determine pressure due to hydraulic fills, Goldbeck	582
Tables of cubic contents of levee embankments, Stiles	582
Cubic yards on sloping cross sections from level cross sections, Stiles	582
Tables of velocity of water in open channels, Stiles	582
Latitude, longitude, and sea level elevation of bench marks in Tex., Stiles_	583
Hydrometric surveys (stream measurements) for 1916, Sauder et al	583
Phosphorus, potassium, and nitrogen of water, Greaves and Hirst	583
The biology of waterworks, Kirkpatrick	583
Chlorination of water, Race	583
Chlorinated lime and halazone in disinfection of drinking water, Fantus_	583
Sterilization and purification of water with sodium hypochlorite, Fralick_	583
Loads on highway bridges	583
Test tractive efficiency of concrete roads, Hines	584
Concrete construction for rural communities, Seaton	584
Absorption tests of slag, stone, and gravel concrete, Smith	584

	Page.
Stresses in wire rope as applied to modern engineering problems. Howe	584
Concentrated load tests of yellow pine beams. Manville and Hill	584
Prolonging life of farm timbers, Berry	584
Results of long-time tests of creosote treated fence posts. Teesdale	585
Fencing the farm, Rutherford	585
The Diesel engine: Its fuels and its uses, Haas	585
Length of motor truck stop varies inversely as braked load	586
Important and neglected features of tire maintenance. Masury	586
Directory and specifications of farm tractors	586
Mole plows worked by horses	586
A barn for the small farm, Musselman	586
Practical hog houses for Indiana, Norman and Schwab	586
Silos and silage in Arkansas, Dvorachek	587
Stall construction, Musselman	587
Greenhouse heating, King	587
Cost of and revenue from electric heating on Minidoka project, Dibble	587

No. 6.

# **RECENT WORK IN AGRICULTURAL SCIENCE.**

# AGRICULTURAL CHEMISTRY-AGROTECHNY.

Agricultural chemistry, E. GAIN (*Chimie Agricole. Paris: Libr. J. B. Baillière, 1918, 2. ed., pp. 510, figs. 137*).—Owing to the advances made in agricultural chemistry since the first edition of this volume 23 years ago, the work has been entirely rewritten following the lines of the course in agricultural chemistry given by the author at the University of Nancy. The subject matter is treated under the five general headings of elements of general agronomy, physiology of the nutrition of plants, study of the soil and of the atmosphere considered from the point of view of the complex phenomena which control the nutrition of the plant and the fertility of the soil, fertilization of the soil, and the chemical composition of agricultural products.

Industrial and agricultural chemistry in British Guiana; with a review of the work of Professor J. B. Harrison, C. A. BROWNE (Jour. Indus. and Engin. Chem., 11 (1919), No. 9, pp. 874-881, figs. 5).—The author describes a few phases of agricultural and industrial chemistry in British Guiana as observed during a recent visit to the British Colonies of tropical America. The industries discussed are the sugar industry with the sugar by-products, alcoholic spirits and molascuit, gold, balata, the congealed latex of the true Minusops balata used as a substitute for gutta percha, and bauxite. The article also includes a description of the researches upon tropical soils conducted by J. B. Harrison, head of the governmental Department of Science and Agriculture of British Guiana, and an account of the government laboratory in Georgetown.

Bulletin from the analytical food laboratories in Surinam, J. SACK (Keuringsdienst Eet-en Drinkwaren Suriname, Bul. E (1919), pp. 21).—This bulletin contains the results of analyses of various seeds for their fat and moisture content, together with the more important constants of the oils extracted from the seeds with carbon tetrachlorid. The seeds selected include many which according to the author have never been analyzed before.

International catalogue of scientific literature. D.—Chemistry (Internat. Cat. Sci. Lit., 14 (1919), pp. VIII+761).—The fourteenth annual issue of this catalogue (E. S. R., 37, p. 501) contains material received between September, 1914, and May, 1916.

The volatile oils, E. GILDEMEISTER and F. HOFFMANN (*Die Ätherischen Öle.* Leipsic: Schimmel & Co., 1916, vol. 3, 2. ed., pp. XVIII+836, pls. 3, figs. 52).— This is the second edition, edited by E. Gildemeister, of the third volume of this work, the second volume of which has been previously noted (E. S. R., 30, p. 310). American tomato seed oil, G. S. JAMIESON and H. S. BAILEY (Jour. Indus. and Engin. Chem., 11 (1919), No. 9, pp. 850-852).—This investigation, reported from the Bureau of Chemistry, U. S. Department of Agriculture, includes an extensive study to determine whether arachidic acid is present in tomato seed oil and determinations of the analytical constants of the oil.

Although the Renard test indicated the presence of a considerable amount of arachidic acid in tomato seed oil, attempts to isolate the acid by various methods resulted in a very small yield, the largest amount being obtained by fractional distillation under diminished pressure of the methyl esters of the solid fatty acids obtained from the oil by the lead salt-ether method. The yield of acid melting at 77° C. indicated that the oil contained about 0.4 per cent of arachidic acid. The conclusion is drawn that the Renard test when applied to unfamiliar oils can not be relied upon to indicate the quantity of arachidic acid present.

A table is given of the physical and chemical constants of nine authentic samples of American tomato seed oil.

Contribution to the study of the ash-constituents of plants, L. and D. LEROUX (Ann. Chim. Analyt., 2. ser., 1 (1919), No. 7, pp. 207-209).—A table is given of the ash-constituents of certain roots and tubercles, including those of the potato, comfrey, dahlia, burdock, field thistle, gentian, carrot, turnip, water lily, nettle, and fern.

The composition of the ash of crab grass (Digitaria sanguinalis) as affected by the soil in which it is grown, G. D. BUCKNER (*Jour. Amer. Chem. Soc.*, 41 (1919), No. 9, pp. 1384, 1385).—Analyses made at the Kentucky Experiment Station of samples of crab grass (*Digitaria sanguinalis*) grown in garden soil and in a limestone roadway are reported.

The sample grown in the limestone roadway contained approximately 16 per cent less ash, 18.8 per cent less  $K_2O$ , 22.7 per cent more  $P_2O_5$ , 44 per cent more CaO, and 27.6 per cent more MgO than the samples grown in garden soil. The percentage of silica was approximately the same in the two samples.

"The outstanding feature in connection with the growth of these two samples of crab grass is that the absorption and retention of these different amounts of calcium, magnesium, phosphorus, and potassium cause no observable difference in their external appearance."

Physical and chemical properties of liquid hydrocyanic acid, G. P. GRAY and E. R. HULBRIT (*California Sta. Bul. 308 (1919)*, pp. 408–428).—The use of hydrocyanic acid gas in citrus fumigation led to the study of the physical and chemical properties of the liquid here reported.

"Two test runs of the liquefying plant were made in order to establish a basis of settlement between plant and fumigator. The liquid hydrocyanic acid recovered in the first test run was 80.1 per cent of the greatest possible yield; in the second, 76.3 per cent; an average of 78.2 per cent. The average purity of the liquid obtained in the first run was 97.57 per cent; in the second, 94.27 per cent. The average purity of the liquid delivered during the past fumigating season was above 95 per cent absolute hydrocyanic acid. Material of 95 per cent or greater purity is considered of a satisfactory grade. As the plant was operated last season, the following is believed to be a fair return per case of 200 lbs. of sodium cyanid: (1) A minimum of 85 lbs. of absolute hydrocyanic acid; or (2) a minimum of 90 lbs. of liquid testing not less than 95 per cent purity." An appended table prepared by the authors shows the weights and corresponding volumes of various grades of commercial liquid and the quantities thereof corresponding to various percentages of the maximum yield.

It was found that the acid is miscible with water in all proportions and will not stratify upon standing. Hydrocyanic acid evaporates more rapidly than water from dilute mixtures of the two. Complete data have been obtained on 1919]

the specific gravity of commercial liquid hydrocyanic acid testing from 70 per cent to 100 per cent purity and upon the extent of variation of hydrometer readings as affected by temperature, and these figures are given in the form of reference tables, by means of which it is possible to determine the quality of a liquid in a moment's time by the use of a hydrometer graduated either in specific gravity or Baumé degrees. These data have made possible the construction of a cyanometer, a hydrometer graduated directly in percentages of hydrocyanic acid and provided with a simple table of temperature corrections.

"A method of analysis has been selected and shown to give concordant results within 0.2 per cent. The development of any color, usually yellow, or an odor of ammonia may be taken as a warning of incipient decomposition of the liquid. Factors and materials favoring decomposition are water in excess of 5 per cent; high temperatures; residue from a decomposed liquid; all alkalis, nitric acid, sodium cyanid; soap; or contact with lead, commercial tin, impure zinc, solder, cast-iron, or steel. The following metals were found to be highly resistant to the acid, somewhat in the order named: Aluminum, block tin, pure zinc, brass, nickel, silver, and copper. Aluminum is the most promising material for the construction of delivery drums. Brass fittings are permissible."

An adiabatic bomb calorimeter, E. B. HOLLAND, J. C. REED, and J. P. BUCK-LEY (*Chem. and Metallurg. Engin.*, 21 (1919), No. 4, pp. 190, 191, fig. 1).—The authors describe certain improvements introduced at the Massachusetts Experiment Station in the construction, thermometers, and lens of an adiabatic bomb calorimeter of the Berthelot-Mahler-Kroecker type. A diagram is given of the calorimeter as modified.

Electrical apparatus for use in electrometric titration, H. S. ROBERTS (*Jour. Amer. Chem. Soc.*, 41 (1919), No. 9, pp. 1358–1362, figs. 2).—The author points out that the choice of apparatus for use in electrometric titration is very different from that of potentiometric apparatus for other purposes owing to the fact that the interest lies in relative rather than absolute values of the electromotive force developed during the titration, that the electromotive force frequently changes sign, and that the apparatus must often be used in an atmosphere charged with acid fumes.

Two simplified potentiometers for use in electrometric titration are described and illustrated, and suitable forms of galvanometers are mentioned.

Indicator test papers, I. M. KOLTHOFF (*Pharm. Weekbl.*, 56 (1919), No. 7, pp. 175–187; abs. in Chem. Abs., 13 (1919), No. 15, p. 1689).—A study is reported of the influence upon indicator papers of various factors such as the kind of paper employed and its preliminary treatment with various reagents, the concentration of the solution used, the manner of testing, and the nature of the solution. This is followed by a discussion of the possible uses of indicator papers, the conclusion being drawn that their chief value is in qualitative analysis within definite limits of H-ion concentration.

A table is included of relative sensitivities of various indicator papers.

A rapid hydrogen electrode method for determination of hydrogen-ion concentrations in bacterial cultures or in other turbid or colored solutions, H. M. JONES (Jour. Infect. Diseases, 25 (1919), No. 3, pp. 262-268, figs. 2).---A simple form of hydrogen electrode apparatus is described which is said to allow rapid saturation with hydrogen gas and to be accurate to at least 0.01 pH. A technique combining the indicator and gas-chain method is outlined for use when large numbers of determinations are to be made, as in bacterial cultures. This consists of taking a portion (2 cc.) of each solution to be tested, diluting with 4 cc. of distilled water, and after arranging the tubes in groups with reference to their degree of turbidity, placing each group in separate rows in test tube racks. Equal amounts of some indicator with a range of color change adapted to the probable acidities of the solution are placed in each tube and shaken. The tubes are then collected in subgroups of similar colors, and one specimen of each subgroup is tested with the hydrogen electrode to determine the H-ion concentration of the entire subgroup.

A sensitive reaction of manganese salts, H. CARON and D. RAQUET (Ann. Chim. Analyt., 2. ser., 1 (1919), No. 6, p. 174).—The authors state that manganese salts in slightly acid solution react in the cold with an excess of an alkaline oxalate and certain oxidizing agents (bichromates, hypochlorites, and sodium peroxid) to form an alkaline manganic oxalate of a deep red color. Potassium oxalate, acetic acid, and potassium hypochlorite are recommended as furnishing the most sensitive reaction, it being possible to detect manganese in a 1:200,000 solution.

Iron in quantity is said to mask the color reaction, while zinc does not interfere with the reaction provided sufficient oxalate is used to dissolve the precipitate of zinc oxalate formed and enough acetic acid is added subsequently to acidify the solution.

The reaction, while less sensitive than those based on the transformation of manganese into permanganic acid by lead dioxid, persulphates, or bismuth peroxid, has the advantage of not being interfered with by chlorids.

Specific colored reaction of oxalates, H. CARON and D. RAQUET (Ann. Chim. Analyt., 2. ser., 1 (1919), No. 7, p. 205).—The reaction noted above is said to be equally applicable as a test for oxalic acid and oxalates in amounts as small as 0.01 gm. In the case of free oxalic acid or a solution having quite a strong mineral acidity, sodium acetate should be used in place of acetic acid. Insoluble oxalates should be boiled for a few minutes with a solution of an alkaline carbonate, and the test made with the cold filtered liquid acidified with acetic acid. Phosphoric, hydrofluoric acid, etc., are said not to interfere with the reaction.

Iodometric studies, I. M. KOLTHOFF (*Pharm. Weekbl.*, 56 (1919), Nos. 13, pp. 391-404; 14, pp. 426-438; 15, pp. 460-465; 16, pp. 514-524; 18, pp. 572-585; 19, pp. 621-634; 20, pp. 644-657, figs. 2; abs. in Chem. Abs., 13 (1919), Nos. 13, pp. 1434, 1435; 14, pp. 1569, 1570).—These numbers report, respectively, a series of quantitative iodometric studies under the following headings: I, Introduction; II, the starch iodid reaction; III, the iodometric bromate determination; IV, the iodometric determination of chloric acid; V, the iodometric determination of chromic acid (with E. H. Vogelenzang); VI, the reaction of thiosulphate with iodin; VII, the reaction between arsenic trioxid and iodin; and VIII, standardization of sodium thiosulphate solutions.

The determination of nitrogen by the Kjeldahl process, A. VILLIERS and A. MOREAU-TALON (Ann. Chim. Analyt., 2. ser., 1 (1919), No. 6, pp. 183–185).—The authors recommend the use of both potassium sulphate and mercury in the digestion process, the sulphate being added at the beginning and the mercury (1 gm.) after the solution has become nearly colorless. The solution is heated gently for 15 minutes or more after the addition of the mercury, and is then distilled into dilute hydrochloric acid and the distillate evaporated to dryness. The nitrogen is calculated by a gravimetric determination of the ammonium chlorid formed, or by a volumetric determination with a standardized solution of silver nitrate using potassium chromate as indicator.

Notes on potash determination, L. G. L. STEUERWALD (Arch. Suikerindus. Nederland. Indië, 27 (1919), No. 9, pp. 435-438; abs. in Chem. Abs., 13 (1919), No. 13, p. 1436).—A modified method for determining potash by precipitation as potassium platinic chlorid and reduction to metallic platinum is described in which sodium formate is used as the reducing agent.

The estimation of sulphates in a concentrated electrolyte and the determination of sulphur in foods, V. K. KRIEBLE and A. W. MANGUM (*Jour. Amer. Chem. Soc.*, 41 (1919), No. 9, pp. 1317–1328).—As the outcome of a study of the oxidation of food by sodium peroxid and the precipitation of sulphates as barium sulphate in solutions containing large amounts of sodium chlorid, a modified method is described which is considered by the authors to be a decided improvement both in the oxidation process and in the final estimation of sulphates in materials such as food samples in which the sulphur content is low.

Danger of the samples either exploding or taking fire during the oxidation is avoided by mixing a suitable quantity of sodium carbonate with the second addition of sodium peroxid in the fusion, and subsequently heating just one side of the nickel crucible in order to start the oxidation locally and keep the rest of the mixture in the crucible relatively cool.

The technique of the precipitation of the sulphates as barium sulphate is as follows: The solution of the oxidized material from 2 or 3 gm. of the original sample is neutralized with concentrated hydrochloric acid, brought to a volume of 350 cc. and heated to boiling on a hot plate. It is then removed from the hot plate and the barium sulphate precipitated by adding slowly with a dropper 10 cc. of a 10 per cent barium chlorid solution. After standing for 48 hours the mixture is evaporated to dryness on a hot plate, the precipitate dissolved in a little water, and from 1 to 2 cc. of concentrated hydrochloric acid added. After standing for 18 hours longer, the precipitate is collected in a Gooch crucible, washed, dried, and ignited to constant weight.

It is stated that the results obtained by this method will be high, and should be corrected by a comparison of the amount of barium sulphate obtained by making a determination on a solution of sodium or potassium sulphate of such strength that the amount taken should give about the same amount of barium sulphate as obtained from the food.

The determination of lactose and of albuminoids in autoclaved milk and in milk preserved by the addition of potassium dichromate, P. DEFRANCE (Ann. Falsif., 12 (1919), No. 125-126, pp. 78, 79).—The author refers to the conclusions of Porcher and Bonis previously noted (E. S. R., 40, p. 613) that the polarimetric determination of lactose in milk preserved with sodium bicarbonate is unreliable, and states that he has arrived at the same conclusion in testing milk preserved with potassium dichromate. In his opinion, however, the change in rotatory power should be attributed to alterations in the casein rather than in the lactose.

On the estimation of sugar in blood, H. MACLEAN (*Biochem. Jour.*, 13 (1919), No. 2, pp. 135-147, figs. 2).—A method for the estimation of sugar in the blood is described which is essentially a modification of a method previously introduced by the author.<sup>1</sup>

The principle of the method consists in separating the proteins by heat coagulation in an acid saline solution and subsequently precipitating any remaining traces of protein by the use of dialyzed iron. The sugar in an aliquot part of the protein-free filtrate is estimated by boiling the liquid with an alkaline copper solution containing potassium iodate and iodid and treating the solution containing the reduced cuprous oxid in suspension with a slight excess of hydrochloric acid. This interacts with the potassium iodate and iodid, liberating iodin equivalent to the amount of potassium iodate in the solution. The cuprous oxid is changed to cuprous chlorid which immediately reacts with the free iodin. The amount of sugar is calculated by a determination of the iodin used.

144402°-19-2

ATION RECORD. [Vol. 41

For blood sugar determinations the method is said to be applicable to 1 cc. or smaller amounts. Detailed instructions are given for the preparation of the various solutions required and for the technique of the procedure when 1 cc. and 0.2 cc. of blood, respectively, is used.

The picric acid method for the estimation of sugar in blood and a comparison of this method with that of Maclean, O. L. V. DE WESSELOW (*Biochem. Jour., 13 (1919), No. 2, pp. 148–152, fig. 1*).—A comparison of the method of Maclean noted above and the picric acid method of Benedict (E. S. R., 39, p. 112) is reported.

The Benedict method was found to give results from 30 to 50 per cent in excess of those obtained by the Maclean method.

"The high results appear to be chiefly due to the presence of an interfering substance or substances mainly concentrated in the corpuscles but present to some extent in the plasma also; this substance reacts with the picric solution at an early stage of the heating. Creatinin probably plays a large part in this reaction. On account of the influence of this interfering factor the accurate estimation of sugar in whole blood by the picric acid method as described by Benedict is impossible."

Notes on the determination of water solubles in leather, R. W. FREY and I. D. CLARKE (*Jour. Amer. Leather Chem. Assoc.*, 14 (1919), No. 9, pp. 488– 499).—Data obtained at the Bureau of Chemistry, U. S. Department of Agriculture, are presented indicating the influence of various factors on the determination of water solubles in leather, and the recommendation is made that the Official Method should be revised and standardized.

The industries of the farm, A. LARBALETRIER (*Les Industries de la Ferme. Paris: Libr. Larousse, 2. ed., pp. 216, figs. 160*).—The industries treated in this volume are milling, baking, starch, sugar, wine, cider, beef, distilled beverages, vinegar, oils, milk, butter, cheese, and preserves.

Methods of preservation of fruits and vegetables, A. MANARESI (Metodi di Conservazione dei Frutti e Degli Ortaggi. Casale Monferrato, Italy: Marescalchi Bros., 1915, pp. XVII+555).—This volume contains general directions for the preservation of fruits and vegetables by inert substances, cold, desiccation, antiseptics, and heat. Special directions are given for certain products under each class, and a bibliography is included for each section.

Fruit preserves prepared in the cold without the addition of sugar, alcohol, or antiseptics, G. BERTBAND (Compt. Rend. Acad. Sci. [Paris], 168 (1919), No. 23, pp. 1162–1164).—The author reports that out of 47 jars of different fruits canned in cold water, after a preliminary washing but with no further treatment, 17 were in perfect condition at the end of 11 months. In the other jars there was greater or less indication of alcoholic fermentation but no evidence of other changes. As a result of this study the author concludes that it is possible to preserve fruits by the elimination of air in flasks filled with water without the necessity of adding sugar or any other substance, or of heating the fruit.

The mechanism of the preservation of fruits in cold water, G. BERTBAND (Compt. Rend. Acad. Sci. [Paris], 168 (1919), No. 25, pp. 1285–1288).—The theory is advanced that the preservation of fruit by the method noted above is due to the action upon the dissolved oxygen originally present of diastases present in the fruits, thus rendering the medium anaerobic and preventing fermentation. The chances of success in the use of this method are consequently thought to depend upon the number, nature, and degree of vitality of the organisms present in the flask, upon the acidity of the fruits, and above all upon the intensity of the biochemical processes which bring about the disappearance of the dissolved oxygen. Cut fruits are apparently better suited to this process than whole fruits on account of the more rapid solution of the cellular juices in the water.

The composition and calorific value of sirups and molasses derived from sugar cane, C. A. BROWNE (*Jour. Amer. Chem. Soc.*, 41 (1919), No. 9, pp. 1432–1440).—This paper contains a brief outline of the changes in constituents of sugar cane juice during sirup manufacture and the resulting changes in calorific value of the juice, followed by experimental data on the composition and calorific value of eight samples of sirups and molasses. These samples included the clear mother liquor from pure concentrated sugar cane juice, openkettle molasses, a sample of first Cuban molasses, three of refiner's sirup, and one of refiner's low grade molasses.

The conclusions drawn from the investigation are as follows:

In the manufacture of sirups and molasses by the ordinary process of defecation with lime there is a progressive increase in the calorific value and carbon content of the organic nonsugars, owing to the formation of dehydration products such as caramel, saccharin, glycinic acid and its humoid derivatives. Filtration over bone black results in a considerable removal of the lime salts of glycinic acid with a decrease in the calorific value and carbon content of the organic nonsugars. Fewer dehydration products are formed in the manufacture of molasses by the sulfitation than by the defection process, the result being a molasses of lighter color and lower calorific value and carbon content of the organic nonsugars.

The calorific value of the total solids in the sirups and molasses varied between 3.6 and 3.8 calories per gram of dry substance, the average being about 3.7 calories. The calorific value of the organic matter in high-grade openkettle sulfitation molasses and in high-grade refinery sirups was found to be about 3.9 calories, and in sugarhouse defecation molasses and refinery molasses 4 calories per gram of dry organic substance. The calorific value of the organic nonsugars in refinery sirups was between 4.04 and 4.16 calories, and in sugarhouse and refinery molasses 4.44 and 4.6 calories, respectively, per gram of dry substance.

The carbon content of the organic nonsugars in open-kettle and refinery sirups varied between 40.32 and 42.74 per cent and that of the organic nonsugars in a sugarhouse and refinery molasses 48.17 and 49 per cent, respectively, per gram of dry substance.

The results of this work are thought by the author to have some bearing upon questions of nomenclature, in that refinery sirups which have been filtered over bone black differ from defecation molasses so distinctly in the composition and calorific value of their organic nonsugars that in a chemical sense they should not be termed molasses.

The deterioration of manufactured cane sugar by molds, N. and L. KOPE-LOFF (Jour. Indus. and Engin. Chem., 11 (1919), No. 9, pp. 845-850).—Essentially noted from another source (E. S. R., 41, p. 416).

**Production of glycerin from sugar by fermentation**, J. R. EOFF, W. V. LINDER, and G. F. BEYEE (*Jour. Indus. and Engin. Chem.*, 11 (1919), No. 9, pp. 842-845, fig. 1).—This is a report of an investigation, conducted by the Division of Chemistry of the U. S. Bureau of Internal Revenue, on the problem of glycerin production from sugar by fermentation.

The yeast finally selected as the best glycerin former was *Saccharomyces ellipsoideus* (var. Steinberg). Favorable results were obtained from solutions of inedible black strap Porto Rican molasses, mixtures of corn sugar and malt sprouts solutions, and solutions of corn sugar and metallic salts. The first formed the cheapest source of sugar and proved to be as efficient for the production of glycerin as the more expensive mixtures.

1919]

It was found that the yield of glycerin was increased by fermentation in alkaline solution. Dry soda ash in proportions of about 5 per cent of the mash proved most favorable as the alkaline agent. The most favorable temperatures for the fermentation were found to be between 30 and 32° C. and the concentration of sugar solution between 17.5 and 20 gm. of sugar per 100 cc. Upon completion of the fermentation, from 20 to 25 per cent of the sugar originally in the mash is converted into glycerin and practically all of the remaining sugar into alcohol and carbon dioxid. On purification of the fermented mash and distillation in a vacuum evaporator, about 50 per cent of the glycerin originally in the mash can be recovered, and by redistillation of the crude product a satisfactory dynamite glycerin can be obtained.

It is thought that the alcohol which can be recovered in this process will be of sufficient value to balance the cost of materials and production, and that the only cost to be considered for the glycerin is that of purification and distillation.

The process as carried out under factory conditions is described, and a diagram is given of the experimental glycerin still employed.

Mannose yeast, G. MEZZADROLI (Staz. Sper. Agr. Ital., 51 (1918), No. 7-8, pp. 306-311).—In searching for a suitable yeast for the fermentation of the must obtained from vegetable ivory (fruit of *Phytelephas macrocarpa*) waste, remaining from the manufacture of buttons, a yeast obtained from Puglia was found to have the most marked action, causing a regular and rapid production of alcohol. This yeast was found to be nonspecific in that sorbose, sucrose, maltose, lactose, raffinose, and inulin were acted upon with almost equal rapidity. The author is of the opinion that this yeast, on account of its polyvalent enzym action, may have some application in the distilling industry, particularly for the fermentation of sugar cane molasses.

The cytological and biochemical properties of the yeast are described in detail.

Conference on recent developments in the fermentation industries (*Jour. Soc. Chem. Indus., 38* (1919) No. 14, pp. 271T-286T).—The report of this conference, held July 17, 1919, in connection with the annual meeting of the Society of Chemical Industry (England), includes papers on The Manufacture of Acetone, by F. Nathan, The Acetone Fermentation Process and its Technical Application, by A. Gill, Employment of Microorganisms in the Service of Industrial Chemistry, and A Plea for a National Institute of Industrial Microbiology, by A. C. Chapman.

Potash from kelp: The experimental plant of the United States Department of Agriculture; preliminary paper, J. W. TURRENTINE and P. S. SHOAFF (*Jour. Indus. and Engin. Chem.*, 11 (1919), No. 9, pp. 864–874, figs. 6).—A detailed description is given of the experimental kelp-potash plant of the U. S. Department of Agriculture at Summerland, Cal., which was "designed for the determination of the best methods of processing kelp for the extraction of potash salts and the simultaneous recovery of other valuable products, was erected during the summer of 1917, and put into operation in the early fall of that year.

"One hundred tons of raw kelp per day are subjected to a process involving drying, destructive distillation, lixiviation, evaporation, and fractional crystallization for the preparation of high-grade potassium chlorid.

"The by-products kelp oils, creosote, pitch, ammonia, bleaching carbons, salt, and iodin are yielded in commercial quantities by this process. The main problem now in hand is their commercialization. It is confidently believed that they will be made to yield sufficient revenue to enable the main product, potash salts, to be marketed successfully in competition with potash from foreign sources. "Complete operating cost data are being tabulated covering the various details of manufacture. These, together with full specifications and designs, will be made available for the use of the interested public. The results obtained to date indicate that it will be possible to establish on kelp as the basic raw material a new American chemical industry of considerable size and of importance and usefulness to the nation."

Charts are included illustrating the general operations and products of the plant, the products of the dry distillation process, and the organization and personnel of the staff.

Hemlock bark as a source of tannin, V. P. EDWARDES (*Chem. Engin.*, 27 (1919), No. 8, pp. 178-182, fig. 1).—This paper gives the results of an investigation conducted at the Forest Products Laboratory, Madison, Wis., of the value of hemlock bark as a source of tannin.

Analytical data on five runs of hemlock bark before and after drying indicated that the tannin content of the bark is not appreciably lowered in the drying process. The percentage of tannin (on the bone-dry basis) after drying varied from 9.1 to 10.5 per cent.

Statistics are given of the amount of hemlock bark available in different States, from which it is estimated that if all the bark could be recovered by improved barking processes there would be more than enough to supply the needs of the tanning industry.

# METEOROLOGY.

Climatological data for the United States by sections (U. S. Dept. Agr., Weather Bur. Climat. Data, 5 (1918), No. 13 pp. 388, pls. 6, figs. 48).—Summaries and detailed tabulated statements of climatological data for the year 1918 are given for each State.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. OSTRANDER and G. A. SMITH (*Massachusetts Sta. Met. Buls.* 367-368 (1919), pp. 4 each).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during July and August, 1919, are presented. The data are briefly discussed in general notes on the weather of each month.

Meteorology, J. B. TRIVETT (N. S. Wales Statis. Reg., 1917–18, pt. 4, pp. 223– 307).—Tables are given which summarize the results of observations at Sydney, New South Wales, on atmospheric pressure, 1917; temperature, 1876–1917; rainfall, 1840–1917; wind, humidity, dew, and fog, 1917; and heavy rainfalls since 1891. Similar data are also summarized for various other stations, 1906–1917, and the general meteorological conditions of New South Wales for each month of 1917 are briefly described.

The mild winter of 1918–19, C. F. BROOKS (Science, n. ser., 50 (1919), No. 1285, pp. 165, 166).—It is stated that "except in the South, the mean temperatures of last December and January were generally 15° F. higher than during the same period of a year before. The snowfall was practically negligible as compared with the great accumulations of the previous 'old-fashioned' winter [E. S. R., 39, p. 114]... The region west of the Rockies, which was so warm in the winter of 1917–18, was generally unusually cold in December, 1918, and in much of Utah, northern Arizona, and New Mexico, where the depth of snow was great, in January, and much of February, 1919, as well. Throughout the rest of the region, the past winter was not very unusual."

A table is given which shows the contrasts in temperature and snowfall in a number of representative cities in the United States. Some characteristics of the rainfall of the United States, R. DEC. WARD (Sci. Mo., 9 (1919), No. 3, pp. 210-223).—This is a brief critical digest of the more important literature on this subject, dealt with under the following heads: Annual and monthly variability of rainfall, consecutive days with and without precipitation, droughts, hourly frequency of rainfall, heavy rainfalls in short periods, instrumental records and noninstrumental evidence of secular variations in rainfall, and the climatologist's attitude regarding noninstrumental evidence of climatic changes. It is stated that in the face of the conflicting testimony on the part of the experts, "the conservative climatologist may well remain open-minded" on the question of noninstrumental evidence of secular climatic changes.

**Bainfall régimes in Mexico, E. LóPEZ (***Rev. Agr.* [*Mex.*], 4 (1919), No. 5-6, pp. 213-218, figs. 2).—The régimes defined and discussed are subtropical calms, simple tropical, tropical and monsoon, tropical and northern, maritime proper, and maritime and northern. The importance of the matter from the standpoint of agriculture is briefly discussed.

The relation of rainfall to configuration, C. SALTER (London: Inst. Water Engin., 1918, pp. 37, pls. 2, figs. 7; rev. in Nature [London], 103 (1919), No. 2579, p. 91).—This article reports a study based upon 35 to 40 years' observations by the British Rainfall Association at a large number of stations but at altitudes as a rule below 1,000 ft. The physical process of rain formation is discussed, and rainfall is classified according to the different circumstances under which air is forced to ascend as convectional, cyclonic, or orographic, the last named being caused by interference of rising land, which makes the moisture-laden air rise.

The first two types are but slightly affected by the configuration of the land. Orographic rain is the predominant type in the British Isles, and the best examples of it occur near the seacoast. It is not frequent in winter. Elevations of only a few feet near sea level affect the amount of rainfall. "The rate of increase per 100 ft. of altitude varies within wide limits. It is lower on slopes parallel to the prevailing winds than on slopes at right angles. On fairly steep ridges close to the sea the maximum rainfall often occurs slightly on the leeward side of the crest." The increase in such cases may be from 1.5 to 2 in. per hundred feet of altitude, but may be smaller when the slope of the land is reduced. Rainfall diminishes steadily on leeward slopes of high land.

Fertilizing value of rain and snow, F. T. SHUTT (*Canada Expt. Farms Rpt.* 1918, p. 19).—In the eleventh year of this investigation (E. S. R., 40, p. 724), 68 samples of rain and 35 samples of snow were analyzed representing a total precipitation of 32.86 in. The total nitrogen supplied amounted to 6,259 lbs. per acre.

The period between blooming and ripening, J. HEGYFOKY (*Met. Ztschr.* [*Brunswick*], 36 (1919), No. 3-4, pp. 79-84).—Observations in Germany on this point with various trees, shrubs, and cultivated plants, and under varying climatic conditions are summarized and discussed, particularly with reference to the conditions causing variations in the length of the period from blooming to ripening.

## SOILS-FERTILIZERS.

The classification of humus-free and humus-poor mineral soils of Sweden according to their consistencies, A. ATTERBERG (Internat. Mitt. Bodenk., 6 (1916), No. 1, pp. 27-37, fig. 1).—The author offers a new classification of the

mineral soils of Sweden which contain either little or no humus, on the basis of consistency. The grouping and classification is as follows:

Group I.-Plastic clays and clay soils containing little or no humus.

Class 1. Highly plastic clay in which the degree of stickiness lies between the flowing limit and the rolling-out limit.

Class 2. Dry plastic clay and clay loam.

Subclass A. Loamy clay of dry plasticity, low flow limit and high firmness.

Subclass B. Loamy clay of dry plasticity, high flow limit, and low firmness.

Subclass C. Poor clay of low consistency and plasticity.

Class 3. Siliceous and sandy clays.

Group II.—Loams of low plasticity which have a relatively high binding power.

Class 1. Heavy clay loam, hard and firm when dry and loose and easily worked when moist.

Class 2. Lighter loams of low firmness.

Subclass A. Fine sandy loam.

Subclass B. Poor weathered clay loam of sedimentary origin.

Class 3. Siliceous and coarse sandy loam.

Group III.—Sandy soils of loose texture, very low firmness, and practically no consistency.

Class 1. Fine sands.

Class 2. Coarse sands.

Class 3. Siliceous sands.

The classification of the mineral soils of high humus content of Sweden, A. ATTERBERG and S. JOHANSSON (Internat. Mitt. Bodenk., 6 (1916), No. 1, pp. 38-59, figs. 3).—Studies of the mineral soils of Sweden, of high humus content, with reference to determining their proper classification, are reported. The results obtained indicate that these soils should be classified into the four following main groups:

(I). Nonplastic soils containing from 3 to 6 per cent humus.

(II). Nonplastic black soils containing over 6 per cent humus.

Subclass 1. Soils with low flow limit containing from 8 to 9 per cent humus.

Subclass 2. Soils with high flow limit containing from 10 to 22 per cent humus.

(III). Kieselguhr black soils containing from 12 to 21 per cent humus and characterized by the high content of diatomaceous residues and high flow limit.

(IV). Clays rich in humus of high plasticity.

Subclass 1. Soils of low consistency.

Subclass 2. Soils of medium consistency.

Subclass 3. Soils of high consistency.

On the basis of these results it is concluded that mechanical analyses are superfluous for these soils, and that volume weight and flow limit determinations are sufficient for their classification.

Soil survey of the Los Angeles area, Cal., J. W. NELSON, C. J. ZINN, A. T. STRAHORN, E. B. WATSON, and J. E. DUNN (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1916, pp. 78, pls. 3, fig. 1, map 1).—This report, prepared in cooperation with the California University Experiment Station, deals with the soils of an area of 360,320 acres in southern California which topographically consists of a fringe of low hills and a low alluvial plain. The area is

[Vol. 41

well drained. With reference to origin the soils of the area are residual soils, old valley-filling, and coastal plain soils, recent alluvial fan and flood-plain soils, wind laid soils, and miscellaneous material. Thirty soil types of 13 series and 4 miscellaneous types are mapped, of which the Ramona loam, the Hanford fine sandy loam, and rough broken land cover 17.6, 15.9, and 10.3 per cents of the area, respectively.

"In the southeastern third of the area the water table is prevailingly high, and injurious amounts of alkali have accumulated over considerable areas. Alkali occurs both in continuous areas of small extent and in patches, as well as in amounts too small to affect plant growth. Sodium sulphate prevails over inland areas, and sodium chlorid or common salt in the marshes along the coast. Black alkali has developed in some small accumulations. Considerable areas have been drained and much of the alkali removed by leaching."

Analyses of soils of Terrell County [Ga.], W. A. WORSHAM, JR. ET AL. (Ga. State Col. Agr. Bul. 172 (1919), pp. 52, flgs. 2).—Chemical analyses are reported of the soils of an area of 213,760 acres in southwestern Georgia, lying entirely within the coastal plains soil province. They show that the principal upland soils are markedly deficient in nitrogen, phosphoric acid, and potash, nitrogen being the relative limiting factor.

Preliminary report on the geology of east central Minnesota including the Cuyuna iron-ore district, E. C. HARDER and A. W. JOHNSTON (Univ. Minn., Geol. Survey Bul. 15 (1918), pp. VI+178, pls. 22).—This report should be of value in a study of the soils of the region.

Rate and extent of solubility of soils under different treatments and conditions, G. J. BOUYOUCOS (*Michigan Sta. Tech. Bul.* 44 (1919), pp. 3–49, figs. 7).—This bulletin describes investigations begun in 1917 on the rate and extent of the solubility of soils as determined by the freezing point method. Clay, clay loam, silt loam, sandy loam, and sandy soils were employed, and were subjected to different salt, fertilizer, and acid treatments accompanied by various moisture contents and temperatures. Untreated samples of a number of types of soil containing various amounts of organic matter and particles of different degrees of fineness were also studied. The moisture contents employed included an optimum and ratios of 1 of soil to 0.7 water, and of 1 of soil to 5 of water. Temperatures of below freezing, room temperature (about 20° C.), and 53° were used. The results may be summarized as follows:

Different classes of soil, with a water content of 1 of soil to 0.7 of water and kept at room temperature, when treated with N/10 salt solutions of  $Ca(NO_3)_2$ , NaNO3, KNO3, KCl, K2SO4, (NH4)2SO4, MgSO4, KH2PO4, CaH4(PO4)2, and  $NaC_2H_3O_2$  and then washed free of all soluble salts showed that the rate of solubility of all the salt treatments except (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> was slow and gradual, and that the process continued for a long time (120 days), but usually for about 50 days. In the case of  $(NH_4)_2SO_4$  the initial velocity was quite rapid but soon slowed down. At the end of about 60 days there was an apparent constancy or equilibrium in the solubility. The extent of solubility at this point was found to be very appreciable in all the salt treatments and in all the soils, with few exceptions. All the soils except sand treated with NaNO3, KNO3, KCl, K<sub>2</sub>SO<sub>4</sub>, (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>, MgSO<sub>4</sub>, and NaC<sub>2</sub>H<sub>3</sub>O<sub>2</sub> yielded quite a large amount of material to solution, the depression in many cases rising from 0.005 to about 0.110° C. or from 125 to 2,750 parts per million of solution. The only salt treatments which did not cause a large solubility product were Ca(NO3)2, KH<sub>2</sub>PO<sub>4</sub>, and CaH<sub>4</sub>(PO<sub>4</sub>)<sub>2</sub>, the depression in some of these treatments rising only from about 0.007° to 0.015° or from 175 to 375 parts per million. As a general rule NaNO<sub>3</sub> and NaC<sub>2</sub>H<sub>3</sub>O<sub>2</sub> in all the soils, except sand, tended to yield the greatest solubility product, CaNO<sub>3</sub>, KH<sub>2</sub>PO<sub>4</sub>, and CaH<sub>4</sub>(PO<sub>4</sub>)<sub>2</sub> the smallest,

and KNO<sub>5</sub>, KCl,  $K_2SO_4$ ,  $(NH_4)_2SO_4$ , and MgSO<sub>4</sub> an intermediate product. In many soils CaH<sub>4</sub>(PO<sub>4</sub>)<sup>2</sup>, and in a few cases, Ca(NO<sub>5</sub>)<sup>2</sup> and KH<sub>2</sub>PO<sub>4</sub> did not only give the smallest concentration but even a smaller concentration than the check, indicating that these salts have an indifferent or depressing effect upon the solubility of soils. As a whole it appeared that the phosphates tend to depress solubility and that they probably act as conservers of bases under field conditions.

"The result of solubility of these singly salt-treated soils goes to indicate that a salt or fertilizer treatment leaves a residual effect upon the soil, and this residual effect continues to be manifested in increased solubility and in increased crop-producing power. These data also go to indicate that the reaction between soils and salts seem to be chemical and not physical. In view of the different residual effects that the different salts or fertilizers have upon the solubility of soils and in view of many theoretical and practical considerations, the solubility factor can not be considered an absolute or reliable criterion for the state of fertility or crop-producing power of soils. In general, however, it can be said that a very heavily fertilized or extremely rich soil gives a greater solubility product than an unfertilized or poor soil."

Although the solubility attained a constancy at the end of about 60 days, this constancy is not believed to be a true equilibrium, the solution not being saturated when solubility ceases. This is said to be demonstrated by the fact that when different proportions of soil and water are employed an apparent equilibrium is attained in all the ratios, while the solubility product is not at all the same when the equilibrium is reached and does not become the same no matter how long the soil and water in the different ratios are kept in contact. Furthermore, considering the character of the soil, it is deemed extremely doubtful if true equilibrium can ever be attained in the soil solution. It is also stated that the solubility process of the soils would undoubtedly go on for a long time, probably almost indefinitely, in view of the extremely slow rate of solubility, if some factors did not intervene.

When different soils were treated with a combination of salts, including  $Ca(NO_3)_2$ , NaNO<sub>3</sub>, KNO<sub>3</sub>, KCl, K<sub>2</sub>SO<sub>4</sub>, (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>, MgSO<sub>4</sub>, KH<sub>2</sub>PO<sub>4</sub>, CaH<sub>4</sub>(PO<sub>4</sub>)<sub>2</sub> and NaC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>, and washed and kept under the same conditions as indicated above their rate of solubility was also slow, but the extent of solubility was very appreciable. The phosphates in this combination did not depress the solubility very markedly, but when (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> and NaC<sub>2</sub>H<sub>3</sub>O<sub>2</sub> were omitted the depression became more marked.

Experimental field soils from the Illinois, New York Cornell, Rhode Island, and Ohio Experiment Stations, which had been fertilized in the usual way, were washed and kept at a moisture content of 1 of soil to 0.7 of water and at room temperature. Their rate of solubility was very slow but their extent of solubility varied, being rather appreciable in some of them and quite small in others, and the variation failing to bear any close connection to the previous fertilizer treatment. These results were in general agreement with those of the single salt-treated soils. Even when these soils were kept at an optimum moisture content and placed outdoors under natural conditions, they failed to give a solubility product which bore a close relation to the previous fertilizer treatment, the rate of solubility being very slow and the extent of solubility quite appreciable but far smaller than that of the salt-treated soils.

Soils treated with HNO<sub>3</sub>, HCl, H<sub>2</sub>SO<sub>4</sub>, H<sub>3</sub>PO<sub>4</sub>, H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>, HC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>, and C<sub>6</sub>H<sub>8</sub>O<sub>7</sub>, washed, maintained at a moisture content of 1 of soil to 0.7 of water, and kept at room temperature showed a quite rapid rate of solubility, although the extent of solubility varied, being very small in the case of the inorganic acids, slightly higher with phosphoric acid, and quite appreciable with the organic acids.

In the untreated soils, which were washed, kept at room temperature, and at a moisture content of 1 of soil to 0.7 of water, both the rate and extent of solubility varied considerably between the different soils, there being no close and consistent relationship between the solubility factor and the class of soil, the organic matter content, and the fineness of particles. Practically the same results were obtained when an optimum moisture content was employed and the soils were kept outdoors under natural conditions, although in some soils more material went into solution when the moisture content was 1 of soil to 0.7 of water than when the moisture content was at optimum. There was a closer relationship on the whole between the solubility factor and the state of fertility or crop producing power of the soil with the former than with the latter.

When natural soils, previously washed, and with a moisture content of 1 of soil to 0.7 of water, were kept at a temperature of 53° their rate of solubility was somewhat appreciably increased. In some soils, however, these factors were not at all affected by the high temperature. The solubility of many soils even at this high temperature continued for a long time, even 60 days, but usually became constant at the end of about 30 days.

At the ratio of 1 of soil to 5 of water the rate of solubility of natural soils was also slow and the extent of solubility extremely small, the amount of material that went into solution at this water content being only about half as great as that at the water content of 1 of soil to 0.7 of water, although an apparent equilibrium was attained at this high water content, just as with the lower water content. Soils having a ratio of 1 of soil to 5 of water kept at 53° showed a slight increase in the rate and extent of solubility. The solubility product, however, was only about one-third as great as that of similar soils kept at the same temperature but having a ratio of soil to water of 1 to 0.7, while an apparent equilibrium was attained in the high ratio just as in the small ratio.

The results of experiments wherein were used a ratio of 1 of soil to 5 of water are held to indicate very strongly "that the concentration of the soil solution depends upon the relative masses of the soil and water and that the soil does not possess a definite solubility like definite compounds do. The amount of material that goes into solution seems to increase as the ratio of soil to water is increased up to about the optimum moisture content, and then it decreases."

Relation of minimum moisture content of subsoil of prairies to hygroscopic coefficient, F. J. ALWAY, G. R. MCDOLE, and R. S. TRUMBULL (*Bot. Gaz., 67* (1919), No. 3, pp. 185–207).—Soil moisture studies conducted for six years at the Nebraska Experiment Station are reported, in which samples of soils were used taken at a depth of 6 ft. or more from the buffalo-grass formation in the semiarid southwestern part of the State and from the prairie-grass formations in the eastern part of the State. The hygroscopic coefficient and the moisture content were determined for every sample and the moisture condition of the soil expressed as the ratio of moisture content to hygroscopic coefficient.

The subsoils of the semiarid prairies were characterized by their persistent dryness. Usually throughout more or less of the first 6 ft. a ratio of moisture content to hygroscopic coefficient of 1.5 or lower was found, and frequently a ratio as low as 1.1 was encountered in one or more of the foot sections.

After droughts of unusual severity the whole of the subsoil to a depth of 6 ft., and in some cases of 12 ft., showed a ratio of approximately 1. There was no appreciable further reduction of the moisture content when, after the subsoil had been reduced to this very dry condition, there followed a 4 or 5-month period of practically rainless autumn and winter weather. After such droughts the surface foot was but little drier than the subsoil.

The subsoils of the humid prairies, on the contrary, showed no distinct reduction of the moisture content through a greater depth than 5 ft., and even in this a ratio as low as 1.2 or 1.3 appeared only under the severest drought conditions. The normal moisture condition in the deeper subsoil (6 to 20 ft.) appeared to correspond to a ratio between 2 and 2.4.

The dry condition of the deeper subsoil so common in the semiarid prairies is attributed to the presence of perennials with a vertical-root range of 15 ft. or more, while the moist condition characteristic of that of the humid prairies is regarded as evidence that the roots of the native vegetation are but little developed below the fifth foot. The occurrence of areas in the semiarid prairies even after a severe drought, in which the subsoil below the sixth foot is quite moist, is attributed to the absence or fewness of deep-rooted perennials in such places.

Relation of soil moisture to orchard irrigation practice, S. FORTIER (Mo. Bul. Cal. Com. Hort., 8 (1919), No. 7, pp. 361-367).—The author presents data based largely on the work of the Irrigation Investigations Division of the Bureau of Public Roads, U. S. Department of Agriculture.

He points out that "the great need of arid soils in general and of orchard soils in particular is an abundant water supply and a larger percentage of organic matter. The effective water-holding capacities of soils should be determined in order to find out how much water to apply at each irrigation and how often to irrigate. Comparatively little moisture is drawn upwards through soils by capillarity. It is only where a water table is found within a few feet of the surface or where a body of free water comes in contact with the soil that this force is efficient in moving soil moisture. Gravity acts on capillary water as well as free water, and draws both downward unless a layer of hardpan or other impervious material intervenes. The expense of substituting the basin method for the furrow method may be saved providing the texture of the soil is improved by the addition of sufficient organic matter."

Partial sterilization of soils and the influence of soil protozoa on their fertility, G. TRUFFAUT (*Génie Rural* [1919], No. 89–90, pp. 22–24).—The theory of the partial sterilization of soils is discussed and a summary of experiments is given, the apparent purpose being to place partial sterilization of soils on a practical large-scale working basis.

It was found in general that treatment of rich soils with carbon bisulphid at the rate of 445 lbs. per acre resulted in increases of crops of cabbage and onions of from 170 to 200 per cent. These tests were conducted on 5-acre plats. The use of such carbonaceous aromatic liquids as benzine, toluene, methylnapthalin, and anthracenic oils at the same rate produced crop increases of from 125 to 145 per cent. When these materials were used it was necessary to supply from 6 to 8 tons of water per acre. The use of carbonaceous solids at the rate of 223 lbs. per acre resulted in increases of from 130 to 160 per cent and were much more economical than the liquids.

Further pot and plat experiments with turnips showed the value of pure calcium sulphid when used at the rate of 445 lbs. per acre. However, decreases were noted if the calcium sulphid contained such impurities as zinc sulphid.

It is concluded in general that the partial sterilization of soils in both field and orchard is feasible.

Soils, W. A. DAVIS (*Ann. Rpt. Bd. Sci. Advice India, 1916–17, pp. 5, 6*).—Six years' field experiments on the economical use and effect of certain fertilizers on acid old alluvial soils of the Assam valley showed the paramount importance of adding basic material, preferably lime. Complete fertilizer mixtures were without effect unless the soil acidity was first neutralized. The necessary degree of neutralization of soil acidity varied with the crop and the soil.

Next to lime, phosphoric acid was found to be the limiting fertility factor in these soils. The best results were obtained from basic slag, rock phosphate, and other basic phosphates. The continued use of superphosphate or ammonium sulphate on these soils when unlimed was unprofitable and the constant use of ammonium sulphate even on limed soil was unprofitable.

Chemical analyses and fertilizer experiments on indigo soils of Bihar showed that the limiting fertility factor of these soils is phosphoric acid.

A soil survey in Bengal indicates that the red laterite soils of the old alluvium in eastern Bengal are deficient in lime and phosphoric acid and contain relatively large amounts of potash, which is, however, practically unavailable until lime has been added. The new alluvial soils are more productive than the lateritic soils and are rich in total potash, but relatively deficient in phosphoric acid.

Investigational work with fertilizers, F. T. SHUTT (*Canada Expt. Farms* Rpt. 1918, pp. 17, 18).—Plat experiments begun in 1915 with truck crops, grain, and hay at five of the experimental farms are reported.

"Prominent features noted in the results from the individual stations include the very decided influence of phosphoric acid at Charlottetown, where it proved the limiting fertilizer factor. By increasing the quantity of phosphatic fertilizer applied, the profitable use of larger nitrogenous applications was permitted, whereas, with inadequate phosphoric acid, an increase in the amount of nitrogen proved ineffective. On the light, sandy loam soil at Kentville, the plats with manure and fertilizers produced yields superior to those from either manure or fertilizers alone. At all the stations the combinations of manure and fertilizers ranked highly and took highest place in the averages. At Fredericton, the heaviest fertilizer applications were found both most productive and most profitable."

"The average profit, for the three years, from the plats receiving both manure and fertilizers was over \$30 per acre, while the average profits from fertilizers alone during the same period was slightly over \$15 per acre."

Further experiments at the five stations proved sodium nitrate to be superior to ammonium sulphate as a source of nitrogen, and at four of the stations showed acid phosphate to be superior to basic slag or bone meal. Calcium nitrate was found to be as effective as sodium nitrate or ammonium sulphate as a source of nitrogen.

Experiments with a chemically treated peat from England showed no evidence of any appreciable fertilizing value.

The synthesis of ammonia at high temperatures, III, E. B. MAXTED (Jour. Chem. Soc. [London], 115 (1919), No. 676, pp. 113-119, fig. 1; abs. in Jour. Soc. Chem. Indus., 38 (1919), No. 7, p. 219A; Sci. Abs., Sect. A—Phys., 22 (1919), No. 258, p. 296).—Previous results (E. S. R., 39, p. 817) were confirmed in the experiments here reported, which were made with larger arcs than were used in the earlier experiments. It was found that rapid flow of gas through the apparatus caused a considerable decrease in the percentage of ammonia produced. The results showed that there was direct synthesis of the ammonia and indicate that oxygen plays no part in the process.

Sodammonium sulphate. A new fertilizer. The utilization of niter cake in the fixation of ammonia, H. M. DAWSON (Jour. Soc. Chem. Indus., 38 (1919), No. 8, pp. 98T-101T, fig. 1).—The chemistry involved in the process of manufacture of sodammonium sulphate is discussed, in which niter cake is used for the absorption of ammonia as a substitute for sulphuric acid.

Preliminary pot experiments with mustard showed that the fertilizing value of sodammonium sulphate, when added to a dressing of calcium carbonate and potassium phosphate, is approximately the same as that of ammonium sulphate containing the same amount of nitrogen. "Available agricultural data thus afford strong evidence in favor of the suitability of sodammonium sulphate as a fertilizer. Its production from niter cake or other acid sodium sulphate represents a very simple process, for the carrying out of which on the large scale the only plant required consists of evaporating pans and crystallizing tanks in addition to the saturators. On the assumption that niter cake is available at a comparatively low price, the cost of fixation of ammonia by the sodammonium process may be expected to be very much smaller than by the ordinary sulphuric acid process."

Availability of the nitrogen in garbage tankage, F. E. BEAR and G. WAL-LEY (Mo. Bul. Ohio Sta., 4 (1919), No. 6, pp. 191, 192).—In a contribution from the department of agricultural chemistry and soils, Ohio State University, the authors describe observations on the availability of the nitrogen in garbage tankage from the Municipal Reducing Plant of Columbus, by means of the alkaline permanganate method and by nitrification tests. The results are held to indicate that nitrogen from this source is only very slowly available, requiring liberal applications for marked results.

Study of nitrification of leather and oil cake, R. GUILLIN (Bul. Soc. Agr. France, 1917, Dec., pp. 357–360, fig. 1).—Comparative studies of the nitrification of dried blood, tanned leather, chrome leather, burnt leather, leather dissolved in sulphuric acid, and oil cake in a calcareous clay soil showed an increase in nitrate in all cases except where the chrome leather was used, in which case there was a marked decrease in nitrate.

Pot experiments with wheat in which chrome leather and dissolved leather were added showed that considering the weight of the crop obtained from the unfertilized soil as 100 the weight of crop where chrome leather was used was only 30, indicating an injurious effect of the chrome leather. The crop was increased to 115 where dissolved leather was used, showing that this has some fertilizing value.

It is concluded that chrome leather has no fertilizing value and that furthermore it is injurious to crops. Neither tanned or burnt leather are considered to have much fertilizing value, while the value of dissolved leather is considered to be relatively high. No marked difference was noted between dissolved leather in liquid or pasty conditions.

The peat deposits of Minnesota, E. K. SOPER (Univ. Minn., Geol. Survey Bul. 16 (1919), pp. IX+261, pls. 21, figs. 9; abs. in Jour. Amer. Peat Soc., 11 (1918), No. 4, pp. 227-243, figs. 8).—This is a report of a survey of the peat deposits of Minnesota, from which it is estimated that Minnesota had originally about 7,000,000 acres of peat land containing peat deposits varying in thickness from a few inches to 30 ft. or more. Of this area about 5,217,000 acres are covered with peat at least 5 ft. thick. The deposits as a whole vary in thickness from a few inches to 63 ft.

The following types of peat are recognized: (1) Deposits which represent filled lakes or ponds; (2) deposits representing accumulations built up on moist depressions, or flat, undrained areas; (3) deposits which represent combinations of types 1 and 2 which consist of lake or pond peat, in the lower portion, and swamp, of sphagnum peat, above; and (4) deposits which occur on flats and lowlands along river valleys.

The prevailing color of Minnesota peat is brown. The commonest texture is fibrous or mossy.

Chemical analyses of 29 samples of typical peat are reported, the most noteworthy features of which are the high average nitrogen content and the comparatively low ash content. These are considered to indicate peat of excellent quality for fuel. The largest and best peat deposits, for fuel especially, are all in the northern part of the State.

**Peat**, P. GUIEU (*La Tourbe. Paris: Libr. Garnier Frères*, 1918, pp. VII+219, figs. 55).—This book deals with the origin and composition of peat and with methods of securing it commercially and its commercial treatment and utilization. Special chapters deal with the uses of peat as fuel and in agriculture. In the former use peat is burned directly or utilized for gas production. The section on the agricultural use of peat discusses its use as litter and as a fertilizer filler and also as a material used in the manufacture of nitrates.

A reconnaissance of the Uinta Mountains, Utah, with reference to phosphate, A. R. SCHULTZ (*Amer. Fert.*, 51 (1919), No. 5, pp. 64-67, 96, 98, 102, 104, 108, 110, 114, 116, 118, 120, 122, 125, fig. 1).—This report deals with the geology and mineralogy of an area of approximately 6,000 square miles in northern Utah, with special reference to the quantity and quality of phosphate present.

"Throughout the Uinta Mountain uplift the entire phosphatic series, which constitutes only a part of the Park City formation, is approximately 35 ft. thick and varies from place to place. In this formation there is a single phosphatic zone in which the beds of phosphate, thick and thin, rich and lean, occur. Some of the beds several inches in thickness consist almost entirely of phosphatic material; others are composed chiefly of chert nodules and lenses with a little phosphate material. The thicker beds consist of cherty limestone, shale, sandstone, and phosphate beds from 1 to 6 ft. in thickness. Individual layers or beds in this series contain more or less phosphatic salts ranging from 1 to 70 per cent tricalcium phosphate, the maximum being equivalent to 32 per cent phosphoric acid."

The fertilizing action of bone meal phosphate, C. BEGER (*Landw. Vers. Stat.*, 88 (1916), No. 3-4, pp. 291-304).—Pot culture experiments with mustard to compare three different types of bone meal, containing respectively 32.1, 23.3, and 21.3 per cent phosphoric acid, with Thomas slag meal and dicalcium phosphate are reported.

The Thomas meal gave the best results, followed in order by the dicalcium phosphate and the bone meals. The bone meals acted much more slowly than the Thomas meal or the dicalcium phosphate, but gave better relative results in larger additions. The results with the bone meals were so near to those with the other phosphates that it is thought that where necessary they will make suitable substitutes.

Our natural resources of potash, F. W. BROWN (*Mining and Sci. Press*, 117 (1918), No. 23, pp. 759–762).—The author reviews the potash resources of this country, including by-products of cement manufacture and of blast furnaces, wool and wood wastes, alunite, lake brines, and kelp. The Pacific coast kelps are considered the most hopeful source of potash at present.

The nature of the recombined potash in cement mill dust, A. R. MERZ and W. H. Ross (*Jour. Indus. and Engin. Chem.*, 11 (1919), No. 1, pp. 39-45).— Studies at different cement mills are reported.

It was found that "the water soluble potash in cement dust owes its source (1) to the volatilization of potash in the burning of the cement, (2) to the decomposition of potash silicates of the raw mix carried over mechanically in the dust, and (3) in the case of coal-fired kilns, to the ash of the coal which may yield up a portion of its potash through the action of the lime in the dust. The first-mentioned source is ordinarily much the most important. The water-insoluble but acid-soluble potash of cement dust is due (1) to a recombination of a portion of the volatilized potash with the ash of the coal used for fuel, (2) to a recombination to a much smaller extent, and only under certain

conditions, with the siliceous material originally occurring in the raw mix, and (3) to a partial decomposition of the silicates of the raw mix and also of any coal ash which is carried over mechanically in the dust. The acid-insoluble potash in cement dust is due to undecomposed silicates and coal ash carried over mechanically in the dust, and to a recombination of the volatilized potash with the ash of the coal when the amount volatilized is low.

"The portion of the potash in the dust which has undergone recombination is of the nature of a potash slag or impure glass. When the amount of potash volatilized is low, and particularly in the presence of carbon, some recombination may take place with the siliceous material of the raw mix as well as that of the ash. It is probable that the extent of the recombination would be reduced if the burning of the cement were done under oxidizing rather than reducing atmospheric conditions. The extent of recombination would also probably be reduced by any procedure that would introduce lime or sodium chlorid into the dust at the hottest part of the kiln. The greater the amount of potash volatilized, the lower will be the proportion that will undergo recombination in the dust."

German potash industry during the war, P. L. EDWARDS (U. S. Dept. Com., Com. Rpts., No. 213 (1919), pp. 1331-1333).—This report indicates that the production of potash salts in Germany during the war was not so abnormally low as was generally believed, due to increased domestic consumption and exports to the allies of Germany. The total productions of crude potash in 1915, 1916, and 1917 were 7,567,424, 9,507,176, and 9,832,612 short tons, respectively, as compared to 12,768,262 short tons in 1913. During 1917 Germany used 917,820 tons of actual potash in agriculture as compared to 589,713 tons used in 1913, and during 1917 a total of 1,056,929 tons of German potash was used in agriculture.

Fertilizer experiments with increasing amounts of potash on lowland moor soils with cabbage and potatoes, I-II, A. J. WERTH (*Mitt. Ver. Förd. Moorkult. Deut. Reiche, 36 (1918), Nos. 17, pp. 305-310; 18, pp. 317-321, fg. 1).* Plat experiments with cabbage and potatoes on lowland moor soils, in which 26 and 40 per cent potash salts were added at rates of 243, 486, 729, and 972 lbs. per acre, are reported. The purpose was to determine the most efficient additions of potash salts on these soils.

The addition of 486 lbs. of 40 per cent salts per acre to cabbage did not give the highest yield. The addition of 729 lbs. materially increased the yield, and in some cases the highest yield was obtained with the 972-lb. addition. It is thought that a residual effect may be expected from the constant potash fertilization of such moor soils, but the effectiveness of greater additions than those noted is considered doubtful.

With potatoes additions of 324 to 405 lbs. per acre of 40 per cent salts did not give maximum results. It is thought that additions of 486 to 567 lbs. of 40 per cent salts or 648 to 729 lbs. of 26 per cent salts will give better results generally, but a depression is noted for greater additions. Even though a depression in crop occurs it is thought that the residual effect of larger additions will be compensating.

The injurious effects of potash and sodium salts upon the soil structure and their cause, G. HAGER (*Jour. Landw.*, 66 (1918), No. 4, pp. 241–286, fig. 1).— Experiments on the effect of potash and sodium salts on soils are reported in which it was found that weak acids have a tendency to split off the combined bases in soils as hydrates. The bivalent cations, lime and magnesium, have a favorable influence on the soil structure, while the monovalent, sodium and potassium, have an unfavorable influence.

[Vol. 41

It is concluded then that the action of alkali salt solution, such as sea water on soils, is one resulting in the displacing of the calcium and in less measure the magnesium compounds by the alkalis. The presence of salts with the same cation in the soil solution was found to interfere with the hydrolysis and the consequent splitting off of the alkali hydrate. With the disappearance of alkali salts with the common ion, hydrolysis of soil zeolites set in and alkali hydrates were found in the soil solution as shown by displacement of the salt solution by washing. Sodium salts had a more injurious influence than potassium salts, which is attributed partly to a greater power to dissolve humus considered as a protective colloid.

Permeability experiments using potassium permutit and sodium permutit gave the same results as the alkali chlorid solutions by displacing these solutions in soils with water. The permeability of the soil was markedly reduced, and the drainage water was brown and contained considerable clay. The alkalinity was high, and the sodium compound gave the most marked results. Addition of a 0.5 per cent solution of common salt stopped the unfavorable action of the sodium permutit, proving the theory noted above.

The comparative value of various forms of limestone, R. STEWART and F. A. WYATT (Soil Sci., 7 (1919), No. 4, pp. 273-278).—Four years' experiments on 114 plats and 14 years' experiments on 64 plats, conducted by the Illinois Experiment Station to compare high calcium and dolomitic limestones on acid soils, are reported.

It is concluded that "for the common farm land of acid regions, an application of 1 ton per acre of limestone once in 3 or 4 years is sufficient to keep the soil alkaline, or sweet, after the initial acidity has been destroyed by heavier applications. Dolomitic limestone can be used successfully on acid soils. It is slightly more effective than high-calcium limestone in neutralizing the soil acidity, is more durable, and has no injurious effects on the crop yields. . . There is no evidence that finely ground limestone is more effective in correcting soil acidity than is the total product from a 4-in. screen, which contains both the finer material for immediate use and the coarser material for greater durability. . .

"Limestone applied to the surface slowly penetrates into the subsurface. This process, however, requires considerable time. On the Odin field after 14 years, one-half the acidity in the subsurface was neutralized where the larger applications had been made to the surface, and one-fourth where the lighter applications had been made. Applications of limestone to the surface soil seem to have no effect upon the acidity of the subsoil. The amount of native limestone found in the subsoil is a variable quantity. In some cases there is none present even at a depth of 40 in., whereas in other cases it extends upward even slightly into the subsurface...

"The annual loss of limestone is not so large as generally assumed. As an average of all determinations, the annual loss from the surface 20 in. was 760 lbs. per acre from the Newton field and 542 lbs. per acre from the Odin field. A study of the total calcium indicates that the actual loss of bases may have been less than is shown by these figures, which are based upon the carbon dioxid and acidity determinations. It is very evident from the data presented that chemical analysis may be depended upon to measure the acidity in the soil, the reduction in acidity due to the action of limestone applied, and also to find the limestone still remaining in the soil, whether from applications made or from a supply native to the soil."

Results of liming experiments by the Finland Moor Culture Society, A. RINDELL (Jahrb. Moork., 3-5 (1914-1916), pp. IX-XXVI).—A number of liming experiments on different moor soils with various field and truck crops are reported.

In most cases liming of moor soils resulted in a decrease in crop yields, or at least no increase. Where upland moor soils were mixed with normal loam soils, the beneficial effect of liming was very small and variable. However, when the loam soil contained injurious iron sulphur compounds liming gave very beneficial results. It was found that the injurious acidity of upland moor soils could be neutralized to better advantage by adding normal loam soils than by liming.

The ammonia-fixing capacity of calcium sulphate, F. E. BEAR and A. C. WORKMAN (Soil Sci., 7 (1919), No. 4, pp. 283–291, fig. 1).—Experiments conducted at the Ohio State University are reported on the power of calcium sulphate to fix ammonia from pure ammonium carbonate.

It was found that calcium sulphate will prevent to a certain degree the loss of ammonia from a mixture containing volatile ammonium carbonate, and it is considered quite probable that the loss prevention is due to the formation of nonvolatile ammonium sulphate by the double decomposition of ammonium carbonate and calcium sulphate. The ammonia-fixing capacity of calcium sulphate was found to be apparently dependent on the temperature. The quantity of ammonia given off by the ammonium carbonate increased as the temperature rose and the percentage of it held by the calcium sulphate decreased.

The effect of manganese on the growth of wheat: A source of manganese for agricultural purposes, J. S. McHARGUE (Jour. Indus. and Engin. Chem., 11 (1919), No. 4, pp. 332-335, figs. 4).—Pot and water culture experiments with wheat conducted at the Kentucky Experiment Station to demonstrate the effect of manganese on the growth of wheat and studies to determine a source of this element are reported.

It was found that manganese in suitable dilution stimulated the growth of wheat, increased the size and nitrogen content of the grain, and apparently performed an important function in the normal growth and development of the plant.

Chemical examinations of a number of different agricultural limestones, raw rock phosphate, and basic slag showed that the first two materials contained very little manganese, but that basic slag contains about 100 lbs. of manganese to the ton. "It is possible that some of the benefit to crops resulting from the use of this fertilizer, on certain soils, may be due to this element."

## AGRICULTURAL BOTANY.

Plant succession in relation to range management, A. W. SAMPSON (U. S. Dept. Agr. Bul. 791 (1919), pp. 76, pls. 6, figs. 22).—A study has been made in the Manti National Forest in central Utah of means for detecting possible overgrazing of ranges, and the author points out what plants may be considered reliable indicators of overgrazing in the various types and how they may be used as guides in revegetation and the maintenance of the forage crop. A list of the most typical primary and secondary species of the respective covers in this region is appended.

He believes that the character of the native vegetation can be used as a reliable indicator of the condition of the range and of the effect on the plant cover of a given method of grazing. It is claimed that if the invading plants are lower in the succession than the predominating vegetation, the range is being utilized unwisely in one or more respects. If the incoming vegetation is somewhat higher successionally than the type as a whole, improvement under the

144402°-19-3

management in vogue is sure to follow. Where the negative indicators are crowding out the more permanent and desirable species, remedial measures should be adopted with a minimum loss of time. Since range depletion is due chiefly to too early cropping or to overgrazing, the application of the deferredand-rotation grazing system, coupled with a correct estimate of the carrying capacity of the range, may be relied upon fully to revegetate the lands where enough plants of desirable species are found for seed production.

Botanical survey [in India], H. G. CARTER (Ann. Rpt. Bd. Sci. Advice India, 1916–17, pp. 32–34).—This contains an account of studies extending the lists of known plants in portions of India, with notices of recent publications on certain groups.

Agricultural botany [in India], A. HOWARD (Ann. Rpt. Bd. Sci. Advice India, 1916–17, pp. 35–43).—A discussion of this phase of economic botany includes, besides mention of technical publications, reports on the improvement of crops, among them cotton, rice, sugar cane, wheat, jute, indigo, fruit, and chilies. Root nodules and soil aeration also receive notice.

Forest botany [in India], R. S. HOLE (Ann. Rpt. Bd. Sci. Advice India, 1916–17, pp. 44–46).—This report, which is complementary to that noted above, deals with soil aeration, forest grasses, sissoo (Dalbergia sissoo), root disease (Fomes lucidus) and spike disease of sandal, with mention of descriptive lists and papers on the systematic botany of this region.

Evolution through normal diversity, O. F. Cook (Jour. Wash. Acad. Sci., 9 (1919), No. 7, pp. 192–197).—The author makes reference to a paper by Meehan published in 1894 (E. S. R., 6, p. 389) in which attention is called to observations by himself, confirming his records extending back about 25 years and tending to show that there is in the plant in question (Impatiens fulva) innate power to vary coexistent with the species itself, independent of any conditions of environment. This definite recognition of normal diversity is referred to on account of the historical interest. Diversity being accepted as a normal and general condition in species, evolution is seen as a process of integration and differentiation of characters, the two essential conditions of evolutionary progress being normal diversity (heterism) and free intercrossing of lines of descent (symbasis).

The symbiomorphoses; recent studies on asexual hybridization, L. DANIEL (*Rev. Gén. Bot., 30 (1918), No. 359, pp. 367, 368).*—In the résumé of this work by L. Defour, it is stated that the author has given attention to certain modifications of plants observed to arise in consequence of grafting. These have been called symbiomorphoses, of which two classes or cases are distinguished, namely those arising when different genera or species are grafted and those arising when grafts are made between varieties. The author reaches the general conclusion that in a given graft one may encounter variations of diverse origin. These symbiomorphoses are almost always resultants of numerous factors which may be physical, chemical, or physiological in character.

It is considered as impossible at present to distinguish the precise action of this or that morphological or genetic factor on account of the extreme complexity of the result.

Underground runners, E. WARMING (K. Danske Vidensk. Selsk. Skr., Naturvidensk. og Math. Afd., 8. ser., 2 (1918), No. 6, pp. 295-378, figs. 43).—This contribution contains a definition and discussion of several types which are distinguished of plagiotropic shoots.

Natural grafting of branches and roots, W. DALLIMORE (Roy. Bot. Gard. Kew, Bul. Misc. Inform., No. 9-10 (1917), pp. 303-306, pls. 2).—Examples of natural grafting occurring in cases observed, either above or below the surface of the ground are given with suggestions or explanations regarding the processes involved.

**Cross-inoculation of legumes,** G. P. KOCH and J. R. BUTLER (Soil Sci., 6 (1918), No. 5, pp. 397–403).—Reporting data from cross-inoculation tests dealing with several common legumes, the authors state that *Bacillus radicicola* isolated from roots of alfalfa, sweet clover, and bur clover all cross-inoculated, although but slight infection followed inoculation of bur clover (roots) with organisms from alfalfa and sweet clover. Organisms from either red, white, crimson, or alsike clover inoculated upon any other of these showed normal vigor. Cross-inoculation succeeded (showing a difference in vigor, however) between vetch, sweet pea, garden pea, and Canada field pea. In nearly all cases organisms from the cowpea group cross-inoculated successfully.

Potassium requirements of bacteria, G. P. KOCH (Soil Sci., 5 (1918), No. 3, pp. 219-224).—This information has already been noted (E. S. R., 39, p. 619).

On the occurrence, behavior, and origin of a smooth-stemmed form of the common foxglove (Digitalis purpurea), E. R. SAUNDERS (Jour. Genetics, 7 (1918), No. 3, pp. 215-228).—The author has continued through several generations a study of some peculiarities observed in work previously noted (E. S. R., 25, p. 229). She states that besides the form which is now considered as the type D. purpurea pubescens another form exists and this is designated as D. purpurea nudicaulis. This resembles the type in all but surface characters, which are described with a discussion of their possible significance.

The purple hyacinth bean, G. F. FREEMAN (Bot. Gaz., 66 (1918), No. 6, pp. 512-523, figs. 7).—Concluding his presentation and discussion of opinion and evidence, the author sustains the designation by Linnaeus of the common annual (in the tropics perennial) hyacinth bean as Dolichos lablab, and the more slender climber (in northern climates perennial) as D. lignosus.

The effect of certain organic substances on seed germination, E. B. FRED (Soil Sci., 6 (1918), No. 5, pp. 333-349, figs. 10).—Experiments conducted at the Wisconsin Experiment Station, in which alfalfa, casein, peptone, and sugar were added in varying amounts to silt loam soil in which alfalfa, buckwheat, castor bean, red clover, corn, cotton, flax, hemp, white lupine, mustard, oats, serradella, soy bean, sunflower, sweet pea, and wheat seeds were planted, are reported.

It was found that nitrogenous substances such as alfalfa powder, casein, and peptone did not seriously injure seed germination unless used in very large quantities. As compared with green manure (nitrogen content), very large amounts of casein and peptone were required to cause a noticeable decrease in germination. Calcium carbonate apparently did not lessen the decrease in germination due to very large applications of alfalfa powder or casein. Sugar greatly increased bacterial growth and retarded the rate of seed germination. In large amounts it decreased the percentage of germination. Soil sterilization often inhibited the rate of seed germination.

Difference in the action of radium on green plants in the presence and absence of light, C. PACKARD (Jour. Gen. Physiol., 1 (1918), No. 1, pp. 37, 38).— Tests carried out with Spirogyra and Volvox exposed to radioactivity are said to have shown that the life of the cell is longer under such exposure in light than in darkness, being prolonged apparently by some condition connected with photosynthesis.

On the dynamics of photosynthesis, W. J. V. OSTERHOUT and A. R. C. HAAS (Jour. Gen. Physiol., 1 (1918), No. 1, pp. 1-16, figs. 5).—The authors describe (with a discussion of results) a study of sea lettuce (Ulva rigida) carried on during August in order to obtain data for the study of the dynamics of photosynthesis. They have developed a method of investigation based on the

fact that as plants abstract carbon dioxid from a solution the latter becomes more alkaline. Minute amounts of photosynthesis in marine plants can be measured accurately by adding a little phenolphthalein to the sea water and observing the color changes. By this method it was found that Ulva after being kept in darkness begins photosynthesis as soon as it is exposed to sunlight, and the rate steadily increases to a constant value.

A method of studying respiration, W. J. V. OSTERHOUT (*Jour. Gen. Physiol.*, 1 (1918), No. 1, pp. 17-22, fig. 1).—Apparatus is described by which small amounts of carbon dioxid given off by organisms can be measured rapidly and accurately. The apparatus can be employed also to measure photosynthesis.

An indicator method of measuring the consumption of oxygen, W. J. V. OSTERHOUT (Jour. Gen. Physiol., 1 (1918), No. 2, pp. 167-169).—The author describes a method of measuring oxygen consumption employing the blood of the horseshoe crab (Limulus sp.). This absorbs oxygen and turns blue when shaken in air, but is quickly decolorized in the presence of certain organisms which consume oxygen. By measuring the time required for the change of color the rate of consumption of oxygen (by animal or plant) may be determined. This method is employed in some of the series below.

Comparative studies on respiration, I-V (Jour. Gen. Physiol., 1 (1918), No. 2, pp. 171-220, figs. 17).—Five papers are presented.

I. Introduction, W. J. V. Osterhout (pp. 171–179).—The author describes the first of a series of investigations on respiration in plants (which is in some cases compared with that of animals), employing infproved quantitative methods dealing with representatives of bacteria, higher fungi, algæ, and flowering plants. It is shown that when anesthetics are employed in sufficient concentration to produce any result, plants show a rise in the rate of respiration followed by a decline. In animals the rise (found in higher concentrations only) was preceded by a temporary fall not entirely due to lowering of muscular activity or tonus. In lower concentrations the effect was merely a decrease of respiration. The results of all the investigations are opposed to the theory of Verworn, namely, that anesthesia is a kind of asphyxia due to the checking of respiration by the anesthetic.

II. The effect of anesthetics and other substances on the respiration of Aspergillus niger, F. G. Gustafson (pp. 181–191.—In this investigation, which was undertaken to compare the action of anesthetics and other substances on the respiration of a fungus (A. niger) with effects produced in other groups of organisms, it was found that in effective concentrations formaldehyde, ether, and acetone first increased and later decreased the rate of respiration. Ether at 3.65 per cent caused an increase with certain cultures, a decrease with others. The reaction producing an increase in the respiration with 7.3 per cent ether is reversible, the reaction producing the decrease irreversible. Caffein at 0.5 per cent produced only a decrease in respiration. A saturated solution caused an increase, which was followed by a decrease.

III. The effect of ether on the respiration and growth of Bacillus subtilis, M. M. Brooks (pp. 193-201).—It was found that all concentrations of ether employed (from 0.037 to 7.3 per cent) caused an increase in the rate of respiration of *B. subtilis*, followed by a decrease. Ether at 7.3 per cent in tap water gave an extraordinary increase (50 times the normal) in the output of carbon dioxid. This increase did not occur when 0.85 per cent sodium chlorid was added. At lower concentrations (0.037 to 1.1 per cent) ether was toxic, and the same was true at higher concentrations (3.65 to 7.3 per cent), while intermediate concentrations stimulated growth.

IV. The effect of ether on the respiration of wheat, H. S. Thomas (pp. 203-207).—The experiments here described show that 7.3 to 3.65 per cent ether

solutions caused an increase in the respiration of wheat, followed by a decrease. These results agree with those of Haas and of Gustafson (above noted), but not with the theory of Verworn.

V. The effect of ether on the production of carbon dioxid by animals, M. Irwin (pp. 209–220).—The purpose of this investigation was to make a comparison of the carbon dioxid output of animals with that of plants under the influence of a typical anesthetic such as ether. The results are considered to show that narcosis is not due to asphyxia, and that the action of anesthetics is not due to their effect on respiration. While in the case of animals the increase in carbon dioxid output is accompanied by irreversible change leading to death, this is not necessarily the case in plants. The reversible (narcotic) action of ether on the animals studied was accompanied by a decrease in carbon dioxid output, while this was not ordinarily the case with plants.

The interpretation of the facts observed is considered to require further investigations.

Analytic and synthetic studies on chlorophyll, A. and A. MARY (Études Analytiques et Synthétiques sur la Chlorophylle. Paris: A. Maloine & Sons, 1917, pp. 40, pl. 1).—This contribution discusses, first, the views of other authors mentioned in regard to characters and properties of chlorophyll; second, spectrum analysis as applied in the study of chlorophyll; third, its chemical relations; fourth, its behavior toward coloring substances (methylene blue); fifth, a comparative study of chlorophyll pigment with anilin; and sixth, the functions of chlorophyll.

Growth rates in plants, O. DEBATIN (*Naturw. Umschau Chem. Ztg.*, 5 (1916), *No. 4, pp. 52–54*).—Rates of growth or of doubling (dimensions) are given with discussion for a number of higher and lower plants.

Abnormal stem growth of soy beans in sand cultures with Shive's threesalt solution, A. G. McCALL, J. B. S. NORTON, and P. E. RICHARDS (Soil Sci., 6 (1918), No. 6, pp. 479-481, pls. 2).—The authors refer to the observations and data reported by Shive (E. S. R., 39, p. 827), in whose work each of the phosphates used singly in the soil cultures caused specific injury to soy beans when the initial concentration of the solution was above 1 atmosphere (monopotassium phosphate producing the least and monocalcium phosphate the most injury). They state that in their study during two years, soy beans growing in sand cultures, supplied with Shive's 3-salt nutrient solution having a concentration initially of 1.75 atmospheres, showed injury in case of widely varying salt proportions. It is suggested that this injury, instead of being correlated with a high concentration of a particular salt, may have resulted from some property which was common to all of the Shive 3-salt solutions.

**O**smotic pressure in plants on mountain heights, O. ARRHENIUS and E. Söderberg (*Svensk Bot. Tidskr., 11 (1917), No. 3-4, pp. 373-380*).—A study of mountain plants carried out during the summer of 1917 at a point in Swedish Lapland and is said to show that these have a relatively high osmotic pressure (corresponding to the concentration of the cell sap), which within certain limits protects the plants against frost injury.

Distribution of materials dissolved in the sap in different portions of the stalk of sugar cane, J. KUIJPER (KUYPER) (Arch. Suikerindus. Nederland. Indië, 26 (1918), No. 39, pp. 1665–1686; also in Meded. Proefstat. Java-Suikerindus., Landbouwk. Ser., No. 11 (1918), pp. 22).—It is stated that the amount of dissolved substance increases with considerable regularity from the top of the cane downward, and generally from the central part outward, the harder parts thus containing larger percentages of solutes.

Some observations on the behavior of turgescent tissue in solutions of cane sugar and of certain toxic substances, D. THODAY (*New Phytol.*, 17 (1918), No. 3-4, pp. 57-68, figs. 8).—Experiments herein described were suggested by observations reported by Brown, both alone and in connection with Worley and with Tinker (E. S. R., 34, p. 626), and his results are said to have been made available at this time on account of the appearance of data contributed by Stiles and Jörgensen (E. S. R., 39, p. 223). Pieces of potato tubers were immersed in cane sugar solution and in solutions of mercuric chlorid, osmic acid, mercuric cyanid, or chloroform for different periods of time, and the resulting data are presented with discussion which is to be continued in a more general form in a later paper.

The law controlling the quantity of regeneration in the stem of Bryophyllum calycinum, J. LOEB (*Jour. Gen. Physiol.*, 1 (1918), No. 1, pp. 81-96, figs. 5).—This is in review and continuation of communications previously noted (E. S. R., 40, p. 224).

A method is noted of measuring the influence of the mass of a leaf of B. *calycinum* on the quantity of shoots regenerated in an isolated piece of stem. The method consists in isolating a section of stem with only two leaves at the basal node and splitting the stem lengthwise into symmetrical halves, each piece containing one of these leaves, one dormant shoot bud, and two half buds. By reducing the size of one of the sister leaves, the influence of leaf mass on shoot regeneration by the stem can be measured.

It is stated that the mass of shoots regenerated at the apical bud increases under like conditions and in equal times in proportion to the mass of the leaf, whether the latter be intact or mutilated. The assumption that growth occurs at the expense of the material furnished by the basal leaf is supported by the fact that in the dark the influence of the leaf disappears more or less completely, and that the attached leaf loses greatly in weight. A certain tendency to wilt, however, interferes more or less with the almost perfect proportionality observed under favorable conditions.

The material furnished by the leaf includes, presumably, both water and solutes. The mass of shoots regenerated by a piece of stem without leaf is so small as to be almost negligible when compared with the mass of shoots produced by a like piece of stem when a leaf of sufficient mass is left attached to its base.

A consideration of certain pathologic conditions in Ambrosia trifida, A. STEWART (*Amer. Jour. Bot.*, 6 (1919), No. 1, pp. 34-46, pl. 1, fig. 1).—A further study of the great ragweed A. trifida (E. S. R., 35, p. 651) in regard to the effects of the disturbance caused by stimuli due to wounding or to attacks by animals or plant parasites, or a combination thereof, is discussed in some detail. It appears that, while wound stimulus is much more powerful than fungus gall stimulus (causing more extensive changes), that due to the presence of the fungus is able to overcome that due to insect attack, when the two occur in the same portion of the plant.

The nature of charred wood, L. A. BOODLE (*Roy. Bot. Gard. Kew, Bul. Misc.* Inform., No. 9-10 (1917), pp. 306-308).—Noting the results of experiments bearing upon the nature of the residue of pine or other woods charred by heat or sulphuric acid or both, the author states that a product was obtained by him which differed from typical charcoal in its behavior toward oxidizing agents, a series of degrees of resistance being obtainable evidently bearing a relation to the severity of the charring process. The general conclusion reached is that in certain cases charred wood contains no free carbon unless it is in a condition differing from that of ordinary carbon.

## FIELD CROPS.

American husbandry, a much overlooked publication, L. CARRIER (Jour. Amer. Soc. Agron., 11 (1919), No. 5, pp. 206–211).—The author briefly reviews a 2-volume treatise on American agriculture issued in London in 1775 under authorship of "An American ", and believed to be the work of John Mitchell. The publication is said to deal with the soil, climate, and agricultural practices and products of the English colonies in America, including Nova Scotia, Canada, New England, New York, New Jersey, Pennsylvania, Maryland, Virginia, the Carolinas, Florida, and the West Indies, and to have been written largely for use in England rather than in America. The books are believed to be of considerable value both from an agricultural and historical point of view.

[Report of field crops work in Florida, 1918], J. M. SCOTT, B. F. FLOYD, J. E. TURLINGTON, and J. B. THOMPSON (*Fla. Sta. Rpt. 1918, pp. 23-26, 28-39, 84-93, figs. 5*).—This describes the continuation of work along the same general lines as previously noted (E. S. R., 39, p. 434).

Replanting Japanese cane in 1915 on variously fertilized plats which had grown the crop since 1909 resulted in yields of green material ranging from 18 tons per acre for the plat receiving dried blood and acid phosphate to 31.9 tons for that receiving muriate of potash and acid phosphate. A decided decrease in yield occurred on all plats in 1916 and a still greater decrease in 1917. Fertilizer experiments with Japanese cane begun in 1914 resulted in an average maximum yield for the period of 1914 to 1917, inclusive, of 17.9 tons for the plat receiving barnyard manure at the rate of 30 2-horse wagonloads per acre.

In fertilizer tests with sweet potatoes, 3-year average yields were secured ranging from 86 bu, per acre for the plat receiving dried blood and acid phosphate to 260.9 bu, for that receiving sulphate of ammonia, muriate of potash, and acid phosphate. The maximum corn yield, 23.31 bu, per acre, was secured from the plat receiving dried blood, sulphate of potash, and acid phosphate.

A series of experiments begun near Hastings in 1917 is described, in which observations were made upon the potash requirements of potatoes and of the relative value of different sources of phosphorus for potatoes. The effect of the different fertilizer treatments upon a cover crop of cowpeas following the potatoes is also noted. In the potash experiments complete fertilizers containing 1, 3, and 5 per cent of potash were compared with each other and with fertilizers containing no potash. The phosphate carriers compared included acid phosphate, finely ground pebble phosphate rock, and soft phosphate rock. Tabulated data are presented showing the yield of potatoes obtained under the different treatments arranged according to grades. Based on the total yields secured the potash plats greatly outyielded the plats without potash, the yields increasing with an increase in the amount of potash applied. No difference in the appearance of the cover crop was noted on either the potash plats or those without potash. Acid phosphate gave better results both in stand and yield than raw rock phosphate, while on the plats receiving no phosphorus the potato plants are said to have averaged fully 50 per cent smaller in size than those on the acid phosphate plats, while marked differences in color and maturity were also noted. The cover crop gave much the same results as the potatoes, the vines being only from 50 to 60 per cent as high on the no-phosphate plats as on those receiving phosphate applications.

Variety tests with cotton are described, in which yields were secured ranging from 336 lbs. of seed cotton per acre for Sosnowski to 726 lbs. for Cook Improved, 35 and 48 per cent of the total yields, respectively, being secured at the first picking.

[Vol. 41

Heavy parent hills of sweet potatoes planted April 5 and 27 produced 0.15 lb. per plant, or approximately 15 bu. per acre, more than light hills. Plantings made on June 25 from cuttings failed to show any correlation between the yield of parent hill and offspring plantings.

Brief notes are presented on certain promising new grasses, including *Pennisetum purpureum*, *P. merkeri*, *P. longistylum*, *Eriochloa subglabra*, *Osterdamia matrella*, *Digitaria didactyla*, *Paspalum notatum*, *Chrysopogon montanus*, *Brachiaria plantaginea*, and *Andropogon faveolatus*. See also a previous note (E. S. R., 41, p. 37).

[Summary report of State and cooperative experiment farms in Wyoming, 1917 and 1918] (*Bien. Rpt. Bd. Farm Comrs.* [Wyo.], 1917-18, pp. 3-102, pls. 15).—Continuing work previously noted (E. S. R., 39, p. 229), numerous field tests conducted at several centers in the State with grain and forage crops are described.

[Report of work with field crops on the Canada Experimental Farms, 1917], J. H. GRISDALE ET AL. (Canada Expt. Farms Rpt. 1918, pp. 9, 10, 12, 13, 14, 15, 20–22, 25–27, 34, 35–37, 43–45, 48–50, 51–60, 63, 68–70, 74, 75, 80–82, 86, 87, 94–97, 100, 101, 105, 106, 107, 109, 112–114, 116, 117, 119, 122, 123, 126, 127, 130, 131, 133, 136, 137, 142–144, 146, 147).—This briefly describes the progress of work conducted along the same general lines as previously noted (E. S. R., 40, p. 735), embracing variety, fertilizer, rotation, and cultural tests with wheat, oats, barley, rye, field peas, flax, hemp, alfalfa, grasses, corn for forage, sugar beets, potatoes, turnips, mangels, carrots, vetches, clovers, rape, and tobacco. Plant breeding work with cereals is also noted.

[Report of field crops work in St. Vincent, 1917–18], F. WATTS (*Imp. Dept. Agr. West Indies, Rpt. Agr. Dept. St. Vincent, 1917–18, pp. 3–10, 15–23).*— This notes the progress of work along the same general lines as previously indicated (E. S. R., 39, p. 835), including manurial experiments with Sea Island cotton, reported on in more detail elsewhere (E. S. R., 40, p. 627), and arrowroot, and breeding work with cowpeas, *Dolichos lablab*, castor bean, and tomatoes. Statistical information is also given relative to the production in the island of cotton, corn, arrowroot and cassava for starch, sugar cane, peanuts, and peas.

Arrowroot mulched with prunings of *Gliricidia maculata* produced on the average 53,950 lbs. of rhizomes per acre as compared with 17,371 lbs. from the untreated plats. In a comparison of different artificial and organic manures, an average yield of 49,385 lbs. per acre followed mulching with Gliricidia prunings, with an application of phosphate and potash next in order with 30,088 lbs., as compared with 20,439 lbs. from the untreated check.

[Report of field crops work in British Guiana, 1917], J. B. HARRISON (*Rpt. Dept. Sci. and Agr. Brit. Guiana, 1917, pp. 6–22*).—Variety tests, hybridization and selection studies, and fertilizer experiments with sugar cane and variety tests with rice are described for the year ended December 31, 1917, in a continuation of similar work previously noted (E. S. R., 40, p. 242).

[Report of field crops work in the Union of South Africa, 1918], F. B. SMITH, W. H. SCHERFFIUS, H. S. DU TOIT, and W. PYOTT (Union So. Africa Dept. Agr. Rpt. 1917–18, pp. 15, 23, 24, 25, 30–33, 69–71, 145–147, 155–158).—The work of the tobacco and cotton, grain, and dry-farming divisions for the year ended March 31, 1918, is outlined as heretofore (E. S. R., 40, p. 524), together with information relative to the acreage and production of corn, wheat, oats, barley, Kafir corn, potatoes, sugar cane, and miscellaneous forage crops. The report of the chief grain inspector is included.

[Report of field crops work in Burma, 1918], A. E. ENGLISH (*Rpt. Dept. Agr. Burma*, 1918, pp. 4-8).—In continuation of work previously noted (E. S.

R., 40, p. 523) variety, cultural, and fertilizer tests with rice, sesame, wheat, peanuts, beans, cotton, sugar cane, tobacco, fiber crops, and miscellaneous forage crops are briefly described for the year ended June 30, 1918.

[Field crops in Burma], H. ADAMSON (Bul. Imp. Inst. [So. Kensington], 16 (1918), No. 1, pp. 50-54).—In an article entitled The Material Resources of Burma the author presents information relative to the area occupied by the principal field crops, together with their respective yields. The crops discussed include rice, sesame, millet, beans, peanuts, cotton, corn, wheat, gram, sugar cane, and tobacco.

[Field crops in Ceylon], W. MOLEGODE, B. F. SCHERFFIUS, C. DRIEBERG, and D. S. CORLETT (Ceylon Agr. Soc. Year Book, 1919-20, pp. 62-68, 72-75).—Brief notes are given on the production of rice, tobacco, dhall (Cajanus indicus), cotton, kapok, and castor in the island.

[The progress of crop investigations in India, 1917–18] (*Rpt. Prog. Agr. India, 1917–18, pp. 11–55, 60–63, 73, 74, pls. 2*).—This comprises a summary of work done in various parts of India to improve the different field crops and to increase production. The crops dealt with include wheat, rice, cotton, sugar cane, jute, indigo, tobacco, oil seeds, and miscellaneous forage crops.

[Report of field crops work in South Australia, 1918–19], W. J. SPAFFORD (*Jour. Dept. Agr. So. Aust., 22 (1919), No. 7, pp. 527–534*).—The progress of cultural, variety, and fertilizer tests with wheat at Hammond, Butler, and Wilkawatt is described as heretofore (E. S. R., 40, p. 332).

Constructive rotations: Considerations in fertility, crops, drainage, and farm labor, J. F. BARKER (Mo. Bul. Ohio Sta., 4 (1919), No. 7, pp. 209-214, fig. 1).—In a contribution from the department of agricultural chemistry and soils, Ohio State University, the author discusses in a general manner practical systems of crop rotation for soil improvement in the State.

The temporary ley, R. G. STAPLEDON (Jour. Bd. Agr. [London], 25 (1919), No. 11, pp. 1280–1311).—Recommendations, based on rather extensive observations in England and Wales, are made relative to what are deemed to be adequate mixtures of legume and grass seeds for temporary pastures. Information is also presented showing the year of maximum yield and the probable duration of the various species included in the different seed mixtures, as well as the date of appearance and maximum development of the indigenous species when commercial seed is not sown.

The grasses and grasslands of South Africa, J. W. BEWS (*Pietermaritzburg:* P. Davis & Sons, Ltd., 1918, pp. VI+161, pl. 1, figs. 24; rev. in Jour. Ecology, 7 (1919), No. 1-2, pp. 84-87).—This work is said to comprise a preliminary contribution to a study of plant ecology in South Africa and also to supplement a previous paper on plant succession (E. S. R., 37, p. 526). A simplified key to the genera and species of South African grasses has been prepared and ecological notes on the principal species of each genus included. The development of the grasslands of different sections of South Africa is discussed in some detail, and various economic aspects of the subject are mentioned.

A list of English, Dutch, Zulu, and Sesuto names of grasses is appended.

[Grasses for paper making in the Union of South Africa], C. F. JURITZ ([Union So. Africa, Min. Mines and Indus.], Indus. Bul. Ser., No. 7 (1919), pp. IV+115).—This comprises rather detailed reports on the grasses of the eastern coast belt available for the manufacture of paper, and on the possibilities and prospects of paper making in the Union of South Africa, together with a comprehensive discussion of the history and of technical and industrial aspects of the subject and of raw materials suitable for paper making in South Africa.

Methods of selection applied to the cereals, J. BEAUVERIE (*Rev. Gén. Sci.*, 30 (1919), Nos. 3, pp. 79-87; 4, pp. 108-114).—This comprises a general discus-

sion of the present status of the subject, with particular reference to crop improvement through pure line selection.

**Twinning in alfalfa**, W. SOUTHWORTH (*Jour. Heredity*, 10 (1919), No. 4, pp. 182, 183, figs. 2).—In connection with alfalfa hybridization work in progress at the Manitoba Agricultural College and previously mentioned (E. S. R., 31, p. 831), three cases of twinning appeared in hybrid seedlings during the season of 1918. The parentage of each pair is briefly traced, all three having descended from the same original cross made in 1911 between alfalfa  $\varphi$  and black medick  $\mathcal{E}$ . Five of the six seedlings are said to have developed into strong vigorous plants.

Variety tests with two-row barley, 1913–1916, K. IVERSEN (*Tidsskr*. *Planteavl*, 26 (1919), No. 1, pp. 1–37).—Tystofte Prentice (Archer), said to have been the highest yielding strain in previous experiments, was grown in comparison with three early, short, and rather stiff-strawed strains and with three new later maturing sorts of barley at seven experimental centers representing different soil conditions for the period indicated. It is stated that the differences in yield between the early and late strains, which were relatively small, depended chiefly on whether the crop remained upright or lodged.

[Observations on beer barleys in Argentina], C. D.-GIROLA (*Pub. Mus. Agr.* [Soc. Rural Argentina], No. 10 (1918), pp. 20, figs. 4).—The production of barley in Argentina for malting purposes is discussed and varieties deemed best suited for this purpose indicated.

[The castor oil plant in Brazil], G. R. P. D'UTRA (Bol. Agr. [Sao Paulo], 20. ser., No. 1-3 (1919), pp. 1-33, figs. 3).—This is a general discussion of the production and utilization of the plant in Brazil.

Red clover, W. M. FINDLAY (North of Scot. Col. Agr. Bul. 24 (1919), pp. 39).— A general discussion of red clover production in Scotland, with recommendations for growing the crop under various soil conditions.

Variety tests of corn [in North Carolina], G. M. GARREN (Bul. N. C. Dept. Agr., 40 (1919), No. 5, pp. 36, figs. 2).—This describes further tests (E. S. R., 38, p. 532) with different varieties of corn during 1917 and 1918, the work having been discontinued with the 1918 experiments. Biggs Seven-Ear, First Generation Cross No. 182, and Southern Beauty are deemed to be the best varieties for the Piedmont and Mountain sections of the State, and Biggs Seven-Ear and Latham Double for the Coastal Plain region.

Some curious freaks of corn, D. F. JONES (*Rural New Yorker*, 78 (1919), No. 4541, p. 1043, figs. 2).—Certain abnormal ears of corn are illustrated and their possible significance in tracing the origin of the corn plant briefly indicated.

Description of a supposed new fossil species of maize from Peru, F. H. KNOWLTON (*Jour. Wash. Acad. Sci.*, 9 (1919), No. 5, pp. 134–136, fig. 1).—A fossilized ear of corn secured from a dealer in curios in Cuzco, Peru, by W. F. Parks, is described as a new species, *Zea antiqua*. Although lacking definite knowledge of the conditions under which the specimen was found, the author states that based on its thorough fossilization "it seems hardly likely to be younger than at least several thousand years," and that it "falls very little short of supplying the needed paleontological data on the antiquity of maize."

A fossil ear of maize, G. N. COLLINS (*Jour. Heredity*, 10 (1919), No. 4, pp. 170–172, flgs. 9).—The author briefly reviews the paper noted above, compares the fossil form with varieties of corn still being grown in Peru and Bolivia, and concludes that "while the fossil ear is not duplicated by any ear in our collection it presents no new characters, but rather a different combination of characters found among the existing types."

The inheritance of immunity to leaf blister mite (Eriophyes gossypii) in cotton, S. C. HABLAND (West Indian Bul., 17 (1919), No. 3, pp. 162-166).—Ob-
servations on the  $F_1$ ,  $F_2$ , and  $F_3$  progeny of a cross between St. Vincent native cotton, said to be immune to *E. gossypii*, and Southern Cross Upland, a susceptible type, are held to indicate that immunity to attack from the blister mite behaves as a simple Mendelian recessive. The  $F_1$  was intermediate though inclining toward the susceptible parent, while the  $F_2$  segregated into 100 immune and 365 nonimmune individuals. In the  $F_3$  10 of the immune families bred true for immunity, while 37 nonimmune families again segregated into immune and nonimmune.

The improvement of the yield of Sea Island cotton in the West Indies by the isolation of pure strains, S. C. HARLAND (West Indian Bul., 17 (1919), No. 3, pp. 145-161).—It is stated that through individual plant selection and selffertilization a marked improvement may be effected in certain morphological characters of Sea Island cotton which have to do with yield. Experimental work conducted in St. Vincent, following the method of pure line selection proposed and dealing with the number of ovules or seeds per loculus, number of loculi per boll, and the lint index (weight of lint per 100 seeds) in several strains of Sea Island cotton, is reviewed. The isolation of a strain capable of producing 31 per cent more lint per boll than the ordinary type grown in the island is said to have resulted.

An improved type of cotton for the southern Maratha country [Bombay Presidency, India], G. L. KOTTUR (Agr. Jour. India, 14 (1919), No. 1, pp. 165–167, pl. 1).—This briefly describes a long staple cotton developed through continued selection from an erect type of a local variety. The new sort is said to produce 12 per cent more seed cotton, ginning 12 per cent higher than the local strain, and to grade 5 per cent higher than the best local cotton.

Some of the problems arising out of the successful introduction of American cotton in the western Punjab, W. ROBERTS (Agr. Jour. India, 14 (1919), No. 1, pp. 42-48).—It is stated that in 1917 a total of 274,000 acres was planted to American cotton, more than one-half of which was pure 4 F, a selection developed by the economic botanist. In connection with the rapid spread of American cotton culture certain problems, herein briefly discussed, have arisen relating primarily to the maintenance of a fair market price, the elimination of mixing with so-called "desi" cotton, and the production of pure seed of the preferred 4 F type.

Egyptian cottons: Their deterioration and means of remedying it, V. M. Mosséri (Bul. Union Agr. Égypte, 16 (1918), No. 124, pp. 53-79; abs. in Internat. Inst. Agr. [Rame], Internat. Rev. Sci. and Pract. Agr., 9 (1918), No. 12, pp. 1441-1443).—The author states that while Egyptian cottons have declined both in production and quality it is more in the nature of a deterioration than a degeneration to be attributed largely to an indiscriminate mixing of varieties. The isolation and purification of superior strains, the dissemination of seed of only approved sorts, and the prevention of subsequent contamination are believed to be essential to the improvement of the crop. The desirability of Government aid in achieving this end is discussed.

Cotton, G. BIGWOOD (London: Constable & Co., Ltd., 1918, pp. VIII+204, pls. 16).—This comprises a popular account of the development of the cotton industry, together with a discussion of some of the problems confronting cotton manufacturers at the present time. A paper on Cotton Futures by C. Stewart is appended.

The early history of cotton in Bombay, J. MACKENNA (Agr. Jour. India, 13 (1918), No. 3, pp. 389-404, pl. 1).—A lecture delivered before the Students' Cotton Association, Sydenham College of Commerce, Bombay, in January, 1918.

The work of the Imperial Institute in connection with British cotton cultivation (Bul. Imp. Inst. [So. Kensington], 16 (1918), No. 1, pp. 79-89).—The activities of the Institute in promoting cotton production in the British Empire are briefly outlined. A list, comprising some 97 reports, special articles, etc., dealing with various phases of the crop which appeared in the *Bulletin* of the Institute from 1905 to 1917, inclusive, is also presented.

Cottonseed by-products (*Nature* [London], 103 (1919), No. 2582, pp. 153, 154).—A paper presented before the Royal Society of Arts by E. C. de Segundo on The Removal of the Residual Fibers from Cotton Seed and their Value for Nontextile Purposes is briefly reviewed. The development of ginning machinery for the more complete removal of lint from cotton seed and a process for removing the last trace of fiber from the hulls after decortication comprise the principal features dealt with.

Fiber plant investigations [in South Africa], E. HOLMES-SMITH (So. African Jour. Indus., 2 (1919), No. 2, pp. 157–172).—This describes a survey of the Transkei and southeastern coastal districts of the Cape Province for the purpose of ascertaining their suitability to fiber production and to the establishment of the fiber industry. It is concluded that the region is well adapted to the production of hard fibers, Agave rigida, Furcraa gigantea, and Phormium tenax being recommended in particular. Directions for growing the crops and for preparing the fiber for market are included.

Production of flax fiber and seed flax in Canada, F. C. ROBERTSON (U. S. Dept. Com., Com. Rpts., No. 124 (1919), pp. 1031-1034).—A report on the present status and future prospects of the flax industry in Canada.

Tests with flax varieties, G. S. GORDON (Jour. Dept. Agr. Victoria, 17 (1919), No. 3, pp. 164–170, figs. 4).—Limited variety tests, conducted at Werribee (Victoria) during 1918 with seed of both American and English origin, are briefly noted.

The flax industry [in Victoria], J. ROBILLIARD (Jour. Dept. Agr. Victoria, 17 (1919), No. 4, pp. 222-230, figs. 8).—Field practices and cultural methods employed in growing the crop and the preparation of the fiber for market are described.

Lalang grass as a paper material, B. J. EATON (Agr. Bul. Fed. Malay States, 7 (1919), No. 1, pp. 28-32).—This comprises a brief discussion of a report on lalang grass (Imperata arundinacea) as a paper material, presented by the Imperial Institute and previously mentioned (E. S. R., 40, p. 823). It is stated that this grass compares favorably with Algerian esparto grass, but is inferior to Spanish esparto.

Official grain standards of the United States for oats, D. F. HOUSTON (U. S. Dept. Agr., Bur. Markets Serv. and Regulatory Announcements, No. 46 (1919), pp. 6).—This contains the order of the Secretary of Agriculture establishing the official standards for oats, effective June 16, 1919.

Handbook official grain standards for oats (U. S. Dept. Agr., Bur. Markets, 1919, pp. 6).—This comprises a tabulated and abridged description of the official standards for oats compiled from the publication noted above.

The spraying of Irish potatoes, R. W. LEIBY (Bul. N. C. Dept. Agr., 40 (1919), No. 3, pp. 38, figs. 12).—This describes experimental work covering the period of 1913–1918, inclusive, conducted at the Buncombe County substation in an effort to ascertain the best practical means of controlling the important insect and disease pests affecting the fall or late Irish potato crop in North Carolina. The plan of the experiment comprised observations on the comparative value of spraying with Bordeaux mixture to control blight, hand-picking to control the Colorado potato beetle, and spraying with Bordeaux mixture and arsenate of lead combined to control both the beetles and blight. The results secured during each year of the experiment are discussed in detail and may be summarized as follows:

Maximum yields were secured by spraying at least four times during the growing season with a 3:4:50 Bordeaux mixture to which had been added 1.5 lbs. of powdered arsenate of lead. An average gain of 51.6 bu. per acre, representing 64.2 per cent, was obtained from the use of this spray over unsprayed potatoes. The labor and materials required to do the spraying were estimated to amount to \$7.67 per acre and the net gain to \$47.17. Bordeaux mixture alone produced an increase in yield of 35 bu. per acre over the check, at an average cost of four applications of \$5.32 and a net profit of \$33.22. Handpicking Colorado potato beetles resulted in an increase in yield of 8.6 bu. per acre, obtained at a cost of \$5.64 and with a net profit of only \$4.82. On the basis of close observations made during the past five years and a general knowledge of insects and diseases attacking the late Irish potato crop in the State, it is concluded that the potato grower may expect more or less destructive outbreaks each year of the Colorado potato beetle, flea beetle, early blight, and tipburn.

Directions for making and applying poisoned Bordeaux mixture are appended.

**Report on the composition of potatoes grown in the United Kingdom** (*London: Food (War) Committee, Roy. Soc., 1919, pp. 31, figs. 5).*—Information is presented relative to the total dry matter and nitrogen content of 227 samples of six main crop and four second early varieties of potatoes and 20 samples of 17 miscellaneous sorts secured from 65 growers in England, Wales, Scotland, and Ireland. The general average for all samples was 22.09 per cent of dry matter and 0.327 per cent of nitrogen.

**Bice** [in Argentina], G. S. Ito (*Bol. Min. Agr.* [*Argentina*], 23 (1918), No. 1, pp. 3-123, figs. 47).—The development and future of the industry in Argentina are discussed in considerable detail.

Preliminary notes on rice selection work at Saigon, E. CARLE (Bul. Agr. Inst. Sci. Saigon [Cochin China], 1 (1919), No. 3, pp. 74-87).—The progress of efforts to improve the rice crop through selection is described. Agronomic data relative to a number of varieties of rice are included.

The transplanting of rice in Egypt, V. M. MOSSÉRI (*Bul. Union Agr. Égypte*, 16 (1918), No. 123, pp. 21-50).—This describes the continuation during 1916 and 1917 of work previously noted (E. S. R., 37, p. 538). The results of the earlier tests were confirmed, the conclusion being reached that seeding rice directly in the field was more advantageous than transplanting from a seed bed.

Utilization of rice and its by-products (*Bul. Imp. Inst.* [So. Kensington], 16 (1918), No. 1, pp. 16-24).—Supplementing a previous account (E. S. R., 39, p. 838), this article comprises a discussion of the suitability of various kinds of Burmese rice for industrial and other purposes. The profitable utilization of rice straw and rice husks in the manufacture of paper is deemed doubtful except in the preparation of low grades or strawboard.

A forage plant from the Solanaceae family, B. H. HUNNICUTT (Jour. Heredity, 10 (1919), No. 4, pp. 184-187, figs. 2).—This comprises a rather popular account of Solanum bullatum, said to be a valuable forage crop found growing wild in many parts of Brazil.

Fertilizer experiments with sugar cane [at Tucumán], W. E. CROSS (*Rev. Indus. y Agr. Tucuman, 9 (1918), No. 5-6, pp. 72-85; abs. in Chem. Abs., 13 (1919), No. 8, p. 885).*—This describes the continuation of work along lines similar to those previously noted (E. S. R., 33, p. 336) for 1915 and 1916, and the inauguration of a new series of experiments with Java cane during 1917 and 1918 in which potassium sulphate, Thomas slag, and ammonium sulphate were used alone on both limed and unlimed soil.

Neither potassium nor phosphorus effected any material increase in the yield of either cane or sugar, while phosphorus delayed the maturity of the cane on unlimed land. Ammonium sulphate resulted in an increase in all cases, but usually without profit.

Experiments on stripping [sugar] cane, W. E. CROSS (*Rev. Indus. y Agr. Tucuman, 9 (1919), No. 7-8, pp. 110-114, fig. 1; trans. in La. Planter, 62 (1919), No. 19, pp. 301, 302, fig. 1*).—Observations made at Tucuman during 1917 and 1918 on the effect upon the composition of the juice of stripping the dried and dead leaves from the lower part of the stalks of sugar cane are held to indicate that the practice did not hasten the maturity of the cane.

Costs of production in the sugar industry (U. S. Tariff Com., Tariff Inform. Ser. No. 9 (1919), pp. 55, pls. 3, fig. 1).—" Comprehensive tables were prepared . . . in which the total costs and the segregated items of cost for every factory from which returns were obtained are displayed in detail. They cover the cane-sugar industry in Cuba, in Hawaii, in Louisiana, and in Porto Rico, and the beet-sugar industry in the continental United States. For each of these regions there are three tables, the first showing costs in the prewar period, the second for the crop of 1916–17, and the third for the crop of 1917–18." For the second period 178 factories are reported and in the third 152. These basic tables show the output in tons, total cost, seggregated items of total and factory cost, and averages by factories and by tonnage.

From the fact that the cost of the raw material is the most important item, it is shown that sugar is essentially an agricultural product. The suggestions from the available data are in favor of large-scale production of cane or beets. In the appendixes there are copies of the schedules used in collecting data, and illustrative charts.

Notes on the germination of tobacco seed.—III, Notes on the relation of light and darkness to germination, T. H. GOODSPEED (Univ. Cal. Pubs. Bot., 5 (1919), No. 16, pp. 451-455).—As a further contribution to work previously noted (E. S. R., 33, p. 636), the author describes observations on the effect of light and darkness upon the germination of five varieties each of Nicotiana tabacum and N. rustica, preliminary to a more thorough and better controlled series of investigations.

Part of the seed was placed in a glass-sided germinating case maintained at a constant temperature of about 30° C (86° F.) and in which a 40-watt tungsten electric-light bulb was hung so that the seed was exposed to the light continuously. Duplicate samples of seed were also subjected to continuous darkness in the germinator by placing them in covered paper boxes. In another series of tests the seeds were kept in darkness in closed boxes and were also left undarkened near a window, but not in direct sunlight and without any attempt to regulate the temperature. Only two-year-old seed of the *N. rustica* varieties was employed, while that of the *N. tabacum* varieties ranged from 2 to 12 years in age. The germinated seeds were counted at frequent intervals over a period of more than 20 days and the data recorded in tabular form.

Contrary to the results secured by Honing (E. S. R., 38, p. 127), working with commercial strains of *N. tabacum* derived largely from the basic types employed in these observations, the seeds of all varieties of both *N. tabacum* and *N. rustica* were found to germinate readily in darkness. It was also noted that old and new seed germinated equally well in darkness.

Nomenclature of wheats grown in South Africa (Union So. Africa, Dept. Agr. Bul. 1 (1919), pp. 15).—The correct name and the names commonly applied to the different kinds of wheat grown in South Africa are presented in tabular form, together with notes on the more prominent agricultural and botanical

characteristics of each. The varieties dealt with include 24 strains of durum wheat, 17 common bearded sorts, and 41 beardless types.

Kota, a rust resisting variety of common spring wheat, L. R. WALDRON and J. A. CLARK (Jour. Amer. Soc. Agron., 11 (1919), No. 5, pp. 187–195, pl. 1).—This paper, a joint contribution from the North Dakota Experiment Station and the Bureau of Plant Industry, U. S. Department of Agriculture, describes observations on the yielding ability, rust resistance, and milling and baking qualities of a bearded hard red spring wheat variety designated as Kota (C. I., No. 5878), as compared with durum wheat and with other common spring wheat varieties. Kota is said to have been separated in 1917 from Monad, a durum sort introduced into this country from Russia in 1903 by H. L. Bolley.

Field observations of pure line selections of Kota are held to indicate that the variety possessed a resistance to the form or forms of stem rust of wheat (*Puccinia graminis tritici*) present at Fargo, N. Dak., Brookings, S. Dak., and St. Paul, Minn., in 1918, which was decidedly greater than that exhibited by the common spring wheats, and second only to that of the more resistant durum wheats. Data from greenhouse inoculation experiments conducted by E. C. Stakman at the Minnesota Experiment Station and by L. E. Melchers at the Kansas Experiment Station with different biologic forms of the rust are also briefly reviewed. Yield data for the season of 1918 showed an average of 31.92 bu. per acre for six durum varieties, 22.82 bu. for ten common spring wheats, and 29.53 bu. for Kota. Marquis produced 29.33 bu.

Kota was found to yield somewhat less flour than the average for the wheats examined, while in the baking tests it exceeded the other common spring wheats except Marquis, which it equaled.

Results of wheat variety and manurial trials, season 1918-19, I, II, (*Jour. Dept. Agr. Victoria*, 17 (1919), Nos. 3, pp. 158-163; 4, pp. 217-221).—This describes the continuation of work previously noted (E. S. R., 39, p. 540; 40, p. 337).

The highest yielding varieties of wheat tested at Longerenong were hybrid Gallipoli, selected Federation, and a hybrid strain, Federation×Bobs, with yields amounting to 41.9, 40.3, and 40 bu. per acre, respectively. In a comparison of a number of hybrid strains with selected varieties, hybrid Gallipoli was again first with 45.8 bu. per acre.

Rate-of-seeding tests with Federation showed a gradual increase in yield with an increase in the rate of seeding up to 75 lbs. per acre for early seeding (May 31) and up to 120 lbs. for late seeding (July 10). In a comparison of early and late seeding for early, midseason, and late maturing varieties the early varieties yielded better when sown late, but not so well as the midseason varieties sown at the same time.

Tests with 8 barley varieties resulted in yields ranging from 55.9 bu. per acre for Kinver to 76.2 bu. for Oregon.

Additional variety tests with wheat were conducted at Ouyen, Cowangie, and Carwarp in the Mallee area. The leading varieties were Dart Imperial and Yandilla King, each with 21.2 bu. per acre for a 3-year average at Ouyen, Federation with 28.3 bu. for a 4-year average at Cowangie, and Currawa with 18.4 bu. for a 3-year average at Carwarp.

Fertilizer tests with wheat, conducted at various experimental centers, are held to indicate that moderately heavy applications of superphosphate give the best results.

Irrigation and the protein content of wheat, J. S. JONES, C. W. COLVER, and H. P. FISHBURN (*Idaho Sta. Bul. 109 (1918)*, pp. 3-43, figs. 11).—Investigations conducted near Gooding, Idaho, during the period of 1910–1916, inclusive, are described which were undertaken in an effort to ascertain the effect of irrigation upon the protein content of wheat, the fundamental reasons for the influence of soil water upon protein formation, and the cumulative effect of different amounts of irrigation water on the protein content. The plan of the experiment involved the growing of three varieties of wheat side by side on one-fifth and one-tenth acre plats in such a manner that varying amounts of irrigation water could be applied. Quantitative determinations of the soil nitrates were made at frequent intervals on certain of the plats to determine the relative amounts present and their possible concentration under the influence of irrigation water in zones beyond the feeding range of the plant roots. Milling tests and analytical work on representative samples of grain from each plat are also reported. Field observations and analytical data are presented in tabular form for each year of the experiment and briefly discussed.

Substantial variations in the amount of irrigation water failed to produce any marked effect on the protein content of the grain. The data also failed to reveal any concentration of soil nitrates in zones beyond the feeding range of the wheat plant. No cumulative or permanent effects of large amounts of water upon the protein content of wheat were observed.

The results secured are held to indicate that while wheat grown under irrigation in the Snake River region is in general soft, starchy, and of low protein content, this condition is not due to irrigation but to a lack of available nitrogen in the raw sagebrush soils brought under cultivation on irrigation projects. The rotation of wheat with alfalfa or red clover is said to result in a decided improvement in the quality of the grain, while protein elaboration was also somewhat stimulated. It is stated that nevertheless carelessness in the use of irrigation water may offset otherwise favorable soil conditions for maximum protein elaboration. It is concluded that however "deteriorated" in quality a really good variety of milling wheat may have become through growth under irrigation on soils depleted of available nitrogen, seed from it will respond with the production of maximum amounts of protein for the variety if given the favorable conditions of growth indicated, and that nothing is to be gained by importing seed of that variety from distant localities. A more rigid selection of varieties on the basis of well-recognized milling qualities is also emphasized.

Official field crop inspection, H. L. BOLLEY (Jour. Amer. Soc. Agron., 11 (1919), No. 5, pp. 196-205; also in Science, n. ser., 50 (1919), No. 1287, pp. 193-199).—In this paper, a contribution from the North Dakota Experiment Station, the author discusses the necessity and desirability of a legal basis for bringing about stability and standardization of varieties in cereal cropping. It is suggested that this be accomplished by a law authorizing crop inspection in the field, seed certification, seed standardization, and seed listing, all under the supervision of an expert preferably associated with the State experiment station.

The size of seed, W. M. FINDLAY (North of Scot. Col. Agr. Bul. 23 (1919), pp. 16).—Field tests, conducted at various experimental centers in Scotland, are described in which observations were made on the effect upon yield of different sized seeds in the same sample of oats, barley, turnips, and red clover; of different sized seeds in different samples of oats, turnips, and red clover; and of sifting out small oat seeds.

The results are held to indicate that in a single sample of seed large seeds produced more than small seeds. In different samples of the same kind of seed the strain and origin of the seed were of more importance than the size of the seed. When ungraded seed was employed, the plants produced by the large seeds exerted a considerable adverse influence upon those from small seeds. It is concluded that small seeds should be discarded and only uniformly large seeds used.

Seed Reporter (U. S. Dept. Agr., Seed Rptr., 3 (1919), No. 2, pp. 8).-The principal features of this number comprise a report on the vegetable seed acreage for 1918 and 1919 and the average crop condition on June 30, 1919, by States and crops, together with an incomplete report on field seed stocks and receipts for the United States as of June 30. Information is also presented relative to the redtop seed crop for 1919, onion sets in the Chicago, Louisville, and other districts, the timothy seed outlook, bur clover seed production in California and the Southern States, vegetable seed crop conditions, the seed garden pea outlook, the crimson clover seed situation, the prospects for seed oats and rye in the South, the early crop alfalfa seed outlook in Texas, New Mexico, Oklahoma, and Arizona, the meadow fescue seed crop for 1919, and Bermuda onion seed production in California. A summarized statement is given showing the results of an inquiry as to the utilization, interest, and relative value of the information published in the Seed Reporter. The usual statistics pertaining to the imports of forage plant seeds permitted entry into the United States are included.

Field weeds in their relation to forage: Determination of their fruit and seed, A. NAUMANN (Arch. Wiss. u. Prakt. Tierheilk., 44 (1918), Sup., pp. 310-356, pl. 1, figs. 20).—The utilization of weeds for forage and of their fruits and seeds in feeding materials is discussed, together with information concerning the relation of weeds to plant diseases. A key for the identification of the fruits and seeds of a number of weeds is included.

Tests of chemical means for the control of weeds, G. P. GRAY (Univ. Cal. Pubs. Agr. Sci., 4 (1919), No. 2, pp. 67–97, figs. 11).—The progress of experimental work begun in 1915 on the use of chemicals for the control of weeds in California, particularly the wild morning-glory, is described. The work embraced two lines of investigation, viz, the eradication of weeds by the rootabsorption method, whereby the soil in the vicinity of the roots of the weeds is more or less permeated with the herbicide, and weed control by the leafabsorption method whereby the foliage is sprayed with the herbicide. In testing the first method arsenic trioxid, sodium cyanid, sulphuric acid, acid sludge, acid tar, common salt, carbon bisulphid, copper sulphate, and iron sulphate were employed, while in the second method an arsenical spray was used.

Results secured with the leaf-absorption method in preliminary experiments in the coast region of the State have already been noted (E. S. R., 38, p. 140), and are also discussed in the present paper. It is stated further that the rootabsorption method failed to control wild morning-glory on agricultural land at a reasonable expense and without serious injury to the soil. Incidental to the main object of the study, data have been secured which are held to demonstrate the superiority of arsenic as a soil sterilizer.

The use of chemical sprays for combating weeds, J. ADAMS (Ann. Rpt. Quebec Soc. Protec. Plants [etc.], 10 (1917–18), pp. 70–78).—Field plat tests conducted at Ottawa during 1916 are briefly reviewed in which observations were made on the effect of spraying wild mustard, purslane, dandelion, and Canada thistle with a 20 per cent iron sulphate solution and with sodium arsenite (1 part to 250 parts of water). Chemical substances regarded as having given promising results in controlling weeds include sulphuric acid, iron sulphate, copper sulphate, common salt, caustic soda, sodium arsenite, carbolic acid, orchard heating oil, and fuel oil. A list of weeds which are said to be amenable to control by chemical methods is also presented, and the material giving the best results in each case indicated.

144402°-19-4

Eradication of weeds by sprays and manures, W. E. BRENCHLEY (Jour. Bd. Agr. [London], 25 (1919), No. 12, pp. 1474–1482).—The author discusses in a general manner the utilization and relative value in the eradication of weeds of chemical sprays, such as copper sulphate, iron sulphate, sulphuric acid, etc., and of finely ground materials applied as dusts, including calcium cyanamid, basis is compare sulphate. It is complete that although no definite recent

kainit, common salt, and lime. It is concluded that although no definite recommendations are justified at the present time the use of finely ground materials offers marked possibilities in weed control in addition to such beneficial manurial effects as the material might exert on the crop.

## HORTICULTURE.

**Practical vegetable gardening**, J. BÖTTNER (*Praktische Gemüsegärtnerei*. Frankfort on the Oder: Trowitzsch & Son, 1919, 9. rev. and enl. ed., pp. 11+386, figs 355).—A treatise on the principles of vegetable gardening, including specific directions for growing various crops.

Grow your own vegetables, S. C. JOHNSON (London: T. Fisher Unwin, Ltd., [1918]. p. 199, figs, 119).—A practical handbook on home vegetable gardening in England.

The garden frame for food and flowers, W. F. Rowles (London: C. Arthur Pearson, Ltd., 1919, pp. 112).—A practical treatise on the use of the hotbed and cold frame, based upon the author's long experience as a gardener in various parts of England and Scotland.

[Report on horticultural work for the year ended March 31, 1918], W. T. MACOUN ET AL. (Canada Expt. Farms Rpt. 1918, pp. 10, 12, 13, 14, 15, 32, 33, 34, 35, 64, 70, 75, 76, 81, 82, 97, 98, 101, 102, 103, 105, 106, 107, 109, 110, 114, 117, 118, 120, 123, 127, 131, 134, 138, 144, 147).—A brief progress report on horticultural work at the Central Farm, together with notes on tests of fruits, vegetables, and ornamentals at the branch farms and stations, and continuing previous work (E. S. R., 40, p. 741).

The carob in California, I. J. CONDIT (*California Sta. Bul. 309 (1919)*, pp. 431-440, figs. 6).—An account of the carob (*Ceratonia siliqua*), with reference to its introduction into California, botany, climatic, and soil requirements, propagation, planting, yield, and varieties.

Notes on the dasheen and chayote, H. W. YOUNGKEN (Amer. Jour. Pharm., 91 (1919), No. 8, pp. 498-510, figs. 15).—Notes on the histology of the Trinidad dasheen and the chayote, including general notes on their cultural status in the United States.

Hardy fruit culture, C. F. LAWRANCE (London: Evans Brothers, Ltd., [1919], pp. [IV]+80, figs. 31).—A small treatise on home fruit gardening in England.

The fruit growers' yearbook and market gardeners' guide, 1918 (*Fruit Growers' Yearbook* [London], 26 (1918), pp. 164, pls. 4).—This annual contains a number of articles relating to fruit and vegetable growing in Great Britain, and includes a monthly working calendar for outdoor and indoor work.

Decade records in Ohio apple orchards, Nos. 2 and 3, H. A. GOSSARD (Mo. Bul. Ohio Sta., 4 (1919), Nos. 6, pp. 171-178, figs. 5; 7, pp. 203-208, figs. 5).— These papers record the results secured from long-continued spraying tests in the second and third of three representative Ohio orchards (E. S. R., 41, p. 239). The method of conducting the tests, as well as cultural and marketing practices, are briefly described. Yields, financial returns, and the record of worminess for each year under different spray treatments are presented in tabular form. The results as a whole indicate that spraying for worminess has been highly profitable. In the Stokes orchard (No. 2), spraying twice, once just after bloom and again soon after bloom, has given an annual average of 90 to 95 per cent of sound fruit as compared with about 98 per cent of sound fruit in the orchard previously reported on, which was sprayed once just after bloom fall and again in midsummer. The average yield per acre for the 10-year period was 448 bu., the average gross income per acre \$406.45, and the average net income per acre \$183.68, figuring the cost at 50 cts. per bushel.

In the Starcher orchard (No. 3), selected to test performance in a hilly section, three sprayings, two soon after bloom and a third in July, gave an average of only 1.66 per cent of worminess while two sprayings made soon after bloom gave an average of 2.92 per cent wormy fruit. Owing to two crop failures the average gross income per acre of this orchard, which was 15 years old at the beginning of the experiment, has not been high; only \$71.93. The estimated annual net income per acre on a cost basis of 50 cts. per bushel was \$23.90. It is pointed out that the cost of producing apples on such cheap hill land is probably much less than 50 cts. per bushel and that actual prices of good fruit are now much higher; hence the man with limited capital may expect good financial returns from orchards developed on these cheap hillside lands.

Using an apple sizing machine, I. P. LEWIS (Mo. Bul. Ohio Sta., 4 (1919), No, 7, pp. 221-224, figs. 3).—A descriptive account with illustrations.

**Experiments** with citrus trees, B. F. FLOYD (*Florida Sta. Rpt. 1918, pp. 39–53, figs. 2*).—A progress report on a number of fertilizer experiments with citrus trees is given.

One set of experiments, here described in detail, includes a comparative test of phosphoric acid from different sources. The phosphoric acid is used in combination with other elements, although no potash has been used thus far. The test is being conducted with young trees on virgin soil, with young trees on soil completely fertilized during the two years before planting, and with bearing trees over 25 years old that have always been well fertilized. Thus far the trees in all of the experimental groves have made satisfactory growth, and no differences have become evident that can be attributed to the fertilizer treatment.

An experiment was started in 1914 to determine the influence of fertilizer treatment upon the coloration of grapefruit in a grove where the fruit showed a greenish tint at maturity instead of a normal deep yellow. The results indicate that the fertilizer treatment was not a controlling factor in the development of the trouble, but that the controlling factor was associated in some way with the influence of the stock upon the scion.

Other experiments, here outlined, that have not been conducted long enough to warrant deductions include a study of the influence of different ratios of phosphoric acid and potash in fertilizers upon tree growth and fruit production, and the efficiency of finely ground phosphate rock, stable manure, and legumes as a fertilizer for citrus trees.

Report of assistant plant physiologist, M. NOTHNAGEL (Florida Sta. Rpt. 1918, pp. 54, 55).—The main line of work for the year has been a study of the time of development and structure of fruit buds in citrus. Material for study was collected from summer, fall, and spring flushes at various stages, ranging from the time the flush started growth until the following flush was beginning growth.

A gross examination of the material showed no external clue to the kind of bud or buds that were to develop in a cluster in the following growth. The microscopic examination showed a cluster of two to four buds in the axil of every leaf and bud differentiation at an early stage in the development of the flush. This differentiation was based upon differences in the crowns of the growing tips. "Those of the fruit buds were rounded, with opposite projections below, that would develop into floral parts, while below these opposite projections there were alternate projections that would mature into leaves. The crowns of the leaf buds were conical, with only alternate projections below, that would develop into leaves. The development of the different buds was followed to the point where the evident growth showed the crown differences to be distinguishing characters." The study is to be continued.

Citrus experiment grove, S. E. COLLISON (*Florida Sta. Rpt. 1918, pp. 79-83*).— In continuation of previous reports (E. S. R., 39, p. 448) measurements are given showing the increase in diameter of the trees of the various plats from 1909 to 1918, together with data showing a partial chemical analysis of leaves and stems collected from the different plats.

A study of the 24 poorer plats led to the conclusion that no particular source of nitrogen can be singled out as having been injurious to vigor or amount of growth, but that too much nitrogen is injurious to growth. An injurious effect on growth was also produced by the use of ground limestone, and poor growth resulted where kainit and Thomas slag were used on the trees. No definite conclusions are thus far drawn as to the best fertilizer treatment.

Analyses of leaves from the different plats showed that the figures for nitrogen, magnesia, iron, and phosphoric acid ran very close together. The average percentage of lime was higher in the leaves from plats receiving lime, but the higher lime content was not found in the stems. In plats receiving excessive amounts of nitrogen, the stems contained less nitrogen than the stems from the remainder of the plats. No striking differences were observed in the leaves and stems from the plat receiving no fertilizer, except that they contained more magnesia than leaves and stems from any of the other plats.

Citrus growing in South Africa.—Oranges, lemons, naartjes, etc., R. A. DAVIS (*Pretoria: Dept. Agr., 1919, pp. 66, pl. 1, figs. 45*).—A practical treatise on the culture, packing, and marketing of citrus fruits.

Experiments in the culture, selection, and manuring of coconuts in Madras, W. McRAE and R. D. ANSTEAD (Inst. Colon. Marseille, Bul. Mat. Grasses, No. 3 (1919), pp. 100-103).—Notes on experiments conducted for several years at Alleppi by G. H. Davey.

The coconut in Cochin China, P. MORANGE (Inst. Colon. Marseille, Bul. Mat. Grasses, No. 3 (1919), pp. 89-94).—A brief report on the present status of and future prospects for the coconut and copra industries in Cochin China.

#### FORESTRY.

Forest management, A. B. RECKNAGEL and J. BENTLEY, JR. (New York: John Wiley & Sons, Inc., 1919, pp. XIII+269, pls. 4, figs. 26).—A text-book and treatise on forest management, the successive chapters of which consider survey of area, forest mensuration, log rules, instruments for forest measurements, the measurement of felled trees, the measurement of standing trees, volume tables, timber estimating, age of trees and stands, growth of individual trees, increment of stands, forest organization, regulation of the cut, the working plan document, forest finance, and forest administration. An appendix contains numerous related tables, outlines for forest description and planting plan, and form for tree measurements.

A National Forest policy, H. S. GRAVES (Amer. Forestry, 25 (1919), No. 308, pp. 1281, 1282).—The author here presents some principles requiring the prac-

tice of forestry on private lands which, it is believed, should form the foundation of the system to be built up through the necessary legislation by the Federal and State Governments.

Some proposals with regard to natural afforestation in a New Zealand mountain area, W. G. MORRISON (New Zeal. Jour. Sci. and Technol., 2 (1919), No. 4-5, pp. 339-349, figs. 3).—The author presents observations on the progress of natural afforestation on the Hanmer Plains area of New Zealand, and advocates regeneration of other mountain areas by the introduction of seed trees adapted to the environment.

The Douglas fir, a tree giving large returns, V. MANVILLI (Italia Agr., 56 (1919), No. 8, pp. 231-237).—The author outlines the successful culture of Douglas fir (*Pseudotsuga douglasii*) in various European countries, and recommends it for mountain planting on a large scale in Italy.

The collection and some uses of the oleoresin of Douglas fir (Oregon fir balsam, Douglas fir turpentine), S. A. MAHOOD (*Amer. Jour. Pharm.*, 91 (1919), No. 6, pp. 345-349, fig. 1).—The methods of collecting the oleoresin and its commercial uses are briefly reviewed.

The Hawaiian genus Kokia.—A relative of the cotton, J. F. ROCK (Bd. Agr. and Forestry Hawaii, Div. Forestry Bot. Bul. 6 (1919), pp. 22, figs. 8).—A descriptive account of the species of this genus.

The true mahoganies, R. A. Rolfe (*Roy. Bot. Gard. Kew, Bul. Misc. Inform.*, *No.* 4 (1919), pp. 201-207).—Descriptive accounts are given of the species of Swietenia, to which what may be termed true mahoganies belong.

Mahogany, and the recognition of some of the different kinds by their microscopic characteristics, H. H. DIXON (Sci. Proc. Roy. Dublin Soc., n. ser., 15 (1918), No. 34, pp. 431-486, pls. 23; also in Notes Bot. School Trinity Col. Dublin, 3 (1919), No. 1, pp. 3-58, pls. 23).—A contribution from Trinity College, Dublin, in which descriptions based on variations in microscopic structure are given of a number of samples of mahogany. In order to facilitate the use of the descriptions in distinguishing the various kinds of mahogany, a key is provided which utilizes some of the characteristic microscopic features. The descriptive text is accompanied by a series of plates illustrating wood structure in various samples.

A. Other methods for field experimentation with Hevea.—B. Some more germination trials with Hevea seed, J. G. J. A. MAAS (*Arch. Rubbercult. Nederland. Indië, 3 (1919), No. 6, pp. 233-245, figs. 3).*—A discussion of improved methods for field experimentation with Hevea, including data on some additional germination trials with Hevea seed (E. S. R., 41, p. 449).

The present germination tests with Hevea seed confirm the previous results in showing that with seed preserved at ordinary temperatures the packing must be moist but not air tight. When being preserved for periods longer than one month the packing material should be moistened once every three or four weeks. At lower temperatures, from 4 to 8° C. (39.2 to 46.4° F.), the seeds will stand better a drier and more air-tight packing, but even under lower temperatures the germination power decreases quickly under air-tight packing. Merely ensilaging Hevea seeds in the ground appears to be good for preserving seeds on the estate for periods not exceeding one month.

Warm water treatment with water about 50° resulted in the germination energy and germination power being slightly improved. Sprinkling with warm water of 45° improved the rapidity of germination a little, but had no significant influence on the germination power.

The structure of cell elements in the bark of Hevea brasiliensis, W. BOBILI-OFF (Arch. Rubbercult. Nederland. Indië, 3 (1919), No. 5, pp. 222-231, figs. 7).— The investigation here reported was conducted primarily with the view of

[Vol. 41

studying the structure of laticiferous vessels of Hevea, and to ascertain some knowledge about the cytology of this tree in connection with the physiological signification of latex.

The author found that in the laticiferous vessels of Hevea both protoplasm and nuclei occur, but the nuclei are larger than those of other cortex cells. The nuclei are placed in protoplasm where also occur vacuoles. It is concluded that the latex of Hevea is cell sap, which generally occurs in the vacuoles of the laticiferous vessels. Frequently many of the nuclei of the laticiferous vessels unite in one spot, and they have also been observed to pass from one vessel to another through the wall openings.

Variability in plantation rubber, C. DE VRIES and W. SPOON (*Arch. Rubber*cult. Nederland. Indië, 3 (1919), No. 6, pp. 246-276).—Results are given of analyses conducted at the Central Rubber Station, showing the variation in rubber samples collected from a number of estates in the Netherlands Indies.

The relation between the specific gravity of latex and serum and the rubber content of latex, C. DE VRIES (Arch. Rubbercult. Nederland. Indië, 3 (1919), No. 5, pp. 183-206, figs. 2).—Results are given of experiments conducted with pure undiluted latex collected from trees under different conditions, such as continued tapping after a period of rest, light or heavy tapping systems, from trees before and after pollarding, from trees given different periods of rest and shallow tapping, and from individual trees.

The tests as a whole show that there is a very close relation between the specific gravity and the rubber content of original latex. For the specific gravity of original serum varying values are to be expected, depending upon the composition of the serum owing to physiological factors, but these variations are within a limited range. Whether the specific gravity of rubber in latex is constant or varies somewhat because of absorption phenomena or changes in the composition of the caoutchouc hydrocarbon remains to be investigated. The rubber content of the original latex is lowered by all factors which put a heavy stress on the trees.

Tapping experiments on Hevea brasiliensis, A. W. K. DE JONG (*Arch. Rubbercult. Nederland. Indië, 3 (1919), No. 6, pp. 277, 278).*—This paper summarizes the results of experiments in which tapping was conducted on a quarter, **a** third, and a half of the circumference of the tree with one left-hand cut. The experiment was conducted on three different tapping areas. Averaging the results of the three areas, the rubber yield increased from 100:114:122 as the cut was increased from one-fourth to one-half of the circumference.

The application of preservatives to renewing bark of rubber, T. PETCH (*Dept. Agr. Ceylon Leaflet 9 (1918)*, *pp. 4*).—This leaflet summarizes in very condensed form considerable information obtained in experiments to determine what amount of injury would be caused to renewing bark of Hevea by the application of preservatives, a number of which were tested in these experiments.

# DISEASES OF PLANTS.

**Report** of associate plant pathologist, C. D. SHERBAKOFF (*Florida Sta. Rpt.* 1918, pp. 68–78, figs. 4).—The author gives a report on investigations of several diseases of truck crops, among them being a rot of eggplants due to *Phomopsis* vexans, bacterial blight or rot of solanaceous plants, buckeye rot of tomatoes, and damping-off of celery.

In the eggplant seed tests, studies were carried on to determine the probability of the seed carrying infection. The results showed that the introduction of the Phomopsis into the seed bed took place by means of seed which had been contaminated with the fungus. It is thought that the fungus is not a native of Florida, as a large number of samples of seed were free from infection.

Considerable reliable information in regard to the cause, occurrence of, and plants affected with bacterial blight has been collected, and suggestions have been given for the control of the disease. Many phases of the blight, unknown at present, such as varietal susceptibility of the plants, the effect of soil type and treatment on the disease, etc., are to be thoroughly studied until determined. Comparatively little disease was found among the tomatoes on which the experiment was made, yet the disease was scattered among nearly all of the varieties.

Continued observations, previously reported (E. S. R., 39, p. 457), are being made on buckeye rot of tomato fruit. The work of the past year demonstrated that infection of the fruit takes place through the soil. Since the preliminary report on this disease, a wider distribution of the fungus has been observed.

Reports are also given of the truck disease survey, with brief description of the damage caused by the late, early, and bacterial blights of the Irish potato, nailhead rust of tomato, blackheart of celery, Phomopsis fruit rot of eggplant, Alternaria fruit spot of eggplant, and Cercospora leaf spot of pepper.

Report of the acting Dominion botanist, J. H. GRISDALE (Canada Expt. Farms Rpt. 1918, pp. 38-41).—Brief summaries are given of the more important lines of work carried on during the year covered by the report.

At St. Catherines, Ont., studies of the white pine blister rust occupied considerable time, and a preliminary investigation was made of a strawberry root disease which appears to have been rather widespread.

At Charlottetown, P. E. I., potato spraying experiments for late blight were continued, and it is held to have been established that not less than four applications of 4:4:40 Bordeaux mixture per season are necessary, though not quite so effective in controlling the disease as six applications. For the control of the blackleg disease of potatoes, experiments have shown that the whole tuber should be treated with disinfectants and not the cut tuber. The disease apparently is not carried over in the soil. Other investigations of potatoes have been continued.

At Fredericton, N. B., the work largely consisted of a series of potato spraying experiments, carried on to determine the increase in yield due to freedom from blight and the number of applications necessary.

At the Brandon, Man., and Indian Head, Sask., laboratories the studies have been mostly on grain rust and other cereal diseases. The principal investigations were made to determine the native and cultivated grasses which act as host plants for the rust, the species of rusts attacking cereals in Western Canada, and the origin of the outbreaks of rust.

Mycology and plant pathology, E. J. BUTLER (Ann. Rpt. Bd. Sci. Advice India, 1916–17, pp. 47–56).—This includes, besides miscellaneous matters, an account of the chief investigations at Pusa during the year. Plant diseases and pests dealt with include ufra of rice, Orobanche spp. on tobacco and other plants (noting certain apparent specializations), Phytophthora investigations, studies on Rhizoctonia and allied fungi, anthracnose of chili and other crops, and sal tree disease.

**Plant** diseases, C. M. HUTCHINSON (Ann. Rpt. Bd. Sci. Advice India, 1916–17, p. 59).—The author states in this portion of a more general report that bacterial diseases of wheat, poppy, and citrus plants were under investigation during the year. A memoir on bacterial diseases in wheat was projected, as was also a description of bacterial rot of poppy, which resulted in a blackening and slimy decay of the stem and leaves. Further study was contemplated of citrus canker, which has been known in India for several years, some forms of this

disease having been shown to be due, here as elsewhere, to *Pseudomonas* citri.

Diseases and animal pests of cultivated plants during 1917 and 1918 in Dutch East Indies, C. J. J. VAN HALL (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Lab. Plantenziekten, Nos. 33 (1918), pp. 42; 36 (1919), pp. 49).—In connection with a discussion of the somewhat unusual weather attending the monsoons of 1916 and 1917, systematic accounts are given for 1917 and 1918 of injury in different sections by diseases and parasitic animals to plants. This is followed by an account of legal measures looking to control of animal pests and plant diseases.

Biologic specialization in the genus Septoria, W. S. BEACH (Amer. Jour. Bot., 6 (1919), No. 1, pp. 1-33, pl. 1, figs. 14).—A study of the genus Septoria is said to show that certain species are differentiated into biologic forms, the species being limited to a few closely related hosts which they infect vigorously, though in some cases members of two or three related genera are susceptible to the same fungus. The symptoms differ with the hosts and conditions, and for this reason are unreliable in taxonomy. It is stated that S. malvicola and S. fairmani are identical. S. convolvuli as described for the host Convolvulus arvensis is said to be biologically, as well as morphologically, distinct from the forms described for the host C. sepium, and to be therefore entitled to rank as a distinct species.

Wheat diseases in Java, B. PALM (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Lab. Plantenziekten, No. 34 (1918), pp. 22, pl. 1, figs. 12).— Ustilago tritici and Gibberella saubinetii (Fusarium rostratum) are said to have appeared recently on wheat in Java, having been imported supposedly with seed grain. Attacks on diseased wheat are noted also as due to Helminthosporium gramineum, H. geniculatum, and Nigrospora panici. A brief account of control measures is followed by a short list of related publications.

The control of rust [in Manitoba], V. W. JACKSON (Agr. Gaz. Canada, 5 (1918), No. 10, pp. 974, 975, figs. 2).—After the 1916 outbreak of wheat rust in Manitoba, which is said to have caused losses aggregating over \$100,000,000 to the Western Provinces, methods were adopted to remove causes so far as known. Following a rust conference at the Manitoba Agricultural College in August, 1917, there was a spring drive on the barberry bushes, which were completely eradicated, with the exception of a few kept for experimental purposes. No outbreak occurred on these until artificially inoculated from stubble of wild barley, which seems to be especially susceptible to the rust and its most dangerous carrier. Wheat stubble tied in barberry bushes developed no infection, though wild barley stubble treated in the same way gave a heavy crop of æcidiospores a few days later.

A disease of flax seedlings caused by a species of Colletotrichum, and transmitted by infected seed, G. H. PETHYBRIDGE and H. A. LAFFERTY (Sci. Proc. Roy. Dublin Soc., n. ser., 15 (1918), No. 30, pp. 359-384, pls. 2).—Attention having been drawn in 1916 to the disease of young flax seedlings in the north of Ireland somewhat similar to that described as yellowing or firing, the authors have studied the disease, isolating a fungus which is claimed to be the cause of the trouble, and which is technically described as a new species under the name Colletotrichum linicolum. A detailed account of the symptoms emphasizes the development of spots on the leaves and lesions on the stems, often causing a sort of damping off. The disease somewhat resembles flax canker in the United States attributed to C. lini, but more closely the disease of flax ascribed to a Colletotrichum of undetermined species in Holland.

The mycelium hibernates within the epidermal cells of the seed coat, from this source infecting the seedlings during or after germination. Deep planting reduced the infection somewhat. Disinfection with formalin and with hydrogen peroxid was not completely effective. Treating slightly moistened infected seed with a mixture of finely powdered copper sulphate crystals and dry sodium carbonate suppressed the disease entirely.

Curtailing potato diseases, W. A. ORTON (*Potato Mag., 1 (1918*), *No. 2, p. 12*).—This paper contains a brief account, with discussion, of mosaic and other diseases of potato in the Northern States as related to crop failures in other sections obtaining seed potatoes from such localities, the system of seed certification now in course of development in Northern States, the production of disease-free seed potatoes, and the control of potato diseases by spraying.

Cooperative spraying [of potatoes for late blight] in Vermont, B. F. LUT-MAN (*Potato Mag.*, 1 (1918), No. 2, pp. 10, 26).—This is an account of the organization and operation of an arrangement for community spraying of potatoes, primarily for late blight, in parts of Vermont. A 50-acre unit was employed, and Bordeaux mixture (early at 3:3:50 and later at 4:4:50) was used, from one to four applications being made. A 50 per cent gain in productiveness is claimed. The claim is made also that potato rot was decreased by spraying.

Is crown gall injurious to apple nursery stock? S. B. FRACKER (*Jour. Econ. Ent.*, 11 (1918), No. 1, pp. 133–135).—The author reports the results of observations by himself regarding the effects of crown gall on apple trees in Wisconsin as related to the size of nursery stock and to fruit production.

In three out of four nurseries discussed, it was found that without respect to variety, the infected trees, if their sale were permitted, would yield (on account of their indicated classification) 17 or 18 per cent less gross returns than would a similar number of noninfected trees, since the infected nurseries show a much larger number of seconds. Although in many cases there seems to be a tendency for the infection to decrease the vigor of the plant without forcing its size below the commercial value, there is a great diminution in the number of first-grade trees when infected and an increased number of seconds, not a single nursery or variety showing as great a proportion of trees of salable size among those having crown gall as in those free from that disease. This reduction in size of apple trees in Wisconsin nurseries is thought to be the direct result of crown gall infection.

Avocado scab, H. E. STEVENS (Florida Sta. Press Bul. 289 (1918), pp. 2).— An account is given of a new and apparently undescribed disease which has come to the author's attention within the last two years. The disease is characterized by the formation of definite spots or blemishes on young leaves and tender shoots, severe attacks causing the leaves to curl or become distorted. The more mature leaves do not seem to be affected. The fungus, *Cladosporium eitri*, is thought to be a strain of the same that causes citrus scab. Spraying with Bordeaux mixture and avoidance of shade and crowded condition of the trees are suggested as means of control.

Report of plant pathologist, H. E. STEVENS (*Florida Sta. Rpt. 1918, pp. 62–67, figs. 4*).—The principal disease reported is that of the avocado scab noted above, which received additional investigation. It has been found that strains of the fungus isolated from avocado and from citrus seem to be identical so far as habits of growth and cultural characters are concerned.

A description is also given of a second disease, avocado fruit spotting, which seems to be of fungus origin, although this has not been definitely determined. In some few cases the disease has been observed on the variety Trapp, though the spotting seems to be confined mainly to seedling fruits. About the time the fruit is approaching maturity the disease makes its appearance, the spots being quite evident on the ripened fruit. Spotting in matured fruits often results in rapid decay. A spotting very similar to that on the fruit has been observed in the green bark of twigs, and a typical leaf spot is frequently associated with the disease.

A bacterial disease of citrus (*Cal. Citrogr.*, 3 (1918), *No.* 11, p. 273).—A brief notice of accounts given under the same title by Doidge (E. S. R., 38, pp. 552, 553), also a brief discussion of the cause of the disease (*Bacillus citrimaculans*), its mode of attack, the injury done, and control measures.

Ustulina zonata on Hevea brasiliensis, A. SHARPLES (Ann. Appl. Biol., 4 (1918), No. 4, pp. 153-178, pls. 6, fig. 1).—The present contribution deals with dry collar rot of old rubber trees caused by U. zonata, as noted by various authors. A previous account (E. S. R., 37, p. 52), economic in its main bearings, is now followed by an outline of observations made since 1914.

The disease is found in old plantations throughout Malaya. Connection is thought to exist between *U. zonata* and attacks on *H. brasiliensis* by boring beetles on trees scorched by forest fires or injured during the process of thinning or during the removal of trees of other species. Apparently this fungus does not readily attack uninjured rubber trees.

Treatments recommended fall in three classes, plantations being divided in this connection into those having young trees not thinned out, those being thinned out but with trees not yet 10 years old, and those having trees over 10 years old. The measures recommended include sanitation, eradication of jungle roots, and removal of old trees.

Further study is regarded as necessary on the rôle played by latex in the metabolism of the tree, and on selection with a view to improving the latex and increasing resistance to attacks by *U. zonata*.

The European poplar canker in the vicinity of Philadelphia, Pa., J. K. PRIMM (Jour. Econ. Ent., 11 (1918), No. 1, pp. 129-133).—In the course of nursery inspection during the summer of 1917 the author found that within a radius of 35 miles of Philadelphia infection of poplars by Dothichiza populea had become well established. Trees of all ages were attacked, though the older trees were more often attacked and suffered more severely, owing possibly to pruning operations. Lombardy poplar (P. nigra italica) appeared to be more susceptible to this fungus than other species. Trees on private estates were attacked as well as young trees in nurseries. The only nursery that was entirely free from the canker was one that had been sprayed regularly every winter with lime-sulphur. It is thought that omission of the pruning formerly practiced, especially as regards the basal branches, when combined with good drainage will do much to decrease the injury to the poplar trees.

Daldinia vernicosa, a pyroxylophilous fungus, A. S. RHOADS (*Mycologia*, 10 (1918), No. 6, pp. 277-284, pl. 1, fig. 1).—A study of *D. vernicosa* on a selected area near State College, Pa., shows this fungus to prefer burnt wood as a substratum. It appears to be confined to dicotyledonous species, attacking saplings killed by fire (especially those of hickory) with great vigor. Morphologically distinct from this species is *D. concentrica*, said to be the only other species of Daldinia in the United States.

## ECONOMIC ZOOLOGY-ENTOMOLOGY.

**Tropical wild life in British Guiana**, W. BEEBE, G. I. HARTLEY, and P. G. Howes (*New York: N. Y. Zool. Soc., 1917, vol. 1, pp. 504, pls. 4, figs. 140*).— Much of this work relates to ornithological observations by W. Beebe and G. I. Hartley, while part 3 (pp. 371-450) deals with entomological investigations by **P. G.** Howes in which a number of insects of economic importance are included. Birds of field, forest, and park, A. F. GILMORE (Boston: The Page Co., 1919, pp. XII+318, pls. 40).—A popular account.

The birds of North and Middle America, R. RIDGWAY (U. S. Nat. Mus. Bul. 50, pt. 8 (1919), pp. XVI+852, pls. 34).—In continuation of the work previously noted (E. S. R., 35, p. 851), the present volume deals with the families Jacanidæ, Œdicnemidæ, Hæmatopodidæ, Arenariidæ, Aphrizidæ, Charadriidæ, Scolopacidæ, Phalaropodidæ, Recurvirostridæ, Rynchopidæ, Stewnidæ, Laridæ, Stercorariidæ, and Alcidæ of the Charadriiformes.

Notes on North American birds, VIII, H. C. OBERHOLSER (Auk, 36 (1919), No. 3, pp. 406-408).—This is a continuation of the paper previously noted (E. S. R., 40, p. 351).

The migration of North American birds, VIII, IX, H. C. OBERHOLSER (Bird Lore, 21 (1919), Nos. 1, pp. 23, 24; 2, pp. 100-102).

Birds of a Washington city dooryard, H. C. OBERHOLSEE (Amer. Midland Nat., 6 (1919), No. 1, pp. 1-13).

Another purple martin roost in the City of Washington, H. C. OBERHOLSER (Bird Lore, 21 (1919), No. 2, pp. 96-99).

Observations on the shifting range, migration, and economic value of the bobolink, W. L. McATEE (Auk, 36 (1919), No. 3, pp. 430, 431).—This is a brief account based upon investigations of the present economic status of the bobolink carried on from New Jersey south to Florida, inclusive, from August to October, 1918. The inclusion of this bird among those protected by the recently consummated treaty with Canada for the protection of migratory birds led to a demand for this information. Attention is first called to the fact that the trend of the bobolink's breeding range is to the northwest, British Columbia now being the western limit. The main fall migration route seems to converge into a funnel not far south of the breeding range, through which the birds pour in a narrow stream along the coast of southern North Carolina, South Carolina, and Georgia, expanding again so as to cover the whole breadth of peninsular Florida.

The once decadent rice industry of the South Atlantic States stimulated by war prices resulted in an acreage in 1919 probably in excess of 6,000. The destruction of this by the bobolink or ricebird averages about 25 per cent, a money loss for the rice alone probably in the neighborhood of \$150,000. As a result of the investigation, an order has been issued by the U. S. Department of Agriculture permitting the killing of the bobolink in Pennsylvania, New Jersey, Delaware, Maryland, and the District of Columbia from September 1 to October 30, inclusive, and in the States from Virginia to Florida from August 16 to November 15.

Eumyias v. Stoporala, H. C. OBERHOLSER (Proc. Biol. Soc. Wash., 32 (1919), p. 47).

The status of the subfamily name Fuligulinæ, H. C. OBERHOLSER (Proc. Biol. Soc. Wash., 32 (1919), p. 48).

The geographic races of Hedymeles melanocephalus, H. C. OBERHOLSER (Auk, 36 (1919), No. 3, pp. 408-416).

A revision of the subspecies of Passerculus rostratus, H. C. OBERHOLSER (Ohio Jour. Sci., 19 (1919), No. 6, pp. 344-354).

Passerherbulus leconteii (Audubon) becomes Passerherbulus caudacutus (Latham), H. C. OBERHOLSER (*Proc. Biol. Soc. Wash.*, 32 (1919), p. 47).

The proper orthography of the generic name Phoethornis Swainson, H. C. OBERHOLSER (*Proc. Biol. Soc. Wash., 32 (1919), p. 48*).

Descriptions of nine North American pikas, A. H. Howell (Proc. Biol. Soc. Wash., 32 (1919), pp. 105-110).

The family name of the American wood warblers, H. C. OBERHOLSER (Proc. Biol. Soc. Wash., 32 (1919), p. 46).

A dangerous snail introduced in California, G. R. GORTON (Mo. Bul. Cal. Com. Hort., 8 (1919), No. 1, pp. 7–10, figs. 5).—The author records the occurrence of Helix pisana at La Jolla in San Diego County, where it is confined almost entirely to a small canyon extending upward from the ocean about three city blocks in length, and to some level ground contiguous thereto. Because of its known destructiveness in the Mediterranean region, where it attacks both field and orchard crops, especially the buds and blossoms of citrus fruits, foliage of olives, loguats, etc., attempts are being made to eradicate it.

In an appended note H. S. Smith calls attention to a report by De Stefani<sup>1</sup> on the status of the pest in Sicily.

**Report of entomologist**, J. R. WATSON (*Florida Sta. Rpt. 1918*, *pp. 56–61*).— In control work with cyanamid for root-knot nematodes, in continuation of the work previously noted (E. S. R., 39, p. 461), very serious burning resulted, not only to the first crop of celery set out one month after application but to another set out three months after treatment at Sanford and Bradentown. The only explanation of the diversity of results obtained in the two years is that there was a difference in the cyanamid used. Thus it appears that a ton per acre is too heavy a dose to be always safe. No such results were noted in the plats at the station farm even when the material was applied at the rate of 3 tons per acre.

In the experimental work during the year sodium cyanid was used at the rate of 100 to 800 lbs. per acre, followed at once by the application of ammonium sulphate in solution, using 150 per cent of the weight of the sodium cyanid. The results are said to parallel quite closely those obtained with cyanamid and the cost to be considerably greater than that of the latter. "Even 800 lbs. per acre did not entirely exterminate the nematodes, but did reduce their numbers to such an extent that they did not again reach destructive abundance for nearly a year. On the plats receiving 300 lbs. or less per acre there was no noticeable decrease in the number of nematodes."

In experiments with summer fallow for nematode control the results were about equal to those obtained by the use of 600 lbs. of cyanid or a ton of cyanamid per acre.

It was found that the hibernation of *Nezara viridula* is incomplete. Many individuals, however, truly hibernate while others remain all winter on green plants, usually actively feeding although they are quiescent during the coldest weather.

The importation of Delphastus catalinx from California was continued during the year, and in at least three groves the beetles maintained themselves throughout the winter and increased at a satisfactory rate.

Other insects of the year mentioned are a plant bug (Adelphocoris rapidus), which attacked cotton squares; the sweet-potato caterpillar (Prodenia sp.); the woolly white fly (Aleurothrixus howardii), reported for the first time from St. Lucie County; the broad-nosed weevil (Epicærus formidulosus), received from Jensen; a slug (Vaginulus floridensis), which was a source of considerable damage to tomatoes at Dania; the big yellow plant bug Corecoris confluentus, which severely injured tomatoes at Bokelia; the Colorado potato beetle received from Panama City, which is the first report from the Gulf coast of Florida though recorded from many of the northern tier of counties; the bollworm, which mined in the buds of geraniums at Vero; a tree hopper (Platycorus 4-vittata), which infested oaks, especially live and water oaks, and was

<sup>1</sup>*Helix pisana* and the Damage Which It is Capable of Doing to Agriculture (Palermo, Sicily, 1913).

548

more common than usual; and the papaw snout beetle (*Derolomus basalis*), which injured cotton squares, causing them to drop.

Unusual nursery insects, H. B. WEISS (N. J. Dept. Agr. Circ. 24 (1918), pp. 13, figs. 6).—Brief accounts are given of the minor insect pests met with in New Jersey nurseries. These include the Iris-leaf miner (Agromyza laterella), which has damaged Japanese Iris in several New Jersey nurseries; the sinuate pear-tree borer, a large and serious infestation of which was discovered in 1918 in a nursery in the central portion of the State; the white poplar leaf hopper (Idiocerus cognatus), first observed at Irvington in the summer of 1917, and since found at several other places in the State, usually on white poplar nursery stock; a European poplar leaf miner (Zeugophora scutellaris), which feeds on the foliage of poplar (Populus deltoides); the lunate onion fly (Eumerus strigatus), which was taken at Rutherford, South Orange, Riverton, and several other places in 1918, these being the first definite records of its occurrence in New Jersey; and the sumac psyllid (Calophya nigripennis), which, while not seriously injurious, often attracts attention in nurseries by reason of its abundance on Rhus cognalinum (E. S. R., 40, p. 754).

Insects of the season (Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 44 (1918), pp. 15–18).—This is a brief report of the occurrence of and work with the more important insects of the year.

**Report of the entomologist**, D. T. FULLAWAY ([*Bien.*] *Rpt. Bd. Comrs. Agr.* and Forestry, Hawaii, 1917-18, pp. 54-60).—This report relates to the propagation and distribution of beneficial insects, etc., for the biennial period ended December 31, 1918.

Insect and arachnid pests of 1917, R. S. MACDOUGALL (*Trans. Highland and* Agr. Soc. Scot., 5. ser., 30 (1918), pp. 56-96, figs. 20).—A discussion of the occurrence of and control measures for some of the more important insect and arachnid pests of the year.

Division of entomology, annual report, 1916–17, C. P. LOUNSBURY (Union So. Africa Dept. Agr. Rpt. 1916–17, pp. 93–105).—This reports on the inspection, regulatory, and investigational work conducted during the year ended March 31, 1917.

Economic entomology, H. H. TRYON (Ann. Rpt. Dept. Agr. and Stock [Queensland], 1917-18, pp. 40-44).—A discussion of the occurrence of and work with the more important insects of the year.

Common insects and diseases of the apple, W. W. CHASE (Ga. Bd. Ent. Bul. 54 (1919), pp. 52, pls. 13, fig. 1).—This replaces Bulletin 38 previously noted (E. S. R., 29, p. 353).

The more important insect enemies of the rose mallow in New Jersey, H. B. WEISS (N. J. Dept. Agr. Circ. 25 (1919), pp. 9, pls. 4).—Substantially noted from another source (E. S. R., 40, p. 754).

Insect pests of stored grains and mill products, F. H. LATHROP (Oreg. Agr. Col., Ext. Bul. 228 (1919), pp. 4, figs. 5).—A brief popular account.

Insecticides and fungicides, F. T. SHUTT (*Canada Expt. Farms Rpt. 1918*, *p. 24*).—This brief account relates to the composition of calcium arsenate and calcium arsenite.

Reliable brands of calcium arsenate in the dry powder form contains arsenic equivalent to approximately 40 per cent arsenic oxid, less than 1 per cent of which is soluble in water. One brand analyzed, however, contained 32.75 per cent arsenic oxid. The arsenical content of the paste forms is about half that of the dry powder. Several brands of calcium arsenite showed an arsenious oxid content varying from 14 to 24 per cent. In order that there be no risk of injuring the foliage, it is advised that both the arsenate and arsenite be used in Bordeaux mixture, lime-sulphur solution, or with an excess of lime in the spray.

The adulteration of insect powder with powdered daisy flowers (Chrsyanthemum leucanthemum), R. C. ROARK and G. L. KEENAN (U. S. Dept. Agr. Bul. 795 (1919), pp. 12, pls. 2, fig. 1).—The authors' studies are reported under the headings of adulteration of insect powder and uses, insecticidal action, chemistry, and morphology of the ox-eye or field daisy (C. leucanthemum).

It was found that while there are certain differences in the chemical composition of *C. cinerariæfolium* and *C. leucanthemum* a chemical analysis is insufficient to show adulteration of insect powder with daisy flowers. Adulteration of insect powder with powdered daisy flowers can be definitely determined by microscopic examination, the powdered daisy flowers being distinguished by (a) the irregular dark-red fragments of the achene, and (b) the palisadelike cells comprising the costal tissue of the achene.

A list of 40 references to the literature cited is appended.

Fumigation with liquid hydrocyanic acid, H. J. QUAYLE (California Sta. Bul. 308 (1919), pp. 393-407, figs. 4).—This is a summary of information on the present status of fumigation with liquid hydrocyanic acid, first used largely in experimental tests on citrus trees in California in 1916 and on an extensive commercial basis in 1917. In addition to the scale insects of citrus trees, more than 75,000 ladybird beetles have been used in comparative tests as an index of results. The results have given discriminating data concerning the diffusion of gas under the tent, showing that the place of greatest concentration is practically the reverse of that from the pot or portable generator.

"The greatest possible yield is 108 lbs. or 18.56 gal. of anhydrous liquid hydrocyanic acid from 200 lbs, of sodium cyanid (51 to 52 per cent cyanogen). The amount of liquid hydrocyanic acid (95 to 98 per cent) that has been recovered at the plant during the past year has been about 78 per cent of the total available. The amount of gas evolved by the pot or portable generator is estimated at 90 per cent of the total available gas. During the past year 75 per cent of the gas from a given amount of cyanid in the liquid form was made to cover the same ground as 90 per cent from the same amount by the ordinary methods of generation. Thus, while there has been a discrepancy of 10 or 15 per cent in the actual amount of gas used through the liquid method, the results in the field have not indicated any important difference on the scale insects. Our own tests, however, both in the field and laboratory, have indicated about such difference as would be expected. This apparent discrepancy between our own tests and commercial work in the field may be accounted for through the great variability in field work and by the difference. as has been determined, in the diffusion of the gas from the different methods.

"Field examinations are usually limited to an examination of the scales within 6 or 8 ft. of the ground. Our own tests have included the top of the tree as well. From these tests, when the results at the center and the bottom only were considered, there was practically no difference between the liquid and the pot, which harmonizes with the results in the field. When the results at the center and top only were considered, the pot method was more efficient than the liquid method. When the results in all parts of the tree are considered, it is necessary to use about 20 cc. of liquid hydrocyanic acid (96 or 98 per cent) to equal 1 oz. of sodium cyanid as given in the schedules of dosage now in practical use. Units representing 20 cc. may therefore be submitted for the ounces, and the atomizing machines should be graduated to deliver 20 cc. from each ounce called for in the schedules."

An account relating to this subject by Woglum has been previously noted (E. S. R., 41, p. 164).

Liquid hydrocyanic gas for fumigation (Cal. Cult., 53 (1919), No. 1, p. 3, fig. 1).—This brief account includes a dosage schedule table for citrus tree fumigation with liquid hydrocyanic acid 95 to 98 per cent pure, prepared by R. S. Woglum of the Bureau of Entomology of the U. S. Department of Agriculture.

The treatment of cloth to prevent mildew, A. W. MORRILL and W. W. YOTHERS (*Proc. Fla. State Hort. Soc., 31 (1918), pp. 81–85).*—This is a report of experiments in Florida conducted by the authors on mildew proofing canvas during the summer and fall of 1908.

Considering the cost and efficiency, the authors recommend the use of any of 3 of the 13 solutions tested, namely (1) sal soda 7.5 lbs., tartaric acid 15 oz., and zinc sulphate 7.5 lbs.; (2) copper sulphate 7.5 lbs. and sal soda 7.5 lbs.; and (3) copper sulphate 7.5 lbs., sal soda 7.5 lbs., and tartaric acid 15 oz., each being sufficient to make 300 gal.

The care of spraying machinery, W. W. Yothers (Proc. Fla. State Hort. Soc., 31 (1918), pp. 77-80).

Two new genera and thirteen new species of Australian Thysanoptera, J. D. Hood (*Proc. Biol. Soc. Wash., 32 (1919), pp. 75–92*).—The genera erected are Asemothrips and Teuchothrips.

Some plant bugs that infest citrus trees, W. W. FROGGATT (Agr. Gaz. N. S. Wales, 30 (1919), No. 5, pp. 325-330, figs. 2).—Notes are presented on the natural food plants and life histories of several of the plant bugs infesting citrus trees in Australia, including the green-spined orange bug (Biprorulus bibax), the painted Capparis bug (Stenozygum personatum), and the painted horehound bug (Agonoscelis rutila).

The genus Phatnoma, E. H. GIBSON (*Trans. Amer. Ent. Soc.*, 45 (1919), No. 2, pp. 181-185).—Seven species of this tingid genus, which is of little economic importance, are recognized, of which two are described as new.

The genera Corythaica Stål and Dolichocysta Champion (Tingidæ: Heteroptera), E. H. GIBSON (*Proc. Biol. Soc. Wash., 32 (1919), pp. 97-104*).

Notes on the North American species of Corizus, E. H. GIBSON (Canad. Ent., 51 (1919), No. 4, pp. 89-92).—This account includes a key for the identification of the species, of which 12 are recognized.

Cicadula sexnotata, a hemipteran injurious to wheat, oats, and barley in Sweden, T. ELLINGER (Vort. Landbrug, 37 (1918), No. 40, pp. 453, 454; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 9 (1918), No. 11, p. 1383).—This pest caused serious damage to wheat in the Province of Östergötland, and spread into southern Sweden as far as Scania during the summer of 1918.

Third contribution to the knowledge of Italian Coccidæ, G. LEONARDI (Bol. Lab. Zool. Gen. e Agr. R. Scuola Sup. Agr. Portici, 12 (1917), pp. 188-216, figs. 13).—This paper describes 25 species, of which 6 are new to science.

An interesting reaction to louse bites, W. MOORE (*Jour. Amer. Med. Assoc.*, 71 (1918), No. 18, pp. 1481, 1482).—In this contribution from the Minnesota Experiment Station the author presents evidence to show that the clothes louse (*Pediculus humanus [vestimenti]*), if present in large numbers, may produce an illness by a toxin introduced at the time of feeding. It is suggested that some of the symptoms of trench fever encountered in certain cases may not be due to the organism of trench fever but to certain toxins introduced by the lice.

Clinical studies on the effects of louse bites, Pediculus corporis, A. D. HIRSCHFELDER and W. MOORE (*Arch. Int. Med., 23 (1919), No. 4, pp. 419-430, figs. 4*).—In continuation of the investigations by Moore above noted, the authors record observations which indicate more strongly the presence of a

substance in the louse sufficiently toxic to give rise to a generalized skin eruption and mild fever. The details of four cases are reported.

The biology of Pediculus humanus, G. H. F. NUTTALL (*Parasitology*, 11 (1919), No. 2, pp. 201-220, pl. 1, fig. 1).—These notes, supplementing the monographic account previously noted (E. S. R., 38, p. 765), deal with color and light reactions; the influence on lice of temperature conditions in clothing and the absorption of radiant heat by cloth; the influence of black, white, and colored backgrounds and of colored screens upon pigmentation in lice, proving that pigmentation is not hereditarily transmitted; and the relative proportions of the sexes.

**Report on typhus conditions in native dwellings**, C. K. BRAIN (Union So. Africa, Dept. Agr. Local Ser. 57 (1919), pp. 20, pls. 4).—This is a report of an investigation conducted in the native territories and eastern Cape Province, where the fever now recognized as typhus has existed for at least 30 years and where, between the early part of 1916 and October, 1917, a widespread epidemic occurred. The investigations have led to the conclusion that the disease is identical with European typhus and that the chief means of transmission is the body louse.

Notes on the tussock moth (Hemerocampa vetusta gulosa) in British Columbia, W. B. ANDERSON (Agr. Gaz. Canada, 6 (1919), No. 2, p. 139).—The author records the devastation of a grove of young Douglas fir (Pseudotsuga mucronata) at Hedley in the Similkameen Valley, B. C., by H. vetusta gulosa.

The European corn borer, J. S. HOUSER (Mo. Bul. Ohio Sta., 4 (1919), No. 6, pp. 185–190, figs. 8).—A brief summarized account, in which attention is called to the importance of the pest.

The history of the codling moth in British Columbia, R. C. TREHERNE (Agr. Gaz. Canada, 6 (1919), No. 1, pp. 19–24, fig. 1).—This discussion includes an account of investigations conducted by the Dominion entomologist during 1916, 1917, and 1918.

Some characteristic differences in the pink bollworm and Pyroderces simplex, R. AVERNA-SACCÁ (Bol. Agr. [Sao Paulo], 19. ser., No. 8-12 (1918), pp. 656-665, figs. 4).—The differentiation of these species is discussed.

Physiological and parasitological studies of economic Lepidoptera, C. GAUTIER (Compt. Rend. Soc. Biol. [Paris], 81 (1918), No. 22, pp. 1152–1155).— In this article, which is in continuation of previous studies (E. S. R., 40, p. 263), the author deals with the oviposition of Apanteles glomeratus, which is parasitic on Pieris brassicæ, the eggs normally being deposited in the small caterpillar.

Coccobacilli parasites of the caterpillar of Pieris brassicæ, A. PAILLOT (Compt. Rend. Acad. Sci. [Paris], 168 (1919), No. 9, pp. 476-478).—The author has found five species of coccobacilli to infect P. brassicæ caterpillars, four of which occur in the Lyonnais region and one at Sellières in Jura. The characteristics of these species, namely, Bacillus pieris fluorescens, B. pieris liquefaciens, B. pieris nonliquefaciens a, B. pieris nonliquefaciens  $\beta$ , and B. pieris agilis, are described.

The Argentine fruit fly (Anastrepha fraterculus), P. CARIDE MASSINI and J. BRÉTHES (An. Soc. Rural Argentina, 52 (1918), No. 5, pp. 273-276, fig. 1).— A brief account of this fruit fly, a more detailed account of which by Rust has been noted (E. S. R., 40, p. 756).

A contribution to the study of the black fig fly (Lonchæa aristella) and its parasites in the Sorrento peninsula of Italy, L. SAVASTANO (Ann. R. Staz. Sper. Agrum. e Frutticol. Acireale, 4 (1916), pp. 113-146, pls. 2; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 9 (1918), No. 6, p. 773).— A report of the author's studies of this pest, which is the source of much damage in Italy.

The maize leaf miner (Phytomyza sp.), C. H. KNOWLES (*Fiji Dept. Agr. Pamphlet 27 (1917), pp. 2; abs. in Rev. Appl. Ent., Ser. A*, 6 (1918), No. 11, p. 475).—It is reported that under certain conditions this leaf miner is capable of affecting corn plants to such an extent as to prevent a crop being raised.

The eggs of this miner are laid in the upper surface of the corn leaf, generally near the tip and in the young leaves, each egg being deposited singly in a small hole that is first made in the leaf. "The larvæ upon hatching burrow into and consume the green cellular matter of the leaf, keeping just under the upper epidermis, which dies and shows a white streak indicating the tracks of the larvæ. The mines generally run toward the tip of the leaf. When mature, the larvæ eat through the thin upper epidermis and escape for pupation."

Lonchæa aristella, a dipteran injurious to the flowers and fruit of the caprifig and the fig, F. SILVESTRI (Bol. Lab. Zool. Gen. e Agr. R. Scuola Sup. Agr. Portici, 12 (1917), pp. 123–146, figs. 19; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 9 (1918), No. 6, pp. 773, 774).—This account relates to a lonchæid, which is the source of much injury to figs in the Sorrento Peninsula, especially in Vico Equense, Italy.

The susceptibility of anophelines to malarial infections in Netherlands India, N. H. SWELLENGREBEL, W. SCHÜFFNER, and J. M. H. SWELLENGREBEL DE GRAAF (Meded. Burgerl. Geneesk. Dienst Nederland. Indië, No. 3 (1919), pp. 1–64, pls. 3; abs. in Jour. Amer. Med. Assoc., 72 (1919), No. 23, p. 1712).—A report of investigations by the authors of the mosquito hosts of malaria in the Netherlands Indies, in which it is pointed out that the experimental index of infectability is very high in Myzomyia ludlowi, which is a true house mosquito.

"Contrary to other observers one can not but consider *M. ludlowi* to be a potent carrier... In the districts where the researches were undertaken and during the periods of observation it was the most important transmitter of all anophelines examined."

The cost of malaria.—A study of economic loss sustained by the Anderson-Cottonwood Irrigation District, Shasta County, Cal., H. F. GRAY (Jour. Amer. Med. Assoc., 72 (1919), No. 21, pp. 1533–1535).—The author presents data on the economic loss caused by malaria in this irrigation district in 1918, where Anopheles maculatus and probably A. punctipennis are present. Estimates are given on the loss occasioned and the cost of control measures.

Mosquito control about cantonments and shipyards, J. A. LE PRINCE (*Pub. Health Rpts.* [U. S.], 34 (1919), No. 12, pp. 547-553).— A brief statement of the work accomplished.

The mosquito problem in Britain, A. C. PARSONS and G. R. BROOK (*Jour. Roy. Army Med. Corps, 32 (1919), No. 1, pp. 1–23).*—A discussion of the problem, with suggestions for a winter campaign against the important mosquitoes and notes on insecticides.

A few general directions with regard to destroying mosquitoes, particularly the yellow fever mosquito, W. C. GORGAS (*Washington: War Dept.* [U. S.], Med. Dept., 1918, pp. 14).—The author calls attention briefly to the leading points in our present knowledge of this subject.

Fishes in relation to mosquito control in ponds, S. F. HILDEBRAND (*Pub. Health Rpts.* [U. S.], 34 (1919), No. 21, pp. 1113-1128, pls. 6, figs. 3).—This is a report of investigations of the value of the top minnow (*Gambusia affinis*) in antimalarial work.

144402°------5

"G. affinis is especially suitable for antimosquito work because (a) it seeks its food at the surface, (b) it is very prolific, (c) it gives birth to welldeveloped young, therefore requiring no special environment for depositing and hatching the eggs, (d) it lives and thrives under a large variety of conditions and frequents areas especially suitable for the support of mosquito larvæ, [and] (e) it usually lives and multiplies in ponds stocked with predacious fishes, providing it has very shallow water for refuge."

The comparative effectiveness of certain culicifuges under laboratory conditions, A. BACOT and G. TALBOT (*Parasitology*, 11 (1919), No. 2, pp. 221-236, fig. 1).—A detailed report of investigations of the comparative efficiency of culicifuges conducted for the British War Office.

"For the purpose of testing culicifuges, numbers of *Stegomyia fasciata* (the yellow fever mosquito) bred in incubators were placed in cages kept in the laboratory. The efficiency of the preparations was tested by coating the forearm with a definite quantity of one or other of them and exposing in a cage, each test being controlled by inserting after a short interval the other and untreated arm in the same cage, the number of bites being compared in each case. By this procedure it was hoped to obtain a measure of the relative protection which the culicifuges might be expected to afford when used under practical conditions against Anopheles mosquitoes.

"In the first series of trials, conducted within 15 minutes of application, 8 preparations out of a total of 22 tested gave satisfactory results. Their active ingredients were (1) oil of cassia and camphor, (2a) oil of cassia and peppermint, (5) oil of eucalyptus and citronella with phenol, (9a) crude naphthalin (coke oven) and camphor, (10) crude 'Parasitox,' (15a) light wood oil, (21) oil of turpentine, (22a) 'Lawson's Anti-mosquito Compound.' These preparations were then tested to ascertain for what period their protection could be depended upon. Preliminary trials indicated that this period was not likely to extend for more than two hours between treatment of the arm and exposure in the cage. None of the preparations gave complete protection in this series of trials."

The tobacco flea-beetle, Z. P. METCALF and G. W. UNDERHILL (North Carolina Sta. Bul. 239 (1919), pp. 47, figs. 34).—A detailed report of studies of the biology and control of the tobacco flea-beetle (*Epitrix parvula*), the most important insect enemy of tobacco occurring in North Carolina.

The adult is the source of most of the injury to tobacco, this injury being characterized by small, round, or irregular feeding punctures scattered over the leaf surface or by a more or less complete skeletonization of the leaf. It was found that a beetle consumes an average of 10.3 times its own weight per day.

The species, which apparently occur in the United States wherever tobacco is grown, is rather widely distributed in the tropical and temperate regions of the world. It feeds by preference on any and all of the members of the Solanaceæ. The adults, in which stage the winter is passed, emerge early in the spring and the damage which they cause to tobacco beds is usually very extensive. The eggs are laid from April to September, on or very near the surface of the ground immediately under the host plant at an average rate of 2.21 per day for a period of, assumed as, at least 90 days. They hatch in from 6 to 8 days in midsummer. In a study of the larvæ in the field they were found to feed upon the roots of the plants of the solanaceous family, none ever being found feeding upon the leaves. In special cases it was found that they not only feed upon but often tunnel the stalks of tobacco and ground cherry plants for a distance of several inches. In the field they were normally found only in the ground within a radius of 10 or 12 in. of the plants, feeding on the fine rootlets. The exact length of the larval stage from hatching to pupation has not yet been determined, although every method that could be devised was tried out. However, larvæ were kept under laboratory conditions for 12 days and reached an average length of 4 mm, but all died before pupating, while larvæ of the same average size collected in the field and placed in breeding cages pupated in from 4 to 5 days, making a total of from 14 to 16 days, which figures are approximately the same as those obtained by Chittenden in 1899. The transformation to pupa takes place in a simple, crude pupal cell about 0.5 to 1 in. deep in the soil, the first pupa having been found in the field on July 16 and the last on October 3. The average length of the pupal stage was found to be 4.46 days.

In dealing with control measures, special emphasis is laid upon three methods of attack: (1) The control of the insect on the plant in the bed, (2) the control of the insect at transplanting time, and (3) the destruction of the suckers after the crop is harvested. But little emphasis is placed upon the spraying of the plants in the field, since this method will not be necessary if the other methods are followed. The plant beds should be provided with a good board frame and a tight beetle-proof cover of the best canvas or cheesecloth. It is recommended that the plant beds be sprayed with arsenate of lead (paste) at the rate of 1 lb. to 10 gal. of water, or with arsenate of lead (powdered) or arsenate of lime at the rate of 1 lb. to 20 gal. of water, or the plants be dusted with powdered arsenate of lead or arsenate of lime mixed with fine sifted wood ashes at the rate of 1 lb. of the poison to 4 lbs. of the ashes. At transplanting time the plants should be dipped in a solution of arsenate of lead, prepared by mixing arsenate of lead (1 lb. paste or 0.5 lb. powder) in 5 gal. of water.

An account of this pest by Morgan has previously been noted (E. S. R., 23, p. 465).

Controlling asparagus beetles, T. L. GUYTON (Mo. Bul. Ohio Sta., 4 (1919), No. 6, pp. 197-199, figs. 2).—A brief popular account.

The passion vine longicorn beetle (Monohammus fistulator), C. FRENCH, JR. (Jour. Dept. Agr. Victoria, 17 (1919), No. 2, pp. 117–119, figs. 4).—A brief account of this borer, which is fairly common in many parts of Victoria, based upon a paper by Froggatt previously noted (E. S. R., 40, p. 654).

Notes on the life history and early stages of Brachys ovatus and B. ærosus, H. B. WEISS and A. S. NICOLAY (*Canad. Ent.*, 51 (1919), No. 4, pp. 86-88, pls. 2).—The authors record observations of the biology of two species of buprestids, the larvæ of which are leaf miners, particularly in oak.

The native lime tree borer (Citriphaga mixta), W. W. FROGGATT (Agr. Gaz. N. S. Wales, 30 (1919), No. 4, pp. 261-267, figs. 4).—This is an account of a borer which badly damages the wild lime tree (Atlantia glauca). It represents a new genus and species, which are described by A. M. Lea as Citriphaga mixta.

The wood borer and its control, A. H. COCKAYNE (Jour. Agr. (New Zeal.], 18 (1919), No. 4, pp. 198, 199, fig. 1).—A brief account of Anobium domesticum, which is the source of considerable destruction to various timbers in New Zealand, being extremely partial in its attack to the New Zealand white pine and kauri.

A contribution to the knowledge of Coeliodes ruber in Italy, F. SILVESTRI (Bol. Lab. Zool. Gen. e Agr. R. Scuola Sup. Agr. Portici, 12 (1917), pp. 155-174, figs. 14; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 9 (1918), No. 5, pp. 647, 648).—A great loss of hazelnuts at Vico di Palma Campania, Province of Caserta, in 1914, led to the investigations in the Nola and Avellino districts here reported. The most serious damage was caused to the petiole and the axis of the buds. An account is given of the morphology and biology of this weevil, which is only known to attack hazel trees.

Catalogue of species of Curculionidæ of the Cholina group, A. DA COSTA LIMA (Arch. Escola Sup. Agr. e Med. Vet. [Pinheiro, Rio de Janeiro], 1 (1917), No. 1, pp. 35-99).—The author recognizes 311 species and 34 genera.

**Report of the apiarist**, F. W. L. SLADEN (*Canada Expt. Farms Rpt. 1918, pp. 41-43*).—This report includes a summary of the average production of apiaries at 16 of the experimental farms since 1913. The average weight of honey production per colony, spring count, varied from 21.8 lbs. at Sidney, B. C., to 106.7 lbs. at Ottawa, Ont., while the value of production per colony, honey and bees, after deducting winter loss varied from \$1.51 at Charlottetown, P. E. I., to \$18.31 at Lethbridge, Alta. Alsike and white clover were the principal sources of honey at all the farms except Lethbridge, where it came from alfalfa, which also gave much of the yield at Summerland, B. C.

The general conclusion drawn from the data obtained is that bees can be kept with profit in the regions served by all the experimental farms, but that eastern Canada offers better opportunities than western. Experiments have been started with fireweed (*Epilobium angustifolium*), which is said to be the most promising honey plant for commercial beekeeping at altitudes and latitudes higher than those at which clover gives best results. An attractive and inexpensive paper container for granulated honey has been devised at the Central Experimental Farm to meet the increased cost and scarcity of tin containers.

Trial of a system of keeping two queens in a hive, F. W. L. SLADEN (Agr. Gaz. Canada, 6 (1919), No. 2, pp. 134–136, figs. 3).—In an attempt to meet the great need for a sure method of preventing swarming without much labor, the author devised a system which has been tried on a small scale during 1918, in which two queens are kept in one hive during 11 months of the year. The trial has shown the system to be workable, and preparations have been made for a more extensive test in 1919.

"Two young queens separated by a double wire-cloth screen were wintered in one hive in the cellar in 1917–18. During the honey flow from dandelion, the bees and queen on one side of the screen were transferred to a separate hive; thus the desire to swarm at this time was not allowed to develop, and there was an uninterrupted and steadily increasing production of young bees from the two queens, with the result that two strong colonies were obtained in time for the opening of the honey flow from clover. The number of bees produced much [exceeded] the number that was obtained in hives that began the season with only one queen, [and] 480 lbs. of honey were produced by these bees.

"In order to prevent swarming during the clover honey flow and to again get two young queens in each hive (all the following stages were carried out in several colonies), the old queen was removed from the brood chamber at the commencement of this honey flow, and 8 days later all queen cells were destroyed except two, one on each side of the wire-cloth division then inserted. A special portico fixed in front of the hives separated the entrance of each half of the hive from that of the other by about 9 in., to prevent the queens that emerged from the cells from meeting after returning from their mating flights. No swarming took place."

How the female Blastophaga works, I. J. CONDIT (Fig and Olive Jour., 4 (1919), No. 1, pp. 9, 12, 13).—An account of observations of the female Blastophaga grossorum in California.

### FOODS-HUMAN NUTRITION.

A selective bibliography on dehydrated foods, E. D. GREENMAN (Spec. Libraries, 10 (1919), No. 4, pp. 108–118).—This is a bibliography of 370 references classified under the following headings: General; apparatus; fruits, including general, apples, apricots, prunes, pears, etc., bananas, figs, raisins, berries; vegetables; potatoes; milk; eggs; and meat.

An aerobic spore-forming bacillus in canned salmon, A. C. HUNTER and C. THOM (Jour. Indus. and Engin. Chem., 11 (1919), No. 7, pp. 655–657).—Bacteriological examination, at the Bureau of Chemistry, U. S. Department of Agriculture, of 530 cans of salmon representing 9 brands showed 237 unsterile cans, 224 of which were found to contain the same organism either in pure culture or in connection with other species. The organism, thought to be a member of the mesentericus group, was an obligate aerobic spore-former, gram positive, and motile. Its most characteristic feature was the production of a dark red ring about half an inch below the colony when grown on solid carbohydrate media. When sterile fish was present in the medium, the red color was often imparted to it and a marked softening of the fish took place.

Only 13 of the unsterile cans showed active spoilage, indicating that the bacteria in most cases were in a dormant state while in the can and would grow only when more favorable conditions were supplied. Several of the sterile cans showed spoilage, indicating that sterility is not to be confused with fitness for food.

The authors state in conclusion that "actual sterility is very properly the aim of the packer. The survival of viable organisms in the final product may occasionally be unavoidable, but calls for a careful survey of their source and significance with a view to their complete destruction."

The nutritive value and cost of some important vegetables, M. RUBNER (Berlin. Klin. Wchnschr., 53 (1916), No. 15, pp. 385–390).—A detailed study is reported of the nutritive value of the edible portion of several winter vegetables and fruits with relation to their cost. Analytical data are given on the composition of apples, rutabagas, beets, horse-radish, comfrey, turnips, red cabbage, carrots, savoy, Brussels sprouts, hazelnuts, kale, edible Boletus, and spinach.

Nutritive value of the carob bean, M. E. JAFFA and F. W. ALBRO (*California Sta. Bul. 309* (1919), pp. 441-450, figs. 2).—Analyses of carob bean (*Ceratonia siliqua*) pods and seeds are reported, and their nutritive value is discussed. The average of the analyses is summarized in the following table:

Product.	Water.	Protein.	Ether extract.	Sugars. Reduc- ing. Sucrose.		Nitrogen- free extract.	Crude fiber.	Ash.	
Pods and seeds Pods Seeds	Per ct. 13.28 11.50 11.74	$\begin{array}{c} Per \ ct. \\ 6.75 \\ 4.50 \\ 16.46 \end{array}$	Per ct. 2.17 2.37 2.50	Per ct. 11.08 11.24	Per ct. 19.44 23.17	Per ct. 39.80 36.30 58.61	Per ct. 9.29 8.78 7.50	Per ct. 2.57 2.72 3.18	

Composition of carob bean pods and seeds.

Because of the richness of the carob bean in sugar, the use as human food is suggested of those varieties which show a minimum of crude fiber. "Excellent use could be made of the powdered carob pod by those who need more roughage than that supplied by the ordinary diet."

[Vol. 41

It is also considered that larger use could be made of it as a feeding stuff. A 13-week trial by F. W. Woll at University Farm, Davis, is noted in which carob bean pods were compared with ground barley as supplements to ground milo maize (1:1) for skim milk calves. The calves relished the pods greatly, and 0.4 lb. practically offset 0.35 lb. ground barley.

**Pumpkin as flour substitute,** E. ALPERS (*Ztschr. Untersuch. Nahr. u. Genussmtl., 36 (1918), No. 11–12, pp. 281, 282).*—Satisfactory bread was made with the use of from 10 to 20 per cent of the thick pulp of cooked pumpkin in place of a corresponding amount of flour. The pumpkin gave a slight yellow color and characteristic flavor to the bread, but was thought to be superior to beets as a flour substitute.

Reports of storage holdings of certain food products during 1918, J. O. BELL (U. S. Dept. Agr. Bul. 792 (1919), pp. 80, figs. 40).—This is the third bulletin in the series previously noted (E. S. R., 41, p. 66). It reports data as to the storage holdings during 1918 of frozen and cured meats, lard, frozen fish, cured herring, and mild cured salmon.

Swiss food book (Schweizerisches Lebensmittelbuch. Bern: Schweiz. Ver. Analyt. Chem., 1917, 3. rev. ed., pp. XXVII+420).—This is the third revised edition, edited by the Swiss Society of Analytical Chemistry, of methods of investigation and standards of valuation of foods, household utensils, and commodities. Among the food products treated are milk and dairy products, edible fats and oils, meats, cereal products, eggs, honey, sugar and confectionery, fruit products, spices, nonalcoholic and alcoholic beverages, and vinegar.

Dependence of the protein requirement on the mineral metabolism, C. Röse and R. BERG (*München. Med. Wchnschr.*, 65 (1918), No. 37, pp. 1011-1016; abs. in Chem. Abs., 13 (1919), No. 11, p. 1222).—This is a discussion of the maintenance of neutrality in the body, based largely upon metabolism experiments.

The protein requirement was found to be at a minimum if the experimental ration contained a sufficient excess of bases during the fore-period and time of the experiment itself. Insufficient bases during the fore-period and a sufficient excess during the main period were found to increase the protein requirement during the latter period from 5 to 20 per cent, while a sufficient excess during the fore-period and deficiency during the main period increased the protein requirement from 10 to 50 per cent. An insufficient excess of bases during both periods increased the protein requirement from 50 to 300 per cent.

On a diet rich in acid-forming elements the energy utilization was found to be less, and consequently the energy requirement greater, than on a diet rich in base-forming elements. For this reason, it is considered necessary in the determination of the protein requirement to consider whether the ration is rich in acid-forming or in base-forming materials.

Accessory factors of growth and equilibrium: Vitamins; auximones, G. SCHAEFFER (Bul. Inst. Pasteur, 17 (1919), No. 1, pp. 1-21, figs. 6; 2, pp. 41-59, figs. 4).—This is a review and discussion of the literature on vitamins, symbiotes, and auximones. A bibliography of 44 titles covering the literature on the subject during 1917-18 is appended.

A lecture on the practical importance of vitamins, F. G. HOPKINS (Brit. Med. Jour., No. 3043 (1919), pp. 507-510).—A general discussion of the subject.

Vitamins and fungi, G. LINOSSIER (Compt. Rend. Soc. Biol. [Paris], 82 (1919), No. 11, pp. 381-384).—The author has found that Oidium lactis, although capable of developing on media exclusively composed of mineral sucstances and a simple carbohydrate-forming food such as alcohol, acetic acid, glycerin or glucose, is sensitive to the action of vitamins. This sensitiveness is

of fat-soluble A in the diet of the adult and the connection between the metabolism of fat-soluble A and the fat of the diet.

The need of the organism for vitamins is apparently proportional to the decrease in vitality, after a certain point the organism being incapable of developing in a medium containing no vitamins. In full activity, however, the organism seems to have the power of existing without vitamins or of synthesizing them.

The lipoids as indispensable constituents of food, W. STEPP (*Ztschr. Biol.*, 66 (1916), No. 9, pp. 365-386; abs. in Zentbl. Biochem. u. Biophys., 19 (1918), No. 14-15, p. 398).—The author's earlier experiments (E. S. R., 31, p. 861) have been repeated, using white mice again as the experimental animal and dog biscuit from which the lipoids had been extracted with alcohol and ether as the basal diet.

It was found that prepared dog biscuit alone, dog biscuit with lipoids, and dog biscuit with a vitamin preparation (orypan) were inadequate for nutrition, but that the combination of dog biscuit, pure lipoids, and vitamins produced satisfactory growth. In the opinion of the author this indicates the indispensability of lipoids for nutrition.

Researches on the fat-soluble accessory substance, I-II, J. C. DRUMMOND (Biochem. Jour., 13 (1919), No. 1, pp. 81-102).—Two papers are presented:

I. Observations upon its nature and properties (pp. 81-94).—The standardized method adopted by the author in testing substances for the presence of fat-soluble A is as follows: Young healthy rats selected from home bred stock and weighing about 50 gm, each are fed upon an artificial ration consisting of purified casein 20 parts, purified starch 50, salt mixture 5, yeast extract (source of water-soluble B) 5, butter fat (source of fat-soluble A) 15, and filtered orange juice (source of water-soluble C) 5 parts. The rats which give evidence of a normal power of growth are removed from the complete ration when they have attained an average body weight of 70 to 80 gm, and are given a similar dietary in which the butter fat has been replaced by an equivalent amount of hardened linseed oil which is known to be deficient in fat-soluble A. When it is definitely established that growth is inhibited by this deficiency of fat-soluble A, the linseed oil is wholly or partially replaced by the substance to be tested and the behavior of the animal closely watched for a period of from 4 to 6 weeks. Absence of fat-soluble A is indicated by failure to grow, followed by a decline in health accompanied by the characteristic eye condition.

The results obtained in a study of the properties of fat-soluble A according to the above method are summarized as follows:

Fat-soluble A, present in certain oils such as butter fat and whale oil, is readily destroyed by exposure for one hour to a temperature of 100° C., by exposure for a longer period of time to temperatures ranging from 50 to 100°, and by exposure for several weeks to a temperature of 37°. The destruction is apparently not a result of oxidation or hydrolysis.

Fat-soluble A is not extracted from oils by water or dilute acid, but is soluble in alcohol and may be removed in small quantity from oils by cold extraction with alcohol. Hydrolysis of oils in a nonaqueous medium at room temperature causes disappearance of fat-soluble A.

In regard to its composition, fat-soluble A has not been identified with any of the recognized components of fats such as glycerol, saturated or unsaturated fatty acids, cholesterol, lecithin, phosphatids, or lipochromes. No evidence has been obtained to suggest that it is not a single substance, but indications point to its being a labile substance of ill-defined constitution.

II. Observations on its rôle in nutrition and influence on fat metabolism (pp. 95–102).—The studies reported in this paper concern the indispensability

of fat-soluble A in the diet of the adult and the connection between the metabolism of fat-soluble A and the fat of the diet.

Feeding experiments conducted according to the method described above indicate that the adult animal organism requires a regular supply of fat-soluble A which is much smaller than the requirement of the young growing animal, but is an important factor in the maintenance of health. "It appears probable that the resistance to diseases of bacterial origin is seriously impaired by a failure of the animal to obtain a sufficient supply of the fat-soluble factor. There is therefore every reason that great care should be taken to insure that dietaries of adults contain an adequate supply of foodstuffs in which fat-soluble A is present."

The symptoms associated with a deficiency of fat-soluble A appear in comparable groups of rats after the same period of time whether the diet contains neutral fat or not. This, together with the fact that fatty acids are absorbed and synthesized into fats, and fats are absorbed in the absence of fat-soluble A, is thought to indicate, indirectly, that pure neutral fats may be dispensable components of the diet.

Note on the rôle of the antiscorbutic factor in nutrition, J. C. DRUMMOND (Biochem. Jour., 13 (1919), No. 1, pp. 77-80).—Feeding experiments with rats through two generations are reported, which confirm the conclusions reported by Harden and Zilva (E. S. R., 41, p. 171) that "the rat requires the antiscorbutic factor in order to achieve a normal development, and that although the requirements of this species are of a very much smaller order than those exhibited by man, the monkey, or the guinea pig, they are sufficiently well-marked to dispel any idea that there exists a fundamental difference in the nutritive requirements of the two types of animal.

"It may therefore be accepted as experimentally proven that the dietary requirements of the higher animals include in addition to a satisfactorily balanced ration of protein, fat, carbohydrate, and mineral salts, an adequate supply of three accessory food factors: Fat-soluble A, water-soluble B or antineuritic factor, and water-soluble C or antiscorbutic factor."

The antiscorbutic property of fruits.—I, An experimental study of dried orange juice, M. H. GIVENS and H. B. MCCLUGAGE (*Amer. Jour. Diseases Children*, 18 (1919), No. 1, pp. 30-41, figs. 4).—Dried orange juice was tested for antiscorbutic properties by means of feeding experiments with guinea pigs, the basal diet being that described in an earlier study (E. S. R., 40, p. 762). The orange juice was dried in two different ways as follows:

For one product, the juice was expressed from the oranges and strained through several layers of cheese cloth until a clear filtrate was obtained. This was concentrated to about two-thirds the original volume by heating in the drier at from 55 to 60° C., using 100 cc. portions in small shallow dishes. Soy bean flour, previously heated under 20 lbs. pressure for one-half hour, was then added in the proportion of 12 gm. to 100 cc. of the original juice and mixed thoroughly. The mixture was kept in the drier at from 55 to 60° until thoroughly dried, the whole process requiring about 50 hours.

For the other product, the juice was dehydrated by a commercial process employed for making milk powder. The juice was pressed from the oranges, strained, mixed with corn sirup, and dried by spraying into a chamber kept at from 75 to 80° C. In this process the juice was dried almost instantaneously.

The results obtained with these products as antiscorbutics indicate that experimental scurvy in the guinea pig can either be averted or cured by the use of a small amount of dried orange juice, the size of the dose depending upon the manner of drying the juice. With the second product, a dose equivalent to 3

cc. of fresh juice was sufficient, while with the first a dose equivalent to 6.25 cc. of fresh juice was inadequate as a preventive of scurvy. When the dose was doubled, however, the animals were cured and protected against a recurrence of the disease. Both products retained their antiscorbutic properties after three months' storage.

The conclusion is drawn that the most satisfactory process for drying orange juice is one in which the temperature of drying is not unduly high and the duration of drying is very short. The possibility is suggested of using dried orange juice as a convenient antiscorbutic for use in infant feeding, on polar expeditions, in the Navy, and in the Army.

The antiscorbutic properties of green malt, J. F. MCCLENDON and W. C. C. COLE (*Amer. Jour. Physiol.*, 49 (1919), No. 1, pp. 145, 146).—The authors state that by grinding green malt in a special mill, bringing the mash to  $70^{\circ}$  C. to partially destroy the oxidases, and evaporating the wort in vacuo to a sirup, a malt extract can be prepared which requires no sterilization or preservative and which retains its antiscorbutic properties. It is suggested that the use of malt extract prepared by this method might avoid the necessity of feeding orange juice to infants when oranges are difficult to obtain.

Studies of infant feeding.-XI, High protein feeding v. high calcium absorption as to the cause of the increase in body temperature of infants, A. W. BOSWORTH and H. I. BOWDITCH (Amer. Jour. Diseases Children, 16 (1918), No. 5, pp. 279-292. fig. 1).-The results of feeding experiments on healthy infants show, according to the data furnished by the authors, that the ingestion of large amounts of calcium as organic salts, if not accompanied by the ingestion of sufficient chlorin or phosphorus to permit the formation of soluble salts, will result in an accumulation of calcium in the tissues which is followed by a toxic condition and the elimination of calcium lactate in the urine. They believe that the toxic condition noticed by others when a high protein synthetic food was fed was probably the result of the high calcium content of the food, the protein being responsible only to the extent that it is the carrier of the calcium in the form of calcium caseinate. The authors are unprepared as yet to state whether this toxic condition is the result of the accumulated calcium itself or to a calcium salt, possibly calcium oxalate. The work of Binger<sup>1</sup> and the observations of Marriott and Howland<sup>2</sup> they believe furnish additional material relating to the same phenomenon.

Earlier work has been noted (E. S. R., 40, p. 661).

The effect of alkali and malt preparations on the retention of calcium in infancy, A. SATO (*Amer. Jour. Diseases Children, 16* (1918), No. 5, pp. 293– 298).—From the results of observations on a normal infant, the author believes that the addition of alkali to milk produces a distinctly unfavorable effect on the retention of calcium, but that the addition of malt extract without . alkali acts beneficially on the calcium storage. He believes that the favorable effect of the malt is not due to the alkali originally contained in it or added to it, since malt extract which contains a considerable amount of alkali has, according to his data, an unfavorable influence on the calcium storage.

Hospital diets and their relation to the treatment of certain diseases, E. G. McCullough (*Canad. Med. Assoc. Jour.*, 6 (1916), No. 5, pp. 385-405, pl. 1, figs. 2).—A discussion of the diet used at the Peter Brent Brigham Hospital, Boston, Mass., in the treatment of typhoid fever, nephritis, diabetes, and other ailments in which careful dietetic measures must be observed.

<sup>&</sup>lt;sup>1</sup> Jour. Pharmacol. and Expt. Ther., 10 (1917), No. 2, pp. 105-119. <sup>2</sup> Arch. Int. Med., 18 (1916), No. 5, p. 708-711.

The etiology of sprue, pellagra, and scurvy, L. NICHOLLS (*Jour. Trop. Med.* and Hyg. [London], 22 (1919), No. 3, pp. 21-24, figs. 2).—The author compares sprue, pellagra, and scurvy on the theory that the predisposing causes of all three diseases are dietary deficiency and pathogenic organisms. The latter is thought to be the predominant factor in sprue and the former in scurvy, while in pellagra both are thought to be fairly evenly balanced. A streptococcus is considered to be the infecting agent in sprue and very probably in scurvy, but the possibility is suggested of some other class of organism being the secondary factor in pellagra. The theories advanced are discussed in detail with several references to the literature.

The scurvy of guinea pigs, III.—The effect of age, heat, and reaction on antiscorbutic foods, A. F. HESS and L. J. UNGER (*Jour. Biol. Chem.*, 38 (1919), *No.* 2, pp. 293–303, pl. 1, figs. 8).—A preliminary report of this study has been previously noted from another source (E. S. R., 41, p. 266). In addition to the investigations reported in the earlier contribution, the factor of freshness and age of the vegetables was found to affect their antiscorbutic properties on dehydration. The author points out that this variable factor renders it very difficult to prepare a table of the comparative antiscorbutic value of various foods, and that when this is attempted all the vegetables should be uniform in their development and freshness. The importance for the dehydrating industry of using only fresh young vegetables is emphasized.

Remarks on the pathogenesis of deficiency diseases and on pellagra, P. RONDONI (*Brit. Med. Jour.*, No. 3044 (1919), pp. 542-544).—The author reports observations on "maidism," the pathological condition induced in guinea pigs by exclusive maize feeding, and compares his results and conclusions with those of McCarrison (E. S. R., 41, p. 264) on the changes in the organs of polyneuritic pigeons. The histological observations reported in the present paper are summarized as follows:

"The organs which are the most affected in guinea pigs fed on maize are the spleen, the thyroid, and the suprarenal glands. The spleen shows sclerotic lesions with increase of elastic and fibrous tissue and reduction of lymphocytes in the folliculi. The thyroid shows, in the first days of maize diet, hyperemia and often proliferation of alveolar epithelium, then hemorrhagic changes and later on sclerosis are prominent."

Certain resemblances are pointed out between the etiology and pathogenicity of maidism in guinea pigs and pellagra in man, but the author is of the opinion that maidism has certain features which differentiate it from pellagra as well as from simple starvation and scurvy.

**Dietetic helps in diabetes, R. R. DONK** (Jour. Amer. Med. Assoc., 73 (1919), No. 1, pp. 25–27, fig. 1).—Tables are given from which can be calculated the combinations of various foods necessary to make up any prescribed diet in the treatment of diabetes. These include values for the 5 per cent group of vegetables and the various increases (potato, bread, broth, fish, egg, fat, lean meat, etc.) calculated in protein, fat, carbohydrates, and calories.

Analysis of normal Filipino urine, I. CONCEPCION (*Philippine Jour. Sci.*, Sect. A, 13 (1918), No. 6, pp. 347-359).—An extensive investigation is reported of the constituents of Filipino urine. The subjects consisted of Bilibid prisoners, hospital servants, laboratory helpers, and medical students. All were allowed to choose their diet except the prisoners, who were on a special ration. The urine analyses were made on the 24-hour samples collected from 3 to 7 consecutive days. The analytical results are presented in tabular form by occupational groups, and a table is also given showing the average chemical compo1919]

sition of Filipino urine as compared with the known standards of Europeans, Americans, and Bengalis.

The composition of Filipino urine as averaged from over 200 specimens was as follows: Daily volume 935 cc., specific gravity 1.019, total nitrogen expressed as N<sub>2</sub> 7.01 gm., urea 9.59, urea nitrogen 4.48, ammonia 0.641, ammonia nitrogen 0.534, creatinin 1.478, creatinin nitrogen 0.549, uric acid 0.376, uric acid nitrogen 0.125, undetermined nitrogen 1.271, total sulphur oxidized expressed as SO<sub>3</sub> 1.475, inorganic sulphates 1.169, ethereal sulphates 0.306, total phosphates as  $P_2O_5$  1.285, and total chlorids as NaCl 5.86 gm.

Certain points of interest are brought out by a comparison of these figures with other standards. The total quantity of urine excreted is lower than the averages found for Europeans and Americans, which is explained by the high humidity and temperature of the Philippine atmosphere. The total nitrogen represents a daily metabolism of 43.81 gm. of protein, which is only 37 per cent of Voit's standard. The figures for urea and urea nitrogen are very low. The urea nitrogen is only 63.86 per cent of the total nitrogen excreted in the urine, a result in agreement with Folin's conclusion (E. S. R., 17, p. 167) that on a reduced protein diet the proportion of urea nitrogen falls to about 60 per cent of the total nitrogen. The creatinin output, which was within the limits of the average excretion in temperate climates, is also in accord with the statement of Folin that the quantity of creatinin excreted on a low protein diet is practically the same as on a high protein diet, and of other observers that there is no evidence of a greater creatinin output in the Tropics. The low ratio of total oxidized sulphur to ethereal sulphates is explained by the vegetable character of the diet.

Metabolism and cooling power, L. HILL and D. HARGOOD-ASH (*Jour. Physiol.*, 52 (1919), No. 6, pp. LXIX-LXXI).—Essentially noted from another source (E. S. R., 41, p. 365).

Energy exchange in man, A. KROGH (*Jour. Physiol.*, 52 (1919), No. 6, p. LXXIV).—The respiratory quotient was determined by the use of a Jaquet chamber and a new gas analysis apparatus accurate both for O<sub>2</sub> and CO<sub>2</sub> to about 0.001 per cent.

The amount of technical work performed varied for the different subjects between 0.7 and 1.1 calories per minute. The metabolic energy, exclusive of resting metabolism, corresponding to 1 calorie of technical work, varied with the subjects between 5.3 and 4.2 calories and corresponding to efficiencies of between 19 and 24 per cent. A distinct influence of training upon the efficiency was observed, in one case the metabolism per calorie decreasing during 25 days from 4.6 to 4.3 calories.

The metabolism per calorie of technical work was found to be a straight line function of the respiratory quotient and distinctly higher for fat than for carbohydrate. When fat was utilized for muscular work a loss of energy took place, amounting to from 8 to 12 per cent of the fat catabolized. It is thought that this can be explained on the hypothesis that carbohydrates can be utilized more or less directly by the muscles, while fat must first be converted to some substance allied to carbohydrates. Most of the subjects found that it was easier to perform the work on a carbohydrate diet than on any other.

## ANIMAL PRODUCTION.

[Association of Feed Control Officials.—Sixth, seventh, and eighth meetings] (Flour, Hay, Grain, and Feed, 26 (1914), No. 1, pp. 25-30, 32, 44, figs. 8; 28 (1915), No. 1, pp. 19-31, figs. 16; 30 (1916), No. 1, pp. 17-27, figs. 9).—Con-

[Vol. 41

tinuing past practice (E. S. R., 28, p. 74; 30, p. 466), the proceedings of three meetings held November 13–14, 1914, November 18–19, 1915, and November 17–18, 1916, respectively, at Washington, D. C., are reported. The 1914 report includes the constitution of the association and the papers of Chapin and Duvel previously mentioned (E. S. R., 32, p. 200). The 1915 report contains discussions and committee reports on tin-plate by-products, "hominy hearts," percentage of grit in poultry feeds, ingredients present in feeding stuffs in small amounts, phosphoric acid standard for meat scrap and digester tanks 2e, and crude fiber standards for cottonseed meal; and a paper by W. F. Ward on Feeding Beef Cattle. The 1916 proceedings include a paper by B. W. Kilgore on Peanut and Soy Bean Products for Feeding Purposes; a discussion of hominy feed; and reports on mill by-products and tin-plate middlings.

[Association of Feed Control Officials.—Ninth and tenth annual meetings] (Feeding Stuffs, 31 (1917), No. 6, pp. 19–26, figs. 3; 34 (1919), No. 1, pp. 19, 20, 27).—These are general accounts of the meetings held at Richmond, Va., November 23–24, 1917, and at Pittsburgh, Pa., January 13–14, 1919. The 1917 report includes a paper by G. S. Fraps on The Composition of Peanut By-products, Coconut Meal, and Soy Bean Meal.

**Commercial feeding stuffs, E. G. PROULX ET AL.** (*Indiana Sta. Bul. 228* (1919), pp. 3–170).—This bulletin furnishes data as to the ingredients identified and the percentages of moisture, fat, and protein found in feeding stuff samples collected in 1918, and includes a general discussion of the Indiana law similar to that in previous reports (E. S. R., 40, p. 72). It is stated that reports of the 1919 inspection will be issued quarterly and will record the complete proximate analyses of the samples collected.

The materials dealt with include alfalfa meal, barley mixed feeds, malt sprouts, brewers' dried grains, buckwheat mixed feed, coconut oil meal, corn bran, corn germ meal, yellow corn germ meal, corn gluten feed, corn feed meal, hominy feed, yellow hominy feed, corn-and-oat chop, cold pressed cotton seed, cottonseed meal, cottonseed feed, cottonseed hulls, dried beet pulp, kapok seed meal, linseed meal, linseed oil meal, linseed meal and screenings, oat middlings and hulls, palm kernel oil meal, peanut oil feed, rice bran, rye middlings and screenings, velvet bean feed, wheat bran, wheat middlings, wheat mixed feed, mixed mill by-products, tin plate by-products, tankage, meat scrap, blood meal, meat-and-bone meal, and dried buttermilk, as well as a number of proprietary mixed feeds, poultry feeds, calf meals, and condimental foods.

Inspection of commercial feeds, P. H. WESSELS (*Rhode Island Sta. Ann. Feed Bul., 1919, pp. 2–12*).—This is a report on the protein and fat content of 139 samples of feeding stuffs collected in 1918. The materials include alfalfa meal, barley feed, cottonseed meal, linseed meal, corn gluten feed, hominy feed, corn feed meal, distillers' and other dried grains, dried beet pulp, wheat bran, wheat bran with screenings, wheat middlings, shorts, red dog, wheat mixed feed, and various proprietary stock, calf, and poultry feeds.

The Texas feed control law.—Special advice to dealers and distributors, F. D. FULLER (*Texas Sta. Control Circ. A* (1918), pp. 5–14, figs. 2).—This publication contains the text of the Texas Feed Control Law of 1907 and directions for complying with it. The material is practically all included in Bulletin 234 (E. S. R., 40, p. 571).

Farm feeds: Grains, mill feeds, and concentrates, their nature and composition, F. T. SHUTT (*Canada Expt. Farms, Bul. 36, 2. ser. (1919), pp. 48*).—Recent proximate analyses in the laboratory of the Dominion chemist of the following products are reported: Wheat bran, wheat shorts, wheat middlings, red dog (feed flour), ground barley, barley feed, ground oats, oat chop feeds, oat hulls, corn-and-oat feeds, corn meal, hominy feed, corn bran, corn gluten feed, corn gluten meal, linseed meal (screw process), flaxseed chaff, flaxseed with bolls, flax straw shives, cottonseed meal, rice bran, rice meal, rice polish, rice shorts, distillers' dried grains, brewers' dried grains, soy beans, soy bean cake, velvet bean cake, peas and pea products, peanut meal, coconut meal, date meal, alfalfa meal, millet seed, cocoa shells, dried beet pulp, tankage, beef scrap, fish scrap, fish meal feeds, mixed chop feeds, elevator screenings, weed seeds (15 kinds), calf meals, chick feeds, and fox biscuits. The protein and oil content of flaxseed and additional samples of linseed meal, and the sugar content of several molasses feeds are also included. Average analyses of some of these materials from American and Canadian sources are presented for comparison, and in many cases the methods of manufacture are indicated. An abridgement of the paper noted below is included.

The composition of bran and shorts as milled under the regulations of the Canada Food Board, F. T. SHUTT and R. L. DORRANCE (Agr. Gaz. Canada, 5 (1918), No. 8, pp. 760-762).—Canadian samples of bran and shorts collected in 1903 and 1917 are compared as to proximate composition with samples collected after April 1, 1918, when regulations became effective in Canada requiring a 76 instead of the customary 72.5 per cent extraction of spring wheat by millers.

The 1918 bran showed a lower moisture content and increases of about 0.75 in the protein percentage, 0.5 in the fat, and 1.5 in the fiber. The shorts showed decreased moisture, increases of about 1.75 in protein and 2.5 in fiber percentage, and a decrease in nitrogen-free extract. The 1918 samples were much more uniform in protein, fat, and fiber content than the earlier collections.

Range management on the National Forests, J. T. JARDINE and M. ANDERSON (U. S. Dept. Agr. Bul. 790 (1919), pp. 98, pls. 32, figs. 4).—The object of this publication is to aid in bringing about uniformity in range management and a better understanding of grazing use in relation to the other uses of the National Forests. The topics covered include the determination of the class of stock to which a range is best suited, grazing periods, grazing capacity, management of cattle on the range, management of sheep on the range, range reseeding, grazing in relation to protection of timber, watersheds, game, and recreational use, and range reconnaissance and inspection. A special bibliography for each of these topics is added. There are also brief sections on stock driveways and poisonous plants, a bibliography for stock-poisoning plants in the United States, and notes on the collection and identification of forage and range plants.

Fattening steers on summer pasture in the South, W. F. WARD, D. T. GRAY, and E. R. LLOYD (U. S. Dept. Agr. Bul. 777 (1919), pp. 24, fig. 1).—Steer feeding experiments during the summers of 1912 and 1913 in collaboration with the Alabama College Experiment Station, and during the summers of 1915 and 1916 in collaboration with the Mississippi Experiment Station, are reported. They form part of a general cooperative series (E. S. R., 40, p. 873) and follow the pasture experiments reported in part 2 of Bulletin 110 (E. S. R., 31, p. 664).

The experiments were designed to compare summer pasture alone with pasture plus cottonseed cake. In two of the years a lot was also fed in which half the cake was replaced by corn. The principal pasture grasses were lespedeza, Bermuda grass, and crab grass. The Alabama pastures were seeded with sweet clover, and the 1916 pasture contained abundant white clover. During 1912, 2- and 3-year-old grades of beef breeds of fair quality were fed. In each successive season poorer and more mature cattle seem to have been used. Jersey blood apparently predominated among the Mississippi steers. Other details and the principal results are given in the following table:

Year.	Lot.	Supplements per day.		Num-	Dura-	Aver- age	Average gain per head.		Feed	Selling	Aver-
		Cotton- seed cake.	Corn.	ber of steers.	tion of test.	weight per head.	Per day.	Total.	per pound of gain.	per cwt.	dress- ing per centage

Steer feeding on southern pastures, with and without supplement.

#### <sup>1</sup> Corn chop.

<sup>2</sup> Corn-and-cob meal.

A pasture charge of 50 cts. per head for each 28 days was assigned in all the experiments. The price of cottonseed cake in the successive years was \$28, \$27.50, \$29.60, and \$32 per ton, respectively. The charge for corn in 1912 was \$5.5 cts, a bushel and in 1913, 70 cts.

The cake-fed steers showed throughout distinctly better finish than the others. This difference is reflected in the comparative selling prices of any one year and in the dressing percentages. The grass-fed steers of 1915 had to be sold as stockers. In spite of the higher cost, cake feeding returned more profit each year than pasture without supplement, except in 1916, when lot 2 was fed at a loss of 5 cents per head. The profits in different years are not comparable, since charges for freight, commission, yardage, etc., were added to the costs in 1915 and 1916, but not in 1912 and 1913. The poor showing of the 1916 cake-fed steers is attributed in part to inferior breeding.

The partial replacement of cake by corn chop or corn-and-cob meal is not considered desirable under the conditions of the experiments reported unless very cheap corn is available.

The use of cottonseed cake as a pasture supplement is recommended because of the higher prices the steers will generally bring, the added fertilizing value of the manure, and the earlier date at which the animals can be marketed.

Cattle feeding experiments, J. M. Scort (*Florida Sta. Rpt. 1918, pp. 18-20*).— Two cooperative experiments on private farms in collaboration with the Bureau of Animal Industry of the U. S. Department of Agriculture are reported.

In the first, 220 native steers 3 to 5 years old, averaging 582 lbs. in weight per head, were turned into an 80-acre Florida velvet bean field November 5, 1917. After 28 days the animals averaged 590 lbs. and the feed was changed to sorghum silage, velvet beans in pod, and cottonseed meal. On the fiftysixth day the weight was 589 lbs., and on the eighty-fourth, when the experiment terminated, 644 lbs. The average daily gain per head was 0.74 lb. There was a \$2 margin and a profit of \$4.02 per head.

In the other experiment 116 native steers similar to the preceding were pastured on an 85-acre field of velvet beans for 72 days, beginning November 6, 1917. They lost considerably in weight for a while in December, but there was an average daily gain for the whole period of 0.267 lb. per steer. The
pasture charge was \$9 an acre and the profit \$6.35 per head, with the same margin as before.

Corn silage for beef production, J. W. WILSON and B. L. THOMPSON (South Dakota Sta. Bul. 182 (1918), pp. 3–12, figs. 5).—Tests during two winters with silage made from corn cut at different stages of maturity are reported. Four lots of 5 steers were fed each season, yearling Aberdeen Angus grades being used in 1917 and 2-year-old Hereford grades in 1918. Silage was the only feed given. The main results follow:

Results of feeding steers with silage made from corn cut at different growth stages.

Stage at which corn was cut.	Year.	Feeding period.	Initial weight per head.	Daily gain per head.	Daily silage con- sumption per head.	Silage consumed per pound of gain.	Dry sub- stance consumed per pound. of gain.
Mature (frosted) Do Glazed stage Dough stage Do Milk stage Do	1917 1918 1917 1918 1917 1918 1917 1918	Days. 119 90 119 90 119 90 119 90 119 90	Lbs. 709 <sup>.</sup> 945 765 943 737 737 947 733 945	$\begin{array}{c} Lbs. \\ 2.18 \\ 2.00 \\ 1.94 \\ 2.61 \\ 2.01 \\ 2.54 \\ 2.01 \\ 1.86 \end{array}$	Lbs. 54. 5 57. 8 62. 4 80. 9 64. 4 82. 4 72. 8 81. 1	$\begin{array}{c} Lbs.\\ 24.9\\ 28.8\\ 31.9\\ 30.9\\ 31.9\\ 32.3\\ 36.1\\ 43.6\end{array}$	$ \begin{array}{c} Lbs. \\ 10.9 \\ 10.5 \\ 8.0 \\ 8.1 \\ 8.4 \\ 8.9 \\ 7.5 \\ 9.1 \end{array} $

It is concluded that silage made from corn cut when the kernels were glazed produced the most satisfactory gains. Proximate analyses of the eight different silages are tabulated.

[Steer feeding experiments in Canada] (Canada Expt. Farms Rpt. 1918, pp. 67, 68, 111).—A continuation of tests at the Kentville, N. S., Experimental Station (E. S. R., 40, p. 768) is reported by W. S. Blair (pp. 67, 68). Two lots of 12 steers each were fed from November 28, 1917, to March 31, 1918. One lot, fed 35 lbs. of corn silage daily, gained at the rate of 1.7 lbs. per head per day. The other, fed 45 lbs. of turnips, made a corresponding gain of 1.8 lbs. There was a hay ration of 12 lbs. and a grain ration when in full feed of 5 lbs. of a mixture of bran, cottonseed, and linseed meal.

Two tests at the Brandon, Man., Experimental Farm are reported by W. C. McKillican (p. 111). A lot of 11 steers made a gain of 140.6 lbs. per head on silage, hay, and grain, at a cost of 13.4 cts. per pound of gain. A comparable lot in the same (undesignated) period made average gains of 143.7 lbs. each at a cost of 15 cts. per pound. In the second experiment, a group of high-grade steers gained 239.1 lbs. per head, while a group of ordinary stockers gained 216.1 lbs. The cost per pound of gain was lower and the labor income and profit per steer higher in the case of the grades. The labor income and profit per \$100 invested in steers and feed was higher in the case of the stockers.

**Raising calves on farms where whole milk is sold**, W. W. SWETT (*Missouri* Sta. Circ. 88 (1919), pp. 13, fig. 1).—Where no skim milk is produced, the use of calf meal gruel after a short period of whole milk feeding is recommended as a makeshift. Methods of preparing gruel and feeding it are outlined. If, however, there is even a limited amount of skim milk available due to the separation of surplus whole milk, the problem, it is pointed out, is considerably simplified. After two or three weeks skim milk can be substituted for whole milk, and no calf meal need be used.

Preliminary report is made of experiments by M. H. Fohrman with Holstein and Jersey calves as to the necessary duration of skim milk feeding under these circumstances. It is claimed that practically normal growth occurred when the calves were fed liberally on skim milk, legume hay, and grain for only 60 days and then changed to a straight hay and grain ration.

Sheep on irrigated farms in the Northwest, S. O. JAYNE (U. S. Dept. Agr., Farmers' Bul. 1051 (1919), pp. 32, figs. 6).—About half this publication deals with the general problems of sheep management on irrigated farms with special reference to feeds and pasture, and summarizes the economic position of sheep husbandry in irrigation agriculture. The rest consists of reports of a survey made by the Office of Farm Management of 12 representative sheep farms in the irrigated districts of Washington, Idaho, and Montana. The reports outline the system of flock management on each farm and give notes on other live stock raised, crops grown, pastures used, prices received for wool, etc.

These farms "illustrate some of the varied conditions under which sheep are being kept to good advantage on irrigated farms, and show that the business is one that need not be confined to farms of any particular size or type or locality... There are not many irrigated farms anywhere in the Northwest on which small flocks of sheep could not be kept with profit, if given proper care."

Does it pay to feed corn to fattening lambs on pasture? J. W. HAMMOND (Mo. Bul. Ohio Sta., 4 (1919), No. 7, pp. 228-231).—Two sets of experiments are reported, one at the Southeastern Test Farm at Carpenter, the other at Wooster. The former consisted of tests during the summers of 1916 and 1917 in which a lot of lambs on blue grass pasture and another lot on a succession of forage crops (rye, red clover, and rape) were given a full feed of corn. Southdown×Merino lambs were used the first season and Merinos the second. The lambs used in experiments 2 and 3, respectively, of a previous report (E. S. R., 41, p. 177) constituted the check lots of the successive years. The feeding of corn increased the gain on blue grass 11.5 per cent in 1916 and 35.5 per cent in 1917, and on forage crops 12.6 and 21.1 per cent, respectively; increased the average dressing percentage in each case; and increased the market value per hundred pounds.

The experiments at Wooster were made in 1917 with 52-lb. grade Shropshire and with 46-lb. Shropshire×Merino lambs on rape pasture. A lot of each was given a full feed of corn, another a half feed, and a third no supplement. The daily gains on rape alone averaged 0.28 lb. per head for the grades and 0.33 lb. for the crossbreds. The corresponding gains on corn, half feed, were 0.37 and 0.34 lb., and on corn, full feed, 0.4 and 0.35 lb. There were practically no differences in the finish of the several lots nor in the average dressing percentages.

For each set of experiments computations are presented showing the profits or loss attending the feeding of corn of different prices to fattening lambs on pasture. It is concluded with some reservations that the operation would be profitable with corn at \$1.12 a bushel but not at higher prices unless good pasture were scarce.

Feeding experiments [with hogs], J. M. Scorr (Florida Sta. Rpt. 1918, pp. 21-23).—Three lots of 5 hogs each weighing about 90 to 95 lbs. per head were put on a 62-day feeding trial beginning December 4, 1917. The respective lots were fed shelled corn alone, shelled corn and unhulled peanut oil feed (6.5:1), and shelled corn and velvet bean feed (5:1), with corresponding daily gains of 0.8, 0.61, and 0.58 lb. per head. Each lot also received 10 lbs. of green rape daily. All of the carcasses were hard after 48 hours in the cooler, and the peanut-fed lot was indistinguishable from the others.

In a later experiment, begun March 7 and continued for 97 days, 6 hogs receiving unhulled peanut oil meal in varied but higher proportions with corn (1:5, 1:4, and 1:3) produced carcasses which did not harden, although the pork was of good quality and was not oily. Two hogs fed on corn as a check made the lowest gains (0.2 lb. per head per day) while the animals receiving the greatest amount of peanut meal made the best gains (0.7 lb.). It is also noted that 3 hogs fed shelled corn and cooked velvet bean feed (3:1 at start, 2:1 later) made an average daily gain of 0.49 lb. per day during the 85 days of the test.

Economical substitutes in swine feeding, G. B. ROTHWELL (Agr. Gaz. Canada, 5 (1918), No. 5, pp. 440-446, figs. 2).—Possible substitutes for the different feeds—corn, barley, wheat by-products, and oats—commonly fed hogs in Canada are discussed on the basis of experiments at the various Dominion experimental farms. Cottonseed meal, gluten feed, linseed meal, buckwheat screenings, tankage, skim milk, whey, and buttermilk are briefly considered. The economy of pasture crops and self-feeders is noted.

Special mention is made of two recent experiments. At Lacombe, Alta., hogs on rape pasture in 1917 consumed 4.34 lbs. of grain per pound of gain when self-fed, and 4.72 lbs. when hand fed. An acre of rape had a carrying capacity of 9,254 lbs. for 146 days when the hogs were self-fed on grain. The self-feeding, it is estimated, saved 2,453 lbs. of grain per acre. At Ottawa in 1917 a lot of pigs fed meal and tankage in a self-feeder gained at the daily rate of 0.53 lb. per head for 66 days, while a similar lot self-fed with meal and skim milk averaged 1.05 lbs. gain during the same number of days. Another lot also receiving meal and skim milk but trough-fed is contrasted with the latter. During 88 days the average daily gain per head was 0.85 lb.

[Swine feeding experiments in Canada] (Canada Expt. Farms Rpt. 1918, pp. 112, 129).—Experiments at the Brandon, Man., Experimental Farm are reported by W. C. McKillican (p. 112). A lot of 10 pigs fed crushed barley and red dog flour made a total gain of 294 lbs. at a cost of 10.4 cts. per pound. A similar lot given crushed barley and boiled pigweed seed gained 175 lbs. at a cost of 14 cts. per pound. A third lot of 10 receiving all three feeds gained 268 lbs. at a cost of 12.5 cts. per pound.

Five lots of 100-lb. hogs were fed to determine the value of grade A screenings as a winter feed. The gains from a lot receiving screenings alone cost 10.1 cts. per pound. Gains from crushed barley alone cost 20 cts., from red dog and screenings (1:1) 18.7 cts., from shorts and screenings (1:1) 13.8 cts., and from shorts and barley (1:1) 15.4 cts. It is also noted that the gains of 20 pigs on pasture cost 6.2 cts. per pound. No other details of these experiments are given.

Brief report of the Lacombe, Alta., experiments noted above is made by G. H. Hutton (p. 129). It appears that a lot of pigs self-fed without pasture was also included in the tests. These animals consumed 6.16 lbs. of grain per pound of gain.

Hogging down rye, W. L. ROBISON (Mo. Bul. Ohio Sta., 4 (1919), No. 6, pp. 179-181).—Experiments at the Miami County experiment farm during the years 1914-1916 are reviewed to show that the practice of hogging down rye, in spite of prior arguments in favor of it, results in slow and expensive gains, as the hogs eat little more than a maintenance ration. Details of the tests have been noted from the annual reports of the county experiment farms (E. S. R., 33, p. 871; 36, p. 869; 39, p. 778).

[Vol. 41

Citrus fruit rinds as a hog feed. R. S. ALLEN (Maryland Sta. Bul. 227 (1919). np. 193-202).-When it is recommended on sanitary grounds that garbage destined for hog feeding be cooked, the author has encountered a belief that cooked citrus fruit rinds are poisonous to hogs. To test this, an experiment with 4 lots of 3 hogs was instituted at the request of the National Research Council. All lots received corn meal, linseed meal, and tankage (94:3:3). One lot was given no additional feed, and the others received liberal allowances of cooked orange rind, cooked lemon rind, and cooked grapefruit rind, respectively. The rinds constituted about a third of the feed consumed. The grapefruit lot was discontinued after 40 days owing to shortage The others were fed 89 days. of material. The weights of the individual pigs every 10 days are tabulated. No toxic influence was detected. The orange and lemon fed lots consumed, respectively, 6.7 and 5.7 lbs. of feed per pound of gain, while the check lot required 10.5 lbs.

[Feed records of Canadian horses] (Canada Expt. Farms Rpt. 1918, pp. 84, 85, 90, 91).—The amounts of feed consumed by 2 foals and their dams at the experiment station, Ste. Anne de la Pocatiere, Que., are reported by J. Begin (pp. 84, 85). A Percheron mare with a 45-day colt was purchased. During 5 months of nursing the mare consumed 1,888 lbs. of grain and chop and 1,975 lbs. of hay, and was on pasture 2.5 months. The feed consumed by the colt during the first 7 months after weaning consisted of 579 lbs. oats, 624 lbs. bran, 309 lbs. chop, 2,234 lbs. hay, 75 lbs. whole milk, and 676 lbs. roots. The mare weighed 1,750 lbs. and the colt at 3 months, 590 lbs., and at 12 months, 1,175 lbs.

The dam of a Percheron filly born April 11, 1917, consumed during the nursing period (up to November 1) 901 lbs. oats, 683 lbs. bran, 100 lbs. chop, and 2,384 lbs. hay, and was on pasture 4.5 months. During the 5 months after weaning the filly ate 478 lbs. oats, 448 lbs. bran, 152 lbs. chop, 71 lbs. whole milk, and 497 lbs. roots. The mare weighed 1,775 lbs. and the colt at 3 months 540 lbs., and at 12 months, 1,125 lbs.

Feeding records of horses at the Cap Rouge, Que., Experimental Station are reported by G. A. Langelier (pp. 90, 91). All feed given to a colt and two fillies was weighed until they were broken and put to work at an average age of 34 months, 7 days. The quantities consumed per head were 13,063 lbs. hay, 4,278 lbs. oats, 4,830 lbs. bran, 29 lbs. wheat, 5 lbs. linseed meal, 1,036 lbs. skim milk, 29 lbs. whole milk, and a "very little pasture." Similar records of 2 working mares for a year are also averaged, the quantities being 4,440 lbs. hay, 4,770 lbs. oats, 972 lbs. bran, and 132 lbs. common molasses per head. The average number of hours of work was 1,639.

Feeding experiments with Leghorns, A. G. PHILIPS (*Indiana Sta. Bul. 227* (1919), pp. 3-28, figs. 7).—Feeding experiments with White Leghorn pullets during the years 1914–15 to 1917–18, in continuation of those previously noted (E. S. R., 34, p. 376), and studies of the influence of confinement on egg production made in 1913–14 with hens and in 1914–15 with pullets are reported. The grain and mash rations and general treatment were the same as in the contemporaneous Plymouth Rock experiments (E. S. R., 40, p. 76). Three pens of 30 birds each were used in each of the six experiments.

The first two feeding experiments were duplicates. One pen received 5.3 lbs. of cottonseed meal mixed with the mash, another had 50 lbs. of buttermilk to drink for each 35 lbs. of standard grain and mash, while the third received 50 lbs. of buttermilk and a double allowance of grain, making the ratio of grain to mash 5:1.

The other two feeding experiments also duplicated each other. One pen was fed only the standard grain and mash, while the second and third received

570

#### 1919]'

3.5 lbs. of meat scraps and 3 lbs. of tankage, respectively, in addition. It was estimated that equal amounts of animal protein would be furnished the latter pens. The main results of the feeding experiments are summarized in the following table:

#### Annual egg and feed records per bird of Leghorn pullets during feeding experiments.

Averages of first and second experiments.				Averages of third and fourth experiments.				
Additions to standard ration.	Num- ber of eggs.	Grain and mash con- sumed.	Total feed per pound ofeggs.	Additions to standard ration.	Num- ber of eggs.	Grain and mash con- sumed.	Total feed per pound ofeggs.	
Cottonseed meal Buttermilk Buttermilk and grain	55.7 166.9 137.9	<i>Lhs.</i> 50. 2 63. 1 64. 2	<i>Lbs.</i> 9.05 17.77 17.23	Meat scrap Tankage None	179. 1 183. 5 59. 5	<i>Lbs.</i> 70.5 71.3 62.0	Lbs. 3.77 3.60 9.32	

<sup>1</sup> Liquid buttermilk computed at 10 per cent of its weight.

Cottonseed meal is considered practically worthless as a protein concentrate for egg production. The egg records of the birds receiving it were especially low during the winter.

In the experiments on the influence of confinement it was found that birds kept housed continuously averaged 112.3 eggs per year, those with access to a small yard (10 by 80 ft.) 124.4 eggs, and those with access to a free range (130 by 160 ft.), 128.75 eggs.

Poultry feeding experiments, R. B. THOMPSON (New Mexico Sta. Bul. 117 (1918), pp. 22, figs. 5).—This bulletin presents in tabular form the production and feed records from January 15 to June 15, 1918, of each of 15 pens of varied size (9 to 33 birds) for each of 5 periods of varied length (28 to 32 days). A group of 5 pens, totaling 11 Rhode Island Red pullets, 29 White Leghorn pullets, and 57 White Leghorn hens, received a mash of bran, ground oats, and meat scrap (2:1:2). Three other groups each received a mash which was a variant of this. Ground milo maize replaced the oats in the mash given to 4 pens comprising 16 White Wyandotte pullets and 84 White Leghorn pullets. Alfalfa meal replaced bran in the rations of 2 pens that included 22 first year and 33 second year White Leghorns. Finally, 3 parts of cottonseed meal was given in place of the meat scrap to the remaining birds, 20 Rhode Island Red pullets and 24 White Leghorn hens. The scratch in all cases consisted of whole oats and milo maize. When the birds did not have access to growing alfalfa they were given green rape and beets.

The records are not summarized so as to compare the different mashes, but all four are considered satisfactory. The hens, but not the pullets of the last group produced eggs showing "cottonseed meals spots."

The experiment was planned at the time of a wheat shortage. It is suggested that whenever a common ingredient of poultry feeds is not available a simple combination of accessible feeds should be tried and not the complex mixtures often sold by manufacturers.

The influence of age of hens on egg production, H. E. DVORACHEK and S. R. STOUT (*Arkansas Sta. Bul. 163 (1919)*, *pp. 3–8*).—The annual egg records of individual hens in their pullet and subsequent years are tabulated. There were two pens of Single Comb White Leghorns and a pen each of Anconas, Single Comb Black Minorcas, Barred Plymouth Rocks, Columbian Plymouth Rocks, White Orpingtons, and Buff Orpingtons. The Ancona pen started with 6 birds, the others with 12. The number of birds was reduced from 90 to 37 in the second year and to 67 in the third. The average egg production of the pullet year was 72.17 eggs per hen, of the second year 61.48 eggs, and of the third year 50.53. Fourteen Plymouth Rocks were retained for a fourth year and produced 24.57 eggs per hen. The birds of the Mediterranean class laid more consistently throughout the first three years than did the Plymouth Rocks or the Orpingtons.

The percentage production of each pen by months is also tabulated. The older birds showed a greater decrease in winter than in summer production.

Artificial illumination of poultry houses to increase fall and winter egg production, V. G. AUBRY (New Jersey Stas. Hints to Poultrymen, 7 (1919), No. 10, pp. 4).—The management of laying hens when winter days are artificially prolonged by the use of electric lights or other sources of illumination is briefly outlined. It is pointed out that no mystery attaches to this much discussed method of increasing egg production; the birds merely have more time to eat.

How to prevent loss in market eggs, G. H. POUND (*New Jersey Stas. Hints to Poultrymen*, 7 (1919), *No.* 9, *pp.* 4).—Notes on the grading, handling, and packing of market eggs are given. It is stated that poultrymen in Petaluma, Cal., because of the attention they give to these matters, are able to undersell New Jersey poultrymen in the wholesale fancy egg market of New York City.

#### DAIRY FARMING-DAIRYING.

Experimental feeding [of dairy stock], G. A. LANGELIER (*Canada Expt. Farms Rpt. 1918, pp. 88, 89*).—Experiments conducted at Cap Rouge, Que., are reported.

A group of 3 calves reared mostly on skim milk and a home-made calf meal composed of corn, oats, and flaxseed (4:2:1), consumed in the first 24 weeks after birth 89.5 lbs. of whole milk, 2,322 lbs. skim milk, 266 lbs. of the meal, 220 lbs. of hay, 103 lbs. of roots, and 15 lbs. of silage per head.

Continuing work previously noted (E. S. R., 40, p. 775) the average feed consumed by a heifer until calving time (about 28 months) was found to be 892 lbs. whole milk, 7,553 lbs. skim milk, 764 lbs. meal, 2,910 lbs. hay, 5,590 lbs. roots, 6,074 lbs. silage, 181 lbs. green feed, and 94 days of pasture.

A group of milch cows allowed an unlimited grain ration consumed a pound of meal for each 2.18 lbs, of milk produced. The profits (on a 1913 price basis) were greater than those from two other groups receiving a pound of meal, respectively, for each 4 and for each 8 lbs. of milk.

There is also a note on the growth of two heifers, twin sisters, one fed a heavy ration, one a light one.

Report on calf-feeding experiments conducted at the college farm, Kilmarnock, in 1916 and 1917, W. G. R. PATERSON (West of Scot. Agr. Col. Bul. 84 (1918), pp. 13-23).—To study economical methods of rearing calves in cheese making districts, 32 Ayrshire calves were fed during the course of the two years' experiments. It was found that the gradual replacement of whole milk by whey between the third and sixth week and then the feeding of whey with grain or other concentrates resulted in calves practically as thrifty and as wellgrown as the check lots fed skim milk and crushed oats. The concentrates fed with the whey included (1) oat meal and fish meal, (2) palm-nut meal, and (3) fine middlings and fish meal.

The escutcheons of dairy cows, J. J. HOOPER (Breeder's Gaz., 76 (1919), No. 2, pp. 52, 53).—A brief discussion is given of the escutcheons of 1,019 dairy

cows examined by the author and J. W. Whitehouse, working at the Kentucky Experiment Station. It was found that Guenon's Flandrine type predominated among Holstein, Guernsey, Kerry, and the few Ayrshire cows examined, while the Selvedges type was most common among Jerseys. Average production records of Jerseys are cited, the types of cows with lower order escutcheons of both the Flandrine and the Selvedges type yielding more milk and butterfat than those with first order escutcheons of corresponding type.

Composite samples, their value to the dairy plant, T. MOJONNIER (*Creamery* and Milk Plant Mo., 7 (1918), No. 12, pp. 32d, 32e).—The use of formaldehyde to preserve composite samples of milk is advocated. Data from 16 samples thus preserved are tabulated to show that no significant changes occurred in the percentages of fat and total solids during 31 days.

Varying bacteriological results obtained by different laboratories, C. H. KILBOURNE (*Creamery and Milk Plant Mo.*, 7 (1918), Nos. 10, pp. 54–56; 11, pp. 40-42, 44).—The author records his efforts to secure greater uniformity in the results of different commercial laboratories in the bacteriological examination of the same samples of milk. Bacterial counts of a number of subsamples distributed to four laboratories are tabulated and the variations in technique noted. A satisfactory degree of uniformity was secured only when analysts from each concern worked together in the same laboratory and made conscious effort to follow the same procedure.

A new method for scoring dairies, H. F. JUDKINS (*Creamery and Milk Plant* Mo., 7 (1918), No. 7, pp. 27–29).—The characteristic features of the proposed system of scoring is that the inspector fills out the answers (usually with "yes" or "no") to a questionnaire as to conditions on each dairy farm visited, and that from these answers a rating is given not to each item of equipment or method but to four groups of items. The groups are: (1) Primary equipment, including health of cows, sanitary conditions of the barns, type of milk pail, and provisions for cooling milk and washing the utensils; (2) secondary equipment; (3) primary methods, including procedure at milking, disposal of manure, washing of utensils, and care of milk; and (4) secondary methods. The scores allowed each group are respectively, 30, 5, 55, and 10 points.

The principal advantage claimed is the latitude allowed the inspector in being able to vary the relative weights of the individual items to meet local conditions or to conform to advances in dairy science. It is also held that the answers to the questions would provide more useful information to the main office than a mere numerical rating.

The Chicago milk inquiry, C. S. DUNCAN (Jour. Polit. Econ., 26 (1918), No. 4, pp. 321-346).—This paper presents a statement of events leading to the formation in December, 1917, of a commission to fix a fair price for milk in the Chicago district; summarizes the briefs presented by the producers, by the distributors, and by the City Club of Chicago which represented the consumers; outlines some of the testimony reported in the (apparently unpublished) record of the commission rendered in February, 1918, and the controversies resulting.

The commission was occupied mostly in considering cost of production. Twelve formulas to determine the amounts of feed and labor required to produce 100 lbs. of milk are tabulated by the author from among those collected by the City Club from various sources. In discussing how these were to be converted into money values, the farmers held that the farm values of homegrown feeds should be used while the consumers would allow only the actual cost of growing and preparing the feeds. The commission in its majority report avoided a decision on this point by assuming that the producers' prices for the years 1908 to 1915 were fair under the conditions then operating, and recommended that the new price be the average price of this period plus a percentage increase equal to the relative increase in the cost of feed and labor.

Report of Chicago Milk Commission (*Creamery and Milk Plant Mo.*, 7 (1918), *No. 3, pp. 17–22*).—The text of the majority report of the commission referred to above is printed, together with a minority report by W. J. Kittle, and statements by E. Davenport and P. G. Holden, two members who refused to vote in favor of the majority report.

## VETERINARY MEDICINE.

The influence of deficient nutrition on the production of agglutinins, complement, and amboceptor, S. S. ZILVA (Biochem. Jour., 13 (1919), No. 2, pp. 172-194, figs. 8).--The author suggests the urgency of a systematic study of the influence of nutrition on the production of immunity, and contributes to this study the report of an investigation of the effect of deficient diets on amboceptor and agglutinin formation and complement content. The influence of the following dietetic deficiencies was studied: (1) diets low in iron, calcium, potassium, sodium, chlorin, and phosphorus, respectively; (2) diets containing 12 per cent and 8 per cent of caseinogen as a source of protein; (3) diets containing 18 per cent of gliadin as the sole source of protein; and (4) diets deficient in each of the three accessory food factors. The influence of the quantitatively restricted diet on the complement content was also studied. Rats were employed for the investigation of the action of deficient proteins, restricted mineral salts, and accessory food factors on the production of amboceptor and agglutining, and guinea pigs for the study of the influence of quantitatively restricted diets on the complement content of the blood and the influence of a diet restricted in antiscorbutic factor on the production of amboceptor and agglutinins. The technique employed and experimental data obtained are described in detail and illustrated by tables and charts.

"Although several of the deficiencies became manifest by the restricted growth and the poor condition of the animals, no differentiation in the titers of the agglutinins and amboceptor could be recorded, except in the group receiving the diet low in phosphorus. Guinea pigs fed on an unrestricted mixed diet, quantitatively restricted mixed diet, and a scorbutic diet, showed no differentiation in the amboceptor and agglutinin titers, or in the complement activity of the blood."

The author states in conclusion that the results of the experiments can at present be considered only an indication, and that further investigation is necessary in order to establish the fact definitely that a diet low in phosphorus is the only one showing a well marked differentiation in the production of agglutinins and amboceptor.

Growth accessory substances for pathogenic bacteria in animal tissues, I. J. KLIGLER (*Jour. Expt. Med., 30 (1919), No. 1, pp. 31-44*).—The object of the investigation reported was to determine (1) the effect of vitamins on the growth of a number of organisms pathogenic for man, (2) the distribution of these substances in animal tissues, and (3) the relative significance of the fat-soluble A and water-soluble B factors in the cultivation of these microorganisms.

The organisms studied included the meningococcus, pneumococcus, streptococcus, *Bacillus diphtheriæ*, *B. pertussis*, and *B. influenzæ*, and in the course of the investigation beef heart, goat blood, rabbit and cat tissues, and human secretions (nasal secretion and saliva) were used. Extracts of the tissues with saline solution were added in graded amounts to nutrient broth or agar, or to phosphate peptone agar, which was then inoculated with small amounts of culture suspensions. The tubes were incubated at 37° C, and observations made daily for several days.

"The growth of all pathogenic bacteria studied was favorably influenced by the addition of small amounts of tissue extracts. Beef heart, rabbit and cat tissues, and human nasal secretions contain substances favorable to the growth of the organisms tested. The mucosa of different organs, spleen, liver, and kidney, are relatively rich in these substances, while muscle is relatively poor. The favorable effect of the extracts is manifested by an enhancement of growth and a reduction of lag."

Evidence is furnished indicating that the favorable effect upon bacterial development is produced by the water-soluble vitamins present in the tissue employed.

Studies on the biology of streptococcus.—I, Antigenic relationships between strains of Streptococcus hemolyticus, A. R. DOCHEZ, O. T. AVERY, and R. C. LANCEFIELD (Jour. Expt. Med., 30 (1919), No. 3, pp. 179–213).—The problem of the complete biological classification of pathogenic organisms is considered by the authors to consist of (1) the development of reliable methods for the determination of antigenic differences between members of the species and the application of these methods to the discovery of the immunological relationships between a limited number of strains, (2) the application of this tentative classification to a large number of strains of the organism obtained under normal conditions of pathogenicity, and (3) a comparison by the same methods of the pathogenic with the saprophytic varieties of the organism.

This paper presents a partial study of *S. hemolyticus* in accordance with the plan outlined above. A technique was developed for studying the immunological reactions of agglutination and protection in 125 human strains of hemolytic streptococci obtained from various sources. By the reaction of agglutination four distinct immunological types, two types at present not completely investigated, and a certain number of unclassifiable strains were descovered. It was found possible to raise the animal virulence of a certain number of strains to a high degree and to produce antistreptococcic sera of sufficiently high titer for reliable protection tests. In all instances in which this was done the protection reaction has corroborated the evidence obtained from the agglutination test.

These results indicate that *S. hemolyticus* of human origin is not a unit type, as was previously supposed, but probably consists of a number of types, at least four of which have been definitely identified. No evidence was obtained to support the contention that freshly isolated human strains change their antigenic properties on animal passage, and that this procedure for the development of animal virulence gives a common antigenic character to all strains. On the contrary, the antigenic differences between strains of *S. hemloyticus* which had been passed through animals were as distinct as those between strains which had not been so passed.

It is emphasized in conclusion that only a beginning has been made in the classification of *S. hemolyticus*, and that much work must be done before the classification is complete and the relative dominance of the different pathogenic varieties determined.

The antigenic properties of proteoses, E. B. FINK (Jour. Infect. Diseases, 25 (1919), No. 2, pp. 97-123).—This paper consists of a summary of the literature on attempts to demonstrate the formation of antibodies against incomplete protein molecules, and a report of an investigation of the antigenic properties of proteoses from Witte peptone and from egg white.

The cold-alcohol-soluble, hot-alcohol-soluble, and alcohol-insoluble fractions of Witte peptone were unable to stimulate the production of precipitins or complement binding antibodies when injected into rabbits. Anaphylaxis experiments with guinea pigs showed that these preparations had only slight power of sensitizing to themselves, were not able to sensitize to beef serum, and did not produce symptoms of anaphylactic intoxication in animals sensitized to beef serum. Beef serum did not sensitize to products of Witte peptone nor produce shock in animals sensitized to such products.

The proteose preparations from egg white were obtained by hydrolysis of the coagulated material, and fractional precipitation with ammonium sulphate. Experiments with rabbits indicated that the 1/4, 1/3, 1/2, and 2/3 saturation products possessed no power of stimulating the production of precipitins or complement binding substances, and were unable to sensitize or intoxicate guinea pigs either to themselves or to egg white. The 3/4 and 4/4 saturation products showed definite antigenic power for both precipitins and complement binding substances, and possessed slight sensitizing and intoxicating properties for guinea pigs. In all forms of antibody reaction the antigenic proteoses were not specific, in that egg white could be used as antigen in place of either fraction.

Is hemoglobin antigenic? C. L. A. SCHMIDT and C. B. BENNETT (Jour. Infect. Diseases, 25 (1919), No. 3, pp. 207-212).—A brief review of the literature on the properties of hemoglobin as a possible antigen is given, and experiments initiated in the belief that the positive results obtained by some workers can be attributed to impurities in the preparation of hemoglobin are described and summarized as follows:

"Hemoglobin was prepared by three methods, one by crystallization from ammonium sulphate . . . and the other two by precipitation as oxyhemoglobin (with and without addition of alcohol) at low temperature and resolution by reduction. Each of the three preparations was recrystallized a number of times.

"Rabbits were immunized with each of the above preparations and both fixation and precipitin tests carried out. These were negative. In the sera of these rabbits no sensitizer was found which in the presence of alexin caused a hemolysis of dog cells. Agglutinins were likewise not produced. Hemoglobin failed to sensitize guinea pigs for the anaphylaxis reaction. The conclusion that hemoglobin is nonantigenic seems warranted.

"Doses of hemoglobin very much larger than the amount of globin which will cause toxic symptoms were injected both intravenously and intraperitoneally into guinea pigs, and toxic symptoms were not shown. Combination of toxic globin with hematin as occurs in hemoglobin renders it nontoxic, but does not, as in the instance when globin is combined with casein, give when rabbits are immunized antibodies for itself."

Prophylactic and curative value of serums and vaccines in veterinary medicine, D. G. IZCARA (Bol. Agr. Téc. y Econ., 11 (1919), Nos. 126, pp. 516-520; 127, pp. 595-604; 128, pp. 697-706).—This is an extract from an address delivered at the National Congress of Medicine (Spain).

The first part deals with prophylaxis by normal virus, prophylaxis by attenuated virus or vaccines, immunization with dead vaccines, virus, and sensitized vaccines, immunization with serum alone (serum immunization) or with serum associated with a virus or vaccine (serum vaccination), and serotherapy. In the second part the applicability of one or another of these methods to the prophylaxis and treatment of various animal diseases is discussed. The diseases considered include cowpox, foot-and-mouth disease, contagious pleuropneumonia, rabies, tetanus, anthrax, glanders, gaseous gangrene, dysentery, strangles, red fever of swine, infectious septicemia, hog cholera, and rinderpest. The serotherapy of snake bites and of wounds is also considered.

Experimental gas gangrene. The protection by antiserum and antiserum mixtures, M. NEVIN (Jour. Infect. Diseases, 25 (1919), No. 2, pp. 178–188).— The experiments reported were planned to show (1) the relative value of *Bacillus welchii* antitoxin and perfringens antimicrobial serum in the treatment of gas gangrene, (2) the value of various antiserums both singly and combined against edematous exudates produced by the inoculation of several anaerobic organisms, and (3) the protective value of various antiserums both singly and combined against mixed anaerobic infections. The experiments were conducted upon guinea pigs, the general plan being to inoculate the animal subcutaneously with the antitoxin or antiserum, and four days later intramuscularly with two minimal lethal doses of a living culture of the organism to be tested or with edematous fluid collected from animals inoculated with different combinations of anaerobes. The conclusions drawn from the study are summarized as follows:

"When Vibrion septique and B. edematicns (B. bellonensis) are present in mixed infections the prophylactic use of the specific serums, even when diluted by another serum, is effective.

"Neither the *B. welchii* antitoxin nor the *B. welchii* (perfringens) antimicrobial serum is of any practical value in the prophylaxis of gas gangrene caused by a mixed infection due to several anaerobic bacilli, such as is commonly found in war wounds today. No accurate investigations of the amount of antitoxin contained in the antiperfringens (*B. welchii*) serum were made, and it is therefore impossible to say whether the protection afforded in pure *B. welchii* infections by the antimicrobial serum was due to the antitoxic principle contained in it, or to other antibodies present, or to a combination of the two. Further studies will be necessary to determine whether a serum of the highest potency can be produced by the inoculation of a sterile filtrate, producing a strict antitoxin, or by the inoculation of whole cultures, producing an antimicrobial serum."

The bactericidal action of the whole blood of rabbits following inoculations of pneumococcus bacterins, G. D. HEIST and S. SOLIS-COHEN (*Jour. Immunol.*, 4 (1919), No. 4, pp. 147–166).—This is a continuation of the experiments on the bactericidal powers of whole blood previously noted (E. S. R., 40, p. 286), the immediate and practical object being to determine whether the test can be made use of in determining the efficiency of prophylatic inoculations of pneumococci, especially of type III. The work reported consisted of two phases, the first concerning the virulence of the pneumococci and the relation such virulence bears to their ability to grow in whole blood, and the second concerning the antibodies present in the blood to be examined and their action on the pneumococci.

The earlier conclusions in regard to the bactericidal activity of whole blood in vitro were confirmed. It was found that increasing the virulence of pneumococci for rabbits increased their ability to grow in rabbit blood in vitro, the mathematical expression of the ability of a strain of pneumococci to grow in the blood of normal rabbits in vitro thus serving as an expression of the virulence of the strain for rabbits.

The test for the bactericidal activity on pneumococci of the whole blood of inoculated rabbits was found to be a more sensitive index of the extent of immunity present as regards types I, II, and III than is the agglutination test, and to have an approximately quantitative value. The production by suitable inoculations of specific bactericidal activity in the blood of rabbits for pneumococci of one type was found to be accompanied by the production of slight bactericidal activity for other types.

Studies upon the bacterial flora of samples of milk with high cellular counts as drawn from the apparently normal udder, L. H. COOLEDGE (*Michigan Sta. Tech. Bul. 41* (1918), pp. 903–910, fig. 1).—Work taken up in connection with investigations of the effect of diseases in the cow upon the milk deals with the relation of high cellular counts to *Bacterium abortus* infected, streptococci infected, and tuberculous udders, and to other abnormal conditions of the cow's udder, respectively. The first of the four parts of the work is here reported upon.

"Milk from actively *B. abortus* infected udders is found to have an average cellular count over five times as high as the apparently normal average. Udders artifically infected with a broth culture of *B. abortus* were quick to show an increase in the cellular count. *B. abortus* infection accounts for many of the samples of milk which have high cellular counts as drawn from the apparently normal udder. Many cases of high cellular counts can not be traced to *B. abortus* infection. Milk with high cellular counts caused by *B. abortus* infection can not be considered dangerous for human consumption as this organism has not been found pathogenic for man."

A list of nine references to the literature is appended.

Contagious abortion in cattle, C. D. MCGILVRAY (Ontario Dept. Agr. Bul. 272 (1919), pp. 8, fig. 1).—A popular summary of information.

The cattle tick pest (Aust. Inst. Sci. and Indus. Bul. 13 (1919), pp. 40, pl. 1, figs. 14).—A revised and enlarged edition of the bulletin previously noted (E. S. R., 38, p. 286).

The pathology and epizootiology of louping ill, S. STOCKMAN (Jour. Bd. Agr. [London], 26 (1919), No. 1, pp. 24-39, pls. 4).—A more detailed account has been noted (E. S. R., 40, p. 383).

A chronic pox-like infection in goats and its successful treatment, R. V. STONE and C. W. FISHER (*Jour. Amer. Vet. Med. Assoc.*, 55 (1919), No. 5, pp. 536-543).—"A condition in goats, benign in character but of economic importance through loss in milk production and flesh, has been observed. Lesions in early stages resemble goat-pox. Whether true goat-pox or a condition having lesions simulating those observable in goat-pox has not been determined. However, a pure Gram positive staphylococcus having an orange pigment and producing marked hemolysis on uncooked blood agar has been isolated from every specimen taken.

"Bacterins prepared from this organism produce a rapid recovery in cases affected. This therapeutic value may be specific or nonspecific, but the organism has been demonstrated as being particularly virulent for goats but nonvirulent for guinea pigs and rabbits. Three distinct forms of infection have been successively treated with bacterins. These forms are (a) arthritis, (b) exanthemata, [and] (c) subcutaneous multiple abscesses. Cases in which bacterin therapy is not employed do not recover rapidly but may persist at least a year and a half."

Observations concerning the dissemination of hog cholera by insects, M. DORSET, C. N. MCBRYDE, W. B. NILE, and I. H. RIETZ (*Amer. Jour. Vet. Med.*, 14 (1919), No. 2, pp. 55–60).—This is a report of studies by agents of the Bureau of Animal Industry of the U. S. Department of Agriculture presented at the annual meeting of the U. S. Live Stock Sanitary Association, held in Chicago in December, 1918. The studies were conducted with the house fly and lesser house fly, representing the nonbloodsucking species; and the stable fly, representing the bloodsucking species.

The experiments seem to show that house flies are capable of taking up and harboring hog cholera virus, and that under experimental conditions they transmitted the disease in a certain number of cases to healthy pigs. In the attempt to determine whether the spread of hog cholera occurs in this way in nature, screened pens were used. In each of the fly-tight pens one or two susceptible pigs were placed and flies caught daily with traps and nets in the virus barn were introduced. While large numbers of such flies were introduced daily for 24 days in two cases and for 31 days in another, all the pigs remained perfectly well and later were proved susceptible, notwithstanding that several thousand flies had been introduced into each pen. In two other experiments a smaller number of flies, for the most part caught feeding on the eye secretions of sick pigs, were introduced into the pens, with the result that one of the two pigs developed cholera within 25 days after the first exposure to the flies and 6 days after the last exposure.

Screened cage experiments with stable flies led the authors to believe that they take up and harbor the virus of hog cholera, and that they may under favorable conditions convey hog cholera to healthy pigs. "The negative results of the screened pen experiments with house flies leads us to doubt whether the house fly is an important channel for the conveyance of cholera from farm to farm, though the possibility of the disease being conveyed in that way is not, in our opinion, excluded."

A new strongylid from the hog, A. RAILLIET, A. HENRY, and J. BAUCHE (Bul. Soc. Path. Exot., 12 (1919), No. 6, pp. 324–332, figs. 5).—Under the name Bourgelatia diducta, the authors describe a form representing a new genus and species found in the cecum and colon of the domestic hog at Hué (Annam).

The blood pressure of the horse, S. SCHILLING (Jour. Amer. Vet. Med. Assoc., 55 (1919), No. 4, pp. 401-416, figs. 5).—Noted from another source (E. S. R., 41, p. 287).

**Epizootic lymphangitis of solipeds**, A. BOQUET, L. NÈGRE, and G. ROIG (*Rev. Gén. Méd. Vét.*, 27 (1918), Nos. 323, pp. 553-566, figs. 2; 324, pp. 617-634, fig. 1).—In this article the authors deal with the parasitology, treatment, and prophylaxis of epizootic lymphangitis in the horse and mule. A report of the pathogenic action and characteristics of the cryptococcus is included, as is a bibliography of 23 titles.

Contribution to the study of ulcerative lymphangitis of the horse, G. MULLIE (*Rec. Méd. Vét., 95 (1919), No. 1-2, pp. 34-50*).—A discussion of the symptoms, therapeutics, and prophylaxis, based upon observations and experiments during the war.

Report on ulcerative lymphangitis in the A. E. F., A. A. LEIBOLD (Amer. Jour. Vet. Med., 14 (1919), No. 8, pp. 387-391, 419).—The author reports on bacteriological examinations of 165 horses and mules of the American Expeditionary Forces suffering from various forms of lymphangitis which were made during 1917 and 1918. In 72.62 per cent of the cases streptococci alone were found, of which 84 per cent were hemolytic; Preisz-Nocard bacillus alone in 6.06; streptococci with staphylococci in 6.06; staphylococci alone in 4.24; streptococci with Preisz-Nocard bacillus in 2.42; staphylococci with Preisz-Nocard bacillus in 0.6; cryptococcus of Rivolta alone in 2.42; and no cultures in 7.21 per cent.

It is pointed out that during the winter of 1917–18 and the summer of 1918 lymphangitis in its various forms became quite a serious problem among the horses and mules in France. "Ulcerative lymphangitis, according to the author's observations, exceeded all other forms many times, occurring in 97.5 per cent of cases of lymphangitis. It has a decided tendency to run a protracted course, often incapacitating animals for weeks." The fact that strepto-

[Vol. 41

coccl were found in such a high percentage of the cases and in the majority of the cases in pure culture, and also that strains injected into laboratory animals proved pathogenic, led to the belief that they are the cause of one form of ulcerative lymphangitis.

The streptococci of equines, F. S. JONES (Jour. Expt. Med., 30 (1919), No. 2, pp. 159–178, pl. 1).—" The lower nasal mucosa and the pharynx of 30 eastern and 23 western horses have been examined for streptococci. Eight of the eastern horses carried nonhemolytic streptococci on the nasal mucosa. From the pharynx of 6, nonhemolytic streptococci were cultivated. The throats of 18 contained strains of the hemolytic type. The nasal mucosa of the eastern horses failed to show hemolytic streptococci. Eight western horses carried nonhemolytic streptococci in the nasal passage; 8 also harbored the hemolytic type. Twenty-two strains were isolated from the pharynx. Eleven were hemolytic.

"Among all the nonhemolytic nasal strains those capable of fermenting mannite predominate. Those of the nonhemolytic types from the pharynx of both classes of horses may or may not ferment lactose but all do ferment either raffinose or inulin. In no instance have any of the nonhemolytic types proved pathogenic for mice. The hemolytic strains from the nasal mucosa of the western horses were all of the *Streptococcus pyogenes* type. They were pathogenic for mice and rabbits. One strain from the pharynx of an eastern horse and 8 from the throats of the western horses were of the same species. All the others corresponded closely in their fermentation reactions with nonhemolytic streptococci from the same region.

"The streptococci from pathological sources were all hemolytic. They have fallen into two groups; the larger group (S. pyogenes) produced acid in dextrose, lactose, saccharose, maltose, milk, and salicin, but failed to change the reaction of broth containing raffinose, inulin, or mannite. The streptococci of the smaller group (S. equi) differ only in their inability to ferment lactose or acidulate milk. Both types are pathogenic for mice. Rabbits are usually more resistant.

"S. pyogenes has been isolated from 18 of 22 cases of influenza, 3 of 6 cases of strangles, and from 8 of 9 abscesses. S. equi was observed in 4 horses suffering from influenza, and 5 others affected with strangles. This species was also found in an abscess and associated with both rhinitis and pharyngitis."

Scrapie, J. P. M'GOWAN (*Jour. Compar. Path. and Ther.*, 31 (1918), No. 4, pp. 278-290).—This is a reply to the criticism by M'Fadyean (E. S. R., 41, p. 85) of the author's work previously noted (E. S. R., 32, p. 276).

Sarcosporidia as the cause of scrapie, J. M'FADYEAN (Jour. Compar. Path. and Ther., 31 (1918), No. 4, pp. 290-299).—A further critical review of the work by M'Gowan (E. S. R., 32, p. 276), in view of the explanations set forth in the paper noted above.

Traumatic action of Strongylus equinus, S. E. PARODI and V. WIDAKOVICH (*Rev. Zootéc.*, 6 (1919), No. 64, pp. 277-282, pls. 3).—A report upon the injury caused by this parasite.

The differentiation and distribution of the paratyphoid enteritidis group.— VI, Avian paratyphoid bacilli: A comparative study of B. pullorum and B. sanguinarium, F. W. MULSOW (*Jour. Infect. Diseases, 25 (1919), No. 2, pp. 135-162*).—The studies here reported, which are in continuation of the series previously noted (E. S. R., 40, p. 478), are summarized as follows:

"There is little exact knowledge at present concerning the distribution of *B. pullorum* and *B. sanguinarium*, but it appears that both cause considerable losses to poultry raisers in many parts of the United States. There has apparently been some confusion at times in differentiating *B. avisepticus* from

B. sanguinarium. B. avisepticus, however, may generally be distinguished from B. sanguinarium by its action in milk, indol production, fermentation of carbohydrates, agglutination reaction, and pathogenesis. B. pullorum and B. sanguinarium do not produce indol, generally form hydrogen sulphid in a lead acetate medium, and produce a temporary acidity in milk, but later alkali is formed. B. sanguinarium usually produces alkali in a shorter time than B. pullorum. The casein is digested by most strains of these organisms. As regards fermentation, B. pullorum produces acid and generally gas in several carbohydrates. B. sanguinarium produces acid but no gas in the same carbohydrates, and in addition produces acid in dulcite and maltose. There is some variation in the reactions in maltose. Some strains of B. pullorum produce slight amounts of acid after several days' incubation, and two strains have produced acid and gas quite promptly in maltose.

"Agglutination tests with these organisms have shown that there is an antigenic relation between these organisms and *B. typhosus*, *B. enteritidis*, and *B. abortus-equinus*. Such antigenic relations were not observed between these avian strains and *B. avisepticus*, *B. dysenteria*, *B. paratyphosus* A and B, *B. suipestifer*, *B. proteus*, and *B. coli*. Absorption tests will differentiate quite readily between *B. typhosus* and these avian strains. Agglutination and absorption tests with serums of rabbits immunized toward these avian types suggest an antigenic relation between *B. typhosus*, *B. enteritia*'s, and these avian strains.

"Feeding experiments indicate that laboratory cultures of these organisms will rarely produce an injurious effect on laboratory ani nals. Two freshly isolated strains of *B. sanguinarium* and one of *B. pullorum* were also fed to various animals without producing serious effects. It has been observed from inoculations that the rabbit is the most susceptible laboratory animal to the strains studied. It generally requires from 2 to 3 cc. of a 24-hour broth culture injected intraperitoneally to produce a fatal infection in a rabbit weighing about 2,000 gm. A few freshly isolated strains were not more virulent for rabbits, guinea pigs, mice, and rats than cultures kept in the laboratory for some time. *B. pullorum* and *B. sanguinarium* produce a toxin when grown under proper conditions which is quite poisonous to rabbits. The action of the toxin produced appears to be the same for the two strains.

"These avian strains may be differentiated from *B. typhosus* by their lack of motility, their fermentation reactions in rhamnose and sorbite, and absorption tests with immune serums. Serologic tests and certain fermentative reactions may be used to differentiate these organisms from *B. dysenteriæ*. They may be differentiated from other members of the paratyphoid enteritidis group by morphologic and cultural characteristics and serologic tests. *B. avisepticus*, as has been mentioned before, may be differentiated in many ways from *B. sanguinarium* and *B. pullorum*.

"B. pullorum may be distinguished from B. sanguinarium by the inability of the former to ferment dulcite, while the latter ferments this carbohydrate. Also, the former organism does not generally produce acid in maltose and generally produces gas in several of the carbohydrates. B. sanguinarium, on the other hand, generally produces acid promptly in maltose and does not produce gas in any of the carbohydrates. Rhamnose is fermented promptly by B. pullorum, while B. sanguinarium does not produce acid before 48 hours' incubation. It appears, therefore, that there are sufficient differences between B. sanguinarium and B. pullorum to regard them as separate types."

Lead poisoning in waterfowl, A. WETMORE (U. S. Dept. Agr. Bul. 793 (1919), pp. 12, pls. 2).—This is a report of studies of a serious affection of ducks and other waterfowl in the United States, intended for sportsmen, naturalists, and summary of the data here presented has

[Vol. 41

others interested in game birds. A summary of the data here presented has previously been noted from another source (E. S. R., 39, p. 687). The work was carried on in connection with investigations of duck sickness found to be due to the toxic action of certain soluble salts in alkalis, a report of which has previously been noted (E. S. R., 39, p. 460).

The author can offer no suggestions of a practical nature to alleviate this danger to waterfowl, which is due to eating shot. He has been able to effect a cure in a few individuals by treating them with magnesium sulphate.

The loco-weed disease, C. D. MARSH (U. S. Dept. Agr., Farmers' Bul. 1054 (1919), pp. 19, figs. 11).—This is a popular account in which the distribution, characteristics, and effects of loco weeds upon animals eating them are described, together with the proper methods of feeding and treating such animals.

## RURAL ENGINEERING.

Tests to determine pressures due to hydraulic fills, A. W. GOLDEECK (Engin. News-Rec., 80 (1918), No. 16, pp. 758-760, figs. 5).—Experiments on the use of the device employed by the Bureau of Public Roads of the U. S. Department of Agriculture for measuring the distribution of pressure through earth fills, to determine pressures due to hydraulic fills in reclamation dike and dam construction are reported. The tests consisted in filling a standpipe with finely divided clay in the same way that the core of a hydraulic fill dam is placed, and then measuring the horizontal and vertical pressures at various heights in the standpipe so as to obtain an idea of the pressure in the core of a dam at various stages of the fill.

"Briefly, the scheme of pressure measurement with this apparatus consists of the equilibration of the earth pressure acting on a sensitive cell by means of air pressure within the cell, detection of the instant of equilibration by the breaking of electrical contact within the cell, and reading the air pressure within the cell at that instant by means of an accurate pressure gauge."

"Readings and pumping have been continued . . . intermittently for a period of more than four months, and the mud line has been rising with a corresponding increase of pressure readings. There is a very noticeable difference in the consistency of the mud from top to bottom, that at the top being quite liquid and that at the bottom more viscous."

"The results seem to point to the reliability of the measuring apparatus for accurately measuring the pressures in such fills. In view of the fact that the cells function just as sensitively now as on the day they were buried in the fill, it would seem that they could very well be employed as a field apparatus for controlling the rate of construction and shape of cross section of hydraulic-fill dams."

Tables of cubic contents of levee embankments, A. A. STILES (*Tex. State Reclam. Dept. Bul. 5 (1917), pp. VII+212, pl. 1).*—Tables of data on the cubical contents of embankments and excavations are given as prepared by the Texas State Reclamation Department.

Factors for obtaining cubic yards on sloping cross sections from cubic yards on level cross sections, A. A. STILES (*Tex. State Reclam. Dept. Bul. 5A* (1918), pp. 25).—These tables were prepared by the Texas State Reclamation Department as a supplement to Bulletin 5 noted above.

Tables of velocity of water in open channels derived from Kutter's formula, A. A. STILES (*Tex. State Reclam. Dept. Bul.* 6 (1917), pp. VII+130).— Velocity tables are given based on Kutter's formula for different values of the coefficient or roughness n, as prepared by the State Reclamation Department of Texas. Latitude, longitude, and sea level elevation of bench marks in Texas, A. A. STILES (*Tex. State Reclam. Dept. Bul.* 7 (1917), pp. VI+284).—This handbook gives the location and elevation of bench marks established in Texas by the State Reclamation Department.

Report of hydrometric surveys (stream measurements) for the calendar year 1916, P. M. SAUDER, V. A. NEWHALL, and W. H. STOREY (*Dept. Int. Canada, Irrig. Branch, Rpt. Hydrom. Surveys, 1916, pp. 609, pls. 5, figs. 3*).—This report presents the results of measurements of flow made on streams, irrigation ditches, and canals in Alberta and Saskatchewan during 1916.

The phosphorus, potassium, and nitrogen content of the waters of the intermountain region, J. E. GREAVES and C. T. HIRST (*Jour. Indus. and Engin. Chem.*, 11 (1919), No. 5, pp. 451-454).—Determinations made at the Utah Agricultural College of the total potassium, phosphorus, and nitrogen in several hundred samples of water representing 58 streams in Utah, the majority of which are extensively used for irrigation, are reported.

The analyses indicate that "the quantity of potassium carried to the soil by one accre-foot of water varies from 2.2 to 133.8 lbs., the phosphorus from zero to 14.9 lbs., and the nitrogen from traces to 66.1 lbs. Although only a few of the waters analyzed were carrying sufficient phosphorus, potassium, and nitrogen to the soil to supply plants with the necessary quantities of the respective elements, yet it is evident in a number of cases that the quantity of plant food carried to a soil by the irrigation water is sufficient to assist in maintaining the fertility, for it is quite certain that where the waters are rationally used the quantity of potassium, phosphorus, or nitrogen carried to the soils exceeds that removed in the drain waters."

The biology of waterworks, R. KIRKPATRICK (*Brit Museum* [Nat. Hist.], Econ. Ser., No. 7 (1917), pp. IV+58, figs. 18).—The purpose of this pamphlet is to outline broadly the relation of natural history to water supplies. The main subjects dealt with are animals and plants that may be associated with water supplies and biology in relation to water purification.

Chlorination of water, J. RACE (New York: John Wiley & Sons, Inc., 1918, pp. VIII+158, figs. 28).—This book is a compilation of information on the various aspects and methods of water purification by chlorination.

Chlorinated lime and halazone in the disinfection of drinking water, B. FANTUS (Jour. Infect. Diseases, 24 (1919), No, 3, pp. 191-203, figs. 4).—Experiments to compare the value of chlorinated lime with halazone (p-sulphondichloraminobenzoic acid) as a disinfectant for drinking water led to the conclusions that "chlorinated lime is a more efficient water disinfectant than halazone, compared on the basis of active chlorin. It is . . . also a great deal cheaper. Hence there is no reason for employing halazone in water disinfection, excepting when its superior tablet-making qualities render its use advantageous."

Sterilization and purification of water with isotonic sodium hypochlorite solution, W. G. FRALICK (*Med. Rec.* [N. Y.], 93 (1918), No. 6, pp. 239, 240).— Experiments on the sterilization of water with isotonic sodium hypochlorite are briefly reported, from which the conclusion is drawn that water can be sterilized with small quantities of isotonic sodium hypochlorite solution and subsequently neutralized by the addition of peroxid of hydrogen. Water so treated was found to be sterile, free from taste, and palatable.

Loads on highway bridges (London: The Concrete Inst., 1918, pp. 39, pl. 1, figs. 31).—This is a report of a joint committee representing the Institution of Municipal and County Engineers and the Institution of Municipal Engineers, giving notes, diagrams, and a table of loads for highway bridges based on three bridge classifications.

Test tractive efficiency of concrete roads, E. N. HINES (Concrete [Detroit, Mich.], 14 (1912), No. 2, pp. 56, 57).—Tests in five counties in Michigan are reported in which a 2-ton truck loaded to capacity was driven over 238.25 miles of concrete, gravel, and dirt roads. The average speed in miles per hour was 16.4 for concrete roads, 9.5 for gravel roads, and 4.6 for dirt roads.

A 10-mile test of a 2-ton truck on a concrete road and on an ordinary country dirt, gravel, and sand road to determine relative gasoline consumptions showed that 1.25 gal. of gas and 42 minutes of time were required on the concrete, as against 2 gal. and 1 gill of gas and 1 hour and 24 minutes of time on the country road.

Concrete construction for rural communities, R. A. SEATON (*New York: McGraw-Hill Book Co., Inc., 1918, 2. ed., pp. XI+223, pl. 1, figs. 95*).—This is the second edition of this book (E. S. R., 36, p. 188), in which the specifications for Portland cement have been revised.

Absorption tests of slag, stone, and gravel concrete, O. R. SMITH (Concrete [Detroit, Mich.], 14 (1919), No. 4, pp. 144).—Comparative absorption tests of slag, stone, and gravel concrete showed that as far as absorption alone is concerned there was very little difference between the three types.

Determination of stresses in wire rope as applied to modern engineering problems, J. F. Howe (Jour. Amer. Soc. Mech. Engin., 40 (1918), No. 12, pp. 1016-1021, figs. 8).—This is a mathematical analysis of the stresses in wire rope, from which formulas for the strength of strands and the whole rope in static and moving tension, on inclines, under indirect or induced stresses and reverse bending, and suspended horizontally supporting a load are derived. It is the opinion of the author that specifications for wire rope should include a tension test, and possibly a bending and torsion test, but that an elongation test is unfair and untrue to actual conditions.

Concentrated load tests of yellow pine beams for shear, L. R. MANVILLE and C. R. HILL (*Engin. News-Rec.*, 83 (1919), No. 2, pp. 69-71, figs. 4).—Tests of long-leaf yellow pine beams are briefly reported, from which it is concluded that, with a concentrated load placed a distance from the end support of a beam equal to the depth of the beam, the beam will hold as much as the timber will stand in cross-grain bearing over the supports, and no horizontal shear failure may be expected.

It is recommended that for the strength of beams in horizontal shear values roughly 50 per cent greater than ordinary design unit stresses may be used, if the unit shear is computed by the usual method, and if heavy concentrated loads occur near the point of support or within about  $1\frac{1}{2}$  times the depth of the beam. "Design unit stresses in horizontal shear such as 120-lb. per square inch for long-leaf yellow pine appear to be very conservative for application to maximum end shear under concentrated loads, although no doubt within safe design limits with a load three depths of the beam from the support. This stress could be increased as recommended above for applied loads nearer the reaction. Timber inspected and graded under the rules proposed by the U. S. Forest Service, dated 1915, which would largely eliminate critical defects, may be used with higher unit stresses, especially in horizontal shear in which defects such as checks and shakes so often play an important part."

Prolonging life of farm timbers, J. B. BERRY (Ga. State Col. Agr. Circ. 66 (1917), pp. 8, figs. 6).—This bulletin deals briefly with the creosoting of farm timbers for their preservation. Posts, to be treated, must be peeled, removing the inner bark especially, and thoroughly seasoned. The temperature of the oil must be controlled within the limits of from 200 to  $220^{\circ}$  F., and should never exceed the latter. A deep penetration of the oil should be secured on the part of the post to go into the ground and for a foot above the ground.

Results of long-time tests of creosote treated fence posts, C. H. TEESDALE (*Engin. News-Rec.*, 82 (1919), No. 26, p. 1254).—Tests conducted by the Forest Service of the U. S. Department of Agriculture in cooperation with the University of Minnesota on over 2,000 fence posts treated and set during 1908 and 1909 are reported.

At the last inspection in 1918, 73.5 per cent of the basswood treated with coal-tar cresote and 78 per cent of that treated with water-gas-tar creosote were still sound. In the case of red oak 94.5 per cent treated with coal-tar creosote and 92.5 per cent treated with water-gas-tar creosote were still sound. It was found that the basswood posts did not take the treatment well, and for this reason this species is not recommended for open-tank treatment.

Fencing the farm, W. J. RUTHERFORD (Saskatchewan Dept. Agr. Bul. 51 (1917), pp. 12, figs. 10).—This bulletin gives general information on farm fencing, with special reference to Saskatchewan conditions.

With reference to posts it is stated that, "in all the tests that have been made with wood, round cedar posts 4 to 6 in. at the small end, cut green in December or January, peeled and seasoned, are the most durable, the life being about 18 to 20 years. The less sapwood the longer lived will be the post, other things being right. Creosoting timber helps to prolong its life. Split cedar posts are cheaper and, if creosoted, give very good satisfaction. Tamarack and spruce are used, but their life is not so long as cedar. Willow and poplar are constantly needing repairs and substitutions after 3 years of use."

It is also stated that a number of years of experiment with steel posts have proved them strong and durable.

"A very effective fence for all practical purposes, except the turning of coyotes and dogs, is the 8-strand 45 in. fabric with one barb wire placed 8 in. above. All these woven wire fabrics should be made of No. 9 gauge horizontals and 11 or 12 gauge uprights, the latter being placed 12 to 16 in. apart. The larger wire is stronger and is better galvanized, which means longer life for the fence and less repairing."

The Diesel engine: Its fuels and its uses, H. HAAS (U. S. Dept. Int., Bur. Mines Bul. 156 (1918), pp. VIII+133, pls. 16, figs. 57).—This report discusses recent developments in the design and construction of the Diesel engine, the fuels suitable for burning in it, and the uses to which it is particularly adapted, with special reference to medium and small power requirements.

With reference to economy, it is stated that although explosion oil engines are materially cheaper in first cost they consume considerably more fuel and lubricating oil than Diesel engines. Their fuel consumption at fractional loads also increases at a greater rate.

"The mechanical efficiencies of four-stroke engines at full load vary from 75 to 82 per cent, 80 per cent being usual for high-grade, low-speed engines of medium and large powers. The engine efficiency, exclusive of the air compressor, is 85 to 90 per cent. The mechanical efficiency of engines having a two-stroke cycle seldom exceeds 70 per cent and may be as low as 65 per cent in high-speed engines."

"The indicated thermal efficiency of the Diesel engine having a four-stroke cycle varies from 45 per cent at full load to 47 per cent at half load, and the effective thermal efficiency from 37 per cent at full load to 30 per cent at half load, which represents the best practice. As regards engines having a two-stroke cycle, the figures are 10 to 15 per cent lower."

"The volumetric efficiency of engines having a two-stroke cycle is generally below unity. For slow-speed four-stroke engines a volumetric efficiency of 90

144402°-19---7

per cent can be reached, which decreases to 85 per cent for high-speed engines, and for extreme speeds may be even lower. These values presuppose highgrade engines with mechanically operated values."

With reference to the effect of high altitudes, it is stated that the horsepower rating of a Diesel engine decreases 3 per cent for every 1,000 ft. of added altitude.

"The high commercial value of the Diesel engine lies in its unsurpassed fuel economy and in its ability to burn low-priced liquid fuels with high boiling points. This great fuel economy is not confined merely to medium or large sized units, for the smallest engine has nearly the same fuel economy as the largest."

Data are given which indicate "that although the absolute fuel price for fuel oil may be several times higher than that of coal in the same market, power may be generated more cheaply with the Diesel than with the steam engine."

The disadvantages of Diesel engines are stated as high consumption of lubricating oil and high installation cost, including heavy foundations.

Length of motor truck stop varies inversely as braked load (*Engin. News*-*Rec.*, 81 (1918), No. 18, pp. 799, 800).—Braking tests conducted by G. W. Smith of motor trucks and automobiles on a concrete road having a thin coating of oily dust showed the advantage of concentrating a large proportion of the load on the braked wheels. It was found that the coefficient of friction for rubber tires on dry paving was from 0.475 to 0.53. With a uniform speed of 20 miles per hour the shortest stops were made by trucks having a relatively high percentage of the total weight carried by the rear or braked wheels, while the longest stops were made by a touring car with relatively light wheel loading.

A second set of tests by L. D. Hemman, in which solid rubber tires were used for 3, 2, and 0.5 ton trucks and pneumatic tires for the automobile, showed that skidding of light trucks took place on wet asphalt when the brakes were applied with a uniform speed of 15 miles per hour. When the asphalt was very wet with a slight coating of sloppy snow, the skidding tendency of the lighter machines was greatly increased, while the larger trucks skidded only 2 or 3 feet out of line.

Important and neglected features of tire maintenance, A. F. MASURY (*Engin. News-Rec.*, 82 (1919), No. 26, pp. 1262–1264, figs. 5).—Data are reported showing that for large motor trucks tire cost and fuel cost are normally about equal. On lighter trucks the tire cost is slightly less than the fuel cost unless pneumatic tires are used, when the tire cost will slighly exceed the fuel cost. In this connection a warning is given against overloading, overspeeding, neglecting cuts and tears, spinning, skidding, and sliding the wheels, and wheel misalignment.

**Directory** and specifications of farm tractors (*Farm Machinery*, No. 1442–1443 (1919), pp. 16, 108).—This directory contains data on 253 farm tractors of 170 different makes.

Mole plows worked by horses (*Jour. Bd. Agr. [London], 25 (1918), No. 1, pp. 36-40, figs. 5*).—Drawings showing the details of mole plows in use for draining land quickly are given.

A barn for the small farm, H. H. MUSSELMAN (*Michigan Sta. Quart. Bul.*, 2 (1919), No. 1, pp. 32-34, figs. 2).—A ground plan and some construction details for a barn for a small farm keeping from 2 to 4 horses and 10 to 15 cows are given.

Practical hog houses for Indiana, C. A. NORMAN and J. W. SCHWAB (Purdue Univ., Dept. Agr. Ext. Bul. 76 (1918), pp. 8, figs. 12).—This bulletin gives draw-

ings and brief specifications for individual and centralized hog houses prepared with reference to Indiana conditions.

Silos and silage in Arkansas, H. E. DVORACHEK (Arkansas Sta. Bul. 164 (1919), pp. 3-16).—This bulletin discusses the various types of silos in common use, and gives general information on their construction with special reference to Arkansas conditions.

Stall construction, H. H. MUSSELMAN (*Michigan Sta. Quart. Bul.*, 2 (1919), No. 1, pp. 35, 36, fig. 1).—The details of construction of a cow stall built of concrete, steel, and wood are illustrated and briefly described.

Greenhouse heating, A. G. KING (Dom. Engin., 88 (1919), No. 8, pp. 340-342, figs. 5).—Information is given on estimating for and installing heating apparatus for greenhouses, including diagrammatic illustrations.

Cost of and revenue from electric heating on the Minidoka project, B. DIBBLE (*Reclam. Rec.* [U. S.], 10 (1919), No. 2, pp. 78-81).—This is an analysis of the cost of domestic electric heating for all the towns and isolated residences on the Minidoka irrigation project using power supplied by the project generating station.

"The indications are that electricity at \$2 per month per kilowatt will compete with coal at \$8 per ton. It has been found on the Minidoka project that the average season for the heating load is from five to six months. In other words, the total consumption of electricity for heating is equivalent to five or six months' continuous use of the maximum demand. Therefore a retail revenue can be expected from this business of from \$10 to \$12 per kilowatt per season."

"It can be said that electric heating is sometimes justified as a 'by-product' load, but that rarely, if ever, will it be economically feasible to develop electricity from water power for the prime purpose of using it generally to heat buildings where fuel can be obtained at reasonable prices."

Analysis of electric cooking situation, S. M. KENNEDY (Elect. World, 72 (1918), No. 8, pp. 351, 352).—An analysis of the electric cooking load of a central station in southern California supplying over 3,000 electric ranges, of which 95 per cent are in private houses, showed that (1) the electric cooking load is a desirable load, (2) the electric range is satisfactory to its consumers, and (3) electric cooking service is along the lines of conservation of both food and fuel. The average annual bill for electric cooking on this system is said to be about \$45, and for combination cooking and water heating the average is \$75.

The relative merits of cast-iron, wrought-iron, and steel pipe for house drainage purposes, W. P. GERHARD (Jour. Franklin Inst., 187 (1919), No. 1, pp. 99-109, figs. 8).—Fracture, threading, corrosion, acid, manganese, and microscopic tests of cast-iron, wrought-iron, and steel pipe were conducted from which it was found that "extra heavy cast-iron soil pipe is a satisfactory material from the corrosion point of view. It is unsatisfactory as regards the calked joints. These become affected by changes in temperature, and do not remain tight under all conditions of service. The screw joint of welded pipe is superior to the calked joint, provided the threads are so cut and the recessed drainage fittings so tapped that the pipe can be screwed well into the shoulder of the fitting. Portions of the thread remaining exposed to view should be protected against external corrosion. The evidence furnished by the investigation leaves no doubt as to genuine wrought-iron pipe being a far more durable material for house drainage purposes than steel pipe."

Rural methods of waste disposal, H. D. EVANS (Bul. State Dept. Health Maine, n. ser., 2 (1919), No. 1, pp. 24, figs. 12).—This bulletin deals briefly with design and construction of sanitary privies, sewage tanks, and absorption areas, with special reference to Maine conditions. The pail privy is considered to be better than the tight-vault privy or the biological privy in that its contents can be more easily and safely disposed of. The biological privy is considered of little use under Maine conditions.

**Rural drainage**, T. J. LAFRENIÈRE (*Bul. Sanit. Quebec*, 18 (1918), No. 1, pp. 170–183, figs. 7).—This report deals briefly with sewage disposal on farms and in rural communities in the Province of Quebec, and gives drawings and brief specifications for sanitary privies and disposal systems consisting of sedimentation tanks and tile absorption areas.

The treatment of sewage from single houses and small communities, E. B. PHELPS (*Pub. Health Rpts.* [U. S.], 34 (1919), No. 7, pp. 271-276, pls. 2, figs. 2).— Experiments on the disposal of residental and institutional sewage are reported. The institutional sewage flow was 100 gal. per capita, and in parts per million contained 7.9 parts ammoniacal nitrogen, 20.4 parts organic nitrogen, and 981 parts total solids, and had an oxygen demand for 24 hours at 20° C. (68° F.) of 121 parts per million. The residental-sewage flow was 21 gal. per capita, and contained 48 parts ammoniacal nitrogen, 65 parts organic nitrogen, and 1,360 parts total solids per million, and had an oxygen demand of 263 parts per million.

Experiments with preliminary tank treatment were confined to the biolytic tank and the Imhoff tank. The latter was found particularly well adapted to the existing requirements. An average removal of 91 per cent of the settleable solids was obtained with the residental sewage and 97 per cent with the weaker institutional sewage.

Experiments with sand filters showed that with moderately course sand having an effective size of 0.35 mm. the area required varied with the dilution of the sewage. About 30 sq. ft. of superficial sand area per capita was required for the residental sewage and 45 sq. ft. for the institutional sewage. Sand layers 24 in. in depth were satisfactory.

Experiments with trickling filters comprised studies of distribution and filter materials. It was found that the lath filter with tipping distributor possessed advantages over all other types tested. This filter is described in detail and illustrated.

"The filter proper ... is built up of layers of ordinary laths, the laths of adjacent layers lying at right angles to one another and those of each layer being parallel and spaced with clear openings of 3 in. Closer spacing down to  $\frac{3}{4}$  in. yielded less satisfactory results. The laths of each layer are also so spaced that they come over the center of the open space in the second layer below. A filter depth of 6 ft. yields an effluent of high degree of oxidation, and one of 3.5 ft. yields an effluent sufficiently oxidized to satisfy the requirements of most situations. A total filter volume of 8 cu. ft. per capita is required."

"The performance of this filter is much superior to that of a good trickling filter of stone, and in 6 ft. depths, with subsequent sedimentation, is approximately equal to that of a well-operated sand filter 2 ft. in depth."

Sewage disposal, E. D. RICH and F. G. LEGG (*Mich. State Bd. Health Engin. Bul. 11 (1917)*, pp. 24, figs. 14).—This is a nontechnical discussion of the subject of the treatment and removal of liquid wastes, prepared for the guidance of the governing bodies of the smaller communities.

Sewage disposal, L. P. KINNICUTT, C. E. A. WINSLOW, and R. W. PRATT (New York: John Wiley & Sons, 1919, 2. ed., pp. XVII+547, figs. 141).—This is a second edition and complete revision of this work (E. S. R., 24, p. 616) in which the authors have attempted to introduce new data and recent viewpoints in connection with all the topics treated.

In particular the chapters on screening, sludge disposal, and chemical precipitation have been entirely reconstructed and much enlarged. A discussion of the Miles acid process is included in connection with chemical treatment. New chapters have been added treating of the newer processes of two-story tank treatment and purification by means of activated sludge. New chapters have also been added which discuss, respectively, the broad principles underlying the selection, design, and operation of a sewage treatment plant and the disposal of excretal wastes from houses and institutions which are not connected with sewerage systems.

A new form of septic tank, DEW. H. WYATT (*Dom. Engin.*, 87 (1919), No. 9, pp. 379, 380, fig. 1).—A new form of septic tank for private sewage disposal in rural districts is described and diagrammatically illustrated which is made entirely of vitrified pipe shapes.

Grease interception from house sewage, H. J. BELMONT (Dom. Engin., 88 (1919), No. 6, pp. 249-251, 285, figs. 5).—Information is given on the construction of grease traps, together with drawings of approved types.

**Treatment and disposal of creamery wastes, E. B.** PHELPS (*Pub. Health* Rpts. [U. S.], 33 (1918), No. 49, pp. 2169–2174, pl. 1).—Experiments conducted in cooperation with the Dairy Division of the U. S. Department of Agriculture on the purification and disposal of creamery sewage are reported. This sewage consisted of wastes from washing cans and cleaning and rinsing churns, together with a small amount of milk, cream, and buttermilk spilled on the floor. The experimental disposal plant as used consisted of a septic tank and two sand filters.

"In May, 1916, the plant was put in operation, the sand filter being operated at a nominal rate of 25,000 gal. per acre per day, and the septic tank on the basis of a 12-hour storage period. The results of the operation were excellent almost from the start. During July the nominal rate of filtration gradually increased to approximately 70,000 gal. per acre per day, at about which point it was maintained throughout the investigation. With the advent of cold weather a noticeable reduction occurred in the degree of nitrification, and a somewhat less marked effect was shown by the relative stability and oxygen demand values. The degree of purification was always satisfactory for discharge into a comparatively small volume of diluting water in cold weather, and the spring of 1917 brought with it increased biological activity and resulting improvement in quality of the effluent. A noticeable and quite unexpected result was the complete neutralization of the characteristic acidity of the settled wastes, the average values for 18 months being 226 parts per million of acidity in the settled waste and 356 parts per million of bicarbonate alkalinity in the filter effluent."

"The results of this investigation indicate the entire feasibility of satisfactorily treating creamery wastes." "It has been demonstrated that plain sedimentation is a satisfactory tank treatment preliminary to sand filtration, and that . . . a disposal plant may readily be designed for satisfactory treatment of creamery wastes."

On the basis of these experiments brief specifications for a disposal plant are given as follows:

"The settling tank should have a net capacity of about one day's output of the creamery. It should have one or more hopper bottoms with side slopes of  $45^{\circ}$  and a sludge outlet pipe running nearly to the bottom. The total depth from water line to sludge outlet should be about 12 ft. There should be a vertical bottom baffle extending 3 ft. above the upper edge between each two hoppers, and scum baffles extending 5 ft. into the liquid over the center of each hopper. The entire tank should be covered with a tight board cover. The effluent from the tank should overflow to a siphon chamber having a capacity of not less than one nor more than six hours' output of waste. This chamber should be provided with an automatic siphon discharging to the filter beds.

"The sand filters should have an area of about 725 sq. ft. per 1,000 gal. daily output of waste.... The upper layer should be composed of 3 ft. of clean fairly coarse sand, such as would be suitable for concrete. This sand should be laid upon an underdrain system composed of parallel or radiating lines of agricultural draintile, suitably embedded in coarse stone graded upward to fine stone and gravel to exclude the upper sand layer. This filter should be divided into not less than 2 and preferably 4 units, with suitable arrangement for diverting the flow to one or another. The units should be used in rotation."

Construction and care of fish ponds, R. C. OSBURN (Mo. Bul. Ohio Sta., 4 (1919), No. 7, pp. 215–220, figs. 4).—This article, a contribution from the department of zoology and entomology, Ohio State University, deals primarily with the construction and care of farm fish ponds, with special reference to Ohio conditions.

It is stated that the greatest depth should not be less than 5 or 6 ft., and that there should be an ample area of shallow water around the edge of the pond from 1 to 2 ft. in depth where weeds will grow thickly. This should have some gravely and sandy areas. The shallow area should be at least half that of the pond. It is stated that in Ohio almost any unpolluted source of water supply will be satisfactory.

The question of stocking with fish is also discussed.

## RURAL ECONOMICS.

**Rural, social, and economic problems of the United States,** C. J. GALPIN and A. B. Cox (*Amer. Assoc. Agr. Leg. Bul. 3* (1919), pp. 2+16).—This is the third of a series of studies published by the American Association for Agricultural Legislation. It consists of a catalogue and summary of about 150 answers to a letter requesting a statement of the chief rural, social, and economic problems sent to a selected list of persons interested in, and acquainted with, agricultural problems.

The proceedings of the First National Country Life Conference (Proc. Nat. Country Life Conf., 1 (1919), pp. 238) .-- In this volume are included a summary of conclusions of committees and the following papers on subjects relating to rural problems heard at the conference held at Baltimore, Md., January 6 and 7, 1919: The Work of the Committee on Country Life, by K. L. Butterfield; Home Service of the Red Cross—Its Significance as an Experiment in Rural Social Work, by J. F. Steiner; Community Councils: Their Present Work; Their Future Opportunity, by E. D. Smith; The County Farm Bureau: A New Factor in Rural Life, by A. B. Graham; The Present Crisis and Future Needs of Rural Education, by H. W. Foght; The Present Demand for Improvement in Rural Government and Needed Legislation, by E. C. Branson; Better Organization for Rural Social Service, by H. I. Curry; Realignment of Religious and Moral Forces for Country Life, by W. H. Wilson; The New Appreciation of Play and Recreation in Rural Life, by E. C. Lindeman; The Problem of the Changing Rural Home, by G. L. White; The Enlistment of Trained Leadership, by W. J. Campbell; Investigation and Teaching of Rural Social Problems, by C. J. Galpin; A Cooperative Plan of National Rural Research (E. S. R., 40, p. 890); The Federation of Country Life Forces, by E. L. Morgan: The Social effects of Improved Communication in Rural Life, by J. M. Gillette; and Internationalizing the Country Life Movement, by K. L. Butterfield, et al. In appendixes are a report of the conference on country life interests held at Washington, November 16 and 17, 1917, reprints from

addresses by E. Davenport (E. S. R., 39, p. 703), K. L. Butterfield, and E. D. Sanderson before the American Association of Agricultural Colleges and Experiment Stations, and the report of community council work during the period of demobilization and readjustment and the permanent organization of communities.

Report of conferences of national organizations engaged in rural social work (*Rpt. Conf. Nat. Organ. Rural Soc. Work* [*Nat. Country Life Assoc.*], 1919, pp. 16).—The conferences held at Washington, D. C., March 14 and April 10, 1919, in accordance with a resolution adopted by the conference noted above, outline social needs of rural communities and means of meeting them, with the presupposed economic and political bases, and report a plan of organization for practical application of principles involved.

First rural life conference of the Rural Welfare League of Texas (Bul. Agr. and Mech. Col. Tex., 3. ser., 5 (1918), No. 7, pp. 76).—Lectures on several phases of rural church problems and land tenure and marketing of farm products are published in the report of this conference.

Summaries of evidence taken before the Agricultural Policy Subcommittee appointed in August, 1916, to consider and report upon the methods of effecting an increase in the home-grown food supplies, having regard to the need of such increase in the interests of national security (*Min. Reconstr.* [Gt. Brit.], Reconstr. Committee, Agr. Policy Subcommittee, Summaries Evidence, 1918, pp. IV+129, pls. 2).—Evidence heard in the preparation of the report discussed editorially (E. S. R., 39, p. 402) is here summarized.

Rural community life in the Haute Marne, E. G. BISHOP (*Studięs Sociol.* [Univ. South. Cal.], 3 (1919), No. 4, pp. 8).—This gives an account of village life, industries, and methods of agriculture as the author found them in the remote sections of France in 1918.

Agricultural organizations in Spain, C. L. JONES (U. S. Dept. Com., Com. Rpts., No. 154 (1919), pp. 26-34).—This article reviews briefly efforts to encourage the agriculture of Spain by organization and education. It covers the history and functions of chambers of agriculture, farmers' communities, agricultural syndicates, rural treasuries, and various important unofficial and unique federations. Several flourishing local Catholic agrarian federations and the Association of Spanish Agriculturists are noted.

The agricultural festival in Moncloa (Inform. Agr. [Madrid], 9 (1919), No. 196, pp. 217-220).—In this report of a congress held under the direction of the Association of Spanish Agriculturists and the National Catholic Agrarian Federation, there are summarized several addresses on the promotion of Spanish agriculture. The recommendations offered by these two organizations relating to legislation, marketing, credit facilities, and cooperation, and by the General Association of Stockmen of the Kingdom regarding production and marketing of live stock and live-stock products are published.

The twenty-first annual report of the Director of the Swiss Union of Peasants, 1918 (*Pubs. Sec. Paysans Suisses No. 58 (1919)*, *pp. 10-55*).—In these pages of this report are outlined certain projects and investigations of an economic character for alleviating the shortage of agricultural products in Switzerland.

Report of the committee of Section IV of the Advisory Council on the employment on the land of returned sailors and soldiers (*Min. Reconstr.* [Gt. Brit.], Rpt. Committee Sect. IV Advisory Council, [1918], pp. 39).—The recommendations of this committee cover questions of housing, the acquisition of land, small holdings, training, wages and employment, the case of disabled men, trade organization, village life, and voluntary effort and private enterprise, often reiterating and supporting those included in the Agricultural Policy Subcommittee Report (E. S. R., 40, p. 91). There is also included a minority report by R. V. Lennard.

The soldier colonists, W. H. WARMAN (London: Chatto & Windus, 1918, pp. XI + 180).—The introduction to this has been written by the Earl of Selborne, and two chapters included by C. Brooks. Historical instances of group settlement and the early theories of E. G. Wakefield are discussed in approaching the subject, also the principles of organization, psychology, and cooperation upon which systematic migration within the British Empire must be undertaken. On the practical side, the author has included a survey of the offers of overseas dominions of land for settlement, and suggestions for advance and headquarters organization for the project, State representatives, district inspectors, group leaders, and others. He reviews much of the Tennyson Committee's Report in chapters on women and religion and shipping and finance.

List of references on women in agriculture, C. R. GREEN (Spec. Libraries, 10 (1919), No. 5, pp. 138-145).—This bibliography was prepared by the library of the Massachusetts Agricultural College, the references being classified under the following headings: General, beekeeping, dairying, education, forestry, horticulture, mechanics, poultry, bibliography, fiction, history, and organization.

[The new laborers' code regulating labor in Germany] (Abs. in Mo. Rev., U. S. Labor Statis., 9 (1919), No. 1, pp. 235-237; Internat. Inst. Agr. [Rome], Internat. Rev. Agr. Econ., 10 (1919), No. 4, pp. 237, 238; Jour. Bd. Agr. [London], 26 (1919), No. 4, pp. 453, 454).—In these publications appear abstracts of the provisions of an ordinance agreed upon by the largest agricultural employment and workers' organization in Germany, and made legal by a decree issued by the people's commissioners and the minister of labor.

One-third-share farm rent, A. BECKERICH (Ann. Sci. Agron., 4. ser., 8 (1919), No. 4-6, pp. 97-106).—Information taken from early French lease contracts based on this system is cited, and tables showing the marked fluctuations in harvests and prices of grains, etc., through a period of years are given to illustrate the equal fairness of share-rent systems in times of good harvests and bad.

Farm management, J. H. ARNOLD (New York: The Macmillan Co., 1919, pp. [6]+243, pls. 10).—This is a general discussion of the principles of selection of the farm, management of soil and crops, problems of time, seasons, power, and marketing in their relation to crops, advantages of and profits from live stock, farm organization and business methods, factors in efficiency, and farm administration.

How to cultivate an agricultural holding, R. VUIGNER (Comment Exploiter an Domaine Agricole. Paris: J.-B. Baillière & Sons, 1917, 2. ed., rev. and enl., pp. 640, figs. 4).—This volume of the Encyclopedia of Agriculture, published under the direction of G. Wery, is a collection of brief treatises based upon the principles of the science and practice of agriculture promulgated in France by the National Institute of Agronomy. The subjects included are soil management, the production of edible and industrial plants, live stock, certain agricultural industries including distilling and wine pressing, sugar refining, and butter and cheese making, laws dealing with holding and cultivation of rural property, and other economic and social phases of agriculture.

Cooperation for farmers, L. SMITH-GORDON (London: Williams & Norgate, 1918, pp. XIV+247).—The development of cooperation for consumers and agriculturists on the Continent and in Ireland is discussed historically. Difficulties of the system when applied to agriculture, types of consumers' cooperation, producers' societies, and credit societies are discussed, and the progress of the cooperative movement in Denmark, Ireland, and the United States, the attitude of the various governments toward it, and the future of the movement are described in detail.

Cooperation in the new world, L. SMITH-GORDON (Better Business, 4 (1919), Nos. 2, pp. 81-97; 4, 249-255).—The first of these articles gives an account of the peoples' banks of Quebec, credit unions of Massachusetts, the remedial loan associations under management of the Russell Sage Foundation, the Jewish credit societies, and credit unions of North Carolina. The second is a summary of the series of articles reporting the author's visits to farmers' cooperative societies in America (E. S. R., 40, p. 591). His final comment is that American cooperation has been largely built up upon the agricultural supply business and the marketing of produce, in which latter sphere there is an advance over anything in other countries and that the chief criticism of the movement as a whole in the United States is its weakness in regard to federation. He points out also that a wide field exists for international cooperative action.

The cooperative marketing of live stock (Agr. Gaz. Canada, 6 (1919), No. 7, pp. 635-646, figs. 4).—Brief reports of the work in Nova Scotia, Quebec, Ontario, Saskatchewan, and Western Canada are given to show the progress of this form of farmers' cooperation.

The cooperative societies for bringing land under cultivation, M. L. TARDY (Compt. Rend. Acad. Agr. France, 15 (1919), No. 2, pp. 79-92; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Agr. Econ., 10 (1919), No. 1-2, pp. 30-35; Sect. Jour. Agr., 2 (1919), No. 3, pp. 422, 423).—This reports the author's inquiry into the work of cooperative cultivating societies in various districts of France in increasing agricultural production and bringing about certain social and economic reconstruction.

Municipal markets in cities having a population of over 30,000, 1918 (*Washington: Bureau of the Census, 1919, pp. 56*).—Data are presented in general tables and in the text relating to them showing organization, classes of employees, areas and buildings, rentals and methods of operation of markets, and regulations and various laws concerning public markets, together with the revenues, costs, and valuations of this enterprise at the close of the year 1918.

Geographical phases of farm prices: Oats, L. B. ZAPOLEON (U. S. Dept. Agr. Bul. 755 (1919), pp. 28, pls. 2, fig. 1).—This study of farm prices of oats is similar in plan to one relating to corn, previously noted (E. S. R., 39, p. 895). Price maps showing sectional differences in farmers' prices of oats, based on averages by counties for the five years, 1910–1914, and the relative importance of different parts of the United States in the production of oats according to the census of 1909 are given; also statistics for the disposition of the crops, farm consumption, commercial movement, influence on price of trade routes and commercial centers, a retrospective view of farm prices of oats, 1871–1915, local price factors, trends of yields, values to the acre, geographical differences in prices, cost of production, and miscellaneous data.

The sugar question and the resupplying of France during the period 1914-1917, H. REMY (La Question des Sucres et le Ravitaillement de la France pendant la Période 1914 à 1917. Paris: Libr. Soc. Rec. Sirey, 1917, pp. 172).—This is a study of production and prices of beet and cane sugar. It reviews the movement of sugar upon the world market and the production and consumption of this commodity in France between 1841 and the years immediately preceding the outbreak of the war. A detailed account is given of State intervention and the various means adopted to secure a supply in France and the foreign countries. In this connection information relating to conditions in Germany is taken from an Abstract of German Economic Legislation During the Present War by T. Reinach. [Agriculture in Alaska] (In Alaska, "Our Frontier Wonderland," 1919. Seattle, Wash.: Alaska Bur., Seattle Chamber Com. and Com. Club, 1919, 7 ed., rev., pp. 73-90, figs. 12).—This section of this pamphlet describes the grain crops and grasses, vegetables, wild and cultivated fruits, wild flowers, forests, and live stock in Alaska and offers information and suggestions to homesteaders.

Statistical report of the California State Board of Agriculture for the year 1918 (*Statis. Rpt. Cal. Bd. Agr., 1918, pp. XXII+477, pls. 14*).—Detailed statistics relating to population, public lands, fruits, farm crops, live stock, irrigation projects, and the value of crops and lands are continued for 1918.

Agricultural statistics of Canada (Canada Census Indus., 1917, pt. 1, pp. XIV+47+XIII, figs. 4).—In these tables are assembled the actual agricultural statistics collected in four agricultural Provinces, and the annual estimate for the Dominion as a whole, relating to field crops, prices of agricultural products, wages of farm help, farm live stock, and agricultural exports and imports, together with comparative figures for previous years and data selected from agricultural statistics of other countries.

[Field crop and live stock report of Canada for 1917], J. H. GRISDALE (Canáda Expt. Farms Rpt. 1918, pp. 5-7).—Data previously noted (E. S. R., 40, p. 792) are continued. According to this report the total value of Canada's field crops for the year was \$1,144,636,456, an increase of more than a quarter of a million dollars over the figures for 1916.

Summary of the present condition of agriculture in Chile, F. R. HUNEEUS (Reseña Sumaria del Estado Actual de la Agricultura en Chile. Santiago de Chile: Min. Indus. y Obras Pub., Dir. Gen. Serv. Agr., 1919, pp. 48, pl. 1).—The character of the country is described by regions, and information relating to areas sown to different crops, fertilizer resources, extent of irrigation, use of agricultural machinery, notes on the cultivation and yield of each of the principal crops, the number and classes of live stock, etc., are given.

[Agricultural statistics of Chile] (Statis. Abs. Chile, 1918, pp. 76-91).— Data previously noted (E. S. R., 38, p. 495) are continued for the year 1917.

[Agricultural statistics of Colombia] (An Estadis. [Colombia], 1915, pp. 121-176).—These pages show the acreage, production, and value of the principal crops for the year 1915 by departments with summaries, also the number and classes of animals.

General abstracts showing the acreage under crops and the numbers and descriptions of live stock in each county and province, 1916–1918 (*Dept. Agr. and Tech. Instr. Ireland, Agr. Statis. 1918, pp. 37*).—Information previously noted (E. S. R., 34, p. 291) is continued for 1916, 1917, and 1918.

Acreage and live stock returns of Scotland, with a summary for the United Kingdom (Agr. Statis. Scotland, 6 (1917), pt. 1, pp. 53).—This annual report continues information previously noted (E. S. R., 40, p. 194).

[Agriculture in Norway] (Statis. Aarbok Konger. Norge, 38 (1918), pp. 25-37).—These pages continue data under the same plan as previously (E. S. R., 39, p. 896).

[Agriculture and live stock in Sweden] (Sveriges Off. Statis., Jordbr. och Boskapsskötsel, 1915, pp. VIII+157).—This annual report continues information previously noted for 1914 (E S. R., 37, p. 191).

Finland's farms and farm life, T. HAYNES (U. S. Dept. Com., Com. Rpts., No. 167 (1919), pp. 378-383).—The author reviews briefly some primitive aspects of farm life in Finland, matters of land holding, private initiative and Government aid, and the establishment of agricultural schools, etc., and gives some statistics for the crops of recent years and the development of the buttermaking industry.

Area, classification of area, area under crops, live stock, land revenue assessment, and transfers of land in British India [and in certain native States], G. F. SHIRBAS (Agr. Statis. India, 33 (1916-17), I, pp. XVI+321, pls. 6; II, pp. IX+116, pl. 1).—The first volume of this report continues statistics previously noted (E. S. R., 39, p. 896), with some additional maps and charts relating to cropped areas, rainfall, etc. The second volume continues other statistical information (E. S. R., 40, p. 793).

#### AGRICULTURAL EDUCATION.

Proceedings of the thirty-second annual convention of the Association of American Agricultural Colleges and Experiment Stations, 1919, edited by J. L. HILLS (*Proc. Assoc. Amer. Agr. Cols. and Expt. Stas.*, 32 (1919), pp. 272).— These proceedings have been previously noted (E. S. R., 39, p. 701).

First and second annual reports of the Department of Vocational Education, 1917–1919, I. COLODNY (Bul. State Bd. Control Vocat. Ed. [Ariz.], No. 4, (1919), pp. 19).—According to this report three high schools and one normal school qualified and participated in Smith-Hughes funds for instruction in agriculture in 1917–18. Of the 30 high schools in the State, only 5 made any effort to teach agriculture. The total number of pupils attending Smith-Hughes classes in agriculture was 112, or only about 20 per cent of the boys attending high schools in strictly agricultural communities.

Approval was given to 5 day schools in home economics. The number of students enrolled in Smith-Hughes classes in home economics was 215 out of a total enrollment of 2,096 in schools approved for home economics.

The University of Arizona enrolled teacher-training classes in the home economics department in 1917–18 and 1918–19, but no students in agriculture. In 1918–19 seven schools qualified in agricultural instruction under the

Smith-Hughes Act, with an enrollment of 129. Two conferences of agricultural teachers were held, at which home-project work and the distinctive features of vocational agriculture were discussed. Five high schools with an enrollment of 128 pupils were subsidized for home-economics instruction. An opportunity school was organized April 5, 1919, by the Department of Vocational Education, in conjunction with the city schools of Phoenix. The most satisfactory work in home economics was done in the evening schools.

Regulations and suggestions concerning county agricultural high schools of Mississippi (*State Bd. Ed. Miss. Bul. 12 (1919)*, *pp. 54*).—This publication contains an outline of the course of study of the Mississippi county agricultural high schools, and of the regulations which become effective in the 1919–20 school session; a list of adopted textbooks; questions and answers relating to the establishment and administration of these schools; agricultural high school laws in Mississippi; and suggestions concerning the course of study in home economics to meet the need of a more uniform and better standard of work in the schools.

It is suggested that three units of home economics, given in either a 3 or 4 year course, be the minimum for graduation. The minimum time required for the ordinary high school unit, viz, five 40-minute recitations a week for 32 weeks, is acceptable, but it is urged that five 45-minute recitations for 36 weeks be adopted. The consensus of opinion seems to be that the strongest arguments are in favor of putting home economics instruction in the first, second, and fourth year of the agricultural high school course. An outline is given of the suggested course.

Agricultural education, H. W. POTTS (*Richmond*, N. S. Wales: Hawkesbury Agr. Col., [1918], pp. 8).—The author describes the facilities for agricultural instruction at the Hawkesbury Agricultural College, Richmond, New South Wales. He states that the total number of students who have passed through the college since its inception, and who have pursued a course of training in farming and live stock, is 2,037. At least 78 per cent of these are putting their training into practice on the land or occupying responsible positions associated with rural pursuits. A total of 621 rural teachers have taken the summer course in nature study, elementary agriculture, school gardening, etc., and 2,180 pupils and 180 teachers have attended the rural camp schools, held under the direction of the department of public instruction with the object, especially, of interesting children in country occupations. In the 12 years since its establishment in 1905, the farmers' winter school has been attended by a total of 1,055 practical farmers.

Itinerant instruction, B. CARQUEJA (Bol. Sec. Estado Agr. [Portugal], 1 (1918), No. 2-4, pp. 95-101).—A brief account is given of the development of movable schools of agriculture in Portugal since the organization of the first school of this kind in 1901.

The present status of itinerant instruction in Algarve, M. PAIS DA CUNHA FORTES (Bol. Sec. Estado Agr. [Portugal], 1 (1918), No. 1, pp. 5-21).—This is an account of the present status and some results of the work of the movable schools of agriculture in the province of Algarve, Portugal, with brief notes on such schools in other countries.

Movable schools of agriculture organized by the Journal of Commerce of Porto (Bol. Sec. Estado Agr. [Portugal], 1 (1918), No. 2-4, pp. 102-111).—The aims, organization, and course of instruction by months, of movable schools of agriculture in Portugal are outlined.

Training of discharged soldiers and sailors (*Scot. Jour. Agr.*, 1 (1918), No. 3, pp. 346-349).—Brief outlines are given of various schemes, prepared and put into operation by the Board of Agriculture for Scotland in conjunction with the Ministry of Pensions, for the training of discharged soldiers and sailors in forestry, gardening, and agriculture.

Training in farm and garden work in reformatory and industrial schools, J. O. PEET (London: Bd. Ed. [Gt. Brit.], 1919, pp. 16).-This report gives some account of the systems of land management and the methods of training boys in agriculture and horticulture practiced at the 12 reformatory and industrial farm schools in Great Britain visited by the Chief Inspector of Reformatory and Industrial Schools of the Board of Education, and presents some general conclusions with regard to the needs and development of the work of the schools. Attention is called especially to the importance of regarding institutions possessing farms as places of training for future land workers, rather than as places of detention to be made as far as possible self-supporting; the need of more and better qualified instructors and of improved equipment, closer coordination between the school work and the practical work and the development of theoretical instruction concurrently with the instruction in the field or the garden, the preparation of properly graded schemes of training in agriculture and horticulture, differentiation in the training of the future market gardener and of the farm workers, provision of more advanced courses for reformatory schools than for industrial schools, and possibly courses of an entirely different type; the desirability of providing classes in gardening for all boys in the institution, and of introducing skilled instruction in bee and poultry keeping and more varied courses in handwork; and a considerable modification or the total abandonment of the practice of hiring out boys to farmers in the vicinity for day work.

Agriculture at the primary school, L. ROUGIER, C. PERRET, and A. MIAILLE (L'Agriculture à l'École Primaire. Paris: J. B. Baillière & Sons, 1914, 3. ed.,

pp. 252, figs. 236).—This book includes outlines of 27 lessons in plant production, 5 lessons in animal production, and 1 each in rural economy and the friends and enemies of the farmer. Each lesson is followed by review questions, problems, and references to the literature.

How to teach agriculture in the primary school, C. PERRET (Comment Enseigner l'Agriculture à l'École Primaire. Paris: J. B. Baillière & Sons, 1910, pp. 96, figs. 33).—The author states the object and method to be employed in agricultural instruction in the primary school, including suggestions for the establishment of a school museum, class experiments, and different ways of demonstrating plant growth, viz, in pots, in water, in the school garden, in the school yard, in demonstration plats, in experiment fields, and in different kinds of soils.

The Allerey Handbook (*Beaune, France: Amer. E. F. Univ., 1919, pp.* [IV] + 263).—This book outlines 14 courses in agriculture prepared by the instructors of the American E. F. University Farm School at Allerey, Saone-et-Loire, France (E. S. R., 41, p. 106), and given in the school. The subjects dealt with are buildings and equipment; field crops, manure and fertilizers, and soils; dairying, types and breeds, feeding and management; poultry; fruit growing; vegetable gardening; agricultural geography, rural sociology, marketing and cooperation, and farm management.

Horticulture, K. C. DAVIS (*Philadelphia: J. B. Lippincott Co., 1919, pp. VII* + 416, *pl. 1, figs. 287*).—This textbook for high and normal schools deals with plant propagation and breeding, gardening, orcharding, small fruit growing, forestry, beautifying home grounds, and the soils and enemies involved. To aid in making the teaching as concrete as possible, numerous suggestions for questionnaires, surveys, local investigations, practicums, field and laboratory exercises, field trips, home projects, etc., are included at the close of the chapters, together with review questions and references to literature. An appendix contains a brief list of horticultural works for school libraries, and useful data with reference to suitable distances and varieties for planting, losses in crop removals, sources of plant food, etc.

Mainly the pedagogy of seeds with some seeds of pedagogy, W. G. VINAL (*Nature-Study Rev.*, 15 (1919), No. 6, pp. 213-232, figs. 2).—Suggestions are offered for making educational measurements with seeds, and on methods of teaching seed germination and dispersal, mounting seeds for class use, and studying seed folk lore, omens, and charms.

Outlines of course of instruction in agricultural nature study for the rural schools of California, O. J. KERN (California Sta. [Pub.], 1919, pp. 55, figs. 60).—The material outlined in this publication is grouped under four general topics, viz, human needs, interests, and activities; plant and animal life, respectively, throughout the year; and natural phenomena and the inorganic world and soil studies. The matter represents part 3 of the syllabi worked out by the author in his course of instruction on the elements of agricultural nature study and school and home gardening, given in the University of California. Parts 1 and 2 have been previously noted (E. S. R., 41, p. 95).

Some considerations in teaching a bird course, J. M. SHAVER (*Nature-Study Rev.*, 15 (1919), No. 2, pp. 53-57).—The author outlines a scheme for field work with birds, and offers suggestions for laboratory work.

Our southern birds, E. B. MILES (*Chicago: National Book Co., 1919, pp. 174, pl. 1, figs. 89*).—This is a nature study book on southern birds for the non-scientific student.

Productive poultry husbandry, H. R. LEWIS (*Philadelphia and London: J. B. Lippincott Co., 1913, 3. ed., rev. and enl., pp. XXII*+574, *pl. 1, figs. 237*).— Chapters on business management, and judging and culling fowls for egg production have been added to this new edition of this text, which has been previously noted (E. S. R., 31, p. 270).

**Civic biology**, C. F. HODGE and J. DAWSON (*Boston and London: Ginn & Co.*, 1918, pp. X+381, pls. 4, figs. 168).—This text is devoted to a solution of local and national problems by civic cooperation in the conservation of natural resources and the extermination of animal and insect pests and disease germs. Instructions are given, by means of type problems, for the study of insects, birds, trees, plants, rodents, fungi, bacteria, fish, etc., for cultivating habits of observation, insight into the workings of living nature, civic ways of thinking, and civic methods of studying and attacking such problems. Chapters are included on equipment, apparatus, and the library; the practical laws of life; how to use national organizations for biological instruction and research; and progress in biological discovery.

#### MISCELLANEOUS.

Annual Report of Florida Station, 1918 (Florida Sta. Rpt. 1918, pp. 93+VI, figs. 16).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1918, a list of the publications of the year, a general review of the work of the station during the year, and departmental reports, the experimental features of which are for the most part abstracted elsewhere in this issue.

Report of the Canada Experiment Farms, 1918 (Canada Expt. Farms Rpt. 1918, pp. 148).—This contains the reports of the director, the Dominion specialists, and the superintendents of the various substations. In addition to experimental work abstracted elsewhere in this issue, meteorological data and minor feeding trials with steers, dairy cattle, horses, sheep, pigs, and poultry are included.

Quarterly bulletin of the Michigan Experiment Station (Michigan Sta. Quart. Bul., 2 (1919), No. 1, pp. 56, figs. 19).-In addition to articles abstracted elsewhere in this issue, this number contains the following: The College Guernsey Herd, and Suggestions for Feeding Cows on Seven Day Tests, both by J. E. Burnett; Selecting Gilts, by G. A. Brown; Self-feeders Reduce Pork Production Costs, by W. E. J. Edwards; Some Remarks About the Diagnosis and Treatment of Infectious Abortion, by H. J. Stafseth; Some Canning Practices From the Bacteriologists Standpoint, and Start Your Vinegar Right, both by Z. Northrup; Legume Innoculation, by R. M. Snyder; Botanical Notes, and Bordeaux Mixture, both by G. H. Coons; Fertilizers for Fall Delivery 1919, by A. J. Patten; Coccidiosis, by W. L. Chandler; The Clover Seed Situation, and Increasing Returns Per Acre From Wheat and Rye, both by J. F. Cox; How May Soldier Farmers Determine Between Soils Fit for Agriculture and Those Suitable for Forestry, by F. H. Sanford; Orchard Cover Crops, by I. T. Pickford: Preparing Fruits for Market, by J. Carmody; Loss of Moisture During Incubation, by C. H. Burgess; Fall Plowing, by C. H. Spurway; Tuberculosis in Chickens, and Hard Milking Cows, both by E. T. Hallman; and Rodent Control-The Field Mouse, by A. C. Conger.

Monthly Bulletin of the Ohio Experiment Station (Mo. Bul. Ohio Sta., 4 (1919), Nos. 6, pp. 169–199, figs. 19; 7, pp. 201–231, figs. 13).—These numbers contain, in addition to several articles abstracted elsewhere in this issue and miscellaneous notes, the following:

No. 6.—Brief notes on Tomato Diseases, by W. Van Pelt, and Lessons from the Southeastern Test Farm, by C. W. Montgomery.

No. 7.—Information on the Ohio Experiment Station Dairy Herd, including herd records.

**5**98

# NOTES.

Alabama Canebrake Station.—The station has leased for five years a tract of 240 acres of adjoining land, which it is planned to put into alfalfa as soon as possible. More work with hogs and dairy cattle is also contemplated.

Illinois University and Station.—Dr. Cyril G. Hopkins, professor of agronomy, chief agronomist and chemist, and vice director of the station, died at Gibraltar, October 6. He was returning to his country from a year's study of means of restoring the exhausted soils of Greece, where his work and recommendations are said to have made a profound impression. He had completed his report, and had been decorated by the King in grateful recognition of his services.

Dr. Hopkins was born in Minnesota July 22, 1866, and graduated from the South Dakota College in 1890. He received the M. S. and Ph. D. degrees from Cornell University in 1894 and 1898, respectively, and had also studied at Goettingen University. After short periods of service as assistant chemist in South Dakota and New York, he went to the Illinois Station in 1894 as chemist. He was made professor of agronomy in 1900 and vice director of the station in 1903.

Dr. Hopkins' death marks the passing of an outstanding constructive force in the application of science to the betterment of agricultural practice. He translated the results of scientific investigation into terms of agricultural practice, and taught that permanent agriculture is the foundation of national welfare with convincing power and profound and far-reaching effect. He rendered an invaluable service in awakening the farmers of the Middle West and elsewhere to the danger of continued overdraft on soil fertility. He looked upon the soil as a legacy which, after supplying our present needs, should be transmitted unimpaired, if not enhanced, in fertility and productiveness. To this end he taught that the farmer should take frequent inventory of the soil constituents and see to it that no one of these runs short of the amount required for maximum crops. He maintained that every farmer should be able to answer affirmatively the question—Am I returning to the soil as much phosphorus or potassium as my crops remove, and am I abstracting from the atmosphere by my rotations enough nitrogen to restore the draft upon the land?

The essential features of the system which he advocated for permanently restoring and maintaining the fertility of ordinary Illinois soils were the full use of the manure produced on the farm, the return of crop residues to the land, the growing of leguminous crops in the rotation with sufficient frequency to maintain the nitrogen supply of the soil, and the application of ground limestone and raw rock phosphate. The direct application of potash was not recommended except in special cases because in his judgment most Illinois soils contain sufficient potash to supply maximum crops for many years.

Dr. Hopkins was a fellow of the American Association for the Advancement of Science and the recipient of other honors. He was the author of many bulletins and articles, as well as several books, the most important of which is Soil Fertility and Permanent Agriculture, published in 1910.

Minnesota University and Station.—The total enrollment in the university is over 7,000, with about 650 in the college of agriculture, forestry, and home economics. The school of agriculture has registered fully 700, as compared with 250 a year ago. Plans have been approved for a superintendent's cottage and small live stock barn at the Waseca substation. A tract of 8 acres at the fruit station at Zumbra Heights has been purchased, and negotiations are under way for a larger tract.

C. P. Bull, professor of agronomy and seed specialist, resigned October 1 to engage in the seed business. J. C. Cort, associate professor of dairy husbandry, has resigned to become manager of a large dairy farm in Wisconsin, and has been succeeded by Allan B. Rayburn as assistant professor of dairy husbandry. Other resignations include A. G. Tolaas as extension specialist in plant pathology to become chief inspector for the newly organized State board of inspection and certification of seed potatoes; Elizabeth Vermilye as assistant professor of home management; R. O. Westley as assistant professor of agronomy at Crookston; and E. S. Proebsting and J. W. Bushnell as instructors in horticulture.

W. H. Alderman, professor of horticulture and horticulturist of the West Virginia University and Station, has been appointed chief of the division of horticulture beginning September 1. Among other appointments may be noted those of George A. Pond as assistant professor of agronomy and farm management: Theodore E. Odland as instructor in agronomy: T. S. Hanson as assistant in forestry; J. E. Chapman as assistant in soils; Harold Macey as assistant in dairy bacteriology; Harold Borst as assistant seed analyst; J. H. Beaumont as assistant in horticulture; E. O. Hanson as assistant in dairy husbandry; Robert R. Smith as agronomist at Crookston; Frank Frolik as extension specialist in plant pathology; Alberta Gustafson as assistant State leader of boys and girls club work; Julia O. Newton as assistant State leader of home economics extension work; Norris K. Carnes as instructor in animal husbandry; Grover C. Matthews as assistant professor of beekeeping; Clyde R. Chambers as research assistant in agricultural economics: Edward C. Torrey as extension specialist in publicity work; and Adele Koch as extension specialist in home economics.

**Pennsylvania Institute of Animal Nutrition.**—Charles D. Jeffries and W. J. Sweeney, 1919 graduates of the Pennsylvania and Massachusetts Colleges, respectively, have been appointed assistants in animal nutrition beginning September 1.

Canadian Agricultural Appointments.—Dr. Simon Frasie Tolmie, member of Parliament for Victoria, B. C., has been appointed Canadian Minister of Agriculture. He is a graduate of the Ontario Veterinary College, and was for many years a Federal and Provincial veterinary inspector, as well as a live stock raiser and president of several live stock organizations.

Dr. J. H. Grisdale, director of the Canadian Experimental Farms and acting deputy minister of agriculture, has been appointed deputy minister of agriculture. E. S. Archibald, Dominion animal husbandman, has been appointed director of experimental farms.

F. M. Clement has been appointed dean of the faculty of agriculture at the University of British Columbia, vice L. S. Klinck, who has been appointed president of the university.

Agricultural Bequest to Wilmington, Vt.—By the will of the late Clinton C. Haynes, his entire estate, estimated at \$20,000 or more, has been left to the people of Wilmington, Vt., in trust "for the benefit of agriculture in said town." The will provides for the investment of the fund, the income to be used as the trustee deems most advantageous to the agricultural interests of the people of the town, but being annually applied for the expense of lectures, experiments, premiums, and other purposes incident to the object for which the fund was created.

#### FIELD CROPS.

The experimental error in field trials, Love	635
The effect of "place" on yield of crops, Chittenden	635
The improvement of agricultural crops by selection and hybridization	636
Further observations on the practical value of line selection, Koch	636
Relation of some morphological characters to lodging, Garber and Olson	636
The farmer and Federal grain supervision, Brown	636
[Report of field crops work in Michigan, 1918], Cox	636
[Report of field crops work in Missouri, 1917–18], Etheridge et al	636
Crop production in the northern sand hills [of Nebraska], Cowan	638
[Report of field crops work in North Carolina, 1918], Williams	638
[Report of work with field crops in Netherlands, 1913–1916], Van Hoek	638
[Field crops work in the Dutch East Indies], Van Breda De Haan	638
[Report of field crops work in Java, 1916–17], van Rossem	639
Harvest report [Roseworthy Agricultural College], Colebatch	639
Sisal and henequen as binder-twine fibers, Edwards	639
The vitality of alfalfa seed as affected by age, Headden	639
The vitality of alfalfa roots, MacMillan	639
A factor analysis of barley, von Ubisch	639
The growing of beans in Scotland, Malcolm	640
CocksfootIts establishment and maintenance in pasture, Cockayne	640
Some flower anomalies of maize, Lopriore	640
The old and the new in corn culture, Biggar	640
"Northerns" cotton, Hilson	640
The improvement of "Tinnevellies" cotton, Thomas	640
Cotton warehousing, Newton and Workman	640
Crotalaria usaramœnsis as a fiber plant, Bley	640
Trials of Sudan durra for brewing	641
[Furcræa fiber], Lopez	641
[Proceedings of the National Hay Association]	641
The retting of hemp: A preliminary note, Carbone	641
Lolium subulatum, "Wimmera" rye grass, Mullett	641
New Zealand flax, Ventry	641
The inheritance of the weak awn in certain Avena crosses, Fraser	641
Some further experiments with potatoes, Wilson and Chittenden	642
Potato production, Stewart	643

	Page.
[Report of work with potatoes in the Rhine Province], Remy	643
The relation of climatic conditions to rice, de Peralta y Leaño	643
Rice [in Tucumán], Raben	643
South Bali [Dutch East Indies] and its rice culture, van der Veer	643
The place of rve in American agriculture. Leighty	643
The composition of the [sugar cane] planting, 1918-19, van Harreveld	644
Sweet potatoes, Cole, Tharp, and Minter	644
The tobacco seedbed, David	644
Selection studies with Deli tobacco, Honing	644
Crop rotation and fertilizer experiments, Miller and Duley	644
The cultivation of wheat in Argentina, III, IV, Girola	645
Fertile wheat-rye hybrids, Love and Craig	645
Some effects of the war on the seed industry. Wheeler and Edler	645
Second annual report Colorado Seed Laboratory, Robbins	645
Seed Reporter	645
The identification and control of Colorado weeds, Robbins and Boyack	646
Weed immigration into Michigan, Darlington	646
The weeds of wheat on the pampas [Argentina], Williamson	646
Devitalization of the seed of Cuscuta, Bresaola	646

#### HORTICULTURE.

Carbohydrate metabolism in green corn, Appleman and Arthur	646
Greenhouse tomato growing in Virginia, Zimmerley	647
Gardens in France, Belgium, and occupied territory, Truffaut and Colt	648
[Work with vegetables and fruit at the Valentine substation], Cowan	648
[Progress report on horticultural investigations]	648
Report of the Lamao Experiment Station	650
Fruit growing and training, Vercier	650
The culture of tree fruits, Gressent	650
Orchard management, Sandsten	650
The commercial apple industry in the United States, Folger	650
Report of division of horticulture, Pillsbury	650
Dried wine grapes	651
Certain relationships between the flowers and fruits of the lemon, Reed	651

#### FORESTRY.

The book of the National Parks, Yard	651
Farm woodlands and the war, Graves	651
[Progress report on forestry investigations]	652
Forest administration in Assam 1917–18, Blunt and Tottenham	652
Forest administration in Coorg for the year 1917–18, Tireman	652
[Report on tree culture in the northern Nebraska sand hills]. Cowan	652
Afforestation: Its practice and science, Duchesne	652
Reafforestation with conifer trees. Breton-Bonnard	652
Effect of removing pulp from camphor seed, Russell	652
Origin of chicle, with descriptions of two new species of Achras. Pittier	653
The European elder (Sambucus nigra), Degli Atti	653
The strawberry tree and its utilization. La Marca	653
Variation in Heven brasiliensis. Whithy	653
Selection and thinning Butgers	653

#### DISEASES OF PLANTS.

Pan American cooperation in plant quarantine, Sundberg	654
Pan American cooperation in plant quarantine, Marlatt	654
Phytopathological inspection of horticultural establishments	654
Seed and soil treatment for vegetable diseases, Cook	654
[Work done in plant pathology], Coons	654
Report of the department of botany, Reed et al	654
Damage from soil fungi, Seaver	655

	Page.
Botany and phytopathology, Canadal, Crerar	. 655
Plant diseases [in Ireland]	. 655
List of diseases of economic plants in Bombay Presidency, Chibber	655
Foot and stalk disease of wheat, Foex	. 655
The black stem rust and the barberry, Stakman	- 655
Immunity and inheritance in plants. McAlpine	656
A little known disease of alfalfa. Fron and Lasnier	656
The pecial stage of alsike clover rust. Davis	656
Diseases of the potato. Heald	656
Potato leaf roll, Blanchard and Perret	656
Potato spraving trials in the Cambridgeshire Fens. 1918. Petherbridge	656
Bacterial blight of sov bean. Tisdale	656
A disease of tomato and other plants. Pethybridge and Lafferty	656
Dry-rot of turning.—Suggestions regarding control. Cockayne	657
Orchard experimental work by Stoke Fruitgrowers' Association	657
Treatment of apple canker diseases. Whitten	657
Apple powdery mildew a serious menace to orchards, Fisher	- 657
Apple scab and its control. Eastham	658
A new and effective disinfectant for pear blight, Reimer	658
June drop and its relation to the weather, Jensen	- 658
Psorosis (scaly bark) of orange trees in California, Fawcett	658
On the life history of the rose blotch fungus, Alcock	. 658
Fomes lucidus as a parasite of trees, Nowell	- 658
Control of oak mildew, van Poeteren	. 659
Pine rust in Sweden, 1917, Sylvén	- 659
Pine rust (Melampsora pinitorqua), Sylvén	659
[Pine rust in Sweden], Sylvén	659
Summary of the white pine blister rust situation, Metcalf	659
Further notes on black-stripe canker, Belgrave	- 659
Field notes and observations on brown bast, Belgrave and South	. 659
Experiments on the prevention of brown bast, Belgrave	- 659
A study of Heterodera radicicola and its control, Duruz	<b>- 66</b> 0

#### ECONOMIC ZOOLOGY-ENTOMOLOGY.

Federal protection of migratory birds, Lawyer	660
Life histories of North American diving birds.—Order Pygopodes, Bent	660
Report of the entomologist, Pettit	660
Entomology	660
Report of the division of entomology, Sherman	660
Notes on some insect pests of Costa Rica, Zetek	660
[Contributions on economic insects]	660
Insect pests on the rosella, Jarvis	661
Common insecticides.—Their practical value, Wilson	661
Derris as an insecticide, McIndoo, Sievers, and Abbott	661
Economic poisons used in control of pests in California, Gray	662
Locust destruction	662
The Coccobacillus acidiorum of d'Herelle, Quiroga	662
Does Bordeaux mixture repel the potato leaf-hopper? Fluke	662
The life history and biology of Macrosiphum solanifolii, Smith	662
The durra asal fly (Aphis sorghi) in Anglo-Egyptian Sudan, King	664
Controlling mealy bugs by their natural enemies, Armitage	664
A new scale insect (Xylococcus alni) on alder, Oguma	664
New studies and observations of Argentine Pieridæ, Giacomelli	665
Ear worm injuries to corn and resulting losses, Smith	665
Status of codling moth in its relation to walnut industry, Mackie	665
Notes on lepidopterous borers found in plants, Mosher	665
Notes on life history of pine tube moth (Eulia pinatubana), Hartzell	665
What hinders dried fruit sales? de Ong	665
Observations on the food of Anopheles larvæ, Metz	665
some aspects of malaria control through mosquito eradication, Metz	666
Infection of A. plumoeus with Plasmodium vivax, Blacklock and Carter_	666
variations in length of naxseed stage of Hessian ny, McColloch	666

V

	Page.
The white grub or grass root bettle (Scitala pruinosa), Froggatt	666
Observations on wingless May beetles, Vickery and Wilson	666
Experimenting with ladybugs	666
Japanese flower beetle, Goodwin	666
Should we dust cotton to control the boll weevil? Hinds	667
How weevils get into beans, Back	667
A source of confusion in the diagnosis of <i>Nosema apis</i> , Sturtevant	667
Bembecia hylxiformis and Sesia tipuliformis, Kemner	667
Revision of the chalcid flies of the genus Harmolita, Phillips and Emery	667

#### FOODS-HUMAN NUTRITION.

Changes in food value of vegetables due to cooking, Denton	667
Effect of pack and depth of water bath in cold pack canning, Castle	668
The supposed occurrence of methylguanidin in meat, Greenwald	668
Nature of the toxic agent in "meat poisoning," Greenwald	668
Composition and food value of bottled soft drinks, Sale and Skinner	669
[Miscellaneous food and drug topics], Ladd and Johnson	669
Budget planning in social case work, Winslow	669
The nutritional standards of adolescence, Lusk	669
Importance of animal proteins and fats in human nutrition, Bottazzi	669
Importance of the fat-protein ratioMinimum of fat necessary, Maignon_	669
Mechanism of the action of fats in utilization of proteins, Maignon	670
Maintenance ration.—Function of carbohydrates, Bierry	670
New conception of rôle of various food constituents in nutrition, Terroine_	670
Influence of lack of vitamins on feeding experiments, Maignon	670
Absence of fat-soluble A vitamin in ductless glands, Emmett and Luros	670
The vitamin requirement of yeast, Williams	670
The connection between food régime and illness, Mendel	671

#### ANIMAL PRODUCTION.

Live stock and reconstruction, Rommel	671
Cattle raising and the meat industry in southern Brazil, Porchat	671
French live stock after three years of war, Massé	671
Government market reports on live stock and meats, Atkinson	672
Saving of meat-storage and shipping space	672
Country hides and skins, Whalin, Frey, Veitch, and Hickman	672
Tandler and Keller on the freemartin, Lillie	672
Creatin excretion in ruminants, Orr	672
Effects of feeding Sudan III to young albino rats, Hatai	672
Behavior of Sudan III in the animal organism, Read	673
Definitions of feeding stuffs by Association of Control Officials, Clark	673
Feeding stuffs—definitions	673
Stock foods, Ladd and Johnson	673
Heavy and light grain rations for fattening steers, Allison	673
Cattle loans and their value to investors, Cole	674
[Swine feeding investigations], Weaver	674
Can hogs be raised at a profit at the present level of prices?	675
Corn and cob meal, linseed meal, and oat straw for horses, Trowbridge	675
Poultry-feeding tests at Milton, Brown	675
Better poultry through community breeding associations, Kinghorne	675
Standard varieties of chickens.—III, Slocum	676
Chickens, Götting	676
Rabbit growing to supplant the meat supply, Dearborn	676

#### DAIRY FARMING-DAIRYING.

Influence of nutrition of heifers and age of breeding, Eckles and Swett	676
Modern methods of feeding the dairy cow, Truman	676
New Zealand dairy cowsImprovement in average production, Singleton_	676
Improving the profits in the dairy business, Taylor	676
Factors that influence the profits in dairy farming, Fraser	677
How to find the price of protein in milk, Esten	677
How dairying built up a community, McDowell	677

	Page.
Factors influencing the composition of milk, Eckles et al	677
Phosphorus and calcium metabolism in milk secretion, Meigs et al	678
Gestation v. stage of lactation, Palmer and Eckles	679
Efficiency of standard agar for estimation of bacteria, Sears and Case	679
The chemistry of churning, Palmer	680
Cheese making under Missouri conditions, Morley	680
The rediscovery of an old dish, Davis	680
The use of surplus milk in a small dairy : Cheese making, Allan	680

#### VETERINARY MEDICINE.

Results of Federal quarantine against foreign live stock diseases, Pope	680
Report of the State veterinarian, Jacob	680
Report of Bengal Veterinary College and civil department, Smith	680
Report of the government veterinary surgeon for 1918, Sturgess	680
Colloids in biology and medicine. Bechhold, trans, by Bullowa	680
Preparation of culture media suitable for organisms in vaccines, Norris	680
The suppression of anaphylactic shock. Kopaczevski and Vahram	681
Experiments on the bactericidal action of sunlight, de Laroquette	681
A study of many strains of streptococci. Jones	681
The relation of forage poisoning to botulism	681
Need of government action to check botulism. McCaskey	682
Becrudescence of rindernest in Egynt Piox Bey	682
Antirinderpest vaccination in calves —Serovaccination, Groveri	682
Experimental study of the therapy of tuberculosis, Volpino	682
The accredited herd plan in tuberculosis eradication. Kiernap	683
Contagious abortion investigations. Connaway, Durant, and Newman	683
Bacterium abortus infection of bulls, Buck, Creech and Ladson	683
Stomach worm disease in cattle and sheen Dalrymple	684
Less cholera more hors Hess	684
Effects of heat on triching, Banson and Schwartz	684
The cause of abortion in marks Murray	684
Stroneylidge in horses Vorke and Macfie	685
Strongylida in horses Snedias in American horses. Vorke and Macha	685
On the transmission of two fowl taneworms Ackart	685
Development of the protozoon of "blockhood" in turkova Turzov	695
Development of the protozoon of blackhead in turkeys, 1yzzer	000

#### RURAL ENGINEERING.

The drainage movement in the United States, McCrory	686
Rainfall, absorption, and run-off on small rural drainage area. Houk	686
Progress report on run-off investigations. Lynde	686
Floods and water-logged land : The Land Drainage Act, 1918	687
Moor drainage, Freekmann	687
Hydraulic efficiency of a drainage ditch. Bamser	687
Canal seenage losses are affected by temperature. Crandall	687
The small irrigation numing plant. Powers and Gilmore	688
Testing agregates in the field Jackson	688
Iltramicroscopic examination of hituminous road materials Lord	688
Efficiency of bituminous surfaces under motor truck traffic Hubbard	688
Preliminary impact tests of auto trucks on roads. Smith and Pauls	689
The vertical movements of concrete payements Lowell	689
State highway mileages and expenditures in the year 1018 Anderson	690
Public Roads	600

# EXPERIMENT STATION RECORD.

Vol. 41.

NOVEMBER, 1919.

No. 7.

The question of the name, the composition, the organization and authority of the Association of American Agricultural Colleges and Experiment Stations has been a fruitful one for discussion from time to time. At intervals considerable attention has been given to these matters. Changes have been made in the constitution as the need for them became evident, and as new features of the college work came into prominence they have been brought within the purview of this organization. Meanwhile the association has gone on for thirty-three years steadily growing in strength, influence, and usefulness, and been a large factor in the unfolding and development of the program of the land-grant colleges. Its meetings have been a great clearing house for ideas and plans relating to the whole field and function, means and ends, of this great group of institutions.

The association has been in many ways a unique organization. Administrative officers and their subordinates, heads of the different branches and experts, have counseled together freely, been stimulated and restrained, given broader vision tempered by sound judgment and expediency. Every deserving cause or proposal has been assured a hearing. It has been a singularly free and democratic organization, representative of the spirit of these public institutions and the novel character of their undertaking. There can hardly be doubt that these things have helped to make the institutions what they have been—steadily progressive without radicalism. The association has formed a vital part of the National system in this period of evolution and development.

The Chicago convention marked a change in this body which affects the name, the representation, and the internal organization, and places matters of policy and legislation more definitely in the hands of the college executives. Under the new or largely revised constitution which was adopted, the Association of Land-Grant Colleges becomes a body composed exclusively of these institutions represented by their presidents. The only exception is the experiment stations receiving the benefits of the Hatch Act but existing separate from the colleges. These heads of the institutions constitute the "executive body," which is charged with all legislative matters relating to the association. There is provision for a series of sections open to delegates from the respective branches or main divisions of the colleges, but the latter are without membership in the association proper and their representatives will have voice only in their sections.

As pointed out in the meeting last year, the change is a reorganizing one rather than one involving any revolutionary principle, since in theory at least no action affecting the policy of the association has been binding in the past without ratification by the section on college work and administration, composed of the presidents of colleges and universities or accredited representatives. The working out of the "unitary character" of the organization is the chief change involved, and, as was explained last year, it is designed to relieve the complexity of the body and definitely centralize authority in the hands of those primarily responsible. Whether or not the end then emphasized has been accomplished, of enabling the executives to know what the sections are thinking about, "to hear what their subordinates are saying, to understand their difficulties," will remain to be determined.

Under the new constitution three main departmental sections are recognized, namely, agriculture, home economics, and engineering; but by common consent subsections for experiment station and agricultural extension work were provided under the section of agriculture, and officers for them were appointed. There will still be opportunity, therefore, for discussion of matters of special interest to these branches, which have been so profitable in the past and are still felt to be needed; and the standing committees of the association from which annual reports have been expected are all retained. The executive committee is to include two members selected at large, and for the coming year these positions are filled by the deans of two of the leading agricultural colleges who are likewise directors of the stations.

While details under the new organization remain to be worked out, the body remains essentially what it has been in the past, an organization in which the various branches of the land-grant colleges find representation; and in the actual workings of the association the changes may not be especially noticeable in most respects.

The new officers elected for the coming year include Chancellor Samuel Avery, of Nebraska, as president, Dr. R. J. Aley, of Maine, as vice president, Dean J. L. Hills, of Vermont, as secretary-treasurer, and two new members on the executive committee, namely Dr. W. E. Stone, of Indiana, and Dean A. R. Mann, of New York. These latter replace President W. O. Thompson and Dr. W. H. Jordan who declined reelection and announced their intention to retire from their present positions during the coming year. Both of these men have rendered long and conspicuous service in the association and on its executive committee. They will be greatly missed from EDITORIAL.

future conventions, and their going will be a loss second only to that experienced by the institutions over which they preside. Expressions of deep regret and of grateful appreciation were embodied in resolutions passed by the association.

The Chicago convention was one of the most interesting and successful ones held in many years. The attendance was large and was widely representative of the country as a whole and of the interests comprised in the association. The program was a broad one, including not only the reports of various officers and committees, but several notable addresses by special speakers and invited guests.

Among the latter were the Secretary of Agriculture, who presented a broad survey of present agricultural conditions and tendencies, and some of the problems which call for studious attention; Col. F. J. Morrow, who spoke upon military education as related to the landgrant colleges; Dr. James R. Angell, president of the National Research Council, who discussed the present scope and organization of research in this country, means for stimulating and promoting it, and the purpose of the research council; and Mr. C. R. Titlow, of Baltimore, who described the Federal system of financing the farmer.

The address of the president of the association, Dr. C. A. Lory, dealt with an institutional program for State development, in which was outlined the larger field of the land-grant colleges and the part they should play in State development, especially in reference to education. Dr. Lory argued for rural school improvement as a part of country life betterment, and held that a better agriculture can not be had without better country schools. The colleges should interest themselves in this endeavor and provide for cooperation and council with the local authorities. Stress was laid upon giving more attention to the human side of agriculture, including in the program rural economics and rural sociology, with both teaching and research.

The training of teachers was held to be an important function of the colleges, in which the provisions of the Nelson Amendment are not being fully measured up to. Development of the engineering branch of the colleges similar to that which has taken place in agriculture was advocated, getting away from the narrow professional view to that of State service, giving attention to the man in industry and his needs as well as to the technical phases. In this connection the need of engineering experiment stations was again pointed out.

In planning for the systematic study and outlining of a State-wide program of development, an advisory council was recommended, and a State development commission was suggested to carry forward consistent plans.

President Kenyon L. Butterfield described the organization and conduct of the educational work carried on among the American Expeditionary Forces over-seas, the various forms which the work took, the interest and success attending it, and some of its outgrowths. The association expressed by resolution its appreciation of the services in this work of President Butterfield and his associates.

In an interesting and significant paper Dr. W. H. Jordan discussed institutional ethics, setting forth the moral responsibilities of the institutions to the supporting public, to one another, and to their staffs. Under the first head he pointed out that the obligation in respect to teaching is that the scientific and technical instruction be sound. This requires that teachers have abundant time for study. In popular teaching a constructive attitude is called for in order to avoid error. In station work the need of conservatism in publishing results was pointed out, together with the danger of selecting problems having a popular slant. The obligations under the Hatch and Adams Acts will only be met, he said, by severe study of fundamental character.

As between institutions, the drawing of men from one to another was declared to be both inconsiderate and unethical. The station work is subject to more serious damage from this cause than that of any other branch of the college. Such change often means disaster to the work and loss of funds. Conference and mutual agreement between the institutions concerned was advocated, to determine the time when a change may reasonably and conveniently be made. Between institutions and members of their staffs it was held that there should be an understanding at the time of employment which will protect the work. This would guard against a teacher going elsewhere before his work with classes is completed or an investigator abandoning his projects.

The bibliographer's report, presented by Dr. A. C. True, dealt with the effect of the war on the course of agricultural and scientific periodical literature in the more important European countries. It was shown that not only were many important serial publications interrupted or discontinued, or failed of their usual distribution, but that to considerable extent track was lost of what was actually published in that period. There is still lack of authoritative information concerning the present status of many of these serial publications, and hence the impressions presented were of unusual interest.

As no provision was made under the new constitution for continuing the office of bibliographer, this will be the final report of a series which in the past quarter century has covered a quite wide field.

Throughout the various meetings of the convention research may be said to have been the key note. It seemed to have assumed unusual importance in the minds of speakers and of members generally. Interest in it was not confined to the station section, but was evident

#### EDITORIAL.

in the program of the general sessions and in the college and extension sections. Various speakers pointed to its present needs, urged that it be generously fostered as the main basis of agricultural growth, and pleaded for the development of wider appreciation and understanding of it.

The subject was introduced at the opening session of the convention in the address of the Secretary of Agriculture, who, in emphasizing the value of the land-grant colleges to our democracy, pointed out that recent events have made it singularly clear that "agricultural institutions must omit no step to add, through research and experiment, to the sum of our scientific knowledge." He referred to the inadequacies of information on important topics, in some instances there being no results on which to base intelligent conclusions. Up to a few years ago investigation had seemed to run ahead of facilities for conveying information, but now "the danger is rather that our teaching may outrun the accumulated stock of knowledge and become sterile."

The Secretary made a strong argument for a well balanced program of both instruction and research throughout the Nation. "То this end it must secure and retain the services of its most talented scientific and practical men; and this means something in terms of dollars and cents. It means that we must not only place the investigator on a higher financial plane but also give those who have talent funds and facilities in generous measure." It is increasingly clear, he said, that in all positions of responsibility the State and the Nation must be prepared to secure and retain men of the requisite training and experience, and to make the conditions sufficiently attractive. "Our democracy is today threatened with inefficient service because of its failure to provide a reasonably decent compensation for men of capacity charged with large responsibilities, and our democratic arrangements may either break down or result in commonplace performance, if reasonable requirements are not met."

The National obligation for scientific research as the reproductive process of science was emphasized in the paper of Dr. Angell, which pointed to the unprecedented illustrations of the value of research developed by the war. The National Research Council aims at the permanent mobilization of the scientific agencies, an end which European countries have attempted to accomplish by subsidy.

Surveying the principal research agencies of the Nation, attention was called to the experiment stations as a class offering exceptional opportunities for systematic inquiry, but handicapped at present by conditions and circumstances which limit their highest attainment. Reference was made to the extent to which the stations are often burdened with routine and quite elementary work at the expense of research, the lack of coordination between stations and within their organizations, and the unusually favorable conditions for developing cooperation.

From a review of conditions surrounding the various classes of research agencies, Dr. Angell declared that the Nation must be aroused to all that the situation implies; salaries must be increased, the number of workers must be increased, and there must be a larger appreciation of what research means to society.

Attention was frankly called to the present position and outlook of the experiment stations in the report of the committee on station organization and policy, based on a special study of them. This showed that the stations have been largely neglected of late, have received practically no increase in funds since prior to the war, and have had to contend with the same adverse conditions as other branches in increased expense, loss of workers, shortage of supplies, and shifting of attention. Hence they are in a relatively weakened condition, out of harmony with their importance to other branches of the college work and to the community. While other lines, like agricultural extension, which are dependent upon continued investigation have grown enormously, the stations have practically stood still, and in not a few cases have lost ground through inability to meet changing costs and the larger competition for men of scientific training.

This being the case, the agricultural system is clearly in danger of getting out of balance, if it has not already become so, and the need of larger administrative attention and increased financial provision are clearly indicated. The gravity of the situation was shown in the measure and extent to which the station work has been retarded in scope, continuity, and ability to meet new needs. In very many instances it has been necessary to suspend or restrict operations on investigations under way, or to omit taking up new ones for which there is demand. At all but ten stations, most of which have liberal State support, numerous standing projects have had to be suspended or materially reduced in scope and it has become impossible to take up others of importance because of lack of funds or workers. In many cases lines of work are being sacrificed in order not to sacrifice quality. Even those stations which have not thus far felt the pinch so severely admit their inability to do their duty toward new problems.

The loss of men from the stations, many of them in responsible positions, has been a great hindrance to progress. This is due in no small part to inability to pay adequate salaries, and is often complicated by an established salary scale for the entire institution or a particular branch of it. In the opinion of the large majority of directors, the salary scale of investigators falls far short of adequately reflecting the special qualifications, ability, and long training which are required for success in that field. Several declare that the present salaries are no longer adequate for retaining men capable of carrying on high grade research, or attracting the best type of men to it. Comparison shows that the entrance salary and the prospects of advance are more attractive in extension than in research, and that the maximum to which workers may ultimately look forward is practically the same in the two lines.

The effect of these conditions is to discourage promising students from undergoing the special training to prepare themselves for research, and the testimony is that relatively few are looking to that field. The feeling is abroad that the inducements for a research career are relatively less attractive than five years ago, and are growing less so from the standpoint of young students. Little apparently is being done by the colleges to counteract this condition, which indicates that severe as the situation has become, the chief cause of alarm lies in the future. The committee warned that "until institutions frankly acknowledge the high quality of research as placing it at the pinnacle of scientific effort in agriculture, and express this in the salary that may be attained irrespective of any general scale, it is quite evident that the supply of persons trained for station work as a career will not be sufficient to meet its requirements and allay constant apprehension for the future."

The committee made two suggestions bearing on this matter. It advocated a larger provision of scholarships or research fellowships to make the approach more favorable for students desiring to prepare for agricultural research. These would afford an incentive and an opportunity which are now often closed to such students of promise, and would thus aid in building up the supply of men of rigid training and broad vision such as the stations require. And to enlarge the outlook in that field and recognize its relative high standing, it was suggested that the colleges establish a limited number of research professorships, to be open to investigators in the stations who have displayed marked ability and become entitled to special recognition. Such positions would stimulate interest in research as a career, and prove an added inducement to those of eminence to remain in that field rather than go over into administrative or commerical positions.

That the funds at present available for the experiment stations are wholly inadequate, and that these institutions have been left behind in the forward development of other branches of the agricultural work, was further emphasized in the discussion before the station section.

Dean Curtiss expressed the belief that there has not been a time within the past quarter of a century when our research work in 149863°-20-2 agriculture has faced such critical conditions as at present; and he made the point that other lines like instruction and extension will recover much more quickly than research. Referring to the fact that experiment station work has not received proper emphasis and support in many States, and that it has been under serious handicap in other States, he said: "I think we will need to place greater emphasis upon the experiment station and give it a more prominent place, a place of higher recognition, and make it more independent of the instruction work." He advocated a force selected by reason of distinctive qualifications and training, and the devotion of time exclusively to investigation. He also held that the position of research men who have demonstrated their ability should correspond in rank with that of heads of departments, although not independent of the latter.

Dean Watts characterized agricultural research as "the weakest link in our agricultural program" from the standpoint of support for maintenance. He showed that for every dollar of Federal money devoted to agricultural experiments considerably over three dollars are available for extension, despite the fact that research is expensive. He indicated that unless adequate provision is made to meet the present shortage of funds for experimental purposes the satisfactory advancement of the entire agricultural program will be retarded. He urged that each State should provide a sum equal to the Federal allotment, and that efforts be made to secure increased Federal appropriations.

On the basis of a questionnaire circulated among the station directors, Dean Burnett confirmed the view that the funds available are much below the requirements of the various States, except in a few cases having liberal local support. He showed that in many cases no new projects are now being established except as old ones are completed, and that even then the money thus released is often needed to meet the growing expenses of the station. Pointing to the fact that the attention of young men in agricultural colleges is being directed away from research toward other lines, he prophesied that the stations would have to be put on a broader and better basis before the situation could be remedied.

The section adopted a resolution earnestly recommending that the Association "take cognizance of the paralysis threatening the work of the stations," and seek a substantial increase in the Federal appropriation. A similar resolution was adopted by the extension section, which evidenced a realization of the situation and its vital relation to the efficiency of all extension effort. These resolutions received the indorsement of the executive committee, which recommended that the present needs of the stations be presented to Congress with a view to securing a supplementary appropriation.

#### EDITORIAL.

The executive committee also endorsed the need of substantial salary increases, as pointed out in reports of the committees on college and experiment station organization and policy, a resolution of the college section, and several speakers. It appeared that a large number of the colleges had already felt the importance of such a step and had provided for quite general advancement.

Another matter which assumed considerable prominence in the Chicago meetings was that of cooperation in research. Reference has been made to Dr. Angell's address, the central theme of which was the organization of research and its effective coordination. He combated the idea that the investigator should be given unqualified freedom and protected in working alone. A large part of the research product, he maintained, is not the result of special genius, and great opportunity lies in the field of ordinary ability. There are many scientific problems which no one scientist working alone is equipped to handle. The need was emphasized for cooperation which brings together scientists in neighboring fields; and cooperation in planning was deemed well worth while even if it went no further.

The subject was one of the leading features in the program of the experiment station section, where a symposium was presented by three speakers with formal papers. Director C. E. Thorne read a paper on cooperation and correlation in relation to soil fertility investigations, and Dr. H. C. Taylor discussed the reorganization of the Office of Farm Management and the extensive plans for conducting its studies in cooperation with the agricultural colleges and experiment stations.

The symposium developed the fact that there was considerable difference of opinion on the value of cooperative effort in station work, the type of investigation to which it is best suited being held to be the large problems in which two or more States are particularly interested, regional questions or those involving different climatic or other factors, and broad basic problems in which a considerable accumulation of data is important. The desirability of standardizing methods of experiment so that the results at different stations will be comparable was emphasized, and it was suggested that in the case of large questions the problem might be divided among a number of workers or that the field might be divided among stations on the basis of climatic or other limiting conditions. The advantage of organized effort in stimulating interest in specific problems was pointed to; and frequent conference among investigators was made a condition of successful cooperation or coordination.

The importance of sufficient duplication to secure a high degree of certainty was urged by several speakers, since it is of first importance that publicly supported research should be able to withstand the most critical examination by scientific method and the most varied test in practical application. The nature of some of the criticisms and attacks by scientific men on one another was thought to lead to "a great and growing skepticism in the mind of the general public of the soundness and impartiality of the findings of research." The development of a real spirit of constructive cooperative attack, and a more friendly and tolerant attitude between investigators, it was believed would do much to remedy public distrust of the objects and the methods of research workers.

Cooperation was also referred to as a means of husbanding the meagre resources of the stations, securing larger results and greater progress in certain lines for the public money spent, avoiding unnecessary duplication, and standardizing the conduct of experiments in similar lines so that they will be more directly comparable.

An illustration of the opportunity for beneficial working together was furnished by Director Thorne in the subject of carriers and forms of phosphorus used as fertilizer. Analyzing the various factors involved in a complete study of the subject he concluded that "no one station can furnish a final answer to all these questions, for they must be studied under a wider range of soil and climatic conditions than are found in any single State. Moreover, the scope of the investigation is so broad that few stations will feel able to undertake the entire inquiry; but by parceling out the work, assigning part to one State and part to another, and so articulating the whole that there will be a common ground on which all will meet, it will be possible at least to very materially enlarge the boundaries of our knowledge on this subject."

In outlining the plans for studies in farm management and farm economics, Dr. Taylor made the point that cooperation is quite necessarily involved, since in considerable extent it involves a crystallizing of the results of investigation in other branches, as well as securing data of wide scope and volume. Hence in his judgment the establishment of right relations with other workers in the field of agricultural research demands the right application of the principles of division of labor and cooperation.

The broad question of a closer union and understanding between the work of the stations themselves and that of the Federal Department of Agriculture was presented in the report of the committee on projects and correlation of research. The report suggested that the time had come for formulating plans looking to more definite coordination. It suggested the provision of an agricultural research council, to be composed of representatives from the stations and the Department, with headquarters in Washington. Such a council, it was thought, would first make a survey of all the work of the stations and the Department, and on the basis of this would EDITORIAL.

formulate plans for effective correlation and coordination in such features as might seem desirable. It was designed through this council to bring the stations and the Department into more intimate relations and to effect a better understanding of the work of both agencies.

The proposal met with considerable favor on the part of station directors, was approved by the experiment station section, and later by the association, and the executive committee was instructed to confer with the Secretary of Agriculture in reference to the establishment of such a council.

Closely related to the subject of the organization of research is the matter of internal organization and administration, which was referred to on several occasions. Dr. Jordan endorsed a statement in last year's report on station organization and policy, to the effect that efficient management "calls for a type of administrative leadership in the stations both competent to guide scientific investigation and with sufficient time for the thoughtful study of work and plans." He took the position that "an experiment station is entitled, if its best interests are to be conserved and its work made as efficient as possible, to have an administrative head who has no other duties. Moreover he should be a man who has actually engaged in research himself. It makes little difference what the field of research is in which he has been active, provided he has come to comprehend sound methods and has acquired an active appreciation of the care and severity with which inquiries should be prosecuted. It is in my judgment a mistake to combine with duties of director teaching duties or other administrative functions."

The current report of the committee on station organization and policy cited a number of directors as referring to the necessity of dividing time of station men with other departments of the college, as a continued disadvantage to the station work. If a station worker has more than nominal connection with teaching his duties are likely to be added to when pressure comes, as was the case this past fall when the attendance at many colleges largely increased. The chief argument for such dual services is expediency or necessity due to lack of funds. It was urged that a more general differentiation in working force is a natural corollary to the differentiation of function which has become commonly accepted. It was suggested that stations might often be stronger as purely research institutions if they had a smaller number of persons on the staff, but these of high ability in research and allowed to concentrate their best efforts in that field.

A number of speakers advocated a station force selected by reason of its distinctive qualifications and training for research, and the devotion of time exclusively to it.

[Vol. 41

Reference was made also to the importance of simplifying or narrowing problems taken up for investigation, resolving broad, complex questions into factors or phases which lend themselves to scientific investigation. Speaking of this Dr. Jordan said: "A very just criticism of the work of experiment stations in the past is that experiments have been carried on so complex in regard to the various factors that have reacted upon the results that no safe conclusions could be drawn in regard to the influence of any one factor. This is true of a large proportion of the field experiments and feeding experiments which have been conducted. . . . If there is any one point of view which needs to be enforced by our experiment station administrators it is that we shall narrow our problems to single factors. We will make little progress until we do this."

The soundness of this contention will appeal to all familiar with station investigation and experiment, and has frequently been emphasized in these pages. Failure to recognize the complex character of subjects presented for investigation and to analyze these problems into workable parts is one of the serious weaknesses in agricultural research. It is accountable for efforts which are unsuccessful or abortive, and it results in an unprofitable use of time and funds. It is a matter deserving of much greater administrative attention.

There was much in the spirit of the times to cause the Chicago convention to evidence a broadening realization of the ultimate function and responsibilities of the land-grant colleges. They are concerned not only with the technical aspects of production but with the conditions under which agriculture is conducted and the welfare of the people living under it. This brings them into increasingly close contact with problems relating to the business side of farming and to life and progress in the country. These wider relations represented in their charter stood out more clearly at this time than ever before to challenge larger attention and incite leadership.

Secretary Houston referred to this when he declared that the colleges owe a duty outside their technical fields of investigation and education, and have a larger task even than that of improving farming. This duty he conceived to be the exercise of leadership along broader lines, the preservation of American ideals and institutions, the Americanization of those who have recently come among us, the exaction of regard for facts and their rightful interpretation by public men. A similar thought was expressed by President Lory relative to the broader duty of engineering toward public affairs and in industrial emergencies.

Altogether, therefore, the convention was one to furnish new inspiration and vision, and to give increasing conviction of the large place these land-grant institutions occupy in the welfare of the Nation.

# RECENT WORK IN AGRICULTURAL SCIENCE.

#### AGRICULTURAL CHEMISTRY—AGROTECHNY.

The art of searching chemical literature, H. HIBBERT (Chem. and Metal. Engin., 20 (1919), No. 11, pp. 578-581).—In this article the question of conducting a search of the chemical literature is dealt with particularly from the point of view of the technical chemist. Methods are suggested, and journals and reference books listed, for the systematic investigation of the literature on organic chemistry, biochemistry, and mining and metallurgical chemistry. Attention is called to special literature for specific information and to certain general indexes.

The condensed chemical dictionary, F. M. TURNER, JR., D. D. BEROLZHEIMER, W. P. CUTTER, and J. HELFRICH (*New York: Chem. Cat. Co., Inc., 1919, pp.* 525).—This reference book of information regarding chemicals and chemical materials ordinarily met with in commerce is designed especially for nonchemists such as exporters and importers, brokers and jobbers, financial houses, lawyers, librarians, purchasing agents, insurance companies, etc., who come in contact with chemical industries.

The data compiled for each substance consist in general of the chemical and commercial names, formula, physical properties, analytical constants, derivation, grades, containers, uses, fire hazard, and railroad shipping regulations. Although the properties described have been restricted to those likely to be of commercial importance and many substances of scientific interest but of no commercial importance have been omitted entirely, it is the hope of the authors that the dictionary will be of considerable value to the chemist as well as to the nontechincal user.

Handbook of chemical preparations, a reference book for workers in chemical laboratories, L. VANINO (Handbuch der Präparativen Chemie, ein Hilfsbuch für das Arbeiten im Chemischen Laboratorium. Stuttgart: Ferdinand Enke, 1913, vol. 1, pp. XX+670, figs. 82; 1914, vol. 2, pp. XVI+849, figs. 26).— This handbook, the aim of which is set forth in the subtitle, consists of two volumes, the first dealing with inorganic and the second with organic preparations. Substances of only special interest and methods which are considered of doubtful value are purposely omitted, but for each of the large number of elements and compounds selected a choice of several methods of preparation is given, with references to the original literature and with a summary of the important properties of the substances in its pure state.

Reports of the progress of applied chemistry (Ann. Rpts. Soc. Chem. Indus. [London] Prog. Appl. Chem., 1918, vol. 3, pp. 495; abs. in Nature [London], 103 (1919), No. 2596, pp. 421-423).—This volume contains the following sections: Plant and Machinery, by J. W. Hinchley; Fuel, by J. T. Dunn; Gas, Destructive Distillation, Tar Products, by A. Meade; Mineral Oils, by A. Philip; Coloring Matters and Dyes, by G. T. Morgan; Fibers, Textiles, Cellulose, and Paper, by J. F. Briggs; Bleaching, Dyeing, Printing, Finishing, by S. H. Higgins; Acids, Alkalis, Salts, Etc., by H. A. Auden; Glass, Refractories, by W. J. Rees; Metallurgy of Iron and Steel, by C. O. Bannister; Metallurgy of the Nonferrous

[Vol. 41

Waxes, by C. Revis and E. R. Bolton; Paints, Pigments, Varnishes, and Resins, by L. M. Nash; India Rubber, by D. F. Twiss; Leather and Glue, by F. C. Thompson; Agricultural Chemistry, by E. J. Russell; Sugars, Starches, and Gums, by J. P. Ogilvie; Foods, by H. W. Bywaters; Water Purification and Sanitation, by E. Ardern; Fine Chemicals, Medicinal Substances, Essential Oils, by G. Barger; and Photographic Materials and Processes, by B. V. Storr.

In the sections on Agricultural Chemistry and Foods the literature of the past three or four yeaers is reviewed, while the remaining sections cover, in general, the literature of 1918. In all sections the influence of war conditions on the trend of progress in applied chemistry is shown.

Acid fermentation of xylose, E. B. FRED, W. H. PETERSON, and A. DAVENPORT (Jour. Biol. Chem., 39 (1919), No. 2, pp. 347-383, pl. 1, figs. 3).—Organisms have been isolated from sauerkraut, silage, and manure which are capable of fermenting xylose rapidly, with the formation of acetic acid and lactic acid in the proportion of about 43 gm. of the former to 57 gm. of the latter, the two acids together representing about 90 per cent of the sugar consumed. The maximum amount of acid per gram of xylose fermented is obtained in cultures containing from 2 to 3 per cent of xylose. Sugars other than xylose are fermented by these organisms with the production of acetic and lactic acids, but in much smaller amounts.

The organisms, to which the name *Lactobacillus pentoaceticus* n. sp. has been given, are nonsporing, gram-positive, facultative anaerobes growing best with a lowered oxygen tension and at a pH of from 3 to 8.6. In yeast water or cabbage juice solutions xylose is fermented much more rapidly than in water solutions containing nitrogen from beef extract, peptone, or gelatin.

The authors call attention to the occurrence of these organisms in silage and their possible significance in the production of the acids of silage.

The action of ptyalin, H. McGUIGAN (Jour. Biol. Chem., 39 (1919), No. 2, pp. 273-284).—The action of ptyalin upon starch was determined by digesting a starch solution in an incubator at  $40^{\circ}$  C. with varying amounts of saliva, diluted 1:5 or 1:10, and filtered. One or 2 cc. samples of the digest were taken at stated intervals, boiled with 8 cc. of Benedict's picric acid solution and 2 cc. of 20 per cent sodium carbonate, made to a convenient volume, and matched in the calorimeter against a standard containing 1 or 2 cc. of a 0.1 per cent dextrose solution.

The results obtained, which are considered to be accurate within 5 per cent, indicate that ptyalin in dilute solutions acts on starch at a rate directly proportional to the amount of ptyalin present until digestion is interfered with by the products formed. The point of equilibrium is reached when about 70 per cent of the starch calculated as dextrose is converted into sugar. The chief cause of the establishment of equilibrium has not been discovered, but the theory is advanced that, since practically the same amount of sugar is formed by the same amount of ptyalin in varying concentrations of starch solutions, the ptyalin may unite quantitatively with the starch during digestion and exert a force which causes hydrolysis. When the starch molecule is converted into sugar the ptyalin is again free to unite with more starch. Dextrose and maltose are thought not to interfere with the normal process of digestion of the starch.

Note on the preparation of a purified agar powder with increased powers of filtration, J. CUNNINGHAM (Indian Jour. Med. Research, 6 (1919), No. 4, pp. 560-568, figs. 2).—The method described consists of a preliminary soaking of the crude agar for ten minutes with dilute hydrochloric or sulphuric acid, after which the product is thoroughly washed with running water until all traces of

615

acid have disappeared. After removing the excess water, the agar is placed on cotton wool filters in funnels resting in filtering tins. These are then autoclaved at 120° C. for one hour. The agar thus melted, sterilized, and cleaned is an approximately 9 or 10 per cent solution, which on cooling, forms a firm jelly. This is broken up into fine threads by passing through a rotary meat grinder. The threads are spread evenly in a thin layer over a number of metal trays, which are placed in a specially designed drying oven and desiccated at a moderate heat.

A series of observations made during the manufacture of different batches of desiccated agar by the above process is reported, which indicates that the best results are produced by the use of a weak solution of sulphuric acid (0.01 per cent). A one per cent solution of agar thus prepared is said to be absolutely firm and suitable for agar slants.

The process is recommended as furnishing a material which, for ordinary purposes, requires no further filtration, and which, owing to the sterilization during the process of manufacture, does not require subsequent sterilization at high temperatures.

New apparatus for the desiccation or concentration of liquids at a low temperature, L. MARMIER (Ann. Inst. Pasteur, 32 (1918), No. 4, pp. 145-149, figs. 2).—The apparatus described and illustrated in this article consists of an evaporator connected with a vacuum pump and tubular condenser and surrounded by an outer jacket through which water at the desired temperature is allowed to circulate. The liquid to be condensed is admitted into the evaporator through a closely fitting funnel communicating with two or more horizontal tubes with perforated outlets, which cause the liquid to be thrown out in a fine spray against the side of the evaporator as the funnel is rotated by means of a pulley or pinion. The funnel is also provided with paddles, which scrape off the condensed product into the lower part of the evaporator.

The author states that the apparatus has been used successfully for the concentration of fresh raisin must and glycerinated serums and for the desiccation of quantities of milk serum and blood. The temperatures of the water bath for these concentrations and desiccations varied from 36 to  $45^{\circ}$  C., while the temperature within the evaporator was as low as from 20 to  $26^{\circ}$ .

A new distilling column for laboratory use and its efficiency, M. H. ROBERT (Compt. Rend. Acad. Sci. [Paris], 168 (1919), No. 20, pp. 998-1000, figs. 2).— The apparatus consists of a column of connecting bulbs each partially filled with glass beads and the whole sealed within an outer glass jacket in which a high vacuum can be maintained. This is surmounted by a reflux air condenser of any type that affords a large condensing surface and in which the flow of air can be regulated. The inner tube of this condenser is connected with the inner tube of a third condenser. This tube is shorter than the surrounding jacket, to which it is fastened at the lower end only. In this tube is suspended a thermometer which, owing to the fact that the outer jacket is closed except for an exit tube at the lower end, records the exact temperature of the condensed liquid. The distillation is controlled by regulating the heating of the flask and the current of air in the reflux condenser.

It is said that by means of this apparatus certain separations may be effected quantitatively in a very short time.

A study of the lactose, fat, and protein content of women's milk, W. DENIS and F. B. TALBOT (*Amer. Jour. Diseases Children, 18 (1919), No. 2, pp.* 93-100).—The experimental work on human milk reported in this paper consisted of studies of the composition of milk at different stages of lactation, of milk at the beginning and end of a single nursing, of milk taken practically

1919]

simultaneously from the right and left breasts, and of the variations in composition of milk taken at three-hour periods during the course of a single day. Lactose was determined by the titration method of Folin and Denis (E. S. R., 38, p. 615), fat by the Babcock method or, when the amount of material was limited, by Bloor's nephelometric method (E. S. R., 32, p. 312), and protein by the Kjeldahl method. The detailed results are presented in tabular form.

There was found to be a rapid increase in lactose during the first few days and a further increase as lactation progressed. This was accompanied by a corresponding decrease in protein. After the colostrum period there was apparently no relation between the stage of lactation and the amount of fat in the milk. The percentage of lactose was usually higher, and fat lower, at the beginning of a single nursing than at the end. There was little if any difference in the protein. The milk taken simultaneously from both breasts of the same woman tended to have the same composition, but often varied in the percentage of fat. The percentage of fat was as a rule higher at midday or midafternoon than at other times during the day.

The results emphasize the importance in the analysis of human milk of obtaining samples both before and after nursing, instead of making the analysis on the first ounce of milk drawn.

The nonprotein nitrogenous constituents of cow's milk, W. DENIS and A. S. MINOT (*Jour. Biol. Chem.*, 38 (1919), No. 3, pp. 453-458).—Figures are given for the nonprotein nitrogen, amino nitrogen, urea, uric acid, creatinin, and creatin in cow's milk as determined by the methods previously described (E. S. R., 40, p. 509). Determinations were made on the mixed product of 4 large milk distributing plants, on 38 samples of milk from individual cows in 3 dairies, on milk obtained from 7 cows fed rations of known composition, and on milk obtained from a single cow during the first 4 weeks after calving.

While different samples of mixed milk of a large number of cows gave practically uniform results, the milk taken from individual cows in different dairies showed noticeable differences in the values for nonprotein nitrogen and urea. The content of nonprotein nitrogen, amino nitrogen, and urea was found to be influenced by the character of the food, being increased in high protein and decreased in low protein feeding. The content of these same constituents was found to be high in colostrum, and to approach normal values only on the fourth day after delivery.

Peroxidases in milk, H. VIOLLE (Compt. Rend. Acad. Sci. [Paris], 169 (1919), No. 5, pp. 248-250).—The freshly cut mammary glands of guinea pigs, washed free from blood and milk, were found to react positively to the gualacum peroxidase test, although the milk exuding from such glands gave a negative test. This is thought to indicate that normal fresh milk may contain only traces of oxidizing diastases, while milk from diseased glands is likely to contain larger amounts. It is further pointed out that although heating to 78 or 80° C. destroys peroxidases, heated milk may be easily adulterated by the addition of peroxidase-containing substances. The author therefore concludes that the quality of milk can not be judged by the peroxidase reaction.

Concentration of ammonia in blood.—Comparison with concentration of ammonia in different secretions and tissues, especially muscle tissue, K. L. GAD-ANDERSEN (*Jour. Biol. Chem.*, 39 (1919), No. 2, pp. 267-271).—A method of estimating ammonia and urea in muscle is outlined by means of which the transformation of urea into ammonia after death is thought to be prevented. This is brought about by stunning the animal on the back of the head, excising the muscle as quickly as possible, and keeping it under alcohol at a temperature of  $-20^{\circ}$  C. until the determinations are made. Ammonia is estimated by aeration and urea by the urease method.

A comparison of the ammonia and urea content of muscle as determined by this method with that of blood estimated by a new micro method indicates that, contrary to the results of earlier investigators, the concentration of ammonia is the same in muscle and in blood. If muscle is left for some time an increase in the concentration of ammonia takes place with a corresponding decrease

in urea, the sum of the two values remaining constant. The concentration of ammonia in bile, spinal liquid, and aqueous humor is also reported to be the same as in blood.

The microdetermination of nitrogen by direct nesslerization and of total solids, in drop quantities of human blood, A. W. PETERS (*Jour. Biol. Chem., 39 (1919), No. 2, pp. 285-298).*—A method is described for the determination of total and nonprotein nitrogen and of total solids in 15- to 30-drop quantities of human blood.

If the three determinations are to be made on the same composite sample, a maximum of 30 to 35 drops of blood is collected in a weighed centrifuge tube containing a small amount of 0.5 per cent sodium fluorid solution. The tube is rotated to mix the contents, weighed to determine by difference the weight of blood, and made up to a volume of 8.5 cc. with the sodium fluorid solution. One cc. of this volume is pipetted into a graduated cylinder and diluted with the collection medium to such a volume that the liquid will represent about 10 mg. of blood per centimeter. This is used for duplicate determinations of total nitrogen.

For the determination of total solids, 2 cc. of the original dilution of blood is pipetted into a small tube containing a few decigrams of pure dry talcum powder. The tube is rotated to distribute the powder uniformly over the inner surface, and is then heated in a nearly horizontal position in a drying oven at  $75^{\circ}$  C. to constant weight. For nonprotein nitrogen, two determinations are made with 2 cc. each of the original dilution of blood or one of 5 cc., depending upon whether about 30 or about 15 drops of blood have been collected.

Standard conditions for conducting the Kjeldahl digestion for both the total and nonprotein nitrogen and for the direct nesslerization of the digests are described in detail. The chief feature of the latter determination is the use of an inorganic color standard, which is matched in varying amounts against a fixed length of column of the different unknowns, and not vice versa as is customary. The standard solution is made by dissolving 6 gm. of ferric ammonium sulphate in 75 cc. of cold distilled water, adding 2 cc. of a 1 per cent picric acid solution, and making the volume up to 100 cc. with distilled water. The mixed color standard is said to remain perfectly clear and of constant intensity of color for a week or more. The quantitative evaluation of the colorimetric results has been adjusted to variations of analytical conditions, so that the variability and certainty of results are said to lie within a few thousandths of a milligram of nitrogen.

Determination of ammonia in blood, O. FOLIN (Jour. Biol. Chem., 38 (1919), No. 2, pp. 259, 260).—The author calls attention to numerous sources of error encountered in the determination of ammonia in blood by the method described by Morgulis and Jahr (E. S. R., 41, p. 413).

Bacon curing on the farm, J. B. FISHER (*Rhodesia Agr. Jour.*, 16 (1919), No. 3, pp. 202-209, pls. 4).—This article contains suggestions for the selection and fattening of pigs to be used for bacon, a list of tools necessary for farm bacon curing, directions for slaughtering, methods for curing the bacon by the dry salt and brine processes, and a description of a simple smokehouse.

Home drying of fruits and vegetables in Washington, F. O. KREAGER and I. N. ARMSTRONG (Wash. State Col. Ext. Dept., Ser. 1, No. 58 (1919), pp. 31, figs. 7).—This bulletin deals with the principles of food preservation in general, the

[Vol. 41

factors and principles involved in preservation by drying, the construction and operation of sun and artificial heat driers, and general and special processes in drying. Special directions are given for the drying of several vegetables and fruits and their subsequent treatment. Tables from Weather Bureau reports are included to show the varying conditions of sunshine, temperature, and humidity in different parts of the State (Washington), and the suggestion is made that in order to develop intelligent methods of drying for any particular community a careful study should be made of the principles of drying and of the climatic conditions of that community.

Industrial drying, P. RAZOUS (*Théorie & Pratique du Séchage Industriel. Paris: H. Dunod & E. Pinat, 1919, 2. ed., rev., pp. 253, figs. 65*).—This volume consists of two parts, the first of which deals with the general principles of evaporation, the principal types of hot air driers, mathematical calculations relative to the establishment of hot air driers, the use of ventilators for the circulation of the hot air, and various heating systems. The second part describes the commercial drying of a wide variety of substances, with advice as to the most economical methods of drying each. Among the materials treated are phosphates and superphosphates, hides, textile material, paper, fruits, vegetables, malt, wood, and fish. The closing chapter gives brief notes on the drying of special materials, including bones, rubber, celluloid, sugar, flour, food pastes, confectionery, pharmaceutical materials, and milk.

The manufacture of tomato products, W. G. HIER (*Denver: Author, 1919, pp. IX*+121, figs. 7).—This manual describes the modern methods for the commercial manufacture of tomato products, and points out the advantages and disadvantages of the different methods considered. Part I deals with the manufacture of whole tomato pulp or puree from the selection of the tomato stock, through the washing, sorting, pulping, and condensing processes to the canning and storing of the finished product. A chapter is included on the microorganisms of tomato products, the attitude of the pure food authorities toward them, and the interpretation of analyses. Part II deals with the manufacture of tomato catsup, chili sauce, trimming pulp, and tomato soup.

The manufacture of tomato paste, J. H. SHRADER (Amer. Food Jour., 14 (1919), No. 9, pp. 13, 14, 35).—The process of manufacture of tomato paste is outlined briefly, and various precautions that must be taken to insure a satisfactory product are discussed. The term tomato paste is given to tomato juice concentrated in the ratio of 5:1. When concentrated in the ratio of 2:1 the product is called tomato pulp, 2.5 or 3:1 tomato puree, and 10 or 12:1 double concentrated. The estimate is given that, in comparison with the manufacture of canned tomatoes, an equal tonnage of tomatoes if converted into paste will require only 25 per cent of the labor, with a reduction of 33 per cent in the consumption of tin and of 50 per cent in cannery waste. The freight saving is indicated by the fact that a 6-oz. paste can contains practically the equivalent of a 32-oz. ordinary tomato can.

Vinegar from wine, A. MARESCALCHI (L'Aceto di Vino. Casale Monferrato: Marescalchi Bros., 1918, pp. VII+127, figs. 9).—This pamphlet contains directions for the preparation of vinegar from wine on a domestic and an industrial scale; and a discussion of possible diseases, alterations, and defects in such vinegar; methods for the analysis of vinegar, and for the detection of adulterations; tables of the composition of Italian wine vinegar; and recipes for the preparation of toilet and medicinal vinegars, including some of historical interest.

Grape-shoot silage a source of alcohol and of tartaric acid, VENTRE (Compt. Rend. Acad. Agr. France, 5 (1919), No. 9, pp. 334-340).—The author states that in the grape-growing regions of France it has been customary for a number of years to ensile grape shoots cut soon after the grapes have been picked and while still in leaf. The silage thus obtained, when subjected to distillation, was found to yield from one to two per cent of alcohol, consisting of 94.8 per cent ethyl and 5.2 per cent methyl alcohol. The stems yielded a slightly larger amount of alcohol than the leaves. The mother liquor left after distillation contained tartaric acid in the proportion of 1.3 per cent in the stems and 1.68 per cent in the leaves.

A simplified process for the preparation of gluconic acid, A. HERZFELD and G. LENABT (*Ztschr. Ver. Deut. Zuckerindus.*, 1919, No. 758, II, pp. 122-128).— In the method proposed, one part of glucose dissolved in five parts of water is shaken with one part of bromin for a number of hours, and after standing for 24 hours is distilled in vacuo until the liquid is colorless. The residue diluted with water is treated with the calculated amount of sodium carbonate to neutralize the hydrobromic acid, and in the hot with an excess of calcium carbonate to bind the gluconic acid. On filtering and cooling, the calcium salt of gluconic acid crystallizes out and can be purified by recrystallization from a water solution.

The method was developed with a view to utilizing the resulting gluconic acid as a substitute for cane sugar.

An important consequence of the industrial synthesis of ammonia, G. CLAUDE (Compt. Rend. Acad. Sci. [Paris], 168 (1919), No. 20, pp. 1001, 1002).— The author suggests the advisability of transforming synthetic ammonia into ammonium chlorid by the Solvay process of manufacturing sodium carbonate, and using the ammonium chlorid thus formed as a fertilizer.

The advantages are pointed out of this transformation as compared with the manufacture of ammonium sulphate for like purposes.

#### METEOROLOGY.

The climate of Liberia and its effect on man, E. Ross (*Geogr. Rev.*, 7 (1919), No. 6, pp. 387-402, figs. 4).—The author summarizes the limited meteorological data available, consisting mainly of observations by himself and L. A. Hurt, on temperature, pressure and precipitation at Schieffiin, Liberia, from May, 1913, to October, 1915, inclusive, and by the German-South American Telegraph Company at Monrovia from January, 1915, to July, 1916, inclusive.

The mean annual temperature calculated from these records was  $78.5^{\circ}$  F. The warmest month was March,  $80.4^{\circ}$ , and the coolest months, July and August,  $76.4^{\circ}$ . The highest recorded shade temperature was  $93^{\circ}$ . "The rainy season occupied about seven months of the year, from mid-April to mid-November. During these seven months the precipitation was 170 in. out of the annual total of 179.5 in. . . The period of longest drought ran from December 28, 1913, to February 19, 1914—a total of 54 days, during which time 0.1 in. of rain fell on the thirty-second day. During July and August there is a period of lessened precipitation known locally as the 'middle drys.'...

"The sensible temperatures of the Liberian coast are not so high as those of many places in intermediate latitudes.... Yet, while the heat is not so extremely and sharply oppressive during a given day or week as may be the case in other and more temperate regions, it is much more dangerous in its steady persistence and the cumulative effect is extremely enervating. Insolation values are exceedingly high.... Negligent or ignorant exposure by a European of a bare head to the sun for periods of 2, 5, 10 minutes, and the like, has resulted at once in prolonged, pernicious fevers and sometimes in death." The habitability of the coast region is improved by land and sea breezes, and of the interior by elevation. Humidity is high, and the dry season is characterized by excessive dews which are sufficient to support plant life. Travel, transportation, communication, and food supply are controlled to a large extent by the rainfall. White people can maintain health only by great care in matters of sanitation and personal hygiene. "At present the relation of whites to the African West Coast can only be one of tolerance."

Climate of British Columbia, F. N. DENISON (*Brit. Columbia Dept. Agr. Bul.* 27, 4. ed. (1919), pp. 23).—Tables give data for temperature, precipitation, and sunshine for the various districts of British Columbia during 1916, 1917, and 1918.

"Generally speaking, the climate of this Province greatly resembles that of the European countries lying within the same parallels of latitude, and extending from the British Isles to the Baltic Provinces. Owing to the tempering effect of the Pacific Ocean, the winters on the coast are remarkably mild and the summers cool. Heavy rains occur in winter on the west coast of Vancouver Island and on the western side of the coast mountains on the mainland, while on the eastern portion of Vancouver Island the precipitation is comparatively light, and at the southern extremity about Victoria it is remarkably so, while the amount of bright sunshine exceeds that recorded at other British Columbia stations. Throughout the interior of this Province the precipitation and temperature vary greatly, according to local physical conditions. In some districts between the mountain ranges the rainfall is so light that irrigation is necessary, and maximum summer temperatures range from 90 to 100° F."

Climate of Brazil (In Dados Estatisticos. Rio de Janeiro: Min. Agr., Indus. e Com., 1918, pp. 13-33).—Tabulated data are given for temperature and precipitation for various places during each month, 1912–1916.

Nitrogen and other compounds in rain and snow, J. E. TRIESCHMANN (*Chem. News*, 119 (1919), No. 3094, p. 49).—Continuing accounts of previous studies (E. S. R., 38, p. 416), the author summarizes the results of determinations of nitrogen compounds, sulphates, and chlorin in rain and snow at Cornell College, Iowa, from October 1, 1918, to June 15, 1919.

#### SOILS-FERTILIZERS.

A soil classification for Michigan, C. O. SAUER (Ann. Rpt. Mich. Acad. Sci., 20 (1918), pp. 83-91).—As a result of studies at the University of Michigan, it is stated that with reference to Michigan soils, "the Bureau of Soils [U. S. Department of Agriculture] classification appears too assertive of the specific identity of soils, too inadequately formulated in the bases of classification, and involved in inconsistency in its largest division, the soil province. As alternative to the establishment of hard and fast soil types, Michigan soils may be classed according to a system similar to that formulated by the committee of the American Society of Agronomy.... The five Atterberg divisions appear to supply a sufficient determination of sizes of soil particles for Michigan conditions, and to be preferable in the determination of upper and lower limits of size."

On this basis a soil classification for Michigan is formulated.

Soil survey of Buena Vista County, Iowa, L. V. DAVIS and H. W. WARNER (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1917, pp. 37, pls. 4, fig. 1, map 1).—This survey, made in cooperation with the Iowa Experiment Station, deals with the soils of an area of 365,440 acres in northwestern Iowa, which topographically includes a morainic division with almost no natural drainage and an erosional division well supplied with natural drainage. The county lies

just within the glacial portion of the glacial and loessial province. Ten soil types of 7 series and 2 miscellaneous types are mapped, of which the Carrington loam and silt loam cover 48.6 and 27.8 per cent and the Webster silty clay loam 15.7 per cent of the area, respectively. All of the soils of the county are predominantly dark colored and well supplied with organic matter.

Soil survey of Henry County, Iowa, A. H. MEYER and T. H. BENTON (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1917, pp. 32, fig. 1, map 1).— This survey, made in cooperation with the Iowa Experiment Station, deals with the soils of an area of 273,280 acres in southeastern Iowa, the topography of which ranges from almost flat to steeply rolling. As a whole the county is well drained. The soils of the county are mainly of glacial drift and loessial origin. Thirteen soil types of 10 series are mapped, of which the Grundy silt loam, Clinton silt loam, and Grundy silty clay loam cover 39.4, 26.9, and 14.9 per cent of the area, respectively.

Mississippi: Its geology, geography, soils, and mineral resources, E. N. Lowe (*Miss. Geol. Survey Bul. 14 (1919)*, pp. 346, figs. 22).—This is a revision of Bulletin 12, issued in 1915 (E. S. R., 35, p. 213).

The agricultural soils of the Italian colonies, A. MAUGINI (*Trans. 3.* Internat. Cong. Trop. Agr. 1914, vol. 2, pp. 381-396).—This is a summary of data from a large number of sources on the physical and chemical composition of the agricultural soils of Eretria, Somali, Tripoli, and Cirenaica.

Soils, B. DE MARCHAND (Union So. Africa Dept. Agr. Rpt. 1917-18, pp. 113-115).—Analyses of 18 samples of soils of five different general types are reported, the general characteristics of which are deficiency in lime and phosphoric acid, together with a relative sufficiency of potash and a fair content of nitrogen.

Notes on some Poverty Bay soils, B. C. ASTON (Jour. Agr. [New Zeal.], 17 (1918), No. 4, pp. 196-200, fig. 1).—Analyses of 16 samples representative of the soils of the Poverty Bay region of New Zealand are reported, leading to the conclusion that the majority of these soils show every chemical indication of great natural fertility. The soils of the area are thought to be composed entirely of river silts and coarser particles, and the mechanical analyses showed no clay fractions in any case.

The need and objects of a soil survey in the Punjab, B. H. WILSDON (Agr. Jour. India, 14 (1919), No. 2, pp. 281-290, pls. 3).—This article deals with the importance of a soil survey in India, and reports mechanical analyses of different Indian soils as a basis for suggested soil classification.

A new method of analysis by washing and sedimentation, G. WIEGNER (Landw. Vers. Sta., 91 (1918), No. 1-2, pp. 41-79, figs. 7).—The author describes a method and apparatus for wash analyses, based on the variation of the specific weight of soil grains and especially of disperse particles during sedimentation. A formula corresponding to the theory is given as follows:  $p = \frac{Pvt}{h}$ , in which p = the weight of the soil after it has settled for a time=t, v = velocity of sedimentation, h = distance of settling, and P = the weight of the soil when t=0 at the beginning of the experiment. The curve of settling, showing quantities of soil and time, could be reproduced for the same soil, and was found to be independent of the height of settling or of the quantity of soil used. Small additions of electrolytes such as potassium chlorid changed the curve entirely.

The chemical composition of clay obtained by the Atterberg washing method, E. BLANCK (*Landw. Vers. Sta.*, 91 (1918), No. 1-2, pp. 85-91).—A study of the chemical composition of clay obtained from six widely different soils by mechanical analysis according to the Atterberg method is reported. From this it was concluded that this clay has a more individual chemical composition than that obtained by mechanical analysis according to the old Schloesing-Grandeau method, and that chemically this clay does not correspond to pure kaolin but progressively approaches it.

Studies of water absorption, percolation, evaporation, capillary water movement, and soil erosion under field conditions, M. F. MILLER and F. L. DULEY (*Missouri Sta. Bul. 163 (1919)*, pp. 65, 66).—The preliminary results of an experiment in which a series of plats was subjected to different systems of cropping and cultivation to determine their effects upon water entering the soil and upon soil erosion showed that the amount of water running off the land during the summer of 1917 from the uncultivated plat was 51.4 per cent of the total rainfall, or about twice the amount which ran off the cultivated plat and more than four times the amount leaving when the plats were kept in grass. The erosion from the bare plat where the weeds were kept down was only slightly greater than that from the cultivated land in spite of the fact that the run-off was greater, but the amount of run-off from the bare plat was nearly thirty times as much as that from the plat kept in sod. The other plats which are not quite so extreme in treatment, such as those in corn and those in small grain, have amounts of run-off which are intermediate between these.

An investigation of soil water, E. MCK. TAYLOR (*Essex Ed. Com., East* Anglian Inst. Agr., Chelmsford, Bul. 25 (1919), pp. 7).—This pamphlet describes a method of obtaining soil water samples by burying pads of absorbent filter paper in the soil for definite periods of time and then extracting the absorbed soil solution by pressure from the pads; and reports analyses of such soil water samples obtained from (1) a derelict soil growing grass for 35 years, (2) a productive chalky bowlder clay soil unfertilized for 5 years, (3) a highly cultivated chalky bowlder clay soil unfertilized for 7 years, and (4) a wet cultivated soil.

A comparison of the analyses of the soils and the corresponding soil waters showed that although the organic matter content in the first soil was higher than in the other three soils, the organic matter contents of the soil water of the other three soils were greater than in the water from the first soil. The second and third soils contained less potash than the first soil, but their soil water contained more than the water from the first soil. The derelict soil water also contained a higher percentage of iron than those from the three fertile soils.

It is concluded that the composition of the soil water is not that which would be inferred from chemical analysis of the soil.

Moisture studies at the Leffingwell Rancho, J. R. ALLISON (*Cal. Citrogr., 3* (1918), No. 12, pp. 290, 308, figs. 6).—This article deals primarily with apparatus and methods used in making soil moisture studies. Data obtained are also reported, indicating that trees growing upon a heavy soil are quickly damaged by too liberal use of water. It is believed that it is often much better to have the available soil moisture somewhat below the theoretical optimum or moisture equivalent, preferably about 5 per cent above the wilting coefficient. This seems to be especially true of heavy soils which have the property of increasing in volume on becoming wet and contracting on drying.

Effect of soil alkali on plant growth, F. S. HARRIS (*Trans. Utah Acad. Sci.*, 1 (1908-1917), pp. 131, 132).—This is a summary of the results of 18,000 determinations on the effect of alkali in the soil on the germination of seeds and the growth of plants.

It was found that only about one-half as much alkali was required to inhibit the growth of crops in sand as in loam. Crops varied greatly in their relative 1919]

resistance to alkali salts, the usual order of resistance being barley, oats, wheat, alfalfa, sugar beets, corn, and Canada field peas. Results from solution cultures and from soil tests did not agree in all cases. The period of germination of seeds was considerably lengthened by the presence of soluble salts in the soil.

The acid and not the basic radical apparently determines the toxicity of alkali salts in the soil, chlorid being the most toxic of the acid, and sodium the most toxic of the basic radicals. The injurious action of alkali salts was not always proportional to the osmotic pressure of the salts. The antagonistic effect of combined salts was not so great in soils as in solution cultures. Toxicity of alkali salts was influenced by the percentage of soil moisture. Salts added to the soil in solution had a greater effect than those added in the dry state.

On nitrification: II, Intensive nitrite formation in solution, A. BONAZZI (Jour. Bact., 4 (1919), No. 1, pp. 43-60, pl. 1, figs. 2).—This is the second of a series of articles on nitrification in soils contributed from the Ohio Experiment Station (E. S. R., 33, p. 421).

It was found that the ordinary Omelianski solution for the growth of the nitrite former will support a very abundant growth of this organism as measured by the production of nitrous acid. The conditions under which this luxuriant growth was produced were (1) shallow layers of the solution inclined at an angle of  $5^{\circ}$ , (2) slow rotary movement of the culture, and (3) a temperature of 25 to  $30^{\circ}$  C. The growths reported are considerably in excess of any yet reported for equal periods of time in solution cultures. "It would seem that better aeration may not be the only factor contributing to intensive nitrification, but that change of local environment is in some way associated with it."

Nitrate production in soil as affected by the crop and cultivation, W. A. ALBEECHT (*Missouri Sta. Bul. 163* (1919), pp. 67, 68).—In studies of the influence of crops and cultivation on nitrate production in soils, it was found during the first year that "the most significant influence of the crops is that of removing the nitrates. A reduction of nitrates takes place when the crop makes its rapid growth. For corn, nitrates accumulated until late in June but decreased very decidedly thereafter. For the grasses, including oats and timothy sod, no significant accumulation ever occurred, although there was slight increase after the crops were harvested.

"Cultivation failed to have any significant favorable effect. The greatest accumulation was obtained in the plat which was plowed in the spring and scraped to remove the weeds. The next highest accumulation resulted where the soil was left entirely undisturbed save that the weeds were pulled by hand. No appreciable difference was given by plowing 4 in. deep as compared to plowing 8 in. deep. Plats left uncultivated were higher in nitrates than those cultivated regularly during the year.

"The straw mulch had a decidedly depressing effect on nitrate accumulation. No significant accumulations occurred. Apparently the high moisture was responsible, since the curve of moisture percentage bears a negative correlation to that of nitrate accumulation."

A possible case of partial sterilization in soil, F. KNOWLES (*Nature [London]*, 103 (1919), No. 2585, p. 205; abs. in Chem. Abs., 13 (1919), No. 15, p. 1736).—A very favorable growth was observed in crops of potatoes, dwarf peas, and dwarf beans grown on a garden soil that had been idle for at least three years and that had received by chance a light top-dressing of a mixture of charcoal and brick earth impregnated with potassium carbonate and hexamethylenetetramin. It is suggested that the unusually good growth of the crops

149863°-20-3

may have been due to the liberation of formaldehyde by the hexamethylenetetramin through the action of dilute soil acids, which caused partial sterilization.

The search for toxin producers, R. GREIG-SMITH (*Proc. Linn. Soc. N. S. Wales, 48 (1918), pt. 1, pp. 142–190*).—Experiments to determine the origin of toxins in soils are reported in which certain soil bacteria, molds, and amœbæ, all reasonably supposed to be capable of furnishing substances of a toxic nature, were grown in various media and under varying conditions. In all cases, the signs of toxicity which became manifest could be attributed to an alteration in the reaction of the media.

"The test organism, *Bacillus prodigiosus*, grows best in a neutral medium, and an indicator is required which will indicate strict neutrality. The methylorange numbers are too high and the phenolphthalein too low. Small divergences from the neutral point strongly affect the growth. The humus of leaf-mold contains two types of humic acid; one absorbs alkali from alkaline carbonates, and the other from alkaline carbonates and hydrates. These were present to the extent of one part of the former to three of the latter. Heating the humus increases the amount of acid, and the increase is largely soluble in water. The effect of reaction is quite of a different order from the evidence of toxic action obtained in former researches."

Unproductive soils, L. GRIMALDI (Le Terre Difficili. Casale Monferrato: Marescalchi Bros., 1917, pp. VIII+98).—This pamphlet deals with the treatment and cultivation of acid peat and swamp soils, heather soils, sands, alkali soil, soils containing hardpan and mineral acids, siliceous and rocky soils, arid soils, and generally worn-out soils as they occur in Italy. A specially interesting feature is the dynamiting of rocky soils preliminary to cultivating.

Timely soil topics, F. E. BEAR, J. F. BARKER, F. A. BACHTELL, and R. B. DUSTMAN (Columbus, Ohio: Authors, 1919, pp. 108, pls. 14).—This volume is the outgrowth of a series of 4-page pamphlets written monthly during the year 1918–19 by members of the department of agricultural chemistry and soils of the Ohio State University, and consists of the material contained in the first thirteen numbers, revised and rearranged. It deals with the management of soils with reference to the production of common farm crops, taking up especially the varying uses of fertilizers on soils for different crops and the preparation of soils for different crops.

Experiments to determine the best systems of soil management for the most important soil types in Missouri, M. F. MILLER, F. L. DULEY, and B. W. TILLMAN (*Missouri Sta. Bul. 163 (1919)*, pp. 68-71, flgs. 3).—Experiments on 14 different fields are summarized.

As an average of all trials a ton of barnyard manure gave a crop increase valued at \$4.20 at present crop values. As an average of all experiments the addition of 300 lbs. of steamed bone meal brought a return in four years of approximately \$20 an acre. An addition of 400 lbs. of acid phosphate brought a return of about the same amount. Rock phosphate additions just about paid for their cost during a period of from 6 to 10 years. The return from a ton of ground limestone was approximately \$8. Green manuring with cowpeas gave generally good results.

Soil fertility experiments, C. B. WILLIAMS (North Carolina Sta. Rpt. 1918, pp. 23-28).—This is a brief sketch of the plan of soil fertility experiments at different farms of the station, together with a statement of results so far obtained.

Among the more important results it was found that at the Iredell substation mineral nitrogenous fertilizers, sodium nitrate and ammonium sulphate,
have given better results than organic nitrogenous fertilizers, there being no marked residual effect of the latter. Finely ground rock phosphate was found not to be as economical a carrier of phosphoric acid as acid phosphate, in spite of the high price of the latter.

"In the study [at the Granville farm] of the value of different sources of nitrogen, phosphoric acid, and potash, and combinations of these for tobacco, results thus far secured indicate that the organic sources of nitrogen are best. Dried blood is probably best, with cottonseed meal next of the more common nitrogenous carriers. When mixed with proper proportions of phosphoric acid and potash, sulphate of potash produces a better quality of tobacco than does muriate of potash. The muriate, however, seems to make a larger leaf, or one with a larger spread. Acid phosphate has given better results as a carrier of phosphoric acid for tobacco than has either bone meal or basic slag. . . . The field experiments in the study of the value of tobacco stems and stalks for fertilizing tobacco have indicated that good tobacco can be grown by the use of these, when they are not used at a rate heavier than 2,500 lbs. per acre, supplemented with a little phosphoric acid and potash, if native or bright tobacco stems are used; and by phosphoric acid and nitrogen when Burley stem and stalks are applied. . . .

In the study [at the Reidsville farm] of the residual effect of fertilizers on small grains, generally wheat and then grass following after tobacco with no additional fertilizer, the residual effect of phosphates was dominant and very important... Even when used with phosphate, the residual effect of materials carrying ammonia was not generally important for more than one year. The use of potash alone or combined with ammonia only had almost no residual effect."

On the persistence of arsenite of soda in the soil, C. W. MALLY (So. African Jour. Sci., 15 (1919), No. 5, pp. 325-329).—Analyses of samples of stable manure treated with sugar and sodium arsenite as fly killer are reported, together with the results of plat experiments with wheat, oats, rye, barley, maize, peas, beans, potatoes, and cabbage, to determine the direct influence and residual effect of sodium arsenite prepared as fly bait and added at rates of 6.25, 12.5, 25, 50, 100, 200, 300, 400, and 500 lbs. per acre, and mixed in the same amounts with stable manure added at the rate of 10 tons per acre. The soil was a deep stiff clay.

The results showed that in the stronger plats (500, 400, and 300 lbs. per acre) the transplants, as well as the seedlings of all kinds, presented a very sickly, spindly appearance from the start, being stunted in growth and of a reddishyellow color, especially at the tips and along the edges of the leaves. On the whole, the sickly appearance was less pronounced from plat to plat as the strength of the arsenite decreased, but there was not much choice between the 500, 400, and 300 lb. plats. In the 200-lb. plat the injury was less severe, and in the 100-lb. plat only noticeable. In the weaker strengths no injury was manifest in comparison with the control and the isolation plats.

The manured plats were better than the unmanured plats. The manured part of the control plat was better than any of the others, including the isolation plats, which received neither manure nor poison. The manure in the poisoned plats clearly counteracted the effect of the poison to some extent.

"The injurious effect of the arsenic was most noticeable during June and July, while the different plants were young. Of the grain crops, severity of injury was apparent in the order named: Oats, barley, wheat, and rye. Oats were very sensitive, and would make a valuable 'indicator' of arsenical poison in the soil. Barley followed it very closely. Wheat was considerably less sensitive than oats or barley. Rye showed a considerable degree of resistance, so much that it would be of little use as an indicator, but this fact establishes its value as a crop to be grown when arsenical soil poisoning is suspected. Peas were much more sensitive than beans—in fact, peas would also serve as a good indicator of arsenical soil-poisoning. Although the other crops showed the effect of the poison, they were not specially sensitive, and were so irregular that no close comparisons could be made. As the rains diminished and the season advanced into spring and summer, all of the plants made more rapid progress. . . .

"The plats were continued through 1916, 1917, and 1918, with the same crops as indicators. The results are in the same order, but distinctly less marked each succeeding season. During the present season (June, 1918) the effect of the arsenic in the stronger plats can still be traced in oats and barley, but it is doubtful whether it will show to any extent as the crops approach maturity.

"In the experimental plats, amounts of arsenic far in excess of any possible bait accumulations in the manure did not have a noticeable effect on the crops grown. It therefore seems justifiable... to conclude that farmers have nothing whatever to fear from the small amount of arsenite of soda in the form of house-fly bait that may accumulate in stable manure."

Liquid manure (Jour. Bd. Agr. [London], 26 (1919), No. 4, pp. 428-431).— Notes are given on the value and use of liquid manure, it being emphasized that the more liquid manure is kept from the air the better will it retain its fertilizing value, and that in storage of liquid manure no solid manure should accompany the liquid into the tank, owing to the resulting fermentation and loss of value.

Fertilizers and their use in Canada, F. T. SHUTT (Canad. Thresherman and Farmer, 24 (1919), Nos. 8, pp. 28-31; 9, pp. 40-42, figs. 2).—The author reviews and summarizes the results of recent years' fertilizer experiments in Canada, which indicate that in most cases excessively large dressings of fertilizer have not given net profits per acre of the same magnitude as medium applications. The larger profits came from using complete fertilizers. In general, it was found that the exclusive use of fertilizers will neither maintain the fertility of the soil nor yield profitable returns, and that it is on soils of medium quality rather than on soils of poor quality that profitable returns can be expected. Furthermore, the use of fertilizer on so-called "money" crops yielded the greatest profit.

Fertilizers and fertilizing, R. HEINRICH (Dünger und Düngen. Berlin: Paul Parey, 1918, pp. VII+158).—This book is intended as a guide for the practical use of stable and green manure and commercial fertilizers in Germany.

Home mixing of fertilizers, C. C. FLETCHER (U. S. Dept. Agr. Yearbook 1918, pp. 185-190, fig. 1).—This is a brief popular description of the process of mixing fertilizers at home.

The effect of different amounts and different methods of applying commercial fertilizer to the corn crop, M. F. MILLER and F. L. DULEY (*Missouri Sta. Bul. 163* (1919), p. 67).—As an average of two years' trials it was found that when the weather is dry the addition of fertilizers in the row produced poorer results than addition with the fertilizer drill in advance of the corn planter. "The early effects of the row fertilization are more marked than the early effects of the fertilizer applied over the whole surface, but corn so fertilized does not seem to be able to stand the drought so well during July and August because of the larger leaf development. Fertilizer applied as a side application along the row at the second or third cultivation has brought fairly good increases as an average of these two years." The fertilizing value of activated sludge, G. G. NASMITH and G. P. MC-KAY (Jour. Indus. and Engin. Chem., 10 (1918), No. 5, pp. 339-344, figs. 7; abs. in Engin. and Contract., 50 (1918), No. 2, pp. 31, 32).—Experiments are reported in which air-dried sludge was compared with air-dried stable manure as a fertilizer for radishes, lettuce, beans, beets, late radishes, tomatoes, carrots, and onions on a poor clay soil low in organic matter. Both sludge and manure were added at the rate of 14.5 tons per acre. Under the rather limited conditions of the experiment it was found that the activated sludge in general gave much better results than the manure.

"From the results obtained it seems to be true that crops such as lettuce, . . . beans, beets, or tomatoes, . . . can be stimulated into very heavy growth by the use of activated sludge. The increase in the yield of onions is also great. . . . In the case of radishes, though the final weight was not materially greater, the radishes matured much more rapidly. . . . The same holds good of lettuce or beets, in which the growth was much more rapid than it was with the other fertilizer tested."

Government Guano Islands, W. R. ZEEDERBERG (Union So. Africa Dept. Agr. Rpt. 1917-18, pp. 149-153).—This report states that the Government Guano Islands of the Union of South Africa yielded from all sources 6,965.5 tons of guano in 1917. Data on distribution and use are given. The average chemical composition of the guano disposed of during 1917 was nitrogen, 11.06 per cent; water-soluble phosphoric oxid, 3.5; citrate soluble phosphoric oxid, 11.41; total phosphoric oxid, 11.46; potash, 2,5; and lime, 11.62 per cent.

The relative availability of nitrate nitrogen and commercial organic nitrogen in cylinder and field experiments, A. W. BLAIR (*Amer. Fert.*, 51 (1919), No. 6, pp. 56, 57).—The results of 20 years' cylinder and field experiments at the New Jersey Experiment Stations are reported on the relative availability of nitrate nitrogen and nitrogen from organic sources.

Two types of loam soil and a loam with varying admixtures of coarse white sand were used. For all of these soils, except those containing 80 per cent or more of sand, the nitrates gave better yields and showed a higher percentage of nitrogen recovered in the crop than the organic materials such as dried blood, fish, and tankage. "Under the most favorable conditions only a little over 60 per cent of the applied nitrogen can be recovered in the crop.... Under less favorable conditions, the percentage recovery is much lower, often amounting to only one-third of the amount applied." In the cylinder experiments only about 38 to 45 per cent of the applied organic nitrogen was recovered. The average recovery of nitrate nitrogen in the field experiments was 37 per cent and of organic nitrogen 26.5 per cent. It is suggested that the superiority of nitrate nitrogen is due to its immediate availability. See also a previous note (E. S. R., 41, p. 22).

The manufacture of ammonia for fertilizer salts, C. BOSCH (*Ztschr. Elektrochem.*, 24 (1918), No. 23-24, pp. 361-369).—This is a review of work in Germany during the year 1918 on the synthesis of ammonia, with special reference to use as fertilizer material.

Potassium ammonium nitrate, a new top-dressing for sugar beets, M. HOFFMANN (Deut. Zuckerindus., 43 (1918), pp. 149, 150; abs. in Ztschr. Angew. Chem., 31 (1918), No. 84, Ref., p. 313; Jour. Soc. Chem. Indus., 37 (1918), No. 23, p. 744A).—Potassium ammonium nitrate, prepared from ammonium nitrate and potassium chlorid, has been found to be easy to distribute over the land and can be safely used as a top-dressing. It contains about 13 per cent of nitrogen, 25 per cent of potash, and front 27 to 30 per cent of chlorin. It has the advantage over ammonium nitrate that it can be spread more uniformly and is much less hygroscopic and explosive.

Economic analysis of the world shortage in phosphate, L. B. ANDERSON (*Amer. Fert.*, 51 (1919), No. 7, pp. 47–59, figs. 4).—In this analysis and summary of the world's phosphate industry, data are reported indicating that the total world shortage in phosphate production occasioned by the war amounts to about 15,000,000 tons. This country contains the greatest known phosphate deposits and is the largest producer of natural phosphate, but the phosphate export business which it was unable to do during the war was about 5,000,000 tons. Basic slag production did not increase rapidly enough to offset the shortage in phosphate, and Tunis now exports more phosphate than the United States.

"The Special Commission to Europe reports a big demand for fertilizer. Ocean tonnage is the principal factor tending to retard the development of the business at the present time. The policy of the Shipping Board will be to meet foreign rates, and develop the business in so far as it can be consistently done. The present methods of selling phosphate are very favorable to the American exporter as contrasted with prewar methods. Europe must import phosphate in large quantities if the original productivity of the soil is to be restored. The United States, owing to her splendid deposits, is in a good position to develop this business when normal conditions again prevail."

The mineral superphosphate industry, E. STAUB (*Chim. et Indus.* [*Paris*], 2 (1919), No. 2, pp. 123–132, figs. 8; abs. in *Chem. Abs.*, 13 (1919), No. 10, pp. 1115, 1116).—This is a review of the process used in the manufacture of superphosphate and also of various other processes that have been proposed for treating phosphate rock, including (1) digestion with sodium acid sulphate, (2) ignition with silica and an alkali salt to form artificial slags, (3) manufacture of tetraphosphate, and (4) manufacture of double superphosphate by treatment with acids.

Artificial phosphatic slag, A. BRUNO and L. RONNET (Compt. Rend. Acad. Agr. France, 5 (1919), No. 20, pp. 592-594; abs. in Chem. Abs., 13 (1919), No. 17, p. 2102).—This is a brief description of an artificial phosphatic slag manufactured from phonolite rock by the Germans during their occupation of Belgium. An analysis shows total phosphoric acid 11.5, citrate soluble phosphoric acid 6.5, potash soluble in strong acid 2.4, and in weak acid 1.07 per cent. The use of this slag on sandy soils is recommended especially for potatoes, although it is the opinion that phonolite was chosen for this material on account of its ease of vitrification rather than for its potash content.

Determination of the relative value of different forms of phosphorus upon the soil at Columbia, M. F. MILLER and F. L. DULEY (*Missouri Sta. Bul. 163* (1919), p. 67).—Comparative trials of rock phosphate, acid phosphate, bone meal, basic slag, and calcined phosphate, on wheat in plats showed that respective average increases of 2.3, 3, 7.5, 3.8, and 5.5 bu. per acre were obtained. The results with calcined phosphate, which is a heat treated rock phosphate, are considered specially promising.

Future of the potash industry, J. W. TURRENTINE (*Chem. and Metall. Engin.*, 20 (1919), No. 7, pp. 310, 311; abs. in *Chem. Abs.*, 13 (1919), No. 10, p. 1129).— This is a plea for scientific organization and cooperation in the development of American potash.

American potash in crop production, E. O. FIPPIN (Cornell Countryman, 16 (1919), No. 3, pp. 121, 122, 140, 142, 144, fig. 1).—The author summarizes data from different sources to indicate the importance of potash as a fertilizer, and draws attention especially to the reduction in crop yields due to the recent scarcity of potash. "It can be expected that potash will come back into com-

628

mercial fertilizer, but in more conservative amounts than was formerly used for the ordinary farm crop."

Potash recovery, N. H. GELLERT (*Chem. and Metall. Engin.*, 20 (1919), No. 7, pp. 308, 309; abs. in Chem. Abs., 13 (1919), No. 10, p. 1129).—A comparison is made of data reported by others, and estimates are given of the cost of operating the Cottrell system for the removal of the dust from blast furnace gases. It is considered that the net revenue derived from the potash that is recovered in the dust should yield profitable returns even if the price of the potash were to drop to a value of \$1 per unit.

Value of blast furnace dust as a potash manure: Report on field trials (*Jour. Bd. Agr.* [London], 26 (1919), No. 4, pp. 387-396).—Plat experiments with potatoes and mangolds to compare low-grade dust, medium-grade dust, high-grade dust, extracted dust, and German potassium sulphate containing respectively 2.21, 5.85, 8.9, 7.37, and 50.24 per cent potash as sources of potash are reported. The fertilizers were added at respective approximate rates of 2,200, 850, 550, 650, and 100 lbs. per acre.

It was found that the extracted and high-grade dusts gave the best results with potatoes, followed by the medium-grade dust and the potassium sulphate. The low-grade dust gave the poorest results. It is noted that the extracted dust, that is, dust very rich in potash from which the bulk of the water-soluble potash had been removed by boiling water, gave among the highest results. It was found to be advisable to add the dust well in advance of the crop owing to the relatively low availability of the potash.

The results obtained with mangolds did not correspond with those obtained with potatoes. Potassium sulphate gave the best results, while the poorest were with low-grade dust and late additions of medium-grade dust. The rest of the dusts gave about equal results in all cases, with about a 10 per cent increase in yield.

Fertilizer from the effluent from potassium chlorid works, W. HÜTTNER (Chem. Ztg., 42 (1918), pp. 434, 435; abs. in Jour. Soc. Chem. Indus., 37 (1918), No. 21, p. 666A; Chem. Abs., 13 (1919), No. 9, p. 985).—In the process of manufacture of fertilizer from the effluent of potassium chlorid works the effluent is introduced into a tank containing quicklime, the latter being covered with the liquid. Heat is developed and the whole is converted into a powdery mass which consists of magnesium oxid, magnesium and calcium oxychlorids and small quantities of potassium chlorid, sodium chlorid, calcium sulphate, etc. The fertilizing value of this material is said to depend chiefly upon the presence of the magnesium oxid.

Bracken as a source of potash, J. E. PURVIS (*Proc. Cambridge Phil. Soc.*, 19 (1919), No. 5, pp. 261, 262; abs. in Chem. Abs., 13 (1919), No. 15, pp. 1736, 1737).—The percentage of potash in samples of bracken collected at Cambridge during different months of the year ranged in the dry material from 3 per cent in that collected in June to 0.82 per cent in the samples collected in October. In Welsh bracken the corresponding range of the potash was from 3.22 per cent to 1.32 per cent as found in the samples collected in July and October, respectively.

These results are considered to confirm the opinion that in the summer months there is more potash than in the later months. "Also there is a clear indication that, on an average, the Welsh peaty soil yields more potash than the Cambridge poor sandy soil."

Bracken: Utilization and eradication, R. A. BERRY (West of Scot. Agr. Col. Ann. Rpt., 14 (1917), pp. 181-193).—Studies on bracken with particular reference to its value as a source of potash are reported. It was found that "the composition of bracken depends mainly upon the age of the fronds, and, to a less extent, on varying soil and climatic conditions. The ash in the dry matter amounts to about 9 per cent, and contains 55 per cent of potash in the young fronds, and to about 6 per cent and 40 per cent, respectively, in the mature fronds. "The rate of fall varies according to soil and climatic conditions.

"The potash in the ash is present largely as the sulphate and the chlorid of potassium. Some carbonate is also present. Over 90 per cent of the total potash, in carefully prepared ash, is soluble in water. By extracting the dry matter with water, more than 90 per cent of the total potash in the form of neutral salts is dissolved out, a fact which will largely account for the very low potash content of ash made from dead bracken, cut in the winter months after exposure to the leaching action of rain. Age of the plant does not affect the solubility of the potash.

"The caustic nature of the ash can be destroyed by the addition, in a fine state of division, of acid salts such as superphosphate of lime, or niter cake (sodium hydrogen sulphate). In the making of the ash, too large a fire should not be kept burning, otherwise a very high temperature may be attained, which might cause some loss by volatilization of potassium in the form of the chlorid, and also fusion of the ash into solid lumps. The best time to cut the bracken to secure the greatest yield of potash is when the fronds have reached their maximum growth, a development indicated by the withering of some of the small leaves and when the green color of the stem begins to change. The date will vary according to season and local conditions. Under the best conditions of cutting, drying, and burning, it requires from 4 to about 8 acres—according to the density of growth and height of the fronds—of fully stocked bracken land to yield 1 ton of ash."

Commercial fertilizers, E. G. PROULX, O. S. ROBERTS, R. O. BITLER, S. F. THORNTON, and O. W. FORD (*Indiana Sta. Bul.* 229 (1919), pp. 3–94, figs. 4).— This bulletin presents the results of analyses and valuations of 1,285 samples of fertilizers and fertilizing materials collected for inspection in Indiana during 1918.

It was found that 69.1 per cent of the samples were equal to the guaranty in every particular, and that 88.9 per cent were equal to the value of the guaranty. The former figure is the highest yet attained in the State while the latter is slightly lower than that of the previous year.

"The largest number of samples having a deficiency of 10 per cent or more of guaranty were in potash, there being 130 inspection samples found deficient in potash, or more than the deficiencies in nitrogen, available phosphoric acid, and total phosphoric acid combined. . . . In nitrogen 28 samples were deficient 10 per cent or more of the guaranty; in available phosphoric acid, 42 samples; and in total phosphoric acid, 21 samples."

Digest and copy of fertilizer law (New Jersey Stas. Circ. 108 (1919), pp. 8).—This is a revision of Circular 9 of the station (E. S. R., 28, p. 326) including the amendments to the law passed in 1919.

### AGRICULTURAL BOTANY.

[Report of the investigation and work in plant physiology], R. P. HIBBARD (*Michigan Sta. Rpt. 1918, pp. 271-273*).—A brief outline is given of the work carried on in the department of plant physiology, the principal investigation being a continuation of that previously reported (E. S. R., 39, p. 419). An account is given of investigations of the soil solution, this work having been continued in experiments conducted in quartz and soil. The three series that have been made are believed to have established the physiological balance in soil cultures.

**Porous clay cones for the auto-irrigation of potted plants, B. E. LIVINGSTON** (*Plant World, 21 (1918), No. 8, pp. 202–208, fig. 1).*—An account is given of the construction, operation, and advantages of a plan for auto-irrigation in the study of plants.

A comparison of permeability in plant and animal cells, W. J. V. OSTER-HOUT (Jour. Gen. Physiol., 1 (1919), No. 4, pp. 409-413).—Disks of Laminaria were studied in connection with comparable pieces of skin taken from the frog (Rana pipiens). The quantitative results showed a striking agreement between the two kinds of tissues as regards certain important aspects of permeability, antagonism, injury, recovery, and death.

Decrease of permeability and antagonistic effects caused by bile salts, W. J. V. OSTERHOUT (Jour. Gen. Physiol., 1 (1919), No. 4, pp. 405-408, figs. 2).— As a result of experiments made by determining the electrical conductivity of Laminaria in solutions to which sodium taurocholate had been added, the author states that this salt decreases permeability and antagonizes sodium chlorid. This fact confirms the hypothesis that antagonistic relations can be predicted from studies on permeability.

Antagonism between alkaloids and salts in relation to permeability, W. J. V. OSTERHOUT (Jour. Gen. Physiol., 1 (1919), No. 5, pp. 515-519, figs. 3).—In order to compare antagonism between alkaloids and salts with that between salts and other salts, the author carried out experiments on Laminaria with nicotin, caffein, and cevadin added in varying amounts to sodium chlorid at 0.52 M.

It appears that solutions which have opposite effects on permeability antagonize each other in case of alkaloids as well as in that of salts. It also appears from this work that certain alkaloids which decrease permeability are able to antagonize sodium chlorid, in this respect resembling salts which decrease permeability.

The effect of ions of sodium chlorid and calcium chlorid upon the electrical conductivity of certain colloidal mixtures, N. B. GREEN (*Plant World, 21* (1918), No. 12, pp. 303-316, figs. 7).—Experiments here outlined were suggested by the discovery of Osterhout (E. S. R., 26, p. 823) that the permeability of plant tissues to various ions can be determined by measuring the resistance offered by such tissues to an electric current. It was found in the present work that when one salt is allowed to penetrate the colloid for a time, and then a second salt substituted, the rate of penetration by the ions of the latter seems to be unaffected by the presence of the former. The mixed solution of sodium chlorid and calcium chlorid showed a fall of resistance similar to that of either of the constituents alone, the curve approaching more nearly that of the predominant salt. Ions of these two substances do not antagonize one another as regards penetration of certain colloidal gels, notably gelatin or mixtures of gelatin, agar, and whole wheat flour.

Determinations of electrical resistance in solutions of gelatin to which salts had been added in varying concentrations showed that the electrical resistance of the gelatin varies directly with the precipitability, which is greatest at the isoelectric point, that is, where the unadsorbed + and - ions of the added salts balance one another.

The water requirement of plants as influenced by environment, L. J. BRIGGS and H. L. SHANTZ (*Proc. 2. Pan Amer. Sci. Cong., 1915-16, vol. 3, pp. 95-107, pls. 2, figs. 4*).—From experiments with grain and other plants, described as employing methods somewhat different from those previously used (E. S. R., 32, p. 127), the authors claim that where the crop is thoroughly adapted to the region in which it is grown the water requirement approaches its minimum, but is relatively high when the crop is not well adapted. Water requirement is not correlated with any one condition of the environment. Cool weather crops as a rule will have a low water requirement in cool seasons and a high water requirement in warm seasons. In case of warm-weather crops the reverse is usually true, although the effect is less marked, a cool season being conducive to a low evaporation rate.

On the osmotic concentration of the tissue fluids of desert Loranthaceæ, J. A. HARRIS (*Mem. Torrey Bot. Club, 17 (1918), pp. 307-315*).—Having continued previous work (E. S. R., 37, p. 47), the author here presents results of studies on sap concentration of the tissue fluids of desert mistletoes and that of their hosts for comparison with those for the rain forest series already noted. The investigation included *Phoradendron coryæ*, *P. macrophyllum*, and *P. californicum* on a number of hosts.

The osmotic pressure of these mistletoes was, roughly speaking, twice as great as was found in the Blue Mountains of Jamaica. In desert Loranthaceæ, as in those of the montane rain forest, the osmotic concentration of tissue fluids was generally, but not invariably, higher than that of the host.

The effect of soaking in water and of aeration on the growth of Zea mays, F. M. ANDREWS and C. C. BEALS (*Bul. Torrey Bot. Club*, 46 (1919), No. 3, pp. 91-100, figs. 5).—In this work it was found that 12 hours is the optimum period of soaking seed of Z. mays in order to obtain increased growth, and that growth is retarded temporarily by too long a period of soaking. Puncturing or partially removing the seed coats accelerates germination. Aerating the culture solution accelerates growth.

Comparative studies on respiration.—VI, Increased production of carbon dioxid accompanied by decrease of acidity, M. IRWIN (Jour. Gen. Physiol., 1 (1919), No. 4, pp. 399-403, figs. 2).—Having noted that high concentrations of ether greatly increased carbon dioxid production by animals, and that this is associated with irreversible changes ending in death, the author, in order to obtain light on the question arising as to whether this increased evolution of carbon dioxid might not indicate increased respiration, experimented with two organisms, Salvia involucrata and S. splendens, in which death is not accompanied by increase of acidity. It was found that in petals of Salvia high ether concentrations increased oxygen consumption and carbon dioxid production, a decrease occurring at the same time in the acidity of the cell content.

On the decomposition of cellulose by an aerobic organism (Spirochæta cytophaga n. sp.), H. B. HUTCHINSON and J. CLAYTON (Jour. Agr. Sci. [England], 9 (1919), No. 2, pp. 143-173, pls. 3, fig. 1).—An account is given of the study of an organism found in the Rothamsted soils which is able to break down cellulose with comparative ease and which presents features of morphological and physiological interest. The organism, which is said to be more closely allied to the Spirochætoideæ than with the bacteria, is named Spirochæta cytophaga. It does not grow in the usual way on nutrient gelatin or on agar. Cellulose is the only carbon compound found to favor its growth. Evidence is adduced to show the relation of cellulose decomposition to the assimilation of atmospheric nitrogen.

Influence of temperature and hydrogen ion concentration upon the spore cycle of Bacillus subtilis, A. ITANO and J. NEILL (Jour. Gen. Physiol., 1 (1919), No. 4, pp. 421-428, figs. 2).—Data resulting from this investigation are given with discussion. Automatic adjustment of the medium seems to play a rôle in the completion of the spore cycle of *B. subtilis.* The results are thought to be capable of practical application in the preservation of food by canning and other methods.

[Viability of Pseudomonas radicicola under aerobic and partial anaerobic conditions], F. O. OCKERBLAD (*Michigan Sta. Rpt. 1918, pp. 255-264*).—On account of the practice of experiment stations and commercial firms of distributing cultures of nodule-forming bacteria in liquid media, the author conducted a series of experiments with 12 strains of *P. radicicola* under various conditions to determine their effect on the viability of the organisms. Liquid and solid cultures were inoculated with a suspension of bacteria and incubated for two weeks at temperatures of 20 to  $23^{\circ}$  C. The containers holding one-half of each lot were plugged with cotton and the others with cork stoppers.

Examinations of the organisms were made from time to time, and it was found that the cultures in cork-stopped bottles died quite rapidly. The organisms living after 160 days averaged 0.21 per cent for the liquid and 3 per cent for the solid cultures. The viability of the organisms in ash-sugar solution was much less than that on ash-sugar agar. On the ash-sugar agar under cotton plugs the different strains died gradually, an average of 91.1 per cent living after 20 days, 46.2 per cent after 100 days, and 12.5 per cent after 160 days. The thermal death point of different strains was determined to fall between 59 and 61°. Four of the 12 organisms were found to stand a temperature of 60°, but none of them was able to grow after being exposed for 10 minutes at a temperature of 61°.

The factors considered to cause a decrease in the number of living organisms are partial anaerobic conditions, accumulation of metabolic and toxic products, and plasmolysis caused by the concentration of the ash-sugar solution through evaporation. In the case of the unsealed liquid cultures, it is believed that the partial anaerobic condition in the medium was a factor in the decreased number of living bacteria. With the sealed cultures of both media, the partial anaerobic conditions, which tended to become wholly anaerobic, are considered the principal cause of the dying off of the bacteria.

Prussic acid in Burma beans, E. J. WARTH and K. K. GVI (Agr. Research Inst. Pusa Bul. 79 (1918), pp. 11).—The results of studies carried out to date with local (Burmese) varieties of Phaseolus lunatus as to their content of hydrocyanic acid are said to show that, while the amount present in the cultures varies considerably with soil and climatic conditions, cultures giving low percentages in one locality give low figures under all conditions tested. Hydrocyanic acid content thus appears to be an inherited character in pure single plant cultures. Differences in the color of seeds from a single culture do not indicate corresponding probable differences in the hydrocyanic acid content of the progeny. While the best cultures thus far found contain some of this poison, the quantity now obtained is only half that contained in the original sample of Madagascar bean which was regarded as safe and introduced into the Province.

A fern having hydrocyanic acid, M. MIRANDE (Compt. Rend. Acad. Sci. [Paris], 167 (1918), No. 19, pp. 695, 696).—The author has found that Cystopteris alpina (C. fragilis alpina) contains hydrocyanic acid in the green parts (fronds). The process of separating the acid is briefly described.

Notes on dune vegetation at San Francisco, Cal., F. RAMALEY (*Plant World, 21 (1918), No. 8, pp. 191-201, figs. 4*).—A description is given of the forms of vegetation on the sand dunes of Golden Gate Park as noted on exposed points, protected areas, and low places. Plant associations are noted. A systematic list is given, containing 40 native and 8 introduced species.

Root habit and plant distribution in the far North, H. E. PULLING (*Plant World*, 21 (1918), No. 9, pp. 223-233, fig. 1).—The author, classifying root systems, regards black spruce, tamarack, and canoe birch as being of rigid shallow habit; white spruce as of flexible shallow root habit; balsam poplar as of deep, flexible root habit; and jack pine and white pine as of deep, rigid root habit. Other differences which are discussed are omitted from the classification as having no apparent bearing on forest composition in the far North.

Acclimatization of plants originally of hot climates, G. ROSTER (Agr. Colon. [Italy], 12 (1918), No. 4, pp. 231-254, fig. 1).—Using the term acclimatization (as opposed to naturalization) of plants, as involving the multiform agencies employed by man, the author gives an account of some adaptations that have been accomplished.

Ends and methods of acclimatization, D. LANZA (Agr. Colon. [Italy], 13 (1919), No. 1, pp. 1-15).—This is largely a discussion of the contribution of Roster, above noted.

Climax formations, F. E. CLEMENTS (Carnegie Inst. Wash. Year Book, 17 (1918), pp. 294, 295).—Much attention has been paid to climax formations and their successional development, principally to the formations of widest extent, such as grassland, sagebrush, mesquite, and chaparral. As a consequence of work done in this connection, it has been possible to recognize and delimit the various associations of the nine climaxes for the first time and to point out their relationships to each other, as well as to the associations of adjacent formations; also to draw more definite distinctions between climax and successional indicators and to apply this to practical problems in grazing and forestry.

Mutations in the jimson weed, A. F. BLAKESLEE and B. T. AVERY, JR. (Jour. Heredity, 10 (1919), No. 3, pp. 111-120, figs. 11).—Continuing former studies (E. S. R., 37, p. 831), the authors have obtained evidence indicating the presence of another (third) pair of factors for the jimson weed (Datura stramonium). A possible fourth factor is under investigation.

In addition to this a study has been made of a number of mutative variants of greater or less distinctiveness which appear to be inherited in a manner not conforming to the Mendelian plan. A few of the more marked types of these are discussed herein. They seem to transmit their distinguishing characters as a complex, usually to a part only of their offspring, chiefly through the female side.

In one instance a mutation has arisen which seems to have established a distinct race or new species, breeding true but seemingly unable to cross with the parent species.

**E**nothera rubrinervis, a half mutant, H. DE VRIES (Bot. Gaz., 67 (1919), No. 1, pp. 1-26).—Reporting, with discussion of facts and bearings, a study of  $\mathcal{C}$ . rubrinervis, its origin and descendants, and some characters of the latter, the author states that  $\mathcal{C}$ . rubrinervis is a half mutant, produced by the copulation of a mutated gamete with a normal velutina gamete of  $\mathcal{C}$ . lamarekiana. In consequence of this origin it produces about one-fourth empty seeds, one-half  $\mathcal{C}$ . rubrinervis which will repeat the splitting, and a mass mutation, amounting to about one-fourth of a pure or double mutant, which has been named deserens and which is constant from seed and has no empty grains as hereditary features.  $\mathcal{C}$ . rubrinervis is not known to mutate otherwise to any noticeable degree, from which it is inferred that the internal constitution causing the mass mutation is not in itself the cause for further mutability.

Crosses of  $\mathcal{C}$ . rubrinervis with  $\mathcal{C}$ . lamarchiana give three types of hybrids, about one-fourth of the seeds being empty. One constant type resembles  $\mathcal{C}$ .

*lamarckiana*, a second is named *lucida*, and the third is either *subrobusta* or *rubrinervis*. These behave in ways which are supposedly explained on the supposition that  $\mathcal{C}$ . *rubrinervis* is a half mutant.  $\mathcal{C}$ . *oblonga* is analogous to  $\mathcal{C}$ . *rubrinervis* in some respects.  $\mathcal{C}$ . *nanella* seems to arise through mutations in the *velutina* gametes of  $\mathcal{C}$ . *lamarckiana*.

The history of Primula malacoides under cultivation, A. W. HILL (Jour. Genetics, 7 (1918), No. 3, pp. 193-198, pls. 2, fig. 1).—A brief account is given of the history of *P. malacoides* since its discovery in 1884 in cultivated fields at Ta-li, Yunnan, China. It is said to have displayed a considerable range of variation during this period, which is short as compared with the time taken to produce the variations which have been observed to occur in *P. sinensis* and *P. obconica*.

Axillary cleistogenes in some American grasses, A. CHASE (Amer. Jour. Bot., 5 (1918), No. 5, pp. 254–258, figs. 5).—As a result of her study of the production of cleistogamous grains by a number of grasses, the author states that the axiliary cleistogenes and the chasmogenes (normal spikelets) produced by the same plant are so unlike that they would not, if their source were unknown, be placed in the same tribe. The cleistogenes are found to be more variable than are the chasmogenes of the same species. The author is inclined to think, from the many cases found by relatively little study, that the cleistogamous habit is not rare among the grasses.

**Plant** introduction opportunities open to all the Americas, D. FAIRCHILD (*Proc. 2. Pan Amer. Sci. Cong., 1915–16, vol. 3, pp. 503–510, pl. 1*).—This is a consideration of the possibilities of plant exchange between countries.

## FIELD CROPS.

The experimental error in field trials, H. H. LOVE (Jour. Amer. Soc. Agron., 11 (1919), No. 5, pp. 212-216).—In this paper, a contribution from the New York Cornell Experiment Station, the author offers a critical discussion of certain features of Kiesselbach's work on the elimination of experimental error in crop tests, previously noted (E. S. R., 39, p. 829). The points considered include observations on competition between rows and the conclusions reached regarding the use of the probable error in interpreting results.

The effect of "place" on yield of crops, F. J. CHITTENDEN (Jour. Roy. Hort. Soc., 44 (1919), pp. 72-74, pls. 2).—Observations on some experimental plats at Wisley are held to indicate that place is an important factor in the yield of potatoes and should receive careful consideration when making comparisons between yields on different plats.

Up-to-Date potatoes were planted in 8 pairs of plats, each plat having three rows of potatoes equal distances apart and each row containing 18 plants equally distributed. The plats were so arranged that the outer row was separated 4 or 5 ft. from the outer row of the next plat and the pair of plats separated at the ends, so that the plants at the ends of the two inner rows had an additional exposure on one side and the end plant of the outer row a greater exposure on two sides than the other plants in their respective rows.

Based on the total yield of the outer row as 100, the average results for the three rows on all plats was as 100:72:72. The yield of the end plats of all rows compared with the average yield of other plants in the same rows was as 100:82. The average yield of the corner plants referred to above was as 100:66 when compared with the other end plants, as 100:79 when compared with the other plants. It is concluded, therefore, that the most advantageous place is at

the corner, the next best location in the outer row, the next at the end of an inner row, and the least desirable in the inner row.

The improvement of agricultural crops by selection and hybridization (Scot. Jour. Agr., 2 (1919), No. 1, pp. 10-20).—This comprises an account of an address delivered by T. Anderson before the Glasgow and West of Scotland Agricultural Discussion Society on the systematic improvement of crops in Scotland.

Further observations on the practical value of line selection as compared with mixed populations in field crops, L. KocH (*Teysmannia*, 29 (1918), No. 7, pp. 389-423).—This supplements work previously noted (E. S. R., 40, p. 623), including observations on pure line selections of rice and peanuts, mixed populations of rice, hybrid strains of corn, and clonal divisions of sweet potatoes and cassava.

A study of the relation of some morphological characters to lodging in cereals, R. J. GARBER and P. J. OLSON (Jour. Amer. Soc. Agron., 11 (1919), No. 5, pp. 173-186, pl. 1, figs. 2).—This paper, a contribution from the Minnesota Experiment Station, describes investigations begun in 1916 to discover some simple morphological character closely correlated with lodging or nonlodging in cereals. For this purpose 15 strains of barley, 7 of oats, 2 each of spring and winter wheat, and Minnesota No. 2 winter rye, representing extreme lodging and nonlodging forms, were selected and most of the material grown both in the field and in the greenhouse. Observations were made on the correlation between lodging behavior and the average size of culm, the average number of vascular bundles, the average area of sclerenchyma, the thickness of the culm wall, the length of the lignified cells, and the thickness of the lignified cell walls. Data are presented showing the percentage and degree of lodging, the yield, and the height of the different varieties grown in the field, while data relative to the morphological characters of each sort are presented for both the field and greenhouse environment.

It is stated that none of the morphological characters studied except thickness of cell wall appeared to be closely related to lodging. Both the early and medium oat strains examined were found to show a distinct correlation between the thickness of the lignified cell walls and lodging. In general, lodging in cereals is said to be dependent upon so many factors of unequal value in the different sorts that no single factor seems to be closely enough correlated with it to be of much value as a selection index in cereal improvement. Among the different strains of oats and barley, the average number of vascular bundles was found to be correlated with the average diameter of the culms.

The farmer and Federal grain supervision, R. H. BROWN (U. S. Dept. Agr. Yearbook 1918, pp. 335-346, pls. 4).—The advantages and method of grading grain at country points according to the Federal standards are described, as is also the subsequent handling of the wheat. Tabulated statements are included showing the standards for shelled corn, wheat, and oats.

[Report of field crops work in Michigan, 1918], J. F. Cox (*Michigan Sta. Rpt. 1918*, *pp. 283-285*, *287*, *288*).—This comprises a brief description of progress in work previously noted (E. S. R., 39, p. 335), including a short account of plant-breeding work by F. A. Spragg.

A report by B. W. Housholder on variety and cultural tests with barley, oats, potatoes, and root and silage crops, made at the Upper Peninsula substation, has been noted elsewhere (E. S. R., 40, p. 731).

[Report of field crops work in Missouri, 1917–18], W. C. ETHERIDGE, C. A HELM, J. B. SMITH, E. M. MCDONALD, L. J. STADLER, and J. T. ROSA, JR. (*Missouri Sta. Bul. 163* (1919), pp. 43–50, 53, fig. 1).—This describes the continuation of work previously noted (E. S. R., 38, p. 632), enforcing variety and cultural tests with soy beans, cowpeas, cotton, corn, grain sorghums, oats, wheat, and barley, together with field tests of various forage crops, and a comparison of northern-grown with home-grown seed potatoes.

A mixture of oats and Canada field peas, with a yield of 3.1 tons of cured forage per acre, gave the best results among spring-sown forage crops tested at Columbia. The best summer forages, included Amber sorghum, White Kafir, and a mixture of White Kafir corn and soy beans with yields anfounting to 6.25, 4.58, and 4.35 tons per acre, respectively. At Warrensburg a mixture of oats and Canada field peas proved best for spring forage and one of soy beans and sweet sorghum for sunfmer forage. In cooperative tests with sweet clover, failures were reported wherever oats was used as a nurse crop. Sudan grass seeded in rows 3 ft. apart produced 2.6 tons of cured forage per acre at Warrensburg. Seeded after rye at Columbia, it produced 1.56 tons and in a mixture with soy beans, 4.2 tons.

Of 84 varieties and strains of soy beans tested at Columbia the leading sorts produced from 18.3 bu, of seed per acre for Morse to 20.8 bu, for Virginia, and from 3.2 tons of hay for Buster Brown to 4.5 tons for Chiquita. At Maryville, the leading varieties were Peking, Wilson, and Virginia, with yields of 19.4, 18.9, and 17.5 bu. per acre, respectively. At Warrensburg, Mongol, Morse, and Mikado were best with respective yields of 17.9, 17, and 14.3 bu. On the Russell farm better yields of both seed and hay resulted from seedings made from May 15 to June 15 than from earlier or later seedings. Practically no difference in yield resulted from seedings made in 16-in. and 42-in, rows, while drilling Jet soy beans in rows 8 in. apart gave the same yields when seeded at the rate of 90 lbs. per acre as at a rate of 120 lbs. At Maryville, seeding at the rate of 25 lbs. per acre in rows 3 ft. apart gave slightly larger yields than lower rates of seeding, while at Warrensburg a 30-lb. seeding rate produced 13.7 bu. per acre and a 20-lb. rate 12.8 bu. New Era cowpeas produced 15.1 bu, of seed per acre as confpared with 12.2 bu, for Medium Yellow soy beans. Leading varieties of cowpeas and soy beans compared for hay production gave average yields of 3.4 and 3.1 tons per acre, respectively.

Shallu, White Kafir corn, and Standard milo maize with respective yields of 81.3, 63, and 43.7 bu. per acre were grown at Warrensburg in comparison with Commercial White, St. Charles White, and Learning Yellow corn, which produced 69.3, 58.3, and 47.3 bu., respectively.

In variety tests with cotton early maturing strains showed a marked superlority over late maturing sorts. King Improved with 380 lbs. of lint per acre and Simpkin Prolific with 330 lbs. were the best early varieties, and Mebane Triumph with 260 lbs. and Rowden with 213 lbs. the best late varieties.

Bigg Seven Ear and Cock Prolific corn grown at Kennett yielded at the rate of 38 and 38 bu. per acre, respectively, as compared with 32 bu. for Reid Yellow Dent and 30 bu. for St. Charles White, the two best native sorts. Cultural tests with corn at Warrensburg resulted in a yield of 59 bu. per acre for surface planting with normal cultivation, 70 bu. for list planting with normal cultivation, and 73 bu. for surface planting with late cultivation. At Maryville, with normal cultivation, surface planted corn produced 75 bu. per acre and list planted corn 84.2 bu.

Leading varieties of wheat tested at Columbia produced from 23.8 bu. per acre for Poole to 30.6 bu. for Harvest Queen. At Warrensburg the yields of the best sorts ranged from 23.5 bu. for Fulcaster to 27.9 bu. for Turkey. Selections of Pole, Early Ripe, and Fulcaster grown at Columbia have produced 4-year average yields of 35, 27.8, and 42 bu. per acre, respectively, as compared with yields of 34.3, 33.6, and 37.1 bu. for the original stock. Variety tests with oats at Columbia resulted in maximum yields ranging from 41.1 bu, per acre for Fulghum to 42.2 bu, for Iowa 105. At Maryville, the best varieties ranged from 65.3 bu, for Silvernfine to 69 bu, for Red Rust Proof. Burt and Kherson grown at Warrensburg each produced about 20.5 bu, per acre. Tests with winter oats have thus far been unsuccessful.

Spring barley produced from 19 to 30 bu. per acre in variety tests at Columbia. It is stated that the crop is fairly safe for the northern part of the State, uncertain for the central part, and generally a failure in southern Missouri.

Crop production in the northern sand hills [of Nebraska], J. COWAN (*Nebraska Sta. Bul. 171 (1919), pp. 3-6*).—Work with corn, small grains, potatoes, beans, and hay and fodder crops at the Valentine substation is briefly reviewed. See also a previous note (E. S. R., 41, p. 434).

[Report of field crops work in North Carolina, 1918], C. B. WILLIAMS (*North Carolina Sta. Rpt. 1918, pp. 28–35*).—Variety tests and crop improvement work with cotton, corn, soy beans, cowpeas, wheat, oats, and rye conducted at various points in the State are briefly described in a continuation of similar work (E. S. R., 39, p. 337). The best varieties of field crops grown at the different experimental centers are indicated in each case. Fertilizer and cultural tests with tobacco are also noted.

Selected strains of cotton isolated during the past four years are said now to present a uniform type and to have transmitted their qualities during the past two years. While in individual strains the values for size of boll, length of staple, percentage of lint, and height of plant have fluctuated from season to season, the strains have maintained the same relation to each other. The lowest yielding strain produced on the average \$1.8 gm. of seed cotton per plant and the highest yielding strain 179.6 gm. In a comparison of Mississippi- and North Carolina-grown seed of the same strain of cotton, very little difference has been noted in the earliness of the plants grown from seed from the two localities, while the Mississippi seed has produced slightly taller stalks and the North Carolina seed a larger yield.

In a comparison of Rosen with Abruzzi rye the former is said to be generally too late for Piedmont and eastern North Carolina conditions, and also to have produced less early grazing than Abruzzi. In the mountain section of the State Rosen has given some promise for seed production.

Tests made on the Granville Farm are held to indicate that the yield of tobacco can be increased by closer planting without injuring the quality of the crop. From 5,000 to 5,500 plants per acre are believed to give the best results. Priming as compared with cutting tobacco resulted in a gain of 240 lbs. per acre. In fertilizer tests conducted at Reidsville an increase in the ammonia content of the fertilizer application was followed by a greater susceptibility to leaf spot and other diseases, while potash appeared to stimulate the resistance of the plant to disease.

[Report of work with field crops in the Netherlands, 1913–1916], P. VAN HOEK (Dept. Landb., Nijv. en Handel [Netherlands], Verslag. en Meded. Dir. Landb., No. 1 (1919), pp. VII+157).—This describes the continuation of similar work previously noted (E. S. R., 32, p. 630). The report is divided into two parts, the first dealing with soil fertility tests, variety, cultural, and fertilizer experiments with potatoes and sugar beets, and variety tests with wheat, rye, oats, and barley; while the second part comprises observations on the establishment and maintenance of pasture land and on weed control.

[Report of field crops work in the Dutch East Indies], J. VAN BREDA DE HAAN (Jaarb. Dept. Landb., Nijv. en Handel Nederland. Indië, 1916, pp. 66-72, 345-354).—Cultural tests with cotton and plant-selection work with rice and other important crops during 1916 are described as heretofore (E. S. R., 38, p. 527).

[Report of field crops work in Java, 1916–17], C. VAN ROSSEM (Dept. Landb., Nijv. cn Handel [Dutch East Indies], Meded. Agr. Chem. Lab., No. 19 (1918), pp. 123).—This describes the continuation of work previously noted (E. S. R., 38, p. 735).

Harvest report [Eoseworthy Agricultural College], 1917-18 and 1918-19, W. J. COLEEATCH (Jour. Dept. Agr. So. Aust., 21 (1918), Nos. 8, pp. 623-634; 9, pp. 686-691; 10, pp. 759-766; 22 (1919), Nos. 8, pp. 610-627; 9, pp. 709-718).— In continuation of work along the same general lines as previously noted (E. S. R., 38, p. 133), crop data relating to wheat, barley, oats, rye, and forage crops are presented for the seasons indicated.

Sisal and henequen as binder-twine fibers, H. T. EDWARDS (U. S. Dept. Agr. Yearbook 1918, pp. 357-366, pls. 4).—The importance of the binder-twine industry in relation to the national food supply is indicated, and the possibilities of production in United States territory of sisal and henequen, said to furnish approximately 90 per cent of the raw material now used in the manufacture of binder twine, are discussed. It is stated that henequen has been grown successfully in Porto Rico and the Philippine Islands, while it is deemed practicable to develop the sisal industry in the Philippines, Hawaii, Porto Rico, and possibly Florida.

The vitality of alfalfa seed as affected by age, W. P. HEADDEN (*Proc. Colo.* Sci. Soc., 11 (1919), pp. 239-249).—The author describes observations on the viability of various grades  $c_{ijk}$  alfa seed held over a long period of years without any effort to preserve ( $n^{chO}$ ) d under definite temperature and moisture conditions.

It is concluded that good, will clean alfalfa seed, kept under fair but not ideal conditions, will retain its vitality for 23.5 years without any perceptible abatement. Good, commercial seed, preserved under rather disadvantageous conditions, retained a fair degree of vitality, 46 per cent, for 27.5 years, while very inferior seed, third quality screenings, kept under rather indifferent conditions, contained 16.5 per cent of viable seeds when 22.5 years old.

The vitality of alfalfa roots, H. G. MACMILLAN (*Proc. Colo. Sci. Soc., 11* (1919), pp. 251, 252, pls. 4).—The author records observations on volunteer alfalfa appearing in tilled fields in northern Colorado during the spring of 1918. Mention is made particularly of a plant found to have grown from an adventitious bud on an old root, three shoots having been sent out although only one survived. The root lacked a crown and both ends were shattered and decayed, no growth having occurred during the summer of 1917. Rootlets also developed. Many plants were found where the new growth had arisen from the old crown.

A factor analysis of barley, G. VON UBISCH (Ztschr. Induktive Abstam. u. Vererbungslehre, 17 (1916), No. 1-2, pp. 120-152, figs. 15; abs. in Genetica [The Hague], 1 (1919), No. 3, p. 301).—The author describes observations on the behavior of certain characters in barley crosses, including the density of the spike, the number of rows of spikelets, the length of the grain, the nature of the hood, and the toothing of the first lateral nerve of the outer flowering glume. The results may be summarized as follows:

The density of the spike is said to be determined by a factor pair designated as Ll, looseness dominating and corresponding to an internodal length of the rachis of more than 3.5 mm. Two-rowedness as compared with six-rowedness depended upon two factor pairs, ZzWw, of which Z must be present either in the homozygous or heterozygous condition in order that the plant is not six-rowed.

149863°-20-4

The length of the grain was dependent upon two factor pairs, Aa, which must be present in order that long grains may appear, and Vv, which has a shortening effect. The influence of the latter factor is said to be less marked than that of the former. The correlation between Aa and Ll is represented by the ratio of 5 AL: 1 Al: 1 aL: 5 al.

The hooded form was determined by a factor pair Kk. The hooded cultures examined are said to have contained the factor A in a latent condition, this being capable of expressing itself only in the presence of k. In the heterozygotic condition of KkAA or KkAa so called stemmed hoods appeared.

Three factors were found to be involved in the toothing of the nerve of the flowering glume. The first factor pair, Gg, which produced marked toothing, was found to be correlated with Zz according to the ratio of 1 ZG: 5 Zg: 5 zG: 1 zg. The second factor G'g' gave rise to isolated teeth, and transmitted itself independently of the first factor according to the simple ratio of 3 scarcely toothed individuals: 1 not toothed. The third factor effected quite fine toothing, perceptible only under the microscope.

The growing of beans in Scotland, J. MALCOLM (Scot. Jour. Agr., 2 (1919), No. 1, pp. 4–10).—This is a general discussion of the field practices and cultural methods employed in growing the bean crop, together with brief notes on insect pests affecting beans in Scotland and on the composition and food value of beans.

Cocksfoot.—Its establishment and maintenance in pasture, A. H. COCKAYNE (Jour. Agr. [New Zeal.], 18 (1919), No. 5, pp. 257–271, figs. 12).—This is a general discussion of the production and maintenance of cocksfoot pastures in New Zealand.

Some flower anomalies of maize, G. LOPRIONE (Staz. Sper. Agr. Ital., 51 (1918), No. 1-2, pp. 5-23, pl. 1, figs. 2).—The asm.  $\mathfrak{r}$  describes and illustrates certain anomalies observed in the inflorescence  $\mathfrak{c}$  counize.

The old and the new in corn culture, H. H. DIGGAR (U. S. Dept. Agr. Yearbook 1918, pp. 123-136, pls. 4).—The author traces the early history of corn culture in America, and briefly discusses the importance of the crop both in the past and at the present time. See also a previous note (E. S. R., 40, p. 137.)

"Northerns" cotton, G. R. HILSON (Agr. Jour. India, 14 (1919), No. 2, pp. 300-314).—The production and marketing of so-called Northerns cotton in the Madras Presidency is described. Improvements in the crop, in cultural methods, and in marketing conditions are suggested. Northerns is said to comprise a mixture of varieties of Gossypium herbaceum and G. indicum.

The improvement of "Tinnevellies" cotton, R. THOMAS (Agr. Jour. India, 14 (1919), No. 2, pp. 315-330).—Suggestions are presented for the improvement of the crop and of marketing conditions in the Tinnevelly tract situated in the southern part of the Madras Presidency. It is stated that the so-called Tinnevellies cotton is grown on an area of about 600,000 acres, and comprises two distinct varieties known locally as karunganni (Gossypium obtusifolium) and uppam (G. herbaceum).

Cotton warehousing—benefits of an adequate system, R. L. NEWTON and J. M. WORKMAN (U. S. Dept. Agr. Yearbook 1918, pp. 399-408, figs. 2).—The authors discuss the necessity for better constructed and better managed cotton warehouses, the functions of the warehouse, the formation of cooperative organizations among farmers for the construction and operation of cotton warehouses, and the location of the warehouse.

Crotalaria usaramœnsis as a fiber plant, G. F. J. BLEY (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Cultuurtuin, No. 12 (1918), pp. 1-13, pls. 6).—The production and utilization of C. usaramœnsis for fiber in Java are described. Trials of Sudan durra for brewing (Bul. Imp. Inst. [So. Kensington], 17 (1919), No. 1, pp. 22-31).—This comprises a review of investigations conducted by L. Briant and H. Harman as to the suitability of Sorghum vulgare for brewing purposes. It is concluded that if sufficient grain is obtainable at favorable prices it can be successfully employed in the manufacture of roasted grain for coloring and flavoring, of flakes, or in the production of sugar of a malto-dextrin type. It is deemed unlikely that durra will ever compete with barley as a malt material.

[Furcræa fiber], A. LOPEZ (*El Fique su Cultivo y Beneficio Industrial*, Medellín, Colombia, 1918, pp. 23, fig. 1).—This describes the production and utilization of various Furcræa fibers in Colombia.

[Proceedings of the National Hay Association] (*Rpt. Nat. Hay Assoc.*, 24 (1917), pp. 298, pls. 2; 25 (1918), pp. 293, pls. 3, figs. 4).—These volumes report the proceedings of the twenty-fourth and twenty-fifth annual conventions of the organization.

The retting of hemp: A preliminary note, D. CARBONE (Staz. Sper. Agr. Ital., 50 (1917), No. 6-8, pp. 261-299, fig. 1).—The author describes in some detail observations on the bacteriological aspects of the retting of hemp.

Lolium subulatum, "Wimmera" rye grass, H. A. MULLETT (Jour. Dept. Agr. Victoria, 17 (1919), No. 5, pp. 266–278, figs. 6).—Based on observations of existing stands and on the experience of various growers, an account is given of the history, present distribution, habits of growth, stock-carrying capacity, methods of propagation, and control of so-called Wimmera rye grass in Victoria. The grass has been identified as L. subulatum, and if controllable is said to give considerable promise as a pasture grass in the wheat belt.

New Zealand flax, VENTRY (Roy. Bot. Gard. Kew, Bul. Misc. Inform., No. 4 (1919), pp. 169–177, pls. 3; abs. in Nature [London], 103 (1919), No. 2595, p. 410).—The possibilities of growing New Zealand flax (Phormium tenax) on a commercial scale in Great Britain are discussed. It is suggested that experimental plantings be made on boggy and poor moorland soils, as the development of the plant under such conditions is said to be encouraging.

The inheritance of the weak awn in certain Avena crosses and its relation to other characters of the oat grain, A. C. FRASER (New York Cornell Sta. Mem. 23 (1919), pp. 635-676, figs. 8).—This paper presents additional data (E. S. R., 39, p. 234) supporting evidence on the inheritance of the weak awn in a cross between Burt and Sixty Day oats, together with a further study of the relationships of the awning factor and the conditions affecting it. The observations were continued through the  $F_3$  generation. The conclusions reached may be summarized as follows:

In a cross between the fully awned Burt and the awnless Sixty Day types there was a nearly complete dominance of the awnless condition. The evidence is held to indicate that both parents contain the factor for awning, but that it is prevented from operating in Sixty Day oats by an inhibitor which is closely linked with the factor for yellow color in that variety. The production of awnless or partly awned plants in the  $F_1$  generation is said to be dependent on the extent to which this inhibitor, I, is dominant over its normal allelomorph i, this dominance, in turn, being regarded as probably dependent to a large extent on environmental factors.

In the  $F_2$  generation, awnless, partly awned, and fully awned plants were produced in approximately the ratio of 1:2:1. The ratio of plants not fully awned to plants fully awned approximated 3:1. An  $F_3$  generation test of  $F_2$ plants showed that the fully awned individuals were pure recessives, and that they bred true for 100 per cent of awns. A test of the partly awned plants showed that nearly all were heterozygous, giving in the  $F_3$  approximately three plants not fully awned to one fully awned plant. The formula for these plants would be *Ii.* A few partly awned plants of the  $F_2$  generation having a very low percentage of awns were found to really belong to the awnless class. The appearance of awns on these plants is thought to be due probably to a slight modification of the action of the inhibitory factor, perhaps by environmental influences. The awnless  $F_2$  plants were found to consist of two genetic types: Those plants which bred true, or practically so, for the awnless condition, and those which gave a segregation like that given by an  $F_1$  plant, the formula for the first being *II*, and for the second *Ii*.

Spikelets having two awns, one on each kernel, were found only on plants having all the spikelets awned. The irregular occurrence of such two-awned spikelets is thought to indicate that no definite genetic factor is involved, but rather that it is the natural behavior of the awning factor to produce two awns occasionally in the absence of the inhibitory factor.

Environment seemed to affect the production of awns to a considerable extent. While experimental evidence is wanting, general observation suggested that an increase in the moisture content, organic matter, and nitrogen of the soil tended to decrease the number of awns.

Strong and intermediate awns appeared in small numbers on a few of the  $F_2$  plants and in about the same relative numbers on the  $F_3$  progeny of these plants, as well as on the progeny of certain other  $F_2$  plants which bore only weak awns. It is stated that such a phenomenon may be due to a reversion of a complex nature.

A strong linkage was observed between the fully awned condition and the medium long hairs at the base of the grain. In 2,341 individuals there were about 5 per cent of crossovers. A similar linkage existed between the fully awned condition and the Burt (similar to *Avena sterilis*) type of basal articulation. Here there were practically 4.14 per cent of crossovers among 2,341 individuals. The non-Burt type of basal articulation was dominant over the Burt type in  $F_1$ , while the  $F_2$  gave three non-Burt plants to one Burt.

Short basal hairs or no basal hairs were dominant over those which were medium long, the  $F_2$  ratio being three of the former to one of the latter.

Two colors were contrasted—a red or yellowish red in Burt, and the clear yellow of Sixty Day, the  $F_1$  plants being intermediate for color. The colors of the F<sub>2</sub> plants were greatly influenced by external factors, and graded into one another in such a manner as to render a perfect classification practically impossible. Burt oats possessed a factor for red and a factor for yellow which was distinct from the Sixty Day factor, and which carried no inhibitor to awning. The genetic formula for Burt would be RR YY y' y', and for Sixty Day rr yy Y' Y'. The  $F_2$  data on color agreed rather closely with the theory as to the genetic constitutions of the two parents. The ratios in two families approximated 48 reds: 15 yellows: 1 white. The F<sub>8</sub> tests supported this theory in a general way. The appearance of a few brown grains is thought to be the result either of mutation or of reversion. Finally, the author states that while other workers have shown that Sixty Day carries a factor inhibiting the production of awns, which is closely linked with the factor for yellow color because of the yellow in Burt, which carries no such inhibitor, the inhibitory effect of the Sixty Day factor was obscured.

Some further experiments with potatoes, J. WILSON and F. J. CHITTENDEN (Jour. Roy. Hort. Soc., 44 (1919), pp. 83-88, fig. 1).—This describes observations made at Wisley during 1918 on the effect of spacing and of the use of seed of different origin on the yield of potatoes, supplementing work previously noted (E. S. R., 40, p. 630). The spacing experiments included plantings made in rows 18, 24, 30, and 36 in. apart with the plants spaced 9, 12, 15, and 18 in. apart in the row for each planting distance.

The best spacing for the variety employed (Arran Chief) was found to be from 24 to 30 in. between rows and 15 in. between plants. In comparative tests of locally-grown seed potatoes with seed from Scotland and Ireland the local seed gave quite favorable results. It is stated that while all the factors making for maximum yields of potatoes are not yet known the source of the seed is a most important one.

Potato production, G. STEWART (Utah Sta. Circ. 40 (1919), pp. 3-54, figs. 20).—This comprises a general discussion of cultural methods and field practices employed in growing the potato crop in Utah, with notes on storing and marketing the product.

[Report of work with potatoes in the Rhine Province], T. REMY (Veröffentl. Landw. Kammer Rheinprov., No. 2 (1919), pp. 96, pls. 14).—This describes variety, cultural, and fertilizer tests with potatoes conducted during 1918.

A study of the relation of climatic conditions to the vegetative growth and seed production of rice, F. DE PERALTA Y LEAÑO (*Philippine Agr.*, 7 (1919), No. 6, pp. 159–183, figs. 4).—In an effort to study the correlation between vegetative growth and seed production in the rice plant and climatic conditions prevailing in the Philippines, plats of Inintiw lowland rice were started every four weeks during the period of April, 1916, to April, 1917, at Los Baños, and observations made on climatic and water conditions and on the growth and seed production of the plants at regular intervals throughout the experiment. The cultural methods were the same as those usually employed in the locality. The data are presented in tabular form, fully discussed, and depicted graphically. The conclusions reached may be summarized as follows:

Rice exhibited an annual vegetative growth and flowering cycle, the period required to attain maturity ranging from 104 to 174 days in the Inintiw variety. The maximum yields of grain were secured from plantings made in April, May, and June, while the yields decreased markedly up to the October seeding, increasing again with the November seeding. No definite ratio between the grain and straw was observed, although it was noted that the grain increased in weight with an increase in straw.

The maximum growth occurred during the period of highest total evaporation and the minimum growth with the least total evaporation. The yield of grain increased with an increase in the length of the panicle. The height of the plants was less during a season of low evaporation and greater during a season of high evaporation. A correlation was observed to exist between the yield of grain and the height of the plant, tall plants being accompanied by high yields. The grain yield was highest during the season of high evaporation and lowest during the season of low evaporation. The longer the period required to attain maturity the greater was the leaf area produced. Low temperature during the first month of growth appeared to induce early maturity in rice. Rice seed kept in a closed vessel at a constant temperature of about  $27.5^{\circ}$  C. (81.5° F.) was appreciably reduced in vitality within a year.

**Rice** [in Tucumán], F. W. M. RABEN (Bol. Min. Agr. [Argentina], 22 (1917), No. 2, pp. 149-171).—Observations on growing the crop in Tucumán are presented, together with notes on field tests of Valencia and Japanese rices.

South Bafi [Dutch East Indies] and its rice culture, K. VAN DER VEER (*Teysmannia*, 29 (1918), No. 7, pp. 367-388, pls. 2).—This comprises a general description of the rice industry on the island of Bali.

The place of rye in American agriculture, C. E. LEIGHTY (U. S. Dept. Agr. Yearbook 1918, pp. 169-184).—The marked increase in rye production in the United States, the adaptability of the crop to certain soil and climatic conditions, and the utilization of rye are discussed.

The composition of the [sugar cane] planting, 1918–19, J. VAN HARREVELD (Meded. Proefsta. Java-Suikerindus., Landbouwk. Ser., No. 2 (1919), pp. 715– 733).—Statistics are presented similar to those previously noted (E. S. R., 40, p. 635), showing the relative distribution of the principal sugar-cane varieties grown in Java for the season indicated.

Sweet potatoes, E. W. COLE, B. C. THARP, and T. S. MINTER (*Texas Dept. Agr. Bul.* 62 (1918), pp. 47, figs. 29).—Sweet potato growing in Texas is described and considerable general information given on diseases affecting the crop, together with notes on insect enemies and on harvesting and storing sweet potatoes.

The tobacco seedbed, P. A. DAVID (*Philippine Agr. Rev., 12* (1919), No. 1, pp. 31-65, pls. 10).—This paper, a contribution from the Experiment Station of the Philippine College of Agriculture, deals with observations made during 1918 on preparing, sterilizing, fertilizing, shading, and planting tobacco seedbeds, together with information relative to the cost of the various treatments. Considerable tabulated data are presented, and the results secured may be summarized as follows:

Shade is deemed important in reducing evaporation and in protecting the seedbed against washing. Germination and development of the seedlings was also best on the shaded beds. A cloth shade gave better results than nipa, cogon, or banana leaves.

Treatment with formalin, copper sulphate, and hot water, as well as roasting and firing, proved to be most satisfactory in soil sterilization and disinfection. Applications of 1:50 and 1:75 formalin at the rate of 10 liters per square meter (about 7.6 qts. per square yard) effectively controlled both damping-off and weeds. A one per cent solution of copper sulphate was also beneficial in controlling weeds. The hot water and firing treatments proved to be of little value in killing weed seeds, while roasting was much more effective.

Based on the average height attained by the seedlings on the variously treated seedbeds at the time of transplanting, dried blood gave the best results, while a combination of sodium nitrate, double superphosphate, and potassium sulphate was next in order. The use of commercial fertilizers as well as manure and compost also hastened germination.

Selection studies with Deli tobacco, J. A. HONING (*Teysmannia*, 30 (1919), No. 1, pp. 1-11, pls. 2).—This describes observations made during 1916 and 1917 on selections of Deli tobacco having to do with leaf color. See also a previous note (E. S. R., 40, p. 635).

**Crop** rotation and fertilizer experiments, M. F. MILLER and F. L. DULEY (*Missouri Sta. Bul. 163 (1919)*, pp. 63-65, figs. 2).—The following tabulated data are presented showing the effect of rotation and manuring on the yield of wheat after 28 years of cropping:

Rotation and manure treatment.	Bushels per acre.
Continuous wheat, nothing Continuous wheat, manured annually. Wheat in wheat, clover rotation, nothing. Wheat in wheat, clover rotation, manured annually. Wheat in corn, wheat, clover rotation, mothing. Wheat in corn, wheat, clover rotation, manured annually. Wheat in corn, oxis, wheat, clover rotation, nothing. Wheat in corn, oats, wheat, clover rotation, manured annually.	$\begin{array}{c} 0.2\\ 10.9\\ 20.7\\ 27.4\\ 13.5\\ 31.0\\ 30.0\\ 39.4 \end{array}$

1917 wheat yield on rotation experiment field.

Data are also presented showing the effect of crop rotation as it influences the return from manure and fertilizer on wheat:

Wheat yields as affected by rotation, manure, and fertilizer, 25-year average.

Treatment.	Bushels per acre.
Continuous wheat, nothing Continuous wheat, manured Continuous wheat, heavily fertilized Wheat in rotation, nothing Wheat in rotation, manured	9.5 17.4 17.9 20.7 25.9
wheat in rotation, neavily leftilized	29.1

The cultivation of wheat in Argentina, III, IV, C. D. GIROLA (Bol. Min. Agr. [Argentina], 20 (1916), No. 1-2, pp. 52-59, figs. 4; 22 (1917), No. 2, pp. 113-130, figs. 5).—In continuation of work previously noted (E. S. R., 35, p. 740), the author describes and illustrates *Triticum turgidum* var. racamosum, and two varieties of durum wheat designated as Candeal and Taganrock, respectively. Three strains of *T. sativum*, Barleta, French, and Italian, together with two additional strains of durum wheat, Medeah and Belotourka, are illustrated, as well as *T. polonicum*, said to be often confused with Candeal.

Fertile wheat-rye hybrids, H. H. LOVE and W. T. CRAIG (Jour. Heredity, 10 (1919), No. 5, pp. 195-207, pl. 1, figs. 11).—In this paper, a contribution from the department of plant breeding, Cornell University, the authors describe a fertile wheat-rye hybrid secured in a cross between Dawson Golden Chaff and common rye. That the seed developed on the  $F_1$  plant resulted from self-fertilization and not from back-crossing with wheat or rye is believed to be demonstrated by the intermediate character of its progeny. It is deemed possible that certain varieties of wheat may produce fertile wheat-rye hybrids.

Some effects of the war upon the seed industry of the United States, W. A. WHEELER and G. C. EDLER (U. S. Dept. Agr. Yearbook 1918, pp. 195-214, figs. 6).—This comprises a general discussion of the effect of the war upon imports and exports of seeds, domestic demands for seed, seed production, and stocks, prices, and movement of seeds, together with some of the local problems of wholesale and retail seedsmen, and the seed reporting service of the Bureau of Markets.

Second annual report Colorado Seed Laboratory, W. W. ROBBINS (Colorado Sta., Seed Lab. Bul., 1 (1918), No. 3, pp. 5-23, figs. 5).—The work of the laboratory for the year ended November 30, 1918, is described. A total of 3,631 samples of seed were examined. The most common impurities of the important crop seeds sold in the State are indicated, and a list is presented showing the weed seeds found in the samples analyzed.

Seed Reporter (U. S. Dept. Agr., Seed Rptr., 3 (1919), No. 3, pp. 8, fig. 1).— Tabulated data are presented showing the estimated acreage, yield, and prices of medium red, alsike, and sweet clover, and alfalfa seed about August 22, 1919; the commercial stocks, receipts, and exports of field seeds and root and vegetable crop seeds for Canada based on the seed survey of June 30; the commercial stocks and receipts of field seeds by geographic divisions for the United States as of June 30; the commercial vegetable seed stocks of the United States on June 30 for each of the past four years; and the imports of forage plant seeds permitted entry into the United States. Information relative to the sugar beet seed situation; vegetable seeds; the red, alsike, and sweet clover and alfalfa seed outlook; the hairy vetch seed crop; and the movement, price, and quality of timothy, redtop, Kentucky blue grass, orchard grass, meadow fescue, and white clover seed August 22, 1919, is also briefly noted.

The identification and control of Colorado weeds, W. W. ROBBINS and B. BOYACK (Colorado Sta. Bul. 251 (1919), pp. 126, figs. 77).—The principal weeds occurring in the State are described and illustrated and control measures indicated in each case. The general aspects of weed control, the Colorado pure-seed law, the losses caused by weeds, the introduction, spread, and distribution of weeds in Colorado, some principles and methods of weed control for both dry land and irrigated farms, and the utilization of weeds for silage are discussed.

Weed immigration into Michigan, H. T. DARLINGTON (Ann. Rpt. Mich. Acad. Sci., 20 (1918), pp. 261-267).—Of 225 weeds mentioned by Beal (E. S. R., 36, p. 739), the author states that 147 have been introduced into the State. Based on official catalogues of plants in Michigan, lists have been prepared giving the names of those weeds present in 1839, and new weeds appearing between 1839 and 1860, 1860 and 1881, 1881 and 1904, and 1904 and 1915, respectively. It is stated, further, that of the introduced weeds 56 per cent are native of Eurasia, 4 per cent of the West or Southwest, 3 per cent of the East or Southeast, and 3 per cent of South America, while 20 of the 25 worst weeds of the State are said to be indigenous to Europe.

The weeds of wheat on the pampas [Argentina], J. WILLIAMSON (Bol. Min. Agr. [Argentina], 22 (1917), No. 2, pp. 141-148, figs. 6).—The distribution, habits, and means of eradication of the principal weeds infesting wheat on the pampas are discussed. The plants dealt with include Chenopodium sp., Salsola tragus, Arjone bulbosa, Avena fatua, and Polygonum convolvulus.

Devitalization of the seed of Cuscuta, M. BRESAOLA (Staz. Sper. Agr. Ital., 52 (1919), No. 3-4, pp. 193-207).—The author discusses further (E. S. R., 31, p. 835) the effect of heat and of sulphuric acid treatment upon the germination of the seed of C. arvensis and C. trifolii.

Exposure to dry heat at  $75^{\circ}$  C ( $167^{\circ}$  F.) for one hour practically inhibited the germination of dodder seed. The seed of *Medicago sativa*, *Trifolium pratense*, and *T. repens* under similar conditions was not seriously injured, while that of *Lotus corniculatus* was actually benefitted by the high temperature. The sulphuric acid treatment appeared to be unsatisfactory.

### HORTICULTURE.

Carbohydrate metabolism in green sweet corn during storage at different temperatures, C. O. APPLEMAN and J. M. ARTHUR (*Jour. Agr. Research* [U. S.], 17 (1919), No. 4, pp. 137-152, figs. 2).—A contribution from the Maryland Experiment Station, dealing with the character and kinetics of the processes involved in the rapid depletion of sugar in green sweet corn after it is separated from the stalk, and more particularly with the relative rates of these processes at different storage temperatures, accurately controlled.

A method was devised by which the rate of sugar loss from green sweet corn could be determined for consecutive 24-hour periods of storage by comparing analyses of corn from the same ear. Stowell Evergreen corn, picked in the typical milk or best eatable stage and having a water content of approximately 80 per cent, was used in the study.

The depletion of sugar in green sweet corn after it is separated from the stalk does not proceed at a uniform rate, but becomes slower and slower until finally the loss of sugar ceases when the initial total sugar has decreased about 62 per cent and the sucrose about 70 per cent. Calculated on the basis of original moisture, the corn contained, when the depletion of sugar ceased,

approximately 1.5 per cent total sugar as invert sugar, 0.7 per cent sucrose, and 0.8 per cent free-reducing substances. Reversibility of the chief processes involved in the sugar depletion, resulting in an equilibrium between the rate of sugar loss and the rate of sugar formation, would account for the cessation of actual sugar loss.

Raising the temperature hastens the attainment of the equilibrium positions, which seems to be about the same for all temperatures. At 30° C. (86° F.), 50 per cent or most of the total sugar loss occurs during the first 24 hours of storage. At 20°, 25 per cent, and at 10°, or good refrigerator temperature, only about 15 per cent is depleted during the same period. The rate of sugar loss, until it reaches 50 per cent of the initial total sugar and 60 per cent of the sucrose, is doubled for every increase of 10° up to 30°.

Respiration in green corn is comparatively high when the corn is first picked, but falls off rapidly with storage. Respiration accounts for only a small part of the actual decrease in the percentage of sugar in the corn during the consecutive 24-hour periods of storage, even at 30°. One ton of husked green sweet corn during the first 24 hours of storage at 30° would lose approximately 3.2 lbs. of sugar on account of respiration. Respiration may become indirectly a more important factor in accelerating the depletion of sugar by raising the temperature on the inside of large piles of green corn.

Most of the decrease in the percentage of sugar in green sweet corn during storage is attributed to condensation of polysaccharids, chiefly starch.

Greenhouse tomato growing in Virginia, H. H. ZIMMERLEY (Virginia Truck Sta. Bul. 26 (1919), pp. 3-23, figs. 2).—Practical directions are given for greenhouse tomato culture, including the control of insects and fungus diseases. Some data on investigations conducted at the station are also included.

In the fall of 1915 a test with the variety Bonny Best was conducted to determine the effect on yield of different planting distances. Plants were set 18, 24, and 30 in. apart in 30 in. rows. The 18 in. planting distance attained the highest yield with 23.3 oz. of fruit to the square foot of bed area; the 24-in. distance gave a yield of 23 oz. to the square foot; and the 30-in. distance, a yield of only 20.7 oz. per square foot. By increasing the spacing from 18 to 24 in. the additional yield per plant was practically sufficient to compensate for the increased bed area. The difference in the size of the fruit produced in the three plats was not sufficient to affect their market values.

Beginning in the fall of 1915 and continuing through three successive seasons an experiment was conducted to compare the effects of the single, double, and triple systems of training as to the season of maturity and total yield of fruit. As an average for the three seasons the single-stem plants yielded highest, with an average yield of 37.9 oz. of fruit per square foot bed area; those with double stems averaged 37.1 oz. per square foot, and those with triple stems only 34.3 oz. per square foot. On an average for the three seasons' test the single-stem plants outyielded the double-stem plants by 1.7 oz. and the triplestem plants by 4.2 oz. to the square foot of bed area, during the period of the early harvest. During the period of midseason harvest the double-stem plants outyielded the single-stem plants by 0.8 oz., and the triple stem by 0.4 oz. per square foot bed surface. During the late harvest the triple-stem plants outyielded the single and double stem plants by 0.2 and 0.1 oz., respectively. These results indicate that increasing the number of stems per plant decreases early production of fruit to some extent. Individual fruits from single-stem plants averaged 0.3 oz. heavier than those of the double-stem plants, and 0.2 oz. heavier than those of the triple-stem plants. The test, as a whole, indicates that the single-stem system of training has proved slightly superior in earliness, in total yield, and in convenience and simplicity of handling.

Army gardens in France, Belgium, and occupied German territory, G. TRUFFAUT and H. COLT (Versailles: Pepinieres Natl. du Touring-Club de France, 1919, pp. 64, pls. 10, figs. 3).—This handbook on vegetable gardening was written with a view to facilitating the starting and management of the army gardens of the Allies and the United States in France. The subject matter is based upon the lines of work determined by the senior author for the French Army gardens in 1917–18.

[Work with vegetables and fruit at the Valentine, Nebr., substation], J. COWAN (Nebraska Sta. Bul. 171 (1919), pp. 6, 7).—Experiments conducted at the Valentine substation indicate that garden vegetables may be grown successfully on the light sandy soil of the northern Nebraska sand-hill region by mulching the ground between the plants with old hay, stable litter, etc., before the dry weather sets in. Under this system, small crops were grown of nearly every kind of vegetable, where without mulching all attempts to grow such vegetables were failures. Crops such as tomatoes were retarded and the ripening of the fruit delayed by mulching. In no case was the benefit derived so noticeable as in the case of potato mulching. The report indicates that mulching must be accompanied by wetting with the hose in lieu of sufficient rain.

Orchard work on dry land at the substation has been an entire failure. No attempt has been made to grow an orchard on bottom subirrigated land, but observation of attempts made on such ground by farmers has failed to discover satisfactory results, although the work in some cases was carried out under expert direction.

[Progress report on horticultural investigations] (*Missouri Sta. Bul. 163* (1919), pp. 53, 54, 55-62).—Concise statements of progress made with various projects (E. S. R., 38, p. 639) during the year ended June 30, 1918, are given.

Among the investigations in charge of J. C. Whitten, the work of breeding apples for the late blooming habit was extended by making crosses between some of the leading commercial varieties and a large-fruited wild crab which blossoms later than any cultivated variety which has been found. Summing up the total observations on the yield of apple trees grown from selected and nonselected buds, no significant difference has been found between the total yield of the trees of high-yielding parents and low-yielding parents. Examination of buds in winter for forecasting probable bloom shows that the proportion of flower buds forced out in water in a sunny window corresponds very closely to the percentage of buds which bloom on the trees the following spring. Peach breeding work was interrupted through the heavy pruning of the trees following severe winter injury. The results of fall v. spring planting tests covering about ten years' work are to be presented in bulletin form. From the work as a whole it is again concluded that fall planting of hardy fruits is better than spring planting, and that late fall planting just before the ground freezes is superior to early fall planting. An exception to this rule is the Ingram apple, which has done better when planted in the spring.

The frost-resistant studies conducted at the station, C. C. Wiggans in charge, indicate that the need of orchard heating may be reduced by maintaining maximum sap concentration and delaying the rest period in the fall by proper spraying, pruning, and soil management. The more concentrated the sap in fruit trees or other plants, the lower their freezing point and consequently the more frost they will endure without injury. The later fruit trees go into their rest \_ period in the fall the later will they wake up from this rest period in spring, and this prolonged dormancy opposes injury from spring frosts.

Further observations on fruit bud development as influenced by treatment and previous crops were made by C. C. Wiggans. The evidence now seems conclusive that, in all our leading commercial varieties of apples observed, a given fruit spur is not usually able to mature fruit and at the same time develop a fruiting bud for the following year. On Gano, Rome, and York only an occasional fruit spur produces blossoms two years in succession. Jonathan, Grimes, and Winesap produce blossoms two years in succession on the same spur somewhat more frequently. It is concluded that Gano, Rome, and York tend to produce only alternate year crops because in the fruiting year practically all their individual fruit spurs produce fruit, leaving very few nonfruiting spurs to blossom the following year. On the other hand, Jonathan and Winesap give more regular annual crops because only a portion of the fruit spurs set fruit in a given year.

Observations since the experiment began show that an individual fruit spur has a fruiting life history ranging from two to eight years. Few spurs, however, begin to bear before they are three years old and but few retain their bearing form beyond six years of age. Under favorable conditions spurs older than this develop into longer branches, upon which a new crop of fruit spurs develop. A study of the above-named varieties on different types of soil has shown that there is apparently no relation between the character of the soil in which the tree grows and the alternation of the individual spurs. Removing the blossoms from a tree by accident or design may result in a change in the fruitful year. Removing the blossoms or fruit (thinning) of an individual fruit spur or branch may to some extent bring about this change.

Sap from bearing spurs has slightly higher concentration (lower freezing point) during a considerable portion of the year than sap from nonbearing spurs. Sugar and starch are present in slightly greater amounts in the bearing spur than in the nonbearing spur. If the blossoms or fruit are removed from a bearing spur this available sugar is apparently directed toward the development of a fruit bud for the following year. Trees pruned to a low head and just now reaching fruiting age are developing fruit spurs in far larger numbers than are high-headed trees of the same age. Apparently long stems and branches not only dry out in the sun in late winter, but they bend and twist and restrict proper flow of sap. In short-stemmed trees there is no such restriction to the ready passage of sap, fruit spur development is better, and a succession of fruit spurs can be more easily renewed than by pruning.

In the orchard management investigations being conducted by J. C. Whitten and C. C. Wiggans, the number of blossoms in the spring of 1918 was much larger on the sod plats containing alfalfa, clover, or timothy than on the plats given clean tillage or tillage followed by late summer and autumn cover crops. Fruit spur development is much more marked on the sod plats, although potential fruit spurs are forming on the tillage plats. The vigor of wood growth is most marked on the tillage with cover crop plats. Thus far no final conclusions are drawn as to the best system of orchard management.

Fruit nutrition studies were continued during the year by J. C. Whitten and C. C. Wiggans. No data were available upon the effects of the various fertilizers upon the peach crop, since the fruit buds of the peach were killed throughout the State as in the preceding winter. It was again noted that the nitrogen-fed trees were in much more vigorous condition than were the trees which received no nitrogen. No visible effects were observable where potash or phosphorus, either singly or in combination, were applied to peaches in past years. Summing up the results thus far secured with both peaches and apples, it is concluded that on the various Missouri soils under test there is no apparent advantage in adding mineral fertilizers even up to the time that the orchard reaches mature bearing age. The experiments have not been conducted long enough to determine whether these fertilizers may prove profitable in prolonging the life or bearing vigor of the tree after it otherwise would have begun to decline.

With one exception young peach trees and apple trees have made much stronger growth and suffered less mortality and have reached bearing age and strength sooner where nitrogen was applied. Blight, however, has during the past three years been very much more severe on the trees rendered more succulent by the addition of nitrogen. The more succulent trees suffer enough more from blight to offset the greater growth produced by the nitrogen.

Counts made in the spring of 1918 show that nitrogen is a very important limiting factor in blossom formation upon the tree. The blossoms were numerous on the nitrogen-fed trees but were entirely absent on those receiving mineral salts, although a few of the check trees had an occasional bloom. The nitrogen-fed trees are establishing a splendid stand of fruit spurs, while no such fruit spur development is beginning on check trees or those fed mineral salts. These tests indicate that available nitrogen is very essential in developing the strength, vigor, and size of young apple trees and in hastening their development to fruiting capacity, whereas no liberal amount of mineral salts is required.

Spraying investigations conducted by W. W. Lawrence during the year indicate that among the arsenicals used to destroy insects that chew and swallow their food the ortho, neutral, or triplumbic form of arsenate of lead produces the least injury to fruit and foliage, and gives satisfactory results from the control point of view. Lime and sulphur gave the most desirable results for early spraying, while Bordeaux gave better results for late spraying.

**Report of the Lamao Experiment Station** (*Philippine Agr. Rev.*, 12 (1919), *No. 2, pp. 80-84, pls. 2*).—Brief statements of progress made in the establishment of experimental plantings of tropical fruits, citrus fruits, pineapples, avocados, papayas, mangoes, coffee, and root crops, including also data on plant and seed distribution.

Fruit growing and training, J. VERCIER (L'Arboriculture Fruitière en Images. Paris: Libr. Larousse, 3. ed., pp. 254, figs. 111).—A manual of information on the culture of various fruits with special reference to training the trees and bushes into special forms. Each fruit is considered with reference to its origin, soil and climatic requirements, planting distance, fruiting period, uses, propagation, methods of pruning, diseases and insect pests, varieties recommended, and manuring.

The culture of tree fruits, GRESSENT (L'Arboriculture Fruitière. Paris: Libr. Agr. de la Maison Rustique, 1916, 13. ed., pp. 1080, figs. 485).—A treatise on intensive and extensive culture of orchard and bush fruits and crops, including forcing and nursery practices, together with suggestions for the care of trees in parks, avenues, and forests.

Orchard management, E. P. SANDSTEN (Colorado Sta. Bul. 250 (1919), pp. 3-20, figs. 10).—This bulletin discusses the general principles of orchard management, and points out some of the local problems that exist in different localities in Colorado, with suggestions for their solution.

The commercial apple industry in the United States, J. C. FOLGER (U. S. Dept. Agr. Yearbook 1918, pp. 367-378, pl. 1, fig. 1).—This article discusses the commercial phases of the apple industry, and briefly describes the relative importance of different regions and the factors which influence their development.

**Report** of division of horticulture, J. P. PILLSBURY (North Carolina Sta. Rpt. 1918, pp. 56, 57).—In the grape-breeding work, hybrids of Vitis rotundifolia and several other species were secured by using pollen of rotundifolia. In all cases except one the pollen of other species proved to be impotent when applied to flowers of *V. rotundifolia*. When the pollen of *V. vinifera* is employed, hybrids are secured with difficulty. Hybrids are readily secured when *rotundifolia* pollen is used on *vinifera*, thus indicating the prepotency of *rotundifolia*. Many of the seeds secured by using *vinifera* pollen were not viable. In view of the fact that thus far it has been impossible to secure hybrids between the wild *labrusca* and *rotundifolia* grapes, the comparative ease with which hybrids were secured with the variety Concord when *rotundifolia* pollen was used would indicate that Concord is a *labrusca-vinifera* hybrid rather than a pure *labrusca*.

In previous grape-breeding work a pink color appeared in the fruits of some of the hybrids, but the source of the color was undetermined. During the year pink-fruited hybrids were secured by using light-colored parents. One of these hybrids is self-fertile. Studies of size inheritance have shown in general that the range in size of fruit in  $F_1$  hybrids extended from slightly below the minimum of the one parent to somewhat above the maximum of the other.

Dried wine grapes (*Cal. State Bd. Vit. Commrs. Bul. 15* (1919), pp. 28, figs. 16).—This bulletin contains the following three articles: The Market for Dried Wine Grapes, by E. M. Sheehan (pp. 3–5); Methods and Returns, by F. T. Bioletti (pp. 6–9), in which the author discusses various means of utilizing wine grapes in lieu of their use for wine making; and An Evaporator for Wine Grapes, by W. V. Cruess (pp. 10–28). This last article describes and illustrates an evaporator, which can be easily and quickly constructed; in addition to its use for drying wine grapes it is also suitable for drying rain-damaged grapes or prunes and other fruits.

Certain relationships between the flowers and fruits of the lemon, H. S. REED (Jour. Agr. Research [U. S.], 17 (1919), No. 4, pp. 153-165, fig. 1).—A contribution from the California Experiment Station, in which a small group of Lisbon lemon trees in a commercial orchard was studied for two years to obtain data on their fruiting habits.

The fruit buds were distributed throughout the season approximately as follows: Sixty-six per cent during March and April, 13 per cent in November, 17 per cent between April and November, and about 3 per cent during the winter months. Few-flowered inflorescences predominated over many-flowered inflorescences. A bud on a small inflorescence had a greater chance to develop into a mature fruit than one on a large inflorescence, where competition seems to be too severe to allow all to survive.

It required from 7 to 14 months, according to conditions, for the fruit to reach maturity. Fruit set in May, June, and July matured soonest. The season at which fruit set was an important but not wholly determining factor in controlling the time required for maturity.

#### FORESTRY.

The book of the National Parks, R. S. YARD (New York: Charles Scribner's Sons, 1919, pp. XVI+420, pls. 56, figs. 4),—This work contains descriptive accounts of the American National Parks, presented with the view of enabling the reader to appreciate their importance, scope, meaning, beauty, manifold uses, and value to the individual and Nation. The parks are grouped under the following general headings: The Granite National Parks, the Volcanic National Parks, the Sedimentary National Parks, and the Grand Canyon and our National Monuments. In describing the several kinds of scenery the author also presents in a popular way the practical findings of science relative to their origin.

Farm woodlands and the war, H. S. GRAVES (U. S. Dept. Agr. Yearbook 1918, pp. 317-326).—The author briefly sketches the part played by farm woodlands in supplying various war needs, and advocates the systematic improvement of farm woodlands to meet the peace requirements of the Nation.

[Progress report on forestry investigations] (*Missouri Sta. Bul. 163 (1919)*, p. 51).—The fence post preservative test being conducted by E. C. Pegg continues to show the superiority of the open-tank method of treatment over all other methods (E. S. R., 38, p. 644).

The basket willow tests were also continued. Thus far no regularity of yield has been shown in relation to different methods of spacing. The problem of sprouting has been worked out through the use of vats or tanks.

**Progress report of forest administration in the Province of Assam for the year 1917-18**, A. W. BLUNT and W. F. L. TOTTENHAM (*Rpt. Forest Admin. Assam, 1917-18, pp.* [82], *pl. 1*).—The usual report on the management and exploitation of the forests of Assam for the year ended June 30, 1918. Important data relative to alterations in forest areas, forest surveys, working plans, forest protection, miscellaneous work, yields in major and minor forest products, revenues and expenditures, etc., are appended in tabular form.

**Progress** report on forest administration in Coorg for the year 1917-18, **H. TIREMAN** (*Rpt. Forest Admin. Coorg, 1917-18, pp. 2+14*).—A report similar to the above on the administration of the State forests in Coorg for the year ended June 30, 1918.

[Report on tree culture in the northern Nebraska sand hills], J. CowAN (Nebraska Sta. Bul. 171 (1919), pp. 7, 8).—Growing trees in quantity, such as is needed for groves and windbreaks on the dry sandy land of the region has been one of the hardest and most expensive operations undertaken at the Valentine substation. Bull pines raised from seed collected in the vicinity have done better than any other variety of tree, but it is questionable whether they will be long-lived. The probable cause of the trouble with both deciduous trees and conifers is the shallow rooting habit induced both by shallow soil and moisture near the surface during the growing season. Also in the case of deciduous trees, borers attack every species grown at the substation.

Afforestation: Its practice and science, M. C. DUCHESNE (*Rpt. Brit. Assoc. Adv. Sci., 1918, pp. 68-79*).—A paper, with discussion following, in which the author emphasizes the importance to Great Britain of an assured national timber supply, and brings out the need for closer association of science with practice in building up future timber reserves.

**Reafforestation** with conifer trees, L. BRETON-BONNARD (*Le Reboisement les Résineux. Paris: J. B. Baillière & Sons, 1918, pp. 276, figs. 61).*—A treatise on reafforestation based primarily on the author's experiences. Introductory considerations point out the importance of reafforestation projects to France. Part 1 contains descriptive accounts of coniferous species and varieties recommended for planting, part 2 contains cultural details, part 3 treats of insects and diseases of conifer trees, and part 4 contains examples of returns from conifer plantations.

Effect of removing the pulp from camphor seed on germination and the subsequent growth of the seedlings, G. A. RUSSELL (Jour. Agr. Research [U. S.], 17 (1919), No. 5, pp. 223-238, pls. 2, figs. 5).—A contribution from the Bureau of Plant Industry, U. S. Department of Agriculture, describing germination tests conducted with camphor seeds to determine the cause or causes of the low germination obtained both experimentally and commercially. The results of the investigation are presented in a series of tables and graphs and fully discussed.

Removing the pulp from the seed was found to hasten germination by an average of two weeks; it also gave an increase in germination of approximately

652

525 per cent over that of unpulped seed. A larger and more sturdy seedling tree was obtained for transplanting than when the pulp was not removed. It is believed that in commercial plantings the removal of the pulp from the seeds will increase the percentage of germination by at least 200 per cent, thus producing 40,000 more seedling trees to each acre of seed bed. The increased germination and the well-developed trees that result will repay many times the cost of the labor involved.

On the origin of chicle with descriptions of two new species of Achras, H. PITTIER (Jour. Wash. Acad. Sci., 9 (1919), No. 15, pp. 431-438).—Investigations conducted by the author indicate that chicle, which is commonly supposed to be the product of the sapodilla or naseberry tree (Achras zapota), is in reality the product of several species belonging possibly to more than one genus of the Sapotaceæ. Two new species of Achras. A. chicle and A. calcicola, are here described.

The European elder (Sambucus nigra), M. DEGLI ATTI (Ann. R. Scuola Sup. Agr. Portici, 2. ser., 14 (1916-17), pp. 13).—An account of the European elder and its economic uses, including a list of consulted literature.

The strawberry tree and its utilization, F. LA MARCA (Il Corbezzolo e la Sua Utilizzazione. Casale Monferrato: Marescalchi Bros., 1914, pp. VIII+105, figs. 4).—An account of the strawberry tree (Arbutus unedo), its importance to Italian agriculture, and its industrial utilization.

Variation in Hevea brasiliensis, S. WHITEY (Ann. Bot. [London], 33 (1919), No. 131, pp. 313-321, fig. 1).—Results are given of observations in the Federated Malay States, which were made to determine the extent to which variation occurs in the amount of rubber yielded by individual trees of H. brasiliensis of the same age and growing under the same conditions, and also as to the possible correlation between the yield of rubber and the girth of the trunk. In addition to data on the above phases, the observations made afford information relative to the extent of variation in the rubber content of the latex of individual trees and other peculiarities observed in connection with the study.

The data as a whole indicate that there is a comparative constancy of the yield from individual trees. A tree which was seen to be a high yielder at one time could be relied upon to give a high yield at all times. The marked variation in rubber yield between different trees examined suggests the great possibilities of seed selection in improving rubber yields. The data secured also indicate that the extent of variation on a normal tapping area may be such that it is quite impermissible to assume that small groups of trees in the tapping area will have the same yielding capacity as similar small groups in the same area. The girth data secured indicate that although there is a definite positive correlation between yields and girth the extent of the correlation is not sufficient to justify very much emphasis being placed on girth when selecting trees for thinning out.

Certain peculiarities were observed in the case of particular trees which were also constant over considerable periods of observations, and which may probably be regarded as characteristic of the trees displaying them. In some cases rapid discoloration of the latex appeared to be characteristic of the tree. The latex of other trees showed a tendency to rapid coagulation. A marked cream-straw color seemed to be characteristic of the latex from a small percentage of trees.

Selection and thinning, A. A. L. RUTGERS (Meded. Alg. Proefsta. Alb. Ver. Rubberplanters Oostkust Sumatra, Rubber Ser., No. 17 (1919), pp. 19, pls. 2).— A lecture on this subject in which the author presents experimental data to show the importance of selection and thinning as factors in reducing the cost price of raw rubber.

# DISEASES OF PLANTS.

Pan American cooperation in plant quarantine, R. SUNDBERG (Proc. 2. Pan Amer. Sci. Cong., 1915-16, vol. 3, pp. 869-874).—An outline with discussion is given of conventions and other steps taken in preparations regarding quarantine as looking to the protection of plants against parasites.

Pan American cooperation in plant quarantine, C. L. MARLATT (*Proc. 2. Pan Amer. Sci. Cong., 1915-16, vol. 3, pp. 888-904*).—This completes the series of which the foregoing has been noted, and includes the discussion which followed.

Phytopathological inspection of horticultural and viticultural establishments (*Bul. Mens. Off. Renseig. Agr.* [*Paris*], 16 (1917), *Apr.-June, p. 262*).— The number of establishments engaged in viticulture or horticulture submitting to phytopathological inspection is said to be increasing steadily, the numbers thereof being 83 for 1914, 103 for 1915, and 132 for 1916. The values of exports also show a steady and substantial increase, which is attributed to the greater assurance of safety conferred by observance of the regulations and precautions regarding inspection.

Seed and soil treatment for vegetable diseases, M. T. COOK (*New Jersey Stas. Circ. 106, pp. 4, fig. 1*).—Specific directions are given for the control of a number of seed-borne diseases, and suggestions are made for soil sterilization by the use of formaldehyde and steam.

[Work done in plant pathology], G. H. Coons (*Michigan Sta. Rpt. 1918, pp. 273-276*).—An outline is given of work in progress in plant pathology at the station, the principal investigation being of diseases of potato, celery, cereals, beans, and muck crops.

In connection with the potato disease work it has been found that the times of treatment with formaldehyde and corrosive sublimate can be shortened from the 1½ to 2 hour period commonly recommended to 15 minutes for formaldehyde and 30 minutes for corrosive sublimate, and still obtain efficient disease control. In the study of the control of cereal diseases by the use of formaldehyde, as a result of field laboratory and greenhouse tests, the author claims that concentrated formaldehyde when applied according to directions does not injure germination, and that where injury occurs it is brought about either from failure to follow directions as to dosage or time of covering, or from allowing the grain to stand too long before planting. Experiments have proved that complete removal of formaldehyde from grain is not possible by airing under ordinary conditions. A recommendation is made for immediate planting after treating seed.

[Report of the department of] botany, G. M. REED ET AL. (*Missouri Sta. Bul.* 163 (1919), pp. 31-33).—A progress report is given of investigations on the physiological relation of powdery mildews to their host plants, forest tree diseases, systematic and physiological studies of rusts, grain smuts and their contfol, and a watermelon disease said to occur in southeast Missouri, the lines of work and results described following quite closely those previously given (E. S. R., 38, p. 645).

Practically all varieties of oats and barley have been found susceptible to their respective mildews. Very few varieties of oats have been found that are not susceptible to crown rust when grown under greenhouse conditions. Inoculation experiments with sorghum smut have again shown that the milos are free from smut and feterita only slightly infected. Other varieties of sorghums vary in the proportion of infection. Oat varieties were found to differ widely in respect to infection by Ustilago avenæ and U. levis. Seed treatments with copper sulphate and formaldehyde were found to be quite efficient in the control of oat smut. A study of the watermelon disease indicates that there are several strains of Fusarium that cause wilt, and that the disease is favored by certain types of soil.

Damage from soil fungi, F. J. SEAVER (Jour. N. Y. Bot. Gard., 18 (1917), No. 212, pp. 186-188).—The considerable damage noted among various plants in the New York Botanical Garden during the season of 1917 is attributed to the fungi which normally inhabit the humus of the soil. Funkias, the foliage of which had been partly killed, showed no leaf fungus in sufficient abundance to account for the injury, but a Sclerotium in the soil appeared to have attacked these plants as well as others, causing considerable damage. Tulips failed to bloom and appeared to be suffering from the presence on the bulb of S. tulipæ, which possibly also originated in the soil. Rootstocks of the wild geranium were injured by another fungus which has been brought under investigation.

[Botany and phytopathology, Canada], T. A. CRERAR (*Rpt. Min. Agr. Canada, 1918, pp. 48-50*).—Forestry investigations have demonstrated the presence, over such wide areas, of white pine blister rust on its secondary host, currant or gooseberry, that it is feared that the control of the disease within the area of general infection will not be possible. Work has been carried on relative to the hibernation of the fungus on currants, longevity of the spores, distance of their transportation by winds, and other phases of the disease looking to its control.

Increased attention has been paid to the control of plant diseases generally. Losses from grain rusts were not severe during the year. Apparently a means has been worked out for controlling peach canker, which now causes much loss. Studies are reported in connection with potato diseases, leaf roll, club root, apple scab, and grain diseases.

Plant diseases [in Ireland] (Dept. Agr. and Tech. Instr. Ireland, Ann. Gen. Rpt., 18 (1917-18), p. 60).—A new disease of potato has been studied and has received the name "foot rot." It is said to be due to a new species of Phytophthora in the soil allied to that producing pink rot, also that producing potato blight.

The Collectrichum causing a disease of flax seedlings has been shown to hibernate in the skin of the seed, infecting the plant while very young. A seed treatment has been worked out which has not yet received practical application in seed tests,

A list of diseases of economic plants occurring in the Bombay Presidency, H. M. CHIBBER (*Dept. Agr. Bombay Bul. 65 (1914*), *pp. 27*).—This list of diseases is arranged according to host plants. An index is given, together with a classified list of the 71 genera of fungus parasites in connection with the host plants. The author records also, 1 bacterium, 1 alga, 5 flowering plants, 2 nematodes, 1 woolly mite (*Phytoptus* sp.), and some diseases due to unknown causes.

Foot and stalk disease of wheat, E. FOEX (Compt. Rend. Acad. Agr. France, 5 (1919), No. 18, pp. 543-548).—A distinction is drawn between the lateral wheat stalk disease caused by Leptospharia herpotrichoides and the more basal, frequently subterranean, and usually encircling attack due to Ophiobolus graminis. The results of observations during several years are outlined as regards the relations to disease of such factors as fertilizers, seeding time, and crop succession.

The black stem rust and the barberry, E. C. STAKMAN (U. S. Dept. Agr. Yearbook 1918, pp. 75-100, pls. 10, fig. 1).—A popular account is given of the 149863°—20—5 black stem rust (*Puccinia graminis*) on various cereals, the losses entailed by the disease, and the relation of the common barberry and other host plants to the spread of the disease.

Immunity and inheritance in plants, D. MCALPINE (Advisory Council Sci. and Indus., Aust., Bul. 7 (1918), pp. 78-86).—Before the conference of Agricultural Scientists convened at Melbourne November 9-16, 1917, the author delivered an address regarding the immunity of plants to disease, its probable cause, and its relation to heredity, with practical suggestions regarding the black or stem rust, which is declared to be the most injurious rust of wheat in Australia.

A little known disease of alfalfa, FRON and LASNIEB (*Compt. Rend. Acad.* Agr. France, 5 (1919), No. 22, pp. 629-631, 642-644).—An account, partly descriptive, is given of a disease of alfalfa attributed to *Urophlyctis alfalfa*, which is thought to affect this plant in widely separated regions.

The æcial stage of alsike clover rust, W. H. DAVIS (*Proc. Iowa Acad. Sci.*, 24 (1917), pp. 461-472, pls. 2, flgs. 6).—A discussion and tabulated statistics regarding characters and behavior are given in an attempt to establish the proper systematic disposition to be made of the rust on alsike clover. It is stated that there are as many morphological differences between the æcial and pycnial stages of the rust on *Trifolium hybridum* and *T. repens* as between those on *T. repens* and *T. pratense*, which are regarded as two separate rusts.

Diseases of the potato, F. D. HEALD (*Proc. Wash. State Hort. Assoc.*, 14 (1918), pp. 115-124).—This is a somewhat systematic discussion from the standpoint of national food conservation of the causation, effects, and control of diseases affecting the potato output in Washington.

Potato leaf roll, E. BLANCHARD and C. PERRET (Compt. Rend. Acad. Agr. France, 5 (1919), No. 10, pp. 356-358).—This is a continuation of the study of potato leaf roll, previously noted (E. S. R., 40, p. 347; also E. S. R., 41, p. 51). Nitrates appear to exert a certain beneficial effect on potato plants in this connection.

Potato spraying trials in the Cambridgeshire Fens, 1918, F. R. PETHER-BRIDGE (Jour. Bd. Agr. [London], 25 (1919), No. 10, pp. 1166–1172).—A detailed account is given of the first trial with horse-drawn sprayers in the Cambridgeshire Fens. Causes of imperfect or undesirable results are pointed out. It is considered that the value of spraying in this locality can not be decided from the results of a single season.

Bacterial blight of soy bean, W. H. TISDALE (North Carolina Sta. Rpt. 1918, p. 59).—This note is largely based on work of the previous head of the department, F. A. Wolf.

The disease is said to be due to a bacterium that has been isolated and named **B**.  $soj\alpha$  n. sp., and has been reported from Nebraska, Connecticut, Wisconsin, and North Carolina. It is characterized by water-soaked angular spots on the leaves and cotyledons. Infected seed are believed to be the chief means by which the disease is carried over winter and introduced into new localities.

A disease of tomato and other plants caused by a new species of Phytophthora, G. H. PETHYBRIDGE and H. A. LAFFEETY (Sci. Proc. Roy. Dublin Soc., n. ser., 15 (1919), No. 35, pp. 487-505, pls. 3; also in Gard. Chron., 3. ser., 65 (1919), No. 1686, pp. 188, 189, fig. 1).—What appears to be a new disease of tomato is here dealt with in systematic detail. The roots and lower stem developed a rot (causing finally death of the plant) for which the name rot is suggested. The fungus is described under the name P. cryptogea. The same type of disease associated with the same fungus occurs in Petunia; also probably in Aster and Cheiranthus. Artificial inoculation showed the fungus to be pathogenic to Solanum tuberosum, Gilia tricolor, and Fagus sylvatica, but not to Senecio vulgaris or Nicotiana affinis. The disease originates in the soil, in which it is thought oospores of the fungus hibernate.

Methods of control as outlined include sterilization by steam, also amputating diseased portions and treating the remaining portion as a cutting.

**Dry-rot** of turnips.—Suggestions regarding control, A. H. COCKAYNE (Jour. Agr. [New Zeal.], 17 (1918), No. 2, pp. 71–73).—Results of investigational work in the field and laboratory are presented showing that infection by Phoma napobrassicæ appeared sooner on early than on late sowings of various crucifers and increased until September, although not much loss occurred in July. All varieties of swedes so far as studied are about equally susceptible. Infected soils show earlier than clean land the appearance of dry-rot, which may be delayed by the application of lime. Swedes under cover keep better than those in the field, though earthing up reduced infection. An outline of suggested work is given with reference to reduction of loss from dry-rot.

Orchard experimental work by Stoke Fruitgrowers' Association (*Jour. Agr.* [*New Zeal.*], 17 (1918), No. 4, pp. 225-230).—In this report, read by W. C. Hyde, experiments are described in which lime-sulphur proved superior to atomic sulphur as a general fungicide in orchards. The invigorating effect of spring applications of Bordeaux mixture to apple trees was confirmed, as was also its favorable action against black spot when properly followed by lime-sulphur as compared with an application of lime-sulphur alone. Weak copper sulphate as a summer spray for apple trees proved impracticable. An application of oil following a fungicide proved uneconomical. Naphthalene lime-sulphur gave promising results as a commercial fungicide and a contact insecticide. Proper timing of orchard cultivation is considered important in connection with fungus infection of orchard trees. It was found that limesulphur 1: 125 and atomic sulphur 15 lbs. to 100 gal. of water applied in summer produced no scorching. Bordeaux mixture is a more effective spray for peaches than is lime-sulphur.

Treatment of apple canker diseases, J. O. WHITTEN (*Missouri Sta. Bul. 163* (1919), p. 54).—The author recommends for the control of apple canker the pruning out of limbs that are dead or practically destroyed. The limbs should be cut close and the wounds painted with common paint containing corrosive sublimate. Where canker occurs in patches on the limbs or side of the tree the wound should be scraped clean and painted with disinfected paint. It is claimed that 80 per cent of canker infection may be avoided by reducing the number of unnecessary wounds during pruning and cultivation.

Apple powdery mildew a serious menace to orchards, D. F. FISHER (Better Fruit, 13 (1919), No. 10, pp. 3-6, figs. 6).—It is stated that apple powdery mildew (Podosphæra leucotricha) is now commonly found in all of the major apple growing districts of the Pacific Northwest, causing loss in which the injury to the tree extends over more than one season. Though the disease is as yet localized, it is feared that favoring conditions may make it general over this region. A discussion is given of its relations to such factors as wind, precipitation, dew, and temperature. The fungus is also occasionally found on pears in this section.

At Wenatchee, Wash., it was found that, while pruning could be made a valuable supplement to spraying, the latter used alone was in the end more economical. Of the means employed, ammoniacal copper carbonate appears to be the best single spray for all seasons, though it is thought that neutral Bordeaux mixture may prove as effective and perhaps cheaper. Copper sprays are regarded as a costly and makeshift supplement to sulphur sprays during the period of burning sunlight when sulphur sprays are unsafe, although

[Vol. 41

these form the chief reliance during the spring when the best progress can be made. Details are given of treatments employing these sprays in this area. The necessity is emphasized of covering every part of leaves and twigs, with special attention to the terminals. For this purpose, pressures of 200 to 250 lbs. are recommended to be employed in connection with eddychamber or whirlpool nozzles of the driving mist type.

Apple scab and its control, J. W. EASTHAM (Canad. Hort., 41 (1918), No. 11, pp. 253, 254, fig. 1).—Outlining recent conditions and experiences regarding apple scab in portions of British Columbia, the author outlines recommendations based on the results now available of work done during the two previous years. The chief defense relied upon as regards apple scab is timely and thorough spraying with lime-sulphur, which is said to have almost entirely superseded Bordeaux mixture for this purpose. Suitable concentrations employed are 1:30 for the dormant, 1:35 or 1:40 for the pink, and 1:40 for any of the latter sprays. The effects on the apple crop of lime-sulphur are not yet fully determined.

A new and effective disinfectant for pear blight, F. C. REIMER (*Better Fruit*, 13 (1919), No. 10, pp. 24-27).—This contains information which has been noted from another source (E. S. R., 41, p. 452).

It is stated that tests on several pear varieties carried out with formaldehyde tend to show that the 10 per cent solution (one part of commercial formfaldehyde to nine parts of water) can be safely recommended for both wounds and tools in connection with blight work during the fall and winter months. Cyanid of mercury was perfectly effective. A test is described as carried out with a solution of the pure cyanid in distilled water prepared fresh every day, carried in glass receptacles, and applied with a clean paint brush, two drops of the blight culture ooze having been applied to each wound in order to constitute a severe test.

Experiments are in progress with commercial mercury cyanid tablets commonly found on the market to determine their value in this connection.

June drop and its relation to the weather, C. A. JENSEN (*Cal. Citrogr.*, 3 (1918), No. 11, pp. 255, 277, figs. 5).—This is a discussion of observations on June drop of the navel orange in its alleged relation to weather (charts covering June of 1917 and 1918 being given), and to other possible factors, no one or combination of which appears sufficient to explain fully its occurrence.

**Psorosis (scaly bark) of orange trees in California**, H. S. FAWCETT (*Cal. Citrogr.*, 4 (1919), No. 5, pp. 107, 133, 139, figs. 5).—The statements here noted are understood to be tentative, as this disease is still under investigation at the California citrus substation. The disease is discussed as to its several stages, favoring conditions, and appropriate treatments.

On the life history of the rose blotch fungus, N. L. ALCOCK (Roy. Bot. Gard. Kew, Bul. Misc. Inform., No. 6 (1918), pp. 193-197, pl. 1, figs. 2; Gard. Chron., 3. ser., 65 (1919), No. 1671, p. 2).—A descriptive discussion is given of the rose disease Actinonema rosæ as regards the effects on the wood, with an account of the survival of the winter stage, varieties attacked, and control measures. The most effective of these consisted of 90 parts sulphur and 10 parts lead arsenate. Another almost as effective was a 5:5:50 Bordeaux mixture.

Fomes lucidus as a parasite of trees, W. NOWELL (Agr. News [Barbados], 17 (1918), No. 412, p. 46).—Plants named as subject to attack by F. (Polyporus) lucidus, usually at the center, include lime trees, Pithecolobium saman, P. unguis cati, Casalpinia coriaria, and species of Acacia. Control of oak mildew, N. VAN POETEREN (*Tijdschr. Plantenziekten*, 24 (1918), No. 3, pp. 83-101).—Having continued observations on oak mildew, which is reviewed as far back as the beginning, in 1908, of the epidemic form, with discussion also of facts noted in 1912 (E. S. R., 28, p. 651), the author states that the injury done, though varying considerably in a given locality, is sufficient to require effective control measures. For this purpose, lime-sulphur is recommended as a suitable spray, one application each season being considered sufficient if applied when the mildew begins vigorous development.

Pine rust in Sweden, 1917, N. SYLVÉN (Meddel. Stat. Skogsförsöksanst., No. 15 (1918), pp. 192-204, XIX-XXII, fig. 1; also in Skogsvårdsför. Tidskr., 16 (1918), No. 4, pp. 308-315).—Pine rust (Melampsora pinitorqua) is said to have caused very little damage in Sweden during 1917. The contrast in this respect with the effects during the previous year is thought to have been due mainly to differences in weather. A principal condition for copious infection of pines and resulting injury is thought to be wet weather during May, or a relatively even distribution of precipitation during this period of spore germination and development, dry weather during May and early June being unfavorable to the development of the fungus.

Pine rust (Melampsora pinitorqua), N. SYLVÉN (Meddel. Stat. Skogsförsöksanst., No. 13-14 (1916-17), pt. 2, pp. 1077-1140, CXXVII-CXXXVI, figs. 28; also in Skogsvårdsför. Tidskr., 16 (1918), No. 4, pp. 265-307, figs. 28).—This is an account of pine rust in portions of southern Sweden due to *M. pinitorqua*, regarding its development and spread as related to weather and to the alternate host (Populus tremula), from which it may spread each year to reinfect the pines.

[Pine rust in Sweden], N. SYLVÉN (Naturw. Ztschr. Forst u. Landw., 16 (1918), No. 3-8, pp. 118-127).—This is an account of the work noted above.

Summary of the white pine blister rust situation, H. METCALF (Jour. Forestry, 16 (1918), No. 1, pp. 85-89).—Referring to reports bearing on the territorial relations of white pine blister rust previously noted (E. S. R., 39, p. 758), the author states that the territorial division of the problem then indicated still holds, though west of the Mississippi River only four centers of infection have been found, none of them so located as to be dangerous. Cronartium on Ribes in Colorado, so strongly resembling C. ribicola as to have been assigned to that species, has been found during the past season to have a Peridermium stage on Pinus edulis and P. monophylla.

Further notes on black-stripe canker, W. N. C. BELGRAVE (Agr. Bul. Fed. Malay States, 6 (1917), No. 3, pp. 154, 155).—Discussing further (E. S. R., 39, p. 459) black-stripe canker, the author states that as a general rule black-stripe tissues need not be cut out and that sterilization of tapping knives is unnecessary if preventive painting is employed.

Field notes and observations on brown bast, W. N. C. BELGRAVE and F. W. SOUTH (Agr. Bul. Fed. Malay States, 6 (1918), No. 4, pp. 181-186).—It is stated that, so far as known, rubber trees having once developed the condition known as brown bast never recover under natural conditions, though they continue to live. Practically all methods intended to be curative or preventive are still in a purely experimental stage. Some of these are discussed with recommendations.

Experiments on the prevention of brown bast, W. N. C. BELGEAVE (Agr. Bul. Fed. Malay States, 6 (1918), No. 4, p. 187).—The suggestions here given, being purely experimental, are recommended to be tried out on small areas. Prominence is given to an application of lime raked into the soil over a radius of 5 or 6 ft., washing the trees with lime from the collar to a height of 12 in., and painting with Izal or formalin bisulphite. A study of the root-nematode (Heterodera radicicola) and its control, W. P. DUBUZ (Soil Sci., 4 (1917), No. 6, pp. 481-492, figs. 10).—Means of control include excess moisture, high temperature, formaldehyde, sphagnum moss extract, and sodium cyanid dissolved in water. All decreased nematode activity and are suggested as means of control.

Sodium cyanid treatment is regarded as practical and satisfactory for nematode infestation. This substance dissolved in water is applied to the soils at the rate of 200 lbs. per acre (one-third gallon per sq. ft. of soil). A second treatment should follow about a week later. After this, the soil should be aerated and leached before planting.

# ECONOMIC ZOOLOGY-ENTOMOLOGY.

Federal protection of migratory birds, G. A. LAWYER (U. S. Dept. Agr. Yearbook 1918, pp. 303-316, pls. 3, figs. 2).—A popular account of the protection of migratory birds by the Federal Government.

Life histories of North American diving birds.—Order Fygopodes, A. C. BENT (U. S. Nat. Mus. Bul. 107 (1919), pp. XIII+245, pls. 55).—This bulletin reports investigations commenced in 1910 and carried on in cooperation with other American ornithologists in continuation of the work begun by Bendire. Twelve plates in colors illustrate the eggs of 37 species. A bibliography of 7 pages and a subject index are included.

Report of the entomologist, R. H. PETTIT (*Michigan Sta. Rpt. 1918, pp. 278-280*).—Among the more important insect enemies of the year here noted are a borer in corn which appeared the previous year and has now been identified as *Noctua fractilinea*; the flower thrips, which was identified as the insect producing blemishes on Elbertas in the western part of the State (E. S. R., 40, p. 650); and *Macrosiphum cynosbati*, which produced witches' broom in Houghton gooseberry. The fungus *Isaria farinosa*, introduced by the author in several localities where the tamarack sawfly abounded, is said to be responsible for killing numbers of this pest.

Entomology (*Missouri Sta. Bul. 163* (1919), pp. 41-43).—A brief report of the work of the year. The Hessian fly practically disappeared from the State, having succumbed to weather conditions and not to parasites or other natural agencies.

Report of the division of entomology, F. SHERMAN (North Carolina Sta. Rpt. 1918, pp. 42-49).—This report of the chief on the more important work of the year with insect pests includes a report of the entomologist, Z. P. Metcalf (pp. 45-49). The latter report deals briefly with the work with the gloomy scale, which is the most destructive insect enemy of shade maples in the State; the bean and pea weevils; the melon beetles; the tobacco flea-beetle; and insects affecting ornamental plants.

Notes on some insect pests of Costa Rica, J. ZETEK (Jour. Econ. Ent., 12 (1919), No. 3, p. 269).—The notes here presented relate to observations made in Costa Rica during the latter part of February and March, 1919.

The author found the spiny citrus white fly (*Aleurocanthus woglumi*) to be very abundant on citrus of various species at Limon and at all the stations of the Northern Railroad as far as Peralta, and the purple scale to be extremely abundant on both leaves and fruit of citrus. The Hawaiian sugar cane borer (*Rhabdocnemis obscurus*) was exceedingly abundant in banana stumps and cuttings. Mention is also made of the high infestation of balsa logs about to be shipped to the United States with lepidopterous larvæ and pupæ.

[Contributions on economic insects] (Ztschr. Angew. Ent., 4 (1918), No. 3. pp. V+335-391).—Among the papers here presented are the following: Intro-
duction to a Graphic Formula of the Biology of Insects, by L. Rhumbler (pp. 335-346); The Control of Flies, by E. Teichmann (pp. 347-365); Control of the Webbing Clothes Moth (*Tineola biselliella*) by Hydrocyanic Acid Gas, by A. Andres (pp. 366-368); The Use of Insects in Medicine, by F. Heikertinger (pp. 369-373); *Thereva nobilitata*, a New Enemy of Rye, by Kleine (p. 373); and An Outbreak of Orthezia insignis at the Royal Botanical Garden at Berlin-Dahlem, by F. Schumacher (p. 374).

Insect pests of the rosella, E. JARVIS (Queensland Agr. Jour., 12 (1919), No. 2, pp. 69-74, figs. 11).—This paper deals particularly with the roselle flea-beetle (Nisotra breweri), which has found Hibiscus sabdariffa more attractive than its own native food plant Commersonia echinata. While N. breweri is the only really destructive insect encountered by the author in Queensland at the present time, several other species also occur on the foliage of roselle at Meringa, namely Lagris cyanea, Rhyparida discopunctulata, Euproctis sp., Dysdercus sp., and Agonoscelis rutilia.

Common insecticides.—Their practical value, H. F. WILSON (*Wisconsin Sta. Bul. 303* (1919), pp. 15, figs. 5).—The data presented in this bulletin are based upon a series of tests made by the author at the Oregon and Wisconsin experiment stations. These tests were made primarily to determine the comparative values of Paris green, arsenite of zinc, arsenate of lead, and calcium arsenate in the control of the Colorado potato beetle. The results are presented in tabular form, and a chart is given in which data relating to these insecticides are graphically compared.

In the course of the work 18 different arsenicals were examined, including both simple arsenicals and proprietary insecticides and the materials used in their manufacture. These are grouped in three classes: (1) Those having no killing efficiency (Prince's mineral, iron oxid, and silicia); (2) those having a slight degree of killing efficiency (basic lead sulphate, lead oxid, zinc oxid, and the compounds of zinc oxid plus lead oxid, and zinc oxid plus lead oxid plus iron oxid); and (3) those having a high degree of killing efficiency (Paris green, lead arsenate, calcium arsenate, zinc arsenite, Bug Death, Kling Kill, Tuber Tonic, and Insecto).

"Paris green and a special brand of lead arsenate gave the best results, with practically a 100 per cent killing efficiency within 24 hours. Ordinary arsenate of lead is second, and zinc arsenite and calcium arsenate are a trifle slower than the others. The materials known as Bug Death, Kling Kill, Tuber Tonic, and Insecto are proprietary compounds which contain as the active ingredient either lead oxid, zinc oxid, or some arsenical compound. They are, therefore, merely diluted combinations of poison and have no advantage over a good grade of arsenate of lead or calcium arsenate. Summarizing, Paris green is the material with the greatest killing efficiency, but it is little better than a certain brand of arsenate of lead. Ordinary brands of arsenate of lead, zinc arsenite, and calcium arsenate are a trifle slower in action, but are sufficiently efficient for all practical purposes for the control of the Colorado potato beetle."

On potatoes Paris green without lime was the only spray that caused any marked damage. On apple foliage it has been found that both calcium arsenate and Paris green cause injury to the foliage unless they are combined with equal parts of lime, lime-sulphur, or Bordeaux mixture, but when so combined no burning was detected.

Derris as an insecticide, N. E. MCINDOO, A. F. SIEVERS, and W. S. ABBOTT (Jour. Agr. Research [U. S.], 17 (1919), No. 5, pp. 177-200).—This is a report of investigations of Deguelia [Derris] spp. as an insecticide, conducted cooperatively by the Bureaus of Entomology and Plant Industry of the U. S. Department of Agriculture. The results of the investigations are reported in part in tabular form and summarized as follows:

"Derris, known widely as a powerful East Indies fish poison, was found to fulfill several of the requirements of a general insecticide; it acts both as a contact insecticide and as a stomach poison, but is of no practical value as a fumigant. Six species of derris were tested, but only two of them (*D. illiptica* and *D. uliginosa*) were found to be satisfactory for insecticidal purposes.

"According to the views of various authors, the toxic principle in derris is a resin, which affects the various classes of animals according to the development of their nervous systems. It kills some insects easily and others with difficulty, but it usually acts slowly and seems to kill by motor paralysis. Denatured alcohol was found to be a good economic solvent for extracting the toxic principle, which when applied in spray mixtures proved to be efficient against certain aphids, potato beetle larvæ, and small fall webworms. For proprietary insecticides it is possible to incorporate the extracts from derris into soft soaps, which when greatly diluted with water are ready for use.

"Derris powder, used as a dust under practical conditions, was found to be efficient against dog fleas, chicken lice, house flies, three species of aphids (*Aphis rumicis, A. pomi,* and *Myzus persicæ*), potato beetle larvæ, and small fall webworms, but of no practical value against bedbugs, roaches, chicken mites, mealy bugs, *Orthezia insignis*, red spiders, or against the crawling young of the oyster-shell scale. Used as powder in water with or without soap under practical conditions, it proved to be efficient against most of the aphids sprayed and also against cabbage worms (*Autographa brassicæ*), the larvæ of apple datanas (*Datana ministra*), oak worms (*Anisota senatoria*), small tent caterpillars, and potato beetle larvæ."

A list of 11 references to the literature is included.

Economic poisons used in control of pests in California, season 1917-18, G. P. GRAY (Mo. Bul. Cal. Com. Hort., 8 (1919), No. 3, pp. 109-112, fig. 1).— Data presented in tabular form show the cost of economic poisons by counties and consumption, prices, and cost in 41 counties.

Locust destruction ([Wellcome Trop. Research Lab.] Ent. Bul. 1 (1914), pp. 16).—Directions are given for the control of locusts by means of arsenicals.

The Coccobacillus acridiorum of d'Herelle, D. S. S. QUIROGA (*Rev. Soc. Med. Vet.* [*Buenos Aires*], 4 (1918), No. 1, pp. 467-479).—This preliminary report to the Agricultural Commission of Defense includes **a** list of 16 references to the literature.

**Does Bordeaux mixture repel the potato leaf-hopper?** C. L. FLUKE, JR. (Jour. Econ. Ent., 12 (1919), No. 3, pp. 256, 257).—The author presents data which indicate that the leaf-hopper is repelled to some extent by Bordeaux mixture, although further experimental work is necessary to prove such to be the case.

The life history and biology of the pink and green aphid (Macrosiphum solanifolii), L. B. SMITH (Virginia Truck Sta. Bul. 27 (1919), pp. 27-79, figs. 12).—This is a detailed report of investigations commenced in the spring of 1915 at Norfolk, in which region M. solanifolii is a serious enemy of potatoes and spinach, two crops of the greatest importance in eastern Virginia, the annual value of which is about \$12,000,000.

In this paper the author deals particularly with certain phases of the life history and habits of *M. solanifolii* as it occurs in the region of Norfolk, together with some of its economic relationships, the literature on which is reviewed, including the studies of Patch (E. S. R., '34, p. 550), Houser et al. (E. S. R., 38, p. 462), Regan (E. S. R., 38, p. 654), Britton (E. S. R., 39, p. 761), and others. Studies relating to the insect in its transmission of spinach blight have been previously noted (E. S. R., 39, p. 550).

The year 1917 is apparently the first time this species proved to be generally injurious over a large territory. In the Virginia trucking region injury to potatoes was first noticed in 1914. Outbreaks were more or less local in 1915, while the most severe outbreaks occurred during 1916, 1917, and 1918, varying from 1 or 2 to 75 or 80 per cent. It has been the source of considerable injury to young eggplant in cold frames and to the blossom and young fruit. Often its injury to tomatoes may occur chiefly on the blossom clusters and terminal shoots, the production of fruit being thus stopped; otherwise it resembles that to potatoes. During outbreaks of the green pea aphis (M. pisi) on peas in 1914 and 1915 the relative abundance of M. solanifolii varied from 13 to 42 per cent.

Although spinach has been severely injured by the attack of aphids for the past 12 or 15 years, the green peach aphis (*Rhopalosiphum persicæ*) has in the past probably caused the greater direct loss. During the past 5 years, however, the potato aphis has become numerous and in 1915, 1917, and 1918 serious outbreaks occurred on spinach during the fall and winter months. In those cases, while *R. persicæ* was present, over 90 per cent of the aphids infesting the crop were *M. solanifolii*. While it reduces both the yield and market value of spinach the greatest loss is caused through transmitting the spinach blight. The loss occasioned by this disease, transmitted by both *M. solanifolii* and *R. persicæ*, has been estimated to exceed \$200,000 annually, which is approximately 20 per cent of the value of the entire crop.

In a study of its host plants it was found to feed and reproduce on 61 species representing 19 families. In the region of Norfolk it does not produce true sexes, the species passing the entire year as viviparous females. On the Eastern Shore peninsula the true sexes are produced occasionally, but are not common.

"Beginning about the first of March, there occurs a period lasting nearly six weeks when the aphids leave their winter host plants and colonize on a large variety of weeds, and also asparagus and potatoes. The aphids remain on asparagus only while the shoots are young and succulent. Potatoes are usually infested first when they are from 1 to 3 in. tall. The date depends largely on the prevailing climatic conditions. The general migration ceases about the first of May, although sporadic flights occur later. During the excessively hot weather, especially if it is dry, little movement takes place among the aphids.

"*M. solanifolii* is relatively abundant on various weeds until about July 1 to 15. Increased numbers of their natural enemies decimate the species, and during the late part of July and August they are exceedingly scarce and difficult to locate. Except when the aphids are sufficiently numerous to destroy the vines, there has not been observed any general migration from the spring crop of potatoes to other crops or weeds. It is believed that the offspring of individuals, which migrate to weeds early in the spring, are the ones which survive the summer.

"By the first of September the aphids are beginning to be more numerous on weeds, and an intermittent period of migration occurs which lasts until the weather becomes cold, usually about November 15. Young kale is occasionally heavily infested for a short period, but most of the aphids eventually find their way to spinach. Scattered individuals are to be found throughout the winter on certain of the Cruciferæ and Leguminosæ. The fall potato crop rarely suffers as severe injury as the spring crop. Outbreaks may occur on spinach at any time during the winter when the weather conditions are favorable. Hard, driving rains and sleet storms are important factors in the natural control at this time of the year.

"Under average conditions, *M. solanifolii* is found associated with *R. persicæ* on spinach, but the former species is more numerous and widely distributed in the fields. Dispersal from plant to plant and field to field is accomplished by both the alate and apterous forms. The latter have been observed to travel several yards in order to reach a fresh food plant. The rate of infestation may be very rapid. In 1918 a 15-acre field of potatoes had 97 per cent of the plants infested within a period of 15 days. Other crops are likewise infested very rapidly.

"It has been observed that early maturing varieties of potatoes were the first to be infested in the spring, and suffer more serious injuries than do later maturing varieties. A variety of spinach has been obtained from Manchuria which is apparently distasteful to the aphids; at least, it is infested only when other food is scarce, or the aphids are extremely abundant. This strain is being used as the basis in our breeding experiments to obtain a blight-resistant strain.  $F_1$  and  $F_2$  hybrids of this strain are showing this character to a certain extent.

"Generation experiments were conducted from 1915 to 1918. Nineteen first born and eight last born generations, or an average of  $13\frac{1}{2}$  generations, were obtained between May 1 and November 20, 1915. Thirty-four consecutive first born generations were obtained between April 1, 1916, and April 1, 1917. The average age at which females gave birth to young was 10.9 days in 1915 and 11.1 days in 1916. The females mature at an earlier age during the summer than at other seasons of the year. The number of young born per day was found to vary, 12 being the maximum obtained. The maximum number of young produced during the life of a single female was 87. The averages were 43.3 in 1915 and 46.7 in 1916. The average life of a viviparous female was 29.2 days in 1915 and 32.6 days in 1916. The length of the reproduction period averaged 17.96 days in 1915 and 18.9 days in 1916. *M. solanifolii* molt four times; the average length of the instars was as follows: First, 54<sup>1</sup>/<sub>2</sub> hours; second,  $65\frac{1}{2}$  hours; third,  $69\frac{1}{3}$  hours; fourth,  $65\frac{2}{3}$  hours.

"Two internal parasites of this aphid have been reared. Aphidius polygonaphis is most abundant; Diaretus rapea parasitizes this species occasionally. The common aphid fungus Empusa aphidis is one of the most important enemies of this aphid during the warm, humid periods of July and August. The two ladybird beetles Hippodamia convergens and Megilla maculata destroy many of the aphids during the spring and autumn."

A bibliography of 26 titles is appended.

The durra asal fly (Aphis sorghi) in Dongola Province, Anglo-Egyptian Sudan, H. H. KING ([Wellcome Trop. Research Lab.] Ent. Bul. 2 [1914], pp. 14).—This is an account of the so-called asal fly of durra (Sorghum vulgare), the staple grain crop of the Sudan. In the northern Provinces of Sudan this fly confines its attention to durra and garowi (Andropogon halepensis) grown on or near the river banks but not on crops far distant from the river.

Controlling mealy bugs by the use of their natural enemies, H. M. ARMI-TAGE (Mo. Bul. Cal. Com. Hort., 8 (1919), No. 5, pp. 257-260).—This is an outline of the work of the California State Horticultural Commission against the citrus-feeding mealy bugs in southern California.

A new scale insect (Xylococcus alni) on alder, with special reference to its metamorphosis and anatomy, K. OGUMA (Jour. Col. Agr. Hokkaido Imp. Univ., 8 (1919), No. 3, pp. 77-109, pls. 3, fig. 1).—This is a report of studies extending over a period of several years of a new scale<sup>1</sup> which infests the branches of

<sup>&</sup>lt;sup>1</sup> In 'O-yô-Konchiugaku, edited by S. Matsumura (1917, vol. 1, p. 294).

alder (*Alnus japonica*) and is found in abundance in swampy places along the streams in Sapporo.

New studies and observations of Argentine Pieridæ, E. GIACOMELLI (*Physis*, 3 (1917), No. 15, pp. 370-385).—Thirty-nine species and 14 genera of this economic group are noted.

Ear worm injuries to corn and resulting losses, R. C. SMITH (Jour. Econ. Ent., 12 (1919), No. 3, pp. 229-233, pl. 1).—In reviewing the injuries caused by the bollworm to corn it is pointed out that two sources of serious loss have been overlooked: (1) That due to its feeding on the germ or lower part of the kernel after the endosperm has hardened and (2) the entrance of grain weevils and other pests through the holes made by it in the husk.

The status of the codling moth in its relation to the walnut industry, D. B. MACKIE (Mo. Bul. Cal. Com. Hort., 2 (1919), No. 5, pp. 250-256, figs. 3).—This is an account of further work with the codling moth as an enemy of walnut, a brief account relating to which has previously been noted (E. S. R., 40, p. 456).

This pest is becoming a serious enemy of walnut in California, as high as 40 per cent of the entire crop being injured and sold as culls in certain orchards in Orange County. It appears that with cooperation the pest can be controlled in the field. The spread of this pest to orchards in sacks in which the worms spin their cocoons can be readily prevented through the use of the electric mangle at comparatively slight expense.

Notes on lepidopterous borers found in plants, with special reference to the European corn borer, E. MOSHER (*Jour. Econ. Ent.*, 12 (1919), No. 3, pp. 258-268, flgs. 4).—This paper is prepared with a view to aiding field workers and others in determining whether or not they have the European corn borer at hand.

Notes on the life history of the pine tube moth (Eulia pinatubana), A. HARTZELL (Jour. Econ. Ent., 12 (1919), No. 3, pp. 233-237).—This is a report of studies made in the vicinity of Ithaca, N. Y., where the larva occurs in injurious numbers on white pine (*Pinus strobus*), which appears to be its only host plant. The species was first recorded in the United States by Comstock in 1880 and was confused with the European species *E. politana* until 1905, when it was described as new by Kearfott.

Tubes are built by the larvæ by drawing together leaves of the white pine with silk, from 5 to 20 leaves being bound together in their construction. Usually two or three of the leaves are left uneaten, which serve to hold the tube in place even after many of the older leaves are dead. The larvæ live singly, and it is thought probable that they may occupy more than one tube during the larval life. The author's observations indicate that the species is singlebrooded in the latitude of central New York. The distribution of the species, though not well known, appears to be throughout the white-pine district of southern Canada and eastern United States.

Records are given of rearings of 25 individual parasites representing 8 species of Hymenoptera, the identifications of which were made by Girault, Cushman, and Rohwer.

What hinders dried fruit sales? E. R. DE ONG (Mo. Bul. Cal. Com. Hort., 8 (1919), No. 5, pp. 240-243, flgs. 4).—A brief discussion of the infestation of dried fruit by the Indian meal moth.

Observations on the food of Anopheles larvæ, C. W. METZ (*Pub. Health* Rpts. [U. S.], 34 (1919), No. 32, pp. 1783-1791).—The author reports studies conducted in the summer of 1918 near Montgomery, Ala., and Lakeland, Fla., which deal with Anopheles punctipennis, A. quadrimaculatus, and A. crucians,

especially the two last named. The experiments show that the diet of Anopheles larvæ may be either heterogeneous or homogeneous, consisting of mixed animal and vegetable materials, mixed vegetable materials, or individual species of plants or animals.

Some aspects of malaria control through mosquito eradication, C. W. METZ (*Pub. Health Rpts.* [U. S.], 34 (1919), No. 5, pp. 167–183, figs. 4).—This discussion relates to drainage, oiling, and accessory measures.

The experimental infection in England of Anopheles plumbeus with Plasmodium vivax (sporoboites in salivary glands), B. BLACKLOCK and H. F. CARTER (Ann. Trop. Med. and Parasitol., 13 (1919), No. 2, pp. 187, 188).—Two of five mosquitoes fed on a volunteer patient suffering from simple tertian malaria acquired in Saloniki were found to be infected. In the first, which died, 12 oöcysts were found in the gut, some being in an advanced state of development. The other was killed and infections of bot gut and salivary glands were found. Both glands were infected with sporozoites in large numbers, the distal extremities of the lobes being chiefly involved. Thirtysix oöcysts varying in size from 18 to 30  $\mu$  have also been obtained in the gut of a female killed on the thirteenth day after the infective feed and kept at laboratory temperature.

Variations in the length of the flaxseed stage of the Hessian fly, J. W. Mc-Colloch (Jour. Econ. Ent., 12 (1919), No. 3, pp. 252-255).—The author finds in rearing 7,461 flies in Kansas from collected material that the average time between collection and emergence was 113.2 days, with extremes of 2 and 1,083 days. It was found that 68.4 per cent emerged during the first month and 98.9 during the first year, while 1.1 per cent did not emerge until after the first year although subject to the same conditions. One Hessian fly from a clump of wheat collected May 8, 1915, emerged May 7, 1919. Allowing approximately a month for the fly to reach the flaxseed stage, this gives a life cycle of 49 months.

The white grub or grass root beetle (Scitala pruinosa), W. W. FROGGATT (Agr. Gaz. N. S. Wales, 30 (1919), No. 7, pp. 505-508, figs. 2).—This species, which has an extensive range along the southern and eastern coast of Australia, often destroys large areas of cereal crops and grass.

Observations on wingless May beetles, R. A. VICKERY and T. S. WILSON (Jour. Econ. Ent., 12 (1919), No. 3, pp. 238-247, pls. 2).—These observations relate to Lachnosterna cribosa and L. farcta in Texas, where they caused serious damage to crops during the spring of 1918.

Experimenting with ladybugs (*Better Fruit*, 14 (1919), No. 1, p. 14).—It is reported that 300 lbs. of ladybird beetles stored at Walla Walla, Wash., during the winter and spring had been liberated in the fruit-growing districts of that section up to June 5. It is estimated that they would cover 2,000 acres of orchards and grain fields. District horticultural agent E. C. Wood reports that the beetles begin to colonize in the mountains in July and remain in colonies during the winter, and can be gathered for a considerable period in the fall and for a period of 10 days during the month of April. In experiments in keeping the ladybird beetles in storage during the winter, those kept in ordinary storage showed a loss of about one-third, while those kept in cold storage showed practically no loss at all.

Japanese flower beetle, W. H. GOODWIN (Jour. Econ. Ent., 12 (1919), No. 3, pp. 247-252).—This is a brief discussion of the occurrence of *Popilia japonica* in New Jersey. Details are given of the eradication work being carried on in the infested territory, which lies between Moorestown and Riverton and at present covers some four or five thousand acres of very productive sandy loam farms. Should we dust cotton to control the boll weevil? W. E. HINDS (Ala. Polytech. Inst. Ext. Serv. Circ. 31 (1919), pp. 35-42).—The conditions under which dusting cotton can and can not profitably be followed are pointed out.

How weevils get into beans, E. A. BACK (U. S. Dept. Agr. Yearbook 1918, pp. 327-334, pls. 3).—A popular illustrated discussion.

A source of confusion in the diagnosis of Nosema apis in adult bees, A. P. STUETEVANT (*Jour. Econ. Ent.*, 12 (1919), No. 3, pp. 269, 270).—The author calls attention to the fact that the starch granules from the pollen grains of corn and most of the cereals closely resemble the spores of N. apis.

Bembecia hylæiformis and Sesia tipuliformis, N. A. KEMNER (K. Landtbr. Akad. Handl. och Tidskr., 58 (1919), No. 2, pp. 69-84, figs. 15; also in Meddel. Centralanst. Försöksp. Jordbruksområdet, No. 181 (1919), pp. 18, figs. 15).— A report of studies of these two species and their occurrence in Sweden. A list of 26 references to the literature is included.

A revision of the chalcid flies of the genus Harmolita of America, north of Mexico, W. J. PHILLIPS and W. T. EMERY (*Proc. U. S. Nat. Mus.*, 55 (1919), pp. 433-471, pls. 10).—In this revision of the genus Harmolita (Isosoma of the authors), which includes some species of very great economic importance, 29 species are recognized, of which 17 are described as new to science.

The species described as new are Harmolita pow, reared from the seed stalks of blue grass (Poa pratensis) at Richmond and Lafayette, Ind.; H. dactylicola, reared from orchard grass (Dactylis glomerata) collected in Indiana, Ohio, Michigan, New York, Pennsylvania, and Virginia; H. agropyrophila, reared from stems of Agropyron sp. collected in eastern Kansas, Indiana, Ohio, Michigan, New York, and Pennsylvania; H. rufipes, reared from stems of species of Elymus collected in Illinois, Kansas, Nebraska, Utah, and New Mexico, in internodes of which it forms inconspicuous galls; H. festuce, which breeds and forms galls in species of Festuca in New York, Ohio, and Virginia; H. hesperus, which forms galls in species of Elymus in Utah, the Dakotas, Nebraska, and Kansas; H. agropyrocola, reared from species of Agropyron collected near Salt Lake City; H. ovata, reared from species of Elymus from Wellington, Kans.; H. elymoxena, reared from Elymus americanus from Santa Cruz Mountains, Cal.; H. elymicola, reared from stems of species of Elymus collected in Indiana and Virginia; H. atlantica, reared from stems of species of Agropyron collected in New York, Pennsylvania, Ohio, Indiana, and Michigan; H. elymophila, described from specimens forming galls on Elymus at Alameda, Cal.; H. poophila, reared from galls in Poa lucida collected at Husted, Colo.; H. elymivora, reared from stems of species of Elymus collected in Arkansas, Kansas, Illinois, Indiana, Ohio, and Virginia; H. elymophthora, reared from stems of species of Elymus in North Dakota and Nebraska: H. occidentalis, reared from inconspicuous galls on stems of species of Agropyron collected in New Mexico and Kansas; and H. gillettei, collected near Glenwood Springs, Colo.

#### FOODS-HUMAN NUTRITION.

Changes in food value of vegetables due to cooking, M. C. DENTON (Jour. Home Econ., 11 (1919), Nos. 4, pp. 143-154; 5, pp. 200-209).—Results of her extended investigations are summarized by the author as follows:

"Boiled vegetables may lose as low as 15 per cent or as high as 60 per cent of their fuel value, according to the method of manipulation. Those vegetables which are cooked within their own heavy, intact jackets, such as unpeeled Irish potatoes and beets, will of course lose much less even than this minimum. The extent of the loss depends upon the amount of soluble carbohydrate and protein present in the vegetable tissues, as well as upon the manipulation.

"Losses in salts and nitrogen often, if not always, slightly exceed the fuel or caloric losses. Blanching for 5 or 6 minutes causes losses of 8 to 15 per cent in salts or fuel value. Peeled and sliced vegetables lose twice as much. Salting the water (1.5 per cent solution, or about 1 tablespoon to the quart) decreases the losses in fuel value due to boiling. Cutting the vegetable crosswise instead of lengthwise, or into small instead of large pieces, increases the losses.

"Steaming usually cuts the caloric losses down almost to zero; also the salt losses, except in case of leafy tissues, such as cabbage or spinach, which expose a very large amount of surface to the action of the condensing vapor. However, if conditions within the steamer are such that water washes down over the vegetable mass, steaming may cause very large losses. Particularly is this the case with pressure steamers. The two factors most potent in causing variations in cooking losses are varying lengths of time of cooking, and varying amounts of water used in proportion to mass of vegetables to be cooked.

"Steamed vegetables always lose in weight. Boiled vegetables may gain in weight because their intercellular spaces take up water at the same time that they are losing heavily in mineral salts and soluble carbohydrates and proteins.

"Home canning often results in a maximum amount of vegetables and a minimum amount of watery juice in the jar, partly because of close packing and partly because liquid is driven off during the period of processing with the seal only partially made. This relatively small amount of juice in the jar is a great advantage from the standpoint of true nutritive economy—whatever may be its effect upon ease of sterilization of the vegetable mass."

Effect of pack and depth of water bath upon interior temperature of jars in cold pack canning, C. E. CASTLE (*Jour. Home Econ.*, 11 (1919), No. 6, pp. 246-251, fg. 1).—Summing up the evidence which this and previous investigations have afforded, the following conclusions are drawn:

"The completeness of sterilization of vegetables packed in glass jars and heated in a water bath for one hour on three successive days, counting time from the beginning of boiling of the water-bath, is questioned. The water-bath should completely immerse the jars, and should be brought to the boiling point after immersion of the jars. When a water-bath method is used very great care should be exercised in the pack. Loosely packed jars only should be used in canning by usual home methods. Home-canned vegetables, particularly solid packed jars, should always be heated before use to avoid the danger of poisoning by the toxin of *B. botulinus*, the spores of which are exceedingly resistant to heat."

The supposed occurrence of methylguanidin in meat, with observations on the oxidation of creatin by mercuric acetate, I. GREENWALD (Jour. Amer. Chem. Soc., 41 (1919), No. 7, pp. 1109-1115).—In the course of an investigation of the nature of the toxic agent in meat poisoning, sufficient evidence was obtained to demonstrate that methylguanidin is not present in meat that is in a fair state of preservation. Since "meat poisoning" is due to meat that is not badly decomposed, the conclusion is drawn that methylguanidin can not be regarded as the toxic agent.

The author has also confirmed the conclusions of Baumann and Ingvaldsen<sup>1</sup> that the oxidation of creatin by mercuric acetate yields methylguanido-glyoxylic acid.

Nature of the toxic agent in "meat poisoning," I. GREENWALD (Amer. Jour. Pub. Health, 9 (1919), No. 8, pp. 595-598).—The author reports negative results in feeding experiments devised to demonstrate the presence of a heat-stable toxin in meat inoculated with various strains of bacteria, including *B. enteritidis*, *B. putrificus*, *B. botulinus*, *B. fecalis alkaligenes*, *B. proteus*, and *B. paratyphosus* **B.** Rats, mice, and guinea pigs were used as experimental animals.

The failure to demonstrate the presence of a heat-stable toxin is considered to be due possibly to the choice of the experimental animals or to the low virulence of the strains used. The occurrence of organisms capable of producing strongly heat-stable toxins is, however, thought to be very rare. The author considers that the rapid development of the symptoms of meat poisoning is due to a heat-labile toxin, and that further study of the problem should take the direction of an investigation of such toxins.

Composition and food value of bottled soft drinks, J. W. SALE and W. W. SKINNEE (U. S. Dept. Agr. Yearbook 1918, pp. 115-122).—This article describes briefly the ingredients of some of the standard types of bottled soft drinks. Investigations by the authors on the use of sugar substitutes in bottled soft drinks have been previously noted from another source (E. S. R., 40, p. 68).

[Miscellaneous food and drug topics], E. F. LADD and A. K. JOHNSON (North Dakota Sta. Spec. Bul. 5 (1919), Nos. 10, pp. 219-263; 11, pp. 242-257).— The first of these numbers contains tabulated results of the sanitary inspection of 2,755 food-producing or distributing establishments. The second consists of data as to feeding stuffs noted on page 673, and an article on Precipitates in Bottled Soda Water, by C. P. Guthrie.

Budget planning in social case work, E. A. WINSLOW (*Charity Organ. Soc.* N. Y. Com. Home Econ., Bul. 3 (1919), pp. 31).—This account of budget planning, which represents the work of the committee on budget methods and standards, it is believed will help case workers to give more efficient service.

The nutritional standards of adolescence, G. LUSK (Jour. Home Econ., 11 (1919), No. 7, pp. 281-287).—In this paper, presented at the U. S. Children's Bureau conference on child welfare standards, in Washington, May, 1919, the subject is discussed on the basis of information accumulated during the war, as well as other data.

Importance of animal proteins and fats in human nutrition, F. BOTTAZZI (Bul. Soc. Sci. Hyg. Aliment., 7 (1919), No. 4, pp. 179-193).—The author discusses the relative value of proteins and fats from animal and from vegetable sources. In his opinion a well-balanced ration should contain at least from 20 to 25 per cent of its total calorific value in fat (in agreement with the recommendation of Starling (E. S. R., 40, p. 170), and this ration of fat should not be composed exclusively of vegetable oils or the storage or depot fat of animals, but should contain a certain amount of the fat of active organs on account of their special lipoids and vitamins. It is also recommended that from one-third to one-half of the total protein be obtained from animal sources, either meat or visceral organs. A certain amount of the latter is recommended as furnishing both proteins and the special fats, the necessity of which is emphasized.

Physiological basis of rationing.—Importance of the fat-protein ratio.— Minimum of fat necessary, F. MAIGNON (Compt. Rend. Soc. Biol. [Paris], 82 (1919), No. 12, pp. 400, 401).—This is a further discussion of conclusions previously drawn that a minimum of fat in the diet is necessary and that the fat-protein ratio should be at least equal to unity. The author summarizes the food requirements of adults as follows: (1) A quantity of protein sufficient for the repair of the tissues; (2) the minimum of fat necessary for the economical and nontoxic utilization of this amount of protein; and (3) an amount of carbohydrate corresponding to the energy expended in physiological work. The fat-protein ratio is considered to be of the greatest importance, as the utilization of nitrogen is thought to depend upon this ratio. It is pointed out that this ratio approaches unity in eggs and in whole milk, and is about 9:8 in meat. It is suggested that the partial skimming of milk not only results in a diminution of the nutritive power of this food but by altering the fat-protein ratio may cause a toxic utilization of its protein.

A study of the mechanism of the action of fats in the utilization and assimilation of proteins, F. MAIGNON (Compt. Rend. Acad. Sci. [Paris], 168 (1919), No. 9, pp. 474-476).—To explain the favorable influence of fats upon proteins in diminishing their toxicity and increasing their nutritive value (E. S. R., 40, p. 463), the theory is proposed that after hydrolytic cleavage in the body the fatty acids may unite with certain amino acids with the formation of specific proteins. In this way amino acids which would not be utilizable otherwise are made available instead of forming toxic products.

Maintenance ration.—Function of carbohydrates, H. BIERRY (Compt. Rend. Soc. Biol. [Paris], 82 (1919), No. 15, pp. 530-533).—The author criticises the work of Maignon, particularly on the rôle of fats and carbohydrates in metabolism noted above, and suggests that the apparent contradictions between his experimental results and those of other workers are due to the fact that the proteins and fats used by Maignon were not pure, but contained carbohydrates and more or less of the accessory factors fat-soluble A and water-soluble B.

In conclusion, the author emphasizes that a maintenance ration must contain a certain quantity of carbohydrates, the amount depending upon the chemical structure and function of the carbohydrates in question and of the other food materials which enter into the composition of the ration.

A new conception of the rôle of various food constituents in nutrition.— Observations on the researches of Maignon, E. F. TERBOINE (*Compt. Rend. Soc. Biol.* [*Paris*], 82 (1919), No. 16, pp. 574–578).—The author agrees with the statements of Bierry noted above and further criticises the work of Maignon, concluding that sufficient evidence has not been furnished to establish the superiority of fats over carbohydrates as protein sparers.

Critical study of the influence exercised by lack of vitamins on the feeding experiments with pure products which have established the rôle of fats in the utilization of proteins, F. MAIGNON (*Compt. Rend. Soc. Biol.* [*Paris*], 82 (1919), No. 12, pp. 398, 399).—The author is of the opinion that in his researches on the rôle of carbohydrates and fats in nutrition, noted above, the lack of vitamins in the experimental rations has not falsified the results obtained, since the experiments reported were conducted during the latent period in which the vitamins of the tissues were able to make up for the deficiency in food vitamins.

The absence of fat-soluble A vitamin in certain ductless glands, A. D. EMMETT and G. O. LUROS (*Jour. Biol. Chem.*, 38 (1919), No. 3, pp. 441-447, figs. 5).—The authors report the absence of fat-soluble A in the fats obtained from the pancreas, thymus, and suprarenal glands by extraction with either acetone or benzine. A table is given which summarizes the presence or absence of fatsoluble A in food substances as based on published results.

The vitamin requirement of yeast, R. J. WILLIAMS (Jour. Biol. Chem., 38 (1919), No. 3, pp. 465-486, pl. 1).—From direct microscopic observation of the growth of individual yeast cells in sterile synthetic salt solutions to which small amounts of the material to be tested had been added, evidence is presented that the water-soluble, beri-beri-preventing vitamin is necessary for the nutrition of yeast cells themselves. Growth of the yeast cells was hastened and greatly increased by the presence of a small amount of the alcoholic extracts of "protein-free" milk, wheat germ, lactose, and pancreas tissue, by

fuller's earth activated by malt wort, and by the phosphotungstic acid precipitate of the vitamins from activated fuller's earth. No increase in growth was produced by hydrolyzed casein or by the extract of fat-soluble vitamin from egg yolk. These results indicate the identity of the substance necessary for the growth of yeast with the water-soluble vitamin.

Further light is thrown on the properties of the water-soluble vitamin by some of the experiments reported. It was found that the growth-promoting substance obtained from an alcoholic extract of dried yeast was partially destroyed by heating under 15 lbs. pressure for 30 minutes. The fuller's earth preparation, as well as the alcoholic extracts of yeast and wheat germ, was found to be quite stable in alkaline solution, thus confirming the observations of R. R. Williams and Seidell (E. S. R., 36, p. 314). The material, when acted on by acid or alkali, appeared to be changed (presumably by hydrolysis) to a form more immediately available for the yeast. A previous exhaustive extraction of the substance with dry ether is thought to render the alcoholic extract obtained afterwards more labile to alkali. This would seem to offer a partial explanation for the divergence of results in stability of the vitamin toward alkali as reported by various observers.

It is the opinion of the author that the method employed in this investigation may be valuable both as a qualitative and ultimately as a quantitative test for the water-soluble vitamin. The advantages in its use are that extremely small amounts of material may be used, and that the vitamin may be detected in the course of only 4 or 5 hours.

The connection between food régime and illness, L. B. MENDEL (*Bul. Soc. Sci. Hyg. Aliment.*, 7 (1919), No. 4, pp. 194–198).—A popular discussion of vitamins and deficiency diseases.

### ANIMAL PRODUCTION.

Live stock and reconstruction, G. M. ROMMEL (U. S. Dept. Agr. Yearbook 1918, pp. 289-302).—Live-stock statistics of the United Kingdom and of France before and during the European War are tabulated and discussed. Pigs and sheep were reduced considerably in numbers, but apparently only the sheep situation was causing uneasiness. Very little pure-bred stock has been sacrificed because of feed shortage. The author anticipates no extensive importations of breeding stock, except perhaps horses, from the United States or from any other country. The function of American live-stock interests during the reconstruction period will be to furnish Europe with meat and dairy products, so that European farmers can devote their energies to increasing the number of breeding animals from the supply at hand.

Cattle raising and the meat industry in southern Brazil, R. PORCHAT (*Proc. 2. Pan Amer. Sci. Cong., 1915–16, vol. 3, pp. 591–596*).—Statistical information on cattle raising and packing-house industries in the southern States of Brazil are presented.

French live stock after three years of war, A. MASSÉ (*Le Troupeau Français après Trois Ans de Guerre. Paris: Min. Agr., 1918, pp. 287*).—This is a report to the Minister of Agriculture, dated October 1, 1917, of the live-stock situation in France. Tables present the numbers of bulls, steers, cows, calves, rams, ewes, wethers, lambs, boars, sows, and young pigs in the country as a whole on December 31, 1913, on December 31, 1914, and semiannually thereafter through June 30, 1917. Similar data for less frequent intervals are given for each of the 87 departments. The means taken to conserve live stock in war time are briefly explained.

149863°-20---6

[ Vol. 41

Government market reports on live stock and meats, J. ATKINSON (U. S. Dept. Agr. Yearbook 1918, pp. 379-398).—The activities and policies of the Bureau of Markets in making periodical reports on fresh and stored meats and on live-stock shipments are explained, and illustrated by sample reports. The value of publicity in these matters, both to producers and to consumers, is pointed out.

Saving of meat-storage and shipping space (Jour Agr. [New Zeal.], 15 (1917), No. 1, pp. 16-19, figs. 4).—A space-saving method of preparing mutton carcasses is reported. The carcass is hung by the fore-legs and the hind part cut off just behind the saddle and inserted in the thoracic cavity.

Country hides and skins, C. V. WHALIN, R. W. FREY, F. P. VEITCH, and R. W. HICKMAN (U. S. Dept. Agr., Farmers' Bul. 1055 (1919), pp. 64, figs. 46).—This is a joint contribution from the Bureaus of Markets, Chemistry, and Animal Industry, and its main purpose is to provide farmers and small butchers with detailed directions for the skinning, salting, curing, shipping, and marketing of hides and skins. The market classes and grades of both packer and country hides and skins are also defined, and the main defects of country hides and skins, and the economic waste resulting from faulty practices, are indicated. Statistical information in tabular and graphical form as to market prices and price fluctuations is included in an appendix.

Tandler and Keller on the freemartin, F. R. LILLIE (Science, n. ser., 50 (1919), No. 1286, pp. 183, 184).—Attention is called to the fact that J. Tandler and K. Keller in a brief paper<sup>1</sup> published in 1911 anticipated certain of the author's observations (E. S. R., 40, p. 466), first announced in 1916, by finding that twin cattle fetuses are inclosed in a common chorion and generally have a joint circulatory system (as shown by examination and injection), and that if the twins are of opposite sexes and their vascular systems are united the female has typical freemartin genital organs.

Creatin excretion in ruminants, J. B. ORE (*Biochem. Jour.*, 12 (1918), No. 3, pp. 221-230).—The author reports the creatin, creatinin, and total nitrogen excreted (1) by an ewe not in milk, a he-goat, and a lactating she-goat under normal feeding conditions (hay, oats, bran, and turnips) and (2) by another she-goat in both a lactating and a nonlactating condition during similar mixed feeding and during high carbohydrate feeding (potatoes).

During normal mixed feeding the creatin excretion of this latter doe was 0.51 gm. per day when in milk, and 0.14 gm. when dry. After several days of potato feeding no creatin appeared in the urine even during lactation, although the milk yield diminished. The creatinin remained approximately constant—about 0.9 gm. per day—throughout the change in feed, and was the same in the lactating as in the nonlactating stage.

These experiments are compared with observations of workers who have made the reverse experiment and found creatin in the urine following carbohydrate privation in the case of animals that do not ordinarily excrete it. It is held that the body tissues constantly produce creatin from some source other than protein, either endogenous or exogenous, and that this creatin is utilized in connection with carbohydrate metabolism.

On several effects of feeding small quantities of Sudan III to young albino rats, S. HATAI (*Jour. Expt. Zool.*, 26 (1918), No. 1, pp. 101-117, figs. 3).—Month old rats were fed Sudan III (Grübler's), dissolved in olive oil, for upwards of 80 days. Litter mates furnished the controls in each series, 135 young from 19 litters being the total experimented with. In all cases the dye-fed individuals were underweight and anemic; olive oil alone did not produce any such effects. Autopsy showed an increase in weight of the liver and pancreas of the experimental animals, and a decrease in the thymus, testes, and ovaries. The rapidity of the thymus atrophy was apparently proportional to the amount of Sudan III administered. There was an increase of the water content in the blood, lungs, and pancreas, and a decrease in the liver, spleen, kidneys, brain, and heart. Previous workers have in general failed to note a growth-retarding influence of Sudan III, but it is pointed out most of the animals used in similar investigations have been adults.

The dye was not detected in the brain or in any of the other organs examined except for slight traces in the liver, pancreas, lungs, and kidneys. This result is interpreted to mean that the organ lipoids are endogenous in origin.

Behavior of Sudan III in the animal organism, B. E. READ (Jour. Biol. Chem., 37 (1919), No. 1, pp. 121-135).—Commercial samples of Sudan III fed to adult rabbits and white rats in relatively large doses caused debility, convulsions, and death. A sample purified by repeated crystallization out of hot glacial acetic acid and fed in conjunction with a mixed diet was not toxic to a rabbit. The author attributes Hatai's results (noted above) to impurities in the dyes used.

The results of Mendel and Daniels (E. S. R., 27, p. 670), with respect to the presence of the dye in the lymph, bile, and blood, and its absence from the urine after Sudan III feeding, were confirmed by experiments with six dogs. When the commercial dye was fed to rabbits, the urine frequently contained a brown-red pigment, which was not, however, Sudan III and which is thought to have been a by-product of impurities in the dye. It is held that the presence of a similar pigment led Salant and Bengis (E. S. R., 36, p. 262), to the view that Sudan III is eliminated through the kidneys.

Definitions of feeding stuffs adopted by the Association of Feed Control Officials of the United States, A. W. CLARK (*Geneva*, N. Y.: Sec. Assoc. Feed Control Off., 1918, pp. 4).—This leaflet is a compilation of 59 official and 13 tentative definitions of feeding stuffs adopted by the Association of Feed Control Officials, and includes the changes authorized at the annual meeting held January 13 and 14, 1919 (E. S. R., 41, p. 564).

Feeding stuffs-definitions (North Dakota Sta. Spec. Bul., 5 (1919), No. 11, pp. 248-254).—A reprint of the above.

Stock foods, E. F. LADD and A. K. JOHNSON (North Dakota Sta. Spec. Bul., 5 (1919), No. 11, pp. 243-248).—These pages include a protest against "patent medicines for animals," a reference to analytical work of the station on condimental feeds (E. S. R., 39, p. 70), excerpts from Wisconsin Station Bulletin 151 (E. S. R., 19, p. 464), and a reprint with the omission of the introductory paragraph of a report from the Massachusetts Station (E. S. R., 24, p. 269) on the value of such feeds.

Heavy and light grain rations when fed in connection with corn silage and clover hay for fattening steers, H. O. ALLISON (*Missouri Sta. Bul. 163* (1919), pp. 22-24, figs. 2).—Five lots of 8 two-year-old steers were fed for 100 days beginning December 18, 1917. Lot 1 received a full feed of corn and linseed meal (6:1) and made an average daily gain of 3.05 lbs. per head. Lot 2 receiving half as much corn gained 2.37 lbs. per head daily, lot 3 with corn during last 40 days only, gained 2.45 lbs., and lot 4 with no corn 2.36 lbs. Lots 2, 3, and 4 each received as much linseed meal as lot 1. Lot 5 with no corn and 5 lbs. of linseed meal daily per head made a daily gain of 2.29 lbs. The preceding experiments in this series were reported in Bulletin 150 (E. S. R., 38, p. 272).

Cattle loans and their value to investors, C. S. COLE (U. S. Dept. Agr. Yearbook 1918, pp. 101-108).—The activities of cattle loan companies, the procedure in making a loan, the factors influencing the size of the loan, the interest and rediscount rates, and the advantages of the system to buyers of cattle paper, to borrowers on cattle security, and to the cattle industry as a whole are briefly explained.

[Swine feeding investigations] L. A. WEAVER (*Missouri Sta. Bul. 163* (1919), pp. 21, 22, 27–31, flgs. 4).—The methods used in three swine feeding projects are outlined, and brief accounts are presented of the experimental results.

The influence of different systems of management upon the cost of producing pork (pp. 21, 22).—A lot of 73 34-lb. weanling pigs were fed a full ration of shelled corn, shorts, and tankage (9:2:1) while on pasture for 119 days beginning June 16, 1917. They were then fed in dry lot until an average weight of 202.6 lbs. was attained, which required 42 more days. A second lot was kept on pasture throughout the grazing season (155 days) and during this time received a ration of concentrated feed equal to half of that consumed by lot 1. They were then full fed until they had reached an average weight of 204.8 lbs. per head, i. e., for 53 more days. The average daily gain of the full feed lot was 1.05 lbs. and that of the half feed lot 0.82 lb. per head. The amounts of concentrated feed required for a pound of grain averaged 3.95 and 4.09 lbs., respectively.

Maintenance of brood sows (pp. 27–29).—In an experiment begun in December, 1916, with 6 lots of 7 Poland China gilts each, farrowed in March and April, the following rations were compared with respect to the number, size, and health of the young produced: (1) corn, tankage, alfalfa hay, 10:1:6; (2) corn, tankage, clover hay, 10:1:5; (3) corn, tankage, 10:1; (4) corn, linseed meal, 5:1; (5) corn, shorts, tankage, 8:2:1; and (6) corn, shorts, bran, tankage, 8:4:1:1. An attempt was made to keep the lots uniform in weight. The lot fed ration 6 produced in the spring of 1917 7.85 pigs per sow, the largest number of any lot, but the average birth weight was the lowest, being 2.48 lbs. per pig. The highest average birth weight (2.79 lbs.) occurred in lot 4. Lot 1 had the largest percentage of weak and dead pigs (41.9), and lot 4 the lowest, (12.2).

Lot 5 was discontinued in 1917 and the number of sows in each of the other lots was reduced to 6. During 1917 and 1918 blue grass was added to rations 3, 4, and 6, while rye forage and rape forage replaced clover hay in ration 2. The second litters in each lot were larger than the first, and again lot 6 produced the most pigs per sow. Lot 1 produced the heaviest pigs (2.78 lbs.) and lot 4 the lighest (2.09 lbs.). Lot 3 had the smallest proportion of weak and dead pigs (5.26 per cent) and lot 6 the largest (24 per cent).

Relation of better preparation of feed stuffs and different methods of feeding upon the rate and economy of gain put on by fattening swine (pp. 29-31).—A 98-day feeding trial was begun December 21, 1917, with 72 Poland China shotes divided into 5 lots. Four lots were fed corn, shorts, and tankage (9:2:1), while the fifth had free choice of these feeds in a self-feeder and selected them in the proportions of 16.25:1.58:1. Corn for one of the hand fed lots was shelled, whereas that for the other lots was ground. The hand-fed lots got corn twice daily and the balance of the ration was fed as a slop either once or twice daily. Grinding the corn and feeding the slop both morning and evening improved the gains. In addition to the regular hand-feeding twice a day, one lot had constant access to the mixed feeds in a self-feeder; they became fatter than the other lots but the gain was the most expensive. The free choice self-fed hogs required the least feed (4.63 lbs.) per pound of gain and, because of the small amount of tankage consumed, their gains were the cheapest.

Can hogs be raised at a profit at the present level of prices? (Bul. Nebr. Bd. Agr., No. 245 (1918), pp. 344-348).—A 60-day feeding experiment at the Nebraska Experiment Station, beginning July 18, 1917, with 5 lots of 12 hogs, is reported. Two lots were used to compare rape and alfalfa pastures when corn and semisolid buttermilk were fed as concentrates. The others provide a basis for comparing corn and hominy feed when self fed with tankage on alfalfa pasture. A comparison between semisolid buttermilk and tankage when combined with corn and alfalfa pasture is also possible. The main results follow:

Lot.	Pasture and method of feeding.	Initial weight per head.	Daily gain per head.	Feed consumed per pound of gain.				0.11/2.2	
				Corn.	Hom- iny feed.	Tank- age.	Semi- solid butter- milk.	price per pound.	Profit per head.
1 2 3 4 5	Rape hand feeding Alfalfa hand feeding Alfalfa self-feeder Do Do	<i>Lbs.</i> 105.8 108.9 105.4 104.4 105.7	<i>Lbs.</i> 1.97 2.14 1.94 1.60 1.79	Lbs. 3.53 3.29 3.44 2.23	Lbs.	Lb. 0.183 .223 .191	<i>Lb.</i> 0.711 .662	<i>Cents.</i> 17.75 17.90 17.74 17.60 17.80	\$4.51 6.50 6.81 5.75 6.71

Comparison of supplements to pasture in fattening shotes.

The prices charged were: Corn \$2 a bushel, buttermilk 3.5 cts. a pound, and tankage \$80, and hominy feed \$70 per ton. The daily pasture charge was 0.5 ct. per head.

Lot 4 carried the least finish of any lot, although they seemed to relish the hominy feed. Lot 5, with access, free choice to corn and hominy feed, finished better than lot 3, but made slower gains and a lessened profit. "From the standpoint of the man who desires to force his pigs, undoubtedly the corn and buttermilk deserves considerable consideration, and its utilization, especially in the crowding of purebred pigs for sale, should not be ignored."

Corn and cob meal, linseed meal, and oat straw as a wintering ration for farm work horses, E. A. TROWBRIDGE (*Missouri Sta. Bul. 163* (1919), pp. 24-27, figs. 4).—To study the possibilities of a winter ration for work horses with oat straw as a basis, 8 Percheron mares were fed for six weeks beginning January 11, 1918, on a ration consisting of corn and cob meal, linseed meal, and oat straw, and were then fed for three weeks on a similar ration in which clover and timothy hay replaced the straw. The former ration was as satisfactory as the latter.

Poultry-feeding tests at Milton, F. C. BROWN (Jour. Agr. [New Zeal.], 16 (1918), No. 6, pp. 331-333).—Tests are reported with White Plymouth Rocks and Black Orpingtons similar to those previously noted (E. S. R., 38, p. 71) with Leghorns. With these breeds also it is found that satisfactory egg records can be secured when whole oats is fed in place of wheat and alfalfa meal replaces shorts in the mash.

Better poultry through community breeding associations, J. W. KINGHORNE (U. S. Dept. Agr. Yearbook 1918, pp. 109-114, pls. 4).—This is a brief discussion of the purposes and activities of community poultry breeders' associations.

It is held that the most potent factor in the success of such an organization is concentration on a single breed. Commonly adopted methods of financing the association at the start and of inducing members to replace their unimproved birds with standard-bred poultry are outlined.

Standard varieties of chickens.—III, The Asiatic, English, and French classes, R. R. SLOCUM (U. S. Dept. Agr., Farmers' Bul. 1052 (1919), pp. 31, figs. 31).—Brief characterizations, similar to those in previous publications of this series (E. S. R., 38, p. 373) are given of the Brahma, Cochin, Langshan, Dorking, Red Cap, Orpington, Cornish, Sussex, Houdan, Crèvecœur, La Flèche, and Faverolle breeds and their recognized varieties. It is pointed out that these are predominantly table fowl.

Chickens, L. GÖTTING (*Las Gallinas. Mexico: Sec. Fomento, Dir. Agr., 1917, rev. and enl. ed., pp. 102*).—This manual covers briefly the classification, housing, incubation, breeding, feeding, and diseases of the domestic fowl. Particular attention is given to systematic record-keeping and the planning of matings.

**Babbit** growing to supplement the meat supply, N. DEARBORN (U. S. Dept. Agr. Yearbook 1918, pp. 145–152, pls. 2, fig. 1).—Several instances are noted where the growing of domestic rabbits for meat in the United States has proved a profitable enterprise. The three utility breeds of rabbits are described.

## DAIRY FARMING-DAIRYING.

Influence of nutrition of heifers and the age of breeding upon their subsequent development, C. H. ECKLES and W. W. SWETT (*Missouri Sta. Bul. 163* (1919), pp. 34-36).—Studies on the protein requirements for growth (E. S. R., 38, p. 682) have been continued with 10 heifers. It is noted that a Holstein heifer receiving 15 per cent of the total energy required for both maintenance (Armsby's determinations) and growth (average results at the station) in the form of protein made about normal growth, but that a Jersey heifer fell below the normal. On a 25 per cent plane a Holstein heifer made more than normal growth and 2 Jerseys were approximately normal.

"The data so far indicate that a 20 per cent plane of protein, or about 75 per cent of that prescribed by the Wolff-Lehmann standard, is ample for normal growth in heifers."

Modern methods of feeding the dairy cow, J. M. TRUEMAN (*Rpt. Proc. Conn. Dairymen's Assoc.*, 36 (1917), pp. 40-51).—The methods of feeding milch cows at the Nova Scotia Agricultural College, Truro, N. S., are outlined. It is explained that oats, peas, and vetches are grown together and used as a silage crop in the parts of Nova Scotia where corn can not be raised. This silage is included in a number of the rations fed to the college herd.

New Zealand dairy cows.—Improvement in average production, W. M. SINGLETON (Jour. Agr. [New Zeal.], 16 (1918), No. 3, pp. 132–135).—It is estimated that the average cow in New Zealand gave 142.1 lbs. of butter fat during the season of 1910–11 and 161.8 lbs. in 1916–17. During the interval the number of dairy cows had increased 22.5 per cent. The result has been a considerable increase in exports of butter and cheese. The increasing number of cow testing associations is given most of the credit for the improved yield.

Improving the profits in the dairy business, H. C. TAYLOB (*Rpt. Proc. Conn. Dairymen's Assoc.*, 36 (1917), pp. 21-39).—On account of the variability in the efficiency of different dairy farms, the author holds that the cost of production is not a satisfactory basis for price fixing. The dairyman who is not making a profit is advised either to get out of the business, so that he will not continue to depress prices by keeping up the supply, or else to improve his methods both by building up his herd and by giving attention to marketing problems. A table showing the variations in efficiency, capacity, and productivity of 51 dairy farms in Barron County, Wis., is presented.

Suggestions are given with respect to purchasing stock and disposing of culls. It is noted that points like longevity, regularity of breeding, ease of milking, and low demand for veterinary services are often overlooked in selecting family lines for specialization.

The discussion of marketing problems consists mostly of accounts of the origin and methods of the Sheboygan County (Wis.) Cheese Producers' Federation and the Milwaukee Milk and Cream Shippers' Association. These are both cooperative organizations of producers. It is stated that the former, consisting of about 45 local associations, successfully fought the monopolistic tendency of the dairy board at Plymouth, Wis., and that the latter opposed the Milwaukee health authorities in their refusal to accept pasteurized milk in lieu of milk from tuberculin-tested herds.

Factors that influence the profits in dairy farming, W. J. FRASER (*Rpt. Proc. Conn. Dairymen's Assoc.*, 36 (1917), pp. 146-152).—In the course of this general discussion, brief mention is made of some results of a survey of the cost of milk production on 317 farms in northern Illinois. The close correlation between the average milk production of the cows of the herd and the labor income is pointed out.

How to find the price of protein in milk, W. M. ESTEN (*Rpt. Proc. Conn. Dairymen's Assoc.*, 36 (1917), pp. 7-14.—Assuming that 5 lbs. of milk sugar and 3.4 lbs. of protein are contained in 100 lbs. of milk, irrespective of fat content, the author presents tables showing that with sugar at 9 cts. and butter fat at 45 cts. a pound, the dairyman generally sells his milk proteins at a lower price than he pays for protein in feeding stuffs and below the market rate for meat proteins. This is especially true for milk of high fat percentage even with a sliding scale of prices based on fat content. The cost of proteins in feeds was computed by assuming that the relative cost of a pound of protein and a pound of carbohydrates or fats is in the ratio of 9:1.

How dairying built up a community, J. C. McDowELL (U. S. Dept. Agr. Yearbook 1918, pp. 153-168, pls. 4).—This is an account of the incidental results to the community of the opening at Grove City, Pa., in May, 1915, of an experimental cooperative creamery established by the Dairy Division of the Bureau of Animal Industry, for the purpose of conducting research work on a commercial scale. It is claimed that a spirit of cooperation has been developed between the business men of the city and the farmers. Farmers have been admitted to the Commercial Club, and the banks finance the purchase of purebred cattle. Active interest has been taken in the local cow-test association, the number of accredited (tuberculosis-free) herds has greatly increased, and a rivalry in the production of clean milk has been brought about. Many silos have been built and barns repaired. A Jersey and a Holstein cooperative bull association, a Guernsey breeders' association, a boys' and girls' purebred cattle club, and an accredited dairy cattle show and sales association have all been organized since the establishment of the creamery.

Factors influencing the composition of milk, C. H. ECKLES, L. S. PALMER, and W. W. SWETT (*Missouri Sta. Bul. 163 (1919)*, *pp. 33, 34*).—The only phase of this project continued during 1917–18 was the "influence of condition at parturition on composition of milk and butter fat." The same cow was used as in the two preceding years (E. S. R., 38, p. 682). When she calved in August, 1917, she was 250 lbs. heavier than in previous years and her milk immediately following parturition was of normal composition. During the two months on a nfinimum protein plane, the protein and fat percentages were higher than those previously observed. The responses to changes in protein intake resembled those of 1916–17. Contributions to the physiology of phosphorus and calcium metabolism as related to milk secretion, E. B. MEIGS, N. R. BLATHERWICK, and C. A. CARY (Jour. Biol. Chem., 37 (1919), No. 1, pp. 1-75, figs. 4).—This paper, a contribution from the Dairy Division of the U. S. Department of Agriculture, presents and discusses the protocols of experiments with 15 dairy cows and heifers in which the phosphorus, and in some cases the calcium, content of the blood was observed either at intervals during the normal processes of growth, pregnancy, and lactation, or for shorter periods under test conditions.

Three cows in milk and 2 dry were used in a study of the blood plasma precursors of milk phosphorus and milk fat. The experimental procedure consisted of obtaining approximately simultaneous samples of blood from (1) the jugular vein, and (2) the subcutaneous abdominal (anterior "milk") vein of each animal and analyzing the blood and plasma from such samples for total phosphorus, phosphatids, and inorganic phosphorus. Sample 1 was taken to represent blood which had not passed through the mammary gland and sample 2 blood which had. Where the mammary gland was active and the experiment proceeded without undue disturbance to the animal, less phosphatid was found in the abdominal than in the jugular plasmas. No essential differences were observed between lactating and nonlactating individuals with respect to inorganic phosphorus of the plasma; in both, the milk vein contained more than the jugular vein. No evidence was found of the occurrence in the plasma of any class of phosphorus compounds other than phosphatids and inorganic phosphorus. The deductions drawn are as follows:

"The fat and phosphorus which are excreted with milk come from some phosphatid body or bodies in the blood. This material is converted in the mammary gland cells to inorganic phosphate and neutral fat; it yields 2.5 or more parts of phosphorus to 45 of fat; and, as milk contains only about one part of phosphorus to 45 of fat, some 60 per cent of the phosphorus which enters the gland cells with the phosphatid precursor of milk fat must be returned to the blood as inorganic phosphate... The taking up of phosphatid by a cow's gland is stopped if she is subjected to an even slight psychological disturbance." The rate at which the taking up of phosphatid occurs is held to be sufficient to account for the daily production of milk fat. The back flow of inorganic phosphorus, it is claimed, would be difficult to explain if the milk fat is derived even in part from fats in the blood.

Data on the relation of age to the blood phosphorus were obtained from 5 animals. For the first few days after birth the corpuscle phosphorus was about twice as high as in older animals, but the condition rapidly disappeared and was hardly noticeable at four months. The plasma phosphatid of newborn calves was very low and increased gradually during the first year. The inorganic phosphorus in the plasma was fairly high at birth but did not reach a maximum until six months; it then fell off again.

The effect of decrease in the weight of feed given on the blood phosphorous was studied with 2 cows at the height of lactation. The total phosphorus in both blood and plasma, the phosphatid and inorganic phosphorus in the plasma, the total phosphorus in the corpuscles, and the relative volume of the corpuscles fell off during the period of low feeding and recovered when heavier feeding was resumed. The inorganic compounds were more responsive to ration changes than the phosphatids. During low feeding there was a more or less clearly marked inverse relation between the concentration of phosphatid in the plasma and the daily milk yield. "We are inclined to explain this by supposing that the phosphatid was poured into the plasma at a nearly constant rate during this period, and that its concentration in the plasma therefore varied inversely with the rate at which it was excreted in the milk." 1919]

Experiments with heifers indicated that feeding disodium phosphate tends to raise the concentration of plasma phosphate, and that feeding with calcium chlorid tends to reduce it. The latter fact is explained by the known influence of calcium feeding on phosphorus excretion.

Evidence was found that the phosphorus content of blood and plasma is likely to be reduced toward the end of pregnancy, even when the phosphorus containing portions of the feed were increased. It is pointed out that pregnant cows could perhaps utilize more phosphorus than they get under ordinary feeding methods.

The most noteworthy accompaniment of lactation observed was a marked tendency for the phosphatid of the plasma to increase during the first month and to remain relatively high throughout lactation. This phenomenon was largely independent of the feed, and is thought to be connected with the tendency for body fat to be thrown out into the blood at the beginning of lactation.

The concentration of calcium in the blood was found to be very constant. Small increases were induced by feeding calcium chlorid. The main factor influencing the calcium content is held to be the mechanism controlling acidosis.

A very full discussion of the analytical methods adopted is given, and the literature on the phosphorus compounds of blood plasma is reviewed.

Gestation v. stage of lactation as factors causing abnormal composition of cow's milk, L. S. PALMER and C. H. ECKLES (*Amer. Jour. Diseases Children*, 13 (1917), No. 5, pp. 413-419).—Data previously noted (E. S. R., 39, p. 280) on the chemical composition of cows' milk and the physical constants of the butter fat toward the end of lactation are tabulated with some additions, mainly further data for 5 of the cows as to conditions during a 7-day period ending 45 days before parturition. The figures are examined for abnormalities, particularly in fat percentage, protein percentage, and Reichert-Meissl number, so as to determine the justification for the legal exclusion from the market of milk furnished by cows due to calve in less than 45 days.

"The data here presented indicate clearly that cow's milk becomes abnormal in composition as soon as the lactation stimulus becomes an artificial one on the part of the dairyman, and that this result bears no relation to the stage of the gestation period. Many cows show these abnormalities several months before the next parturition, while very heavy producing cows with periods of parturition the usual interval of 12 to 13 months apart may continue to produce perfectly normal milk up to the very hour of the next parturition. The latter are the exception, however, rather than the rule. The great majority of dairy cows in this country are relatively small producers. In these cases the high protein and fat content and abnormal composition of the milk fat characteristic of the end of the lactation period may become important questions in connection with infant feeding long before the 45-day limit is reached."

Some observations on the efficiency of the present standard agar for the estimation of bacteria in milk, H. J. SEARS and L. L. CASE (Jour. Bact., \$ (1918), No. 6, pp. 531-536).—Tests are reported to show that agar prepared according to the provisional recommendations of the laboratory section of the American Public Health Association<sup>1</sup> does not, of itself, provide enough nutrients for the growth of many bacteria of the lactic acid type. The small quantity of milk added to the medium in plating 1 cc. of a 1:100 dilution was found to supply the deficiency, but this was not true of higher dilutions. When, however, the higher dilutions were made in sterile 1:100 milk instead of in sterile water, the counts obtained were in general sufficiently consistent with the results of 1:100 dilutions.

<sup>&</sup>lt;sup>1</sup> Standard Methods of Bacteriological Analysis of Milk, M. P. Ravenel, et al. (Amer. Jour. Pub. Health, 6 (1916), No. 12, pp. 1315-1325).

[Vol. 41

The chemistry of churning, L. S. PALMER (*Missouri Sta. Bul. 163* (1919), pp. 40, 41).—The microscopic examination of butter made from cream stained with Sudan III and fuchsin is held to confirm the theory of Fischer that buttermaking consists of the transformation of a fat-in-colloid-hydrate emulsion (cream) into a colloid-hydrate-in-fat emulsion (butter). The physical chemistry of difficult churning is being investigated.

Cheese making under Missouri conditions, L. W. MORLEY (*Missouri Sta*. Bul. 163 (1919), pp. 39, 40).—In connection with a study of cheese-ripening methods, a trial has been made with a method of curing cheeses in an atmosphere of carbon dioxid. It is thought that this plan, which effectively prevents the growth of mold, may solve the problem of curing cheese satisfactorily in pound packages.

The rediscovery of an old dish, H. P. DAVIS (U. S. Dept. Agr. Yearbook 1918, pp. 269-276, pl. 1).—The author describes the recent nation-wide cottage cheese campaign inaugurated by the Department for the better utilization of skim milk for human food. As an indication of the success of the campaign it is stated that in one city the quantity of cottage cheese sold daily jumped from 10 to nearly 3,000 lbs., and in another from 350 lbs. to more than a ton, and that a creamery which formerly poured 10,000 lbs. of skim milk down the sewer daily later turned it into 700 lbs. of cottage cheese. It is pointed out in conclusion that the extent to which cottage cheese will be used in the future depends largely on its quality, and that the same attention should be paid to its production and refrigeration as to that of other dairy products.

The use of surplus milk in a small dairy: Cheese making, R. G. ALLAN (*Agr. Jour. India*, 13 (1918), No. 4, pp. 628-638).—Successful methods of making both soft and hard cheeses on a small scale from buffalo milk are reported as the result of tests at the Agricultural College Experimental Dairy, Nagpur.

### VETERINARY MEDICINE.

Some results of Federal quarantine against foreign live stock diseases, G. W. POPE (U. S. Dept. Agr. Yearbook 1918, pp. 239-246, pls. 2).—A popular summary of information on the results obtained through Federal quarantine.

**Report** of the State veterinarian, M. JACOB (*Bien. Rpt. Tenn. Dept. Agr.*, 1917-18, pp. 14-44).—Included in this report is a discussion of disease investigations, particularly control work with hog cholera.

Annual report of the Bengal Veterinary College and of the civil veterinary department, Bengal, for the year 1917-18, A. SMITH (Ann. Rpt. Bengal Vet. Col. and Civ. Vet. Dept., 1917-18, pp. [30]).—This is the usual annual report (E. S. R., 39, p. 582).

Report of the government veterinary surgeon for 1918, G. W. STURGESS (Ceylon Admin. Rpts. 1918, Sect. IV, pp. F1-F6).—The usual annual report (E. S. R., 39, p. 787).

Colloids in biology and medicine, H. BECHHOLD, trans. by J. G. M. BULLOWA (*New York: D. Van Nostrand Co., 1919, pp. XIV*+464, *pl. 1, figs. 70*).—This is a translation of the second edition of this volume, the first edition of which has been previously noted (E. S. R., 27, p. 881).

A further note on the preparation of culture media suitable for the growth of organisms used in vaccines, D. NOBRIS (*Indian Jour. Med. Research, 6* (1919), No. 4, pp. 569-584).—This paper, in continuation of the investigation previously noted (E. S. R., 40, p. 667), reports the results of a study of the essential conditions for optimum growth of *Bacillus typhosus* on trypsinized media. A 10 per cent concentration of the substrate proved to be the best for hydrolysis. At this concentration the substances required by the organism appeared to be formed during the early stages of hydrolysis. With crushed soy beans as a substrate, it was found possible to prolong the hydrolysis beyond its optimum nutritive value, showing further that prolonged hydrolysis is unnecessary.

The action of varying concentrations of enzym on the course of hydrolysis showed that an optimum amount is soon reached, after which further increase appears to have little effect. The temperature of sterilization appeared to influence the nutritive value of the medium, a high temperature being more detrimental than a low one. The temperature at which hydrolysis was effected did not, within limits, influence greatly the nutritive power of the medium. All hydrolyses which gave a small yield of amino acids gave poor growths of bacteria, but a large yield of amino acids did not necessarily indicate a nutritive medium.

A comparison of various media showed that good results could be obtained using a purely vegetable basis, although none of these equalled the results obtained with fresh pancreatic extract and casein. The hydrolysis products of maize did not furnish an efficient medium, which is considered of interest inasmuch as zein on hydrolysis does not yield glycocoll, tryptophan, or lysin.

Peptic digestion did not yield the substances necessary for the growth of *B. typhosus* under the conditions tried, which furnishes a further proof that amino acids are necessary for bacterial growth.

The suppression of anaphylactic shock, W. KOPACZEVSKI and A. VAHRAM (*Compt. Rend. Acad. Sci.* [*Paris*], 169 (1919), No. 5, pp. 250-252).—The authors have been able to suppress anaphylactic shock in guinea pigs by the intravenous injection of small doses of sodium oleate, saponin, and sodium taurocholate and glycocholate. The action is thought to be due to a lowering of the surface tension of the blood, and the possibility is suggested of utilizing similar substances to prevent anaphylactic accidents in man.

Experiments on the bactericidal action of sunlight, M. DE LABOQUETTE (Ann. Inst. Pasteur, 32 (1918), No. 4, pp. 170-192, figs. 3).—Experiments to determine the bactericidal action of solar rays of various wave-lengths and of white light upon different organisms in solid and liquid media are reported.

The general conclusion is that, from a practical point of view, in hygiene and therapy the direct bactericidal action of sunlight is of only limited value, particularly in temperate regions. In heliotherapy the bactericidal action of light is important only in the treatment of superficial wounds, burns, and skin affections. The indirect action of luminous rays upon living tissues, as evidenced by increased circulatory activity and functional activity of the organs, is considered to be due to a reinforcement of natural means of defense.

A study of many strains of streptococci with special reference to the streptococci isolated from bovine mastitis, L. R. JONES (*Michigan Sta. Rpt. 1918*, *pp. 238-252*).—A report of investigations by the author, presented in large part in tabular form, which is summarized as follows:

"From the diseased udders of cows, hemolyzing and nonhemolyzing streptococci have been isolated. These organisms through their fermentative activities are to be classified as *pyogenes* and *mitis*. None are to be considered as belonging to the *anginosus* group, which is considered as the etiologic factor of sore throat. Future research is necessary to demonstrate the correlation between exaltation in virulence, as by animal passage, and that of fermentative properties together with hemolytic determinations."

The relation of forage poisoning to botulism (Jour. Amer. Med. Assoc., 73 (1919), No. 8, pp. 611, 612).—An editorial review of the more recent work on

the subject, in which references are made to papers previously noted, namely, by Dickson (E. S. R., 40, p. 176), Buckley and Shippen (E. S. R., 37, p. 179), Graham, Brueckner, and Pontius (E. S. R., 38, pp. 383, 384), Graham and Brueckner (E. S. R., 41, p. 280), Curfam,<sup>1</sup> and McCaskey.<sup>2</sup>

Need of government action to check botulism, G. W. McCASKEY (Jour. Amer. Med. Assoc., 73 (1919), No. 11, p. 854).—In referring to the article noted above, the author records his personal observation of the striking recovery of a patient through the use of serum furnished by Graham.

"The neutralization of the botulinus toxin by fats can not be too strongly emphasized, and clearly demands the prompt and energetic use of castor oil or some other laxative fat, for the double purpose of clearing out the ingested toxins, which are largely performed under saprophytic conditions, and of lowering or destroying the virulence of the toxins by combination with fats. This must be done quickly as intestinal paralysis rapidly supervenes, after which laxatives are, of course, entirely inert."

**Recrudescence of rinderpest in Egypt,** PIOT BEY (Ann. Inst. Pasteur, 33 (1919), No. 3, pp. 197-207).—The author discusses the reappearance of rinderpest in Egypt during 1916-17, and the measures taken for its eradication. The conclusions drawn from observations made during this time are as follows:

On the appearance of a focus of rinderpest, vaccination by the simultaneous method of all subjects exposed to the contagion is the most effective means of arresting suddenly the extension of the disease and conferring absolute immunity. In the absence of serum, individual isolation of animals will give momentary security. The use for vaccination of virulent blood containing the hematozoa of bovine malaria is, in Egypt, absolutely without danger to both calves and adult animals.

In Egypt the susceptibility to rinderpest is almost absolute in calves but diminishes as the animal grows older, varying in adults in the neighborhood of 50 per cent. Acquired immunity in both parents is apparently transmissible to the offspring, but immunity in one parent alone appears to be without effect on the offspring. The immunity resulting from vaccination persists experimentally for at least three years, and practically for more than five years.

Antirinderpest vaccination in calves born of an actively immune mother.— Experiments in serovaccination for rinderpest (method of Kolle and Turner) in suckling calves and after weaning, P. GROVERI (Bul. Soc. Path. Exot., 12 (1919), No. 2, pp. 65-71).—Attempts at antirinderpest immunization of calves during the time of suckling and after weaning are reported, which indicate that the milk of an actively immune mother confers a passive immunity on the calf which continues during the period of suckling and for some time after, although no longer than three months. Between the periods in which the calf is immune and in which it reacts to vaccination in the normal manner there exists a period in which the calf is somewhat receptive, but the presence of a few antibodies in the circulation renders the reaction feeble and limited to slight elevation of temperature or a slight lachrymation.

Experimental study of the therapy of tuberculosis, G. VOLPINO (Ann. Inst. Pasteur, 33 (1919), No. 3, pp. 191-196).—This is the report of a series of experiments conducted by the author, with the collaboration of Colombino, Fornaroli, and Milesi, to determine the effect of xylene and other aromatic hydrocarbons in tuberculosis therapy. It was found that if periodic xylene injections were begun in guinea pigs not too seriously infected on the eighth or tenth day after

<sup>&</sup>lt;sup>1</sup> Colo. Med. Jour., 14 (1917), No. 2, pp. 35-41.

<sup>&</sup>lt;sup>2</sup> Amer. Jour. Med. Sci., 158 (1919), No. 1, pp. 57-67, fig. 2.

infection the animals could be kept alive for 40 days without the manifestation of more than limited signs of infection, while in control animals widespread external and internal lesions developed by the fifteenth or eighteenth day after infection.

In a repetition of the experiments with homologues of xylene, cumene was found to be more effective and toluene and mesitylene less effective than xylene. Several essential oils were likewise found to be effective, although some were useless on account of their irritating effect on injection. The author attributes the therapeutic effect of these substances not so much to their chemical composition as to their physical properties, the mechanism consisting largely of a stimulating effect on phagocytosis, which results in a progressive reduction in the number of bacilli followed by a decrease in the tubercular lesions.

The treatment has also been applied with encouraging results in the human subject in cases of localized tuberculosis of joints, glands, and bones. Daily intramuscular injections of a 10 per cent solution of xylene or cumene in sterilized olive oil were easily tolerated and brought about a rapid improvement in the tubercular lesions.

The accredited herd plan in tuberculosis eradication, J. A. KIERNAN (U. S. Dept. Agr. Yearbook 1918, pp. 215-220, pls. 2).—This is a brief account of the manner in which tuberculosis is being eradicated through the accredited herd plan.

Contagious abortion investigations, J. W. CONNAWAY, A. J. DUBANT, and H. G. NEWMAN (*Missouri Sta. Bul. 163 (1919)*, pp. 72-76).—Sixty-three herds, comprising 856 animals, were given the complement fixation test during the year, which with retests made a total of 1,981 tests in 29 counties. Of the 63 suspected herds investigated, samples from 45 gave a positive reaction.

Bacterium abortus infection of bulls, J. M. BUCK, G. T. CREECH, and H. H. LADSON (Jour. Agr. Research [U. S.], 17 (1919), No. 5, pp. 239-246, pls. 3).— This is a preliminary report from the Bureau of Animal Industry, U. S. Department of Agriculture, of an investigation to determine the frequency with which abortus infection can be demonstrated in the generative organs of bulls giving positive or suspicious reactions to the agglutination test for this disease, and to determine whether or not pathological changes are commonly associated with such infection.

The procedure employed consisted in securing blood samples from the animals upon their arrival at one of the abattoirs for slaughter, and applying the agglutination test to the samples. At the time of slaughter, those animals giving positive or suspicious reactions were autopsied and the organs of the genital system tested culturally for the presence of *B. abortus* infection.

The agglutination test for abortion disease was applied to 325 mature bulls with negative results in 288 cases. Of the 37 bulls whose blood serum showed the presence of *B. abortus* agglutinations, the presence of *B. abortus* infection was demonstrated in four, with marked lesions in two. The findings in these cases are described in detail and illustrated by photographs and photomicrographs of the diseased organs. A description is also given of the examination and findings of a fifth bull, together with a history of the development of the pathological changes associated with the infection.

As a result of the study reported the following conclusions are drawn:

"B. abortus infection may involve organs of the generative apparatus of bulls, producing chronic inflammatory changes. Of the generative organs, the seminal vesicles appear to furnish the most favorable site for the lodgment and propagation of abortion infection. The presence of B. abortus infection in bulls appears to be more strongly indicated by relatively marked than by slight reactions to the agglutination test for this disease."

Stomach worm disease in cattle and sheep, W. H. DALRYMPLE (La. Agr. Col., Ext. Div. Circ. 31 (1919), pp. 8, figs. 6).—A brief summary of information.

Less cholera, more hogs, O. B. HESS (U. S. Dept. Agr. Yearbook 1918, pp. 191-194, pls. 2).—A popular discussion, in which attention is called to the manner in which hog cholera is now being combated and the results obtained.

Effects of heat on trichinæ, B. H. RANSOM and B. SCHWARTZ (Jour. Agr. Research [U. S.], 17 (1919), No. 5, pp. 201-221).—This is a report of work commenced and carried on in 1913, 1914, and 1915 by the senior author and taken up since the latter part of 1915 by the junior author, both of the Bureau of Animal Industry of the U. S. Department of Agriculture.

The authors find that the vitality of the larvæ of *Trichinella spiralis* is quickly destroyed by exposure of the parasites to 55° C. (131° F.), gradually attained, the result apparently of irreversible coagulation changes in the protoplasm.

"Trichina larvæ exposed to temperatures slightly below 55° for short periods of time may recover from this exposure; but they die if exposed for longer periods, recovery or death depending apparently upon whether or not beginning coagulation of the protoplasm has proceeded beyond a stage from which a return to normal may occur. Exposed to temperatures in the neighborhood of 50°, trichina larvæ die if the application of heat is sufficiently long continued, apparently as a result of exhaustion following excessive activity to which they are stimulated by the heat.

"The longevity of trichina larvæ freed from their cysts by artificial digestion and kept at temperatures ranging between limits at which they became quiescent from the effects of heat and cold, respectively, varies inversely with the temperature.

"Methods of destroying trichinæ by heating at temperatures below the thermal death point, which may be utilized in connection with the preparation of certain kinds of cured pork products, appear not to be applicable in the case of fresh pork.

"Upon the basis of the results of experiments recorded in this paper, the Bureau of Animal Industry has selected a temperature of 137° F. (58.33° C.) as the minimum temperature to which pork and products containing pork are required to be heated when cooked in establishments operating under Federal meat inspection. This temperature is several degrees above the thermal death point of trichina larvæ, thus providing a certain margin of safety."

The literature is reviewed and a list of 14 references is appended.

The cause of abortion in mares, C. MURRAY (Jour. Infect. Diseases, 25 (1919), No. 4, pp. 341-348).—" From an outbreak of abortion in Iowa there was isolated an organism of the paratyphoid-enteritidis group, which in cultural and morphologic characters and in serologic reactions is apparently the same as the organism studied by Good, Meyer, and others [E. S. R., 27, p. 580; 30, p. 586], and variously named by them *B. abortivo-equinus*, *B. abortus equi*, etc. The dry, brittle, membranous growth on slanted agar which was observed by these investigators was present in the cultures isolated in this outbreak, and this peculiarity is of great value in identification of the organism. With this organism abortion was produced in the rabbit, guinea pig, sow, and mare by intraperitoneal or intravenous injection of minute doses in 2, 6, 2, and 11 days, respectively. Feeding and intravaginal introduction of the organism did not result in abortion in any animals thus treated. "The organism is agglutinated by immune serum for the organisms of paratyphoid-enteritidis group in fairly high dilutions. Serum of rabbits immune to this organism also agglutinate *B. suipestifer*, *B. enteritidis*, and *B. paratypho*sus A and B in dilutions high enough to indicate a close serologic relationship to these organisms."

Strongylidæ in horses, W. YORKE and J. W. S. MACFIE (Ann. Trop. Med. and Parasitol., 13 (1919), Nos. 1, pp. 57-62).—In continuation of previous papers (E. S. R., 41, p. 87), the authors describe a seventh new species to which the name Cylicostomum pateratum is given.

Strongylidæ in horses.—Species found in American horses, W. YORKE and J. W. S. MACFIE (Ann. Trop. Med. and Parasitol., 13 (1919), No. 2, pp. 137-143, pls. 3).—In continuation of the paper above noted, the authors list the species of Strongylidæ found in 15 horses from the United States examined in England, of which 3 belong to the genus Strongylus, 3 to Triodontophorus, 2 to Gyalocephalus, and 12 to Cylicostomum. This is followed by a complete list of all the Strongylinæ in horses, donkeys, and mules recorded from different parts of the world. The pathological findings and their pathogenicity are briefly considered.

On the transmission of two fowl tapeworms, J. E. ACKEET (Anat. Rec., 15 (1919), No. 6, p. 341; abs. in Jour. Roy. Micros. Soc., No. 1 (1919), p. 43).—In investigations at the Kansas Experiment Station, the author has found that the house fly may transmit to chickens two tapeworms, one which appears to be Davainea tetragona, the other D. cesticillus. Flies were trapped in poultry yards where chickens were known to be infested and were fed to 17 isolated chickens. Two of 4 chickens examined were found to be parasititized by D. tetragona. In similar experiments in 1917, D. cesticillus was transmitted to chickens (E. S. R., 40, p. 359).

Developmental phases of the protozoon of "blackhead" in turkeys, E. E. TYZZER (Jour. Med. Research, 40 (1919), No. 1, pp. 30, pls. 2).—" The parasite Amæba meleagridis presents a variety of forms which it would be difficult to identify except for the constant presence of an extranuclear body. From this are derived the division centers and a well developed paradesmose which may stretch from side to side of the dividing cell. Binary nuclear division of a character similar to that described in trichomonads is encountered frequently. No indication of any process of multiplication other than binary division has been found.

"Motility, as observed in the warm chamber, is of the nature of amoeboid motion of a slow rate. A large proportion of the organisms examined show no motion.

"The various forms assumed by the parasite and their relationship to the pathological process indicate distinct phases of development. In the invasive phase, the parasite may ingest solid particles as food, and migrates freely through the tissues. The vegetative phase is characterized by the loss of motility and by the absorption of fluid in the place of ingesting solid material. The cytoplasm in both these phases is distinctly basophilic. The resistant phase is characterized by its small size, acidophilic cytoplasm, and by encystment.

"Multiplication by binary division is most active in the invasive phase, continues in the vegetative phase, and ceases in the resistant phase.

"Contrary to Hadley's claim (E. S. R., 36, p. 781), *A. meleagridis* should not be regarded as a cell parasite. Although it migrates freely through the tissues, it does not occur within cells except after motility is lost, when it is soon phagocyted. Within cells the reaction of the organism is purely defensive; multiplication ceases, it decreases in size, and develops a resistant membrane.

[Vol. 41

"As Smith has pointed out, this infection furnishes a remarkable example of the production of extensive destruction of the tissues of the host through pressure exerted by a rapidly growing parasite.

"Supplementing the presence of morphological characteristics not seen in any of the amoebæ, the daily feeding of Chaparro amargosa, a drug having definite amoebical properties, has failed to prevent infection in young turkeys when exposed to infected birds.

"While the parasite shows a type of nuclear division similar to that of trichomonads and an extranuclear body resembling a blepharoplast, various other features characteristic of trichomonads have not been demonstrated. No intermediate forms connecting this parasite with the trichomonads associated with it in the caeca have been observed."

A bibliography of 99 titles is included.

# RURAL ENGINEERING.

The drainage movement in the United States, S. H. MCCRORY (U. S. Dept. Agr. Yearbook 1918, pp. 137-144, pls. 6).-It is stated that there are approximately 102,800,000 acres of swamp, overflowed, and tidal marsh land in the United States, of which about three-fourths are timbered. The author discusses the general features of drainage on a large scale, and emphasizes the importance of collective action in such matters.

Rainfall, absorption, and run-off on small rural drainage area, I. E. HOUK (Engin. News-Rec., 82 (1919), No. 18, pp. 875, 876).-Observations of rainfall, run-off, and soil absorption on a farm in the Miami (Fla.) Conservancy District are reported. The soil is clay loam containing some sand and gravel, and is underlain by comparatively thick glacial deposits of sand and gravel. About 7 per cent of the surface is wooded, and the natural slope varies from 1 to 20 per cent.

From a 24-hour rainfall of 3.51 in. an average increase in moisture content in the soil of about 5.7 per cent was found. Run-off measurements indicated that no run-off occurred on plats with sod covering. Considerable run-off occurred on cultivated plats, varying from 37 to 44 per cent of the rainfall and depending probably on the extent of cultivation.

Run-off measurements from the total drainage area taken after this storm showed an average maximum rate of run-off of 900 sec. ft., or 346 sec. ft. per square mile, which is equivalent to a run-off rate of about 0.54 in. per hour.

A hydraulic jump of about 2 ft. occurred abruptly at the lower end of a concrete-lined channel where the water entered the earth channel, this rise taking place within a length of 50 ft.

Progress report on run-off investigations on Third Creek, Iredell County, H. M. LYNDE (North Carolina Sta. Rpt. 1918, pp. 74-87, figs. 5).—This report is based upon investigations by the station and the U.S. Department of Agriculture, covering five years and nine months, and conducted on a dredged canal through Third Creek Valley for the purpose of determining the relation existing between rainfall and run-off from drainage districts in the Piedmont section of the Southern States. The water shed area is from 2 to 5 miles long, with an average width of about 4 miles. The surface is rolling from the bottom lands, terminating in narrow, flat uplands. The valley has a fall of 6 to 7 ft. per mile at the lower end and about 15 ft. per mile at the upper end. The bottomland soils are sandy and silty loams, and the upland soils are clay and sandy loams. The conclusion drawn is that for rainfall, topographic, and other conditions like those in the Third Creek drainage area, drainage improvements should provide for a run-off of 0.75 to 1 in. depth per 24 hours.

Floods and water-logged land: The Land Drainage Act, 1918 (*Jour. Bd.* Agr. [London], 25 (1918), No. 8, pp. 961-968).—This is a brief summary of the changes made and the facilities afforded by the new Land Drainage Act in England and Wales. This act is intended to facilitate the establishment of drainage boards, to render possible a revision of drainage areas to suit modern conditions, and to assist otherwise in the renewal and extension of arterial drainage, including such matters as determining benefits and benefit assessments.

Moor drainage, W. FRECKMANN (*Mitt. Ver. Förd. Moorkult. Deut. Reiche*, **36** (1918), No. 23, pp. 379–382).—Six years' experiments with open ditches, pole bundle drains, lath drains, plain tile drains, tile drains with plastered joints, and tile drains laid on laths in a coarse-grained alluvial sand soil are reported. Oats, beans, barley, beets, and rye were planted on soil with underdrainage, and oats, wheat, beets, and potatoes on soil drained with open ditches.

It was found that pipe drains laid on laths gave the most intensive drainage. Plain pipe drains gave almost as good results, but are not considered as satisfactory for moor soils owing to the fouling of the pipes. The pipe drains with plastered joints, designed to prevent the fouling of the pipes by roots, etc., gave only slightly less effective results than the pipe drains laid on laths. The lath drain gave considerably less favorable results than the pipe drain on laths. The pole bundle drains gave the least effective results. Open ditches about 4 ft. deep and about 80 ft. apart gave approximately the same results as pipe drains laid on laths and spaced about 40 ft. apart.

With reference to crop yields a general improvement on all drained soils was noted. The conditions governing this were, however, too variable to permit judgment of types of drains on this basis.

Hydraulic efficiency of a drainage ditch for five different channel conditions, C. E. RAMSER (Engin. News-Rec., 82 (1919), No. 11, pp. 522, 523, figs. 5). Experiments to determine the values of n in Kutter's formula, made on five courses of the South Forked Deer River in Tennessee, are reported.

The channels along these courses varied from a newly dredged channel in excellent condition to a very crooked course of the old channel in very bad The lowest values of n were obtained in the new, straight, and condition. uniform channel. The effect of roughness and irregularities is shown in a considerably increased value of n. "The values of n for the discharge of 715.1 sec.-ft. are 0.0367, 0.0619, and 0.146 for the dredged, old straight, and old crooked channels, respectively, and the slope of the water surface required for this discharge was over three times as much for the old straight as for the dredged channel.... The difference in the relative capacities of the old straight and the old crooked channels is not due entirely to the curves in the latter, since the accumulation of trees, logs, and other drift was greater in the crooked channel. However, the difference in the condition of the two channels may be directly attributed to the presence of the curves, since there is a greater tendency for drift and obstructions to accumulate in a curved than in a straight course of channel."

Canal seepage losses are affected by temperature, L. CRANDALL (Engin. News-Rec., 82 (1919), No. 7, pp. 323, 324, figs. 2).—Data from seepage investigations on canals of a western irrigation project comprising some 2,600 acres of wet surface are reported. These show that the seepage losses increase with

149863°-20-7

[Vol. 41

warmer water, and that in general the variation in temperature during the irrigation season may cause a variation of 30 per cent in the rate of seepage losses.

The small irrigation pumping plant, W. L. POWERS and W. J. GILMORE (Oregon Sta. Bul. 160 (1919), pp. 16, figs. 4).—This bulletin gives general information on the planning and construction of a small irrigation pumping plant.

Testing aggregates in the field, F. H. JACKEON (U. S. Dept. Agr., Public Roads, 2 (1919), No. 15, pp. 11-13, figs. 3).—An outfit of field apparatus for testing aggregates in the field is described and illustrated, which has been developed recently by the Bureau of Public Roads. The field equipment so far developed consists of the following units:

One set interchangeable stone screens, with screen plates having perforations  $3, 2\frac{1}{2}, 2, 1\frac{1}{2}, 1, \frac{3}{4}, \frac{1}{2}$ , and  $\frac{1}{4}$  in. in diameter; 1 set interchangeable sand sieves, of 10, 20, 30, 40, 50, 80, 100, and 200 mesh; 1 circular spring scale having a capacity of 30 lbs. and sensitive to 0.1 lb.; 1 straight spring balance having a capacity of 200 gm. and sensitive to 1 gm.; 1 demountable cubic foot box; 1 ordinary camera-folding tripod; 1 250-cc. graduate; 1 strip of screen wire about 22 in. in length and 5 in. high; and 2 canvas bags about 18 by 18 in. in size. The total outfit weighs approximately 18 lbs. The apparatus for making screen analyses weighs approximately 10 lbs. and may be packed in a space measuring 17 by 8 by 6 in.

Ultramicroscopic examination of disperse colloids present in bituminous road materials, E. C. E. LORD (Jour. Agr. Research [U. S.], 17 (1919), No. 4, pp. 167-176, pl. 1, fig. 1).-In this article, a contribution from the Bureau of Public Roads, U. S. Department of Agriculture, the author describes the method and apparatus employed in the ultramicroscopic analysis of bituminous road materials, and reports the results of a number of examinations to determine the various colloidal materials contained in different types of bitumens. These bitumens were separated into two groups, the first containing clay as colloidal material, and the second in which this mineral matter was replaced by carbonates, sulphates, and acetates of copper, iron, zinc, and lead. On examining solutions of the second kind under the ultramicroscope it was found that the copper carbonate salts had been largely reduced to red cuprous oxid accompanied by an enormous colloidal dispersion, while with the remaining salts the reduction was much less complete or entirely lacking and the development of colloids correspondingly less.

"It may be stated, therefore, that the colloidal capacity of the second group of materials taken as a whole was dependent largely upon the degree of chemical reaction between the bitumen and the salts employed, while in the first group this supporting value was related more directly to the physical character of the bitumen. A comparison of the duplicate counts . . . indicated that a maximum variation of less than 10 per cent was attained in samples of the first group, while in the second group, the results were, on the whole, less concordant, owing largely to the greater dispersion of colloidal matter. In conclusion, it may be stated that the accuracy of this method for counting colloidal particles in bituminous solutions depends chiefly upon accuracy in construction and calibration of the cell employed, as well as upon the proper consistency and optical purity of the supporting liquid."

Efficiency of bituminous surfaces and pavements under motor truck traffic, P. HUBBARD (Munic. and County Engin., 56 (1919), No. 3, pp. 98-100).—This is a general review of experience on the subject, in which it is stated that "maintenance by the Bureau of Public Roads [of the U. S. Department of Agriculture] of experimental bituminous surfaces on the Rockville pike, Maryland, which is a macadam road, have demonstrated that such surfaces constructed with suitable tar and oil products are efficient under reasonably heavy traffic, provided the patrol system of maintenance is followed. If such a system had not been in use during the past year, when from 28 traffic counts an average of 135 motor drays, 816 motor pleasure vehicles, and 61 horse-drawn vehicles per day passed over the road, it would from all indications have been completely destroyed."

Preliminary report of impact tests of auto trucks on roads, E. B. SMITH and J. T. PAULS (U. S. Dept. Agr., Public Roads, 2 (1919), No. 15, pp. 8-10, figs. 3).—Preliminary data are reported from tests of the impact of a 3-ton U. S. A. class B motor truck with solid rubber tires on roads.

The apparatus used in these experiments consists of a heavy steel cylinder in which is fitted a plunger 4 in. in diameter and 8 in. long. A hole is left in the bottom of the cylinder in order to prevent air cushioning under the plunger. On the top or head of the plunger there is securely fastened a heavy steel plate, on which the impact of the truck wheel is received. This whole apparatus is surported rigidly in a concrete box placed in the road in such a position that the height of the steel plate on top of the plunger may be made just flush with the road surface. The height of the upper surface of the plate can be varied by proper steel disks placed under the plunger. In order that the front wheel may pass over and not touch the steel plate on the plunger, a steel bridge is used which is automatically tripped by the front wheel in passing over it. This releases a catch and allows a weighted lever to pull the bridge clear from the apparatus, thus leaving the steel plate exposed and ready to receive the impact of the rear wheel.

Copper compression cylinders  $\frac{1}{2}$  in. in diameter and  $\frac{1}{2}$  in. long are used for recording the impact values. These are placed under the plunger of the jack. The impact condition under which the tests were conducted was the simple falling of the truck wheel from one level to another at different speeds of the truck, the height of drop varying from  $\frac{1}{4}$  to 3 in.

The data indicate a general tendency of increased impact with the higher speeds, although the increment of increase is less as the speed increases. Also there is a general increase in impact with increase of height of drop. It was found that the action of the truck springs had a great influence on the impact results. When the wheel left the jump-off point the spring snapped open and produced a greater downward acceleration of the unsprung parts than that due to the action of gravity alone. It was also found that the impact was appreciably affected by the conditions of power on or off. When coasting the impact was less than when the power was being applied to the rear wheels, the difference amounting in some cases to as much as 30 per cent.

Further tests are in progress.

An investigation of the vertical movements of concrete pavements, J. W. LOWELL (Proc. Amer. Concrete Inst., 14 (1918), pp. 366-373, figs. 4; also in Engin. and Contract., 50 (1918), No. 19, pp. 441-443, figs. 4).—Observations for 12 months on the vertical movement of 87 slabs of reinforced concrete pavement 7 in. thick at the sides and 10 in. thick at the center are reported. The road was of 2-course construction, the base being 1:2.5:4 pebble concrete and the wearing course 1:1:1.5 concrete. Thirty-eight slabs had a subgrade of tough compact clay; 16 slabs had a sand loam subgrade; 14 had a clay, loam, and fine sand subgrade; and the remaining slabs had a sand subgrade. "Of 86 slabs, 56 cracked. Thirty-eight which cracked deflected at one or both joints more than  $\frac{1}{16}$  in. in the 32-ft. width between outside points, 18 less than  $\frac{1}{16}$  in. and of these 8 were between  $\frac{3}{5}$  and  $\frac{1}{16}$  in., while 4 slabs having as great deflection failed to crack. Six of the 10 remaining slabs which cracked, having maximum deflection of from  $\frac{3}{5}$  to  $\frac{4}{16}$  in. evidently cracked from abnormal settlement of a portion of the subgrade below the original level, leaving 4 slabs, one of which cracked at  $\frac{4}{16}$ , one at  $\frac{4}{16}$ , and two at  $\frac{4}{52}$  in., which defy explanation unless the deflection had been greater at some period between readings. Every slab reaching a deflection of more than  $\frac{4}{16}$  in. cracked, and there were 38 out of 86, so it is safe to assume that such deflection in 32 ft. of width is sufficient to crack any pavement slab of this width built in accordance with present specification and practice. It is also evident that even greater deflection than  $\frac{4}{16}$  in. can be expected when the subgrade is clay or loam undrained. . . .

"Thirteen consecutive slabs... on sand subgrade acted quite differently and more uniformly than the others. The average upward movement was  $\frac{11}{16}$  in. on the west and  $1\frac{1}{16}$  in. on the east side, while the center went  $\frac{31}{2}$  in. The greatest rise of any point was  $1\frac{15}{2}$  in. The movements were so uniform that greatest deflection was  $\frac{1}{6}$  in. Unlike the other slabs there was practically no settlement below the initial reading, the greatest recorded being  $\frac{3}{32}$  in."

It is concluded that cracking may be eliminated by slab design or by controlling the moisture content of the subgrade. The latter method is considered more feasible from the standpoint of economy.

State highway mileages and expenditures in the year 1918, A. P. ANDERSON (U. S. Dept. Agr., Public Roads, 2 (1919), No. 15, pp. 3-7).—Data are reported showing that, on the basis of complete reports from 44 States, cash expenditures on the rural roads and bridges of the United States for the calendar year 1918 amounted to \$286,098,193. Adding the approximate value of statute and convict labor will bring the total expenditure up to about \$300,000,000.

The most striking single development through the year was the tremendous increase in motor truck traffic. During the year the several State highway departments improved a total of 11,944 miles of road, of which about 7,000 miles consisted of grading preparatory to surfacing. The State departments also supervised the maintenance of 203,556 miles, most of which were main and trunk line highways.

Public roads (U. S. Dept. Agr., Public Roads, 2 (1919), No. 15, pp. 32, figs. 17).—This number of this periodical contains, in addition to 3 papers noted separately in this issue and miscellaneous notes, the following articles: Road Building in the Southwest, by M. O. Eldridge; June a Record-Breaking Month for Federal-Aid Allotments; Primary Road Maintenance Costs, by E. G. Cotterill; and Test and Research Investigations of the Bureau of Public Roads, by P. Hubbard.

Rainfall influence on durability of zinc-treated crossties, C. H. TEESDALE and S. W. ALLEN (*Engin. News-Rec.*, 82 (1919), No. 5, pp. 234, 235).—Data from a large number of service records on crossties treated with zinc chlorid are considered to indicate "in a general way that the arid Western States and the Central, Atlantic Coast, and New England States north of the 40-in. rainfall line form a definite area where crossties treated with straight zinc chlorid may be expected to give from 8 to 10 years' service."

Electric light and power from small streams, A. M. DANIELS (U. S. Dept. Agr. Yearbook 1918, pp. 221-238, figs. 3).—The general features of the subject are discussed with particular reference to the installation of small power plants on farms supplied by small streams.

Internal-combustion engine lubrication and lubricants, P. H. CONRADSON (Amer. Soc. Testing Materials Proc., 18 (1918), pp. 387-392; extract in Power, 48 (1918), No. 3, p. 107).—It is pointed out that the viscosity test of lubricating oil for internal-combustion engines is of value only when the user is familiar with the characteristics of the different crudes of which the oil is made, and that the flash point test is of no consequence after the oil enters the cylinder. Evaporation losses are usually greatest in oils of low flash points. It is further pointed out that specific gravity in no way indicates whether or not lubricating oil will stand up under service conditions.

**Prevention of and protection from smut dust explosions and fires in grain** separators, G. E. THORNTON (*Wash. State Col. Ext. Dept., Ser. 1, No. 46 (1918), pp. 8, pl. 1, figs. 4*).—This circular gives popular information on methods of prevention of fires and dust explosions in grain separators, based on experiments previously noted (E. S. R., 32, p. 386).

The Shoup oat sprouter, G. R. SHOUP (Washington Sta., West. Wash. Sta. Mo. Bul., 7 (1919), No. 5, pp. 75-82, flgs. 3).—This article describes the construction and operation of an oats sprouter for the preparation of germinated oats for poultry feed.

The sprouter consists of a series of trays with sliding bottoms arranged one above another. The bottoms may be pulled out, while the fronts, sides, and backs remain stationary. This allows the oats to drop to the empty compartments below, which effects the necessary stirring. The daily sprinkling is performed by pouring the soaked oats, water and all, in at the top, which lifts up and back on hinges. The outside cabinet may be made of any common lumber surfaced on one side with the smooth side in. The sprouter should be 5 ft. high for best results.

Silo construction, C. K. SHEDD and W. A. FOSTER (*Iowa Sta. Bul. 189* (1919), pp. 97-148, figs. 44).—This is a revision of Bulletin 141 (E. S. R., 30, p. 89) incorporating data of additional value obtained since 1913. With reference to the water tank placed on top of a masonry silo, it has been found that treatment of the inner surface of the tank with a coating of asphalt followed by cement plastering apparently prevents leakage.

Capacities of silos and weights of silage, C. H. ECKLES, O. E. REED, and J. B. FITCH (*Missouri Sta. Bul. 164* (1919), pp. 3-24, figs. 2).—This bulletin reports data from investigations at the Kansas and Missouri Experiment Stations in which the weight of silage to the cubic foot was taken, by means of a specially designed apparatus, in 32 silos representing five seasons. The weights were taken as the silos were emptied.

It is concluded that the weight of silage is subject to so much variation and is influenced by so many factors that no table of silage weights and silo capacities can be more than approximately correct. The modification of King's table published by the Nebraska Experiment Station (E. S. R., 37, p. 887) is considered to give reasonably accurate results when used to estimate the weight of silage at the time filling is completed. "None of the tables so far published is adapted to estimating the weight of settled silage."

It was found experimentally that the proportion of grain influenced the weight of silage to the cubic foot, but that the fineness of cutting did not appear to be a factor. Weigings of the contents of three silos containing sweet sorghum silage and three containing Kafir corn silage showed no wide variations in weight as compared to corn silage, and it is recommended that, until more data are available, the same table as designed for use with corn silage be used in estimating the weight of silage from these crops. A new table is given, based upon the experimental data and designed for use in estimating the weight of settled silage, as follows:

	Esti- mated weight of silage per cubic foot.	Average weight of silage per cubic foot.	Diameter, feet.						
Depth of silage, feet.			10.	12.	14.	16.	18.	20.	
1	$\begin{array}{c} Lbs.\\ 32.0\\ 32.7\\ 33.4\\ 34.1\\ 34.8\\ 35.4\\ 35.4\\ 36.0\\ 36.6\\ 37.4\\ 38.0\\ 38.4\\ 38.8\\ 39.2\\ 39.6\\ 40.0\\ 40.2\\ 40.4\\ 40.6\\ 40.0\\ 41.2\\ 40.4\\ 41.6\\ 41.2\\ 41.4\\ 41.6\\ 41.2\\ 42.6\\ 42.8\\ 43.0\\ \end{array}$	$\begin{array}{c} Lbs,\\ 32.0\\ 32.4\\ 32.7\\ 33.1\\ 33.4\\ 33.4\\ 34.1\\ 34.4\\ 34.7\\ 35.0\\ 35.3\\ 35.6\\ 35.9\\ 36.2\\ 36.4\\ 36.7\\ 37.3\\ 37.5\\ 37.6\\ 37.8\\ 37.3\\ 37.5\\ 37.6\\ 37.8\\ 38.0\\ 38.1\\ 38.3\\ 38.4\\ 38.6\\ 38.7\\ 38.9\\ 38.0\\ 38.4\\ 38.6\\ 38.7\\ 38.9\\ 39.0\\$	$\begin{array}{c} Tons. \\ 1.26\\ 2.54\\ 3.85\\ 5.19\\ 6.55\\ 10\\ 9.37\\ 10.80\\ 12.26\\ 13.74\\ 15.25\\ 16.77\\ 19.90\\ 21.44\\ 23.05\\ 24.63\\ 24.63\\ 26.52\\ 27.83\\ 20.45\\ 31.00\\ 32.65\\ 31.00\\ 32.65\\ 33.50\\ 37.60\\ 37.60\\ 39.20\\ 40.92\\ 44.83\\ 45.94\\ 45.94\\ 5.96\\ 37.60\\ 39.20\\ 45.94\\ 5.96\\ 39.20$	$\begin{array}{c} Tons.\\ 1.81\\ 3.66\\ 5.54\\ 7.48\\ 9.45\\ 11.44\\ 13.50\\ 15.56\\ 17.66\\ 19.79\\ 24.15\\ 26.38\\ 28.65\\ 30.88\\ 33.21\\ 35.47\\ 37.76\\ 40.07\\ 42.41\\ 51.70\\ 54.15\\ 56.46\\ 47.02\\ 49.41\\ 51.70\\ 54.15\\ 56.46\\ 38.94\\ 61.28\\ 63.79\\ 60.08\\ \end{array}$	$\begin{array}{c} Tons.\\ 2,46\\ 4,98\\ 7,55\\ 10,19\\ 12,85\\ 115,56\\ 18,37\\ 24,04\\ 26,95\\ 32,89\\ 32,28\\ 39,02\\ 42,04\\ 45,21\\ 48,30\\ 39,02\\ 45,21\\ 48,30\\ 57,75\\ 60,79\\ 64,03\\ 67,29\\ 70,40\\ 73,72\\ 76,87\\ 80,24\\ 83,43\\ 86,86\\ 90,09\\ \end{array}$	$\begin{array}{c} Tons.\\ 3.22\\ 6.51\\ 9.86\\ 13.31\\ 16.78\\ 20.32\\ 23.99\\ 27.66\\ 31.39\\ 35.18\\ 39.92\\ 7.66\\ 31.39\\ 35.18\\ 39.02\\ 42.93\\ 46.90\\ 50.93\\ 54.87\\ 89.01\\ 63.04\\ 67.11\\ 71.22\\ 75.38\\ 58.58\\ 87.84\\ 91.90\\ 91.93\\ 100.34\\ 104.74\\ 108.90\\ 0113.37\\ 117.59\\ \end{array}$	$\begin{array}{c} Tons. \\ 4.07 \\ 8.23 \\ 12.46 \\ 8.23 \\ 12.48 \\ 30.31 \\ 34.95 \\ 39.66 \\ 44.45 \\ 49.31 \\ 54.25 \\ 69.34 \\ 74.57 \\ 79.67 \\ 84.81 \\ 90.00 \\ 95.25 \\ 100.28 \\ 105.61 \\ 110.50 \\ 100.28 \\ 105.61 \\ 110.50 \\ 126.80 \\ 132.36 \\ 137.62 \\ 137.62 \\ 137.62 \\ 137.61 \\ 137.62 \\$	$\begin{array}{c} Tons.\\ 5.03\\ 10.17\\ 15.00\\ 20.79\\ 226.22\\ 31.75\\ 37.48\\ 43.21\\ 49.03\\ 54.95\\ 60.98\\ 67.07\\ 73.27\\ 79.57\\ 85.77\\ 85.77\\ 85.77\\ 85.77\\ 99.49\\ 104.84\\ 111.27\\ 117.75\\ 123.97\\ 130.56\\ 137.22\\ 143.56\\ 150.33\\ 156.75\\ 163.63\\ 170.13\\ 177.11\\ 183.69\\ \end{array}$	

Estimated weight of settled silage.

Estimating silo capacities and silage weights, C. H. ECKLES (*Missouri Sta*. *Circ.* 89 (1919), pp. 4).—This circular is based on Bulletin 164 noted above.

[Warehouse construction and fire protection], R. L. NEWTON and J. M. WORKMAN (U. S. Dept. Agr. Yearbook 1918, pp. 408-416, figs. 4).—This section of this article deals with the important factors in the design and construction of cotton warehouses, with special reference to protection against fire. Fire fighting equipment is briefly described.

Housing the worker on the farm, E. B. MCCORMICK (U. S. Dept. Agr. Yearbook 1918, pp. 347-356, figs. 8).—This is a general discussion of the sociological phases of the subject, with plans for four houses and general layout plans for farm buildings, with special reference to the house and laborers' house.

The ideal servant-saving house (London: W. & R. Chambers, 1918, pp. VII+122, figs. 48).—It is the purpose of this book to show how servants can be largely or entirely dispensed with, chiefly by the installation and use of better heating and cooking appliances and other apparatus operated by electricity or gas, specially designed to reduce the labor of the housewife to the smallest possible dimensions and to free it from all disagreeable features."

Septic tanks, J. P. FAIRBANK (Washington Sta., West. Wash. Sta. Mo. Bul., 7 (1919), No. 5, pp. 72-74, fig. 1).—Brief instructions are given for the construction of a sewage disposal system consisting of a siphon discharge septic tank and aeration system, with special reference to conditions in western Washington.

#### RURAL ECONOMICS.

Arable land in the United States, O. E. BAKER and H. M. STRONG (U. S. Dept. Agr. Yearbook 1918, pp. 433-441, pls. 10).—This article describes in detail the location and extent of the present arable, nonarable, and potentially arable land in the United States. Maps show the approximate percentage of the total land area which was improved farm land April 15, 1910, and the location of the land not in farms on the same date. Factors limiting the crop area in the United States are similarly illustrated. Those natural conditions limiting agricultural development which prevail over the area of potentially arable land are considered, and the lands classified as forest and cut-over lands, swamps, and other wet lands susceptible of drainage, potentially irrigable land, and unimproved lands other than woodlands.

It is estimated that 850,000,000 acres of land are at present in crops and potentially available for the production of crops. Of this area, nearly 480,000,000 acres were "improved" in 1910, 200,000,000 acres were of potentially arable forest and cut-over land, 60,000,000 acres were swamps and other wet lands awaiting drainage, 30,000,000 acres of potentially irrigable land, and 80,000,000 acres of other lands. These undeveloped lands may provide about 3,000,000 farms. It is stated that 1,000,000,000 acres or more of nonarable land consists of about 360,000,000 acres of absolute forest land, 615,000,000 acres of grazing land, and 40,000,000 acres of desert land; also, there are about 40,000,000 acres in cities, rural highways, and railroad rights of way. It is asserted that the forest area will probably never be reduced to 360,000,000 acres, that an appreciable proportion of the land suitable for crops will be kept in pasture, and that due to certain economic factors the area in crops will probably never reach the estimated possible total of 850,000,000 acres; but that when the population of the United States becomes as dense as that of northwestern Europe the improved land will be about half of the humid area of the Nation, or from 600,000,000 to 700,000,000 acres.

Allotments for all, G. W. BUTCHER (London: George Allen & Unwin., Ltd., 1918, pp. 96, pls. 8).—This is a popular account of successes with war gardens in and about the city of London, with suggestions for winning security of tenure for allotment holders and a description of the aims of the National Union of Allotment Holders.

Legal decisions affecting alienation of agricultural and forest lands, P. SABATINI (Die Gesetzlichen Bestimmungen über die Veräuszerung Land und Forstwirtschaftlicher Grundstücke. Vienna and Leipzig: Carl Gerolds Son, 1918, pp. 77).—This is a handbook giving the text of several decrees and decisions of dates August 9, 1915, to March 27, 1918, inclusive. An appendix by E. Reichel is included.

Some points brought out by successive surveys of the same farms, H. W. HAWTHORNE (Jour. Farm Econ., 1 (1919), No. 1, pp. 24-37).—This discussion centers around three areas, a hill section of Ohio, a dairy section of Wisconsin, and the corn belt in Indiana, for each of which continued surveys extending over five years or longer have been conducted. The object of this paper is to show the variations as they occur year after year, and the variations for the years prior to the war or prior to 1916, as compared with the variations during the war or in 1916 and 1917.

The labor income variation from year to year in each of these areas is first shown. All the areas show higher labor incomes in 1916 than the earlier years, and the Ohio and Wisconsin areas still higher in 1917, owing to combinations of higher price levels and increased production. The percentage return on the

[Vol. 41

investment after deducting the farmer's labor from the farm income shows the same tendencies to variation as the labor incomes, but the variations are not so wide. In each area and for each year before the war the percentage return on investment was under 5 per cent, while for each year during the war it was over 5 per cent.

From a study of receipts and expenses during the war, compared with those before the war, it is observed that expenses did not increase as rapidly as receipts, yet, separating the years 1916 and 1917, it is found that the percentage increase in expenses in 1916 was only about one-third as great as the increase in receipts. In 1917 it was about two-thirds as great, and the author predicts that when 1918 data for the Ohio area are tabulated, they will show the percentage increase in expenses equal to or in excess of the increase in receipts.

In the Ohio area, with an increase of 2 per cent in the amount of labor, the crop area was increased 9 per cent and the amount of live stock 15 per cent. In the Wisconsin area, with an increase of 4 per cent in the amount of labor, the crop acreage was maintained and the number of cows was increased 13 per cent. In the Indiana area, with no increase in the amount of labor, the corn acreage was increased 15 per cent and the number of hogs sold increased 5 per cent.

The annual output per man of several farm products is tabulated. Dealing with individual farmers for successive years, the author shows that the variations of yearly labor incomes are somewhat greater than the average of all in any of these areas, even though the incomes of entire groups from year to year may be fairly constant. It is observed that the study of an individual farm for a single year will in many instances lead to erroneous conclusions. In trying to find an indication as to the number of years that it might be well to conduct studies of individual farms, the surveyors determined the rank in labor income of each farmer for 1912, then of each for the average of 1912 and 1913, or a 2-year average, then the 3-year average, and so on to the 6-year average. Allowing for variation of two places each time, it was found that there were 14 farmers who changed their relative standing when comparing 1-year with 2year average and 12 when comparing the 2-year and the 3-year average, while only 4 changed relative standing more than two places when comparing the 5-year and the 6-year averages. Finally, the author summarizes the advantages of both a single year's studies and continued studies.

Farm management, R. M. GREEN (*Missouri Sta. Bul. 163* (1919), pp. 50, 51).— Studies were conducted during the year to determine the cost of milk production near St. Louis, St. Joseph, and Kansas City, Mo., also factors in farmliving conditions in one of the richest and one of the counties below average, on owned and on tenant farms, and the system of land rental, rate, value of land, yields, and other related data. The conclusions as briefly stated here are, respectively, that farmers who were selling milk wholesale, in general, failed to receive a price that covered cost of production; that the farmer has been able to finance his plant and provide cash for the education and comfort of his family on his operating profits only in the richest sections; and that records secured on 848 farms show that where the price of land is about equal to the agricultural value of the land, a tenant can secure the use of capital at a much cheaper rate by renting the best farms.

The thrashing ring in the corn belt, J. C. RUNDLES (U. S. Dept. Agr. Yearbook 1918, pp. 247-268).—On the basis of 80 replies received to a questionnaire sent to 300 ring members mainly from Ohio, Indiana, Michigan, Illinois, and Iowa, problems such as the size of ring, property owned in partnership, thrashing for nonmembers, capital involved and plan of purchase, arranging for the thrashing help and settling the difference in the labor furnished, and others are discussed, and ring regulations drawn up to embody the main features in cooperative agreements are submitted as a guide.

In the discussion of the question of ring ownership and management of the thrashing outfit as against ring hiring, the author points out that 75 per cent of the replies indicated no objection to the ownership of the rigs. He illustrates the economic and financial possibilities of ring ownership with examples of a large, medium-sized, and three small rings. From these reports it is concluded that a rig under favorable conditions can pay for itself within 5 years, that it will give good service for from 10 to 15 years, that in several cases 20 to 25 per cent dividends have been declared, and that where an outfit can thrash at least 800 acres of grain, the financial return can be much greater than for a smaller outfit.

Agricultural cooperative enterprises in Canada (Mo. Rev., U. S. Bur. Labor Statis., 9 (1919), No. 2, pp. 127-129).—This is a brief summary taken from a statement, dated Alberta, April 15, 1919, by the United States Consul at Calgary, of the agricultural cooperative organizations in Canada considered in two classes, commercial and educational.

The report of the Agricultural Organization Society for the year ended March 31, 1917 (*Rpt. Agr. Organ. Soc.* [London], 1917, pp. VIII+64, pls. 2).— The work of the Food Production Department of this organization, its cooperation with the Ministry of Munitions, the work of trading, credit, insurance, and small holdings and allotments societies, the Women's Institutes Movement, and other details are reported on.

[Handling cotton under the United States Warehouse Act], R. L. NEWTON and J. M. WORKMAN (U. S. Dept. Agr. Yearbook 1918, pp. 416-432, figs. 4).— Suggestions to warehousemen for facilitating weighing, classifying, and conditioning cotton, devices for handling, and methods of insuring cotton in warehouses with a short-rate table showing percentage of average premium for 1-year policies earned in varying periods of days are given. The forms available in a system of accounts outlined by the Department (E. S. R. 37, p. 594) are listed, and the details of the issuance of licenses under the terms of the U. S. Warehouse Act, and regulations covering receipts are discussed.

**Report of division of markets and rural organization**, W. R. CAMP (North Carolina Sta. Rpt. 1918, pp. 60-71).—This report covers investigations of cotton prices and cotton grading, surveys of the supply and methods of marketing hogs, needs of farmers for new marketing and credit facilities, and others; also the organization of marketing and credit unions and other service work of the division in the way of grading cotton, assisting in cooperative marketing, supplying market news, etc.

Following the produce markets, G. B. FISKE (U. S. Dept. Agr. Yearbook 1918, pp. 277-288, figs. 2).—The advantages to growers and shippers of crop forecasts, market news, and reports of weather conditions are set forth, and the Government services for reporting these matters and inspecting produce on arrival are described. Figures illustrate the extent of the leased wire system of the Bureau of Markets and the location of the 32 branch offices at market centers maintained by the market news service on fruits and vegetables during the 1918-19 shipping season, and the 91 temporary farmers' service offices at shipping points, the latter accompanied by a list giving the State, station, and crops reported.

Monthly Crop Reporter (U. S. Dept. Agr., Mo. Crop Rpt., 5 (1919), No. 8, pp. 73-84, fig. 1).—Statistics and notes are presented showing the estimated farm

value of important products July 15 and August 1, average prices received by producers, and range of prices of agricultural products at important markets, the United States crop summary for August 1, estimated crop conditions with comparisons, a general review of various crops and combined conditions of crops by States, and the cotton condition for July 25 with comparisons. The number also contains data as to farm prices of horses during the last decade, the causes and extent of cotton damage, riding plows used by cotton growers, the disposition of feed crops on farms, war-time wheat prices, condition and forecast for 1919 for beans, hops, grain sorghums, and broom corn, the area of wheat and rye for 1919 compared with 1918, exports of meats and breadstuffs, and miscellaneous notes.

## AGRICULTURAL EDUCATION.

The report of the conference at the New York State Veterinary College during the semicentennial celebration of Cornell University, June, 1919 (Cornell Univ., Off. Pubs., 10 (1919), No. D, pp. 89+IV, figs. 37).—This publication contains the following papers presented at this conference : Half Century of Veterinary Medicine in Cornell University, by J. Law; Doctor James Law: A Biography, by S. H. Gage; The Establishment and Growth of the New York State Veterinary College, by G. S. Hopkins; The Problems and the Opportunities of the Veterinarian, by W. L. Williams; The Relation of the Veterinary College to the State, by V. A. Moore; The Administration of the College and Its Needs, by F. H. Miller; and Buildings and Equipment, by H. J. Milks.

Agricultural education and promotion, F. R. HUNEEUS (Santiago de Chile: Min. Indus. y Obras Pub., Dir. Gen. Serv. Agr., 1919, pp. 40-48, pls. 2).—This is a summarized statement of the present organization of agricultural education and research in Chile.

The first step in agricultural education in Chile was the creation in 1851 of a practical school of agriculture under the auspices of the National Society of Agriculture. This school was discontinued, but in 1870 was reestablished in the Agricultural Normal School of Santiago (Quinta Normal de Agricultura) and still exists. The creation of a ministry of agriculture has been under consideration by the Chilean Congress for some time. In the meantime the Direction General of Agricultural Services has for five years undertaken the promotion of agricultural education and research in Chile.

Officers' agricultural training scheme: Residential training with selected farmers, H. E. DALE (Jour. Bd. Agr. [London], 26 (1919), No. 3, pp. 329-332).— The text is given of a circular letter addressed by the Board of Agriculture and Fisheries to county agricultural executive committees on May 14, 1919, explaining various points in connection with the administration of the scheme for the residential training of officers with selected farmers during the period of about three months that it has been in effective operation. The points covered include the training for candidates with no capital or insufficient capital to start farming, candidates proposing to go abroad on the completion of their training, candidates training with near relatives, candidates who have started training on their own account with a farmer before any grant was made, etc. A brief statement of general progress is made.

Employment of the agricultural instruction grant to assist school agriculture (Agr. Gaz. Canada, 6 (1919), No. 7, pp. 682-686),—Particulars are given with reference to the amounts allotted from the Agricultural Instruction Act for school agriculture, and the purposes for which they are employed in the Provinces of Prince Edward Island, Nova Scotia, New Brunswick, Ontario, and Manitoba.
The agricultural short course in the high school, C. K. McWILLIAMS (School Sci. and Math., 19 (1919), No. 7, pp. 614-618).—The author finds that Minnesota and Wisconsin have taken the lead in the organization of these short courses. Minnesota has for some time made the holding of a short course in agriculture a part of the requirement for high school State aid. In Wisconsin, high schools may establish winter courses beginning between October 30 and November 10. The State provides aid to the extent of two-thirds of the salaries of additional teachers required in not more than 15 high schools and not to exceed \$500 a school. The course must be approved by the State superintendent of public instruction. In Oregon a unique form of organization is being tried out this year, in which each year's work in agriculture is divided into four units, and two units of each semester are alternated each year. This enables the boys to attend only in the winter months, and yet to take all of the work offered in agriculture.

The short course which has been in successful operation for six years at the Geneseo, Ill., township high school, is briefly described. There is no sequence of subjects, and the student may enter any year. Since the agriculture is operated under the Snfith-Hughes law the boys of the short course, as well as those in the regular course in agriculture, carry out a project during the summer months. The short course diploma is awarded on completion of the full four years' work.

The author finds books dealing with the specific subjects preferable to a text in general agriculture, and gives a brief list of texts. In his opinion the problem of the length of the course and when to begin it is not one of a nice adjustment to the course of study, but rather the best accommodation to the boy. He also prefers the employment of the regular teaching staff, provided it is not already overburdened, to the employment of a special teacher for this work. The entrance requirements should not be so rigid as for regular high school work.

School gardens, S. H. FREMANTLE (Agr. Jour. India, 14 (1919), No. 2, pp. 256-264, pl. 1).—In order to encourage the organization of school gardens as an essential factor in a truly rural education, the author explains the objects of the school garden in India and outlines a plan for laying out a garden which involves cooperation with the local educational, agricultural, and horticultural authorities to bring it into effect. In the author's knowledge there has been no organized effort to provide either teachers of nature study or school gardens as reconfinended by the Government of India in 1913.

Applied economic botany, M. T. COOK (*Philadelphia: J. B. Lippincott Co.,* 1919, pp. XVIII+261, pl. 1, figs. 151).—The aims of the author in this book are to give a brief statement of the recognized facts and principles concerning plants and plant growth for secondary schools, a list of simple exercises and suggestions for observations which the pupil can conduct without great difficulty, and which will demonstrate many of the statements made in the book, and a list of questions which are intended to be suggestive to the pupils and to encourage further studies. Suggestions are also given with reference to necessary equipment and method. References to helpful literature and a glossary are appended.

A demonstration of the coefficient of correlation, for elementary students of plant breeding, H. F. ROBERTS (School Sci. and Math., 19 (1919), No. 7, pp. 619-628, flgs. 7).—This is a discussion of a method of demonstrating the coefficient of correlation for use when biometric work forms a part of the schedule in agricultural classes in plant breeding. Textiles and clothing, E. B. McGowAN and C. A. WAITE (New York: The Macmillan Co., 1919, pp. IX+268, pl. 1, figs. 71).—This text for the high school deals with the source, composition, classification, and general characteristics of textile fabrics; the development of spinning and weaving methods; the structure of fabrics; the origin, classification, distribution, cultivation or production, manufacture, finishing processes, and finished products of cotton, flax, wool, and silk; textile testing; care and repair of clothing; and economics and hygiene of clothing. A bibliography and glossary are included.

Clothing for the family, L. I. BALDT (Fed. Bd. Vocat. Ed. Bul. 23 (1918), pp. 115, pls. 4, figs. 60).—This course is designed especially to meet the needs of part-time and evening schools and classes for a general course of instruction in the principles of clothing. It is intended primarily to equip the beginner with the fundamental principles of clothing economics, including a knowledge of textiles, an appreciation of design, training in the elementary technical processes of sewing, and a knowledge of the elements of the care and repair of clothing. The five sections of the course deal, respectively, with the making of undergarments, 16 lessons; elementary dressmaking, 17 lessons; advanced dressmaking, 30 lessons; infants' and children's clothing, 17 lessons; and millinery, 19 lessons. Suggestions and outlines for a group of lessons on the conservation of clothing are included. A lesson plan and bibliography are appended.

#### MISCELLANEOUS.

Yearbook of the Department of Agriculture, 1918 (U. S. Dept. Agr. Yearbook 1918, pp. 760, pls. 62, figs. 50).—This contains the report of the Secretary of Agriculture; 31 special articles abstracted elsewhere in this issue; an appendix containing a directory of the agricultural colleges and experiment stations, the State officials in charge of agricultural and extension work, and National and International livestock associations; and the usual statistics of the principal crops, farm animals and their products, the Federal meat inspection, imports and exports of agricultural products, crop summaries, States leading in staple crops, crop value comparisons, estimated value of farm products, world production and export trade in important crops, foreign trade in foodstuffs, miscellaneous information relating to various crops and to live stock, production per man and per acre for different countries, movement of farm produce, prices paid by farmers for miscellaneous articles, information pertaining to farm labor, value of plow land by States, depth of plowing by States, index numbers of prices of crops and meat animals, materials used in brewing in the United States, hop movement and consumption, farm prices of turnips, cabbage, onions, turkeys, and chickens, railway freight tonnage for 1915-17, wagon and motor-truck hauls from farms to shipping points, rural and agricultural populations and area of agricultural land by countries, area and utilization of the National Forests, area and carrying capacity of pasture land by States, and bushel weights of commodities for which bushel weights have been established in the United States and in the different States.

Thirty-first annual report of Michigan Station, 1918 (*Michigan Sta. Rpt.* 1918, pp. 231-931, figs. 307).—This contains a financial statement for the year ended June 30, 1918; reports of the director and heads of departments on the work of the station during the year, the experimental features of which have been for the most part abstracted elsewhere in this issue, but including also bacteriological analyses of well waters and canned fruits and vegetables and brief notes on a stump-clearing test and feeding trials with pigs on velvet beans, velvet bean feed, and garbage; and reprints of Bulletins 279-281, Special Bulletins 82-89, Circulars 33-35, and Technical Bulletins 34-42, all of which have been previously noted.

Work and progress of the agricultural experiment station for the year July 1, 1917, to June 30, 1918 (*Missouri Sta. Bul. 163 (1919)*, pp. 78, figs. 21).—This contains the organization list, a report by the director on the work and publications of the station, and a financial statement for the Federal funds for the year ended June 30, 1918. The experimental work reported and not previously noted is for the most part abstracted elsewhere in this issue.

Forty-first Annual Report of North Carolina Station, 1918 (North Carolina Sta. Rpt. 1918, pp. [128], pls. 11, figs. 9).—This contains the organization list, a report of the director and heads of departments, a financial statement for the year ended June 30, 1918, a special article noted on page 686, and reprints of Bulletins 238 and 240 and Technical Bulletin 14, which have already been noted. The experimental work reported is for the most part abstracted elsewhere in this issue.

Monthly bulletin of the Western Washington Substation (*Washington Sta.*, *West. Wash. Sta.*, *Mo. Bul.*, 7 (1919), *No.* 5, *pp.* 65–83, *figs.* 6).—In addition to articles abstracted elsewhere in this issue, this number contains brief articles on the following subjects: Extension of the Work of the Experiment Station, by W. A. Linklater; Concerning Courses Offered at the State College of Washington, by J. L. Ashlock; Work of the Extension Service, by S. B. Nelson; Founding a Purebred Dairy Herd, by K. B. Musser; Early Fall Spraying for Apple Anthracnose, by A. Frank; and Missing Cylinders are Dangerous, by J. P. Fairbank.

How to do things (*Philadelphia: Wilmer Atkinson Co., 1919, pp. 572, figs. 921*).—This is a compendium of a large number of farm and household devices, helps, hints, recipes, formulas, etc., as reprinted from *The Farm Journal*.

# NOTES.

Colorado College and Station.—Dr. W. W. Robbins has resigned as professor of botany and botanist to accept a position with the experimental department of a sugar beet company.

Connecticut State Station.—R. E. Andrew has been appointed assistant chemist vice C. B. Morison, whose resignation has been previously noted.

Iowa College and Station.—Dr. Paul Emerson, associate bacteriologist at the Idaho Station, has accepted an appointment as assistant professor of soils and assistant chief in soil chemistry. H. W. Johnson has been transferred from assistant soil bacteriologist to associate professor of soils and assistant chief in soil chemistry and bacteriologist in humus investigations.

Kansas College.—Dr. A. G. Hogan, assistant professor of chemistry and assistant in animal nutrition, has resigned to become professor of biochemistry in the Medical School of the University of Alabama. Dr. J. S. Hughes has been appointed assistant in animal nutrition. A. C. Hartenbower, superintendent of farmers' institutes and extension schools, has resigned to engage in farming.

Kentucky University and Station.—Dr. W. R. Pinnell, special bacteriologist in the public service laboratories; Otis Kercher, State leader of boys' club work; F. J. Sutton, assistant professor of horticulture; W. D. Iler, assistant chemist; and A. L. Brueckner, assistant in animal pathology, have resigned. John B. Nelson has been appointed assistant bacteriologist and Miss Marie Jackson, seed analyst.

Maryland Station.—E. H. Parfitt has been appointed assistant in dairy research.

Massachusetts Station.—Recent appointments include Miss Anne C. Messer as assistant chemist in the research laboratory, Arthur M. Clarke as assistant chemist in the fertilizer laboratory, and Miss Marguerite G. Ickis, curator in the department of botany, vice Mrs. S. W. Wheeler, resigned.

Minnesota University and Station.—Increases of tuition, averaging in the College of Agriculture \$18 per term, have been decided upon beginning July 1, 1920, to meet the increased expenses due to the unexpectedly large enrollments.

Construction of a new administration building for the university has been authorized. A comprehensive building plan is being prepared.

An experimental wheat flour mill is to be built next spring at Minneapolis by the State railway and warehouse commission and the State department of agriculture, with the advisory assistance of the College of Agriculture. An appropriation of \$35,000 was made by the legislature at its recent special session for this purpose. The mill will have a capacity of about 100 bbls. a day. It is expected to be used principally in the study of grain grading and marketing problems and to obtain cost data as to flour making.

New York State Station.—Laura G. Collison has been appointed editor and librarian and Millard G. Moore assistant chemist.

**Pennsylvania College and Station.**—J. W. Miller, instructor in plant pathology, has resigned. W. A. Kuntz has been appointed assistant in botany.

Clemson College.—L. V. Starkey, extension specialist in animal husbandry at the University of West Virginia, has been appointed professor of animal husbandry.

# EXPERIMENT STATION RECORD.

Vol. 41.

DECEMBER, 1919.

No. 8.

The place which the economic and social sciences are to occupy in the program of the agricultural colleges from now on is becoming increasingly clear. Conviction on that point is now rapidly crystallizing, and a stage has been reached where development in these lines is looked upon as one of the most essential features.

While these subjects in their special relations to agriculture are far from being new, until quite recently they have made relatively slow progress in the institutions as a whole, except in a few lines. In a sense, they represent a departure from the trend in which development has occurred, for in their broader ranges they lie in a different field from the class of subjects which have hitherto received main attention. This has made their growth contingent on an enlarged view of the field and function of the agricultural colleges. The Chicago convention bore evidence to the growth of sentiment in this line and the importance which is now being attached to these subjects. The business and social relations of farming were accepted as being quite as much in the field of the colleges as the technical factors of production. The cultivation of this field was recognized as not only desirable but as a prerogative of the agricultural college.

A noticeable feature of the convention was a wider departure from the strictly professional and pedagogic view of certain subjects in the field of these colleges to the idea of more direct service to the State, to the people concerned in its industries and their general welfare as well as their productive efficiency and business prosperity. While this aim has for some time been exemplified in the work of these colleges, it is assuming increasing prominence as a part of the college function.

The matter was emphasized by Dr. Lory in his presidential address, and the acceptance of the views he expressed showed how general this attitude of public service has now become. Undoubtedly it is in a measure a result of the war activities of these colleges, which forced them forward into new prominence and an enlarged field of responsibility and action. Dr. Lory argued for greater attention on the part of these colleges to what has been designated as the human side of agriculture, the business and the social relations as embraced in rural economics and rural sociology, country life and conditions for a virile rural population. He included both research and extension work in his program, with attention to improvement of the rural schools along with country life advancement, for he maintained that better farming is dependent on better country schools. The development of departments of education in the colleges, with special provision for teacher training in agriculture and home economics, has prepared the way for the exercise of this external interest and influence that should reach out through the country districts, studying the situation and extending cooperation and council.

Others emphasized the field of the social sciences and such subjects of vital interest to the industry as marketing, and urged that the colleges must take the lead in developing the basis for these lines of effort. The range of their purview has extended beyond production, to distribution and marketing; and on the other hand, the conditions under which production is necessarily carried on make the living conditions of the country, the environment of the farmer and his family, a matter of special concern. The enlargement of the opportunities of country life call for a study of conditions as a basis for devising ways and means, and for the development of local leadership, since improvement is recognized as ultimately dependent on the country people themselves.

Similarly, the Secretary of Agriculture in his address to the association laid much emphasis on the human factors in agriculture, the provision of aid in relation to markets, organization for cooperation, the development of leaders, and the breaking down of the barrier of misunderstanding which surrounds the industry. He referred to the fact that many people ignorant of rural problems speak and write as if farming were not a business, and as if production did not involve the expenditure of capital and labor; and he declared that "the farmer as well as the industrial worker is entitled to a living wage and to a reasonable profit on his investment. He is entitled also to satisfactory educational opportunities for his children, and to the benefits of modern medical science and sanitation." He maintained that when these requirements are met there will be no difficulty in retaining in the rural districts a sufficient number of contented and efficient people; and he declared that "what we need is not back to the land propaganda but an acceleration of the work for the improvement of the countryside which will render the abandonment of farms unnecessary and the expansion of farming inevitable." Advocating a broad survey of rural life, its special problems and relationships, the Secretary did not restrict the need of this to the formulation of a comprehensive flexible program, but pointed also to its importance in the education of the American public, " particularly the urban part of it."

In another address the Secretary emphasized the importance of marketing studies in aiding the farming industry, and insisted that the agricultural colleges should recognize the burden upon them for training men for this service.

There is no longer any question, therefore, as to the existence of a rural problem, or doubt as to the great importance of its study. Such uncertainty, and even resentment, as was manifested when the subject was mapped out by the Commission on Country Life less than twelve years ago has given way to a live interest and action. This shows how far we have already come in this direction.

Few things are more interesting than tracing the development of an idea, the working out of a new departure or line of action. The history of agricultural institutions is especially rich in such opportunity. Each new proposal has had to make its way step by step, in the face of more or less opposition or lack of response, before it has been accepted and given support. This doubting attitude has characterized not only farmers but often their leaders and those who speak for them. It is natural that it should be pronounced when it touches the customs, traditions, methods, and even the individuality of a people who have developed on the basis of self-reliance and independence.

We have only to recall how hard was the beginning of the agricultural school and later of the agricultural college. Few institutions ever passed through darker days. Relatively few people believed in them, and still less understood their opportunities for usefulness. There are still those who contend that these colleges were designed and should have continued to be only trade schools. Later when the experiment station was suggested it was received with little enthusiasm and had to justify itself largely by the analysis of commercial fertilizers to protect the farmers from imposition. The station was the first attempt to do something tangible for the farmers themselves, and it proved an entering wedge which was ultimately most effective. But at the outset most farmers thought they knew of their own knowledge and the experience of their forbears how to farm their lands and take care of their herds, and they were living in a time when they could hardly help making a living on the farm. Even after the station became a subject of Government patronage it had its difficulties at home, in working out its functions and devoting means to ends. We can see now that if there had been more vision and courage in the early years progress might have been more rapid in some of the States.

By sheer force of the results of their work the stations gradually compelled recognition, to a constantly broadening extent, and won confidence in the belief that theory had a place in practice. It is an interesting fact that the coming of this recognition marked a breaking down of the reserve between the college and the farmer in matters that pertained to his methods and practices in production. From it developed in course of time the agricultural extension work, which brought about the more intimate relationships and prepared for an increasing measure of public service.

But the business side of farming, the things which pertain to its relationships and to the conditions of living in the country had hardly been touched. These were more personal and secure against intrusion; and besides, farmers were noted for their shrewd business traits and the country famed for its healthfulness and its superior output of men. There were few who recognized that there was a real country problem susceptible of study and remedy, and fewer still who had the courage to declare publicly that it was a concern of the agricultural college and ought to be brought within its sphere of action. Gradually, however, it came to be urged that mere productiveness does not solve the farm question; that the farmer cares less for the second blade of grass than he does for the proper return from the first blade, and that farmers must prosper, not individually here and there but as a class. It was said that the farmer "must know the laws of economics as well as the laws of soil fertility"; and moreover that it is not enough that the farmers of the country be skilled growers of produce, successful sellers of what they grow, but that the farming class must keep pace with other classes in its general, social, and intellectual powers. It was maintained that they must secure for themselves the highest possible position, not only in industry but in the political and social organization of society.

The doctrine of the broader field of the college was regarded as quite radical when a speaker at a convention of the land-grant colleges over a dozen years ago declared that they "must purpose to stand as sponsor for the whole rural problem," and unfolded a program for economics which involved much more than adding three or four subjects of study to the agricultural course. "It involves," he said, "the very function and policy of the college itself. It alone gives proportion to the problem of agricultural education, because, while distinctly admitting the need of better farming and the consequently fundamental necessity of the technical training of farmers, it emphasizes the importance of the economic and political and social aspects of rural development. And it thereby indicates that only by a due recognition of these factors, in purpose, in organization, and in course of study, can the American agricultural college fulfill its mission to the American farmer."

This broad vision, however, and other forceful references to the matter, brought little response; and when the Commission on Country Life was appointed in 1908 it was received with surprise and even skepticism, and regarded by some as in the nature of a reproach. Those who remained open-minded toward it were often none the less doubtful as to the meaning of it or the necessity for it.

The commission was a response to a belief that, while farmers at that time were probably more prosperous than at any previous period, country living and the opportunities for a healthful and satisfying life were trailing considerably behind those of urban communities, and that this was having an unmistakable effect upon the welfare of the agricultural people and upon the industry itself. In appointing the commission, the President expressed the view that while public attention had rightly been concentrated at the beginning on means of increasing production, when this had been accomplished "the effort for better farming should cease to stand alone and should be accompanied by the effort for better business and better living on the farm." He held that the great rural interests are human interests, and that good crops are of little value to the farmer unless they open the door to a good kind of life on the farm.

The inquiry and the recommendations of the commission rested in the belief that country life might be made to supply the four great requirements-health, education, occupation, and society; that the disadvantages and handicaps that are not a natural part of the farmer's business should be removed, and that forces should be encouraged and set in motion which would stimulate and direct forcefully local initiative and leadership. Its life was too short to do more than open up the subject and set in motion a train of thought which gradually led to study and action, and has resulted in much progress in improving material conditions. It is interesting to note how many of the suggestions made in its brief report have been put into effect in the less than twelve years that have intervened. These include the establishment of an agricultural extension system on a national basis, a rural credit system, parcel post and postal savings banks, a national system of road improvement, the provision of a vast amount of information on marketing, market conditions, prices, warehouses, etc., the establishment of standards for grading products, promotion of organization and cooperation, the control of liquor traffic, greater attention to rural health, and numerous other measures which have a vital bearing on farming and life in the country.

Progress in the introduction of rural economics in the colleges has been quite steady in the past few years, and as a teaching subject it is now accorded a definite place. Nation-wide activity has been organized in aid of marketing farm products, and farm management has become a well recognized branch. But investigation in the broad field of rural economics has been quite limited thus far, and has not yet formed a prominent feature of the experiment stations.

The need for investigation, however, and especially for fundamental inquiry has become more urgent with the growth of teaching and the attempts at regulation or improvement of economic methods. These have revealed the fragmentary character of information based on broad investigation, and have suggested topics which need more systematic study. Naturally the first effort has been to build up a substantial background of fact to show what the actual conditions are and thus give a basis for more intensive inquiry. There is a feeling that a point has been reached where the latter type of work should become more extensive, in order to disclose relationships and reasons and thus to develop the principles which are operative.

Specialists maintain that the method of science is quite as applicable to questions in farm economics as to those in other branches, and that the field embraced may furnish subjects just as scientific and suitable to high grade investigation as the physical and biological aspects of agricultural practice. These may be approached in the same spirit and given the same careful treatment in the gathering and analysis of data as subjects bearing on soil fertility or the cause and control of plant disease. The fact that the problems differ in kind and in method of study does not necessarily imply that in one class the work is in any sense inferior in character, less searching, or more rigid in interpretation.

Because the statistical instead of the experimental method is employed seems no reason why economics should be excluded from the experiment station, which as the research branch of the agricultural college is comprehensive in its scope. After all, the character of the work is what determines its grade and entitles it to be ranked as scientific research. Questions relating to the technology of production were first taken up by the experiment stations, and these have usually more than absorbed the funds thus far available. In the provision for expansion effort should undoubtedly be made for this newer branch, in which there will evidently be increasing demand for information.

Doubt as to the importance of a general expansion of economic research is perhaps attributable to the character of much of the work in the past, and the feeling that the number of broad underlying principles which may be developed is relatively limited. The taking of data has sometimes appeared to be an end in itself, supplying interesting information on conditions which are constantly fluctuating rather than permanent, and are not shown to conform to fixed laws. A census or a survey may furnish the basis for research without itself being in that field. It may bear the same relation to original inquiry that deriving results from a series of simple experi-

#### EDITORIAL.

ments has. In either case the plan and purpose in accordance with which the data are taken, the adequacy of the plan to supply the necessary dependable data to carry out the purpose of the inquiry, and the analysis and interpretation of the data in a manner to disclose true relationships, will determine the grade of a piece of work and the rank it is entitled to. The result may be more exact or final in one case than in another, but the method of science must be evident in all activity classed as research. The difference in grade may be analogous to that between tabulated popular opinion based on experience and the weighed evidence deduced by the scientist. The first may be interesting and helpful, but it needs the skilled interpretation of the investigator to give it the authority of science.

In any new subject dependent on public support it is necessary to do a certain amount of work which will show the possibilities in that field and tend to arouse popular interest in it. In agriculture the gathering of data on existing conditions and practices is helpful as a starting point, and gives something of a background of fact. This has been true in economics. Just as in the early days interest and support were aroused for larger things by analysis of commercial fertilizers and the making of local tests, so in this newer line it has been necessary to arouse interest by opening up the field and by doing things which are to some extent in the nature of personal or advisory service. But as the subject has progressed and become more widely accepted in the curriculum and in framing public measures, the necessity has grown for fundamental data which are general instead of local or individual, and express a broad principle.

The field of investigation in farm economics has been considerably clarified by the recent reorganization and enlargement of the Office and Farm Management. The proposal for extensive cooperation between the Department and the experiment stations in carrying on studies in this field, and the discussion which has been going on regarding the character of investigation to be undertaken will undoubtedly have an important bearing on the development of systematic inquiry. The more definite setting forth of fundamental problems and the working out of plans for specific inquiries can hardly fail to stimulate and intensify investigation. The formation of the American Farm Economic Association and the character of papers presented at its recent meeting in Chicago are evidence of a redirection which is taking place.

The inclusion of the human factors in farm economy along with farm economics and farm management has paved the way for enlarged attention to rural sociology and problems of country life. The meeting of the Annual Country Life Conference at Chicago,

153351°-20-2

now a large, live, and many sided organization, and its joint sessions with the Farm Economic Association, are further evidences of progress in that field.

This second Annual Country Life Conference was devoted principally to rural health, and developed the agencies which are now engaged in studying rural health conditions and problems, rural public health, nursing, rural social welfare work, and housing, education and recreation in relation to rural health. In his presidential address before this conference, President Butterfield made some practical suggestions for the work of the organization, stressing especially an attempt to correlate the efforts of different groups engaged in country life activities. Interest in various aspects of country life, he reported, is steadily growing. Farmers are more ready to recognize, for example, that there is a rural health problem; and this problem was defined as embracing three phases—public health, rural sanitation, and body building. It was suggested that there should be an effort to put rural health into the program of agricultural extension work.

President Butterfield declared that the farmers are thinking more to-day in terms of economic problems than in those of technical problems. He maintained that the program of agricultural education has been too narrow to meet the needs of farming people. He urged the importance of training for leadership, and of developing local initiative and leadership so that a movement once under way will not die because a leader drops out.

An important paper from the standpoint of investigation in rural sociology was one by Dr. C. J. Galpin, one of the few in this country who has specialized in this field. His paper on The Human Side of Farm Economy dealt with the subject in its relations to the farmer, the investigator, and the public. He explained the importance of the human factor in the success of farming, and quoted Dr. H. C. Taylor to the effect that "whatever affects man as an agent in agricultural production seriously affects the results of this basic industry."

The general absence of specialists in this particular field and the scarcity of trustworthy information and data on which to base generalizations were cited as standing out with startling clarity, in relation to both inquiry and teaching. Rural sociology lacks as a working basis a classified census of the farm population as distinguished from the rural population, and until the farm population is sorted out and classified with respect to its characteristics, attainments and shortcomings, Dr. Galpin explained that progress in a National study will be greatly handicapped.

One of the most suggestive features of the paper was the analysis of the field and the setting forth of certain quite specific lines of EDITORIAL.

inquiry. This will be helpful to those who have accepted in an academic way the growing importance of this subject, but have only conceived dimly the research aspects of it or the specific lines along which inquiry should proceed. Here, as in rural economics, the securing of a sufficient background of data will be essential to the development of facts of limited range, and the taking of these will naturally constitute a rather elementary type of work. The broader surveys will clear the way for more detailed and intimate studies and at the same time will disclose actual conditions on which remedial or corrective measures must rest.

It is the consensus of opinion that the individual and the circumstances which surround him are vital factors to be taken account of in farm management and farm economic studies, and it is natural therefore that the Office of Farm Management should supply the nucleus for the new line of study relating to the farmer and his environment. For, as Professor Galpin shows, the rural problem, the problem of how to maintain a high standard of rural citizenship, is a much broader one than that of financial prosperity. Fundamentally it is the maintenance of American standards of living on the farm. The conditions of it are as yet unknown because unstudied. The country people often solve it by moving away from the land, thus taking from the country the persons possessing seasoned farm practice and the high qualities which it is especially desired to retain there. The problem, as he states, "is a very complicated social, human, psy-chological, and political problem, having to do with a class of people whose cultural, esthetic, and intellectual aspirations have hitherto been very largely postponed by one force or another, by one set of circumstances or another." That these things can be analyzed and studied in a way to develop trustworthy relations between cause and effect there can be little doubt.

## **RECENT WORK IN AGRICULTURAL SCIENCE.**

#### AGRICULTURAL CHEMISTRY-AGROTECHNY.

A study of the oil from sumac (Rhus glabra), H. W. BRUBAKER (Jour. Indus. and Engin. Chem., 11 (1919), No. 10, p. 950).—Oil extracted with dry ether from 'he berries of the common sumac (R. glabra) gathered in Kansas was found to have the following average constants: Specific gravity at  $15^{\circ}$  C. 0.92577, index of refraction at  $20^{\circ}$  (Abbé's refractometer) 1.471, acid value 0.9, acetyl value 9.235, saponification number 192.6, iodin number 126.76, soluble fatty acids 0.766 per cent, and insoluble fatty acids 93.54 per cent.

The oil, which averaged over 11 per cent of the ground seeds, is said to have a mild odor, pleasant taste, and a deep yellow color, and to be rather viscid at ordinary room temperature. It has fairly good drying qualities and saponifies readily, giving a sodium soap of semisolid consistency. The author is of the opinion that it might readily find a use as an edible oil, or in the soap-making industry, or as a semidrying oil in the paint industry.

The composition of the fruit of the Virginia creeper (Ampelopsis quinquefolia), G. D. BEAL and E. A. GLENZ (Jour. Indus. and Engin. Chem., 11 (1919), No. 10, pp. 959, 960).—The analyses reported include determinations of the proximate constituents of the fruit of the Virginia creeper (A. quinquefolia) by extraction with benzene, methyl alcohol, water, and sulphuric acid, and the analytical constants of the oil as extracted from the seeds by petroleum ether. The seeds yielded on 16-hour extraction in the Soxhlet apparatus 25.6 per cent of an odorless oil of the appearance of olive oil and with a slight taste suggestive of castor oil. The oil belongs in the castor oil group of fatty oils as shown by the following analytical constants: Specific gravity at  $15.5^{\circ}$  C. 0.924, index of refraction at  $15^{\circ}$  1.4762, saponification number from 186 to 194, and iodin number 86 to 90.

The indigenous tans and vegetable dyestuffs of New Zealand.—II, Experimental, B. C. ASTON (Jour. Agr. [New Zeal.], 16 (1918), No. 6, pp. 358-365).— In continuation of the article previously noted (E. S. R., 38, p. 309), experimental data are reported on the tannin content of New Zealand trees, and directions are given for dyeing woolen goods with the bark or root of Coprosma grandifolia, the kanono or tree-karamu of the Maori.

Manipulations of applied analytical chemistry, M. FRANCOIS (Manipulations de Chimie Analytique Appliquée. Paris: Octave Doin & Son, 1919, pp. 268, figs. 18).—This manual, the material of which corresponds to the laboratory work in chemistry of the fourth year of the Schools of Pharmacy, France, consists of four sections as follows: Analysis of drugs, analysis of food materials, biological analyses, and toxicological analyses.

In the selection and grouping of material a general knowledge of chemistry and analytical chemistry is presupposed, the arrangement of manipulation is such that one passes from the more easy to the more difficult procedures, and one method only is given for the analysis of each substance.

The original text for the section on biological analysis was written by Grimbert.

710

Electrometric titrations, with special reference to the determination of ferrous and ferric iron, J. C. HOSTETTER and H. S. ROBERTS (*Jour. Amer. Chem. Soc.*, 41 (1919), No. 9, pp. 1337–1357, figs. 15).—An electrometric titration method with standard dichromate is described, which is said to permit the determination of a few tenths of a milligram of ferrous iron in the presence of any quantity (up to 100 gm.) of ferric iron and which can be applied to other oxidation and reduction reactions. The various factors affecting the determination have been studied in detail, and the technique has been so developed that as sharp end points can be obtained with N/100 or even with N/2000 dichromate solutions as with the more concentrated solutions usually employed.

A new feature of the apparatus employed consists of a titrating head used to cover the flask which contains the solution to be titrated, in order to control the atmosphere above the solution and to support the calomel half-cell and the platinum electrode. Readings are made with the slide wire potentiometer of Roberts, previously noted (E. S. R., 41, p. 503).

Some of the advantages of the electrometric method for oxidizing and reducing reactions are summarized as follows:

"This method permits the use of potassium dichromate with its numerous advantages. The reduction of the solution with electrometric control eliminates the removal of excess reducing agent, which must be done with the usual methods of reduction. Conditions, such as acidity, need not be controlled except within very wide limits, and hydrochloric, sulphuric, or hydrofluoric acid, or mixtures of these, may all be used. . .

"The sensitivity and accuracy of the method makes possible (a) the determination of a few tenths of a milligram of tin, chromium, ferrous or ferric iron, and probably many other elements, in the presence of large quantities of some other element, and (b) the determination of blanks involved in some of the ordinary determinations by reducing or oxidizing agents.

"The time within which a determination can be carried out is greatly shortened. The content of ferrous and ferric iron in a silicate, for instance, can be determined in from 15 to 30 minutes. The precision attainable is comparable to the best of the ordinary volumetric determinations."

The hydrochloric acid color method for determining iron, J. C. HOSTETTER (Jour. Amer. Chem. Soc., 41 (1919), No. 10, pp. 1531-1543, figs. 4).—This paper gives the results of experiments undertaken to establish conditions for the development of a method for the determination of iron by means of the color developed in hydrochloric acid solution, and certain applications of the method as finally developed.

The temperature coefficient for the color varied from 2 to 3 per cent per degree, depending on the concentration of iron and probably also on the acidity. The color developed by a given amount of iron varied with the acid concentration, reaching a maximum intensity at from 26 to 28 per cent of hydrochloric acid. The use of constant-boiling acid is recommended as being the most satisfactory concentration. Sulphates were found to cause bleaching, and chlorids, particularly calcium chlorid, intensification of color.

A few results are quoted which show good agreement between the hydrochloric color method and the electrometric method of Hostetter and Roberts noted above.

The genesis of petroleum as revealed by its nitrogen constituents, C. F. MABERY (Jour. Amer. Chem. Soc., 41 (1919), No. 10, pp. 1690-1697).—A special volumetric method of analysis for the determination of minute amounts of nitrogen in oils is described, which is essentially a combination of the Dumas procedure for nitrogen and the oxygen combustion procedure for carbon. A

table is given showing the percentage of nitrogen in 21 samples of oil as determined by this volumetric process and by the Kjeldahl method.

The presence of nitrogen in the petroleum of all the principal oil fields is thought to furnish sufficient proof of the organic origin of these oils.

**Regeneration of Nessler's solution**, D. PULLMAN (*Analyst*, 44 (1919), No. 517, pp. 124, 125).—A method of regenerating Nessler's solution is described, which consists in recovering all the mercury and iodin of the solution by precipitation with a solution of a mercuric salt in amount equivalent to the mercury present, and using the mercuric iodid thus formed in the preparation of the Nessler's solution as follows:

A hot suspension of 431 gm. of the mercuric iodid in 500 cc. of water is treated with 31 gm. of zinc and the mixture stirred and heated for 5 minutes, after which the hot solution of zinc mercuric iodid is filtered, the precipitated mercury washed with boiling water, and the total filtrate made up to about 3,000 cc. with warm water. To this, after cooling, a saturated solution of mercuric chlorid is added, a few cubic centimeters at a time, until a distinct permanent red precipitate is formed. Then 540 gm. of sodium hydroxid, dissolved in about a liter of water, is stirred in quickly, and the volume made up to 5 liters. It is said that the best results are obtained with this solution by adding about 3 cc. to every 50 cc. of liquid to be nesslerized.

The cause of and remedy for certain inaccuracies in Hausmann's nitrogen distribution method, S. L. JODIDI and S. C. MOULTON (*Jour. Amer. Chem. Soc.*, 41 (1919), No. 10, pp. 1526–1531).—To determine the sources of error in Hausmann's nitrogen distribution method a series of experiments, conducted at the Bureau of Plant Industry, U. S. Department of Agriculture, is reported in which the nitrogen distribution in casein was determined by the method as modified by Osborne and Harris (E. S. R., 15, p. 221), with the exception that varying amounts of magnesium oxid were employed.

It was found that the proportion of acid amid nitrogen was constant, and did not depend upon the amount of magnesium oxid employed in the distillation. The proportion of nitrogen found in the magnesium oxid precipitate was higher, and that of diamino and monamino nitrogen correspondingly lower, the greater the quantity of magnesium oxid employed in the distillation. These results were also corroborated in a study of the nitrogen distribution in spinach.

The authors conclude that "in order to obtain uniform results and a minimum of 'humin' nitrogen it is necessary to use the least possible amount of magnesia which is sufficient to render the substance to be distilled alkaline. In the case of plant and animal materials the uniform application of 1 gm. of magnesium oxid seems to be satisfactory, while in the case of proteins 0.5 gm. suffices."

The modified Benedict method for the estimation of sulphur in feeds, feces, and foods, J. O. HALVERSON (*Jour. Amer. Chem. Soc.*, 41 (1919), No. 10, pp. 1494–1503).—The author, at the Ohio Experiment Station, has modified the Wolf and Österberg procedure (E. S. R., 24, p. 609) for the estimation of the total sulphur in solid organic matter by a simplified technique, which requires much less attention than the original method. The principal change in the process consists in digesting the material on the steam bath to almost complete solution with a diluted fuming nitric acid instead of heating with the fuming acid alone. The modified technique is as follows:

About 3.44 gm. of feces or 2.7476 gm. of feeds is weighed out on half a filter paper, which is then rolled up and put into a 300 cc. Kjeldahl flask. Ten or 15 cc. of hot water is added, the flask rotated occasionally (preferably

in the steam bath) to hasten the disintegration of any hard lumps, 20 cc. of a mixture of fuming and concentrated nitric acid (1:4, added, and the flask stoppered with a small funnel. After standing at room temperature for half a day, the flask is placed in the steam bath and allowed to digest slowly for about four days, with occasional rotation. Another 10 cc. of the acid mixture is then added, and the digestion is continued until the solution is clear or contains only small quantities of resistant residue. The solution is transferred in portions to a 60-cc. evaporating dish and treated with 20 cc. of the Benedict reagent during evaporation to complete dryness on the steam bath.

Blanks on the reagent are given the same treatment, with the exception that to prevent spattering or heating 5 cc. of a 10 per cent sucrose solution is added before evaporation to dryness. After the evaporation to dryness the samples and blanks are baked slowly on a gas hot plate or sand bath until the material has fused. After slow cooling, about 20 cc. of hot dilute hydrochloric acid is added and the dish is covered with a watch glass and heated on the steam bath for 15 minutes. The clear solution is then filtered into a 250 cc. beaker, made up to a volume of at least 100 cc., heated to boiling on a hot plate, and 10 cc. of a boiling 5 per cent barium chlorid solution added drop by drop from a calcium chlorid tube. The covered solution is digested on the steam bath for 2 or 3 hours, and then allowed to stand in the cold for at least 48 hours, after which it can be filtered without difficulty.

The method was checked by the modified peroxid method of Krieble and Mangum (E. S. R., 41, p. 505), which had been previously checked by the official peroxid method. Removal of the silica in feeds and feces gave results in the peroxid method agreeing closely with the new method, the latter checking the peroxid method within an average of 3.17 and 4.17 per cent, respectively, for feces and feeds.

Estimation of small quantities of lead in foods and substances containing calcium phosphate, B. W. J. WARBEN (Analyst, 44 (1919), No. 519, pp. 199, 200).—The technique of the method, which was devised to avoid loss of lead through occlusion with precipitated phosphates, is as follows:

Ten gm. of the material is incinerated in a silica dish, dissolved in a little water to which 1 cc. of nitric acid has been added, filtered, and washed. The colorless filtrate is treated with a slight excess of ammonia and the precipitate washed well. The precipitate, which contains practically all of the lead, is washed into a Nessler cylinder with water and 5 cc. of dilute acetic acid is added, followed by an aqueous solution of hydrogen sulphid. The color of the slightly turbid solution is matched with a standard consisting of a dilute lead solution treated in a similar manner with ammonia, dilute acetic acid, and finally hydrogen sulphid solution.

The estimation of the approximate quantity of meat in sausages and meat pastes, G. STUBES and A. MORE (Analyst, 44 (1919), No. 517, pp. 125-127).—The method described has been in use in the Government Laboratory (England) in testing sausages under the Meat Rationing Order, 1918, of the Ministry of Food, which fixes the minimum quantity of meat in first quality and second quality sausages at 67 and 50 per cent, respectively. The method is based on the assumption that meat (beef, mutton, or pork) is free from carbohydrate and crude cellulose matter and contains a fairly uniform percentage of nitrogen calculated in the fat-free meat (3.75 per cent in beef and mutton and 4 per cent in pork), and that the substances used as fillers contain, when in condition suitable for mixing, about 40 per cent of water, about 50 per cent of carbohydrate and crude cellulose matter, and 1 per cent of nitrogen.

[Vol. 41

The determinations include water, fat and nonfatty solids, nitrogen, and ash. After estimating the amount of carbohydrate and crude cellulose matter and calculating the quantity of nitrogen associated with it, the balance of nitrogen is calculated to the quantity of defatted meat which it represents, and to this amount is added the fat, the total representing the amount of meat present.

The analysis of sausages, meat pastes, and army rations, A. W. STOKES (*Analyst*, 44 (1919), No. 517, pp. 127-132).—The method employed by the author in the analyses reported is based on the assumption that meat naturally contains 70 per cent, and bread 40 per cent, of water. The meat is dissolved by boiling in alcoholic soda solution, which also forms a soap with the fat. The insoluble matter is placed in an aqueous caustic soda solution to dissolve the starch, which is then precipitated by strong alcohol. Total solids, water, and ash are estimated in the usual way on 5 gm. of the material.

The actual fat is calculated on the assumption that the fatty acids equal 95 per cent of the actual fat. The dry meat is calculated by subtracting the weight of starch and fat from the total solids. To this is added 2.33 times its weight of water to give the fat-free flesh. The bread is estimated by adding to the starch 0.66 times its weight of water.

Tables are given of the composition of samples of sausages, meat pastes, and army rations, the determinations including percentage of fat, bread, flesh, water present, water allowed, and water excess.

A rapid method for the determination of fat in cocoa and chocolate, E. B. HUGHES (*Chem. News*, 119 (1919), No. 3098, p. 104).—The method, which involves the use of the Leffmann-Beam centrifugal machine or similar apparatus consists in centrifuging a 2 gm. sample of the finely powdered material twice with 30 cc. of 50 per cent alcohol, decanting and discarding the clear liquid, and subsequently centrifuging the residue twice with 25 cc. of a mixture of equal volumes of ordinary ether and petroleum ether. The ether extracts are decanted into a tared flask, the ether is distilled, and the residue of fat is weighed. It is stated that two extractions are usually sufficient, and that the extracted fat is free from impurity.

A chemical test to distinguish between caffein and theobromin, F. P. STROUP (*Amer. Jour. Pharm.*, 91 (1919), No. 9, pp. 598, 599).—A color test to distinguish between caffein and theobromin is described which involves the use of a solution of potassium dichromate made by dissolving 0.05 gm. of the salt in 1 cc. of concentrated sulphuric acid.

The test consists in adding two drops of this reagent to a small amount of the alkaloid on a white porcelain surface. With caffein the yellow color of the reagent is changed almost immediately to a bright bluish-green, while with theobromin the color changes to a dark purple, later an olive-green, and finally to the same color as that given by caffein. Similar color changes are produced when the alkaloid is dropped upon a small amount of the potassium dichromate reagent on a white surface.

Color standards for cottonseed oil, H. V. ARNY, C. KISH, and F. NEWMARK (Jour. Indus. and Engin. Chem., 11 (1919), No. 10, pp. 950-953).—The authors have examined the color standards "Co-Fe-Cu" and "Co-Cr-Cu," devised by Army and Ring (E. S. R., 35, p. 204), with reference to their suitability for the grading of cottonseed oil. The "Co-Fe-Cu" blends, the preparation of which is outlined, were found to be satisfactory for matching cottonseed oil when properly standardized. Approximately good matches were obtained when the oil samples and the standardized fluids were compared in 1-oz. round bottles, while practically perfect results were secured by placing the liquids in one-half inch cells in the Lovibond tintometer.

Tables are given of the analytical data obtained in the investigation.

Lemon oil.—I. Fractional distillation and critical temperature of solution, G. AJON (Ann. R. Staz. Sper. Agrumic. e Fruttic. Acireale, 4 (1916-1918), pp. 209-218, figs. 2).—The critical temperature of solution in alcohol of a definite strength of the products of the fractional distillation of lemon oil is considered, by the author, to be a more accurate index of adulteration of the oil than the temperatures obtained in the fractional distillation of the oil.

Data are furnished which show that the later fractions of an adulterated oil have a lower critical temperature of solution in alcohol than the pure oil, while there is but little variation in the distillation temperatures of the pure and adulterated oils.

The U. S. P. test for methyl alcohol in ethyl alcohol, J W. EHMAN (*Amer. Jour. Pharm.*, 91 (1919), No. 9, pp. 594–597).—As the result of a series of experiments undertaken to determine the cause of variable results obtained with the U. S. Pharmacopœia test for methyl alcohol the following modified procedure is recommended:

The fuchsin-sulphurous acid is prepared by dissolving 0.5 gm. fuchsin in 300 cc. of warm water, cooling and adding 11.2 gm. sodium sulphite (90 per cent) dissolved in 200 cc. of water, and finally adding 20 cc. hydrochloric acid. The other reagents and the method of procedure are the same as in the official test, with the exception that the technique proposed involves running a blank determination with pure 10 per cent ethyl alcohol and adjusting the temperature of both tubes to 25° C. after the addition of each reagent. If the blank is violet after ten minutes too high a temperature is indicated, while if a bright red color persists, too low a temperature. In either case the temperature should be varied and the test repeated.

With quantities of methyl alcohol of 1 per cent or more, the color produced is said to change from violet to purplish red in a few minutes when viewed either vertically or transversely, while with ethyl alcohol the solution is colorless or a pale yellow. With smaller quantities of methyl alcohol (0.25 to 0.5 per cent), 10 or 15 minutes are required for the test. The final color is pale violet when viewed from above under artificial light. Viewed transversely by daylight the solution may appear to be colorless.

Notes on the assay of hypochlorite solutions, F. X. MOERK and R. R. FORAN (Amer. Jour. Pharm., 91 (1919), No. 9, pp. 592, 593).—Difficulty in obtaining definite end reactions in the assay of Dakin's solution and other hypochlorite solutions by the directions given in the Ninth Revision of the U. S. Pharmacopœia is attributed to the use of acetic acid in place of hydrochloric acid. The suggestion is made that for Dakin's solution the amount of acetic acid be increased from 2 to 3 cc. and for Labarraque's solution from 5 to 10 cc., if immediate titration is to be made. Other suggested possibilities of avoiding an indefinite end point are to allow the prepared test to stand one hour before titrating, or to replace the acetic acid by a diluted hydrochloric or sulphuric acid.

The canning of apples.—Preventing pinholing, W. D. BIGELOW (Canner, 49 (1919), No. 15, p. 34).—The author states that pinholing or perforation of apple cans is caused by the action of malic acid in the apples on the tin plate, and may be prevented by using cans with a heavy tin coating, by tight sealing, so that external air will be absolutely excluded, by filling the cans completely, by expelling the air from the apple cells with a vacuum pump or with sufficient exhaust, and finally by allowing the cans to cool to the center before they are stacked away.

Alcoholic fermentation of banana must, R. PEROTTI and V. RIVERA (Staz. Sper. Agr. Ital., 50 (1917), No. 9-10, pp. 433-450; abs. in Abs. Bact., 2 (1918), No. 6, p. 339).—A must obtained by the extraction of the skins and pulp of

bananas was found to contain four organisms, a saccharomyces designated S. musæ, a bacterial form not identified, a variety of Oospora lactis, and a variety of Mycoderma. Fermentation of banana must by means of S. musæ is said to yield, if sugar is added to the must, a slightly alcoholic liquor of good color and attractive organoleptic properties.

#### METEOROLOGY.

Temperature influence on planting and harvest dates, J. B. KINCER (U. S.Mo. Weather Rev., 47 (1919), No. 5, pp. 312-323, figs. 20).—The author discusses certain significant temperature values which seem to establish the average spring planting dates of wheat, oats, early potatoes, corn, and cotton, together with the heat necessary to bring them to maturity after planting known as the "thermal constant" or "the accumulated day-degrees of temperature above the mean temperature at which planting is accomplished."

As thus computed, very little difference was found in the amount of heat necessary to mature most staple spring-planted crops when the average variety of corn was considered. It is suggested that the mean temperature at which the planting of a given crop takes place be employed as a base for any method of temperature summation rather than a general base for all crops. It is stated that the normal daily temperatures accompanying the beginning of the seeding of the principal spring-grown crops are from 37 to 40° F. for wheat, 43° for oats, 45° for early potatoes, 55° for corn, and 62° for cotton. The successful commercial production of cotton and corn is said to be limited by available thermal constants of approximately 2,000° and 1,600°, respectively.

Agricultural meteorology (Science, n. ser., 50 (1919), No. 1293, pp. 350, 351).—Recent publications on the subject are noted, attention being called especially to the following articles published in the Monthly Weather Review: Relation Between Vegetative and Frostless Periods, by J. B. Kincer (E. S. R., 41, p. 118); and Temperature Influence on Planting and Harvest Dates, by J. B. Kincer; Alfalfa Growing in Western South Dakota, by H. N. Johnson, and Alfalfa Seed Growing and the Weather, in Utah, by J. C. Alter, of all which are noted elsewhere in this issue.

Monthly Weather Review (U. S. Mo. Weather Rev., 47 (1919), Nos. 5, pp. 279-365, pls. 26, figs. 39; 6, pp. 367-446, pls. 16, figs. 28).—In addition to special forecasts and warnings, river and flood observations, notes on the effect of weather on crops, halo phenomena, and seismological reports for May and June, 1919; lists of additions to the Weather Bureau library and of recent papers on meteorology and seismology; notes on the weather of the months; solar and sky radiation measurements at Washington, D. C., during May and June, 1919; condensed climatological summaries; and the usual climatological tables and charts, these numbers contain the following articles:

No. 5.—The First Trans-Atlantic Flight (illus.) by W. R. Gregg; The Flight of Hawker and Grieve, by W. R. Gregg; A New Evaporimeter for Use in Forest Studies (illus.), by C. G. Bates (see p. 725); The Measurement of Rainfall and Snow, by R. E. Horton (Abs.) (E. S. R., 40, p. 715); The Relation of Rainfall to Configuration, by C. Salter (Rev.) (E. S. R., 41, p. 510); Storm Rainfall of Eastern United States; Panama Rainfall (illus.), by H. G. Cornthwaite; Uncle Sam's Dampest Corner (illus.), by G. K. Larrison (see p. 717); Additional Meteorological Data Needed by Engineers, by R. E. Horton (reprinted); Elements of Hydrology, by A. F. Meyer (Rev.); The Weather and Daily Stream Flow for Hydro-electric Plants (illus.), by J. C. Alter; The Colorado River (illus.), by F. H. Brandenburg; Water Supply in California, by A. H. Palmer (Abs.); Temperature Influence on Planting and Harvest Dates (illus.), by J. B.
Kincer (see p. 716); A Graphic Summary of Seasonal Work on Farm Crops (illus.), by O. E. Baker, C. F. Brooks, and R. G. Hainsworth (Abs.); Dufrenoy's Observations of the Temperatures of Plants in Sunlight and Shade; Note on the Heating of Plants in Sunlight as a Factor in Growth, by D. A. Seeley; Measuring the Temperature of Leaves, by E. B. Shreve (reprinted rev.); Alfalfa Growing in Western South Dakota (illus.), by H. N. Johnson; and Alfalfa Seed Growing and the Weather, in Utah, by J. C. Alter (see p. 732).

No. 6 .- Some Observations on Temperatures and Winds at Moderate Elevations Above the Ground (illus.), by V. E. Jakl; Results of Some Empiric Researches as to the General Movements of the Atmosphere (illus.), by H. H. Hildebrandsson (translation); General Circulation of the Atmosphere, by L. Gangoiti (Abs.); Thunderstorm at Tulsa, Okla., June 6, 1919 (illus.), by J. A. Reihle: Tornado at Fergus Falls, Minn., June 22, 1919 (illus.); Hailstorms in South Carolina, June 8 and 9, 1919 (illus.), by R. H. Sullivan; Suggestions as to the Conditions Precedent to the Occurrence of Summer Thunderstorms, with Special Reference to That of June 14, 1914 (illus.), by J. Fairgrieve (Abs.); Wind Stratification Near a Large Thunderstorm (illus.), by L. A. Warren; Pressure Fluctuations During a Thunderstorm (illus.), by E. F. Pigot; Mammato-Cumulus Clouds and Thunderstorm at Binghamton, N. Y., June 24, 1914 (illus.), by J. R. Weeks; Types of Mammato-Cumulus Clouds (illus.), by C. F. Brooks; Cloud Shadows (illus.), by H. H. Martin; Measuring Visibility, by A. H. Thiessen; The Aurora of March 7-8, 1918 (illus.), by H. Lyman and C. F. Brooks; Wolfer Provisional Sun-spot Relative Numbers; The Weather Data Needed by Eclipse Expeditions (reprinted); Land and Sea Breezes in the Vicinity of Corpus Christi Bay, Tex. (illus.), by C. E. Heckathorn; Land and Sea Breezes at Bayonne, France, by M. Rouch (Abs.); The Sea Breeze on the Coast of Catalonia, by E. Fontseré (reprinted rev.); Land and Sea Breezes at Sierra Leone (reprinted); The First Successful Non-stop Trans-Atlantic Flight, by W. R. Gregg; Ocean Weather Reports and Forecasts for Aviators (reprinted); New World's Airplane Altitude Record; A New Recension of Aristotle's Meteorology, by F. H. Fobes (Rev.); Lord Rayleigh, Meteorologist, 1842-1919; Richard H. Curtis, 1847-1919 (reprinted); Unification of the Astronomical with the Meteorological Day (reprinted); Further Note on the Hurricane of August 6, 1918 (illus.), by R. A. Dyke; Panama Rainfall (illus.), by H. G. Cornthwaite; and Panama Cloud Phenomena (reprinted).

Uncle Sam's dampest corner, G. K. LARRISON (U. S. Mo. Weather Rev., 47 (1919), No. 5, pp. 303-305, pls. 2, figs. 2).—Measurements by engineers of the U. S. Geological Survey of rainfall in the Hawaiian Islands, at various elevations up to more than 5,000 ft., showed that during a period of nearly five years the average annual rainfall on Mount Waialeale, elevation 5,080 ft., was 476 in. The records show a great contrast in amounts of rainfall at stations only a few miles apart but varying considerably in altitude or exposure. Special forms of rain gauges and methods used in obtaining the records are described.

"As a rule November, December, March, and April are the wettest months, although the rule is not 'hard and fast,' and records are available showing just the reverse. A comparison of local records with those on the mainland northwest indicates no relation whatever in seasonal precipitation . . . Hawaiian precipitation is also of the 'showery' class, and heavy rains rarely last more than a few hours. The applicability of the general rule—that even in wet periods heavy downpours lasting a few minutes are interspersed with short periods of sunshine—varies considerably with the altitude and location. In the upper valleys, with few exceptions, showers are daily occurrences, even in dry weather, though on extreme leeward points showers are rare. On the high peaks, like Mount Waialeale and Puu Kukui, the mornings are usually clear and the afternoons and nights very wet."

Annual report of the [Philippine] Weather Bureau for the year 1916 (Ann. Rpt. [Philippine] Weather Bur., 1916, pt. 3, pp. 341).—Daily records of observations on pressure, temperature, precipitation, humidity, wind, and clouds for each month of 1916 at the 51 secondary stations constituting the Philippine meteorological service are tabulated. Observations at 2, 6, and 10 a. m., and 2, 6, and 10 p. m., at the first and second class stations and at 6 a. m. and 2 p. m. at the third and fourth class stations are recorded.

Climate and meteorology, M. FRASER (New Zeal. Off. Yearbook 1918, pp. 52-62, pls. 2, figs. 2).—Climatic data, especially rainfall and temperature, for 1917, are summarized.

#### SOILS-FERTILIZERS.

Instructions for the sampling of soils, H. LAGATU (*Prog. Agr. et Vitic. (Ed. VEst-Centre*), 40 (1919), No. 39, pp. 298-303, fig. 1).—Information is given regarding the sampling of soils for analysis.

Analyses of soils of Turner County, W. A. WORSHAM, JR., ET AL. (*Ga. State Col. Agr. Bul. 182 (1919), pp. 30, figs. 3*).—Analyses of samples of the representative soil types of an area of 177,920 acres in south-central Georgia are reported and discussed.

Over 65 per cent of the soils of the area are classified as sandy loam. The analyses indicate a relative deficiency in all the nutritive elements, nitrogen being relatively in minimum and potash being relatively in maximum. The soils are also in need of lime and organic matter and deeper cultivation.

Lime and magnesia in Queensland soils, J. C. BRÜNNICH (Queensland Agr. Jour., 11 (1919), No. 4, pp. 162-169).—A summary of the results of analyses of 1,773 samples of Queensland soils conducted at the Sugar Experiment Station is reported, showing that 27.64 per cent of the soils contain less than 0.25 per cent calcium oxid, 44.7 contain from 0.25 to 0.75, 21.1 contain from 0.75 to 1.5, and 6.8 per cent contain over 1.5 per cent calcium oxid; and 35.7 per cent contain less than 0.25 per cent magnesium oxid. Comparing the contents of lime and magnesia, it is shown that 34 per cent have a magnesia-lime ratio of 1:1, and 6.6 per cent have a ratio of 1:3.

Some observations about the soils of the Northeast Indian tea districts, G. D. HOPE (Agr. Jour. India, Indian Sci. Cong. No., 1918, pp. 102-113, pls. 2).— This is a description of the tea soils of Northeast India, with special reference to their origin, and mechanical and chemical composition.

These soils are all of alluvial origin, with the exception of those on certain steep slopes. Alluvium derived from tertiary sandstone has several distinguishing characteristics, chief among which is the invariably high percentage of fine sand and its even composition to a great depth over extensive areas. It is deficient in nutritive constituents, organic matter, and lime.

In a special study of this alluvial soil it was found to consist mainly of four definite subtypes, in all of which fine sand is the chief ingredient. There is a definite gradation in quantity from fine sand through silt and fine silt to clay, while the amount of coarse sand varies, and this variation is chiefly responsible for the difference in type. "Wherever the hills bordering the plains consist of rock other than sandstone, a difference in the type of soil is immediately noticeable...

"A very much larger part of the Dooars tea districts, relatively to that of the others, is made up of the old red soils known as the Red Bank. This soil is of great depth and is characterized by being comparatively rich in coarse sand and clay, and poor in fine sand, silt, and fine silt. It is a loam, though a heavy loam, rather than a silt soil, and is capable of assuming a very fine tilth if well cultivated. These red soils are usually acid, contain very little lime, and are rather deficient in phosphoric acid, and citric acid-soluble phosphoric acid is low. A very important feature of these soils is the fact that the ratio of clay to fine silt is usually high, which fact, taken with others, indicates that the soil has been in situ long enough to have weathered considerably."

The next most characteristic soil is a gray sandy loam. "These soils have been deposited from the rivers which come down from the Himalayas, and they consist of coarse or fine quartz sand accompanied by a large percentage of talc and potash mica. They possess fairly high percentages of phosphoric acid and remarkably high figures for citric acid-soluble phosphoric acid. They are rich in potash and the percentage of citric acid-soluble potash is unusually low, and is often present in traces only."

Other soils of special character are described.

Contribution to the knowledge of the soil profile in the neighborhood of Buitenzorg [Java], J. D. WHITE (Meded. Landbouwchoogsch. [Wageningen], 16 (1919), No. 3, pp. 57-88, pls. 3).—This is a report of mineralogical, physical, and chemical studies of the soil profile in the vicinity of Buitenzorg in eastern Java.

This profile is divided into four layers, A, B, C, and D, of which B, C, and D constitute a fossil soil of one geological origin over which is layer A, a well-weathered brown soil of volcanic origin. Layer B-C-D is in a much more advanced stage of weathering and decomposition than layer A. Both layers are, however, considered to be stages of lateritic decomposition. Another layer of soil called CX is a yellow soil. This color is ascribed to the presence of augite, and it is thought that this is less weathered than B-C-D and more than A. It is also considered a stage of lateritic decomposition.

It is generally concluded from these studies that hygroscopicity is a fair measure of the degree of weathering of soils of similar origin and type of weathering.

The physical texture of soils in its relation to crop production, D. CLOUSTON and A. R. PADMANABHA AIYER (Agr. Jour. India, Indian Sci. Cong. No., 1918, pp. 89-94, pls. 2).—This is a brief description of the laterite soils of the Central Provinces, which contain about 69 per cent of gravel and stone and only 31 per cent of fine soil. It has been found that owing partially, at least, to the porosity of this soil, it can be made relatively productive by irrigation, cultivation, and manuring.

**Phenomena of clay plasticity explained**, R. F. MACMICHAEL (*Brick and Clay Rec.*, 55 (1919), No. 8, pp. 677-680, figs. 2).—This is a technical description of the causes of plasticity in clay as well as other physical characteristics of clay on the addition or expulsion of fluids, based on several years of experiments.

It has been found that the strength of clay, whether plastic, dry, or burned, is due to the molecular cohesion of the clay particles themselves. Water, when added to a mass of dry clay, produces a disruptive force within the mass, opposing cohesion and reducing the strength of the clay. Plasticity results from a balancing of the forces of cohesion and disruption. Fluids other than water may be used to produce plasticity in clay. Organic matter, soluble salts, and colloids, except as the latter are considered to be merely very fine, insoluble particles of the clay itself, are not essential to plasticity. Shrinkage is considered to be merely a rearrangement of the clay grains. Chemical reactions of the soil, MARTIN and WIRBEL (Ann. Chim. Analyt., 2. ser., 1 (1919), No. 8, pp. 246-252).—This is a brief review of studies on the chemical reactions in soil between acid and alkaline soil solutions and the effect thereon of soil colloids.

It is concluded that clay, silica, and humus should be considered not especially as colloids possessing the power of absorbing the bases of soluble fertilizers, but more particularly as catalyzers permitting a speed of reaction between salts in accordance with the more or less rapid transformation of the character of the soil. It is thought that precipitated phosphate should give as good results as superphosphate in soils, on the grounds that under the influence of soil colloids and calcium carbonate in the presence of alkaline salts a gradual dissolution of the phosphate takes place. The improvement of tough soils by the incorporation of organic matter is explained on the basis that the presence of so-called humic acid prevents the dissolution of silica to a large extent. It is further pointed out that the manner of fixation and dissolution of phosphoric acid in soil is the same as that of potash or ammonia.

Soils and soil conditions, W. H. HARRISON (Sci. Rpts. Agr. Research Inst. Pusa, 1917-18, pp. 27-30).—Studies of the relationship of the gaseous products of decomposition to paddy soils have shown that carbon dioxid when present alone can persist as such, but that in admixture with hydrogen and under biological influences a recombination occurs of such intensity that the absence of any large quantity of these gases from the atmosphere in paddy soils is accounted for. Incidentally, distinct evidence has been obtained to show that marsh gas can be produced by a combination of these two gases under biological influences. The important fact has also been obtained that this reaction between carbon dioxid and hydrogen is not peculiar to paddy soils, but that it can be induced in dry soils with the utmost ease when the conditions are approximately anaerobic in character.

Pot experiments with sterile so-called "bara" soils after the salts present had been washed out with ordinary water resulted in the almost entire inhibition of germination. An examination of the soil showed that the bicarbonate of lime in the water had brought about a reaction leading to the production of alkaline carbonate in the soil. The soil experimented with originally contained a comparatively small amount of alkaline carbonate and a considerable proportion of sulphates and chlorids, whereas after the washing process the sulphates and chlorids were reduced in amount, but the carbonate content had considerably increased, so that the effect had been to change the original condition of white alkali into one of black alkali.

Preliminary experiments in relation to the reactions occurring between calcium phosphates and calcium carbonate under varying conditions showed that "superphosphate reacts very rapidly at ordinary temperature with calcium carbonate, the product of the reaction being the comparatively insoluble dicalcic phosphate, and that the latter in turn slowly reacts with more CaCOs forming tricalcic phosphate. At higher temperatures the intermediate stage practically disappears and tricalcic phosphate is formed with great rapidity."

Soil biology, J. MACKENNA (*Rpt. Prog. Agr. India, 1917–18, pp. 101–103*).— Field studies on the seasonal variation and effect of cropping and of fallow on soil nitrification showed that the presence of a crop, while diminishing the apparent amount of nitrification as measured by the nitrate found in the soil, actually increased the amount if it is assumed that the crop takes its nitrogen entirely as nitrate. Experiments on the specific nature of various strains of *Bacillus radicicola* and upon apparent symbiotic fixation of nitrogen without nodule formation, in the case of inoculation with foreign strains gave clear evidence of stimulation of growth by nonsymbiotic nitrogen fixation both by azotobacter and nodule organisms. The practice of pitting and rotting a green manure crop before applying it to the land has been found to give crops as good as those raised after green manuring in the usual way.

Studies on the phosphate requirements of soil bacteria led to the conclusion that "increase in available phosphoric acid greatly increases the general bacterial activity of a soil, and therewith the formation of carbon dioxid. There is a positive relation between the amounts of carbon dioxid thus formed and the solubilization of phosphate in the soil, but this varies with the character of the latter." Addition of soluble phosphate increased the ammonification rate in all the soils examined. Addition of phosphate in many cases diminished the nitrification rate, apparently owing to the disproportionate increase in nonnitrifying organisms. The final result over long periods of time in most cases showed no increase in the total nitrate formed.

Studies on the nitrogen content of liquid manure, II-IV, E. BLANCK (Landw. Vers. Sta., 91 (1918), No. 5-6, pp. 253-269, 271-290, 309-346).—These three articles explain more in detail experiments previously noted (E. S. R., 40, p. 723).

II. The transformation of the nitrogen of urine in soil.—Studies on the chemical and bacteriological transformation of the nitrogen of liquid manure in light sandy soil are reported, in which it was found that bacterial decomposition of urine in sandy soil began very quickly. While this action was somewhat retarded by phosphate treatment, eventually the loss of nitrogen through the formation of ammonia assumed large proportions. This led to the conclusion that the conservation of liquid manure with acids is unprofitable. No nitrification of the ammonia formed was observed, this being attributed to the deficiency in lime of the sandy soil. It was found that during nine weeks nearly 75 per cent of the total nitrogen in urine added to sandy soil was lost. It is concluded that the use of liquid manure on light sandy soils deficient in lime is not to be recommended.

III. The loss of nitrogen from liquid manure and urine due to their use as top-dressings.—Experiments on the loss of nitrogen from urine and liquid manure when used as a top-dressing on light sandy soil and when mixed into the soil are reported.

It was found that the greatest loss of nitrogen from urine and liquid manure took place during the time of addition and the sinking of the liquid into the soil. Smaller losses took place through evaporation and escape of free nitrogen while the liquid lay in the soil. The washing out of nitrogen from the soil by atmospheric movement is not considered great. A nitrogen loss due to the evaporation of urine or manure liquid was also observed, the older the urine the greater being the loss of nitrogen. Mixing the liquid under the soil prevented the nitrogen losses only partially, but the losses decreased as the depth of mixing increased. Treatment of urine and liquid manure with sulphuric acid was found to be a better method of preventing nitrogen losses.

IV. The influence of formalin and sulphuric acid on the conservation and fertilizing action of liquid manure nitrogen.—Studies are reported in which it was found by cropping experiments that liquid manure neutralized with sulphuric acid gave as good results as ammonium sulphate. The liquid manure kept in air gave considerably poorer results than the liquid neutralized with sulphuric acid and the ammonium sulphate, but gave much better results than liquid manure treated with either 5 or 10 per cent formalin solution. Liquid manure treated with formalin gave very poor results with reference to its nitrogen content, and this was more marked the greater the concentration of formalin solution used. It is concluded that a marked decrease in the value of

Action of chemical fertilizers on mountainous prairies, C. DUSSERRE (Ann. Agr. Suisse, 18 (1917), No. 1, pp. 7, 8).—Two years' experiments with grain and leguminous crops on mountain prairie soils which are gravelly and relatively deficient in lime are reported.

liquid manure results from the addition of formalin.

The best results were obtained with a mixture supplying phosphoric acid and potash, while about the same results were obtained where phosphoric acid alone was added and where phosphoric acid, potash, and nitrogen were added, slightly poorer results being obtained in the latter case. It is concluded that the use of Thomas slag and 30 per cent potash salts is profitable on these soils. Nitrogenous fertilizers such as sodium nitrate or ammonium sulphate are beneficial if applied in moderate amounts.

**Experiments** on the action of different fertilizers manufactured from peat, **TACKE** (*Mitt. Ver. Förd. Moorkult. Deut. Reiche, 36* (1918), No. 22, pp. 369– 373).—Pot culture experiments with oats on an unproductive sand soil to which a specially prepared moor soil fertilizer and a peat silica fertilizer were added at the rate of about 100 kg. of nitrogen per hectare (89 lbs. per acre) are reported.

The growth of oats in both cases was very poor, but was materially improved by an addition of sodium nitrate, showing the need of the soil for nitrogen. The action of the humus fertilizers was very weak, and the increase in crop attributed to them was very small. Liming had little effect in furthering their action, the increase in the case of the peat silica fertilizer being attributed to a decrease in assimilation of silica rather than an increase in nitrogen assimilation due to liming.

Further experiments are reported with oats on an unproductive heather sand soil to which lowland moor soil untreated and treated with hydrochloric acid was added. The soil used was found to be in need of nitrogen. Neither the natural moor soil nor the treated moor soil appeared to function as an active source of nitrogen for the crop. It is concluded that the question of the socalled humus fertilizer needs further investigation before practical results may be expected.

Investigations on the absorptive power of peat litter for nitrogen in the form of liquid manure or ammonia, H. MINSSEN (Mitt. Ver. Förd. Moorkult. Deut. Reiche, 37 (1919), Nos. 6, pp. 63-72; 7, pp. 197-206; 8, pp. 217-223).-Laboratory experiments are reported in which it was found that slightly decomposed new sphagnum peat is especially adapted for the conservation of liquid animal excrement on account of its extraordinary high absorptive power for liquids and its marked power for combining physically and chemically with ammonia. The power of combining chemically with ammonia was found to depend on a high content of so-called humus acids. Considerable quantities of nitrogen were physically absorbed by peat kept moist, well packed, and protected from air and sun. The chemically combined nitrogen was found in different forms but mostly in what were considered to be ammonium humates, which are not very resistant to the action of high temperatures or strong acids or alkalis. Other nitrogen compounds were found to be practically insoluble. It was also found that peat, on account of its acid nature, was capable of taking up ammonia out of the air and combining with it as permanently as out of solutions. Peat saturated with ammonia was found to be useful as a fertilizer and to give excellent results in pot experiments with sandy soil and barley as compared with sodium nitrate. As much nitrogen was absorbed chemically from urine as from ammonia.

Utilization of nitrogenous refuse, E. DONATH and G. ULRICH (Chem. Ztg., 1917, No. 20, pp. 165–168; abs. in Ztschr. Angew. Chem., 31 (1918), No. 56, Ref., p. 218; Chem. Abs., 13 (1919), No. 9, p. 985).—It has been found that when refuse such as leather and horn waste, which is rich in nitrogen, is heated with waste sulphuric acid to about 300° a portion of the nitrogen is converted into ammonium sulphate and recovered, and the remainder is obtained in the form of a highly nitrogenous charcoal. Products which are practically dry and rich in ammonium sulphate are obtained by heating for several hours at over 240°. If large proportions of acid are used, pasty products are obtained from which fertilizer mixtures may be prepared by combining them with ground lime or phosphate. The yield of ammonium sulphate can be increased by carrying out the process in the presence of certain catalytic agents at preferably 250 to  $270^{\circ}$ .

Field trials with the newer nitrogenous fertilizers, S. RHODIN (K. Landtbr. Akad. Handl. och Tidskr., 57 (1918). No. 7-8, pp. 443-471; abs. in Chem. Abs., 13 (1919), No. 9, p. 986).—Tests of calcined catalyzers for use with calcium cyanamid to improve its physical condition are reported. The catalyzers consisted mostly of by-products from iron and stone works containing iron, manganese, and aluminum. Sodium chlorid and powdered charcoal were also used.

The results of field trials were so contradictory with respect to most of the catalyzers that no definite conclusions could be drawn except regarding powdered charcoal. The pronounced results obtained with this substance are thought to be due to its great absorptive power. Further field trials comparing Chili sodium nitrate with Norwegian nitrate, basic Norwegian nitrate, calcium cyanamid, German ammonium sulphate, Swedish ammonium sulphate, and Norwegian ammonium nitrate are reported. The largest crop increase was obtained with ammonium nitrate followed by the different other nitrates, all of which gave essentially the same results. Ammonium sulphate was third in value, and the smallest crop increases were obtained with calcium cyanamid.

Recovery of high percentage calcium phosphate in connection with ammonia in fecal matter, J. GONNE (*Chem. Ztg., 43 (1919), No. 10, pp. 39, 40; abs. in Chem. Abs., 13 (1919), No. 12, p. 1355).*—A combined distillation and precipitation process is very briefly described for the recovery of ammonia in different commercial forms and of phosphates of 40 to 44 per cent water solubility with a by-product of a fertilizer similar to guano.

Bisulphate superphosphate, G. LEFORT (Vie Agr. et Rurale, 9 (1919), No. 36, pp. 172-176).—This is a discussion and brief description of the manufacture of superphosphate by treatment of phosphate rock with sodium bisulphate instead of sulphuric acid. Analyses show that such superphosphate contains from 8 to 10 per cent water-soluble phosphoric acid and from 9 to 12 per cent citrate-soluble phosphoric acid. It also contains from 21 to 25 per cent of sodium sulphate.

Comparative results with different phosphatic manures (*County Northumb.* Ed. Com., Bul. 29 (1919), pp. 35-38).—Comparative tests of high, low, and medium grade slags and bone meal with hay showed that the slag of greatest citrate solubility gave poorer results than the slag of medium citrate solubility, but better than the slag of lowest citrate solubility. Bone meal gave on the average poorer results than basic slag.

New experiments in potash fertilization, H. G. SÖDERBAUM (Meddel. Centralanst. Försöksv. Jordbruksområdet, No. 177 (1918), pp. 14; also in K. Lantbr. Akad. Handl. och Tidskr., 57 (1918), No. 7-8, pp. 501-512; abs. in Chem. Abs., 13 (1919), No. 9, p. 986).—Experiments are reported with salts made up to simulate such salts as may be obtained by the evaporation of sea water, and char-153351°-20-3 acterized by a low content of potassium chlorid and high contents of sodium chlorid and calcium chlorid. Experiments with oats showed that the presence of chlorin up to a certain amount was beneficial to the formation of grain, but that it was very injurious beyond this point. The most significant result obtained was that a large amount of chlorin can be tolerated in the presence of a sufficient amount of lime, which is taken to indicate that marine salts can be used on soils well supplied with lime.

Further experiments are reported with potash lime, manufactured by mixing one part of feldspar of high potassium content, one part limestone, and one part gypsum, all finely ground, briquetted, and burned at  $1,180^{\circ}$  C. Larger crop yields were obtained with this fertilizer on a soil deficient in lime than with a mixture of 80 per cent potassium chlorid, 10 per cent sodium chlorid, and 10 per cent calcium chlorid. The good results obtained with potash lime are in a measure ascribed to its lime content.

Lime and chalk: The pressing need for these on Essex soils, G. S. ROBERT-SON (*Essex Ed. Com., East Anglian Inst. Agr., Chelmsford, Bul.* 24 [1919], pp. 16).—This pamphlet discusses the use of lime and chalk on Essex soils. Analyses of about 90 samples of Essex soils show them to be relatively deficient in lime, which deficiency it is thought has limited their productive capacity. General information on the purchasing and use of lime is also given.

**By-product lime**, B. KOSMANN (*Tonindus. Ztg.*, 42 (1918), pp. 579, 580; *abs. in Jour. Soc. Chem. Indus.*, 37 (1918), No. 23, *pp.* 744A, 745A; *Chem. Abs.*, 13 (1919), No. 9, *p.* 985).—This is a very brief summary of the various processes patented for preparing a lime fertilizer from the waste liquors obtained in the extraction of potassium from the Stassfurt salts. They consist essentially in treating the liquor with an excess of calcium oxid. Magnesium hydroxid and calcium chlorid are formed, and these together with an excess of lime form the principal constituents of the product. An analysis of one sample showed a content of 9 per cent magnesium hydroxid, 50 per cent calcium hydroxid, and 34.26 per cent calcium chlorid.

Agricultural utilization of tanning wastes, B. FALLOT (*Vie Agr. et Rurale*, 9 (1919), No. 36, pp. 180–182).—This is a brief discussion of tanning waste with reference to its fertilizing value.

Analyses show that average tanning waste contains important amounts of phosphoric acid, potash, and lime, and a certain amount of nitrogen. It is stated that the tannic acid present may be neutralized with lime or removed by treatment with a solution of iron sulphate.

Fertilizer analyses [and registrations], A. F. WOODS and H. B. MCDONNELL (*Md. Agr. Col. Quart., No. 85 (1919), pp. 40*).—This pamphlet presents the results of analyses and valuations of 661 samples of fertilizers and fertilizing materials made in Maryland from March to July, 1919, together with a list of firms and brands registered for 1919, and the text of the Maryland fertilizer law.

## AGRICULTURAL BOTANY.

**Researches on growth and movement in plants by means of the high magnification crescograph, J.** C. BOSE and G. DAS (*Proc. Roy. Soc.* [London], Ser. B, 90 (1919), No. B 631, pp. 364-400, figs. 17).—Describing the construction and operation of the crescograph, by which it is stated very small movements can be made to register their direction and amount on a greatly enlarged scale, the authors give an account of the employment of this appliance for making graphic records in the study of very small or brief movements of plants in growth or response to stimulus; also of the relations of each of these

to the other, and more particularly in tropisms of several sorts which are indicated. A study is reported of the relation between response and stimulus of growing and of nongrowing organs. Some of the more important results thus far obtained from experiments are outlined.

Growth rate under lowering temperature undergoes diminution, and arrest at a definite temperature. Temperature rise enhances growth rate to an optimum, after which a decline sets in. At 60° violent contraction occurs, which is termed the spasm of death. The effect of heat is an increase in growth rate, which is retarded by radiation. Very close parallelism has been established between the response given by pulvinated and that by growing organs. Every stimulus gives rise to distinct impulses in two directions, namely, a rapidly propagated hydropositive impulse independent of tissue conductivity, and a slowly propagated excitatory negative, dependent upon conducting power and considered as a phenomenon of conduction of protoplasmic change. The former impulse gives rise to expansion, the latter to contraction. Transverse conductivity in the organ is much less than its longitudinal conductivity.

It is claimed that a general statement of the effect of all kinds of stimuli may be made in the form of the law that direct application of stimulus induces contraction and indirect expansion. All induced movements of plants under environmental changes are, therefore, the definite effects of direct or indirect stimulation.

A new evaporimeter for use in forest studies, C. G. BATES (U. S. Mo. Weather Rev., 47 (1919), No. 5, pp. 283-294, pl. 1, figs. 4).—This article gives an account of the development and operation of a device, designated as Type 4 "sun" wick evaporimeter, which is claimed to give the nearest approach yet attained to complete duplication of the physical features of the plant leaf in relation to the factors which are influential as regards its response to evaporation stimuli. The Type 4 evaporimeter is said to parallel the total transpiration of 12 small coniferous trees more closely than does any other instrument yet devised. The instrument is described in detail with enumeration of the advantages claimed for the different features. It is said to be eminently practical, integrating solar and atmospheric conditions in much the same way as does the plant, and no new difficulties presenting when it is used for climatological studies continuing throughout the year.

The temperature coefficient of photosynthesis, W. J. V. OSTERHOUT and A. R. C. HAAS (Jour. Gen. Physiol., 1 (1919), No. 3, pp. 295-298).—The authors have studed photosynthesis in the plant (Ulva rigida) previously noted (E. S. R., 41, p. 523), which forms thin layers permitting adequate control of temperature. This was kept within about 1° of a chosen constant (17 and 27° C.) in sea water containing an indicator and exposed to direct sunlight. Values were obtained from which the authors conclude that the true coefficient of photosynthesis in that plant within the limits here employed is 1.81. They suggest an explanation based upon the assumption that the process involves a light reaction with a low coefficient, followed by an ordinary reaction with a high coefficient.

Changes of electrical conductivity under geotropic stimulation, J. SMALL (*Proc. Roy. Soc.* [London], Scr. B, 90 (1918), No. B, 630, pp. 349-363, figs. 14).— The author has made a study of the resistance of the root tip of Vicia faba to the electrical current. The present investigation is claimed to have shown that the mechanism of geotropic response by the roots depends upon changes in permeability, the perception of gravity by plants being thus brought into line with response in animals to the same stimulus. The claim that the perception of gravity in plants is a protoplasmic phenomenon is considered to be proved by the record of the change in the second millimeter of one side of the root tip in the case of V. *faba* at various angles to the vertical. These changes are said to show the same curve as is shown by animal tissues in response to stimuli.

Permeability increases in the cortical cells of both the upper and lower sides (but chiefly in those of the latter) of the root tip when the root is placed at an angle to the vertical. The consequent relatively greater turgidity of the cells of the upper side explains the curvature. The increased permeability, giving decreased turgor, on both sides of the root is supposed to explain retardation or elongation of the axis during the period of curvature.

The translocation of the mineral constituents of the jack bean, G. D. BUCKNER (Jour. Amer. Chem. Soc., 41 (1919), No. 2, pp. 282-287).—Certain features of experimentation along the lines previously indicated with Lima beans (E. S. R., 34, p. 427) having proved somewhat unsatisfactory, the author found the jack bean (Canavalia ensiformis) more suitable to the purpose. He carried out experimental studies on the material taken from the cotyledons by the young plant during early growth, and on that remaining in the cotyledons after the seedlings had died, apparently from exhaustion.

It was found that the jack bean retains considerable calcium, magnesium, phosphorus, and silicon in the cotyledons during the growth of the seedlings in distilled water, large accumulation of these materials occurring in the leaves and a much smaller relative amount in the roots. The largest proportion of these translocated elements is found in parts having the greatest surface (therefore being capable of the greatest anabolic activity and evaporation). The considerable proportion remaining in the cotyledons is supposed to indicate the activity of this part of the mineral matter in promoting catabolic changes.

The paraffined paper cups and the method employed have proved very satisfactory for growing seedlings, while successfully excluding entraneous mineral matter. Other experiments in progress are expected to throw further light on the physiology of germination and the nutrition of embryos. It is thought that other uses in physiological investigations may be made of deductions which may be drawn from the data here presented.

Studies on anthocyanins: Color variation in anthocyanins, K. and Y. SHIBATA and I. KASIWAGI (Jour. Amer. Chem. Soc., 41 (1919), No. 2, pp. 208-220, figs. 16)—Departing from the custom of using metallic zinc or magnesium and excess of inorganic acid for the reduction of the flavone and the flavonol series, the authors have employed organic acids, and have been able to isolate some of the pigments and to examine their properties. The work and results are discussed in detail.

The function of wood vessels, E. GILTAY (*Ztschr. Bot., 10 (1918), No. 12, pp. 753-756, fg. 1*).—An account is given of the construction and operation of a device which, by internal reflection and resulting concentration of strong light, gives a good view of the end of a plant stem cut a little above the soil. By continually wiping dry the cut surface, it was seen that in the specimen described (*Sambucus nigra*) the flow was limited to the vessels.

Mendelism and the cytological mechanism of heredity, Y. DELAGE and M. GOLDSMITH (*Rev. Sci.* [*Paris*], 57 (1919), Nos. 4, pp. 97-109; 5, pp. 130-135).— This is an exposition and critique of the Mendelian theory of heredity with its implications.

Gametogenesis and fecundation in Zea mays as the basis of xenia and heredity in the endosperm, P. WEATHEBWAX (Bul. Torrey Bot. Club, 46 (1919), No. 3, pp. 70–90, pls. 2, figs. 2).—Summarizing experimental and other evidence as presented, the author states that of the four potential megaspores in maize only one persists and becomes functional. The embryo sac is a modified form of the ordinary 7-celled type. The antipodals undergo division. The sperms are matured inside the pollen grain. Although external conditions and length of the silk determine the time required for the growth of the pollen tube, fecundation has occurred about 24 hours after pollination. The work of Guignard on double fecundation (E. S. R., 13, p. 620) is conidered as verified by these observations. A triple fusion occurs almost simultaneously with fecundation of the egg, but the endosperm develops much more rapidly than does the embryo. The assumption that the endosperm is sporophytic is considered sound. The cytological data substantiate practically all the assumptions of cytological fact upon which recent experiments on endosperm heredity in maize have been based.

The ancestry of maize, J. H. KEMPTON (Jour. Wash. Acad. Sci., 9 (1919), No. 1, pp. 3-11).—This is mainly a discussion of a contribution by Weatherwax (E. S. R., 40, p. 728).

Hybrid perennial sunflowers, T. D. A. COCKERELL (Bot. Gaz., 67 (1919), No. 3, pp. 264-266).—It is stated that near Boulder, Colo., where Helianthus orgyalis and H. maximiliani have been growing in close proximity for a number of years, a distinct form has appeared which is on the whole intermediate between these two, and which is supposed to be a hybrid resulting from their intercrossing. In order to bring out clearly the features of the new plant, each character is described in connection with a corresponding character of each supposed parent.

Chondriosomes in plants, C. J. CHAMBERLAIN (Bot. Gaz., 67 (1919), No. 3, pp. 270, 271).—This is a summary of results reported by investigators in the study of chondriosomes, chiefly in plants, the name (of the many mentioned which have been proposed for structures of this order) being favored on account of its noncommittal character. Attention is called to the bibliographies given in reports of studies on such bodies, that by Cavers (E. S. R., 33, p. 631) covering the literature of the subject up to 1914, and that by Mottier (E. S. R., 39, p. 332) bringing it up to 1918.

It is considered to have been established that chondriosomes are not artifacts, that they multiply by division, and that some of them give rise to plastids. Their part in heredity, however (if they have any), remains to be demonstrated.

The physiological basis of morphological polarity in regeneration, I, J. LOEB (Jour. Gen. Physiol., 1 (1919), No. 3, pp. 337-362, figs. 18).—Continuing previous reports (E. S. R., 41, p. 526) the author presents qualitative evidence regarding the inhibitory effect of a leaf upon shoot formation, discussion of more quantitative experiments being reserved for a later paper.

In *Bryophyllum calycinum*, growth of two apical leaves suppresses shoot formation in all dormant buds situated lower down the shoot, that of one apical leaf influencing the lower buds on that side (half) of the stem. Removal of one-half of the petiole of a leaf permits growth of lower buds in the corresponding quadrant of the stem. This inhibitory influence of the leaf diminishes or disappears when the mass of the leaf is reduced below a certain limit. The inhibitory influence of an apical leaf in case of horizontal suspended stems is greater when the leaf is on the upper side of the stem. The facts observed are considered to justify the suggestion that the inhibitory influence of the leaf upon shoot formations is due to inhibitory substances secreted by the leaf and carried with the sap toward the base of the stem. An apical leaf accelerates root formation in the basal part of the stem in proportion to the mass of the leaf.

[Vol. 41

It is concluded that this inhibition of shoot formation and the favoring of root formation are factors concerned in the determination of the polar character of regeneration.

On certain shoot-bearing tumors of eucalypts and angophoras, and their modifying influence on the growth habit of the plants, J. J. FLETCHEE and C. T. MUSSON (*Proc. Linn. Soc. N. S. Wales, 43 (1918), pt. 1, pp. 191–233, pls. 24*).—This is an account of the presence and apparent relations of tumors discussed herein as found on eucalypts and angophoras, but mentioned also as occurring on about 10 species of other genera, observations regarding which cases are also to be published. The presence in some species of water-storing roots is also briefly discussed.

## FIELD CROPS.

Irrigation of field crops in Nevada, C. S. KNIGHT and G. HARDMAN (*Nevada Sta. Bul. 96* (1919), pp. 5-42, figs. 19).—This bulletin comprises a discussion of irrigation practice in Nevada, the water supply and drainage areas of the State, factors affecting the duty of water, and experimental work with irrigated field crops, including alfalfa, wheat, potatoes, red clover, and sugar beets, already reported on from time to time (E. S. R., 41, p. 231).

Approximately 1.3 per cent of the area of the State was irrigated in 1918, of which about 145,000 acres was in alfalfa, 80,000 acres in wheat, and 15,000 acres in potatoes, these being the most important cultivated crops grown under irrigation. The Humboldt, Truckee, Carson, Walker, and Muddy are said to be the principal rivers supplying water for irrigation, and more than 50 per cent of the irrigated area received its water from the Humboldt River. The greater portion of the alfalfa and grain is irrigated by the border method of flooding, while the furrow method is used in the irrigation of potatoes and other similarly cultivated crops. The important factors affecting the duty of water in Nevada are designated as soil type, topography, hardpan near the surface, annual rainfall, and evaporation, the type of soil causing greater variation in the amount of water required under general field conditions than any other one factor.

The average results of early investigations with alfalfa, 1906–1911, show a total irrigation of 3.27 acre-ft. of water, producing a yield of 5.93 tons per acre. During the 5-year period 1914–1918, inclusive, practically no precipitation was received during the growing season that was sufficient to affect the moisture content of the soil. The irrigation water was measured into each plat through calibrated galvanized-iron pipes 2 in. in diameter, while check plats were used to prevent, as far as possible, any errors due to variation in soil. Alfalfa allowed to reach the wilting point before irrigation produced a relatively low yield per acre, but excellent returns were realized when irrigation was withheld until the plants turned dark green in color. The most economical use of water with alfalfa was accomplished with a total irrigation of 3.5 ft., applied when plants showed need of water by the dark-green color of the foliage, producing 5.59 tons per acre.

Soil-moisture determinations showed that 70 per cent of the 6-in. applications was retained in the first 4 ft. of soil. The use on this plat was equivalent during the period of irrigation to a delivery of water at the rate of 1 second-ft. for 85 acres, or 0.47 miner's in. per acre. The highest yield of alfalfa, 6.18 tons per acre, was obtained with an application of 81 in. of water when the crop was irrigated before plants showed need of water, but this was accompanied by the lowest yield per acre-ft., 1.03 tons. Soil-moisture determinations showed that only 25 per cent of the 12-in. application was retained in the first 4 ft. of

0

soil. In the irrigation of alfalfa the decrease in soil-moisture content at harvest was generally greatest with 9- and 12-in. applications, while the total amounts of water held in the soil were greatest with the last two stages of wilting.

In experiments with wheat made during 1914–1918, inclusive, 3- and 7-in. applications were given at two or more of the five stages of growth, including the 5-leaf, boot, bloom, milk, and dough stages. The highest yield was obtained with 28 in. of water in four applications, when an irrigation was omitted at the 5-leaf stage. The highest yield with three irrigations occurred with 21 in. of water when applications were omitted at the 5-leaf and dough stages. The average yields of wheat were considerably higher with 7-in. than with 3-in. applications. The yields were relatively low when irrigations were omitted at the boot and bloom stages, indicating that a very critical period occurs in the irrigation of wheat between the boot and milk stages. The highest yield with two irrigations was secured with 9-in. applications, one before and one after heading. High yields per acre were generally accompanied by the greatest decrease in soil-moisture content at harvest as compared with the soil-moisture content before the first irrigation.

In work with potatoes conducted during the period 1914–1917, inclusive, the highest yield was obtained with a total irrigation of 16.5 in. made in 3-in. applications, given when the plants showed a tendency to wilt.

Irrigation experiments with clover made in 1914 showed a gradual decrease in yield in the different plats with the same applications of water as the wilting stage advanced before water was applied.

The greatest yield of sugar beets during the two-year period 1914–15 was obtained with 18 in. of water made in 3-in. applications.

The results of these investigations are held to show that the most economical use of water was obtained with a total irrigation of 3.5 ft. in 6-in, applications for alfalfa and clover, 2.3 ft. in 7-in, application for wheat, and 1.5 ft. in 3-in, applications for potatoes and sugar beets. When alfalfa fields are used for fall pasture, usually an additional irrigation is required after the last crop of hay is harvested.

[Report of work with field crops in Nova Scotia, 1918] (Ann. Rpt. Sec. Agr. Nova Scotia, 1918, pt. 1, pp. 27-39).—Variety and fertilizer tests with oats and field tests with wheat, barley, mangels, turnips, and hay and pasture crops are briefly described.

[Report of field crops work in Tortola] (*Imp. Dept. Agr. West Indies, Rpt. Agr. Dept. Tortola, 1917-18, pp. 3, 4, 5, 7-9*).—This describes work with sugar cane, sweet potatoes, corn, cassava, beans, and cotton on the island for the year ended March 31, 1918.

Guide to experiments for 1919 [in Northumberland County, England], D. A. GILCHEIST (*County Northumb: Ed. Com. Bul. 29 (1919)*, pp. 4–18, pl. 1).— This describes the continuation of rotation, fertilizer, and variety tests with field crops along the same general lines as previously noted (E. S. R., 40, p. 624).

[Report of seed testing and experimental work at Oerlikon, Zurich], A. VOLKART ET AL. (*Landw. Jahrb. Schweiz*, 33 (1919), No. 1, pp. 38-77).—This describes the continuation for 1916–17 and 1917–18 of work along the same general lines as that previously noted (E. S. R., 38, p. 538).

Food and fodder plants, J. H. HOLLAND (Roy. Bot. Gard. Kew, Bul. Misc. Inform., No. 1-2 (1919), pp. 1-84).—The important food and fodder plants occurring in the Leguminosæ, Gramineæ, Cruciferæ, and Rosaceæ are enumerated, together with additional important products occurring in other families. The chief countries of production, the imports into Great Britain, the approximate production of the principal crops in the United Kingdom, brief notes on their utilization, and other information deemed of interest relative to the various crops are presented.

Rotations and crop distribution, F. PARISOT (Rotations et Assolements. Paris: Libr. Larousse, [1911], pp. 136, figs. 2).—A practical treatise on the subject.

The effect of drying on the germination of cereals, R. G. STAPLEDON and M. ADAMS (*Jour. Bd. Agr.* [*London*], 26 (1919), No. 4, pp. 364-381).—The authors describe observations made at the English Seed Testing Station on the effect upon the germination of samples of wheat, barley, rye, and oats of drying the seed for three days at 40° C. ( $104^{\circ}$  F.), and of holding it without drying for three weeks as compared with tests made upon the samples as received. Observations were also made on the effect of drying upon poorly developed and sprouted grain. The results secured are believed to have a significant bearing, both on routine seed testing and on the problem of "conditioning" grain.

Some risk is said to be involved in sowing these cereals, even when in a sound condition, early in the fall and immediately after thrashing. Kilndrying with subsequent air-drying is recommended for wheat, barley, and rye under such circumstances, while in the case of oats air-drying for two or three weeks is deemed best. It is also stated that tests made after drying or holding the seed are much more representative of the commercial value of the sample than tests made when the sample is received.

A new cultural process for cereals, C. Rossi (Nuovo Processo per la Coltivazione dei Cereali. Milan: Ulrico Hoepli [1917], pp. 8, pls. 7, figs. 5; abs. in Physiol. Abs., 4 (1919), No. 5, p. 244).—Immersing the seed of cereal crops in a 3 per cent solution of ammonium nitrate for from 12 to 14 hours is said to have increased the yield of grain 25 per cent and that of straw 30 per cent.

Breeding small grains in Minnesota (Minnesota Sta. Bul. 182 (1919), pp. 5-56, figs. 14).—This bulletin comprises two parts, as follows:

Part I. Technique and results with wheat and oats, by H. K. Hayes and R. J. Garber (pp. 5-44).—The methods employed in plant breeding work at the station are described, and the results secured with winter and spring wheat and oats outlined. The work may be summarized as follows:

Cereal breeding includes introductions of new sorts, selections, and crosses followed by selection. New introductions are deemed essential if the breeder is to have the best material as a basis for study. Introductions that appear promising in preliminary row tests are used as a basis of selection, while selections from commercial sorts are also made. The head selection method is used, from 50 to 200 heads being selected the first year. Nonpromising sorts are eliminated in the field and the second year three systematically distributed plats of a single 18-foot row each are grown for each selection, one foot being removed from each end before harvest. The third year tests are made in three plats of three 18-foot rows each, the central row only of each plat being used for the yield test. Border rows are grown to obtain more accurate data on lodging and to overcome competition between near-by sorts.

Crosses are made between parental sorts selected because of some particular characters. No selections are made in the  $F_1$  of a cross, as all plants are of the same genotype. Noncrosses are immediately discarded. A large plat is grown in the  $F_2$ , individual plants selected, and the seed of each plant sown in a separate plat in the  $F_3$ . Selection by this method is continued until many homozygous forms are obtained. As homozygous sorts appear they are placed in the rod-row test and handled thereafter the same as selections. All row tests are

examined yearly for possible genetic impurities, and reselection practiced if the type is segregating. Mechanical mixtures are rogued out. A bulk plat of a cross is grown for several years, the cross becoming homozygous automatically according to the formula  $\left(\frac{2n-1}{2n}\right)^m$ , in which *n* is the number of generations elapsing since the cross, and *m* the number of allelomorphic pairs by which the parent sorts differ. After several years individual selection is practiced.

Rod-row plats of a standard sort are grown every third to fifth plat and the yelds determined. The probable error of the average of three plats systematically distributed as determined by the checks is multiplied by three, and when subtracted from the higher yielding sort a somewhat arbitrary figure is obtained below which it is considered safe to discard all sorts for the season in question without eliminating a high yielding strain. A similar method is used in determining higher yielding sorts after a three-year test. Promising sorts are also tested in rod rows in cooperation with several of the substations. After a three-year test in rod rows, sorts of promise are placed in the plat varietal test conducted by the section of farm crops. Pedigreed sorts produced at this or other stations are ultimately distributed to the farmers. The investigational staff of the division acts as a board to determine, on the basis of performance, which sorts to distribute.

New introductions of winter wheat obtained from the Office of Cereal Investigations, U. S. Department of Agriculture, proved less hardy than selections and crosses which were made at this station many years ago. Some selections and crosses stand up much better than others, including both subcorneous and substarchy types. Odessa, a late-maturing sort, was crossed with Turkey, which matures somewhat earlier, homozygous forms having been produced which range in maturity from the early to the late parents. Several of these crosses proved as hardy as the Odessa parent, or slightly hardier, and gave much higher yields, while some of them were nonhardy. Other crosses were made, none of which gave as hardy wheat as when Odessa was used as a parent, indicating the value of using as a parent a type which excels for the character desired. Pure lines which excelled in hardiness include a Turkey selection, I-03-120; Big Frame I-06-6; and I-03-229, a bearded, smooth, red-chaffed form with subcorneous kernels selected from an introduction from Padui, Russia.

Cooperative rust investigations conducted with the hope of producing a rust resistant bread wheat of milling quality limited other agronomic breeding studies with spring wheat, but recent pathological investigations (E. S. R., 40, p. 642) in which many biologic forms have been found are believed to have rendered questionable the value of further rust-breeding studies. Row tests of bread wheat sorts indicated that Marquis is a very desirable variety for Minnesota conditions. Several crosses made in 1908 between Turkey Winter and Wellman Fife are deemed better than Haynes Bluestem (Minnesota 169), although none appeared to be of more value than Marquis. Based on a comparison with D-1 and D-4, North Dakota selections; Acme, a South Dakota pedigreed sort; and other Arnautka and Kubanka pedigreed varieties, Mindum, a selection from the Arnautka (durum) group, is said to have given evidence of being a valuable sort for Minnesota.

Oats breeding consisted of a study of the value of selection, it being found comparatively easy to produce a higher yielding sort by selection from a commercial variety. Results with Sixty Day oats are regarded as especially striking, although only a single year's test in rod rows is available. One pure line, I-17-72, which stood up better than commercial Sixty Day and also excelled it in yield, seems to be of much promise as compared with Iowa 103. On the basis of the three-year yield test, pure lines of several varieties gave evidence of promise. From the breeder's standpoint it seems that the isolation of a higher yielding strain is more important than the variety. Selections of the following varieties are deemed worthy of further test: Minota (a Minnesota selection), Garton 473, Garton 784, Scottish Chief, Irish Victor, Silvermine, Lincoln, and Kherson. It is stated that all the plant breeder can hope to accomplish in three or four years is to determine the sorts which deserve further test, the final trial being for the purpose of determining the adaptability of the sorts to special conditions and localities. The pairing method for the determination of the probable error gave about the same result for the 1918 oat test as the use of check plats systematically distributed and grown every third to fifth plat.

Part II. Investigations in barley breeding, by H. V. Harlan and H. K. Hayes (pp. 45–56). This describes work conducted in cooperation with the Office of Cereal Investigations, the results of which may be summarized as follows:

Some head selections of Manchuria barleys proved to be low yielders each year, while others gave high yields each year. Nearly as wide variations in yield were found when comparing head selections within a variety as were obtained by comparing different varieties. Several smooth-awned sorts were compared with standard Minnesota types, the results indicating that smoothawned barleys of high yielding ability can be obtained. A cross between Manchuria and a low-yielding stiff-strawed sort, known as South African, has given two selections having yielding ability and stiffer straw than the Manchuria parent. Results reported are said to show the necessity of testing a new production in various localities of the State before recommending its general introduction.

Leguminous crops on the prairies [of Canada], T. J. HARRISON and J. MC-CAIG (Agr. Gaz. Canada, 6 (1919), No. 6, pp. 552–557, figs. 5).—Brief notes are presented on the adaptation and production of alfalfa and red, alsike, white Dutch, and sweet clovers in Manitoba, and alfalfa and red, alsike, and sweet clovers in Alberta.

Paper-making materials of the Philippines, J. F. BOOMER (U. S. Dept. Com., Com. Rpts., No. 178 (1919), pp. 632-649).—Based on data gathered by G. F. Richmond, information is presented relative to fiber and other raw materials suitable for the manufacture of paper pulp and of raw materials required for the production of chemicals employed in paper-pulp making found in the Philippine Islands. The paper-making materials mentioned include bamboo, abaca waste, cogon (Imperata exaltata), talthib (Saccharum spontaneum), plantains (Musa paradisiaca), bananas, maguey (Agave cantula), and miscellaneous minor sources of paper stock. Raw materials for the manufacture of papermaking chemicals include lime, clays, and sulphur.

Silage crops other than corn [in Canada], J. M. TRUEMAN, R. SUMMERBY, H. BARTON, BROTHER ATHANASE, W. TOOLE, J. H. ELLIS, J. BRACKEN, J. MCCAIG, and P. A. BOVING (Agr. Gaz. Canada, 6 (1919), No. 6, pp. 538-544).—Information is presented on the utilization of various crops other than corn for silage in different parts of Canada, including notes on alfalfa, rye, clover, soy beans, Sudan grass, millet, rape, buckwheat, sunflowers, and mixtures of cereals, peas and vetch.

Alfalfa seed growing and the weather, in Utah, J. C. ALTER (U. S. Mo. Weather Rev., 47 (1919), No. 5, pp. 330-332, figs. 3).—The relation of temperature and rainfall to alfalfa seed production in Utah is discussed.

It is stated that the crop requires sufficient moisture during its early growth to produce vigorous plants followed by rather dry weather during the blooming period, and that the best results are secured with spring temperatures averaging from 3 to 5° F. a day above the normal, and summer temperatures from 2 to  $4^{\circ}$  a day below normal. A temperature of from 26 to 28° in the foliage is said to result in serious damage to partly ripe and unripe seed burrs. The seed is usually ready to harvest from one to two weeks before the average date for the first killing frost, but protection of the seed crop from early frosts by means of smudging is deemed sufficiently promising to merit careful consideration, especially where the practice can be made a community affair.

[Lodging in barley], C. KRAUS (*Jour. Landw.*, 66 (1918), No. 1, pp. 53-70).— Experimental work is described, from which it is concluded that potash aids in the production of stiff straw in barley, although inherent varietal characteristics with regard to lodging and various other cultural factors are also believed to play an important rôle in this respect.

Soil and fertilizer conditions which determine the tendency of the beet to produce seed the first year, O. MUNERATI and T. V. ZAPPAROLI (*Staz. Sper. Agr. Ital.*, 51 (1918), No. 1-2, pp. 24-40, pls. 2, figs. 2; abs. in Chem. Abs., 13 (1919), No. 13, p. 1511).—Supplementing work previously noted (E. S. R., 31, p. 330), the authors describe observations on the effect upon seed production the first year of growing beets on different types of soil and with various fertilizer treatments. The number of plants producing seed the first year ranged from 1 to 2 per cent of those plants grown on sandy soil without fertilizers to 55 per cent of those grown on a loam soil receiving applications of manure and chemical fertilizers.

Chenopodium quinoa in the Netherlands, F. F. BRUYNING (Cultura, 31 (1919), No. 369, pp. 182-190).—This describes cultural tests with C. quinoa conducted during 1918.

Inheritance of spotted aleurone color in hybrids of Chinese maize, J. H. KEMPTON (Genetics, 4 (1919), No. 3, pp. 261-274, figs. 3).—This paper, a contribution from the Bureau of Plant Industry, U. S. Department of Agriculture, describes six crosses made during 1913 between a colored Algerian pop corn and a Chinese white waxy corn previously described (E. S. R., 22, p. 443) in a study of the inheritance of a spotted type of color distribution. A large number of hand-pollinated ears bearing seeds representing the  $F_2$  generation were secured in 1914, the progeny of all but one of the six crosses producing ears with some spotted seeds. The inheritance of these spotted seeds is analyzed and conclusions reached as follows:

In the seeds of certain ears borne on white-seeded plants pollinated from colored plants the aleurone color was distributed in numerous small spots, while the reciprocal crosses were self-colored. Spotting is assumed to be due to a dominant spotting factor, S, which functions as a partial inhibitor. The results of these observations are held to indicate that factor S can operate only when factor R is heterozygous, and also that it is not present in the female gamete but is introduced into the zygote by the male gamete. Since the male gamete contributes one nucleus while the female gamete contributes two, it is thought that the difference between reciprocals may be ascribed to the fact that the female parent contributes twice as much chromatin material as the male parent. It is deemed evident, therefore, that a single nucleus does not contain a sufficient amount of factor R to produce a self-colored seed in the presence of the dilution factor S. The percentage of spotted seeds and their appearance only on those self-pollinated ears which have no correlation between aleurone color and endosperm texture has led to the conclusion that there is a coupling or linkage between factor R and factor S. The gametic ratio in these hybrids approximated a series of 7RS: 1Rs: 1rS: 7rs, said to

[Vol. 41

Cotton variety tests, 1918, A. C. LEWIS and C. A. MCLENDON (Ga. Bd. Ent. Bul. 52 (1919, pp. 40, figs. 2).—This describes the continuation of work previously noted (E. S. R., 40, p. 237).

[Cotton production in French North Africa], V. CAYLA (Ann. Sci. Agron., 4. ser., 8 (1919), Nos. 1-3, pp. 1-46; 4-6, pp. 145-203, pl. 1).—This comprises a rather detailed account of the status of the industry in Egypt, Tunis, Algeria, and Morocco during 1917. A bibliography containing 53 titles is appended.

Cotton culture [in Rhodesia], H. W. TAYLOR (*Rhodesia Agr. Jour., 16 (1919)*, *No. 3, pp. 197-201, pls. 2*).—The possibilities of the crop in Southern Rhodesia are indicated.

Cotton and the cellulose industry, I-II, J. MEUNIER (*Rev. Sci. [Paris*], 57 (1919), Nos. 5, pp. 135-142, figs. 16; 6, pp. 168-177, fig. 1).—This comprises a general discussion of the utilization of cotton in the industry.

Utilization of delint for paper making, O. KRESS and S. D. WELLS (*Cotton Oil Press*, 3 (1919), No. 3, pp. 27-36, figs. 18).—In this paper, a contribution from the Forest Products Laboratory of the U. S. Department of Agriculture located at Madison, Wis., the authors describe investigations in which an effort was made to ascertain the suitability of second cut cotton linters, cotton shavings, and hull fiber for paper manufacture. It is concluded that a high-grade paper stock can be produced from these materials.

Flax as a fiber plant in British East Africa, H. SIMPSON (*Dept. Agr. Nairobi* [*Brit. East Africa*] *Bul. 3 (1919), pp. 10, pls. 4*).—This comprises a brief description of flax production and of the preparation of the fiber for market.

Oil from British-grown linseed (*Jour. Bd. Agr.* [London], 26 (1919), No. 4, pp. 420-428).—This comprises a review of papers prepared by J. V. Eyre and R. S. Morrell on the agricultural possibilities of flax production for oil in England and on the commercial value of the oil.

**Prospects of hop growing in South Africa**, G. SHAW-SCOTT (So. African Jour. Indus., 2 (1919), No. 6, pp. 519-530, figs. 2).—The possibilities of hop growing in South Africa are discussed.

The indigo of Nigeria and its value as a dye (Bul. Imp. Inst. [So. Kensington], 17 (1919), No. 1, pp. 31-37).—Lonchocarpus cyanescens, described as indigenous to West Africa, is said to yield the same blue dye as Indigofera spp. Native methods of extracting the dye are briefly noted and the results of analyses given of several samples of indigo from L. cyanescens examined at the Imperial Institute. The yield of indigo was found to be considerably less than that secured from Indigofera.

[Reseeding frost injured oat fields on moor soils], H. VON FEILITZEN (Svenska Mosskulturför. Tidskr., 33 (1919), No. 4, pp. 360-364, fig. 1).—The results are reported of experiments conducted to determine the relative advantages of reseeding and not reseeding oat fields severely injured by late spring frosts.

In the spring of 1918, when late heavy frosts had largely destroyed the parts above ground of growing oat plants, one-half of a plat laid out in one of the frost-damaged fields was reseeded June 8, while on the other half the frosted crop was allowed to remain. The reseeded half produced 59 per cent more straw and 103 per cent more grain than were secured fom the other half of the plat. It was found also that the crop when cut from the reseeded half contained only 2 per cent of weed plants as compared with 45 per cent for the half with the frost-damaged crop.

Potato experiments, 1917 and 1918, H. O. WEENER (North Dakota Sta. Bul. 129 (1919), pp. 3-22, figs. 3).—Variety tests conducted at several points in the State and cultural experiments made at Fargo are described. The results of the variety tests are held to indicate that Irish Cobbler potatoes might well be grown to a greater extent, while Burbank is deemed unsuited to North Dakota conditions.

Experiments with different sized seed pieces indicated that the best average results are secured from 1.5 oz. seed pieces. The selection of seed potatoes from the bin is regarded as much less satisfactory than hill selection. Little difference was observed in the comparative value of buds from various parts of the tuber, or between seed pieces having 1, 2, or 4 eyes. In a comparison of different methods of cutting seed potatoes, the maximum yield, 275.7 bu. per acre, was secured from hand cutting with the cuts made just above the bud and slanting toward the stem end of the tuber. The rapidity of emergence of shoots showed little difference for seed pieces of different sizes, for pieces from various parts of the tuber, for pieces with 1, 2, or 4 eyes or for seed cut in different ways, except that tubers quartered lengthwise were much slower than the others.

In 1918 the highest yield, 259.1 bu. per acre, was secured from the earliest planting (May 4). In spacing experiments made during 1918 the net yield decreased as the area per plant increased. The total yields ranged from 195.7 bu. per acre for a planting distance of 2.5 ft. between rows with 24 in. between plants to 373.4 bu. for a distance of 2 ft. between rows and 6 in. between plants. Seed treatment and spraying with Bordeaux mixture resulted in increased yields on both manured and unmanured plats, this being more marked on the former than on the latter. Hilling potatoes reduced the yield as compared with level cultivation.

In a study of the time and rate of tuber growth in Green Mountain potatoes during 1917, the total yield secured August 10 was 121.6 bu. per acre as compared with 220 bu. on September 11 when the vines were killed by frost. The daily increase during the first 10-day interval was found to be 2.34 bu. per acre, and during the last 3-day interval 5.27 bu.

The prickly pear in Australia, W. B. ALEXANDER (Aust. Inst. Sci. and Indus. Bul. 12 (1919), pp. 48, pl. 1, figs. 16).—This comprises a somewhat detailed account of the introduction and spread of the prickly pear, particularly the socalled pest pear (Opuntia inermis) in Queensland and New South Wales, together with a discussion of its utilization and of methods of eradication. The use of arsenicals either as a spray or as a gas is said to have given the most promising results.

Probable material for the study of the experimental evolution of Oryza sativa, var. plena, R. K. BHIDE (Agr. Jour. India, 14 (1919), No. 3, pp. 494-499, pls. 2).—Variations in different varieties of rice grown at Alibag (India) tending toward the so-called double grain rice or O. sativa, var. plena are described. The possibility of developing the double grain type from an ordinary variety without crossing is indicated.

**Propagating sorghum by cuttings**, A. PIÉDALLU (*Bul. Soc. Natl. Acclim. France*, 66 (1919), No. 1, pp. 15-17).—The author states that sorghum can be readily propagated by means of cuttings of the stem and that desirable varieties can thus be maintained in a pure state.

The effect of soy bean germination upon the growth of its nodule-forming bacteria, A. R. C. HAAS and E. B. FRED (Soil Sci., 7 (1919), No. 3, pp. 237-243, pl. 1).—In this paper, a contribution from the Wisconsin Experiment Station, the authors describe investigations in which a study was made of the toxic effect of the germination of soy bean seeds upon the growth of nodule bacteria inoculated upon the seed coat. The studies also involved observations on various methods of sterilizing soy bean seeds.

The results secured are held to indicate that the germination of soy bean seed favors the growth of the nodule bacteria. When bacteria-free seeds were obtained directly from the pods and inoculated with soy bean bacteria, no toxic action of substances excreted from the germinating seed upon the growth of the nodule bacteria was observed. It was also found that the use of mercuric chlorid as a sterlizing agent in studies of this sort is not permissible.

Louisiana seedling canes, W. G. TAGGART (Sugar [New York], 21 (1919), No. 8, pp. 426-429, 439).—This describes the continuation of work previously noted (E. S. R., 26, p. 235) in an effort to develop varieties of sugar cane in Lousiana.

It is stated that since 1911, 164 lots of cane seed have been received from which 887 varieties have been tested in the field. Only one variety, L 974, surpassed L 511, the leading variety up to 1911, in the sucrose content of the juice. L 974 produced 14.05 per cent sucrose in the fall of 1918, as compared with 13.86 per cent for plant cane and 15.29 per cent for stubble of L 511.

The effect of salinity on the growth and composition of sugar cane varieties, K. KRISHNAMURTI Row (Agr. Jour. India, 14 (1919), No. 3, pp. 476-493, pls. 8, fig. 1).—The author describes observations made at the Coimbatore (India) cane breeding station during the period of 1914-1918, inclusive, on the effect of a saline condition of the soil upon different varieties of sugar cane.

It is stated that soft, thick, juicy varieties failed to develop at all on saline land, while thin, hard, less juicy sorts made a fair growth. Sodium chlorid was found to be the limiting factor involved. Irrigation with saline water resulted in impure juice containing large amounts of chlorin and potash.

A method for the direct determination of chlorin in the juice by means of lime water and alumina cream is described and is said to give satisfactory results for field work. Large quantities of chlorin in the juice lowered the sucrose and glucose contents as well as the purity of the juice.

[Proceedings of the Hawaiian Sugar Planters' Association] (*Proc. Hawaii.* Sugar Planters' Assoc., 38 (1918), pp. 346, pls. 3, figs. 20).—This comprises a report of the thirty-eighth annual meeting of the association held at Honolulu during December, 1918. Committee reports dealing with the following subjects were presented and discussed: Forestry; cultivation, fertilization, and irrigation on irrigated plantations; cutting, loading, and general transportation; manufacturing machinery; labor saving devices; the sugar-cane experiement station; sugar manufacture and utilization of by-products; agricultural machinery and implements; and cultivation and fertilization on unirrigated plantations.

Hereditary flower anomalies in tobacco, G. KLEBS (Ztschr. Induktive Abstam. u. Vererbungslehre, 17 (1916), No. 1-2, pp. 53-119, pl. 1, figs. 16; abs. in Genetica [The Hague], 1 (1919), No. 2, p. 187).—The author describes the appearance of a flower anomaly in Nicotiana tabacum which he designates lacerata, and traces its behavior through various crosses. The lacerata form is said to agree with the original stock in all vegetative characters, while the flowers are abnormal, having strongly petaloid calyx somewhat thickened at the base and in many cases exhibiting a torn or divided corolla.

A bibliography of 44 titles is appended.

An improved strain of Wisconsin tobacco: Connecticut Havana No. 38, J. JOHNSON (Jour. Heredity, 10 (1919), No. 6, pp. 281-288, figs. 3).—In this paper, a contribution from the Wisconsin Experiment Station, the author traces the development of a commercial type of tobacco.

A cross made in 1909 of two strains of tobacco designated as 26 and 27, respectively, and said to be mutants from common Connecticut Havana, gave rise to a strain (No. 38) said to possess considerable commercial value. The

chief advantages claimed for No. 38 are the quite erect leaves of uniform size from top to bottom of the plant, being somewhat broader in proportion to their length than ordinary Havana leaves; the presence of one or two leaves more to the plant, on the average, than Havana, together with a greater average size of leaf; and an estimated yield of from 7 to 10 per cent more than ordinary Havana. The quality is said to be equal to that of Connecticut Havana. It is also estimated that approximately one-fourth of the total acreage devoted to tobacco in Wisconsin will be grown to this type in 1919.

The Canadian water weed as a fodder plant (Jour. Bd. Agr. [London], 26 (1919), No. 3, pp. 321, 322).—The utilization of Canadian water weed or water thyme (Elodea canadensis) for silage is briefly discussed.

Harmful effects upon germination of the formalin treatment for seed, L. KIESSLING (Jour. Landw., 66 (1918), No. 1, pp. 7-51).—The author discusses in considerable detail the effect upon germination of dipping winter and spring wheat and oats in formalin solutions of different strengths and for varying lengths of time, together with observations on the effect of the treatment upon injured grain and upon moist stored grain.

[Proceedings of the American Seed Trade Association] (*Proc. Amer. Seed Trade Assoc., 36* (1918), pp. 126, pl. 1).—This comprises an account of the thirty-sixth annual convention of the association held in Chicago during June, 1918. In addition to committee reports and other business the following papers were presented and discussed: Seed Reporting as a Public Service, by W. A. Wheeler; Persistent Varietal Character in Garden Vegetables, by W. W. Tracy; The Home Garden as a Means of Increasing the Food Supply, by W. R. Beattie; Community Building in War Times, by A. K. Lovrien; and Some Immediate Responsibilities of the Seed Trade, by R. A. Oakley.

Seed growing in Great Britain (Jour. Bd. Agr. [London], 26 (1919), No. 3, pp. 318-321).—This comprises a brief account of the industry in Great Britain with special reference to vegetable seed production.

The control of weeds in field crops, E. KORSMO (*Tidsskr. Norske Landbr.*, 26 (1919), No. 5, pp. 193-227, figs. 20).—This article discusses combating weeds in field crops by means of seed treatment, cultivation, spraying, and fallowing, and reports the results of a number of experiments along some of these lines. Directions are given for the preparation of the solutions used in seed treatment and spraying.

In 1917, the results of experiments with wheat and rye showed the following average increase in grain yield under the different methods of weed control: Harrowing once before the plants appeared above ground 18 per cent, spraying with iron sulphate solution 24 per cent, dusting with cyanamid 24.25 per cent, spraying with sulphuric acid solution 28 per cent, and hand weeding 27 per cent.

Experiments were conducted for four years with potatoes for the comparison of clean, ordinary, and no culture as affecting the percentage production of large and small tubers as well as the starch content. Clean culture by means of cultivation and weeding gave 83.5 per cent of large tubers, the removal of the weeds without cultivation gave 81.2 per cent, ordinary culture 78.3 per cent, and no cultivation or weeding during the growing period 39.1 per cent. The starch content ranged from 15.8 per cent in the tubers grown under clean culture with cultivation and seeding to 16.5 per cent in those grown without any cultivation or weeding.

A similar series of experiments was carried on with turnips, kohl-rabi, and carrots. Clean culture by means of cultivation and weeding gave on the average 29 per cent more turnips, 26 per cent more kohl-rabi, and 54 per cent more car-

rots than were secured with ordinary cultivation. Keeping these crops clean by hand weeding as compared with no cultural treatment increased the yield of turnips 153 per cent, of kohl-rabi 131 per cent, and of carrots 193 per cent. In all these tests also higher yields of foliage were recorded where the crops were kept free from weeds.

The results of tests with cultivated and uncultivated fallow are reported as largely in favor of cultivation, either on the level or in ridges. Ridging the fallow together with deep plowing in 1917 resulted in 1918 in an increase of 134.5 per cent of grain and of 80 per cent of potatoes as compared with the yields secured on the uncultivated fallow. On the level or flat cultivated fallow the corresponding increases in yield were 102.3 and 85 per.cent. The proportion of straw in the grain crops was decreased on both types of cultivated fallow.

#### HORTICULTURE.

**Report of the professor of horticulture,** P. J. SHAW (Ann. Rpt. Sec. Agr. Nova Scotia, 1918, pt. 1, pp. 75–100, pl. 1).—Notes on cultural and varietal experiments with fruits and vegetables conducted at the Nova Scotia Agricultural College Farm.

A comparative study of the development of lettuce in the sunshine and in the shade, L. DANIEL (*Compt. Rend. Acad. Sci.* [*Paris*], 168 (1919), No. 13, pp. 694-697).—During the years 1917 and 1918 the author grew lettuce plants of the same kind in similar soils, one plat being in the open light and the other in the shade.

Observations made on the plants of both plats showed that the attenuated light caused the orbicular leaves of the rosette to become elongated and, at the same time, tended to prevent heading. This effect increased as the light was reduced. In other respects, when the optimum exists for the various other development factors, the lettuce behaves like other plants submitted to attenuated light. There is a direct correlation between the respective developments of the vegetative and reproductive parts. If the water supply is reduced the inhibitory action of the light on growth under semishade is more or less quickly compensated, then destroyed. The height of the plant is reduced at the same time that the sexual reproductive faculties rapidly weaken. Therefore, within the limits of optimum illumination, there must be a complete harmony of other development factors, especially water supply, to assure the maximum of development.

Acclimatization trials of Lima beans (Phaseolus lunatus), E. MATHIEU (Garden's Bul. Straits Settlements, 2 (1919), No. 4, pp. 121–129).—Notes are given on tests conducted with several American varieties of Lima beans in the Straits Settlements during the years 1918–19. Two subsequent generations of seed raised in the Straits Settlements from the imported seed were also tested. Results in general indicate that the bean has not suffered degeneration through change of climate and habitat, and it may now be considered as acclimatized.

The influence of soil on the saccharine content of cider apples, A. TRUELLE (Ann. Sci. Agron., 4. ser., 8 (1919), No. 4-6, pp. 107-116).—Analyses collected during several years are given of cider apples grown on plateau, hillside, and valley soils. A study of these data as a whole indicates that soil situation has only a relatively small influence on the sugar content of the apple.

A further note on the genetics of Fragaria, C. W. RICHARDSON (Jour. Genetics, 7 (1918), No. 3, pp. 167-170).—In continuation of a previous note (E. S. R., 30, p. 740), notes are given on crossing experiments with strawberries, which were started in 1910. In addition to a discussion of character

inheritance the author presents some notes on the technique of crossing, based on his own experiences.

Thus far the author has failed to find a case of a female flowering plant becoming male or hermaphrodite; whereas it is almost impossible to say that a given apparently male plant will not set an occasional well-developed fruit or an occasional seed. The crossing of species has not resulted in any fruit markedly larger than either of its original parents. No free fruiting plants have been obtained from crosses made with  $vesca \times daltoniana$ , garden varieties, and *chiloensis*. The author is inclined to believe that vesca has nothing to do with the present garden varieties.

Berry fruits and berry wines, M. LEBL (Beerenobst und Beerenwein. Berlin: Paul Parey, 1915, 3. rev. ed., pp. VI+114, figs. 39).—A treatise, revised by G. A. Langer, on the culture of bush and cane fruits, strawberries, and rhubarb, including directions for making wine and fruit juices.

The limits in hybridization of Vitis rotundifolia with related species and genera.—First report, L. R. DETJEN (North Carolina Sta. Tech. Bul. 17 (1919), pp. 5-26, figs. 3).—A brief review of the work of earlier grape breeders, with special reference to the hybridization of V. rotundifolia, and an account of work done along this line at the station from 1912–1918, inclusive. A list of cited literature is gven.

The work thus far conducted at the station shows that V. rotundifolia will hybridize with V. munsoniana and some species of Euvitis, namely V. vinifera, V. bourquiniana, V. labrusca, V. cordifolia, and V. æstivalis, also with the varieties Winchell, Concord, and others. The limits of hybridization have not been established, but the results indicate what may be expected in hybridizing rotundifolia with the above related species and genera.

Rotundifolia will also hybridize with its own  $F_1$  hybrids with other species of Vitis. When used as the male parent it will hybridize quite readily with some species of Euvitis, but when used as the female parent it will hybridize only rarely. Certain combinations are more congenial for hybridization than others. Rotundifolia failed to hybridize either way with such related genera as Parthenocissus quinquefolia, P. tricuspidata, or Ampelopsis heretophylla var. elegans.

Other species are to be reported on later as time and material permits, but the author considers that it is doubtful whether *rotundifolia* will hybridize with all species of Vitis.

Some  $F_1$  hybrids of Vitis rotundifolia with related species and genera, L. R. DETJEN (North Carolina Sta. Tech. Bul. 18 (1919), pp. 51, figs. 33).—During the course of the above-noted study numerous hybrid plants of different parentage have been produced. This bulletin gives a list of nine parental combinations effected and describes and illustrates the characters of several hybrid vines. A general survey is then given of the hybrid characters in  $F_1$ , and the status of so-called "false hybrids" is discussed.

A careful study of hybrids derived from V. rotundifolia and such other species as V. vinifera, V. labrusca, V. bourquiniana, V. cordifolia, and the hybrid variety Winchell indicates that they are generally more or less intermediate in character. The Rotundifolia group when hybridized with Euvitis species is less prepotent as to external characters than has generally been supposed. Such hybrids are almost sterile, and this sterility is due mainly to hybridization, especially in perfect hermaphrodite forms. In the imperfect hermaphoditic and staminate vines, sterility is due to the double phenomenon of sex or intersexualism and hybridization.

153351°-20-4

A number of so-called "false hybrids," originated by T. V. Munson, and described in Foundations of American Grape Culture (E. S. R., 22, p. 42) were grown in the station collection under constant observation for nine years. It is concluded that these "false hybrids" are in reality not hybrids, but straight seedlings of the supposedly dominant parent species, V. rotundifolia and V. munsoniana.

The hybrid direct bearers for the reconstitution of vineyards, E. ROUART and L. RIVES (*Les Hybrides Producteurs Directs pour la Reconstitution du Vignoble. Paris: Libr. Agr. Maison Rustique, 1918, pp. 132, figs. 17*).—The authors briefly review the work of viticultural investigations in hybridizing American and European grapes, with the view of producing varieties resistant to phylloxera, chlorosis, mildew, etc., discuss the importance of this work to the grape industry in France and give descriptive notes on hybrid direct bearers produced by various breeders. The concluding chapters contain details relative to the culture of these hybrids, notes on wines produced from them, and a classification by color and earliness of the hybrids studied.

The acidity of the sap in some grapevines and their resistance to disease, M. DEGLI ATTI (Ann. R. Scuola Sup. Agr. Portici, 2. ser., 14 (1916), pp. 16).— An analytic study of the sugar and acid content of several European and American varieties of grapevines leads the author to conclude that there is a direct relation between the disease resistance of vines and the acidity of their sap.

Late maturing vines, which were more subject to parasitic attack than early maturing vines, have a relatively low-acid content in the sap, a high sugar content, and organs rich in oxidases. Earlier maturing vines, on the other hand, were either immune or less subject to parasitic attack. They had a relatively high acid and low-sugar content and organs poor in oxidases. The early maturing class included certain early European varieties, the American varieties, and phylloxera infested vines. Reduced root activity, due to phylloxera attack, tends to precocious maturity and a high acid content.

The growing, pruning, and care of grapevines in cold climates, on walls, espaliers, and in grape houses, R. BETTEN (*Erziehung Schnitt und Pflege des* Weinstocks im Kälteren Klima an Wänden, Spalieren, und in Rebhäusern. Frankfort on the Oder: Trowitsch & Son, 1919, 4. ed., rev. and enl., pp. VIII+ 172, j 78. 152).—A practicable treatise on grape culture, both outdoors and under glass, with special reference to German conditions.

[H rticultural investigations in the Gold Coast, 1916 and 1917], W. S. D. TUDHCPE ET AL. (Govt. Gold Coast, Rpt. Agr. Dept., 1916, pp. 3, 4, 5, 14, 16-19, 23, 24, 25, 26, 28, 30, 31, 35, 36, 37, 38, 39, 42, 43, 44, 48, 49, 50, 51, 52, 55, 56; 1917, pp. 3, 4, 5, 7, 10, 11, 13, 16-18, 23, 24, 25, 28, 29, 31, 32, 38, 39, 42, 43, 44, 45, 48, 49, 54, 55, 56, 57, 59, 60, 61).—Progress reports on cultural experiments with cocoa, cola, coconut, coffee, and other economic plants in the various agricultural stations and substations in the Government of the Gold Coast.

The anay, a new edible-fruited relative of the avocado, S. F. BLAKE (Jour. Wash. Acad. Sci., 9 (1919), No. 16, pp. 457-462, fig. 1).—A general account, together with a botanical description and illustration, is given of the anay, an avocado-like fruit collected by W. Popenoe in Guatemala.

The author's study of the branchlets, leaves, and floral parts of this fruit shows it to belong to the genus Hufelandia, and it is here described as *H. anay* n. sp. The fruit of the anay resembles certain avocados in its ellipsoidpyriform shape and general appearance. The skin is smooth, glossy, purplish black in color, and is very thin and membranous, adhering closely to the firm, oily, rather scanty flesh. The flesh has a rich, bland flavor like that of a very good avocado, but is faintly sweetish. The anay grows in moist regions of Guatemala at an elevation of only 300 to 365 meters (984 to 1,197 ft.), hence Popenoe believes that it will not succeed in California, but that it may do well in southern Florida. Seedling trees are now being cultivated in the Plant Introduction Garden at Miami.

A related species, *H. ovalis* n. sp., collected by H. Pittier in Costa Rica several years ago, is also described.

Further observations upon the application of manure in citrus orchards with the furrow-manure system, A. D. SHAMEL (*Cal. Citrogr.*, 4 (1919), No. 12, pp. 332, 333, figs. 8).—The author here describes and illustrates a cheap homemade plow, which has been found to make a much more satisfactory furrow than the ordinary walking plow in applying manure by the furrow-manure system (E. S. R., 40, p. 246). This system is coming into increasing use in California in citrus orchards.

Efficiency in citrus irrigation, F. M. EATON (Chula Vista, Cal.: The San Diego Land Corporation [1919], pp. 16, figs. 10).—The author emphasizes the need for greater efficiency in orchard irrigation, and analyzes a few of the factors which must be considered before proper irrigation is possible. Much of the data presented has special application to the Chula Vista district of California.

Yields of Washington navel oranges in relation to pruning, G. SURR (Cal. Citrogr., 4 (1919), No. 11, pp. 290, 325).—A contribution from the California Citrus Station describing pruning experiments started by the station in 1915 on a 20-acre grove of Washington navel orange trees, and giving the yields for the four years 1916–1919 under different methods of pruning.

The average total yields for the four seasons are 100 lbs. per tree lower on heavily pruned trees than on lightly pruned trees. The results, in general, suggest that any improvement in the quality of fruit due to pruning may be more than offset by the greater cost of the resulting smaller crop. Light pruning, in this experiment at least, was more satisfactory than heavy pruning.

Immature citrus fruits: Laws, rules, and regulations, R. E. Rose (*Tallahassee*, *Fla.: T. J. Appleyard*, 1918, rev., pp. 24, fig. 1).—This pamphlet contains laws, rules, and regulations defining immature citrus fruits and fixing standards for mature citrus fruits, together with the rules, regulations, and methods for applying the "ratio of acid to total solids" test by inspectors. Instructions to growers for applying the test are also given.

Cocoa production in the British Empire (Bul. Imp. Inst. [So. Kensington], 17 (1919), No. 1, pp. 40–95).—A comprehensive account of the present production of cocoa within the British Empire, including also statistics on cocoa production in foreign countries.

First report on activities in connection with the selection of coffee and cacao, G. STAHEL (*Dept. Landb. Suriname Bul. 36* (1919), pp. 24).—An account of work accomplished in the selection and recording of high-yielding trees, the propagation of stocks, and budding and grafting, and in the increase of propagating wood on particularly good yielding trees.

Improvement of coffee by seed selection and hybridization, R. D. ANSTEAD (Agr. Jour. India, 14 (1919), No. 4, pp. 639-644).—A paper on this subject in which the author calls attention to some results of hybridization and selection work with coffee in the Dutch East Indies and South India.

At Dubari, A. H. Jackson has produced a hybrid which is fertile and comes true to seed. It is a vigorous, healthy type of *arabica* coffee, apparently disease-resistant to a high degree. It comes into bearing early and gives a high yield. Manuring experiments in tea garden, IV, C. BERNARD and J. J. B. DEUSS (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Proefsta. Thee, No. 62 (1919), pp. 29, pls. 2, figs. 8).—Manuring experiments conducted in a number of tea gardens in Batavia during the years 1916–17 are reported.

The walnut tree, its propagation and care, F. SCHÖNBERG (Der Walnutzbaum, Seine Anzucht und Pflege. Stuttgart: Eugen Ulmer, 1917, pp. VII+77, figs. 35).—A short treatise on the culture of the Persian walnut (Juglans regia), including a description of the more important varieties.

The National rose test-garden in 1918, F. L. MULFORD (Amer. Rose Ann. 1919, pp. 116-122).—This report covers the two principal groups of cut-flower roses, the Hybrid Perpetuals and the Teas and their hybrids, for the seasons 1917 and 1918 as far as the different varieties were available for observation during this period. The data given show the year when received, general average height of the plant, growth habit, growth of the foilage, time of first bloom, and average number of blossoms per plant each month during the growing period.

Frank N. Meyer's rose contributions, P. BISSET (*Amer. Rose Ann. 1919, pp. 38-41, pls. 2*).—A brief account of the various rose species collected by F. N. Meyer during his Chinese explorations. Reference is also made to a number of other ornamentals, as well as fruits and nuts, collected by Meyer.

**Rose-breeding notes for 1918**, W. VAN FLEET (*Amer. Rose Ann. 1919, pp. 29–34*).—A progress report on breeding investigations conducted by the author during 1918 at the Bell Experiment Plat, Glenn Dale, Md. The breeding work is being conducted primarily for the production of hardy garden varieties.

**Fragrant roses**, W. VAN FLEET (*Amer. Rose Ann. 1919, pp. 14–20*).—A general discussion of various types of fragrant roses and various forms of rose fragrance and the production of attar of roses. A list is given of species and varieties that have proved themselves satisfactory to the author from the standpoint of fragrance.

Monograph on the doubling phenomenon in tulip flowers, K. OETLEPP (Monographie der Füllungserscheinungen bei Tulpenblüten. Leipzig: Theod. Oswald Weigel, 1915, pp. VI+267, pls. 3, figs. 8).—In this monograph the author presents in detail the results of long-continued studies relative to the method and nature of doubling in tulip blooms. In part 1 is described various forms of doubling and the method of doubling in different kinds of tulips. Part 2 describes the cultural experiments conducted and the influence of various cultural methods upon doubling. Appended to the monograph are notes on the culture of tulips in beds and the forcing of tulips in pots and under glass.

Briefly summarized, the author's investigation shows that the intensity and method of doubling in tulips is quite variable. The flowers of daughter bulbs are only occasionally double like those of the mother bulbs, and the flowers of the sister bulbs rarely ever show similar doubling.

All floral parts are, in their development and number, undergoing a continuous change from generation to generation. Cultural experiments conducted for a number of years show that rich manuring causes an increase, and moderate and no manuring a decrease in doubling. Doubling was specially stimulated by manures having a high nitrogen content.

Tulips and their ways, W. R. DYKES (Gard. Chron., 3. ser., 66 (1919), Nos. 1703, pp. 89, 90, figs. 4; 1705, pp. 113, 114, figs. 4).—A discussion of the growth behavior of the wild species of tulips.

Small atlas of wild, useful plants, W. OBERMEYER (Schreibers Kleiner Atlas der Wild-Nutzpflanzen. Munich: J. F. Schreiber [1918], pp. 36, pls. 12, fig. 1).— The atlas contains colored illustrations of wild vegetables, berries, fruits, and other useful plants, including notes on their distinguishing characteristics and uses.

Our more important wild, medicinal, aromatic, and tea plants, H. Ross (Unsere Wichtigeren Wildwachsenden Heil-, Gewürz- und Teepfanzen. Munich: Natur und Kultur, 1918, pp. 128, figs. 51).—A descriptive account of the native medicinal, aromatic, and tea plants of Germany, including information relative to their cultivation and use.

### FORESTRY.

Annual report on the progress, literature, and important happenings in the realms of forestry, hunting, and fishing for the year 1914, H. WEBER (Allg. Forst u. Jagd Ztg., 1915, Sup., pp. VIII+148).—In continuation of previous reports (E. S. R., 33, p. 49), this supplement contains abstracts of the more important world literature dealing with various phases of forestry, together with notes on the principal occurrences relating to forestry, hunting, and fishing during 1914.

Massachusetts and her forests, F. W. RANE (*Boston: State, 1919, pp. 7*).— A brief summary of the present status of forestry in Massachusetts, including recommendations relative to future forest policies.

Commercial forestry in Britain: Its decline and revival, E. P. STEBBING (London: John Murray, 1919, pp. VI+186, pl. 1).—The author reviews the history of forestry in Great Britain since the days of the Roman occupation, discusses the present and future position as regards the provision of timber supplies essential to the industries of the country, and then examines the afforestation problem in its various aspects. Afforestation is considered under the following general headings: What afforestation will do for the people, what afforestation will do for the Nation, forestry, and agriculture, the protection of the afforested areas, forestry education, State owned v. privately owned forests, and the afforestation schemes.

Forest-making in the United Kingdom, S. L. BASTIN (Jour. Bath and West and South. Counties Soc., 5. ser., 13 (1918–19), pp. 45–54).—The author considers the problem of reforestation in Great Britain and gives a descriptive list of some of the most valuable timber trees that are especially suitable for planting in that country.

[Report of the] mission for the study of forest conditions sent to the French Colonies by the ministries of war, armament, and the colonies.—I, The woods of the Ivory Coast; II, The woods of Gabon, A. BERTIN ET AL. (Mission d'Etudes Forestières Envoyée dans les Colonies Francaises par les Ministères de la Guerre, de l'Armement, et des Colonies.—I. Les Bois de la Côte d'Ivoire; II. Les Bois du Gabon. Paris: Govt., 1918, vols. 1, pp. [10]+179, pls. 9, figs. 2; 2, pp. [7]+307, pls. 18, fig. 1).—During 1916 and 1917 the senior author headed a Government mission to the French Colonies of East Africa to study the possibilities of exploiting the colonial forests. The two volumes here noted give the results of studies made in the Ivory Coast and in Gabon.

In the Ivory Coast some 62 species and in Gabon some 90 species were selected by the mission as being of practical value for replacing European woods, some for general industrial uses and others for special uses. Information is given relative to the local and technical nomenclature of these woods, their physical properties, uses, distribution, and supply.

The native forests of western Australia, M. ZALOCOSTAS (Ann. Gembloux, 25 (1919), Nos. 2, pp. 60-75; 3, pp. 98-109).—An account of the native forests of western Australia and the economic importance of their products, including

descriptions of a number of species which the author believes to be suitable for reafforestation in the Mediterranean Basin.

Administration report of the forest circles in the Bombay Presidency, including Sind, for the year 1917–18 (Admin. Rpt. Forest Circles Bombay, 1917–18, pp. II+178+3).—A progress report on the administration and management of the State forests in the Northern, Central, Southern, and Sind Circles of the Bombay Presidency, including a financial statement for the year 1917–18. All important data relative to alterations in areas, forest surveys, working plans, miscellaneous work, yields in major and minor forest products, revenues, expenditures, etc., are appended in tabular form.

Report on the forest administration of the Central Provinces for the year 1917-18, M. HILL (*Rpt. Forest Admin. Cent. Provs.* [*India*], 1917-18, pp. 10+35+LXXI).—A report similar to the above relative to the administration of the State forests of the Northern, Southern, and Berar Circles of the Central Provinces for the year 1917-18.

Annual administration report of the forest department of the Madras Presidency for the twelve months ended June 30, 1918, H. A. LATHAM, H. B. BRYANT, P. M. LUSHINGTON, and C. D. MCCARTHY (Ann. Admin. Rpt. Forest Dept. Madras, 1918, pp. 80+LVII+11).—The usual progress report (E. S. R., 38, p. 846) relative to the administration of the State forests in the Northern, Central, Southern, and Western Circles.

**Progress report of forest administration in the Punjab for the forest year** 1917-18, R. MCINTOSH (*Rpt. Forest Admin. Punjab, 1917-18, pp.* [12]+13+LI, *pl.* 1).—A report similar to the above relative to the administration of the State forests of the Punjab for the year 1917-18.

**Report** on the forest administration of the United Provinces for the year 1917-18, P. H. CLUTTERBUCK (Ann. Rpt. Forest Admin. United Provs. India, 1917-18, pp. [6]+44+LX+7).—A report similar to the above relative to the administration of the State forests of the United Provinces, including a financial statement for the forest year 1917-18.

Influence on the dimension of trees on the efficacy of the thinning, E. MER (*Rev. Eaux et Forêts, 57 (1919), Nos. 7, pp. 141–146; 8, pp. 165–175).*—Investigations conducted by the author with stands of fir indicate that in order to secure maximum results from thinning the operation should be started when the trees are young. It is concluded that most thinnings are conducted too late, and the resulting stands are consequently less productive.

Notes on acacia, II-III, J. H. MAIDEN (Jour. and Proc. Roy. Soc. N. S. Wales, 51 (1917), pp. 71-124, 238-274, pls. 4).—Continuing the series previously noted (E. S. R., 36, p. 45), the first of these articles consists of a contribution to the bibliography of the genus Acacia in tropical Western Australia, including descriptions of new species of Acacia. The second article deals similarly with extra-tropical Western Australia.

Flower development and branch growth of the red beech (Fagus sylvatica), M. BÜSGEN (Ztschr. Forst u. Jagdw., 48 (1916), No. 6, pp. 289-306, figs. 18).— The results of a study of reproduction and growth in the red beech are presented.

Notes on Eucalyptus, with a description of a new species, V, J. H. MAIDEN (Jour. and Proc. Roy. Soc. N. S. Wales, 51 (1917), pp. 445-466).—In continuation of previous papers (E. S. R., 36, p. 45), supplementary notes are given on several species of Eucalyptus, and a new species, *Eucalyptus stowardi*, is described.

Some ironbarks of New South Wales, R. T. BAKER (Jour. and Proc. Roy. Soc. N. S. Wales, 51 (1917), pp. 410-422, pls. 5).—According to the author

*Eucalyptus paniculata*, as previously systematically placed, includes four distinct timbers varying in color and other qualities. It is here proposed to take the white, gray, or light chocolate-colored timber as the type *E. paniculata* and to give specific rank to the other three timbers as follows: Bloodwood-bark ironbark (*E. fergusoni* n. sp.), pink ironbark (*E. nanglei* n. sp.), and narrow-leaved ironbark (*E. beyeri* n. sp.).

These species are described and illustrations are given of the fruits and the color and texture of the woods.

[Rubber investigations on the Gold Coast, 1916 and 1917] (Govt. Gold Coast, Rpt. Agr. Dept., 1916, pp. 3, 4, 6, 7, 8, 15, 16, 20, 25, 26, 27, 29, 30, 31, 32-34, 35, 37, 38, 40, 42, 43, 48, 49, 52, 55, 56; 1917, pp. 3, 5, 6, 7, 12, 23, 24, 25, 27, 30, 31, 32-37, 39, 41, 42, 45, 46, 47, 54, 55, 57, 59, 60, 61).—Progress reports on cultural and tapping experiments with various kinds of rubber at the various agricultural stations and substations in the Government of the Gold Coast.

On the occurrence of crystals in some Australian timbers, R. T. BAKER (Jour. and Proc. Roy. Soc. N. S. Wales, 51 (1917), pp. 435-444, pls. 9).—Out of 22 orders of Australian trees examined, calcium oxalate crystals were found to occur in the secondary wood of 15. A descriptive list is given of the species in which crystals were found, including illustrations of microsections of the wood showing the crystals.

# DISEASES OF PLANTS.

Studies on Fusarium diseases of potatoes and truck crops in Minnesota, G. R. BISBY (*Minnesota Sta. Bul. 181 (1919)*, pp. 5-58, figs. 30).—Results are given of the study of Fusarium diseases of potatoes and truck crops, the investigations being made during the summers of 1916, 1917, and 1918. In addition to the rots of potato tubers, Fusarium diseases of peas, beans, sweet corn, various cucurbits, and tomatoes were studied.

The potato wilt, due to *F. oxysporum*, the Fusarium dry rot of the tubers, due very largely to *F. discolor sulphureum*, and the wilts of the various truck crops named above, are described. Studies were made on the effect of temperature, moisture, and other factors on the growth of the organisms. Results from cross inoculations are described, and suggestions made for control measures, particularly for the prevention of potato wilt and potato dry rot.

Cross inoculations seem to indicate that the wilt or root rot producing Fusaria may exhibit a selective tendency in their common occurrence on certain host plants, although they are semiparasitic in their action, being distinctly influenced by conditions unfavorable to the host plant. The isolations and cross inoculations made demonstrate that no single species of Fusarium is responsible for the common storage rots of vegetables, cucumbers, and tomato fruits. The author claims that all the organisms produced substances in old solutions that inhibited the germination of the same or other fungi. After boiling, such old solutions allowed normal germination. The species of Fusaria studied were found to withstand considerable desiccation and exposure to low temperatures or to alternate freezing and thawing, and can utilize a wide variety of food substances. Although many of the species are parasites, Fusaria are efficient saprophytes.

**Fungus diseases** [in Ceylon], T. PETCH (*Ceylon Agr. Soc. Year Book*, 1919-20, pp. 114-120).—This contains a general discussion of diseases and remedies therefor in such locally occurring plants as arrowroot, artichoke, okra, beans, beet, eggplant, crucifers, celery, chillies, cucumber, pumpkin, dhall (pigeon pea), peanut, horseradish, mustard, pea, and tomato.

Cooperation in plant quarantine service among (the) Pan American countries, J. R. JOHNSTON (*Proc. 2. Pan Amer. Sci. Cong.*, 1915–16, vol. 3, pp. 884– 888).—This discussion is in line with those previously noted (E. S. R., 41, p. 654). A short list of related publications is also given.

Concerning the introduction into the United States of extra limital wooddestroying fungi, J. R. WEIR (*Mycologia*, 11 (1919), No. 2, pp. 58-65).—Recent observations noted in part (E. S. R., 39, p. 357) regarding fungi as related to climatic modifications due to altitude are here cited to support the view that extended investigations in tropical countries are highly desirable in order to increase the safeguards against the importation of plant disease fungi, which may here find more favorable conditions and cause more injury than is usual to them in their native environment.

New Japanese fungi: Notes and translations, IV, T. TANAKA (Mycologia, 10 (1918), Nos. 2, pp. 86-92; 6, pp. 285-288; 11 (1919), Nos. 2, pp. 80-86; 3, pp. 148-154).—This continues the series formerly noted (E. S. R., 39, p. 753).

A novel method of ascospore discharge, D. ATANASOFF (*Mycologia*, 11 (1919), No. 3, pp. 125-128, figs. 3).—The author notes a method of ascospore discharge, observed in species of Pyrenophora and Pleospora, which is described as unique and somewhat complicated.

A study of some factors influencing the stimulative action of zinc sulphate on the growth of Aspergillus niger.—II, A comparison of two strains of the fungus, R. A. STEINBERG (Bul. Torrey Bot. Club, 46 (1919), No. 1, pp. 1–20, figs. 4).—Continuing previous work (E. S. R., 40, p. 222), the author publishes some results of interrupted work and observation involving two strains of A. niger which were continued for more than six months. The apparent effects of zinc are noted with discussion.

The author considers it probable that the differences apparent in the literature of the subject between the results obtained by different investigators are at least in part attributable to the use of strains having different zinc optima. The unrecognized presence of zinc in minute quantity may have been, it is thought, an additional factor in such cases.

Studies in the genus Gymnosporangium.—II, Report on cultures made in 1915 and 1916, B. O. DODGE (Bul. Torrey Bot. Club, 45 (1918), No. 7, pp. 287-300, pl. 1).—The author has followed up as far as 1918 his work related to that previously reported (E. S. R., 35, p. 244; 41, p. 152), and gives a tabulation with discussion of observations made on cultures of G. clavipes, G. macropus, G. globosum, G. ellisii, G. clavariæforme, G. juvenescens, G. nidusavis, G. transformans, and G. fraternum.

Studies in the genus Gymnosporangium.—III, The origin of the teleutospore, B. O. Dodge (*Mycologia*, 10 (1918), No. 4, pp. 182–193, pls. 3).—Having employed as material for this work some of the above-named fungi, the author gives an account with discussion of his observations. The origin of the teleutospores from the subterminal cells of the tissues composing the primordium has been shown to be a very common method in this genus of the rusts. The hosts attacked by the six species studied represent three species and two genera of conifers.

Take-all and flag smut, two wheat diseases new to the United States, H. B. HUMPHREY and A. G. JOHNSON (U. S. Dept. Agr., Farmers' Bul. 1063 (1919), pp. 8, figs. 4).—A popular description is given of take-all and flag smut, two diseases of wheat and other cereals which have recently been discovered in the United States. The take-all disease, which is attributed to Ophiobolus graminis, is believed to be identical with this disease in Australia and Europe. It first made its appearance in Madison County, Ill., and as reported July 25, 1919, it had been found in three counties in Illinois and three in Indiana. The flag smut, which is caused by *Urocystis tritici*, is reported from Madison County, Ill. Attention is called to these diseases in order that the occurrence might be reported and their possible spread prevented. Suggestions are given for their control, which are based largely on proper rotations, and for the flag smut the treatment of seed before planting.

[Earberry and wheat rust], E. M. FREEMAN (Minn. Hort., 46 (1918), No. 4, pp. 168–170, figs. 2).—This is a brief exposition of contrasts between the common barberry (Berberis culgaris) as a bearer of wheat rust and the Japanese barberry (B. thunbergii), which is harmless in this respect, with a discussion of the success attending the eradication of the former species, which is a host of the black stem rust.

Ear cockles in wheat, W. SOMERVILLE (Jour. Bd. Agr. [London], 25 (1918), No. 7, pp. 850–853, fig. 1).—In experiments carried out with the varieties Nursery and Dutch White Wheat, it was found that steeping for 24 hours in 1 per cent copper sulphate solution reduced nematode infection and gave a considerably increased percentage of sound grains.

Smut diseases of barley and oats, W. B. and S. P. MERCER (*Jour. Bd. Agr.* [*London*], 25 (1919), No. 12, pp. 1486-1493, pls. 2).—This paper is complementary to the one previously noted (E. S. R., 37, p. 839), and is intended to complete the account of smuts affecting the ordinary food cereals in England. The series concludes with a synoptic survey in tabular form of such diseases, their diagnostic symptoms, and appropriate treatments.

Segregation of susceptibility to parasitism in maize, D. F. JONES (Amer. Jour. Bot., 5 (1918), No. 6, pp. 295-300).—The inbred strains of maize reported upon by East and Hayes (E. S. R., 27, p. 428), continually selfed up to the time of this report, are said to show striking differences in the number of plants affected by the smut fungus (Ustilago zex) and an unidentified leaf blight organism. This organism in 1914 injured seriously a few inbred strains of flint maize and in 1916 affected the same strains in the same way, other selfed strains from different varieties in adjoining rows being almost entirely free from this organism. First generation hybrids of these susceptible strains with resistant types grown in the same field were only slightly affected. No plants showed in 1917 any injury from the leaf-blight fungus, but several strains were seriously attacked by smut. The data are tabulated for studies carried out on the susceptibility of strains differing as to genetic history.

The facts here recorded are considered as additional support to the hypothesis previously advanced by the author (E. S. R., 38, p. 367; 40, p. 226) that the increase in development commonly shown by hybrids is due to conjunctive action of a large number of favorable, dominant growth factors contributed by both parents. Vigor is thought to be, in this case, only a minor factor causing variation. The evidence from these inbred strains of maize and their first and second generation hybrids is thought to show that susceptibility is governed by factors capable of being segregated into some lines and not into others, the modification of the expression of parasitism by the vigor of the plants being a minor consideration.

A bacterial root rot of field corn, H. R. ROSEN (Arkansas Sta. Bul. 162 (1919), pp. 3-7, pls. 4).—A description is given of a disease of field corn which was observed by the author on a farm in this State. The characteristic feature of the disease is said to be shown when the stalks are cut through their long axis. The lower node or joints to which the roots are attached showed a purplish-brown discoloration on the cut surface, while the internodes preserved their normal white color. The extreme base of the stalk was similarly

discolored, and the brownish tissue was either dead or in the process of discoloration. From this tissue a bacterial organism was obtained, and inoculation experiments indicate that it was responsible for the trouble. The author reviews some of the literature pertaining to the bacteria which cause diseases of corn, pointing out some of the differences, but makes no attempt to describe the organism at present. Attention is called to a bacterial disease of foxtail previously described (E. S. R., 40, p. 643), but the organisms isolated from foxtail and corn roots and leaves have not been identified as the same species.

Seed potatoes and potato diseases, G. R. BISBY (*Minn. Hort.*, 46 (1918), No. 4, pp. 164–167, figs. 2).—In addition to precepts based on experiences regarding the maintenance and improvement of potatoes through breeding operations, the author gives an account of experiments carried on for some years with potato late blight. This disease was best controlled with Bordeaux mixture, the beneficial effects (as evidenced in the increased yield in case of Rural and Early Ohio) increasing with the concentrations employed ranging from a 2:2:50 to 5:5:50 solution.

Investigations on potato diseases, IX-X, G. H. PETHYBRIDGE (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 18 (1918), No. 4, pp. 410-416; 19 (1919), No. 3, pp. 271-292, pls. 2).—The continuation of this work (E. S. R., 39, p. 249) was still somewhat limited in scope during the season of 1917, though experiments were carried out at two stations, both in the County of Galway. The first outbreak of blight (*Phytophthora infestans*), noted June 12, was retarded by good weather, but August was favorable to the spread of blight. Spraying, however, reduced the loss considerably.

Burgundy mixture alone was used in 1917, this fungicide being more convenient to prepare and apply, equal to Bordeaux in efficacy, and generally preferred by farmers in Ireland. The differences observed as between the 1 and the 2 per cent strength were slight, though the latter is preferred where only two sprayings are employed and where cost of material is not the prime consideration.

Resistance was shown by a few varieties in marked degree. Clifden Seedling and Champion II were almost completely resistant, while "K" Seedling, Shamrock, and Northrn Invincible were less so. Great Scot, Provost, Kerr Pink, Dominion, and Burnhouse Beauty, though known to be immune to wart disease (black scab) (which is, however, absent from the west of Ireland), were not resistant to blight (*P. infestans*), to corky or powdery scab (Spongospora), or to pink rot (*P. erythroseptica*).

The work carried out in 1918 was also somewhat limited in scope, consisting chiefly in spraying trials against ordinary blight, though trials on a small scale with certain disease resistant varieties were carried on this year.

Conditions for the spread of blight were on the whole not very favorable. The efficacy of the 2 per cent and that of the 1 per cent Burgundy mixture were practically equal. A second and a third spraying were highly remunerative in every case; a fourth spraying was so in three cases and paid for itself in the fourth instance. Any physiological check attending the use of the spray was small and temporary. Substitutes for soda were tried with somewhat favorable but not conclusive results.

Blight resistance showed a general correspondence to the tendencies noted the previous year. Pink rot (*P. erythroseptica*) was very prevalent in some western districts in 1918, causing considerable loss. Varieties resistant to black scab (though not to pink rot) as named in order of their resistance were Kerr's Pink, Dominion, Burnhouse Beauty, Provost, and Great Scot.

Silver scurf (Spondylocladium atrovirens), which is of little importance beyond the results due to a slight skin blemish of the tuber, was widely prevalent in 1918. It was found difficult to control this trouble with formaldehyde solution without injuring the eyes. Mercuric chlorid solution at 0.1 to 0.2 per cent injured the tubers (without killing the fungus), causing at each lenticel a spotting appearance resembling pit rot, which is itself supposed to be caused by the entrance of some poisonous gas, vapor, or liquid. Experiments with heat showed that an exposure of cultures to temperature of  $43-43.5^{\circ}$  C. (109.4 to  $110.3^{\circ}$  F.) for 18 to 24 hours kills the fungus. However, tests with infected potato tubers showed that these are not able to endure treatments by heat sufficient to kill the fungus of silver scurf.

Leaf roll was not produced by heating seed tubers to 42 or 43° for 5, 12, 20, or 40 hours after a preliminary heating of 2 hours.

Pit rot is described. It is thought to be due neither to the fungi generally associated with the pits nor to bacteria, and it does not appear to be hereditary. A very similar or identical rot has been produced artificially. It is thought that some gas may be the cause of this rot, which, as above noted, starts at the eyes of the tubers. Ventilation of the pit and exclusion of diseased tubers are recommended.

Potato-spraying experiments at Wye College Fruit Experiment Station, East Malling, Kent, E. S. SALMON and H. WORMALD (*Jour. Bd. Agr.* [London], 26 (1919), No. 1, pp. 71-77, pl. 1).—Although the practice of spraying the main crop varieties of potatoes is almost invariable, that of spraying such second early varieties as British Queen has not become general, notwithstanding the fact that such varieties frequently suffer severely from blight. Field experiments were carried out during 1918 with this variety. It was found that, under certain seasonal conditions, one application of Bordeaux or Burgundy mixture resulted in loss on account of its lengthening the period of ripening without protecting the crop from blight; while, under the same seasonal conditions, two sprayings increased the yield  $2\frac{6}{3}$  and  $1\frac{1}{2}$  ton per acre for these two mixtures, respectively.

Blast of paddy, W. McRAE (Agr. Jour. India, 14 (1919), No. 1, pp. 65-70).— An account is given of the shortage of the 1918 second rice crop of the variety of rice (Oryza sativa) called Korangu Samba. This disease is described as being due to the fungus *Piricularia oryza*, which is noted as causing much damage to rice in certain other countries. The consensus of opinion connects the susceptibility of rice to this disease with the employment of nitrogenous fertilizers.

A disease of the yam, E. M. WAKEFIELD (Roy. Bot. Gard. Kew, Bul. Misc. Inform., No. 6 (1918), pp. 199-201, fig. 1).—A disease affecting Dioscorea prehensilis in the southern provinces of Nigeria is described. The disease attacks the stems, rarely the whole vine, preferring poor or swampy situations, and confining itself to the round-stemmed yams. The fungus is considered a new species of Bagnisiopsis, and is described under the name B. dioscorea.

Vegetable diseases and their remedies, G. B. HOERNER (*Minn. Hort.*, 46 (1918), No. 4, pp. 148-154, figs. 4).—This is an address to Minnesota vegetable growers, having in view the needs associated with the war conditions then existing.

**Preventing** winter injury to fruit trees, J. C. WHITTEN (*Minn. Hort.*, 46 (1918), No. 10, pp. 364-367).—In Missouri, as contrasted with Minnesota, winter injury to fruit trees is ordinarily due rather to the occurrence of warm, sunny days in winter than to extreme or continued cold. On such days thermometers inserted in a fruiting twig of a peach tree often registered from 15 to  $20^{\circ}$  higher than in the air around them, the result of this condition being that the buds swelled, became tender, and were thus liable to be killed during the cold nights which followed.

Spraying of twigs with whitewash kept these buds at the same temperature as the atmosphere by reflecting the sun's heat. As a result, the buds swelled and bloomed considerably later on these than on the unsprayed trees. In 10 years two crops are said to have been saved by this means, although this plan has not yet proved a commercial success. Other means of securing the desirable late and prolonged rest include severe pruning during the previous winter, judicious thinning of fruit, growing and turning under cowpeas, and otherwise maintaining the growth until late in the season.

The menace of silver leaf (*Jour. Bd. Agr.* [*London*], 25 (1918), No. 7, pp. 870, 871).—Reports indicate the increasing seriousness of silver leaf disease in fruit trees, this trouble almost amounting to a scourge in some localities, threatening with extinction some of the choicest varieties of plum, and attacking apples somewhat less frequently.

The only treatment found effective is early and thoroughgoing removal and destruction of all affected trees or parts thereof.

Growth of apple trees injured in the nursery by crown gall and woolly aphis, W. J. SCHOENE and R. R. REPPERT (*Quart. Bul. Va. State Crop Pest Comm.*, 1 (1919), No. 2, pp. 3-11, figs. 10).—In view of the indefinite state of opinion, information, and practice regarding the sale, shipping, and planting of nursery stock showing evidence of crown gall or woolly aphis, investigation was made of these features on an orchard planted in 1914 and partly dug out four years later.

It is found that hard crown galls on or near the graft union grow as rapidly as does the tree itself. Hairy root disappeared in some instances, crown-gall tissue developing in the same region. Generally speaking, trees with galls made less growth than did trees free from gall. Trees severely injured by woolly aphis in the nursery are regarded as unfit for planting. Trees slightly injured may recover and develop a satisfactory root system.

Field experiments in spraying apple orchards for the control of apple blotch, A. J. GUNDERSON (Illinois Sta. Bul. 222 (1919), pp. 551-575).—Apple blotch is said to be one of the most destructive diseases of apple orchards in southern Illinois. Experiments for its control were carried on during 1916, 1917, and 1918 to determine the relative values of—Bordeaux mixture and lime sulphur; the value of different applications of these fungicides, and the effect of interchanging them; the effect of dormant applications of copper sulphate, Scalecide, lime sulphur. and a combination of lime sulphur and copper sulphate; the effect of the addition of arsenate of lead to lime sulphur; and the relative values of dusting and spraying.

Bordeaux mixture and lime sulphur have been found practically equal for the control of apple blotch. Dormant applications of the fungicides proved of no value for checking the disease. Arsenate of lead appears to have the same value as a spray for prevention of blotch, but the addition of this material to lime sulphur did not increase the value of that spray. Dusting with a mixture of finely ground sulphur and powdered arsenate of lead was valueless for the control of the disease. The most important application of lime sulphur or Bordeaux mixture was three weeks after the fall of the petals; and the second important application is that given five weeks after their fall. Later applications were found of little value in reducing blotch infection.

An undescribed species of Ophiodothella on Ficus, E. A. BESSEY (*Mycologia*, 11 (1919), No. 2, pp. 55-57, pl. 1).—An account is given of a fungus found on fig leaves at points near Miami, Fla., in 1907 and 1908. The species is considered new and has been designated as O. fici.

1919]

Spraying [grapevines for downy mildew] after July 15, A. CADORET (*Prog. Agr. et Vitic.* (*Ed. VEst-Centre*), 39 (1918), No. 27, pp. 9, 10).—Reaffirming (E. S. R., 40, p. 750) the necessity and efficacy of thorough spraying with Bordeaux mixture at intervals of 8 to 12 days in very moist weather between June 10 and July 15, or of monthly spraying during an ordinarily dry summer, the author insists also on the necessity of prolonging such treatment until the crop is gathered in case black rot is present.

The action of copper on vegetation, A. CADORET (*Prog. Agr. et Vitic.* (*Ed. VEst-Centre*), 39 (1918), No. 40, pp. 319, 320).—The author states from previous observations, recorded above, that in ordinarily dry summers mildew attacks during August are sufficient to decrease the foliage of grapevines. Vines properly sprayed (as evidenced by the resulting blue coating) retain their healthy appearance despite any deficiency of nutrition associated with lack of moisture, therein showing resistance to drought as well as downy mildew. The bearings of the facts observed are discussed.

Further notes on the powdery mildews and the ammonium polysulphid wash, J. V. EYRE, E. S. SALMON, and L. K. WORMALD (Jour. Bd. Agr. [London], 25 (1919), No. 12, pp. 1494–1497).—During the past three years further investigations (E. S. R., 38, p. 853) have been carried out on the control of powdery mildews by means of washes containing sulphur. The object of the present article is to give notice of new facts discovered relative to the killing point of powdery mildews, and of an improved formula for making the concentrated ammonium polysulphid solution. The work was carried out with hop mildew (Sphærotheca humuli), but the facts as noted are thought to apply to other mildews.

In making up the stock solution, 1 gal. of a 30 per cent aqueous solution of ammonia is saturated at ordinary temperature with hydrogen sulphid gas until the density is 0.955. Two gallons of 30 per cent aqua ammoniæ are added and 112.5 oz. of sulphur stirred into the liquid. Hydrogen sulphid gas is then passed through the liquid until all the sulphur dissolves and the density reaches 1.036 at  $17^{\circ}$  C. (62.6° F.). The resulting clear dark-colored solution constitutes the new stock solution, and this is referred to as ammonium polysulphid stock solution, 1918, or as A. P. S., 1918. This should contain 19.2 per cent ammonia and 24.2 per cent of sulphur, of which 10.6 per cent is in the condition known as sulphid sulphur, and 13.6 per cent in the form known as polysulphid sulphur. After standing 12 hours and being diluted with approximately 50 to 100 times as much water, the fluid may become cloudy and finally thick with sulphur.

To prepare this diluted wash 5 lbs. of soft soap (or 10 lbs. if the water is very hard) are dissolved in 99 gal. of water, after which 1 gal. of the stock solution, A. P. S., is added while stirring to give strength (a). Strength (b) requires the same proportion of soap with twice the percentage of stock solution. Both these are to be used as soon as made. Precautions as regards handling are the same as those for lime sulphur. A nozzle giving a fine misty spray is required.

Lime-sulphur is thoroughly reliable for early sprayings against American gooseberry mildew, but it should be dispensed with in favor of the abovedescribed wash before the marketing qualities of the berries are affected.

Further data on the citrus canker affection of the citrus species and varieties at Lamao, H. A. LEE (*Philippine Agr. Rev.*, 11 (1918), No. 3, pp. 200-206, pls. 7).—Investigations begun by the author in 1917 on possible control methods for citrus canker have yielded data which are here presented in tabular form, with discussion to supplement the observations recorded by

Wester (E. S. R., 39, p. 458). Attention is called to the appearance of susceptibility in varieties formerly listed as immune; also of partial or complete immunity appearing in other varieties which are indicated.

Carnation stem rot and its control, G. L. PELTIER (Illinois Sta. Bul. 223 (1919), pp. 579-607, figs. 5).—The author describes some experimental work undertaken with a view to the control of carnation stem rot due to *Rhizoctonia* solani noted in a previous publication (E. S. R., 35, p. 749). The general character of the fungus, together with an account of its occurrence, is given. The conditions influencing the growth of the parasite and host plant are described at considerable length, and accounts are given of experiments carried on in the greenhouse for the control of the stem rot.

From the data obtained, it appears that the control of stem rot of carnation is to be studied along the lines of growing conditions and the use of clean soil. Soil disinfection proved of little value, but steam sterilization has been quite effective. In growing carnations the temperature should be kept as low as possible, and no more water applied to the soil than is absolutely necessary for the healthy growth of the plant. These statements apply also to the growing of the seedlings and cuttings. Steam sterilization of soil and sand is recommended to be used wherever possible.

Snapdragon rust, G. L. PELTIER (Illinois Sta. Bul. 221 (1919), pp. 535-548, figs. 5).—A description is given of rust of snapdragon due to Puccinia antirrhini, which is known to have been present in California since 1879 and which appeared in Illinois in 1913, since which time it has become the cause of considerable loss. The symptoms of the disease, description of the fungus, and host relationship and resistance are described, after which an account is given of experiments for its control. The use of Bordeaux mixture, ammoniacal copper carbonate, or Fungine can neither prevent, check, nor control it in the field or greenhouse.

Important relations were established between the spread of the fungus and the conditions under which the plants were grown. It is claimed that the practice of syringing plants in the greenhouse is favorable for the dissemination of the spores and the rapid infection of the plants. Watering from below only, so as to avoid wetting the foliage, is a means of checking the rust. The rust was not found to be carried on the seed, and it is believed that the disease could be avoided by the propagation of plants from seed instead of cuttings.

Some diseases of trees in greater New York, A. H. GRAVES (Mycologia, 11 (1919), No. 3, pp. 111-124, pl. 1).—The author gives some results of studies during the summer of 1918. The diseases noted, with associated fungi (which were not identified with certainty in all cases), include a bark disease (Melanconium sp.) of butternut (Juglans cinerea), canker (Nectria sp.) of sweet birch (Betula lenta), winter injury or leaf scorch of beech (Fagus atropunicea), heart rots (several fungi) of oaks (Quercus spp.), disease of the white oak (Q. alba), bark disease (Creonectria purpurea) of the paper mulberry (Broussonetia papyrifera), blight (Gnomonia venata) of sycamore (Platanus occidentalis), and heart rot (Pyropolyporus robiniæ) of locust (Robinia pseudacacia). Severe injury to trees during 1917 and 1918 is ascribed to the unprecedented combination of unfavorable winter conditions.

[Direct] transmission of blister rust from pine to pine, C. VON TUBEUF (*Naturw. Ztschr. Forst u. Landw., 16 (1918), No. 3-8, pp. 280-282).*—This is a discussion of recent contributions on the life history of pine rust (*Peridermium pini*).

Diaporthe taleola, an ascomycete injurious to oaks, M. MOREILLON (abs. in Internatl. Inst. Agr. [Rome], Internatl. Rev. Sci. and Pract. Agr., 9 (1918), No.
3, pp. 397, 398).—In September, 1917, isolated and comparatively shallow rooted oaks on dry calcareous soil southwest of the Vaudois Jura at an altitude of 1,850 ft. were observed to have lost in some cases as much as 1 per cent of their twigs. The trouble proved to be due to *D. taleola*. The same fungus is said to have caused similar injury in other localities mentioned.

The distribution of mistletoe in Switzerland, J. COAZ (*Naturw. Ztschr. Forst u. Landw.*, 16 (1918), No. 3-8, pp. 138-195, figs. 3).—A discussion of mistletoe in Switzerland concludes with a comparison between Switzerland and Germany as regards the occurrence, distribution, and hosts of mistletoe in the two countries.

## ECONOMIC ZOOLOGY-ENTOMOLOGY.

Game laws for 1919, G. A. LAWYER and F. L. EARNSHAW (U. S. Dept. Agr., Farmers' Bul. 1077 (1919), pp. 80).—This is the usual annual summary of the provisions of Federal, State, and Provincial statutes (E. S. R., 40, p. 54).

The animal ecology of Johnson County, D. M. BRUMFIEL (Univ. Iowa Studies Nat. Hist., 8 (1918), No. 1, pp. 37, pls. 23).—A preliminary survey of the major animal habitats of Johnson County, Iowa, with an atlas.

A nest study of the Maryland yellow threat, N. E. SHAVER (Univ. Iowa Studies Nat. Hist., 8 (1918), No. 2, pp. 12, pls. 4).—This paper is based upon a continuous study of the nest life of Geothlypis trichas trichas, made during the summer of 1917 at the Iowa Lakeside Laboratory on Lake Okoboji.

The nest studied contained three eggs of the yellow throat and one of the cowbird. The shell of the cowbird's egg by adhering to one of the yellow throat prevented the latter from hatching, causing  $33\frac{1}{2}$  per cent mortality. Data presented in tabular form show the feeding activity of the parent birds, distribution of food to the young, classification of nestling food, and sanitation of the nest. The data show that the cowbird received 55 per cent of all the food brought to the nest.

A list of birds observed in Clay and O'Brien Counties, Iowa, I. N. GABRIEL-SON (Proc. Iowa Acad. Sci., 24 (1917), pp. 259-272).

Birds of the Kansas City region, H. HARRIS (*Trans. Acad. Sci. St. Louis, 23* (1919), No. 8, pp. 213–371, figs. 4).—This work includes a summary of the dates on which the regular spring migrants may be looked for, residents which occur in the vicinity throughout the entire year, winter residents, irregular winter residents, summer residents, occasional or very rare breeders, former breeders, possible breeders, and migrants, a bibliography of 18 pages, and a subject index.

Studies of the birds in northwest Australia, R. Söderberg (K. Svenska Vetensk. Akad. Handl., 52 (1918), No. 17, pp. 116, pls. 5, figs. 25).—A report of ornithological researches conducted in tropical northwest Australia.

Studies of the tsutsugamushi disease, T. KITASHIMA and M. MIYAJIMA (*Kitasato Arch. Expt. Med.* [*Tokyo*], 2 (1918), No. 2, pp. 90–146, pls. 6).—A further report of studies of this affection, also known as Nippon river fever, which is transmitted by the larva of a trombidiid (*Leptus akamushi*) that develops on field mice (*Microtus montibelli*). It occurs in certain river valleys of Japan and also in Formosa (E. S. R., 39, p. 870).

Camallanus americanus n. sp.—A monograph on a nematode species, T. B. MAGATH (*Trans. Amer. Micros. Soc.*, 38 (1919), No. 2, pp. 49–170, pls. 10, figs. 16).—This monograph deals with a parasitic nematode found in the upper 2 in. of the intestine of certain turtles. Of 47 turtles examined 78 per cent were parasitized.

[Vol. 41

Absence of complement in the blood of insects, A. C. HOLLANDE (Compt. Rend. Soc. Biol. [Paris], 82 (1919), No. 6, pp. 218-220).—In investigations conducted the author failed to find complement present in the blood of a number of insects, including Vanessa urticæ, V. io, Bombyx rubi, Chelonia caja, Sphinx ligustri, Decticus verrucivorus, Orphania denticaudata, and Ephippiger terrestris.

Guide to the collection and preservation of insects, I. DE SAGARRA (Mus. Barcinonensis Sci. Nat. [Mus. Cienc. Nat. Barcelona] Opera, Scr. Zool., No. 4 (1918), pp. 99, figs. 65).—This is intended as an aid to the young entomologist.

On the absence of insect pests in certain localities and on certain plants, T. D. A. COCKERELL (Jour. Econ. Ent., 12 (1919), No. 4, pp. 345-347).—The author records observations of the occurrence of garden insects at Boulder, Colo., in 1918.

On some phases of insect control by the biological method, H. S. SMITH (*Jour. Econ. Ent.*, 12 (1919), No. 4, pp. 288–292).—This is a discussion, based upon work of the California State Commission of Horticulture, in which the author considers the more important factors which govern control by entomophagous insects.

Effect of excessive sterilization measures on the germination of seeds, E. R. DE ONG (*Jour. Econ. Ent.*, 12 (1919), No. 4, pp. 343-345).—Experiments conducted with a view to determining the germination percentage of beans after treatment with excessive heat and excessive dosage of potassium of cyanid and carbon disulphid are reported in tabular form. It is shown that fumigation and heat sterilization are safe practices both for grains and legumes at the dosages commonly used, with proper precautions as to the length of exposure and ventilation afterwards.

The stratification of liquid hydrocyanic acid as related to orchard fumigation, R. S. WOGLUM and M. B. ROUNDS (Jour. Econ. Ent., 12 (1919), No. 4, pp. 300-303, pl. 1).—The authors found that in each of the 11 experiments conducted where the liquids were brought together slowly stratification occurred regardless of whether the water was added to the hydrocyanic acid or the hydrocyanic acid to the water. If, however, the materials were brought together violently and thoroughly shaken stratification was not produced.

The strength of nicotin solutions, V. I. SAFRO (Jour. Econ. Ent., 12 (1919), No. 4, pp. 349-351).—The author calls attention to the fact that neither odor nor color is an indication of the comparative strength of nicotin solutions. A statement of the percentage of nicotin content alone is insufficient as indicating its exact strength. "The nicotin may be in the form of 'free' nicotin or in the form of nicotin sulphate, but the percentage refers to the amount of nicotin, by weight, because it is the only method of knowing definitely how much actual nicotin is contained in the solution, and such designation is required by the Federal Insecticide Board. It is necessary, then, to know the specific gravity of the preparation in order to know the actual nicotin content."

The value of molasses and sirups in poisoned baits for grasshoppers and cutworms, A. W. MORRILL (Jour. Econ. Ent., 12 (1919), No. 4, pp. 337-343).— The author concludes that molasses or sirup of any kind is absolutely unnecessary as an ingredient of poisoned baits against many of the common cutworms. The addition of molasses, however, increases the attractiveness of the bait for some species under certain conditions. Evidence has also accumulated to the effect that the use of molasses or sirup is unnecessary in combating some species of grasshoppers.

Report of the State entomologist and plant pathologist (Tenn. Bien. Rpt. Dept. Agr., 1917-18, pp. 53-72, fig. 1).—This report includes a discussion of the

occurrence of and control measures for a number of the more important insects of the year, including the wheat-joint worm, strawberry-root louse, cabbage-root maggot, bagworm, cotton boll weevil, Hessian fly, horn fly, ox warble.

etc. A dormant and summer spray schedule for apple trees is appended. Insect enemies of the allotment holder, F. V. THEOBALD (Wye, England: Author, 1918, pp. 59, figs. 27).—A brief popular account.

Insect problems of western shade trees, F. B. HERBERT (*Jour. Econ. Ent.*, 12 (1919), No. 4, pp. 333-337).—This is a brief summary of a survey made by the Bureau of Entomology of the U. S. Department of Agriculture in the fall of 1916.

Notes on Thysanoptera from British Columbia, R. C. TREHERNE (Canad. Ent., 51 (1919), No. 8-9, pp. 181-190, pl. 1, figs. 8).—The author presents notes on 10 species of thrips found to occur in British Columbia, including one new to science, namely, *Æolothrips auricestus* taken from western wild rye grass (Elymus condensatus).

Some work of the insectary division in connection with the attempted introduction of natural enemies of the beet leaf-hopper, E. J. VOSLER (Mo. Bul. Cal. Com. Hort., 8 (1919), No. 5, pp. 231-239, figs. 9).—This is a brief report by the late author on his trips to Australia in the attempt to secure enemies of the beet leaf hopper.

The saltbush (*Atriplex muelleri*) was found badly infested with a leaf hopper in the vicinity of Sunshine, near Melbourne, which was parasitized to the extent of 90 per cent by two egg parasites, *Ptergogramma acuminata* and a mymarid. Upon introduction into this country both failed to attack the beet leaf hopper, and as they were given a fair trial it is concluded that they found *Eutettix tenella* to be an unsuitable host.

Notes on the behavior of the beet leaf-hopper (Eutettix tenella), H. H. P. SEVERIN (*Jour. Econ. Ent.*, 12 (1919), No. 4, pp. 303-308).—These notes relate to sexual behavior, nocturnal habit, reaction to heat, phototaxis, and reaction to shadow.

Investigations of the beet leaf-hopper (Eutettix tenella) in California, H. H. P. SEVERIN (Jour. Econ. Ent., 12 (1919), No. 4, pp. 312-326, pl. 1).—The data here presented have been substantially noted from another source (E. S. R., 41, p. 456).

An infestation of apple sucker (Psylla mali) in Nova Scotia, W. H. BRIT-TAIN (Agr. Gaz. Canada, 6 (1919), No. 9, pp. 823-827, figs. 5).—The author records the discovery of the introduction and establishment of this European species near Wolfville, N. S., and gives an account of the nature and extent of its injury. This is said to be the first record of its occurrence in North America.

Preliminary tests as a guide for future work in the control of the pest were made after its discovery. Nicotin sulphate, 1 pint to 100 gal. of water, was applied on June 12 by means of a Friend spray gun, and in spite of the unfavorable conditions. the leaves having attained practically their full size, almost perfect results were secured. Several contact dusts were also tested for comparison with the liquid spray, the applications being made by means of the Johnson orchard duster. Nicotin sulphate was the basis of three of these dusts, it being mixed, dried, and ground with kaolin, yellow clay, and sulphur, respectively, at the rate of 2 lbs. to the hundred. Free nicotin solution combined with sulphur, using the same percentage of nicotin, was also tested, as was a mixture composed of 50 per cent of finely ground tobacco dust ground together with 25 per cent of dry lime-sulphur and 25 per cent of hydrated lime.

153351°-20-5

1919]

[Vol. 41

756

None of the dust mixtures gave results comparable to the liquid spray, owing to the mechanical impossibility of driving the dust into all the hiding places of the insect, due to the large size of the leaves at the time. All the dust mixtures, however, seemed to destroy the insects whenever they came in contact with them, although the green apple bug was practically unharmed.

Spray pink and green potato aphids, E. M. PATCH (Potato Mag., 1 (1919), No. 12, pp. 8, 9, 31, figs. 2).—A brief summary of information on Macrosiphum solanifolii, in which the more recent work with remedial measures is discussed, including references to the work in Ohio by Houser et al. (E. S. R., 38, p. 462), and in Connecticut by Britton and Zappe (E. S. R., 41, p. 162.)

On the life history and bionomics of Myzus ribis (red currant aphis), M. D. HAVILAND (*Proc. Roy. Soc. Edinb.*, 39 (1918–19), No. 1, pp. 78–112, figs. 10).— The studies here reported have been summarized by the author as follows:

"*M. ribis* (red currant aphis) on *Ribes rubrum* is dimorphic in respect of certain features of the antenna and of abdominal and wing dimensions. The nature of the food, whether healthy or blistered by the attack of the fundatrix, seems to be the determining factor of this dimorphism. The form from healthy leaves is probably identical with *M. whitei* and *M. dispar*.

"M. ribis is migratory, and in summer colonizes certain Labiatæ and other weeds; but this migration is not obligatory, and the entire life cycle may be passed on currant. On its summer host plant this species has been previously described as *Phorodon galcopsidis*.

"There is a decline in fertility in the later part of the summer among the forms remaining on currant. This is caused by a lower birthrate, and not by the shortening of the life of the parent. This decline, together with the attacks of predacious and parasitic enemies, accounts for the frequent disappearance of the species from currant in August and September.

"Both sexual forms may be produced, and eggs may be laid, on either host plant. Males transferred from Labiatæ to Ribes can fertilize the females on the latter plant."

A small braconid, Aphidius ribis, is its principal enemy in England.

A bibliography of 28 titles is included.

**Observations on some mealy bugs (Hemiptera; Coccidæ)**, G. F. FERRIS (*Jour. Econ. Ent.*, 12 (1919), No. 4, pp. 292-299, figs. 3).—The data here presented, which supplement the systematic account previously noted (E. S. R., 40, p. 262), deal largely with species which are already of economic importance or may be regarded as awaiting only a favorable opportunity to become so.

It is pointed out that the name *Pseudococcus citrophilus* given by Claussen to the so-called citrophilus mealy bug must give way, as the species was first described by Green as P. gahani from specimens taken from Ribes sanguinea in London, England. P maritimus of Ehrhorn (= P. bakeri Essig) has been reported by Green to occur on various plants in greenhouses in England and by Chaffin from sweet potato, tomato, and avocado on the Dry Tortugas Islands, near Key West, Fla. P. pini is recorded from this country for the first time, having been collected on pine in a Japanese nursery at Oakland, Cal. P. bromeliæ appears to have become established in Florida, where specimens having been collected from the roots of bananas at Florence Villa, pineapple at Frost Proof, and citrus at Ft. Meyers. P. virgatus, a species previously recorded from cactus and other plants at Brownsville, Tex., has been taken from magnolia and mulberry at Gainesville, oleander at Key West, and an undetermined plant at Winter Haven, Fla. P. comstocki, a dangerous mealy bug originally described from specimens taken from mulberry and maple in Japan, is said to occur in the eastern part of the United States, and has been collected

from apple, horse chestnut, hydrangea, maple, mulberry, wild cherry, and some other hosts on Staten Island, N. Y., by Doane. The author states that he has also received the same species from various hosts in Maryland. A species from citrus at Ojai, while very close to *P. citri*, is apparently distinct and most closely resembles *P. kraunhiæ* from Japan.

Descriptions of P. pini, P. bromeliæ, and P. virgatus are given, together with the synonymy of P. quercus, Lachnodius phoradendri, and Cryptoripersia arizonensis.

Lac-producing insects in the United States (Hemiptera; Coccidæ), G. F. FERBIS (Jour. Econ. Ent., 12 (1919), No. 4, pp. 330-333).—A brief discussion of this subject, based upon a review of the literature and investigations conducted in the Southwest during the course of a trip, reference to which has been previously made (E. S. R., 41, p. 457). The author failed to find Tachardia larrea to occur in sufficient quantity to be of commercial importance.

Spray v. fumigation in the control of gray scale on citrus trees in Tulare County, F. R. BRANN (Mo. Bul. Cal. Com. Hort., 8 (1919), No. 3, pp. 104-107, fig. 1).—A general discussion of the control of the gray citrus scale (Coccus citricola [longulus]), in which attention is directed to the disadvantages of spraying as compared with fumigation. It is said that fumigation with liquid hydrocyanic acid gas has advantages over all other methods.

On the use of the names Lachnus and Lachniella, A. C. BAKER (Canad. Ent., 51 (1919), No. 8-9, pp. 211-212).—The author finds Lachnus punctatus to be the type for Lachnus, and Lachnus fasciatus for Lachniella, and erects the genus Wilsonia for Lachniella gracilis of Wilson.

Some observations on the webbing clothes moth (Tineola biselliella), M. T. SMULYAN (*Psyche*, 26 (1919), No. 3, pp. 71-73).—The data here presented supplement the information given in the paper by Benedict, previously noted (E. S. R., 38, p. 657), and confirm that author's conclusions that *T. biselliella* rather than *Tinea pellionella* is the more common species in the North.

Some recently recorded parasites of the oriental peach moth, L. A. STEARNS (*Jour. Econ. Ent.*, 12 (1919), No. 4, pp. 347, 348).—During investigations of this pest in Virginia 11 parasites were reared, 7 of which have not been previously recorded as attacking the oriental peach moth.

Physiological and parasitological studies of economic Lepidoptera, C. GAUTIER (Compt. Rend. Soc. Biol. [Paris], 82 (1919), No. 19, pp. 720-723).— Continuing work previously noted (E. S. R., 41, p. 552), notes are presented on Apanteles glomeratus and on the blood of a number of species of Lepidoptera.

The striped skipper eaterpillar of the coconut (Hidari irava), S. LEEFMANS (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Lab. Plantenziekten, No. 35 (1919), pp. 15-31, pls. 4).—Reports of damage by this caterpillar to coconut trees in Java, Sumatra, and Bali led to this study of its life bistory and parasites.

The attack of the caterpillar results in the leaves being stripped up to the big veins. From 8 to 9 days were found to be passed in the egg stage, from 32 to 37 as a caterpillar, and from 10 to 11 as pupa. Several parasites were observed, of which a tachinid and a braconid were the only ones of importance. As control measures, Paris green and lead arsenate are very efficient and do not burn the leaves.

New Jersey's work in mosquito control, W. E. DARNALL (Jour. Amer. Med. Assoc., 73 (1919), No. 19, pp. 737-742, figs. 7).—This is an address delivered before a selection of the American Medical Association in June, 1919, by the president of the Atlantic County Mosquito Exetermination Commission.

Contribution to the study of the Brazilian Trypaneidæ or fruit flies, A. LUTZ and A. DA COSTA LIMA (Mem. Inst. Oswaldo Cruz, 10 (1918), No. 1, pp. 5-16, pls. 2; Trans., pp. 1, 2).—This account is based upon the specimens found in collections at the Institute of Manguinhos and of the Museum of Natural History in Sao Paulo. Anastrepha fraterculus, a very variable species, an account of which by Rust has been previously noted (E. S. R., 40, p. 757), is the most important form. A list is given of the species of the genus Apyrgota, subfamily Pyrgotinæ, and a description of the new species A. personata which might be mistaken for a Trypeta. A catalogue of the genus Anastrepha with synonyms, literature, and a bibliography follows.

Notes on Pelenomus sulcicollis, R. MATHESON (Canad. Ent., 51 (1919), No. 8-9, pp. 199-201, pl. 1, fig. 1).—The weevil here considered is said to have destroyed a small patch of fringed loosestrife (Steironema ciliatum) growing on the bank of a stream at Ithaca, N. Y.

The two-colored coconut leaf beetle (Bronthispa froggatti), S. LEEFMANS (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Lab. Plantenziekten, No. 35 (1919), pp. 1-14, pls. 3).—The beetle here considered, which has not previously been recorded by Dutch entomologists, is thought to be the species which has caused serious loss in New Britain and the Solomon Islands. On the west coast of Sumatra and in west Java only plants up to four years of age are damaged by it. It is the author's opinion that the injury caused by the adults and larvæ is considerably increased by a fungus (Pestalozzia palmarum) which penetrates the leaf tissue through the wounds caused by this insect.

The larvæ hatch out after a period of 7 to 10 days, the pupal stage lasts from 7 to 9 days, and the beetles live under laboratory conditions from 6 to 8 months, during which period as many as 93 eggs have been recorded from a single beetle. At Padung the eggs were severely parasitized, 62 per cent being recorded.

The application of a 2 per cent solution of lead arsenate was found to be the most effective in destroying both the adults and larvæ.

Biological notes on the flat-headed apple-tree borer (Chrysobothris femorata) and the Pacific flat-headed apple-tree borer (C. mali), H. E. BURKE (Jour. Econ. Ent., 12 (1919), No. 4, pp. 326-330).—The author has found C. mali to be far more common and injurious in the Pacific States than C. femorata. "Numerous rearings have given us C. femorata from the prune and plum a few times and C. mali from the currant, apple, plum, prune, cherry, peach, and apricot a number of times. C. mali is also more common in shade trees and brush forests, while C. femorata is commoner in the oaks and the aspen forests of the high Sierras. C. femorata occurs throughout the United States, and C. mali has been reported from Oregon, California, Nevada, Utah, Colorado, and Arizona. Many of the published records of damages by C. femorata in the Rocky Mountains and the Pacific States undoubtedly refer to damage by C. mali."

Notes on forest insects.—I, On two bark beetles attacking the trunks of white pine trees, M. W. BLACKMAN (*Psyche*, 26 (1919), No. 4, pp. 85–96, pl. 1, fig. 1).—The biological observations here reported relate to *Ips longidens*, which in central New York works on the inner bark of white pine, and *Hylurgops pinifex*, which attacks white pine by preference.

Weevils in Australian wheat in California, R. W. DOANE (*Jour. Econ. Ent.*, 12 (1919), No. 4, pp. 308-312).—The author has found the rice weevil to be the most common beetle occurring in shipments of Australian wheat. In some lots the granary weevil was also very abundant, in other shipments but few were found.

"The saw-toothed grain beetles, Silvanus surinamensis, were always abundant. The confused flour beetles, Tribolium confusum, were common in all shipments, and T. ferrugineum was also often quite common. The lesser grain borer (*Rhizopertha dominica*) was always quite abundant and apparently very destructive. The flat grain beetle (*Lamophlaus minutus*) was common in all lots. The cadelle and a few other beetles were more or less common. *Mesaporus calandra*, the cosmopolitan parasite of grain weevils, was common on nearly all lots of Australian wheat examined, and it was exceedingly abundant in some of the lots."

A suggestion of a possible control of pea and bean weevils, R. E. CAMP-BELL (Jour. Econ. Ent., 12 (1919), No. 4, pp. 284–388).—In work carried on in California the author found the percentage of infestation of broad or horse beans by the broad bean weevil ([Bruchus] Laria rufimana) to be very much less in crops from seed planted late in the season than from crops from seed planted early. While the first eggs are laid soon after the middle of March and a few may be laid as late as the middle of May, the most extensive deposition occurs during the month of April.

Data presented in tabular form show a maximum of 50 and 63 per cent of weevil infestation, and averages of 14.5 per cent for the 1916 and 1917 crops, when the seed was planted both early and late, as contrasted with a maximum of only 17.2 per cent and an average of 2.92 per cent of weevil infestation for the 1918 crop, when no seed was planted until after March 1. Many samples of the 1918 crop were entirely free from infestation, particularly those from seed planted in April and May.

Wintering bees in Indiana, E. G. BALDWIN (Purdue Univ., Dept. Agr. Ext. Bul. 85 (1919), pp. 2-8, figs. 2).—A popular account.

The European elm sawfly leaf miner, R. N. CHRYSTAL (Agr. Gaz. Canada, 6 (1919), No. 8, pp. 725–728, fig. 1).—This sawfly leaf miner (Kaliosysphinga almi), first recorded in America by Felt in 1898 as unusually destructive at Albany and Troy, N. Y., was first discovered in Canada at Kingston, Ont., in July, 1915. Recent investigations have shown the species to occur in the city of Kingston in a few localities, mainly on the Camperdown variety of Scotch elm, the American elm not being attacked.

A series of experiments by Hutchings with an allied species, the alder sawfly leaf miner (K. *dohrnii*), at the Central Experimental Farm, Ottawa, showed kerosene emulsion, 1 part of stock solution to 7 parts of water, to be effective when used at the time the larval mines were just commencing. This indicates that this remedy would also be effective against K. *ulmi*.

An account of its life history by Slingerland in 1905 has been noted (E. S. R., 17, p. 680), as has been an account by Herrick in 1913 on its control (E. S. R., 29, p. 556).

Euura laeta in Sweden, A. TULLGREN (K. Landtbr. Akad. Handl. och Tidskr., 58 (1919), No. 2, pp. 59–68, figs. 9; also in Meddel. Centralanst. Försöksv. Jordbruksområdet, No. 180 (1919), pp. 12, figs. 9).—A brief account of this small gall-making sawfly, which is a source of injury to Salix viminalis.

The mason wasps, J. H. FABRE, trans. by A. TEIXEIRA DE MATTOS (*New York:* Dodd, Mead & Co., 1919, pp. [VIII]+318).—A translation of the author's Souvenirs Entomologiques treating of wasps. This work, which comprises the second of a series dealing with wasps (E. S. R., 35, p. 468), takes up the Eumenes, Odyneri, Pelopæus, Ageniæ, Volucella, etc.

Mites affecting the poison oak, H. E. EWING (*Proc. Iowa Acad. Sci.*, 24 (1917), pp. 323-326, fig. 1).—The author here describes a new gall mite (*Phyllocoptes toxicophagus*) from Oregon, which so far as known is restricted to a

Pacific slope species of poison ivy (*Rhus diversiloba*). He also records the feeding of the spider mite (*Tetranychus telarius*) on poison ivy in the vicinity of Corvallis, Oreg., likewise a leaf roller.

# FOODS-HUMAN NUTRITION.

A biometric study of basal metabolism in man, J. A. HARRIS and F. G. BENEDICT (*Carnegie Inst. Wash. Pub. 279 (1919), pp. VI+266, figs. 30*).—The purpose of this study is expressed by the authors as "to present the results of a first attempt to analyze the data of basal metabolism in normal men and women by the higher statistical or biometric formulas."

The unfamiliarity of most physiologists with biometric methods and the relative paucity of data on basal metabolism are believed to be responsible for the slowness with which the higher statistical methods have been applied to this field of research. The data accumulated from experiments on basal metabolism in the Nutrition Laboratory of the Carnegie Institution now comprise those for age, body weight, pulse rate, and gaseous exchange, together with computed heat production for 136 male and 103 female adults, and represent a nonnegligible contribution to the problem of human metabolism. They are here statistically analyzed by biometric methods, the principles underlying the establishment on them of standard basal metabolism constants are discussed. and standard multiple prediction tables for normal basal metabolism are worked out. These tables are based on the factor of body weight, with correction factors for age and stature, and are given for men and women separately. The authors summarize the plan and significance of the study as "to emphasize the necessity for the establishment of statistical normal basal metabolism standards, which may serve as a basis of comparison in all special nutritional investigations; to supply convenient tables of such standards based on the most extensive series of normal data as yet available; to illustrate the practical use of such tables in the solution of problems in nutritional physiology."

"Biologically the most rational and practically the most satisfactory standard is that secured by taking into account the body weight, stature, and age of the subject in predicting basal metabolism. This method is therefore an extension and modification of the selected-group method, employed earlier at the Nutrition Laboratory. In the new method, which we have designated as the multipleprediction method [the authors], replace the empirical determinations of the metabolism of individuals of specific weight, stature, and age by values given by multiple-prediction equations based on the statistical constants of all available normal data. These equations have been tabled for both men and women for a range of weight, stature, and age which will be met in practical work with adult subjects, and give a set of multiple-prediction tables of standard normal adult basal metabolism constants.

"The illustrations of the practical application of these multiple-prediction tables show first of all their great usefulness in the detection of differences between series of metabolism measurements. Thus, as far as [the authors] are aware, the anomalous nature of the series of determinations by Magnus-Levy and Falk and those by Palmer, Means, and Gamble has heretofore quite escaped the notice of physiologists, and their data have been combined freely with other series for the purpose of generalization. The aberrant nature of these series becomes evident as soon as comparison of the actual measurements with the theoretical values from the multiple-prediction tables is made. "The use of the tables shows the clear differentiation of athletes and diabetics from other individuals in their metabolic level, thus confirming conclusions already drawn at the Nutrition Laboratory.

"The use of the standards shows the existence of a well-marked differentiation in the level of metabolism of men and women, and shows that the differences are persistent throughout adult life instead of disappearing in later years as maintained by Sondén and Tigerstedt. There is no evidence for such differentiation in new-born infants.

"While the novelty of the conception underlying these standards will probably limit somewhat their immediate adoption by physiologists, the illustrations show that for purposes of more refined analysis they have great practical value. We believe that ultimately the great convenience of these multipleprediction tables will result in their general adoption as standards of reference in all work on human nutritional physiology.

"When larger series of basal data are available we expect to revise these tables so that they may represent the broadest and most secure foundation for comparative nutritional investigation."

Report on the metabolism of female munition workers, M. GREENWOOD, C. HODSON, and A. E. TEBB (*Proc. Roy. Soc.* [London], Ser. B, 91 (1919), No. B 635, pp. 62-82).—This detailed report consists of a general description of the factory conditions and of the salient features of individual processes studied, a criticism of the results from the experimental point of view, a summarized interpretation of the data obtained, and a brief discussion of the economic implications of these results. The metabolism was determined by indirect calorimetry, the respiration apparatus used being a modification of the Douglas bag combined with a face mask.

A study of the detailed tables shows that in a majority of the operations the range of variation from subject to subject is very great, due either to the individual peculiarities of metabolism or to great variations in the amount of physical work actually performed during the experimental periods, or to both factors. A provisional grouping of the figures on the basis of the general means is given as follows:

(1) Light turning, turning, and forging requiring about 100 calories per square meter per hour; (2) tool setting, heavy turning, stamping, finishing copper bands, and shell hoisting, all needing about 125 calories; (3) gauging, walking, and carrying, requiring 160 calories; and (4) laboring, and cleaning and drying, requiring 180 calories per square meter per hour. With these figures as a basis the average daily food requirement for the four classes is calculated as 2,810, 3,120, 3,555, and 3,805 calories, respectively.

Attention is called to the fact that while the energy requirement of the lightest class is about 74 per cent of the heaviest, the remuneration of the kinds of work included in the heaviest class has been much less than that of several operations needing decidedly fewer calories. The importance is emphasized of taking into account the physiological element of working-class expenditure.

Preparation of protein free from water-soluble vitamin, T. B. OSBORNE, A. J. WAKEMAN, and E. L. FERRY (Jour. Biol. Chem., 39 (1919), No. 1, pp. 35-46, pl. 1).—This paper reports the results of a study of the relative efficiency of the various methods used to remove the water-soluble vitamin from preparations of different proteins, as determined by comparing the length of life or rate of decline of young rats fed on diets containing the protein under examination, together with a basal ration supposedly free from water-soluble vitamin. The proteins selected represented a wide variety in chemical constitution and in methods of extraction and purification.

On the diets containing lactalbumin, gliadin, ovovitellin, pure or crude casein, or meat residue, nearly all the rats lost from 30 to 40 per cent or more in weight, and all but one died within 50 days unless water-soluble vitamin was supplied. The prompt recovery on the administration of yeast demonstrated a lack of water-soluble vitamin in the proteins employed. On diets containing crude edestin or cottonseed globulin rats were maintained for three months without notable change in body weight, and when the amount of protein was doubled all but one gained weight fairly rapidly. Evidence of a decided lack of water-soluble vitamin in edestin was obtained only after the edestin had been purified by seven recrystallizations. The suggestion is made that the persistence with which the water-soluble vitamin is retained by edestin may be due to a chemical combination therewith, and that in this respect the vitamin resembles acids which combine with edestin to form salts. Similarly the ease with which the vitamin is separated from casein and from ovovitellin may be due to the acid character of these proteins, which would render them incapable of entering into chemical combination with the vitamin, provided the latter has acid properties. The absence of the vitamin from preparations of gliadin and of meat residue is ascribed to the small amounts of the vitamin in the original substances.

In conclusion, the authors emphasize the importance of proving a diet to be free from the water-soluble vitamin before considering it suitable for use in feeding experiments designed to show the proportion of this vitamin in any other element of food.

Nutritive factors in plant tissues.—II, The distribution of water-soluble vitamin, T. B. OSBORNE and L. B. MENDEL (*Jour. Biol. Chem.*, 39 (1919), No. 1, pp. 29-34, figs. 2).—In continuation of previous work (E. S. R., 39, p. 665), a preliminary report is given of the distribution of the water-soluble vitamin in plant tissues. To the list of plant tissues in which it has previously been found, the authors now add the bulb of the onion, the root of the turnip, the leaves, stems, and root of the beet, and the fruit of the tomato.

To permit more accurate comparison of the water-soluble vitamin content of natural foods, a procedure has been adopted which consists in feeding each day small known quantities of the vegetable product under investigation apart from the basal ration which is fed ad libitum. This method has been applied to a study of the effect of the maturity of plants upon their vitamin content, and it has been found that hay made from immature plants of clover, alfalfa, and timothy is much more efficient as a source of water-soluble vitamin than the hay prepared from mature specimens. The fact that such a difference exists is thought to have importance in feeding young animals and dairy cows, and the possible advisability is suggested of using hay made from immature clover or alfalfa to replace part, at least, of the milk fed to young stock and to replace entirely the hay ordinarily used for dairy cows.

Accessory factors in food, F. G. HOPKINS and H. CHICK (Lancet [London], 1919, II, No. 1, pp. 28, 29).—This memorandum has been issued by the committee on accessory food factors appointed by the Medical Research Committee and the Lister Institute (England) for the guidance of those engaged in the administration of food relief to famine-stricken districts. The accessory food factors are classified as the antineuritic or antiberiberi factor identified with the water-soluble B growth factor, the fat-soluble A growth factor or antirachitic factor, and the antiscorbutic factor. A brief description is given of the distribution and properties of these factors, with an accompanying table showing their distribution in the common foodstuffs, followed by a discussion of the practical application of the facts presented to the prevention of diseases. The hydrogen-ion concentration of foods, J. F. MCCLENDON and P. F. SHARP (Jour. Biol. Chem., 38 (1919), No. 3, pp. 531-534).—From a series of determinations of the H-ion concentration of foods, the analytical data of most of which are not presented, the authors report that the foods "were all on the acid side of neutrality no matter what the condition of freshness, modè of storage, stage in the preparation (cooking), or dilution with water (extract, soup, or pot liquor)."

A table is given of the pH of the juice of fruits and vegetables (young carrot, potato, cabbage, orange, and lemon) in the raw state and after boiling. The differences between the pH of the raw and cooked product were very slight.

Efficiency of oat protein in adult human nutrition, H. C. SHERMAN, J. C. WINTERS, and V. PHILLIPS (*Jour. Biol. Chem.*, 39 (1919), No. 1, pp. 53-62).— This investigation was conducted under conditions similar to those described in the previously noted study of the efficiency of maize proteins (E. S. R., 39, p. 873). One of the two subjects in the present study served as subject in the earlier investigations, and the diet was selected to conform as closely as possible to that of the previous study with the substitution for the corn of an amount of oatmeal furnishing the same amount of nitrogen.

In the main experiments of 12 days each the two subjects, receiving only sufficient calories to meet the energy requirement and but 0.57 or 0.55 gm. of protein per kilogram of body weight (furnished by oatmeal  $\pm 100$  gm. of milk), showed, respectively, nitrogen balances of  $\pm 0.0$  and  $\pm 0.2$  gm. per day as compared with a nitrogen balance of  $\pm 0.1$  gm. per day on the maize protein diet. The nitrogen balances during 12 days on the oat diet without milk and 8 days on the comparable maize diet without milk were, respectively, -0.7 and -0.6 gm. per day.

The authors conclude "that for the purpose of practical dietetics equal weights of oat and maize proteins may be regarded as essentially equal in value, and that even the minimum amount of milk which can possibly be regarded as permissible in the light of our present knowledge of nutrition will apparently so supplement the proteins of either the maize or oat kernel as to make them function with an efficiency comparable with that of the average protein of mixed diet in the maintenance metabolism of man."

[Miscellaneous food and drug topics], E. F. LADD and A. K. JOHNSON (North Dakota Sta. Spec. Bul., 5 (1919), No. 12, pp. 258-277, figs. 7).—This number contains brief notes on several food and drug topics. Data showing the variation in weight per box of strawberries are reported by F. C. Himber, together with the text of the State law of February 14, 1919, as to containers for small fruits. An article by W. G. Bowers on The Chemical Analysis of a Few Food Preparations Compared to the Claims on the Labels, presents analyses and discussions of several proprietary pie fillings, a baking powder, and two canned boiled dinners.

The restricted rations of prisoners of war in Germany considered from the point of view of the minimum of nitrogen, A. BENOIT (*Compt. Rend. Soc. Biol.* [*Paris*], 82 (1919), No. 4, pp. 151-153).—Observations are reported of the effects of a restricted diet upon 78 Russian officers in a German prison from June, 1915, to October, 1916. The observations included determinations of total and nitrogen intake, nitrogen excretion, and changes in weight of each subject.

The diet furnished a daily average per man of 48.7 gm. of protein, 332 gm. of carbohydrate, 48.7 gm. of fats, and 1,704 calories, or 27 calories per kilogram of body weight. During the period of 16 months in which observations were made none of the prisoners presented any evidence of nutritive disorders, and the average individual loss in weight was only about 140 gm.

That no appreciable trouble was caused by the restricted amount of nitrogen is attributed by the author apparently to the successful distribution of the protein of the ration from the point of view of the various constituents of the protein molecule. It was estimated that of 100 gm. of protein ingested, 49 gm. was in the form of gliadin-glutenin (bread and flour), 23.3 as casein and milk albumin (cheese), 16.3 as various animal proteins (meat and fish), and 11.5 as vegetable proteins (beets and potatoes). It is pointed out that in spite of the meagerness of the diet none of the indispensable amino acids were missing.

Studies on the behavior of inulin in the animal body.—II, Inulin in the alimentary canal, R. OKEY (*Jour. Biol. Chem.*, 39 (1919), No. 1, pp. 149–162, figs. 2).—This paper is a continuation of the investigation previously noted (E. S. R., 41, p. 12). The study of the behavior of inulin in the alimentary canal deals with (1) the hydrolysis of inulin in vitro by concentrations of hydrochloric acid comparable to those in normal gastric juice, (2) the action of gastric juice on inulin in vivo, and (3) the demonstration of the presence of an inulase in fecal extracts.

The results of hydrolysis of inulin in vivo and in vitro indicate that, while the acidity of the gastric juice is usually sufficient to produce a fair degree of hydrolysis, inulin is seldom retained in the stomach long enough to be changed to levulose. The presence of an enzym capable of producing a reducing sugar from inulin was demonstrated in sterile extracts of three samples of human feces from radically different diets. The marked gas formation which always follows inulin digestion is thought to indicate that further decomposition of the reducing sugar thus formed takes place so rapidly that appreciable absorption is impossible.

Studies of the gastric residuum.--III, Amino-acid nitrogen, R. CESSNA and C. C. Fowler (Jour. Biol. Chem., 39 (1919), No. 1, pp. 25-28).--In continuation of the studies by Fowler previously noted (E. S. R., 39, p. 670), determinations are reported of the amino-acid nitrogen content of the gastric residuums of 25 apparently normal young women and one apparently normal man. For purposes of comparison the total and free acidity, pepsin, and trypsin were also determined.

The amount of amino-acid nitrogen was in all cases higher than the values reported by Carlson<sup>1</sup> and other observers, the average content being 31.86 mg. per 100 cc. The amount apparently bears no relationship to acidity or pepsin or trypsin content.

The amount of fat and lipoid in the blood in the Tropics (Meded. Geneesk. Lab. Weltevreden [Dutch East Indies], 3. Ser. A, No. 2-3 (1919), pp. 29-67, pl. 1).—Two papers are presented.

I. Chemical analysis, by F. and E. Weehuizen and C. Alting (pp. 29-43).— •The authors discuss Bang's micro method for determination of blood lipoids (E. S. R., 41, p. 116) and propose certain modifications in the process.

II. Physiological chemical part, by C. D. de Langen and H. Schut (pp. 44-67).—Analytical data based on determinations by the method noted above are presented of the fat and lipoid content of blood of normal persons and those suffering from various diseases, including beriberi. The amount of total fat found in the blood of normal persons varied between 1.5 and 2 per cent. In fever-free malaria patients and in tuberculous patients the figures for fat approached the higher level, while in cases of beriberi the amount of fat was very low.

The authors suggest the possible influence of the lipochrome lutein on beriberi, pointing out that in patients with beriberi the amount of lutein is generally very low and that animal and vegetable substances which have a high antiberiberi value are all derived from organs which contain many lipochromes.

Effect of diet on the alkaline reserve of the blood, J. F. MCCLENDON, L. VON MEYSENBUG, O. J. ENGSTRAND, and F. KING (*Jour. Biol. Chem.*, 38 (1919), No. 3, pp. 539-548, figs. 3).—Determinations of the alkaline reserve of the blood, as represented by the bicarbonate concentration of the plasma on the basis of a normal solution of sodium bicarbonate, were made on a man of 75 kg. (165 lbs.) body weight who was placed on an acid-forming diet for 3 days, then on a mixed diet for 3 days, and finally on a base-forming diet for 3 days.

The results, as well as similar results obtained with dogs, show that the alkaline reserve is not appreciably changed by a change in diet. The rabbit was found to be more susceptible to the effects of diet and fasting.

The authors conclude that "there is no foundation for the view that the alkaline reserve of man is endangered by acid-forming diets, but such diets as usually eaten are deficient in antiscorbutic substances."

An improved form of titration electrode is described and illustrated.

Factors influencing the hydrogen-ion concentration of the ileum, J. F. Mc-CLENDON, F. J. MYERS, L. C. CULLIGAN, and C. S. GYDESEN (*Jour. Biol. Chem.*, 38 (1919), No. 3, pp. 535-538).—Data are presented to show that the length of the ileum is an important factor in determining its H-ion concentration. The shorter the intestine with reference to the length of the body the higher is its acidity. As the gastric juice mingles with pancreatic secretion in the duodenum a large amount of carbon dioxid is produced, more of which is absorbed the longer the intestine.

Food conditions and nutritional diseases in Europe; with some remarks on the etiology of pellagra, S. HARRIS (*Med. Rec.* [N. Y.], 96 (1919), No. 3, pp. 89-95).—This paper presents the results of observations in France, Italy, Austria and Hungary, Germany, and Belgium during the war of the effect of food conditions upon disease, with particular reference to pellagra.

The author points out that with much the same food conditions in a number of European countries that exist among the poor in the rural districts in the South there has apparently been little pellagra. In Italy this disease has even decreased during the war. The inference is drawn that perhaps some other etiological factor than the unbalanced diet is responsible for pellagra, and the suggestion is made that the disease is possibly due to an organism which may be discovered by studying the blood, tissues, and excretions of pellagrins with the dark field microscope.

Experimental mammalian polyneuritis produced by a deficient diet, C. VOECTLIN and G. C. LAKE (*Amer. Jour. Physiol.*, 47 (1919), No. 4, pp. 558-589, figs. 18).—An extensive investigation is reported, the purpose of which was to produce deficiency polyneuritis in mammals, which could be used to better advantage than pigeons in studies on experimental polyneuritis and the physiological function of the antineuritic vitamin.

Experimental evidence, as indicated by the symptomatology, treatment, and pathology of the disease is reported, proving that polyneuritis has been produced in cats and dogs as the result of an exclusive dietary of lean beef which had been heated for three hours at 120° C. in the presence of an alkali, sodium carbonate. The disease was shown to be due to a deficiency of the diet in antineruitic substance and not in other essentials (amino acids, fat-soluble vitamin, etc.). Similar treatment of the beef without the previous addition of alkali did not completely destroy its antineuritic power, indicating that the ordinary preparation of meat for human consumption does not lessen its food value in that respect. Cats were found to respond to the deficient diet with the greatest regularity, and are therefore considered best adapted for physiological studies of the antineuritic vitamin.

Vitamin studies.—IV, Antineuritic properties of certain physiological stimulants, R. A. DUTCHEB (*Jour. Biol. Chem.*, 39 (1919), No. 1, pp. 63–68).— In continuation of the previously noted vitamin studies conducted at the Minnesota Experiment Station (E. S. R., 40, p. 563), prelimnary work is reported on an attempt to discover substances whose physiological action has been studied which will bring about a physiological response in polyneuritic pigeons similar to that of the vitamin extracts.

The administration of thyroxin, desiccated thyroid gland, pilocarpin hydrochlorid, and tethelin apparently produced definite relief from paralytic symptoms in acute cases of avian polyneuritis, but in no case was the response as rapid as when vitamin preparations were fed. This is thought to be due perhaps to the fact that the vitamin preparations contain, in addition to the socalled vitamin, phosphorus, sulphur, and organic compounds needed for the repair and building of tissue.

The study is being extended to other chemical substances.

## ANIMAL PRODUCTION.

Experimental studies on growth.—IX, The influence of tethelin upon the early growth of the white mouse, T. B. ROBERTSON and M. DELPRAT (*Jour. Biol. Chem.*, 31 (1917), No. 3, pp. 567-574, fig. 1).—This paper continues a series of experimental studies (E. S. R., 36, p. 366), and summarizes the growth records of 60 litters of white mice for the first 49 days after birth.

Tethelin, a lipoid extracted from the anterior lobe of the pituitary body, was fed to the mothers of one group of litters but was apparently not secreted by the mammary gland, as no effect on growth was detected. When it was mixed with the feed eaten by the young after their eyes had opened (at the age of 14 days), a marked acceleration of growth occurred during the period designated by Robertson as the second growth cycle (second to fifth week). This was followed by a definite retardation during the third cycle, similar to that found in Study IV (E. S. R., 35, p. 865), when tethelin feeding was begun at the end of the second cycle. The retardation occurred even though the administration of tethelin had been discontinued at the end of the fifth week.

Experimental studies on growth, X-XIV, T. B. ROBERTSON and L. A. RAY (Jour. Biol. Chem., 37 (1919), No. 3, pp. 377-463, figs. 25).—The five papers listed below are added to this series of reports. Studies X, XI, and XIV deal with the body weights of white mice at successive ages, and include tables which give, by weeks to the age of 30 weeks and fortnightly thereafter, the following data for each group of experimental or normal (control) animals considered: (1) The number weighed, (2) the average weight, (3) the difference between the latter and the average at the corresponding age of the normal with which it is compared, (4) the ratio of this difference to its probabl error, and (5) the percentage variability of the weights composing the average. The average weights of each group are also presented graphically as the ordinates of growth curves.

X. The late growth and senescence of the normal white mouse, and the progressive alteration of the normal growth curve due to inbreeding (pp. 377-391).— Amplifying the growth records of Study II (E. S. R., 35, p. 864), the authors first summarize the complete series of weights of the two earliest groups of normals used in their experiments, the males and females born in July, 1914. The records cover the ages from 4 to 150 weeks, i. e., until the death of all the mice. "The average weight of animals of both sexes increases, with a continuously decreasing velocity, to a definite maximum, attained at about 91 weeks of age in the male and at about 94 weeks of age in the female. After attaining this maximum the [growth] curve descends rather steeply, the loss of weight being much more rapid than the immediately preceding gain. This loss of weight is the expression of senescence, and continues without interruption until the decease of the last surviving animal. . . .

"The average duration of life (110 weeks in the male, 103 weeks in the female) exceeds by a definite interval the period during which the weight of the animals is increasing. The attainment of the average duration of life is therefore preceded by a decided measure of senescence which must consequently have affected the viability of the majority of the animals and played a leading part in determining the mean duration of life."

The rest of the paper presents similar data for two groups of males and two of females born at later dates. Each group is compared with its predecessor of the same sex. The intervals between the birth dates were, respectively, 4 and 20 months in the case of the males, and 24 and 15 months in the case of the females. Having due regard to the probable errors of the differences, these data "reveal a regularly diminishing velocity and absolute magnitude of growth in each succeeding batch of animals." The differences were more marked between the first and second than between the second and third groups of each sex, and this is held to indicate an approach to a stable type. The decrease in size and rate of growth is attributed to inbreeding, which was unavoidable since new strains have not been introduced.

XI. The growth and senescence of white mice fed upon pituitary (anterior lobe) tissue, tethelin, egg lecithin, or cholesterol (pp. 393-426).—The growth data presented in Studies III to VI (E. S. R., 35, pp. 865, 866) are extended to cover the later periods of life so that the tables now published are complete from the first weights at the age of 4 or 5 weeks to the time of death of the last survivor. In the course of the four experiments ox pituitary, tethelin, "lecithin" (ether extract of egg yolk precipitated once with acetone), and cholesterol were each fed to a particular group of males and a particular group of females that received in addition a normal mixed diet. A definite amount of each substance was given daily throughout life except in the case of the tethelin female group, where the administration was intermittent and ceased before maturity.

"In all the growth curves senescent loss of weight precedes by a definite interval the average duration of life, and the terminal oscillations of the curve reveal successively steeper descending limbs, showing that senescent loss of tissue is proceeding with augmenting velocity as age increases. The position of the maximum of the growth curve is, however, considerably affected by the administration, and almost disappears in the curve of the tethelin males (which received tethelin continuously) and in the curves of the lecithin-fed animals. The hump of the normal curve is replaced in these cases by a long, flattened plateau, gradually rising (tethelin males) or falling (lecithin males and females) till the relatively rapid fall due to senescence supervenes. It is probably significant that the greatest flattening of the curve (i. e., slowing of the rate of change of growth velocity) occurred in precisely those groups of animals which displayed the greatest duration of life (tethelin males), or else in which certain exceptional individuals displayed a remarkably enhanced duration of life (lecithin males)."

XII. The influence of pituitary gland (anterior lobe) tissue, tethelin, egg lecithin, and cholesterol upon the duration of life of the white mouse (pp. 427442).—This paper deals with the age at death of those mice in the authors' experiments which reached adult life (age of 210 days). In the case of the groups of animals fed either pituitary tissue, lecithin, or cholesterol, the deviations of the average length of life from the average of normal adults were found not to be much, if any, greater than the probable errors of the differences. However, the males fed tethelin lived on the average 99 days (13 per cent) longer than normal males, and the females which had received tethelin lived 81 days (11 per cent) longer than the control females.

XIII. Lesions exhibited by normal, pituitary-, lecithin-, cholesterol-, and tethelin-fed white mice at the occurrence of natural death, with especial reference to the incidence and development of spontaneous cancer (pp. 443–453).

XIV. Further experiments on the influence of tethelin upon the growth of the white mouse (pp. 455-463).—Report is made of the first 50 weeks' growth of 48 female mice (born in 1916) fed tethelin in daily doses continuously, and of the first 30 weeks' growth of 24 females (1916) and 22 males (1917) fed tethelin from the fourth to the twelfth week of life only.

All three groups showed the characteristic retardation in the adolescent stage which normally is the period of most rapid growth. The curve of the continuously-fed group remained below the normal curve until late in life, when the postponement of senescence typical of tethelin feeding caused the curve to meet the descending normal curve. The other two groups after the administration of tethelin had ceased shot rapidly above the normal, and remained above throughout the period under consideration. This acceleration, already noted to a much less marked degree in the two tethelin groups of Study IV, is not attributed to the tethelin directly, but to "compensatory factors which develop in the animal itself in response to the abnormal dosage of the active principle of the anterior lobe of the pituitary body." It is stated that some exceptionally large animals have been secured as the result of brief periods of tethelin feeding.

The growth of the ovarian follicle of the guinea pig under normal and pathological conditions, L. S. N. WALSH (*Jour. Expt. Med.*, 26 (1917), No. 2, pp. 245-261, figs. 2).—The ovaries of 6 guinea pigs were cut into serial sections, and the percentage of granulosa cells in the process of mitosis was determined for a number of normal follicles in different stages of growth.

In small follicles (averaging 215 by  $130\mu$ ) 0.66 per cent of the cells were dividing, in medium sized follicles (506 by  $450\mu$ ) 1.2 per cent, in large follicles (788 by  $611\mu$ ) 0.73 per cent, and in fully mature follicles (930 by  $629\mu$ ) 0.06 per cent. About 220,000 cells were examined in making these determinations. It is held that the growth energy is at its maximum in medium-sized follicles. Most of the cell divisions were observed in the vicinity of the ovum.

The extent of cell division in atretic follicles and in follicles of ovaries which were not functioning normally was also studied. The proliferative power of living granulosa cells is apparently reduced during the atresia which follows ovulation.

Live stock breeding, P. P. VAN DER POEL (Jaarb. Dept. Landb., Nijv. en Handel Nederland. Indië, 1916, pp. 291-333).—Information is provided as to the live stock interests of Java and Madura, Sumatra, Celebes, the Dutch possessions in Borneo and most of the lesser East Indian Islands, but not of New Guinea and the Molukka Islands, together with statistics of imports and exports, the numbers of cattle and buffalo slaughtered for meat, and the distribution of dairy cattle according to breed and locality.

Famous Angus cows of Scotland, H. W. MUMFORD (Breeder's Gaz., 76 (1919), No. 11, pp. 462, 463).—The author selects five Aberdeen-Angus cows, Erica, Pride of Invershie, Elba, Jilt, and Pride of Aberdeen, for special mention on account of the noteworthy qualities of their descendants.

Determining the age of cattle by the teeth, G. W. POPE (U. S. Dept. Agr., Farmers' Bul. 1066 (1919), pp. 4, figs. 6).—A series of cuts is given showing the appearance of the internal face of the incisors of cattle shortly after birth and at the ages of 2, 3, 4, 5, and 12 years. There is a brief explanatory text.

The availability of the energy of food for growth, C. R. MOULTON (Jour. Biol. Chem., 31 (1917), No. 2, pp. 389-394) .- To study the utilization for beef production of metabolizable energy derived from the feed and not needed for maintenance, two mature beef steers at the Missouri Experiment Station were fattened immediately after they had been subjected to a prolonged maintenance trial in a thin condition. The feeds offered—corn chop and linseed meal (8:1), and alfalfa hay to the extent of 40 per cent of the grain ration—were the same in kind and proportion as during maintenance. The data from a digestion experiment with these feeds and the maintenance trial have been published (E. S. R., 33, p. 569), the animals being included in the "regular-maintenance" group. In estimating the energy requirement for maintenance from the results for the thin steer it was assumed that the energy required is proportional to the five-ninths power of the body weight, in accordance with previous determinations of the author (E. S. R., 35, p. 64). The metabolizable energy of the feed was computed from the chemical composition by the Armsby method and was found to be 1.72 therms per pound of digestible organic nutrients.

One steer (No. 121) was slaughtered when in full prime condition and the other (No. 48) when 40 to 50 days under prime. Proximate analyses were made of the dressed carcasses. A third steer (No. 18) which had also been on the maintenance trial, was slaughtered at the beginning of the fattening period. The percentage composition of its carcass was taken as the initial percentge composition of the other two steers, and in this way the chemical constitution of the gains made by the latter are estimated. It was assumed, using average data of other workers, that the thermal equivalents of the protein and of the fat in the gains were respectively 5.6776 and 9.4889 calories per gram.

The main results are assembled in the following table:

Steer No.	Condition at slaughter.	Initial weight.	Feed- ing period.	Gain in dressed carcass.	Protein in gain.	Fat in gain.	Metabolizable energy.		Energy recovered.		Propor- tion of
							Used for main- te- nance.	Avail- able for gain.	In pro- tein gained.	In fat gained.	avail- able energy recov- ered.
121 48	Medium Prime	Lbs. 764 842	Days. 153 567	Kg. 212 418	P. ct. 11. 8 8. 5	P. ct. 46.1 59.4	Therms. 1,900 8,646	Therms. 2,000 4,873	Therms. 141 203	Therms. 926 2,356	P. ct. 53.4 52.5

Recovery of available energy in fattening steers.

It is pointed out that about the same proportion of the available energy was recovered in both the very fat and the medium fat steer. The former, however, had 5.06 therms while the latter had only 3.98 therms available for each pound of gain, a difference explained by the higher proportion of fats in the gains of the latter.

It is estimated that if the grain and alfalfa hay of Armsby and Fries' experiments (E. S. R., 33, p. 72) had been fed in the same proportions as in those reported by the authors, about 55 per cent of the available energy would have been utilized. Compared with the author's average of about 53 per cent, "this is a remarkably close agreement, and is an experimental verification of the work done by Armsby in his calorimeter."

Supplementary feeds in fattening lambs, H. J. GRAMLICH (Nebraska Sta. Bul. 173 (1919), pp. 24, figs. 8).—A feeding experiment beginning December 30, 1915, with 308 Wyoming lambs divided into 11 lots is reported. A preliminary account of certain results has been noted (E. S. R., 38, p. 271). In one lot (lot 8) the lambs received corn and linseed meal in a self-feeder, were allowed all the prairie hay they would eat, and were marketed in 40 days. The other lots were all hand fed, received alfalfa hay ad libitum, and were marketed in 75 days, all at the same selling price. Three lots were used in testing heavy, medium, and light corn feeding without other concentrates, and 3 in comparing linseed meal, cottonseed meal, and cold-pressed cottonseed cake when fed in definite amounts with such corn and alfalfa as would be consumed. The main results from these 6 lots are tabulated below.

Lamb feeding, 1915-16. Value of limiting corn rations and comparison of supplements.

Lot.	Corn ration per head.	Supplement fed.	Nutri- tive ratio.	Initial weight per head.	Daily gain per head.	Feed consumed per pound of gain.			Cost	Profit
						Shelled corn.	Supple- ment.	Alfalfa hay.	pound ofgain.	head.
1 2 3 5 6 7	Lbs. 1.33 .86 .72 1.22 1.29 1.29	Nonedo do Linseed meal Cottonseed meal Cottonseed cake	1: 6.61: 5.41: 5.21: 5.31: 5.01: 5.4	$Lbs. \\ 60.3 \\ 60.9 \\ 60.9 \\ 61.3 \\ 59.7 \\ 59.1$	<i>Lbs</i> . 0.337 .329 .298 .407 .437 .430	$\begin{array}{c} L5s.\\ 3.94\\ 2.60\\ 2.42\\ 2.99\\ 2.96\\ 2.84\end{array}$	Lbs. 0.535 .517 .748	Lbs. 2.99 4.99 5.58 2.65 2.45 2.41	Cents. 5.53 4.90 4.94 5.43 5.15 5.18	\$2.13 2.27 2.12 2.48 2.65 2.60

Shelled corn was charged at 60 cts. per bushel and alfalfa hay at \$8.50 a ton. The price per ton charged for linseed meal was \$40, for cottonseed meal \$35, and for cold-pressed cake \$29. The relative profits are influenced slightly by the fact that the initial costs for lambs varied from lot to lot.

It is pointed out that a medium corn ration under the conditions was more economical than a heavy or a light ration.

With regard to the supplements, it is estimated that \$53 could have been paid for linseed meal, \$55 for cottonseed meal, and \$41.50 for cottonseed cake without reducing the profits from lots 5, 6, and 7, below the lot 1 profit.

Lot 4, in addition to alfalfa and a full feed of shelled corn, was given a daily corn-silage ration which was gradually reduced from 2 lbs. per head at the beginning to 0.5 lb. at the end of the test. The average daily gain was 0.388 lb. The silage consumed per pound of gain was 3.93 lbs., this amount replacing 0.74 lb. of the corn and 1.4 lb. of the alfalfa required by lot 1 for a pound of gain. With silage at \$4 a ton, the cost of gain was 4.95 cts. a pound and the profit per lamb \$2.52.

Lot 9 was treated like lot 1 except that hominy feed was substituted for corn. To make a pound of gain these lambs required 3.57 lbs. of hominy feed and 3.01 lbs. of alfalfa, at a cost of 5.78 cents, with hominy feed at \$25 a ton. The daily gain was 0.36 lb. per head and the profit about equal to that of lot 1. It is pointed out that with hominy feed and corn priced the same, the former would have been distinctly more profitable. Sliced sugar beets were added to the corn and alfalfa ration of lot 10. The daily gain was 0.366 lb. per head. Compared with the results of lot 1, 2.98 lbs, of beets took the place of 0.5 lb. of corn and 0.38 lb. of alfalfa in producing a pound of gain and reduced the cost 0.08 ct. if the beets are valued at \$4 a ton.

Lot 11 (corn and alfalfa hay) was fed in the open, whereas the other lots were all under shelter. The corn consumption per unit gain was the same as in lot 1; the alfalfa consumption was 0.14 lb. less.

Lot 8 (self feeder) made an average daily gain of 0.5 lb. per head for the 40 days of the test and consumed 2.65 lbs. of corn, 2.09 lbs. of linseed meal, and 0.7 lb. of prairie hay per pound of gain, at a cost of 7.34 cts. The charge for prairie hay is not indicated. Unless a high finish is required in a short time, this method of feeding is not recommended.

A table is included showing the changes in cost of gains of each lot with changes in the prices of the feeding stuffs used.

Ninety-five-day lamb feeding experiment, November 23, 1916, to February 25, 1917 (*Bul. Nebr. Bd. Agr., No. 245* (1918), pp. 353-357).—Eight lots of 27 Wyoming lambs and one of 26 were fed at the Nebraska Experiment Station. Lots numbered 1 to 8 were intended as duplicates of the lots bearing corresponding numbers in the preceding winter's experiment noted above. A selling price was assigned to each lot according to the finish. The results from the tests of limited corn feeding and from the comparisons of protein supplements may be summarized as follows:

Lamb feeding, 1916–17. Value of limiting corn rations anr comparison of supplements.

Lot.	Corn ration per head.	Supplement fed.	Initial weight per head.	Daily gain per head.	Feed consumed per pound gain.   Shelled corn. Sup- ple- ple- hay.		Cost per pound of gain.	Selling prices per pound.	Profit per head.	
1 2 3 5 6 7	Lbs. 1. 32 1. 09 .84 1. 09 1. 09 1. 10	Nonedo do Linseed meal Cottonseed meal Cottonseed cake	<i>Lbs.</i> 53. 2 53. 9 54. 7 52. 6 53. 7 54. 1	$\begin{array}{c} Lbs. \\ 0.397 \\ .356 \\ .299 \\ .420 \\ .395 \\ .371 \end{array}$	Lbs. 3.32 3.06 2.81 2.60 2.76 2.96	Lbs. 0.81 .86 1.05	<i>Lbs.</i> 3.30 3.93 4.72 3.17 3.29 3.21	Cents. 6.64 6.56 6.57 7.30 7.72 8.15	Cents. 13.90 13.75 13.75 14.05 14.20 14.20	\$3.55 3.18 2.82 3.53 3.39 3.11

The following prices were charged: Corn 84 cts. a bushel, and alfalfa \$10, linseed meal \$45, cottonseed meal \$45, and cold-pressed cottonseed cake \$40 a ton.

The amounts of alfalfa hay consumed were about equal in lots 1, 2, and 3, and it is pointed out that the gains were in proportion to the quantity of corn eaten.

Lot 4, which received silage in addition to corn and alfalfa, gained at the rate of 0.377 lb. per head per day and consumed 3.08 lbs. of silage per pound of gain. This quantity of silage effected a reduction of 0.7 lb. in the corn and 0.36 lb. in the alfalfa required for a pound of gain if lot 1 is taken as the check. With silage charged at \$5 a ton, the cost of a pound of gain was 6.18 cts. This lot sold for 14.1 cts. a pound and yielded a profit of \$3.70 a head.

153351°-20---6

[Vol. 41

Two lots were given linseed meal and shelled corn in self feeders, one (lot 8) having access to prairie hay and the other (lot 9) to alfalfa hay. Both lots were marketed in 64 days. Lot 8 gained at the daily rate of 0.422 lb. per head and consumed 2.42 lbs. corn, 2.84 lbs. linseed meal, and 1.42 lbs. of hay per pound of gain. The corresponding consumption by lot 9 was 2.07, 2.42, and 1.76 lbs., respectively. The average daily gain in lot 9 was 0.459 lb. In spite of the fact that prairie hay was charged at \$1 less per ton than alfalfa, the cost of a pound of gain in lot 8 was 10.7 cts. and in lot 9, 9.4 cts. Both lots sold for the same price but the alfalfa feeding resulted in over twice the profit (\$2.45 as compared with \$1.04).

Sheep and wool in South Africa and their relation to industrial development. C. MALLINSON (So. African Jour. Indus., 1 (1918), No. 12, pp. 1105–1112).— Notes on the extent and nature of the sheep industry in the Cape Province, Orange Free State, the Transvaal, and Natal are presented, as well as statistics on the export of wool, mohair, sheepskins, and goatskins from the South African Union from 1909 to 1917.

Our National herds of buffalo, T. S. PALMER (Ann. Rpt. Amer. Bison Soc., 10 (1915-16), pp. 40-62, figs. 2).—Information is provided concerning the origin and increase of the various herds of American bison located in National parks and game preserves.

The efficiency of pigs, R. C. ASHBY (Swine World, 8 (1919), No. 2, p. 15).—The feeding and growth records of 63 pigs, each kept in a separate pen at the Minnesota Experiment Station, are briefly summarized with respect to individual variation in the economy of gain. Different groups of from 5 to 16 animals were fed in the course of 3 years, some on pasture and some in dry lot, but the individuals of any one group were all furnished the same choice of feeds. Fuller reports of some of the groups have been noted (E. S. R., 40, pp. 770, 771). The feet consumption per unit gain of 22 animals deviated, it is stated, more than 10 per cent from the average of their respective groups and that of 19 deviated between 5 and 10 per cent.

"The next step is to select many individuals and through breeding experiments determine whether it is possible to develop strains of hogs that are unusually efficient producers."

Measuring a hog's efficiency, R. C. ASHBY (Breeder's Gaz., 76 (1919), No. 11, p. 462).—This paper is the same as the one noted above.

The behavior of chickens restricted to the wheat or maize kernel, II, E. B. HART, J. G. HALPIN, and H. STEENBOCK (*Jour. Biol. Chem.*, 31 (1917), No. 2, pp. 415-420, pl. 1).—This paper, from the Wisconsin Experiment Station, reports what is essentially a repetition of the earlier work of Hart, Halpin, and McCollum (E. R. S., 36, p. 668) with somewhat younger (or at least lighter weight) birds. Nine cages (lots) of Rhode Island Red pullets were used, 3 to a cage, and the experiment continued for 8 months during the winter and spring of 1916-17.

The lots fed corn meal and corn gluten feed, with or without complex salt mixtures, and the lot fed corn meal and case in continued to thrive and made slow gains. In contrast to the previous results with more mature birds, all but one of the 12 chickens whose grain feed was from the wheat plant exclusively died within 3 months. "The birds that died became greatly emaciated, but no other symptoms of striking character developed. However, when excited, they would often be seized with serious spasms, provoking extraordinary flapping of the wings, followed by exhaustion and collapse." The one that survived belonged to a lot receiving case in and butterfat in addition to wheat meal. Blood fat in domestic fowls in relation to egg production, D. E. WARNER and H. D. EDMOND (*Jour. Biol. Chem.*, 31 (1917), No. 2, pp. 281-294).—The percentages of fat (total ether extract) in samples of blood collected at the end of October from 94 White Leghorn fowls at the Connecticut Storrs Experiment Station are reported.

The mean for 16 hens that had about completed their pullet year but which were still actively laying is given as 1.109 per cent. The mean for 54 similar yearlings that had stopped laying some time before (51.7 days on an average) was 0.199. The mean for 12 hens at the end of their third year and not actively laying was 0.171, and that for 12 cockereds was 0.176. The blood samples of the males seemed to be much less variable in fat content than those of the females.

The pullet year egg record of each of the 70 yearlings is also recorded. The average of the laying birds is given as 162.8, that of the others as 139.1. Twelve of the former and 6 of the latter were classified as having pale beaks, legs, and vents. The average egg production of the 18 individuals was 168.2 and the average blood fat content 0.816 per cent. Nine of the mature hens and 23 of the inactive yearlings were classified as having yellow beaks, legs, and vents. The average egg production of this group of 32 was 117.9 and the average blood fat content 0.196 per cent.

The following are some of the conclusions drawn from these facts: "There is little or no correlation between the amount of fat in the hen's blood and her yearly egg yield. On the other hand the blood of a hen laying at the time the sample is taken is much richer in fat than that of a hen that is not laying... There exists a close [negative] correlation between the color of the beak, legs, and vent and the percentage of fat found in the blood.... This would show that birds that were not laying were storing fat in the body cells, and consequently their legs, beaks, and ani would become yellow, the natural color for all American breeds and the Leghorns."

The blood samples of 12 hens were known to have been taken after a 16hour fast. The average fat percentage was 0.009 higher than that of another group of 12 which had not fasted. The difference is considered trifling.

The cholesterol in the blood samples of a few of the birds was determined by the colorimetric method described by Bloor (E. S. R., 35, p. 13). The average of 11 active layers was 0.114 per cent, of 7 inactive yearings 0.086 per cent, and of 4 males 0.086 per cent.

Note on the relation of blood fat to sex, and on the correlation between blood fat and egg production in the domestic fowl, O. RIDDLE and J. A. HARRIS (Jour. Biol. Chem., 34 (1918), No. 1, pp. 161-170).—Correlation coefficients between percentage of fat in the blood and the annual egg production are computed from the data concerning yearling hens furnished by Warner and Edmond in the paper noted above. For the 16 actively laying birds this correlation was found to be  $\pm 0.351 \pm 0.147$  and for the 54 inactive birds  $-0.296 \pm 0.084$ . "Now, while the probable errors of these correlations are large, because of the relatively few determinations, the correlations suggest at once that while the birds are laying those which have the highest percentages of blood fat are those which make the highest egg records, but that after the bird has ceased laying in the autumn those which have laid the greatest number of eggs during the year have the blood most depleted of fat; or, at any rate, have blood with least fat."

The inactive birds were further subdivided according to the time elapsed since laying ceased. For the 16 which had laid within 24 days the correlation was  $\pm 0.054 \pm 0.168$ . For the 22 whose inactive period varied from 25 to 29 days the correlation was  $\pm 0.132 \pm 0.141$ , and for the 16 which had not laid for 60 or more days it was  $\pm 0.620 \pm 0.103$ . Attention is called to the progressive change in correlation. The correlation was  $-0.411 \pm 0.117$  in the case of the 23 birds with beak, legs, and vent colored yellow, and  $+0.532 \pm 0.114$  in the case of the 18 in which these organs were pale.

Mainly on the basis of these determinations some of the conclusions of Warner and Edmond are criticized, and these authors are also charged with ignoring prior work of Lawrence and Riddle (E. S. R., 37, p. 773).

Blood fat in fowls, D. E. WARNER and H. D. EDMOND (Jour. Biol. Chem., 34 (1918), No. 1, pp. 171-174).—This is a reply to criticisms of Riddle and Harris (noted above).

The authors state that they do not consider a correlation to be marked unless the absolute value of the coefficient is 0.3 or more and is at least 6 times the size of the probable error. They also hold that the work of Lawrence and Riddle "does not fulfil the requirements for carefully controlled experimental study" inasmuch as (1) only 3 males, 3 nonlaying females, and 5 laying females were used, (2) four different breeds were represented and several of the birds were mongrels, (3) the ages varied from 11 months to 4 years and are vaguely designated, and (4) the blood samples were not all collected at the same season of the year.

Fertilization of hens' eggs, D. F. LAURIE (Jour. Dept. Agr. So. Aust., 22 (1919), No. 6, pp. 459-464).—In November, 1918, 6 hens that had been isolated from male birds for several months were each allowed to mate once. Two laid fertile eggs up to the fifteenth day afterwards, 2 until the fourteenth day, and 2 laid only infertile eggs. A previously published table (E. S. R., 29, p. 574), showing the continued production of fertile eggs by flocks of hens up to the seventeenth day after the removal of the cock, is reprinted, but with the date of observation changed from the summer (December, 1911, and January, 1912) to the spring (October and November, 1911).

**Experiments in caponizing fowls,** D. F. LAURIE (*Jour. Dept. Agr. South Aust.*, 22 (1918), No. 1, pp. 40-43).—The post mortem examination is reported of several cocks which had been incompletely castrated as cockerels, and which had subsequently developed the secondary sexual characters and behavior of typical males. In the cases where both testes had been operated on, it was found that a mutilated piece had continued to function and often had grown into a more or less normal testis.

### DAIRY FARMING-DAIRYING.

The consumption of milk in the United States, L. B. COOK (Ann. Rpt. Internatl. Assoc. Dairy and Milk Insp., 5 (1916), pp. 281-283).—Replies to a questionnaire regarding milk consumption and milk prices sent out by the Dairy Division of the U. S. Department of Agriculture to cities in the United States are summarized by geographical (census) divisions. In general, regions where the price was high reported a low per capita consumption.

Ice cream, a factor in dairying, R. M. WASHBURN (*Milk Mag.*, 7 (1919), No. 4, pp. 16, 52).—The author estimates that the amount of butterfat consumed annually in the United States as ice cream is five times as large as the amount of butterfat exported as butter, and holds, therefore, that the summer ice cream trade helps to maintain the price of butterfat during the period of excess milk production. Ice cream is also considered a profitable outlet for the solids-not-fat of milk.

The importance of clean utensils in clean milk production, G. B. TAYLOR (Ann. Rpt. Internatl. Assoc. Dairy and Milk Insp., 6 (1917), pp. 164–172).— Physical and bacteriological examinations of a number of 10-gal. shipping cans washed in a commercial milk plant are reported. The material for plating was secured by pouring 400 cc. of distilled water into the can.

In a limited number of cases satisfactory conditions were found when the cans had been inverted over a steam jet for from 30 to 60 seconds. Cans held for 6 minutes in a washing machine, where they were scrubbed, steamed, and then dried in a current of warm air, were in general without musty odor and yielded relatively few bacteria, except when the cans were very rusty or the rinse water was turbid.

Two simple and inexpensively operated devices for heating water on dairy farms are also described.

Observations on the pasteurization and subsequent handling of milk in city milk plants, R. S. SMITH (Ann. Rpt. Internatl. Assoc. Dairy and Milk Insp., 7 (1918), pp. 96-114; abridged in Creamery and Milk Plant Mo., 8 (1919), No. 5, pp. 33-35).—Several specific instances are reported of faulty practices in city milk plants whereby pasteurized or supposedly pasteurized milk contained unduly large numbers of bacteria at the time of marketing. The practices include (1) "pasteurization" at unintentionally low temperature, (2) allowing a rise in temperature after cooling, and (3) use of unsterile coolers, bottling machines, milk bottles, and bottle caps. The number of bacteria introduced by the various pieces of apparatus were estimated by washing them in measured amounts of water and plating the wash water. In continuation of the work of Webster (E. S. R., 41, p. 373), with which the author was connected, results of the bacteriological examination of 236 freshly washed milk cans intended for pasteurized milk are also summarized to show that these likewise are a fruitful source of bacteria.

Health officials are cautioned not to assume that the mere passage through a pasteurizer of all the milk sold in a city necessarily insures a sanitary supply.

The sediment test as applied to dairy inspection, W. E. WARD (Ann. Rpt. Internatl. Assoc. Dairy and Milk Insp., 7 (1918), pp. 54-60).—The author cites illustrative data to show a close correlation between an inspector's reports of conditions on a series of dairy farms, and the color of the cotton disks used in sediment tests of milk from these farms made independently at receiving stations and railroad platforms. It is held that systematic sediment tests and temperature determinations of milk at delivery points would enable inspectors to determine what farms need most attention or require reinspection.

The author also claims that by examining the material collected on the disk with a lens he can judge quite accurately what faulty conditions occur on the farm furnishing the milk.

Simplified city milk inspection, H. A. HARDING (Ann. Rpt. Internatl. Assoc. Dairy and Milk Insp., 7 (1918), pp. 201-211).—The author would (1) reduce or perhaps abolish farm inspection, (2) require all milk sold to be pasteurized, (3) establish rigorous inspection of pasteurizing plants, and (4) require the market grade and fat percentage to be marked in the bottle cap. Only three market grades are considered necessary, viz, special, table, and cooking milk, the classification (with pasteurization assumed) being based on cleanliness and keeping qualities. Samples collected from the distributors' wagons would be subjected to the Babcock and sediment tests and some simple test of keeping quality, such as the acidity and flavors developed after holding for 24 hours at 60 or 65° F. More complicated tests, including bacterial counts, are omitted so that the dealer himself can readily determine what grade of milk he is selling. A dealer caught misbranding his milk would lose his license.

Any proposed additions to these requirements "should be carefully scanned both as to their soundness and as to their results. The price of milk is already high. Every additional requirement either raises the price of milk or decreases the supply, and neither of these results will be taken kindly by the consuming public."

Modern developments in dairy inspection, E. KELLY (Ann. Rpt. Internatl. Assoc. Dairy and Milk Insp., 7 (1918), pp. 37-41).—The author claims that dairy inspection properly includes attention to general cleanliness about the premises, partly to increase the morale of milk handlers and insure their vigilance in more essential matters, and partly to advertise milk as an inviting article of food.

Report on questionnaire to health officers concerning control of the milk supply, G. B. TAYLOB (Ann. Rpt. Internatl. Assoc. Dairy and Milk Insp., 7 (1918), pp. 118-200).—In order to obtain information regarding laboratory control of the milk supply and the extent of dairy inspection in the United States, a questionnaire was sent by the Dairy Division of the U. S. Department of Agriculture in April, 1918, to the health officers of all cities of over 5,000 population and to State and Territorial boards of health. Replies were received from 481 cities in 40 States and Hawaii, and from 24 State laboratories or similar agencies. Each reply is summarized in the appendix to the author's paper. There are also a list of health departments having no laboratories for the examination of milk, and a tabultion by cities of opinions concerning inspection and bacterial counts. The replies cover chemical and bacteriological methods in use and the manner of collecting the samples.

The author provides a general summary and discussion, and deplores the lack of uniformity in methods and the poor control over milk supplies generally exercised by the smaller cities.

Milk inspection from the point of view of the Bureau of Chemistry of the U. S. Department of Agriculture, C. L. ALSBERG (Ann. Rpt. Internatl. Assoc. Dairy and Milk Insp., 5 (1916), pp. 296-306).—This is an informal account of the effort of the Bureau of Chemistry, working in collaboration with the Dairy Division, to improve the efficiency of milk inspection. The author suggests regional clearing houses for inspection reports so that one dairy farm will not be inspected by several different agencies.

Cooperation and the organization of the dairy industry (Jour. Bd. Agr. [London], 25 (1918), No. 9, pp. 1081-1090).—This is an account of the development of cooperative cheese factories and milk depots in England, particularly since the establishment of the dairy branch of the Agricultural Organization Society in 1912. The activities of the cooperative cheese schools in operation during 1917 and 1918 are also explained. Part of the business of these schools is to train cheese makers, but their main function, apparently, is to demonstrate to the farmer the advantages of the cooperative factory system, and to urge on financial grounds the desirability of more cheese making and less butter making in country districts.

**Report on the working of a cooperative cheese school** (*Jour. Bd. Agr.* [*London*], 25 (1918), No. 9, pp. 1091-1093).—This is a report of a cheese school held near Newbury, in Berkshire, from May to September, 1918.

The cooperative dairy at Telinkheri in its relation to dairying in the Central Provinces, D. CLOUSTON (Agr. Jour. India, 13 (1918), No. 1, pp. 54-64, pls. 3).—An account is given of the operation under governmental auspices in the Central Provinces of India of a privately owned plant for the distribution of milk and the manufacture of butter and ghee. The milk is furnished by a number of buffaloes and a few cows housed on a government dairy farm, most of the stock being the property of the native professional milkmen (gowlies), who by tactful management have been persuaded to form cooperative societies under the supervision of the farm overseer. The plans are also outlines for improving the three local breeds of buffaloes by the use of Delhi sires brought in by the government. The cost of raising young buffalo stock is also estimated. The expenses per head, except where grazing is cheap, were found to exceed the value of an adult of the native breeds.

Buffaloes' milk collected at the dairy for analysis in 1917 (146 samples) averaged 7.1 per cent of butter fat, while the cows' milk (37 samples) averaged 4.2 per cent. To produce a pound of butter required 11 lbs. of buffaloes' milk or 19.5 lbs. of cows' milk.

Fifth annual report of the creamery license division for the year ending March 31, 1919, O. E. REED and T. H. BROUGHTON (Indiana Sta. Circ. 93 (1919), pp. 3-56, figs. 4).—This report contains the names of licensed testers in Indiana, a list classified by counties of the licensed creameries, cream stations, milk stations, condenseries, etc., in the State, and miscellaneous matter similar to that in preceding reports (E. S. R., 39, p. 884).

### VETERINARY MEDICINE.

Report of the twenty-second annual meeting of the United States Live Stock Sanitary Association (Rpt. U. S. Live Stock Sanit. Assoc., 22 (1918), pp. VIII+213, figs. 14).—This report of the proceedings of the annual meeting held at Chicago, December 2 to 4, 1918, includes the following papers: Tuberculosis Eradication, by J. A. Kiernan (pp. 29-52) (E. S. R., 40, p. 681); The Retest of Reacting Cattle, by J. G. Wills (pp. 53-84); Efficiency Principles Applied to the Animal Tuberculosis Problem, by B. R. Rogers (pp. 84-95); Blackleg Immunization, by A. Eichhorn (pp. 102-112); Hemorrhagic Septicemia, by R. Graham and E. Records (pp. 113-124); Some Phases of Parasitism, by A. T. Kinsley (pp. 125-134); Necrobacillosis, by C. P. Fitch (pp. 135-147) (E. S. R., 41, p. 87); Relation of the Sanitarian to the Stock Breeder, by D. A. Wallace (pp. 161-163); Observations Concerning the Dissemination of Hog Cholera by Insects, by M. Dorset, E. N. McBryde, W. B. Niles, and J. H. Rietz (pp. 163-174) (E. S. R., 41, p. 578). Reports of committees relating to hog cholrea control, tick eradication, accredited herds, tuberculosis eradication, infectious abortion, etc., are included.

Report on operations of the veterinary sanitary service of Paris and the Department of the Seine during the year 1917, H. MARTEL (*Rap. Opér. Scrv. Vét. Sanit. Paris et Dépt. Seine, 1917, pp. 150, figs. 6*).—This is the usual annual report (E. S. R., 39, p. 679), with the usual tabular data.

Annual administration report of the civil veterinary department in Baluchistan for the official year, 1918-19, J. G. CATTELL (Ann. Admin. Rpt. Civ. Vet. Dept. Baluchistan, 1918-19, pp. 14).—This report includes tabular data which show the number of deaths from contagious diseases among animals during the year under report.

Annual administration report of the Bombay Veterinary College and civil veterinary department in the Bombay Presidency (including Sind) (Ann. Admin. Rpt. Bombay Vet. Col. and Civ. Vet. Dept. Bombay, 1916-17, pp. 58; 1917-18, pp. 52).—These reports include data on the number of deaths from contagious diseases among animals.

Theory of invasion by infective agents, A. G. MCKENDRICK (*Indian Jour. Med. Research, 6 (1919), No. 4, pp. 614-632, figs. 6*).—Certain considerations regarding the formation of antibodies in response to the invasion of the body by infective agents are discussed and summarized as follows:

"The introduction of organisms (or their products) into the body system causes an acceleration in the rate of production of antibodies. It is reasonable to assume that the degree of response is proportional to the logarithm of the stimulus, and to the tissue reactivity. The stimulating power of an organism (or its products) probably depends upon its degree of saturation (sensitization)."

On the basis of this theory a system of classification of diseases due to organismal invasion on the one hand and influences acting in a contrary manner on the other is outlined, in which the main clinical types of diseases fall into a broken series. At the two extremes of this series stand diseases like pneumonia, in which protective efforts are in excess, and chronic infection in which protective efforts are continually overbalanced. Malta fever, representing a type of relapsing disease, lies near the neutral point in this scheme, where the balance between protective efforts and opposing influences is exact.

The effect of feeding yeast on antibody productions, E. P. Wolf and J. H. LEWIS (*Jour. Infect. Diseases, 25 (1919), No. 4, pp. 311–314*).—With a view to a possible explanation of the therapeutic value claimed for yeast in infectious diseases, the effect of the feeding of yeast on the production of antibodies to sheep blood cells in rabbits was studied.

From the results obtained, the authors conclude that yeast does not act by increasing antibody formation in the rabbit. On the contrary, it may even cause a reduction in the amount of antibodies formed as compared with those of the control animals. Yeast was also found to be lacking in the laxative value.

Hydrogen-ion concentration of cultures of pneumococci of the different types in carbohydrate media, O. T. AVERY and G. E. CULLEN (*Jour. Expt. Med.*, 30 (1919), No. 4, pp. 359-378, figs. 2).—This paper reports a study of the H-ion concentration of cultures of pneumococcus in carbohydrate media under different conditions, the results of which may be summarized as follows:

The optimum H-ion concentration for the growth of pneumococcus is pH 7.8. If sufficient fermentable carbohydrate (above 0.4 per cent) is present in broth cultures of pneumococcus, growth continues until a final H-ion concentration of about pH 5 is reached, but if less carbohydrate is present growth ceases at a lower H-ion concentration. If no carbohydrate is present except that extracted from the meat of which the broth is made, growth initiated at pH 7.8 ceases at about pH 7.

If bacteria-free filtrates of plain broth cultures in which growth has ceased are readjusted to pH 7.8 and reinoculated with pneumococcus, no growth occurs unless carbohydrate is added, but a similar readjustment of bacteria-free filtrates of dextrose broth cultures causes growth.

All of the carbohydrates which were fermentable under the conditions used gave the same results in the rate of reaction change and final H-ion concentration attained, and the different immunological types of pneumococcus behaved alike in fermenting these carbohydrates.

The pathogenicity of Bacterium melitensis for guinea pigs, K. F. MEYER, E. C. FLEISCHNER, and E. B. SHAW (*Proc. Soc. Expt. Biol. and Med.*, 16 (1919), *No. 8, pp. 152-156*).—The authors confirm the relationship of *Bacillus abortus* to *B. melitensis* previously demonstrated by Evans (E. S. R., 39, p. 289), and announce two additional characteristics of similarity as follows:

(1) Guinea pigs infected with *B. abortus* developed striking reactions of cutaneous hypersensitiveness with melitensis protein, and in animals successfully infected with *B. melitensis* skin reactions were obtained with abortoprotein. (2) By intratesticular injection in guinea pigs of a one-tenth agar slant of strains of *B. melitensis*, a disease was produced with pathological changes which could not be distinguished from those seen in guinea pigs suffering from abortion disease. The lesions of two guinea pigs were diagnosed definitely to be the result of a *B. melitensis* infection only by cross agglutination and absorption with the recovered bacteria.

Some morphological and biological characters of the spirilla (Vibrio fetus n. sp.) associated with disease of the fetal membranes in cattle, T. SMITH and M. S. TAYLOR (*Jour. Expt. Med.*, 30 (1919), No. 4, pp. 299-311, pl. 1).—In this paper are reported further observations on the morphological and cultural characteristics of the spirilla previously found to be associated with certain cases of infectious abortion in cattle (E. S. R., 40, p. 383), together with studies of the agglutinative affinities of the various strains.

Twenty-two fetal and two calf strains of spirilla, obtained from one large herd into which cattle from outside were introduced at irregular intervals, were studied. Of the fetal strains, all but one agreed closely in morphological and biological characteristics, and all belonged to the same group with respect to agglutination affinities. Of the two calf strains, one had definite agglutination reactions with the fetal strains and the other none. Both resembled the fetal strains morphologically and culturally.

Since the organism appears in both long spiral and short comma forms in fetal fluids, but tends to assume the comma form in its early most active stage of multiplication in cultures and has single polar flagella, it has been designated *V. fetus* n. sp., although the term spirillum is still used as a general expression.

Attention is called to the fact that there is a decided difference between the cultural characteristics of early and late cultures, the organisms gradually becoming saprophytized.

The etiological relation of spirilla (Vibrio fetus) to bovine abortion, T. SMITH (Jour. Expt. Med., 30 (1919), No. 4, pp. 313-323).—To determine whether V. fetus, noted above, is a true agent causing disease of the fetal membranes or simply an invader from the more external tract, or from the blood after the fetus has been injured or killed by other nonbacterial agencies, four pregnant cows were inoculated intravenously with agar cultures of V. fetus obtained from aborted fetuses. After the birth of the calf the placentas and postpartum discharges were examined for evidences of V. fetus and of Bacillus abortus.

In two of the cases disease of the fetal membranes resulted, corresponding with the lesions found in earlier cases associated with spirilla. Spirilla were found in the early postpartum discharges of one of these animals. No evidence of *B. abortus* was obtained. Although the other two cases were entirely negative, it is felt that strong evidence has been given in this study that *V. fetus* is an etiological factor in bovine abortion.

The bacteriology of bovine abortion, with special reference to acquired immunity, T. SMITH (Jour. Expt. Med., 30 (1919), No. 4, pp. 325-339).--In this paper the author has tabulated and discussed the bacteriological data obtained in the study of cases of abortion in the herd mentioned in the above paper and earlier contributions, with a view to determining the bearing of the bacteriological results upon the nature of the infectious process leading to the death and expulsion of the fetus and upon the acquisition of immunity by the cow against later infection. The bacteriological examination included a relatively thorough study of the fetus and of the membranes or swabs from the uterus.

Of the 109 cases of abortion studied 62 were associated with *Bacillus abortus*, 26 with spirilla, 2 with *B. pyogenes*, and 19 were either sterile or else the digestive and respiratory tracts had been invaded during or after birth with miscellaneous bacteria. On the assumption that purchased cows coming from small herds were free from any immunity and that their first pregnancy in the new herd was equivalent to that of a native heifer and may be counted as first, the distribution of *B. abortus* and *V. fetus* in succeeding pregnancies was as follows:

*B. abortus* was associated with the first pregnancy in 42 cases, with the second in 14, with the third in 5, and with the fourth in one case. In pur-

chased cows, spirilla were associated with the first pregnancy in 6, with the second in 9, with the third in 5, and with the fourth in 3 cases. In native cows there were no spirilla associated with the first pregnancy, 1 with the third, 1 with the sixth, and 1 with the eighth.

A tentative explanation of the fact that thus far spirilla have not been encountered in native heifers of the herd giving birth the first time is that "the young stock is kept segregated from the older and purchased cows until shortly before calving. The occasional discharge of a fetus among the young stock in pasture tends to keep up the disease due to *B. abortus*. Later on, association with older cows brings about infection with spirilla (*V. fetus*) and more rarely with other possible agencies of fetal disease. On the other hand, abortions may occur among the pastured stock from time to time and remain unrecognized. Not until both groups of animals are subjected to the same daily scrutiny will it be possible to affirm that abortion associated with spirilla does or does not occur among young stock."

An interpretation of the agglutination reaction to Bacillus abortus in 75 cases of bovine abortion bacteriologically controlled, E. W. SMILLIE, R. B. LITTLE, and L. FLORENCE (*Jour. Expt. Med.*, 30 (1919), No. 4, pp. 341-357).—This paper gives the results of a study of the agglutination test for *B. abortus* in 75 of the cases noted in the above article, together with tests for *B. abortus* in the milk in certain cases.

Of 19 cases in which spirilla were found, 11 gave negative results in the agglutination test for *B. abortus* (considering an agglutination titer up to and including 1:40 as negative). In 2 cases a maximum titer of 1:1280 for *B. abortus* was associated with the presence of this bacillus in the milk. In 4 cases the titer indicated an earlier infection with *B. abortus*, the milk tests of 3 of these cases being negative. One case showed a remarkable rise in agglutination titer following the discharge of a fetus containing spirilla, but not *B. abortus*. One case gave a titer of 1:640 after an abortion associated with positive spirilla cultures and negative tests in the milk.

Of 11 cases of abortion characterized by sterile fetuses or by miscellaneous infection of the digestive and respiratory tracts, 8 showed a titer of 1:20 or lower. The higher titers in the other cases could be explained by earlier *B. abortus* infection. Of 44 cases of abortion associated with *B. abortus* in the fetus, the membranes, or the udder, agglutination titers of less than 1:80 were obtained in 8 cases, of 1:80 in 2, of 1:160 in 3, of 1:320 in 6, of 1:640 in 16, and 1:1280 in 9 cases.

The authors conclude as a result of these observations that, although no definite rules can be formulated for the interpretation of the agglutination reaction quantitatively, it is, when so carried out as to give the entire range of serum dilutions to the limits of clumping, a delicate test which reflects a variety of conditions involved in infection with *B. abortus*, such as its time relation to the act of abortion and the length of time the abortion bacilli live and multiply in the pregnant uterus. In the individual cow, in general, a titer of 1:40 or less is thought to indicate that the cow is not infected with *B. abortus* at the time of blood examination. It does not, however, exclude former infections in the case of older cows, nor exclude absolutely very recent infection. The highest titers, 1:640 and above, are considered to indicate recent infection of the udder. Intermediate titers may indicate a gradual rise or decline of agglutinins preceding or following abortion without infection of the udder, or a relatively high resistance or partial immunity in the cow.

"In any herd a uniformly low titer (1:40 or less) in all animals may be regarded as indicating the entire absence of *B. abortus*. A high titer in any

one cow serves to indicate quite definitely the presence of infection in the herd. To determine more accurately the character of the infection in any individual cow there is needed, in addition to the quantitative agglutination test, a bacteriological study of the milk and of any prematurely discharged calf or fetus."

A comparative study of Leishmania infantum of infantile kala azar and Leptomonas (Herpetomonas) ctenocephali parasitic in the gut of the dog flea, E. E. TYZZER and E. L. WALKER (Jour. Med. Research, 40 (1919), No. 2, pp. 129–176, pls. 3, figs. 3).—This is a report of an investigation which was limited to the study of the flagellate of the dog flea (Ctenocephalus canis) of the United States and the parasite of human kala azar of the Mediterranean region (L. infantum). The authors prefer to consider the leptomonads as constituting one or more genera comprised of many distinct species rather than collectively as races or varieties of a single species.

A list of 49 references to the ilterature is included.

Necrobacillosis, G. B. Morse (Amer. Jour. Vet. Med., 14 (1919), No. 9, pp. 457-460).—An address delivered at Omaha in July, 1919.

The effect of potassium iodid on experimental sporotrichosis, D. J. DAVIS (*Jour. Infect. Diseases, 25 (1919), No. 2, pp. 124–131*).—" Experimental sporotrichosis in rats responds promptly to potassium iodid. The lesions in the peritoneal cavity become firm, hard, and small, and are surrounded by a dense fibrous capsule; within the nodules living sporotricha are found for a long time (at least four months). Potassium iodid will not prevent experimental sporotrichosis, but will cure it.

"It is suggested that sporotrichosis, so readily produced experimentally, furnishes a good opportunity for the study of the behavior and reactions of iodin and iodids in chronic infections."

A comparison of the life cycle of Crithidia with that of Trypanosoma in the invertebrate host, I. McCulloch (Univ. Cal. Pubs. Zool., 19 (1919), No. 4, pp. 135-190, pls. 5, figs. 3).—This report of investigations conducted includes a bibliography of 26 titles.

**Tuberculin tests**, C. C. WALKER (*Jour. Amer. Vet. Med. Assoc.*, 56 (1919), No. 1, pp. 5–14).—The author discusses the value of the subcutaneous, intradermal, and ophthalmic tuberculin tests in tuberculosis eradication work, with illustrations from actual practice in 11 herds in Montana. In some of these herds the intradermal test proved more efficient than the subcutaneous, and in others the value of the two tests appeared to be about equal. The ophthalmic test is considered valuable in checking the findings of the other two tests.

New and nonofficial remedies, 1919 (*Chicago: Amer. Med. Assoc.*, 1919, pp. 388+XXIX).—The 1919 edition of this book contains certain revisions and additions to the 1918 edition previously noted (E. S. R., 40, p. 284), while other articles, a list of which is given in the preface, have been omitted. "Attention is called to the revision of the article on digestive ferments; to the description of chlorinated eucalyptol; to the replacement of the monograph for neutral solution of chlorinated soda by one for surgical solution of chlorinated soda; to the discussion of sulphoichthyolate preparations; to the revision of the article on silver preparations."

Note on the Hygienic Laboratory method of standardizing disinfectants (*Pub. Health Rpts.* [U. S.], 34 (1919), No. 42, pp. 2297, 2298).—A modification of the Hygienic Laboratory method of preparing beef extract medium for use in the standardization of disinfectants is described as follows:

A 500-gm. portion of finely chopped round steak is placed in 1,000 cc. of tap water and allowed to stand in a cool place for 24 hours, and is then strained through cheesecloth by means of a tincture press until 1,000 cc. of filtrate is obtained. This is heated in streaming steam for 1 hour, filtered through paper, and the volume made up to 1,000 cc. and titrated. The reaction is corrected to approximately neutral with N sodium hydroxid, after which 1 per cort of paperon and 0.5 per cert of reduce their of the density of the densi

cent of peptone and 0.5 per cent of sodium chlorid are added and the liquid is heated in streaming steam for 30 minutes. The final reaction is corrected to pH 7.6. The medium is filtered through paper into test tubes, 10 cc. per tube, and sterilized in steam for one and one-half hours, or in an autoclave for 15 minutes at 15 lbs. pressure.

Studies on anthelmintics, III-IV, M. C. HALL (Jour. Amer. Vet. Med. Assoc., 55 (1919), No. 6, pp. 652-659; 56 (1919), No. 1, pp. 59-70).—Experiments in continuation of those previously noted (E. S. R., p. 480) indicate that chloroform is safe, and is more effective against hookworms in single dose than any other anthelmintic.

In experiments with combinations of oil of chenopodium and chloroform, "the best results in the removal of hookworms by a single-dose treatment ... were obtained by the use of oil of chenopodium in a dose approximating 0.1 mil per kilogram, as near as the dose can be approximated in 5 and 10 minim soft, or soluble elastic, capsules, followed immediately by 30 mils of castor oil containing chloroform at the rate of 0.2 mil per kilogram or with this amount of chloroform given in hard gelatin capsules... This same treatment was 97 per cent effective against ascarids in tests on 15 dogs, of which 9 had ascarids. The treatment was comparatively ineffective against whipworms, which require repeated treatments, not single treatments. The treatment was also ineffective against tapeworms, but neither of these drugs is dependable against tapeworms."

Further report on lymphangitis in cattle caused by acid-alcohol-fast organism, J. TRAUM (Jour. Amer. Vet. Med. Assoc., 55 (1919), No. 6, pp. 639-652, flgs. 5).—This is a further report of studies of the affection previously noted (E. S. R., 36, p. 82).

The investigations show the disease to resemble tuberculosis in the character of the lesions and by the presence of acid-fast organisms in the lesions. "It further resembles tuberculosis by the fact that a large percentage of cases under discussion give positive reactions to the intradermal tuberculin test; a number of such reactors have been autopsied . . . and in none of the cases did we find tuberculosis; in fact, in some of the reactors tuberculosis could be definitely eliminated.

"That it is not tuberculosis is satisfactorily demonstrated by the failure to produce a single case of tuberculosis in the large number of guinea pigs inoculated with materials from the above-described and other cases. The organism isolated from lesions and described here as the probable causative agent resembles tubercle bacilli to some extent, differing, however, sufficiently in the character and speed of growth and microscopic appearance of smears from the cultures to easily differentiate it from tubercle bacilli."

Iris poisoning of calves, E. A. BRUCE (*Jour. Amer. Vet. Med. Assoc.*, 56 (1919), No. 1, pp. 72-74).—The author records the death of several calves from 3 to 6 months of age from having fed on the leaves of a blue-flowering bulbous variety of iris grown under cultivation at Abbottsford, B. C.

Don't feed foxtail hay to lambing ewes, C. E. FLEMING and N. F. PETERSON (*Nevada Sta. Bul.* 97 (1919), pp. 18, figs. 12).—This is a report of studies made of the injurious effects of feeding ewes during the lambing season on hay containing quantities of squirrel tail grass (*Hordeum jubatum*), also known as tickle or foxtail grass and wild barley, a recent account of which grass by Pammel in Iowa has been noted (E. S. R., 39, p. 842.)

Due to awns or beards on this grass it is one of the worst pests occurring in Nevada, not only because it is directly or indirectly responsible for loss of condition and death of sheep but also because of the pain and suffering produced when fed in hay. This grass is now widely and abundantly distributed in Nevada and across North America. In many places it is becoming a serious menace on land which is used for the production of hay. It is dangerous as soon as it heads, which at Reno is about June 1, and when dried and fed in considerable quantities it becomes obnoxious and destructive.

"The number of seeds in a head varies from 30 to 60, with an average of approximately 40 seeds to the head. A plant 4 inches across the crown will produce about 50 heads to the plant with a total of approximately 2,000 seeds or 14,000 awns per plant."

Being a perennial it is difficult to control. A practical means of preventing losses from it on haylands is to graze with sheep early in the spring when the grass is high enough to be tempting and palatable. In this way the vitality of the squirrel tail grass is reduced and the other grasses are given an even chance to grow.

The injury when fed to live stock is caused by infestation of the delicate tissues in the region of the eye, the membranes of the mouth, the sides of the jaw, or the wool of the head, neck, and back. As soon as the awns become lodged, they begin to work into the flesh, causing injuries which affect the condition of the animal and frequently lead to very serious consequences or death.

"In the examination of heads of sheep the following types of injury were observed: (1) Some awns found in the ears, where they caused abscesses, due to mechanical injury and subsequent infection by bacteria; or (2) in the mucous membranes of the upper and lower eyelids, causing inflammation with a discharge of a yellowish-white opaque creamy pus. (3) They were commonly found between the eyeball and the tissues of the orbit, causing semi or total (4) Many awns had penetrated the skin of the head between the blindness. nose and the forehead or on the cheek and around the eye, causing the wool and hair to slough off with the formation of pustules, or small abscesses. (5) They had become imbedded in the lips, causing redness and swelling, with a formation of small pimple-like elevations filled with pus. (6) Awns were common on all surfaces of the tongue; and (7) in the openings of the gland secreting into the mouth. (8) Others had penetrated into the nasal passages, causing extreme irritation. (9) In nearly all heads examined, masses of awns were imbedded in the gums beside the molars of both upper and lower jaws. (10) They had worked in around the incisors and caused them to loosen in their sockets and fall out. The gums had shrunken away from the teeth and in many cases there was ulceration and decay. In other instances they were imbedded in the palate. (11) Many were found in the soft tissues under the tongue."

Brief accounts are given of the findings in examinations made of 21 heads selected at random, March 14, 1919, from a pile of over 300 carcasses of range ewes that had been feeding on hay containing a high percentage of squirrel tail grass. Yearling lambs and aged ewes were found to suffer the most, and Merino and Rambouillet sheep to be injured more than the more open-wooled and smooth-bodied breeds.

Bacillus necrophorus infection in swine, H. R. SCHWARZE (Amcr. Jour. Vet. Med., 14 (1919), No. 2, pp. 51-54).—The author reports upon eight cases investigated, both clinically in the field and bacteriologically at the State laboratory at Springfield, Ill.

"Taking into consideration the post-mortem findings, the demonstration of swine plague and hog cholera in a large percentage of the cases, and the results from bacterin treatment, it would seem that necrobacillosis, where the lesions are internal, especially of the lung and intestines, is a secondary disease following swine plague and hog cholera. However, the local necrobacillosis, such as bull-nose, necrotic stomatitis, canker of the feet, etc., may be a local lesion primarily due to some abrasion of the skin or membranes, the necrophorus bacilli and other ubiquitous organisms gaining entrance in that way causing

Hog cholera and the swine industry, U. G. HOUCK (Amer. Jour. Vet. Med., 14 (1919), No. 9, pp. 461-465).

Ascarid infestation in swine, H. B. RAFFENSPERGER (Amer. Jour. Vet. Med., 14 (1919), No. 8, pp. 433, 434).—This is an address delivered before the Illinois Veterinary Medical Association in July, 1919, in which the author presents data based upon investigations by the Bureau of Animal Industry, U. S. Department of Agriculture.

In considering the incubation of the egg of this ascarid it is stated that it will develop to the infective stage in about three weeks at a temperature of  $71^{\circ}$  to  $77^{\circ}$  F., and in about two weeks at a temperature of about  $90^{\circ}$ . The mortality from infestation with the lung stage is greatest, especially in suckling pigs, at the age of two to six weeks. In investigations made to determine the effect upon pigs, one that survived infestation out of a litter of seven weighed 33 lbs. 30 days after the infestation, whereas each of the two control pigs weighed 65 lbs. Older pigs becoming infested stand a better chance of recovery.

**Recurrence** of horse plague (*Amer. Jour. Vet. Med.*, 14 (1919), No. 10, pp. 494, 495, figs. 3).—An outbreak of so-called forage poisoning or epizootic spinal meningitis in the Arkansas Valley in western Kansas and eastern Colorado is said to have resulted in the loss of a large number of animals. A brief statement by A. T. Kinsley, who investigated the outbreak, is presented.

Cerebro-spinal meningitis of the horse in Argentina (Vet. Rev., 3 (1919), No. 3, pp. 294-296).—This is a review of papers on the subject by Lignières, Bossi, and Flores, respectively.

Contribution to the clinical study of glanders in the mule, CABAYÉ, COLLE, and LAMARQUE (*Rev. Gén. Méd. Vét., 28 (1919), No. 326, pp. 65-70; abs. in Vet. Rev., 3 (1919), No. 3, p. 288).*—Post-mortem examinations made of some 500 glandered mules and mallein tests of some 10,000 remounts in a Greek depot led the authors to conclude that there are two forms of glanders in the mule, namely, acute and chronic.

A preliminary note on a new coccidium of rabbits, E. A. BEUCE (*Jour. Amer. Vet. Med. Assoc.*, 55 (1919), No. 6, pp. 620, 621).—The author reports briefly upon a new coccidium (*Eimeria* sp.) which infects the intestinal tract of the rabbit in British Columbia. It is especially pathogenic for very young rabbits, often causing the loss of a whole litter. Mature animals are affected, but appear to suffer no ill effects and may carry coccidia for several months. It differs from previously described forms "in the extreme variation of the size of its oocysts, the pinkish orange color of its larger oocysts, the excessive formation of material for the oocyst wall, the pink color of its sporozoite nucleus, and the presence of a very well-marked globular residual body."

Klein's fowl plague, H. VAN STRATTEN and B. J. C. TE HENNEPPE (Folia Microbiol. [Delft], 5 (1918), No. 2, pp. 103-125, flg. 1).—The authors discuss the disease caused by Bacillus gallinarum, which is of more importance to the poultry industry in Holland than is fowl cholera, causing great losses in some localities.

tissue necrosis."

#### RURAL ENGINEERING.

Ground water in the San Pacinto and Temecula Basins, Cal., G. A. WARING (U. S. Geol. Survey, Water-Supply Paper 429 (1919), pp. 113, pls. 14, figs. 15).— This paper was prepared in cooperation with the State of California.

The San Jacinto Basin is an area of 1,000 square miles in southern California, the topography of which is diverse. The ground water of the basin "is derived wholly from the rain and snow that fall on its surface... The ground water is stored almost entirely in the deposits of sand and gravel that underlie the valleys. In some places the lowlands are bordered by partly consolidated sediments which yield small quantities of water, but the underlying granitic and other crystalline rocks contain very little water, even for the supply of domestic wells."

The Temecula Basin is drained in its western part by Murrieta Creek and in the east by Temecula River. "Throughout the lowland of Murrieta Valley the ground-water level is within 20 ft. of the surface, and beneath the greater part the depth to water is less than 10 ft. . . . The sampled well waters from Murrieta Valley range in quality from fair to good for domestic uses and for irrigation. . . . In the lowland along Murrieta Creek for two or three miles above Temecula, the ground-water level is within 6 or 8 ft. of the surface, and the continual evaporation from this moist area has caused the concentration of alkali. Chemical examination of the waters tested indicates that in most of them sodium is the predominant base. . . . Throughout the lowland of Temecula Valley proper ground water is found within 20 ft. of the surface, and in the wide sandy flats of its upper portion is less than 10 ft. below the surface.... In the minor valleys in the upper part of the Temecula Basin, water is generally found relatively near the surface in the alluvial and residual materials." Analyses of samples of water from a shallow and a flowing well in the area and from Temecula River showed that "the waters from both wells are suitable for domestic use, but the river water is only fair because of its rather high total solids and its hardness. It is also classed as fair for irrigation."

Pumping tests made at six irrigation plants in San Jacinto Valley by Herman Stabler are also reported, together with a description of each plant. Data on the total cost per acre of pumping water for a season of 200 days of 12 hours with duty of water at 3 acre-feet per acre show that the cost per acre that can reasonably be expected in the irrigation of alfalfa with distillate at 10 cts. per gallon is \$9.64. "By continuous operation throughout the irrigating season the cost could be still further reduced to \$7.56 per acre with distillate at 10 cts. a gallon."

Influence of forests on water power supply, A. A. GRIFFIN (*Jour. Electricity*, 42 (1919), No. 6, pp. 268-270, figs. 5).—Studies of snow melting on the Tumalo area in central Oregon, the Wind River area in southern Washington, and the Yakima area in central Washington are reported.

It was found that drifting of snow by the wind was of comparatively small importance. It was also found that the retardation of snow melting in forests is five to eight days in general and may be several weeks, and that in the forest the snow tends to be deepest and last longest in the small openings of the denser forests. "This tendency was especially noted on the Wind River area and may partly account for the late melting of the snow in the small open areas characteristic of the Tumalo area. In large openings the protecting influence from the forest would be dissipated and melting consequently more rapid. An unusual factor in delaying the melting within the Douglas fir type of forest is the protection given by the irregular layer of even very slight bits of moss, twigs, bark, and other litter weathered from the trees. . . . An opposing influence appears in the ability of the brushes, tree trunks, and other large objects to hasten melting by radiating or reflecting into the snow the heat which they receive from various sources. . .

"Expressed in irrigation terms, the figures given mean that on the areas studied the average square mile of forest cover retained the equivalent of between 720 and 160, averaging 400, acre-feet of water in the form of snow after the open areas had become bare. . . In terms of time, the effect of the forests was to spread the 400 acre-feet of retained snow through a period averaging 17 days in length. The retardation of this amount of snow is sufficient to be of great importance to irrigation interests, especially as it is generally understood that a forest cover tends to 'flatten out' the crest of a flood and thus to increase the minimum flow at periods of low water."

**Irrigation of lowland moor soils,** M. OEHME (*Jahrb. Moork., 3-5 (1914-1916, pp. XXVII-XXXIX*).—Five years' experiments on a moor soil growing grain are reported. Irrigation by flooding from a reservoir and furrow irrigation were practiced. The plats were unfertilized, fertilized with potash or phosphoric acid alone, or completely fertilized.

It was found that the best crop results were obtained in four out of five years on the unirrigated plats which were completely fertilized. On the irrigated plats furrow irrigation gave better results than flooding. Irrigation added only a very small amount of plant nutrients to the soil.

A second set of four years' experiments with soil tanks in which drainage and ventilation of the soil were controlled gave similar results as far as irrigation affected crop yield. A third set of four-year experiments on a low-lying moor soil showed that the best results were obtained with complete fertilization and spring irrigation.

It is concluded that irrigation of lowland moor soils in general gives unfavorable results, except where under normal conditions plenty of water containing considerable plant nutrients is available and the soil is well drained naturally.

Drainage of lands under irrigation, D. G. MILLER (*Proc. Iowa Engin. Soc.*, 30 (1918), pp. 28-38).—This is a brief summary of the important general features to be considered in the planning of drainage systems for irrigated lands.

Some engineering methods used in the construction of tile drainage districts, D. P. DALE (*Proc. Iowa Engin. Soc., 30 (1918), pp. 39-47*).—A brief outline of methods is given.

An investigation of tests of Iowa shale draintile, W. J. SCHLICK (*Iowa Engin. Expt. Sta. Bul. 49* (1918), pp. 71, figs. 18).—Investigations (1) to determine the best method of making actual accelerated freezing and thawing tests upon draintile, (2) to study the effects of such tests upon Iowa tile, (3) to determine the best method of making absorption tests, and (4) to discover the relations between the results of the freezing and thawing tests and the absorption and strength tests, are reported. The investigations were confined to hard burned and soft burned shale tile from four representative Iowa factories, together with a few concrete tile.

It was found that "Iowa shale tile such as were included in this investigation will withstand 100 freezings and thawings without excessive deterioration when the absorption obtained by the standard boiling test does not exceed 9 per cent. All of the tile tested met the freezing and thawing requirements of the American Society for Testing Materials for 'extra quality' draintile with the exception of a certain 8-in. soft tile from one factory, which had a very high percentage of absorption. "The percentage of absorption obtained by immersion in water below the boiling point increases as the temperature of the immersion water decreases. This is true both in cooling after the boiling test and in the regular immersion test. The variation in the percentage of absorption due to this cause is usually noticeable, but it is not in constant ration to the temperature change and is nearly always small; it is large enough, however, to make it advisable that the temperature of the water in all absorption tests should be specified.

"The principle does not apply to immersion in boiling water. It was found that there is a definite and fairly constant ratio between the results of the recommended standard boiling test for determining absorption and those of the absorption test by 72 hours' complete immersion in water at room temperature. The average of a large number of determinations made in this investigation indicates that for Iowa shale tile the percentage of absorption by the recommended standard boiling test is approximately 1.4 times that after 72 hours' complete immersion in water at room temperature. The boiling absorption test is to be preferred to the immersion absorption test. The boiling absorption test has been adopted as standard for draintile by the American Society for Testing Materials, and all absorption tests of draintile should be made in strict compliance with sections 21 to 25, inclusive, of the 'Standard Specification for Drain Tile.'

"In these tests, as in many others, it was found in general that the strength increased as the absorption decreased. This relationship was clearly apparent in the case of tile with widely different strengths and absorptions, but was obscured by other factors where the range in either strength or absorption was small. It is now very generally recognized that draintile from several factories can not be judged correctly by a single color standard. It is almost as generally believed that the product of a single plant, while using the same methods and similar clays, may be judged correctly by color. This is upon the assumption that, with the same clays treated in the same manner, the quality of the product will depend upon the burning, and that this will be indicated very clearly in two cases, that this rule will not apply even to the product of a single factory unless the full history of the manufacture of the product is known and considered.

"The best method for making freezing and thawing tests of draintile is that prescribed in sections 26 to 31, inclusive, of the Standard Specifications for Draintile of the American Society for Testing Materials. The above method is similar to that used in the 'final' artificial freezing and thawing tests reported . . . and produces much more decisive results than those obtained in 'preliminary' tests. Sodium sulphate tests by the 'recommended method' developed in this investigation gave results approximating those obtained by three times as many standard freezing and thawing tests."

The sampling of deposits on road stone and gravel in the field, L. REINECKE and K. A. CLARK (*Amer. Soc. Testing Materials Proc.*, 18 (1918), pp. 393-415).— This is a preliminary report on a series of studies upon variations in the roadmaking qualities of deposits of bedrocks, bowlder aggregates, and gravel.

The investigations on bedrock showed that "the results of an abrasion test expressed as percentage of wear are liable to an error of 0.2 per cent due to variations caused by laboratory procedure. No additional error is introduced into the results of abrasion tests by the process of sampling when samples are collected in the manner outlined. Results of abrasion tests on rock in place in a deposit represent, within a probable difference of 0.4, the percentage of wear that will be shown by a crushed product produced from the deposit. In the case of deposits consisting of stone of a very uniform character and appearance, the results of abrasion tests on samples taken at one

153351°-20-7

[Vol. 41

point in the deposit can be regarded as representing within the probable error due to laboratory manipulation the percentage of wear of the stone over quite a considerable area, at least a quarter of a square mile. It is possible to assign average values and fairly narrow limits of variation of this value for the percentage of wear and the toughness of the material occurring in a limestone formation covering areas up to 50 and 60 square miles and with thicknesses up to 500 ft., even though stone varying in character is included in the formation. These values and limits will include the majority of results of tests made on samples collected throughout the formation and its various horizons... The results of abrasion and toughness tests over a series of diabase dikes of the same age and structure reveal very uniform results in deposits of the same grain. A change in the average size of grain affects the toughness value slightly."

In the investigation on bowlder aggregates it was found that bowlder deposits in any one area consist of many combinations of three or four rock types of fairly uniform durability, and that the percentage of wear of any combination of the rock types found in deposits of bowlder aggregates could be calculated by the following formula if the percentages of wear of each of the rock types were known:

$$W_m = \frac{\Sigma C W}{100},$$

in which  $W_1, W_2, \ldots, W_m$ =percentages of wear of the various rock types, and  $C_1, C_2, \ldots, C_n$ =percentage proportions in which the rock types are present in the combination.

In the sand and gravel investigation a large variation was found between the results of duplicate granulometric laboratory analyses on the same sack of gravel. The variation in texture over one deposit of gravel of 800 acres was found to be large.

An abrasion test for stone, gravel, and similar aggregates, H. H. SCOFIELD (*Amer. Soc. Testing Materials Proc.*, 18 (1918), pp. 416-428, figs. 7).—It has been found that the standard Deval test for road materials is somewhat misleading in its results due to the retention within the abrasion chamber of the dust worn from the charge. An apparatus is described which was devised at Purdue University, to fill the need of a rapid and practical abrasion test for road materials which is simple in construction and allows the dust of abrasion to escape. The machine is a small type rattler in which dust and chips from abrasion escape between the staves as fast as formed. The opening between staves is  $\frac{1}{16}$  in. The abrasion chamber is octagonal in shape with a volume equivalent to that of the Deval cylinder. Recent tests with this apparatus upon 12 Indiana limestones show in general that the new test gives a greater range of results and a consequent better differentiation of quality.

Effect of controllable variables on the toughness test for rock, F. H. JACK-SON, JB. (Amer. Soc. Testing Materials Proc., 17 (1917), pp. 571-588).—Studies on the effect of certain controllable variables on the accuracy of the toughness test for rock for road building are reported.

It was found that "the quality of the product of a rock quarry may vary from time to time to such an extent that it is advisable to test the material, as nearly as possible, at the time it is to be used. Great care should be exercised in selecting samples for the toughness test in order to insure obtaining an average value for the toughness of the entire product. All materials exhibiting any indication of foliation or bedding should be tested in two directions; one set perpendicular and the other set parallel to the foliations. A greater total variation than 1 mm. in either the diameter or height of the test specimen should not be allowed. Variations in the moisture content of test specimens

788
affect the results very little, although for purposes of uniformity it is recommended that all specimens be dried out prior to testing. Very accurately prepared bearing surfaces are essential if reliable results are to be expected. The effect of vibrations of the plunger and secondary blows produced by the rebound of the hammer during the progress of the test are apparently negligible."

Tests of concrete road aggregates, J. P. NASH (Amer. Soc. Testing Materials Proc., 17 (1917), pp. 394-421, figs. 12).—In studies of the causes of deterioration of concrete in roads, tests were conducted on concrete, using various coarse aggregates, including wear and tension tests. The conclusions drawn from these tests are as follows:

"Uniformity of wear is obtained when the mortar and the coarse aggregate wear equally, such as when crushed limestone or limestone gravel is used in a 1:2:4 mix. The coarse aggregate should be limited in size to about 1.5 in. When hard, tough stone is used, the size should be limited to about 1 in. and the cement content increased. It is questionable if a richer mix than a 1:2:4 is an economical one to use with crushed limestone of the ordinary hardness. Crushed slag when hard and uniform should be satisfactory as a concrete road aggregate from the standpoint of wear. In a 1:2:4 concrete, a gravel composed of very hard stones such as flint, or quartz, does not wear uniformly. The action of the cubical shot on the test specimens is a trifle more severe than the traffic on the road. It can not be said that either the crushed stone or gravel tested is superior as an aggregate to produce concrete having a higher tensile strength."

A new consistency tester for viscous liquid bituminous materials, P. HUB-BARD and F. P. PRITCHARD (*Amer. Soc. Testing Materials Proc.*, 17 (1917), pp. 603-626, figs. 8).—In attempting to devise a convenient laboratory instrument for determining consistency at normal temperatures, the authors followed the general principle of the Lunge and Hutchinson tar testers with a view to improvement in certain important details. After numerous trials an instrument was obtained made of aluminum and weighted with lead shot.

The instrument is 3 in. long and weighs exactly 2.8 gms. It consists of two aluminum rods of different diameters one of which is hollow, a thin aluminum disk 1.25 in. in diameter, and a tapered bottom weight. The larger rod is about one-half the length of the smaller which passes through it and screws into the bottom weight. The aluminum disk is riveted transversely to the rods where they join about midway of the length of the instrument thus forming a balanced plummet.

A special bitumen container is used with this instrument. It consists of a cylindrical flanged copper cup 2 in. in diameter and 3.75 in. deep, which is placed in a water-bath fitted with a stirrer passing through the flange of the cup. The flange is also provided with a small hole for the insertion of a thermometer in the bath.

Before making a test, the bituminous material which fills the inner compartment of the water-bath is brought to a temperature of exactly  $25^{\circ}$  C., which must be maintained in the bath throughout the test. The surrounding atmosphere should also be as close to  $25^{\circ}$  as possible. The test is made by allowing the instrument to sink of its own weight in the bituminous material from the upper edge of a lower scale marking on the small rod to that of an upper marking, and noting the time required.

This instrument was found to have a wide range of usefulness, as shown by numerous tabulated test results. At normal temperatures it may be used for all bituminous materials outside of the range of the Engler viscosimeter and the usual penetration machine. When used in connection with a representative set of commercial bituminous road materials, it was found that comparatively few materials whose penetration at  $25^{\circ}$  could not be ascertained required more than 30 minutes for a test with the new instrument. Most of the material prepared for hot-surface treatment showed a test of less than 15 minutes.

Progress reported on wood-block experiments in Minneapolis, C. H. TEES-DALE and J. D. MACLEAN (*Engin. News-Rec.*, 82 (1919), No. 5, pp. 233, 234, fig. 1).—The results of an investigation made on an experimental wood block pavement after 12 years' service under heavy traffic conditions are reported. The purpose was to study the relative merits of various species of wood for paving material and to investigate the influence of (1) heartwood and sapwood, (2) length of blocks, and (3) angle of courses. Seven species of wood were employed—including tamarack, Norway pine, long-leaf pine, white birch, Douglas fir, western larch, and hemlock. The long-leaf pine was used as a basis for comparison.

It was found that the order of efficiency of service was as follows: (1) Longleaf pine, (2) white birch, (3) eastern hemlock, (4) tamarack, (5) Norway pine, and (6) western larch. The depressions and wear of Douglas fir were from two to three times as much as those of the long-leaf pine portion laid at the same time. For most of the species the depressions were very slight during the first four or five years' service. After this period the depressions increased at a very rapid rate. Certain sections showed wearing qualities of Norway pine which compared favorably with those of long-leaf pine and white birch. The western larch sections had the greatest percentage of area affected by depression. This was also one of the species which showed the heaviest wear. The order of the species, beginning with that showing the least wear, was as follows: White birch, long-leaf pine, Norway pine, tamarack, eastern hemlock, and western larch.

The presence of sapwood did not seem to be an important factor affecting the durability of the pavement. The various lengths of blocks employed had no apparent influence on the wearing qualities of the pavement. Less joint wear was noted in sections laid at 45 and  $67\frac{1}{2}^{\circ}$  than in the section of blocks laid at an angle of 90° with the curb.

Distribution of pressures through earth fills, A. T. GOLDBECK (Amer. Soc. Testing Materials Proc., 17 (1917), pp. 640-661, figs. 9).—The object of this investigation was to obtain data on the distribution of vertical pressures through earth fills under concentrated loads, with particular reference to the design of highway structures. Sand fills were investigated up to a depth of 5 ft. and the pressures under them measured with a special diaphragm cell. The principles of pressure measurement with the use of this instrument depend upon (1) the equilibration of the soil pressure with air pressure within a small cell buried where the pressure is desired, (2) the detection of the instant of equilibration by the breaking of electrical contact within the cell, and (3) the measurement of the air pressure within the cell at the instant of equilibration by the use of a sensitive gauge.

The cost of farming with a tractor (*Farm Machinery*, No. 1446-1447 (1919), pp. 25, 26, 84, 86, 88, figs. 3).—This is a report in detail of a 310-hour run of a tractor in harvesting 127 acres of wheat, thrashing the grain, disking 34.5 acres of land, and plowing all of it. This test is considered to simulate a season's work for the tractor.

The total cost per acre for fuel and oil in harvesting was 14.5 cts., for thrashing 14.32 cts., for disking 10.84 cts., and for plowing 47.06 cts. Out of the total operating time of 310 hours and 9 minutes, 7.2 per cent was lost on account of implement trouble and 3 per cent on account of tractor trouble. It was found that the tractor was better than horses for opening up a field of wheat for

cutting. While the plowing was the hardest operation, this was the best performance, as the outfit averaged an acre an hour. It was also found that the operator is one of the most important factors in the operation of a tractor on account of the carelessness factor.

Common tractor troubles, H. H. FENTON (Kans. Agr. Col. Ext. Circ. 13 (1919), pp. 12).—This circular outlines tractor troubles and their remedies.

A common-sense farm home, L. J. SMITH (Canad. Thresherman and Farmer, 24 (1919), No. 8, pp. 36-38, figs. 2).—The author presents a farmhouse plan in which it has been endeavored to secure a well-arranged interior together with an attractive exterior. This plan is based on Manitoba conditions.

Plans for the construction of a privy for use in towns and villages ([Bien.] Rpt. Bd. Health Miss., 1916-17, pp. 359-372, pl. 1, figs. 3).—General information, drawings, and specifications are given on sanitary privy construction, with special reference to types from which the receptacles are removed from the inside or outside.

#### RURAL ECONOMICS.

Farm leases in Kansas, W. E. GRIMES (*Kansas Sta. Bul. 221 (1919)*, pp. 32, figs. 9).—Data are presented which were gathered in 1914, 1915, and 1916 by surveys of farms in eastern and central Kansas. It is stated that in 1910, 36.8 per cent of all farms in the State were operated by tenants, and eastern counties had more tenants in proportion to the total number of farmers than western counties.

A comparison is made of farm business and practices of owners and tenants to show their successes as operators in matters of profits from crops and live stock, crop yields, and rates of interest and terms of loans granted them. It is shown that tenants' labor incomes were higher than owners', that the owner's interest on investment was greater than the landlord's rent, and a smaller labor income to the owner than to the tenant resulted. Owners kept at least one-third more live stock than tenants, and tenants' live stock returned relatively less than owners', one of the most important reasons for which was that landlords limit the area of pasture and feed crops as much as possible. Crop yields on farms operated by owners were on the whole higher than on tenant farms, and the yields on tenant farms tend to further depression under present methods of leasing. The tenants paid from 1 to 2 per cent more interest than the owners, and they borrowed for much shorter terms.

Undesirable economic and social conditions developed on rented farms are discussed. Comparisons of the methods of renting in common use indicate the following advantages and disadvantages: Cash renting is least profitable to both landlord and tenant. Crop-share renting is the most common method and more profitable than cash renting to both landlord and tenant. Stock-share renting is less frequently used, but produces more desirable conditions than any of the other methods. The author's suggestions for methods of improving leases in Kansas are by a wider adoption of the stock-share lease, elimination of absentee ownership of land, providing better methods of maintaining soil fertility of farms rented for cash or for a share of the crops, and improved credit facilities and the provision of better opportunities for acquiring ownership.

The evolution of share renting during a hundred years, A. M. DES RO-CHETTES (Jour. Agr. Prat., n. ser., 32 (1919), No. 25, pp. 505-507).—This article briefly describes the stipulations in contracts of métayage, a system of share renting peculiar to France, and shows that the advantage to the renter has been consistently greater through the period from about 1810 to the present.

Evolution in rural life; scientific cultivation, C. BLANCHAED (L'Evolution dans la Vie Rurale—La Culture Scientifique. Macon [France]: X. Perroux & Son, 1919, pp. 54).—The evolution and manner of land ownership and exploita-

[Vol. 41

tion in France are briefly described in the first part of this pamphlet, and in the second, principles of scientific management. The author favors collectivism in agriculture and maintains that it may be fostered by agricultural education and organization.

Report by the Scottish Land Court as to their proceedings under the Small Landholders Acts, 1918 (*Rpt. Scot. Land Court, 1918, pp. XX+141).*—Special orders of the court in matters of cultivation of, improvements on, and tenure of small holdings, a summary of statistics, and appendixes showing details of the work of the court and the principal judgments issued are included in this report.

Military agricultural colonies in southern Albania, C. MANETTI (Agr. Colon. [Italy], 13 (1919), Nos. 2, pp. 92–125; 3–6, pp. 147–153, pls. 4).—This article describes the topography, climate, native vegetation, and principal crops in the region of Argyro-Castron, and the progress of military agricultural colonies and experimental plats recently established there.

Soldiers' settlements in Queensland, J. M. HUNTER (Brisbane: Govt., [1918], pp. 5, pls. 5).—The supervisory organization for soldiers' settlements is described, and the areas set aside for this purpose and improvements under way are reported upon.

Agriculture and the war, P. PERREAU PRADIER (L'Agriculture et la Guerre. Paris: J. B. Baillière & Sons, 1919, pp. 220).—The author reviews agricultural development in France, and shows the immediate effects of the war in decreasing production, increasing cost of labor and fertilizers, and in causing loss of live stock; also in the stimulus given to the rearrangement of parcelled holdings, cultivation by motor power, rural credit and cooperation, and to State aid in furnishing agricultural labor. He then devotes his discussion to the need of repopulation of rural districts and agricultural education for the rural public.

Land, the restorative, Roquette-Buisson and M. A. HÉRUBEL (*La Terre Restauratrice. Paris: Payot & Co., 1919, pp. 240*).—The author discusses the present food needs of the world, the principal world markets, food restrictions in several countries during the war, the necessity of equilibrium in the economic development of any nation, the industrial ambitions of nations, and their attempts to conquer markets. He maintains that the problems that France is facing are the need of assembling scattered agricultural holdings, organization for acquiring agricultural capital, checking the rural exodus, providing technical education, and intensive cultivation of the land. He describes the needs for and functions of a rural party.

The problems of national reconstruction (Montreal: Standing Com. Plans and Propaganda, Canad. Natl. Reconstr. Groups, 1918, 2. ed., pp. 71).—In this pamphlet is published an outline for discussions to be held in Canadian National Reconstruction Groups. It is intended to be preliminary to a report on Canadian reconstruction policy. One chapter relates to land and agriculture. Recommendations submitted are stated to be based on Canadian public opinion and on literature, largely of British origin, which is listed in the appended bibliography.

Agricultural reconstruction, J. LONG (Jour. Bath and West and South. Counties Soc., 5. ser., 13 (1918–19), pp. 6–21).—The author describes the way in which necessary increased food production in England depends upon the increase of the arable area, the extension of small holdings and allotments, the increase in the number and quality of live stock kept upon improved uplands, minimum prices for corn, the compulsion of landowners and farmers who are not already doing their duty by the land, the establishment of open markets for the sale of farm produce, the establishment of farm schools for the training of the sons of small farmers at nominal fees, and the reconstruction of village life. The economic revival of Italy, L. MARCHETTI, trans. by M. SINDICI (*Turin*, *Italy: Unione Tipografico-Editrice Torinense*, 1918, pp. 91, pls. 7, figs. 20).—This describes the production of wheat, corn, rice, wine, special export products, and raw materials, and other phases of Italy's agricultural industry. Recent developments of Italian manufacturing and commerce and Italy's problems of finance are described and illustrated, and the fact is brought out that the nation is undergoing a transition from an agricultural to an industrial economy.

Russia: Her economic past and future, J. M. GOLDSTEIN (New York: Russ. Inform. Bur., 1919, pp. 99+IV, pls. 4, figs. 65).-The author states that the capital invested in industry in Russia was very insignificant under the bureaucratic régime, and that not until local self-government bodies, created after the liberation of the peasants, learned that subsidies were indispensable to the economic development of a country did agricultural industries show any marked progress. He shows by means of numerous diagrams Russia's production of grain foodstuffs, rôle in the world market, cattle raising, industrial production, foreign trade, principal items of export and import, grain elevators, etc., in comparison with that of other countries, particularly with the United States. The study includes also a survey of canals, ports and their trade, and railroads, with proposed improvement and expansion. Russian banking and its recent development are described and illustrated to emphasize the extent to which capital was being invested in Russian enterprises just prior to the war. The purpose of this study is to urge the strategic necessity to Russia of the investment of capital there by the Allies, and particularly by England and the United States.

Agricultural extension in Spain, G. F. DE LA ROSA (Bol. Agr. Téc. y Econ., 9 (1917), Nos. 106, pp. '925-935; 107, pp. 981-993; 108, pp. 1086-1098).—The author discusses past efforts at agricultural federation in Spain and proposes the establishment of institutes for agricultural extension, one for each of the several districts into which the country would be divided. He suggests that the functions of these bodies should be the determination by a survey of geographic, meteorological, and economic conditions of the local needs of their respective communities, and the adaptation to those needs of lectures and demonstrations.

[Rural credit, cooperation, and insurance in the Philippines] (*Philippine* Agr. Rev., 12 (1919), No. 2, pp. 60-68).—The status of 82 rural credit associations is indicated in a table showing the distribution, capital stock, and capital paid at incorporation. A report is made of the work of these associations, services of rural credit agents, and results of organization of this type. Projects under the direction of the cooperative organization and cooperative marketing sections of the Philippine Bureau of Agriculture and the activity of the Animal Insurance Board in securing data concerning the local market value of work animals preparatory to administering the Work Animals Insurance Act are also described.

A study of the origins, the functions, and the achievements of agricultural syndicates, E. DAMECOUR (*Etude sur les Origines, l'Action et les Œuvres des Syndicats Agricoles. Coutances*, [*France*]: J. Bellée, 1918, pp. 37).—The functions of French syndical societies for purchase and sale, education, credit, insurance against live-stock loss, fire, and accident, and establishment of pension funds are described.

[Classification principles and results as regards necessary agricultural and industrial workers] (War Dept. [U. S.], Rpt. Provost Marshal Gen., Oper. Selective Serv. System, 2 (1917-18), pp. 135-147, 159, 407, 419).—A description of the system of deferments and furloughs, with selections from the Selective Service Regulations and the War Department General Orders, is given. It is shown that deferments, as necessary workers, of men engaged in agriculture were 7.19 per cent of those classified as compared with 1.96 per cent of industrial workers. A comparison of rural and urban physical rejections shows 21.68 per cent of those examined rejected in urban regions as against 16.89 per cent rejected in rural regions. This, and data in one of the appendixes giving a percentage comparison of rejections by disqualifying defects for eight urban and eight rural districts covering 45,000 rejects, nearly equally divided between city and country, indicate the physical advantage of the boy reared in the country.

Maternity and infant care in two rural counties in Wisconsin, F. B. SHER-BON and E. MOORE (U. S. Dept. Labor, Children's Bur. Pub. 46 (1919), pp. 92, pls. 11).—This report describes economic and social conditions and topography and types of farming in two counties in which surveys of a limited number of townships were made covering two main topics: The conditions affecting the health of the childbearing mother and the care—especially the feeding—and survival of the babies. The report is based upon information concerning 614 families who live in these selected districts, 453 in the northern and 161 in the southern county.

It was found that the infant mortality rate in the northern county was low compared to the average for the United States birth registration area. The stillbirth rate was somewhat higher than the rates found for six of the eight cities in which infant mortality studies have been made, and the death rate of mothers from causes connected with childbirth was high. Many births were attended by midwives in certain sections of this territory; a proportion as high as four-fifths was found in one of the Polish settlements.

In the southern county the infant mortality rate was higher than in the northern county, but the stillbirth rate was lower. Only one mother had died at childbirth. Practically all the births were attended by physicians.

In neither district were the housewives on the farms obliged to provide for large crews of hired men at any special season. Birth registration proved to be defective in both districts, especially the northern.

Monthly Crop Reporter (U. S. Dept. Agr., Mo. Crop Rptr., 5 (1919), No. 9, pp. 85-96, fig. 1).-In this are presented the usual data relating to estimated farm value of important products August 15 and September 1; average prices received by producers in the United States, and the range of prices of agricultural products at important markets; the United States crop summary for September 1; statistics on the condition and forecast on September 1, with comparisons, of corn, spring wheat, oats, barley, potatoes, sweet potatoes, tobacco, rice, wild and tame hay, clover for seed, timothy, alfalfa, millet, pasture, buckwheat, flaxseed, apples, peaches, pears, grapes, watermelons, cantaloups, sorghum for sirup, sugar beets, peanuts, beans, grain sorghum, broom corn, field peas, tomatoes, cabbage, onions, hops, and cranberries; also detailed estimates of the acreage of commercial cabbage, 1919, with comparisons, and of beans by varieties, the total number of stock hogs in the United States September 1, 1919 and 1918, honeybees and honey plants, the production of wool, with comparisons, commercial acreage harvested and total production of late onions, 1918, and of acreage planted, 1919; a cotton report for August 25: and reports of pecan conditions September 1, and numbers of live stock and live-stock changes. Index numbers of crops and live-stock prices are given; combined monthly receipts of hogs since January, 1914, at twelve important markets are tabulated; and various data relating to crop conditions, with an illustration of composite crop conditions of all crops, and miscellaneous special articles are included.

Prices and supplies of grain, live stock, and other agricultural produce in Scotland (Agr. Statis. Scot., 5 (1916), pt. 3, pp. 80-109).—Information previously noted (E. S. R., 40, p. 194) is continued for 1916. The prices of fertilizers and feeding stuffs are shown for the first time.

#### AGRICULTURAL EDUCATION.

Materials for a policy of agricultural education, H. M. LEAKE (Agr. Jour. India, 14 (1919), No. 1, pp. 1-20).—Continuing a previous discussion (E. S. R., 40, p. 601), proposals are outlined for constituting a scheme for providing for the educational needs of the largest section of the community in India. This the author thinks will suffice for the main educational function, namely, that of fitting the average youth for a useful and contented life in the conditions under which he was born.

He finds that education in India fails in two directions, viz, practicality and accuracy. In the government grants for educational development, which are largely devoted to the erection of new school buildings, too much attention is given to the number of schools teaching a standard curriculum and too little to that improvement of the pay and prospects of teachers, which alone will attract a better class to the profession and thus remove the necessity for that rigid standardization which stultifies individual initiative.

Two aspects of the educational problem in India are considered, namely, the insignificance of the system as compared with the individual and the provision of a ladder by which those intellectually qualified can rise. In discussing the functions of the agricultural college the author states that these will be fulfilled only when the main source of recruitment is the zemindar class, a class relatively small, perhaps, but numerically large and potentially powerful. The college must also supply the agricultural teachers for the secondary schools.

For the education of the masses there is found to be need for a cheap form of secondary education, complete in itself and complete within the limits provided by the age at which the average boy leaves school. The primary object of such a school will be to raise the receptivity of the younger generation of agriculturists, and the method of attainment must be through education under conditions which retain the association of the land. The author describes his conception of the organization of such a school in its environmental and educational aspects.

The school is represented as a village, the unit of communal life, composed of families, the unit of private life. The school will have approximately sufficient land to provide for each "family" of five students an area, roughly, equal to the average holding of the locality. The teacher will assume the rôle of the zemindar and his agents. This organization is compared with one of the few existing vernacular agricultural schools, in which the form of education provided is deemed too expensive and the admission requirements too high for the mass, and which also attempts instruction suited to collegiate students.

Attention is also called to the difference between the proposed type of school and vocational schools whose main function is to impart technical skill and in which theory is taught only in so far as it bears on the particular trade. In the former, subjects bearing upon the education may be taught but only for their internal value as a means of education, and the practical application is left to be drawn by a process of natural inhibition in the daily life. It is here, the author thinks, that the efforts which have been made to introduce agriculture into existing schools have failed. The practical difficulties, not the least of which is the lack of qualified teachers, are such that the development of the proposed schools must be slow and will afford ample opportunity for gaining useful experience.

The organization of public professional instruction in agriculture in France (Vie Agr. et Rurale, 8 (1918), No. 37, pp. 182–184).—The text of the law of August 2, 1918, on the reorganization of public professional instruction of agriculture in France is given. A new depature under this law is the establishment of sections or departments of practical agriculture on the estates of the national schools of agriculture at Grignon, Montpellier, and Rennes, at the National Agricultural Institute, and the National School of Agricultural Industries, to provide a thorough practical training for students leaving the National Agricultural Institute who wish to take up an agricultural career or to become professors of agriculture. Students from the national schools of agriculture and special students may also attend these departments.

In view of the poor results obtained by running the farms in connection with some of the practical schools of agriculture on a commercial basis, so that the director-farmer, obliged to make the greatest possible profit out of the farm, looked upon the students as laborers rather than real pupils, it is provided that farms in connection with the schools, save in exceptional circumstances, will be run either on behalf of a commune, a department, or the State. Winter or seasonal agricultural schools, either fixed or traveling, and under the control of the minister of agriculture, are to be established throughout the country with the joint financial support of the minister of agriculture and the department or commune.

Continuation instruction in agriculture is provided for, either in public schools or in premises placed at the disposal of the State by a commune or private persons. The instruction will be given to boys 13 years of age and over, and will extend over at least four years with a minimum of 150 hours each. A certificate will be awarded on the completion of the course.

A permanent central commission of the ministry of agriculture is also established, consisting of representatives of the ministries of agriculture and public instruction and of leading farmers designated by the minister of agriculture. This commission will be consulted regarding the regulations relating to continuation instruction, its general organization, and course of study, and on agricultural instruction given at the normal primary school.

Instruction in agriculture and housewifery for girls is provided for in the National Agricultural Institute, the national schools of agriculture, in connection with one of which a higher normal section for the preparation of professors and directors of schools of agriculture for women may be established, the agricultural housewifery schools which may be fixed, temporarily fixed, or temporarily traveling, and the course of continuation instruction in agricultural housewifery given to girls over 12 years of age in the public rural schools or in premises put at the disposal of the State.

Report of the education branch for the years 1917-18 and 1918-19 (Jour. Bd. Agr. [London], 26 (1919), No. 3, pp. 279-300).—This report deals with the grants made for the biennium ended March 31, 1919, for educational, advisory, and research work, and with the progress made therein by the various institutions and local education authorities during the academic biennium ended September 30, 1918.

The total attendance of the institutions providing higher agricultural education is reported as 576 in 1917–18, as against 387 in 1916–17. No regular courses were given at the University of Leeds, and at Oxford practically the whole staff was absent on war work. At the 1916–17 session of the Harper Adams Agricultural College, women students were admitted for the first time to the full diploma and certificate courses. The total attendance on special and short courses in 1917–18 was 1,791, as compared with 897 in the previous year, the increase being due to a large extent to the attendance on courses in farm work for women and on courses for disabled officers.

Brief reviews are given of the advisory work conducted at the institutions for higher agricultural education, as well as notes on the work of the research institutions. The services of a considerable portion of the staffs of these institutions were requisitioned for work under the food production department.

The schemes of agricultural instruction in the counties continued to be worked in the modified form necessitated by the war. In 1917–18, 416 organized day courses in agricultural subjects were held with an attendance of 4,989 as compared with 303 such courses with an attendance of 3,251 in 1916–17. In each of the two years 136 evening schools and classes in agriculture, horticulture, poultry keeping, farriery, and basket making were held, with a total attendance of 2,835 and 3,062, respectively. Lectures and instruction in manual processes were also given. The returns from 9 institutions providing residential courses of the farm institute type show that instruction was provided for 317 students in 1916–17 and 389 students in 1917–18.

There are at present about 40 organizers, whose duties and responsibilities are mainly to supervise all the agricultural work done by the county or counties employing them. They may give some instruction, but their main function is to act as the organizing head of the county staff and the mainspring of its activities.

Local authorities have been asked to prepare a comprehensive and satisfactory scheme of agricultural education for their areas by means of the establishment and maintenance, or contributions thereto, of an institution for higher agricultural education and of a farm institute or farm school; the provision of a county staff of agricultural instructors, including particularly the appointment of an agricultural organizer; the provision of technical advice for farmers, of regular short courses at an approved center or centers, and of local courses, lectures, practical demonstrations, etc., through the agency of the county agricultural staff or otherwise.

The grants for 1918–19 amounted to a total of \$368,054.50, including \$71,802.70 for universities and colleges, \$35,979.20 for advisory work, \$119,105.08 for research institutes and other research centers, \$13,055.48 for special research and other investigations, \$118,783.92 for the maintenance of farm schools, technical classes, local lectures, etc., and \$418.48 for the establishment of farm schools, \$43.79 for the expenses of advisory councils, and \$8,865.85 for forestry advice, research, and experiments.

Agricultural [and forestry] education and research (*Rpt. Bd. Agr. Scot.*, 7 (1918), *pp. XXI-XXVI*, *LXXIV-LXXVI*).—An account is given of the work of the three agricultural colleges, the two veterinary colleges, and extension and research work in 1917–18.

The attendance at the day classes of the agricultural colleges was 117, practically the same as for the preceding year, while that at the evening classes was 462 as compared with 337 in the preceding year. The extension work was conducted under extreme difficulty owing to war conditions. Grants of seeds and plants not to exceed  $\pounds 1$  in value in each case were supplied to 344 schools conducting garden work.

The research work for which grants were paid from the development fund included an investigation of the economic problem of crane flies, cheese-making problems, a geological soil survey, research in animal nutrition, the production of improved varieties of potatoes and turnips, and the investigation of sheep diseases.

The activities under schemes providing agricultural and forestry training for discharged sailors and soldiers are briefly described.

# NOTES.

California University.—W. R. Camp, professor of agricultural economics and marketing at the North Carolina College and Station, has been appointed associate professor of rural institutions. J. P. Benson has been appointed assistant professor of agricultural extension and E. V. Jotter, assistant professor of forestry.

Connecticut State Station.—Miss Edna L. Ferry, who for ten years has been first assistant in the nutrition research laboratory, died October 7, 1919. Michael D'Esopo, assistant chemist in the analytical laboratory, resigned December 1.

Delaware College and Station.—Harry Hayward, dean and director since 1906, resigned effective January 1, to accept a commercial position in Philadelphia. C. A. McCue, head of the department of horticulture, has been appointed to succeed him. A. E. Grantham, for twelve years head of the department of agronomy, has resigned, effective February 1, to become manager of the agricultural service bureau of a fertilizer company with headquarters at Richmond, Va.

Florida University and Station.—J. L. Earman, chairman of the board of control, resigned July 15, 1919, and has been succeeded by H. B. Minium. J. T. Diamond of the board resigned November 10. J. B. Hodges has been elected chairman of the board.

S. W. Hiatt, district agent for North and West Florida, resigned October 1 and was succeeded by H. G. Clayton, formerly county agent for Manatee County. R. W. Blacklock, county agent for DeSoto County, has been appointed assistant boys' club agent vice L. R. Highfill, resigned September 15. B. F. Floyd, plant physiologist, resigned November 15.

Michigan College.—Dr. J. L. Snyder, president emeritus, died at East Lansing October 22, 1919, at the age of 60 years.

Dr. Snyder became president of the college in 1896, continuing until 1915. During this long period the student body increased from 300 to nearly 2,000, much more substantial aid was secured through the passage of the State tax law, and a home economics course, a veterinary course, and a course in forestry were established. He was for many years a prominent figure in the Association of American Agricultural Colleges and Experiment Stations, and served as its president in 1908.

**Ohio State University.**—Bids have been asked for a swine building to cost \$10,000 and a sheep building to cost \$15,000. These buildings will constitute the first units of an animal husbandry group to be erected under a comprehensive building plan, and will be located some distance west of the present campus and across the Olentangy River.

H. C. Ramsower, professor of agricultural engineering, has been appointed director of the agricultural extension service. A. D. Burke has been appointed instructor in dairying.

**O**regon **College.**—O. D. Center, director of the extension service, has resigned to assume charge of extension work in McLean County, Ill. W. D. Pine has been appointed instructor in dairying, and H. S. Selby instructor in farm management.

Association of Official Agricultural Chemists.—The thirty-sixth annual convention of the association was held November 17–19, 1919, at Washington, D. C. The registration of 264 was somewhat smaller than at the previous meeting in 1917, but unusual interest was shown in the reports and papers and the attendance at the various sessions was very regular.

The usual reports of the referees and associate referees were read and discussed. Particular interest was manifested in the report of the sugar referee, A. H. Bryan, and accompanying papers on The Double Polarization Method for the Estimation of Sucrose and the Evaluation of the Clerget Divisor, by R. F. Jackson and C. L. Gillis, and The Attitude of the New York Sugar Trade toward the new U. S. Bureau of Standards Value for Standardizing Saccharimeters, by C. A. Browne. Prolonged discussion of the question of the Brix and Beaumé scales and of the standardization of quartz plate saccharimeters resulted in the appointment of two committees, the first to report later in the session on the Beaumé scale and the other to investigate quartz plate polarization during the coming year. Subsequently a resolution was adopted prescribing the Beaumé scale of the Bureau of Standards (Modulus 145), as given in Table 31, Circular 44, U. S. Bureau of Standards, as the official Beaumé scale of the association, and eliminating all Beaumé tables and references thereto not in accordance with this scale.

Supplementing the regular reports of the other referees the following papers were presented: The Determination of Water in Cereals and Meat Products, by F. C. Cook; Commercial Feeding Stuffs, by A. McGill; The Determination of Small Amounts of Chlorids in Chemical Reagents, by W. Heath; The Effect of Manure-Sulphur Composts on the Solubility of the Potassium of Greensand, by A. G. McCall; A Comparison of the Results obtained by the De Roode, Official Lindo-Gladding, and Modified Lindo-Gladding Methods for the Determination of Potash in Mixed Fertilizers, by E. R. Tobey; The Solubility of Calcium and Magnesium Arsenates in Carbon Dioxid and its Relation to Foliage Injury, by A. J. Patten; The Determination of Water-soluble Arsenic Oxid in Calcium Arsenate, by J. J. T. Graham; Ripe Olives, by C. Thom; Some Biochemical Characteristics of a Spinach Disease, by S. L. Jodidi; Physicochemical Methods for Determining the Grade of Flour, by C. H. Bailey; An Error in Gravimetric Vanillin Determinations in Vanilla Extracts, by H. J. Wichmann; The Cryoscopic (Freezing point) Method of Determining Percentages of Added Water in Milk, by J. Hortvet; and A Method for the Determination of Borax in Fertilizer Materials, by G. F. Lipscomb and C. F. Inman,

In the absence of C. S. Hudson and S. F. Sherwood, who were to have presented a paper on The Occurrence of Melezitose in Honey-Dew Honeys, a report on the subject was made by E. T. Wherry. Supplementing the report of the referee on Coffee, F. B. Power gave a brief report on An Improved Method for the Quantitative Determination of Caffein in Vegetable Materials. This method, which has been published (E. S. R., 41, p. 412), was adopted by the association as a tentative method to be studied in connection with the present Official Methods.

Following the usual custom, a part of the second morning's session was devoted to addresses by the retiring president of the association, Dr. P. F. Trowbridge, and by the honorary president, Dr. H. W. Wiley. The former selected as his general subject The Meat Problem, and presented an urgent plea for the greater conservation of world foodstuffs in the fattening of animals for the market. The waste of food materials suitable for human consumption brought about by the common practice of hogging-down corn was convincingly pointed out in statistics obtained in experiments conducted by the author at the North Dakota Station. Incidentally a plea was made for the more extensive use of horse flesh in place of beef. The reports of committees occupied practically all of the sessions of the third day. Dr. Alsberg, as chairman of the Board of Editors of the *Journal*, announced that arrangements had been made to continue its publication and that the next number would be issued in a short time. As the mailing list for the *Journal* is unavailable, a request was made that all past subscribers send their names and addresses to the editor to insure the receipt of the remaining numbers of the incomplete volume. Dr. Alsberg also announced that arrangements had been completed for printing the Official Methods, which will consist of a revision of Bulletin 107, including all changes and additions made through 1917, but not changes in methods adopted at the present meeting. These will, however, be published in the *Journal* as a supplement. The committee on form of recommendations by referees presented a blank form of report to be used by all referees.

The committee on the methods of sampling fertilizers to cooperate with a similar committee of the American Chemical Society offered the following recommendations, which were adopted: (1) That a sampler be used that removes a core from the bag from the top to the bottom; (2) that at least 1 lb. of material should constitute each official sample sent in to headquarters; (3) that the entire sample submitted to the chemist be passed through a 10-mesh sieve previous to the subdivision for analysis; and (4) that cores be taken from not less than 10 per cent of the bags present unless this necessitates cores from more than 20 bags, in which case a core shall be taken from one bag from each additional ton represented. If there are less than 100 bags not less than 10 bags all shall be sampled.

An important change in the appointment of referees was recommended, with a view to eliminating unnecessary work on subjects so well developed as not to necessitate regular study. Under the new plan adopted, a general referee is appointed for certain related groups of subjects, with a sufficient staff of associate referees to work with him or under his direction in the investigation of certain important questions in the field covered by the work of the general referee. The general referee is expected to keep in touch with the literature dealing with the subjects embraced in his field, and to make recommendations for special inquiries at the annual meetings, or institute them in the interim if the situation is urgent.

The subjects in which a grouping has been made and the newly appointed referees are as follows: Fertilizers, R. N. Brackett; saccharine products, H. S. Paine; foods and feeding stuffs, G. L. Bidwell; canned foods, W. D. Bigelow; meats and meat products, R. Hoagland; dairy products, J. Hortvet; cacao products, W. C. Taber; and drugs, G. W. Hoover.

The following officers were elected for the coming year: H. C. Lythgoe, president; W. F. Hand, vice-president; C. L. Alsberg, secretary and treasurer; members of the executive committee, C. H. Jones and W. W. Skinner; and members of committee on recommendations of referees and revision of methods—subcommittee A, W. H. McIntire (1924), subcommittee B, E. M. Bailey (1924), and subcommittee C, W. W. Randall (1922) and W. D. Collins (1924). As chairmen of other committees, there were selected for the committee to cooperate with other committees on food definitions, W. Frear; editing methods of analysis, R. E. Doolittle; vegetation tests on the availability of phosphoric acid in basic slag, C. B. Williams; methods of sampling fertilizers, to cooperate with a similar committee of the American Chemical Society, C. H. Jones; and revision of methods of soil analysis, C. B. Lipman. The board of editors of the Journal consists of C. L. Alsberg (chairman), E. F. Ladd (1921), R. E. Doolittle (1923), C. B. Lipman (1922), and L. L. Van Slyke (1920).

## CONTENTS OF VOL. 41, No. 9.

	Page.
Recent work in agricultural science	801
Notes	898

#### SUBJECT LIST OF ABSTRACTS.

#### AGRICULTURAL CHEMISTRY-AGROTECHNY.

First report on colloid chemistry and its industrial applications	801
Second report on colloid chemistry and its applications, Donnan et al	801
Crystallography, Wherry and Yanovsky	801
The nitrogenous constituents of yeast, Meisenheimer	802
Nonprotein nitrogenous constituents of human milk, Denis et al	802
Analytical study of Spanish olive oil, Fernández and Bustamante	802
Oil of fenugreek, Wunschendorff	803
Estimation of chlorate and perchlorate in saltpeter, Wogrinz and Kuber	803
Determination of humus, Mendes de Godoy	803
Determination of nonamino nitrogen, Hiller and Van Slyke	803
Determination of gluten, Marchadier and Goujon	803
Determination of citric acid in mixtures and compounds, Broeksmit	803
Determination of salicylic acid in presence of salicylic aldehyde, Berg	804
The electrical conductivity of milk, Coste and Shelbourn	804
Table for sorting of milk samples, Harris	804
Methods of calculating added water in milk, Harris	805
Milk calculations: A criticism, Richmond	805
Calculation of the original milk from analysis of cheese, Richmond	805

I

[Vol. 41

	Page.
The temperature of solution of butter fat in various reagents, Johnston	805
Hydrogenation of peanut oil, Heim, Job, and Sturzwage	805
Kaolin for tannin analyses, Frey	805
Conference on production and consumption of sugar in British Empire	806
The paper making qualities of Hawaiian bagasse, Little, Inc	806
Unfermented grape juice : How to make it in the home, Dearing	806
Culture of cabbage for sauerkraut, Lebrun	807
Low temperature-vacuum food dehydration, Falk et al	807
Work of Harriman Research Laboratory, Roosevelt Hospital, Falk	807

#### METEOROLOGY.

Climatological data for the United States by sections	Smithsonian meteorological tables	808
Meterological observations at Massachusetts Station, Ostrander and Smith808 808   Climatic factors [at the Hettinger substation, N. Dak.], Ogaard809 809   The weather of the past agricultural year, Brodie809 809   Swedish meteorological observations809 809   Warm season droughts809 809   Average summer rainfall809 809   Weather and corn, 1919810 810   Weather and winter wheat, 1918-19810 810	Climatological data for the United States by sections	808
Climatic factors [at the Hettinger substation, N. Dak.], Ogaard809   The weather of the past agricultural year, Brodie809   Swedish meteorological observations809   Warm season droughts809   Average summer rainfall809   Weather and corn, 1919810   Weather and winter wheat, 1918–19810   Start and winter wheat, 1918–19810   Summer Tainfall810	Meterological observations at Massachusetts Station, Ostrander and Smith_	808
The weather of the past agricultural year, Brodie	Climatic factors [at the Hettinger substation, N. Dak.], Ogaard	809
Swedish meteorological observations 809   Warm season droughts 809   Average summer rainfall 809   Weather and corn, 1919 810   Weather and winter wheat, 1918–19 810   Storeday mistakes about the weather Talman 810	The weather of the past agricultural year, Brodie	809
Warm season droughts	Swedish meteorological observations	809
Average summer rainfall	Warm season droughts	809
Weather and corn, 1919 810   Weather and winter wheat, 1918-19 810   Everyday mistakes about the weather Talman 810	Average summer rainfall	809
Weather and winter wheat, 1918–19810	Weather and corn, 1919	810
Everyday mistakes about the weather Talman 810	Weather and winter wheat, 1918–19	810
Every and and about the weather, rannah 010	Everyday mistakes about the weather, Talman	810

#### SOILS-FERTILIZERS.

Soil samples, maps, and profiles, van Bijlert	810
Soil survey of Mercer County, Pa., Deeter et al	810
Soil analysis, Harlow	811
Black soils, Harlow	811
Further studies on the soils of North Wales, Robinson and Hill	811
Biological analysis of soils, Padmanabha Aiver	811
Cultures of bacteria on sterilized soil, Barthel	812
Nitrification in Egyptian soils, Prescott	812
Relationship between contraction and the percentage of colloidal clay	812
The influence of stones in soil on the growth of plants, Pfeiffer et al	813
Soils and manures	813
Sand hill land: Tillage, fertilizer, and crop adaptation, Smith and Camp	813
Influence of kind of soil and fertilization on crops, Maschhaupt	813
Manures in their relation to soils and crop production, Clouston	813
Soil deficiencies in India, with special reference to indigo, Armstrong	814
Fertlizers, McDonald	814
Peat and its utilization, de Montgolfier	814
Experiments with night soil as manure, Patil	814
The pressing of sewage sludge, Allen	814
Commercial oxidation of ammonia to nitric acid, Parsons	815
Physiological action of ammonium salts on plants, II, Söderbaum	815
An afterwar fertilizer, ammonium nitrate, Malpeaux	815
Influence of dicyandiamid on plant growth, Johnson	815
Availability of nitrogenous manures in cotton soil, Plymen and Bal	816
The value of phosphate manures in India, Davis	816
Phosphate rock in 1918, Stone	817
Triplite: A possible source of phosphoric acid, Zealley	817
On the manner of occurrence of potassium nitrate in Oregon, Nattress	817
Separation of potash salts, Bassett	818
Potash production in Russia	813
Limestone action on acid soils, Sewart and Wyatt	818

#### AGRICULTURAL BOTANY.

Plant physiology, Knight	818
Plant physiology, Blackman	818
Plasmolysis of epidermal cells in petals of tulip, Guilliermond	818
The activation of buds in the Composite, Bohn	818
Bud formation of plant hypocotyls. Clark	818
Artificial absorption of glucose by the mulberry tree, Acqua	818

	Page.
Behavior of plants in unventilated chambers, Newcombe	819
[Temperature and seasonal progress of vegetation], Ritter	819
Demonstration of methods for the study of stomatal action, Pengelly	819
Conductivity as a measure of permeability, Osterhout	819
Note on effect of diffusion on conductivity of living tissue, Osterhout	819
Method of measuring electrical conductivity of living tissues, Osterhout	819
A comparative study of permeability in plants, Osterhout	819
Structures of coniferous woods and penetration by preservatives, Kitchen_	819
Salt ratios in soil cultures, Hibbard	820
[Mineral nutrient solution for maize], Mazé	820
Plant ecology and its relation to agriculture, Waterman	820
Dwarf shore floras, Clark	820
Notes of the introduced flora of the Douglas Lake region, Gleason	820
Notes on the Michigan flora, Farwell	821
A botanical trip to Mexico, I–II, Hitchcock	821
Note on inheritance in Phaseolus, Brotherton	821
Mendelian segregation in <i>Enothera pratincola</i> , Cobb and Bartlett	821
Studies in classification and nomenclature of bacteria, VIII-X, Buchanan-	821
Comments on the evolution and classification of bacteria, Breed et al	821
Bacteria which survive in fractional sterilization, Eckelmann	821
Studies on proteolytic enzyms of soil fungi and Actinomycetes, Waksman	822

#### FIELD CROPS.

Crop rotation and soil fertility, Doneghue	822
[Field crops work at Hettinger, N. Dak., 1913-1918], Lanxon et al	824
[Report of field crops work in Montserrat, 1917–18], Watts	825
[Field crops work at St. Kitts-Nevis stations, 1916–17 and 1917–18], Watts_	825
[The Woburn field experiments, 1918], Voelcker	825
[Report of field crops work in Mysore, 1916–17]	826
[Report of field crops work in the United Provinces, India, 1918], Burt	-826
Grain yields for 1919, Stookey	826
Statistical notes on cereals	826
[Fiber plants of Brazil], Corrêa	827
The agaves, Berger	827
Australian saltbush, McKee	827
The cultivation of barley in Chile, Opazo G	827
The barley of Tripoli, De Cillis	827
Buckwheat, Leighty	827
Selection of pseudo-starchy endosperm in maize, Jones	827
[Cotton culture in French colonial possessions]	828
Cawnpore-American cotton: Its improvement, Burt and Haider	828
Report of the Indian Cotton Committee	828
Inheritance of certain characters in the cowpea, Harland	828
Henequen in Yucatan, Barba	829
A giant legume as a forage crop for Cuba, Calvino	829
Production of late or main-crop potatoes, Stuart	\$29
Industrial and nutritive value of potato in Ireland, Johnson and Boyle	829
Rice experiments [in Trinidad], 1915–1918, de Verteuil and Brunton	829
Cross-pollination of sugar cane, Cowgill	-830
Varieties of sugar cane in Porto Rico, Earle	-830
Breeding timothy at Svalöf, Witte	-\$30
Inheritance of branching habit in tobacco, Johnson	830
Flue-cured tobacco in Canada, Digges and Freeman	831
The 1919 yields from ten wheat fields in "Egypt," Hopkins et al	832
[The cultivation of the greater yam (Dioscorea alata)], Burkill	832
The longevity of Bacillus radicicola on legume seeds, Fellers	-832
Farm weeds of North Carolina, II, Burgess and Waldron	833

#### HORTICULTURE.

Aerial fertilization of plants with carbon dioxid, Cummings and Jones	833
Is cooperative marketing applicable to Illinois conditions? Lloyd	834
Some economic aspects of fruit and vegetable storage, Lloyd	834
Olneya beans, Cook	834
Studies on the biology and culture of superior mushrooms, Boyer	834

	Page
Report of plant industry, Glenn	835
Some important problems in pomology and their significance, Gould	835
Fruit blossoming records, Terry	835
Fruit and fruit products of South Africa, Davis	835
[Fruits and ornamentals recommended for planting in Wisconsin	835
The cost of building an orchard, Davis	835
The outgo and income of a 10-acre apple orchard, Hedrick	835
Distance between trees in planting at the station orchard, Green	835
Apple bud selection: Apple seedlings from selected trees. Crandall	835
Apple grading laws,—Their value and requirements, Hetzel	837
Controlling enemies of pear in Pacific Northwest, Fisher and Newcomer	830
Pruning experiments, Chambers	836
Spoilage of cranberries after picking, Shear	836
Beduction of cranberry losses between field and consumer. Shear et al	836
"Reversion" and resistance to "big bud" in black currants. Lees	836
Raspherry growing on small holdings, Hodge	836
Report of the viticulture station at Auvernier for 1917–18. Godet	836
Native fruits of North Dakota, Waldron	836
Applying the furrow manure in citrus groves. Shamel	837
Yield of coffee trees in Surinam cultural garden during 1918. Van Drent_	837
Olive growing and oil pressing. Opazo G	837
Manual of practical olive culture. Vitetta	837
The nalms of the Philippine Islands, Beccari	837
A pineapple fertilizer experiment, Gonzales	837
First report on fruit culture as practiced in Barakzai	837
A variety nut orchard	837
Note on condition of trees at Hettinger substation 19181 Downey	837
Commercial drug growing in the United States in 1918 Stockherger	837
Commercial aray storing in the childer States in 1916, Stochool Ser	001

#### FORESTRY.

Report of the director of forestry for 1918, Campbell et al	838
The forests of British Columbia, Whitford and Craig	838
Reafforestation and the economic development of France, Descombes	838
A forest policy for Australia, Lane-Poole	838
Effect of changed conditions upon forestry, Ashe	838
A brush-disposal policy for yellow-pine forests of Southwest, Chapman	839
Making best use of idle lands in New York, Stephen	839
What is potential forest land? Hoar	839
The segregation of farm from forest land, Lovejoy	839
New Indian species of forest importance, Gupta	839
Indian species of Carissa, Haines	839
Cultivation and tapping of Castilla rubber in the Philippines, Aldaba	839
The distribution of walnut, Lamb	839
Instructions for the planting and care of conifer trees in shelter belts	840
Mechanical aids in stem analysis, Pegg	840
Mensuration in France, Bruce	840
Pathological marking rules for Idaho and Montana, Weir and Hubert	840
[Fire protection in Maine in 1918]	840
Report of the chief forest fire warden for the year 1918, Wirt	840
Forest fires in Canada, 1917	840
Observations on some effects of fires in the chir forests, Champion	840
Pulp and paper, 1917	840

#### DISEASES OF PLANTS.

	040
Mode of dissemination of fungus and bacterial diseases, Gardner	840
[Unreliability of certain appearances in diagnosis of diseases], Neger	840
Michigan nlant disease survey for 1917, Coons	841
Plant diseases [British Guiana], Bancroft	841
Investigations on diseases of plants and their treatment, Grove	841
Philippine economic-plant diseases. Reinking	841
Porto Bican fungi old and new. Stevens	842
Some new Porto Rican funci Miles	842
The mate of the Douglas Lake region Bonar	842
The fusion of the Douglas Date region, Donar	842
Notes on <i>Uephaleuros virescens</i> , mgley	014

	Page.
A means of distinguishing between species of Penicillium, Wöltje	842
Lime-sulphur sprays, Vermorel and Dantony	842
Stem rust of grains and the barberry in Wisconsin, Johnson and Dickson_	842
Take-all, the wheat growers' worst enemy, Pridham	842
Phyllachora as the cause of a disease of corn, Dalbey	843
Studies on tracheomycoses: Verticilliose of cucumber, van der Lek	843
Frost injury of potato tubers, Kotila	843
Unknown corpuscles in diseased spinach roots, Schoevers	843
Sugar-cane varieties and froghopper blight in Trinidad, Williams	843
The leaf mold of tomatoes caused by <i>Cladosporium fulvum</i> , Makemson	843
Occurrence of Alternaria in a characteristic apple spot, MacInnes	844
An apple rot caused by <i>Gliocladium viride</i> , MacInnes	844
Longevity in soil of Sclerotina causing brown rot, Pollock	844
The control of brown rot of plums and plum pocket, Stakman and Tolaas_	844
[Sap acidity and disease resistance in grape varieties], Atti	844
Recent studies on the treatment of grape downy mildew, Ravaz	845
Treatment of downy mildew, Mazotta	845
The action of polysulphid on Oïdium, Capus	845
Recent views regarding arricciamento (roncet) in grapevines, Petri	845
Distribution of <i>Fusarium cubense</i> , the cause of banana wilt, Brandes	845
Notes on the general treatment of fungus diseases, Tunstall	845
The Fusarium wilt of China aster, Beach	846
[Injury to coniferous forest trees near manufacturing plants], Mangin	846
Tests with some chemicals against root nematodes, II, Schoevers	846

#### ECONOMIC ZOOLOGY-ENTOMOLOGY.

The raptorial birds of Iowa, Bailey	846
Notes on North American Birds, IX, Oberholser	846
Notes on the races of <i>Quiscalus quiscalus</i> , Oberholser	846
The status of Larus hyperboreus barrovianus, Oberholser	846
[Contributions on economic insects]	846
Some plagues of our cultivated crops, Arango	847
Contribution on the Javanese mole crickets, Roepke	847
[Thysanoptera of Florida], IV-V, Watson	847
Hemiptera collected by the Yale Dominican expedition of 1913, Gibson	847
Notes on <i>Gargaphia tilia</i> , the linden lace bug, Weiss	847
Hyalopeplus smaragdinus n. sp., a new tea capsid in Java, Roepke	847
The potato leaf hopper and the hopperburn that it causes, Ball	849
The potato leaf hopper and its relation to the hopperburn, Ball	849
Report of second collection of Nova Scotian leaf hoppers, McAtee	849
The plant lice injuring the foliage and fruit of the apple, Matheson	849
Miscellaneous aphid notes, I, Davis	850
Fitch's thorn leaf aphis, Baker	850
Trench fever, Strong et al	851
Mosquitoes in relation to yellow fever, Noguchi	851
Notes on Allograpta fracta (Diptera: Syrphidæ), Davidson	852
A contribution to the knowledge of Brazilian Œstridæ, Lutz	852
The prevention of blow-fly attacks on sheep by spraying, McDonald	852
Experiments for the control of the grape root-worm, Hartzell	852
Life history of the orchid pest <i>Crioceris subpolita</i> Motsch?, Leefmans	853
The quince curculio in western New York, Strickland and Achilles	853
The life history of some social wasps in Java, Roepke	853
Studies on the biology of Paracopidosomopsis, I-IV, Patterson	853

#### FOODS-HUMAN NUTRITION.

Nutrition in war and lessons to be learned from it, Rho	854
Practicability of scientifically balanced ration in Army camps, Anderson_	854
Average food consumption in training camps, Murlin and Hildebrandt	854
Food consumption by recruits and seasoned troops, Howe et al	854
Note on the acid-base balance of Army rations, Blatherwick	855
Dried vegetables for army use, Prescott	855
American military hospital dietaries, Hoskins	855
Energy and food requirements of women workers, Rosenheim	856
Gastric responses to foods	857

19191

v

[Vol. 41

Page. The influence of diet on teeth formation, Mellanby\_\_\_\_\_ 858 Effect of cow's milk and human milk upon smooth muscle, Meyer\_\_\_\_\_ Regeneration of blood serum proteins, Kerr et al\_\_\_\_\_\_ Investigation of changes in the blood and urine from fatigue, Hastings\_\_\_\_\_ 858 859 860 Experimental scurvy in monkeys, Harden and Zilva\_\_\_\_\_\_Antiscorbutic value of raw juices of root vegetables, Chick and Rhodes\_\_\_\_\_\_A note on the value of germinated beans in scurvy, Wiltshire\_\_\_\_\_\_ 860 860 861 Beer and scurvy, Smith\_\_\_\_\_\_ Efficacy of lime juice for the prevention and cure of scurvy, Smith\_\_\_\_\_ 861 861 Antiscorbutic properties of raw lean beef, Dutcher et al\_\_\_\_\_ 861

#### ANIMAL PRODUCTION.

Mitosis and amitosis, Conklin	861
Studies on cytolysins, I, Guyer and Smith	861
Suckling and the rate of embryonic development in mice, Kirkham	862
Production of hypotypical ovaries through underfeeding, Loeb	862
The concrescence of follicles in the hypotypical ovary, Loeb	862
The effect of alcohol on the reproductive tissues, Arlitt and Wells	862
Germ cells in mammalsEffect of alcohol, Stockard and Papanicolaou	863
Studies on inbreeding, I–IV, King	864
Cross involving three allelomorphic characters, Detlefsen and Roberts	866
Fluctuations of sampling in a Mendelian population, Detlefsen	867
Demonstration of origin of two pairs of female identical twins, Riddle	867
Genetic variability, twin hybrids and constant hybrids, Muller	867
Fluctuations in a recessive Merdelian character and selection, Roberts	-867
Selecting cattle for hornlessness, Wentworth	868
Commercial feeding stuffs, quarterly report, Proulx et al	868
Inspection of feeding stuffs	868
Poultry foods, Brünnich	868
Carrying capacity of ranges in western United States, Hensel	869
The cattle industry of the Southeast, Rommel	869
Cattle industry, Coope	869
Some camel feeding experiments, Cross	869
Domestication of animals in Peru, Cook	869
Making money from hens, Lewis	869
Fall poultry problems, Lewis	869
Feeding hens for egg production, Lamon and Lee	869
Egg laying contests.—I, II, Card and Kirkpatrick	870
Final report of the fourteenth egg-laying competition, Potts	8:0
Final report of the fifteenth egg-laying competition, Queensland	810
Convenient method of indicating time element in hen's record, Goodale	870
Fertility experiments, Kaupp	871
The results of single, one-day matings, Martin and Anderson	871
Note on the behavior of capons when brooding chicks, Goodale	811
Concerning artificial lighting, Shoup	011
Cottonseed hulls, a sanitary and vermin-proof litter, Taubenhaus	811

#### DAIRY FARMING-DAIRYING.

Calf feeding: Corn silage; whole milk dilutions, White and Kuelling	871
The feeding of oats to calves, Hanly	873
Study of relative reliability of official tests of dairy cows, Yapp	873
Dairying industry, Coope	873
Cheddar cheese manufacture for Rhodesian farm conditions, Coope	873
A study of the eye formation of Emmental cheese, Clark	873

#### VETERINARY MEDICINE.

Report for 1918 of principal of the Royal Veterinary College, McFadyean_	\$73
Fifth and sixth reports of the director of veterinary research, Theiler	873
Report of the civil veterinary department, Assam, for 1918–19, Harris	874
Report of civil veterinary department, United Provinces, 1919, Oliver	874
A manual of bacteriology, Hewlett	874
Heterolysins, II, Sordelli and Fischer	874
Influence of desiccation on certain bodies, Karsner and Collins	874

	Page.
Notes concerning the concentration of antitoxic sera, Sordelli	874
The production of antiserum for agglutination tests, Reynolds and Hill	875
Phenolut, a colloidal cresol solution as a disinfectant, Schürmann	875
Anaplasma marginale, Di Domizio	875
The antigen of <i>Bacillus anthracis</i> , Warden and Connell	875
Australian epidemics of an acute polioencephalomyelitis, Cleland et al	876
Glycerinated rinderpest vaccine, Kakizaki	876
Report of bacteriological investigation of tetanus, Tulloch	876

No. 9.

# **RECENT WORK IN AGRICULTURAL SCIENCE.**

#### AGRICULTURAL CHEMISTRY-AGROTECHNY.

First report on colloid chemistry and its industrial applications (*Brit.* Assoc. Adv. Sci., Rpt. Colloid Chem. [etc.], 1 (1917), p. 86).—This report is the outcome of the work of a committee appointed by the chemical section of the British Association for the Advancement of Science, for the purpose of compiling information regarding the advances which have been made in colloid chemistry, with special reference to industrial processes. Two methods of classification have been adopted: First, a classification according to the nature of the property, principle, or phenomenon concerned, based on the recognized divisions of the science of colloid chemistry; and second, a classification in terms of the various technical processes themselves.

In the present report one subject only has been considered according to the first classification, namely: The Viscosity of Colloid Systems, by E. Hatschek. The subjects dealt with under the second classification, and contributors thereto are as follows: Colloid Chemistry of Tanning, by H. R. Proctor; General Review and Bibliography of Dyeing, by P. E. King; Colloid Chemistry in the Fermentation Industries, by A. J. Brown; Rubber, by H. P. Stevens; Colloid Chemistry of Starch, Gums, Hemicelluloses, Albumin, Casein, Gluten, and Gelatin, by H. B. Stocks; Colloids in the Setting and Hardening of Cement, by C. H. Desch; Nitrocellulose Explosives, and Celluloid from the Standpoint of Colloidal Chemistry, by E. R. Chrystall; and Colloidal and Capillary Phenomena in their Bearing on Physiology and Biochemistry, by W. Ramsden.

In a few of these reports bibliographies of the literature alone are given, and in all an attempt has been made to cover the literature to date (1917).

Second report on colloid chemistry and its general and industrial applications, F. G. DONNAN ET AL. (*Brit. Assoc. Adv. Sci., Rpt. Colloid Chem.* [etc.], 2 (1918), pp. 172; also in Rpt. Brit. Assoc. Adv. Sci., 1918, Sect. B, pp. 172).—This report follows the general lines of the report noted above. The subjects and authors are as follows: Report on Peptisation and Precipitation, by W. D. Bancroft; Emulsions, and The Liesegang Phenomenon, both by E. Hatschek; Electrical Endosmose, by T. R. Briggs; Colloid Chemistry in the Textile Industries, by W. Harrison; Report on the Part Played by Colloids in Agricultural Phenomena, by E. J. Russell; Sewage Purification with Reference to Colloid Chemistry, by E. Ardern; Colloid Problems in Dairy Chemistry, by W. Clayton; Colloid Chemistry in Physiology, by W. M. Bayliss; and The Administration of Colloids in Disease, by A. B. Searle.

Crystallography, E. T. WHERRY and E. YANOVSKY (Jour. Wash. Acad. Sci., 9 (1919), No. 17, pp. 505-513, figs. 2).—Crystallographic measurements of mor-

phine and some of its derivatives by the method previously noted (E. S. R., 39, p. 415) are reported from the Bureau of Chemistry, U. S. Department of Agriculture. The substances examined included morphine monohydrate, codeine, codeine monohydrate, codethyline monohydrate, and heroin.

Nonprotein nitrogenous constituents of human milk, W. DENIS, F. B. TAL-BOT, and A. S. MINOT (*Jour. Biol. Chem.*, 39 (1919), No. 1, pp. 47–51).—A similar study to that previously noted (E. S. R., 41, p. 616) was made of human milk obtained from normal women whose infants were free from digestive disturbances.

Variations in the amount of the different extractives present in samples of milk drawn at different periods throughout the day were relatively small and of no apparent uniformity. The results of the examination of 71 samples of milk are summarized as follows:

Constituents.	Quantity per 100 cc. milk.		Questitues to	Quantity per 100 cc. milk.	
	Mini- mum.	Maxi- mum.	Constituents.	Mini- mum.	Maxi- mum.
Total nonprotein nitrogen Urea nitrogen . A mino nitrogen	$Mg.\ 20.0\ 8.3\ 3.0$	Mg. 37.0 16.0 8.9	Preformed creatinin Creatin Uric acid	Mg. 1.0 1.9 1.7	Mg. 1.6 3.9 4.4

Nonprotein nitrogenous constituents of human milk.

Attention is called to the fact that the values found for nonprotein nitrogen, urea, preformed creatinin, and uric acid in milk are along the same general level as the values for the corresponding substances in blood. The amount of amino nitrogen is in some cases comparable with that in blood but in some cases lower, while the values for creatin are much lower than in blood

The nitrogenous constituents of yeast, J. MEISENHEIMER (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 104 (1919), No. 5–6, pp. 229–283).—An analysis of hydrolyzed yeast by Fischer's ester method is reported. Glycocoll, alanin, valin, leucin, prolin, phenylalanin, aspartic and glutaminic acids, tyrosin, and tryptophan were positively identified, and serin and cystin with less certainty. There was also some evidence of the presence of an aminobutyric acid.

Analytical study of Spanish olive oil, O. FERNÁNDEZ and F. BUSTAMANTE (Bol. Inst. Nac. Hig. Alfonso XIII, 15 (1919), No. 58, pp. 85-92; also in Rev. R. Acad. Cien. Madrid, 17 (1919), No. 7-9, pp. 281-286).—The analytical constants of 33 samples of Spanish oil are reported, the maximum, minimum, and average values of which are given in the following table:

Sample.	Density.	Index of refrac- tion.	Iodin number.	Saponifi- cation number.	Acidity.	Specific tempera- ture of reaction.
Maximum . Minimum A verage	0.9180 .9128 .9154	1. 4694 1. 4629 1. 4661	89.5 76.3 83.9	221. 0 160. 0 196. 9	Per cent. 3.2 .173 1.34	Degrees. 97.9 94.0 95.9

Analytical constants of Spanish olive oil.

802

These constants are compared with reported values for California and Italian olive oil.

Oil of fenugreek, H. E. WUNSCHENDORFF (Jour. Pharm. et Chim., 7. ser., 19 (1919), No. 11, pp. 397, 398).—The physical properties of the oil obtained from fenugreek seeds are described, and a table is given of its analytical constants. The oil is of a golden yellow color and disagreeable taste and odor. It belongs to the drying oils, solidifying very rapidly when exposed to the air. The analytical constants are as follows: Specific gravity at 15° C. 0.9471, index of refraction at 22° 1.4774, saponification number 189.5, iodin number 137.8, and acidity 3.2 per cent.

The estimation of chlorate and perchlorate in saltpeter, A. WOGRINZ and J. KUBER (*Chem. Ztg., 43 (1919), No. 5-6, pp. 21, 22; abs. in Chem. Abs., 13 (1919), No. 14, p. 1571*).—This is a critical discussion of various methods of determining chlorates and perchlorates in potassium and sodium nitrate.

Comparative determination of humus by the Grandeau and Hilgard methods, J. MENDES DE GODOY (Escola Agr. "Luiz de Queroz," Piracicaba, Brazil, Ser. Chim. Agr. Bol. 2 (1919), pp. 12, fig. 1).—Experiments with 13 different soils to compare the methods of Grandeau and Hilgard for determining humus content are reported.

In all cases a greater humus content was indicated by the Grandeau method than by the Hilgard method, and in most cases the Grandeau method indicated more humus in the subsoil than in the soil, while the opposite was the case with the Hilgard method. It is concluded that the Hilgard method is the better.

Direct determination of nonamino nitrogen in the products of protein hydrolysis, A. HILLER and D. D. VAN SLYKE (*Jour. Biol. Chem.*, 39 (1919), No. 3, pp. 479-488).—A modification of the Van Slyke method of analyzing proteins (E. S. R., 34, p. 505) is described, in which the nonamino nitrogen instead of being determined indirectly is determined directly in the nonamino acid fraction of the products of protein hydrolysis.

The procedure is exactly the same as that used in the former method for protein analysis until the hexone bases have been separated from the remaining amino acids. After the removal of the phosphotungstic acid from the filtrate with amyl alcohol and ether, the primary amino nitrogen is removed by warming with sodium nitrite and hydrochloric acid, the excess nitrous acid removed by reduction to ammonia with a zinc-copper couple by Scales' method (E. S. R., 36, p. 504), and the residual nonamino nitrogen determined by the ordinary Kjeldahl method.

The results of this method in analyses of casein and gelatin are said to agree closely with the results obtained indirectly. This indicates that "the original method, although indirect, contains no inherent errors, and that when due precautions in regard to calibrated apparatus and standardized solutions are observed, results of practically the same degree of accuracy can be obtained by the original, somewhat simpler indirect method, as by the present direct one."

**Determination of gluten**, MARCHADIER and GOUJON (Ann. Chim. Analyt., 2. ser., 1 (1919), No. 8, pp. 243-246; also in Jour. Pharm. et Chim., 7. ser., 19 (1919), No. 12, pp. 425-434).—A method for the determination of gluten in flour is described, which consists essentially in centrifuging 1 gm. of flour with 10 cc. of pure acetic acid for about five minutes at 1,500 revolutions per minute, pouring off the supernatant liquid, and repeating the process twice. The combined solutions of gluten in acetic acid are evaporated on a water bath to dryness and heated in an oven at 100° C. for an hour, the resulting residue representing the dry gluten.

Determination of citric acid in mixtures and compounds, T. C. N. BROEK-SMIT (*Pharm. Weekbl.*, 56 (1919), No. 31, pp. 1047-1052).—The method consists essentially in oxidizing the citric acid in acetic acid solution with potassium permanganate, and treating the acetone thus formed with ammonia and an alcoholic solution of iodin to form iodoform. The technique for the procedure with fruit juices, milk, and various salts of citric acid is described. In the cases of fruit juices and milk a preliminary treatment is necessary, which consists in adding alcohol, filtering, and adding barium acetate to the filtrate to form barium citrate. This is then treated with acetic acid, potassium permanganate, etc., as noted above.

Volumetric method for the determination of salicylic acid in the presence of salicylic aldehyde, R. BERG (*Chem. Ztg.*, 43 (1919), No. 32-33, p. 129).—The method described depends upon the fact that colorless solutions of salicylic aldehyde develop a strong citron yellow color on the addition of traces of alkali, and that this color disappears on the addition of a weak acid such as carbonic acid.

The ether solution of the substance to be tested is shaken 3 times with N/20 sodium carbonate solution and then washed 3 or 4 times with water. If the last wash water on the addition of a drop of N/20 sodium hydroxid remains coloriess, sodium carbonate must be added again. When the reaction is complete, the combined extract is titrated with N/20 sulphuric acid until colorless, warmed to allow escape of carbon dioxid, and titrated with N/20 sodium hydroxid until the yellow color is again produced. The amount of salicylic acid *a* is calculated from the formula  $a = (t - [t_1 - t_2]) \times 0.0669$ , *t* being the number of cubic centimeters of sodium bicarbonate,  $t_1$  of sulphuric acid, and  $t_2$  of sodium hydroxid employed.

The electrical conductivity of milk, J. H. COSTE and E. T. SHELBOURN (*Analyst, 44 (1919)*, *No. 518, pp. 158–164, figs. 2*).—An investigation of the effect of certain factors upon the electrical conductivity of milk is reported and summarized as follows:

The temperature coefficient of electrical conductivity in the region of  $15^{\circ}$  C. is 0.000093, or about 2.3 per cent of the total conductivity. The electrical conductivity of presumably genuine milks may vary from  $K_{15}$ =0.0035 to 0.0047, but in more than 50 per cent of the 200 or more samples examined it was between 0.004 and 0.0042. The electrical conductivity of milk increases up to a certain point with the development of acidity, but reaches an almost constant value while the amount of acid is still increasing. There is no well defined correlation between electrical conductivity and total solids or total ash, but a marked correlation between the electrical conductivity and the chlorin content of milk. The specific conductivity of a mixture of milk and water decreases with dilution, but that of the milk in the solution increases greatly as the dilution increases ,owing probably to dissociation of phosphates and citrates.

In explaining these conclusions the authors refer to the work of Jackson and Rothera (E. S. R., 33, p. 203), in which the results of measurements of the electrical conductivity, percentage of milk sugar, and depression of the freezing point of milk are interpreted from a physiological viewpoint.

The authors conclude that the value of the electrical conductivity of milk is not sufficiently well defined to make the determination generally useful for detecting adulteration. "It would, however, be useful in a large dairy or institution as a check on watering of milk which had already been examined by the conductivity method, and which had afterwards passed through various hands."

Table for sorting of milk samples, L. J. HARRIS (Analyst, 43 (1918), No. 512, pp. 375-377, fig. 1).—A table, calculated from Richmond's formula T=0.25G+1.2F+0.14, is given which is said to enable the analyst to determine at a glance, knowing the specific gravity and total solids of the sample, whether it is above

or below the mnimum standard of the British Board of Agriculture, and in the latter case whether the deficiency is in fat, or solids-not-fat, or both.

A phase-diagram is also given, which summarizes the conditions under which milk samples will be above or below the standard. .

Methods of calculating added water in milk, L. J. HARRIS (Analyst, 44 (1919), No. 515, pp. 43-45).—The author suggests possible methods to obviate the long computations involved in the use of the formula proposed in an earlier paper (E. S. R., 40, p. 412) for calculating added water in milk. The first method suggested consists of a shorter calculation of the solids-not-fat in the fat-free milk and the determination of the extraneous water by reference to a table which has been worked out by the author. Suggestions are also given for the use of an alignment chart, or a slide rule.

Milk calculations: A criticism, H. D. RICHMOND (Analyst, 44 (1919), No. 519, pp. 200, 201).—The author criticizes the two papers of Harris noted above and two earlier ones previously noted (E. S. R., 39, p. 612; 40, p. 412), on the ground that the assumptions on which they are based are not wholly true.

Calculation of the composition of the original milk from the analysis of cheese, H. D. RICHMOND (*Analyst*, 44 (1919), No. 519, p. 202).—To calculate the fat and solids-not-fat in the original milk from the analysis of the cheese made from it, the author proposes the formula given below (F=percentage of fat in cheese and P=percentage of proteins in cheese):

Fat in original milk= $\frac{100F}{35.4P+F}$ +0.25. Solids-not-fat in original milk= $\frac{333P}{35.4P+F}$ .

The temperature of solution of butter fat in various reagents, J. H. JOHN-STON (Jour. Dairy Sci., 2 (1919), No. 2, pp. 130-132).—The author refers to the discussion by Fryer and Weston (E. S. R., 39, p. 110) regarding the Valenta test, and suggests the use of absolute alcohol in place of the mixture of ethyl and amyl alcohols recommended in the article noted. The result, or Crismer number, is said to vary from 51 to 56° C. for butter fat, the number in most cases being 53 to 54°. For margarin made chiefly from beef fat the number is over  $65^{\circ}$ , and from vegetable fats below  $45^{\circ}$ . With old butters, the acidity calculated as oleic acid after titration with N/10 alkali should be multiplied by the factor 1.5 and the result added to the observed temperature to give the corrected Crismer number.

Hydrogenation of peanut oil, F. HEIM, A. JOB, and H. STURZWAGE (Bul. Off. Colon. [France], 11 (1918), No. 127-128, pp. 355-361, figs. 2; abs. in Internatl. Inst. Agr. [Rome], Internatl. Rev. Sci. and Pract. Agr., 10 (1919), No. 1, pp. 108, 109).—The authors describe an apparatus for the hydrogenation of oils on a small scale with the use as a catalyzer of hydrated nickel formate,  $(H COO)_2$ Ni, 1.5 H<sub>2</sub>O, and describe the hydrogenation of arachis (peanut) oil with the apparatus. The hydrogenated oil obtained was a hard wax-like solid with the following analytical constants: Iodin number 13.5, temperature of solidification 47.8° C., and melting point 53°. The possibility is suggested of altering these constants by varying the time and temperature of the reaction so as to obtain a fat of the same hardness as different animal fats.

Kaolin for tannin analyses, R. W. FREY (Jour. Amer. Leather Chem. Assoc., 14 (1919), No. 7, pp. 393-401).—The author, from the Bureau of Chemistry, U. S. Department of Agriculture, has collected data from various contributions on kaolin for tannin analysis, on the basis of which a tentative scheme of kaolin specifications is proposed. Conference on the production and consumption of sugar within the British Empire (Jour. Soc. Chem. Indus., 38 (1919), No. 15, pp. 287T-314T, figs. 2).— This account of the conference on the production and consumption of sugar within the British Empire, held in London on July 16, 1919, contains the preliminary report of the Empire Sugar Supply (Technical) Committee with discussions of the same. The report consists of statistics on the prewar sugar position of the British Empire as regards production, consumption, and the quantity, nature, and source of the sugar imported or exported by each unit of the Empire; the economic sugar-producing possibilities of each unit, the most likely localities for increased supply, and the kind of sugar required by the various consumers throughout the Empire; and technical suggestions for the development of the industry.

The paper making qualities of Hawaiian bagasse, ARTHUE D. LITTLE, INC. (Hawaiian Sugar Planters' Sta., Agr. and Chem. Bul. 46 (1919), pp. 51).—This detailed report consists of the following sections: General survey of the question of the utilization of Hawaiian bagasse for paper making, discussion of the various previous attempts to utilize bagasse as a paper making material, description of the principal paper making processes, discussion of the technique involved in handling Hawaiian bagasse for paper making with special reference to the experimental results obtained, commercial aspect of the paper making possibilities of Hawaiian bagasse, estimates of investment and production costs, and tabulation of experimental data.

Hawaiian bagasse fiber was found to have practically the same characteristics as the fiber from Cuban bagasse. The fiber is somewhat shorter than so-called soda pulp, the shortest bleached fiber in large-scale use in the United States, and is thought to have certain points of superiority over it. Used alone, it is suitable for book paper and certain grades of writing paper, but it is thought that the widest application of bagasse pulp would be in admixture with rag, sulphite, or soda fibers for the production of such papers. For wrappings and other papers in which strength is the principal consideration bagasse pulp is considered of little value. Failures of previous attempts to develop bagasse as a paper making material are attributed, chiefly, to a lack of comprehension of the characteristics of bagasse, and to attempts to convert it into a grade of paper to which it was ill adapted.

From experimental results obtained in the application of various processes to different samples of Hawaiian bagasse, it was found that for the largescale separation of pith the bagasse should be given a somewhat finer shredding than is necessary in the sugar mill, that the sulphate process with the sphericalrotary type of digestion is best adapted for cooking the bagasse, and that the pulp can be easily bleached with 15 per cent of bleaching powder. The relative yields of bleached pulp from different varieties of Hawaiian bagasse in percentage of air-dry bagasse are estimated as 30 per cent for the Yellow Caledonia variety, 26.7 per cent for Hawaii 109, and 22.3 per cent for Lahaina bagasse. No marked difference in quality of the pulp from the different sources was noted.

Estimates of investment and production costs on the basis of prewar conditions as existing in 1912 indicate that a bagasse pulp and paper mill with a daily capacity of 30 tons of paper would yield a net profit of 25.3 per cent after deducting interest at 6 per cent on the total capital involved, and that under the same conditions a mill with a 10-ton output might be expected to yield a return of 15.6 per cent.

Unfermented grape juice: How to make it in the home, C. DEARING (U. S. Dept. Agr., Farmers' Bul. 1075 (1919), pp. 32, figs. 20).—This bulletin gives directions for the home preparation of unfermented grape juice. Descriptions are

given of the three types of these juices corresponding to the types of grapes grown in the principal grape-growing districts of the United States, and of the two general methods employed in preparing the juice.

The types of juices are (1) the northeastern type, prepared especially from the northeastern fox grape, *Vitis labrusca*, which is characterized by its relatively high content of acid in proportion to sugar; (2) the western type, prepared from the European grapes, *V. vinifera*, of the Pacific coast grape sections, which have a high sugar content; and (3) the southeastern type, prepared from Muscadine grapes (*V. rotundifolia* and *V. munsoniana*) of the Southeastern States, which are somewhat lower in sugar content and higher in acidity than the western grapes but resemble them in the transparency and brilliancy of their juices.

The cold-press method of extracting juice is considered preferable for use with the western and southeastern types and the hot-press method for the eastern type. The main steps of the process in both methods, from the selection of the grapes to the storage of the final product, are outlined and discussed, and diagrams with accompanying descriptions are given of homemade grape crushers and presses of different types.

Culture of cabbage for sauerkraut, L. LEBRUN (Culture du Chou a Choucroute. Paris: Libr. Agr. Maison Rustique, 1918, pp. 32, figs. 2).—This pamphlet contains directions for the culture of cabbage to be used for sauerkraut, for the manufacture of sauerkraut on a small and a commercial scale, and for its preparation for the table.

Low temperature-vacuum food dehydration, K. G. FALK, E. M. FRANKEL, and R. H. MCKEE (Jour. Indus. and Engin, Chem., 11 (1919), No. 11, pp. 1036– 1049, fig. 1).—In this article a description is given of the low temperaturevacuum dehydration process originally developed for the dehydration of meat, but later employed successfully for the dehydration of vegetables and fruits as well as meat and fish. The process consists briefly in heating the meat (or other food products), cut in pieces of suitable size, to a temperature below that at which cooking or appreciable changes take place, continuously maintaining a degree of vacuum such that the vapor pressure of water at the temperature employed is greater than the pressure within the vacuum drier, thus causing boiling and evaporation of the water from all parts of the meat, and introducing a sufficient quantity of heat to evaporate the large amount of water liberated.

In the commercial vacuum shelf drier used, hot water or low-pressure steam circulates through the shelves upon which are placed galvanized iron wire-gauze trays containing the substance to be dried. In the dehydration of meat the vacuum maintained corresponds to a pressure of 2 in. of mercury, and the temperature of the circulating fluid is kept at about 70° C. The time of dehydration varies with the size of the individual pieces of meat used. With steaks 0.25 in. thick dehydration requires from 2 to 3 hours. The final product weighs about 28 per cent of its original weight, contains approximately 10 per cent of water, and occupies about one-half the original volume. If kept under ordinary atmospheric conditions, no perceptible chemical change has been found to occur at the end of a year.

Fish, shell fish, fruits, and vegetables have been dried by this process without difficulty and with very satisfactory results. In general, the process has been found to cause less destruction of enzyms and less loss of volatile products than with air-blast dehydration.

The work of the Harriman Research Laboratory, Roosevelt Hospital, New York City, in affiliation with the Division of Food and Nutrition, Medical

158071°-No. 9-20-2

1919]

Department, U. S. Army, K. G. FALK (Jour. Indus. and Engin. Chem., 11 (1919), No. 11, pp. 1062, 1063).—A brief statement is given of the lines of investigation which have been carried on at the Harriman Research Laboratory in a study of the protein decomposition of meat. These have included the chemical study of meat spoilage, the published results of which have been noted from various sources (E. S. R., 40, pp. 712, 713); a study, by I. Greenwald, of the factors upon which the toxic action of spoiled meat depend (E. S. R., 41, p. 668); and a study of the methods for preventing spoilage which resulted in the new process of dehydration noted above.

#### METEOROLOGY.

Smithsonian meteorological tables (*Smithsn. Misc. Collect.*, 69 (1918), No. 1, pp. LXXII+261, fig. 1).—This is the fourth revised edition of these tables, the original edition of which was issued in 1893. The revision was "prepared under the direction of Prof. Charles F. Marvin, Chief of the U. S. Weather Bureau, assisted by Prof. Herbert H. Kimball. . . .

"All errata thus far detected in the earlier editions have here been corrected. New vapor pressure tables, derived from the latest experimental values by means of a modification of Van der Waals' interpolation formula devised by Professor Marvin, have been introduced. The table of relative acceleration of gravity at different latitudes has been recomputed from a new equation based upon the latest investigations of the U.S. Coast and Geodetic Survey. These values have been employed in reducing barometric readings to the standard value of gravity adopted by the International Bureau of Weights and Measures, supplementing a table that has been introduced for directly reducing barometer readings from the value of gravity at the place of observation to its standard value. The new values of vapor pressure and of gravity acceleration thus obtained, together with a recent and more accurate determination of the density of mercury, have called for an extensive revision of numerous other tables, and especially of those for the reduction of psychrometric observations, and the barometrical tables. Among the new tables added are those for converting barometric inches and barometric millimeters into millibars, for determining heights from pressures expressed in dynamic units, tables of gradient winds, and tables giving the duration of astronomical and civil twilight, and the transmission percentages of radiation through moist air. The tables of international meteorological symbols, of cloud classification, of the Beaufort scale of winds, of the Beaufort weather notation, and the list of metorological stations, are among those extensively revised. Tables for reducing barometric readings to sea level, and tables of logarithms of numbers, of natural sines and cosines, of tangents and cotangents, and for dividing by 28, 29, and 31, with a few others, have been omitted from this edition."

The volume includes thermometrical tables, conversions involving linear measures, conversion of measures of time and angle, conversion of measures of weight, wind tables, reduction of temperature to sea level, barometrical tables, hygrometrical tables, geodetical tables, and miscellaneous tables.

Climatological data for the United States by sections (U. S. Dept. Agr., Weather Bur. Climat. Data, 6 (1919), Nos. 5, pp. [203], pls. 4, figs. 2: 6, pp. [201], pls. 4, figs. 2).—These volumes contain brief summaries and detailed tabular statements of climatological data for each State for May and June, 1919, respectively.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. OSTRANDER and G. A. SMITH (*Massachusetts Sta. Met. Buls.* 369-370 (1919), pp. 4 each).—Summaries of observations at Amherst, Mass., on
pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during September and October, 1919, are presented. The data are briefly discussed in general notes on the weather of each month.

Climatic factors [at the Hettinger substation, N. Dak.], A. J. OGAARD (North Dakota Sta. Bul. 130 (1919), pp. 31-35, figs. 5).—Rainfall data for Hettinger from 1910 to 1917, inclusive, and for New England, about 40 miles northwest, and Orange, 30 miles southeast of Hettinger, from 1894 to 1909, inclusive, are summarized in tables and diagrams. Data are also given for evaporation, temperature, frost-free period, and wind velocity at Hettinger, 1911-1917.

The average annual rainfall for the region was 14.03 in., the average for Hettinger being 14.37 in. The average seasonal rainfall was 10.84 in. The average seasonal evaporation (April to September) was 32.78 in. The average frost-free period at Hettinger was 112 days, varying from 91 days in 1911 to 128 days in 1912. May 15 is considered a comparatively safe date for planting corn, in most years. The data recorded do not indicate any progressive climatic changes in the region.

The weather of the past agricultural year, F. J. BRODIE (*Jour. Roy. Agr. Soc. England*, 79 (1918), pp. 174–184).—The weather conditions, particularly rainfall, temperature, and sunshine in Great Britain during the winter of 1917–18 and the year 1918 are briefly summarized as in previous reports.

Swedish meteorological observations (Met. Iakttag. Sverige (Observ. Mét. Suéd.), Met. Centralanst., 57 (1915), pp. XIII+181; 58 (1916), pp. XIV+181).— These are the detailed tabular reports of the Central Meteorological Institute of Sweden for 1915 and 1916.

Warm season droughts (U. S. Dept. Agr., Nat. Weather and Crop Bul., No. 19 (1919), pp. 2, 3, figs. 2).—Two charts are given which show the percentage of years with 30 consecutive days or more without 0.25 in. of rain\_all in 24 hours from March to September, inclusive, and the longest period in 20 years when similar conditions prevailed.

Drought periods of the character indicated "occur with less frequency in the interior of the Northeast, in the area extending northward from the central Appalachian Mountain districts through Ohio, and in the Southeast. In these sections there is experienced, on the average, only about one year in three having a period of one month's duration without 0.25 in. of rainfall in 24 hours. The percentages increase, as a rule, to the westward, and in the more western portions of the Great Plains phenomena of this character are practically of yearly occurrence. In the Ohio, central Mississippi, and lower Missouri Valleys the percentages range from 40 to 50, but are somewhat higher to the southward, while they show a rapid increase from the eastern portions of the Plains States toward the western portions." The number of consecutive days without 0.25 in. of rainfall from March 1 to September 30 during a period of 20 years ranges from a maximum of about 80 in the western Great Plains to a minimum of about 40 from the central Appalachian Mountains northward to Lake Erie.

Average summer rainfall (U. S. Dept. Agr., Nat. Weather and Crop Bul., No. 20 (1919), pp. 2, 3, figs. 2).—Charts are given which show for the various sections of the country the average amount of rainfall for the three summer months. June to August, inclusive, and the percentage of the annual precipitation that occurs during the summer months. A wide difference in summer rainfall in different parts of the country is shown, the minimum being in the southern Pacific coast districts and the maximum along the west coast of the Florida Peninsula,

"In the Pacific Coast States the summer is almost rainless, except in the more northern section, where showers may be expected to occur occasionally, especially in the mountains... In the Plains States it is comparatively heavy, and in New Mexico and eastern Arizona much of the annual precipitation occurs during the summer months, mostly in July and August. In the central and east Gulf and south Atlantic coast districts rainfall is usually heavy during this season, the totals ranging from 16 to 25 in., and it is comparatively heavy also in portions of the Appalachian Mountain region, where locally as much as 20 in, is received on the average...

"In the central and northern Plains States from 45 to 50 per cent of the annual amount occurs during this season, as a rule; the agricultural importance of that area is largely due to this fact. Large percentages of the annual amount occur during the summer months also from western Texas to central Arizona. Along the southern Pacific coast, however, less than 1 per cent of the annual rainfall occurs during the three summer months. In most of the country east of the Great Plains the percentages range from 25 to 30. In this area the seasonal distribution of precipitation is comparatively uniform, except in the Florida Peninsula, with no distinctive types of special agricultural significance, although the comparatively light falls in the cotton belt during much of the cotton picking season are favorable for the prosecution of that work."

Weather and corn, 1919 (U. S. Dept. Agr., Nat. Weather and Crop Bul., No. 27 (1919), p. 2, figs. 6).—Diagrams are given which indicate the variations of temperature and rainfall from the normal, by weeks, during the season of 1919 in the principal corn-growing States, and also show the condition of corn on the first of July, August, and September, respectively, expressed in percentages of the 10-year average. The relations of weather and crop conditions are briefly discussed.

Weather and winter wheat, 1918–19 (U. S. Dept. Agr., Nat. Weather and Crop Bul., No. 27 (1919), p. 2, figs. 9).—Diagrams are given which show for the more important winter-wheat States the total precipitation and departure of the mean temperature from the normal, by months from August 1918, to May, 1919, inclusive, and also the condition of winter wheat on the first of December, 1918, and April, May, and June, 1919, expressed in percentages of a 10-year average. The correlation of the weather conditions and the growth and yield of crop are briefly discussed.

Everyday mistakes about the weather, C. F. TALMAN (*Ladies' Home Jour.*, 36 (1919), No. 9, pp. 49, 168).—This article deals with popular fallacies regarding the moon's influence on the weather, long-period forecasts, very cold winters of former times, change of climate, effect of the Gulf Stream, battles and rain, equinoctial storms, Indian summer, cyclones, and violent storms.

#### SOILS-FERTILIZERS.

Soil samples, maps, and profiles, A. VAN BIJLERT (Meded. Landbouwhoogsch. [Wageningen], 16 (1919), No. 1-2, pp. 29-36, pls. 4).—Information is given on the taking and preparation of soil samples and soil profiles, and the preparation of soil maps for display and instruction purposes.

Soil survey of Mercer County, Pa., E. B. DEETER, R. A. WINSTON, and W. I. GALT (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1917, pp. 40, pl. 1, fig. 1, map 1).—This survey, made in cooperation with the Pennsylvania Experiment Station, deals with the soils of an area of 448,000 acres in northwestern Pennsylvania, the surface of which ranges from level to hilly.

The soils of the county consist principally of glacial till derived from the Late Wisconsin glaciation. "Where the soils have developed under conditions of good drainage they are brown in the surface horizon, while the subsoils are "yellowish to brownish yellow. From this condition there are various gradations down to the extremely wet and impervious soils, where the surface soils and subsoil are light gray in color." Fifteen soil types of 10 series and 2 miscellaneous types are mapped, of which the Volusia and Canfield silt loams cover 39.3 and 28.7 per cent of the area, respectively. The soils of the county are said to be generally in need of lime.

Soil analysis, L. C. HARLOW (Ann. Rpt. Sec. Agr. Nova Scotia, 1918, pt. 1, pp. 135-140).—Analyses of several samples of upland soils of Nova Scotia, representative of about 400 samples analyzed, showed that the organic matter and nitrogen contents of virgin soils were very low, while in pasture and cultivated soils there were sufficient quantities of nutritive materials. In old so-called "run out" soils, a considerable nitrogen accumulation was found. Physical analyses showed that the upland soils are usually sandy soils.

Black soils, L. C. HARLOW (Ann. Rpt. Sec. Agr. Nova Scotia, 1918, pt. 1, pp. 145–147).—Analyses of 13 samples of the so-called black soils of Nova Scotia are reported, indicating a high organic matter content and low mineral matter content. These soils are usually from low spots, but it is the opinion that a well-decayed black soil, when composted with manure, provides nitrogen and humus in good quantity and retains moisture and liquid manure. Such soils are usually quite acid and need liming.

Further studies on the soils of North Wales, G. W. ROBINSON and C. F. HILL (Jour. Agr. Sci. [England], 9 (1919), No. 3, pp. 259-282, figs. 2).—This is a second paper on the subject (E. S. R., 38, p. 116), in which studies on the general characteristics of the carboniferous soils and the soils derived from the northern drift, together with associated deposits, are reported.

The soils studied are generally lowland soils. Mechanical and chemical analyses are reported showing that the coarsest fractions of these soils consist almost entirely of quartz sand. They are all generally deficient in lime, but contain reasonable quantities of potash.

Biological analysis of soils, A. R. PADMANABHA AIYER (Dept. Agr. Cent. Provs. and Berar [India], Rpt. Agr. Col., Nagpur, Bot. and Chem. Research [etc.], 1918, pp. 17–19).—Studies of embanked wheat soils to determine whether the gradual deterioration of wheat yields was due to lack of any of the normal biological activities are reported. Samples were taken from three plats. Plat I was kept open and plowed at the beginning of the rains and harrowed at intervals between rains. Plat VI was flooded until one month before planting, when it was drained and harrowed. Plat VII was flooded and not cultivated before planting.

Moisture determinations showed that soils from Plat VII contained 32 per cent, from Plat VI 31 per cent, and from Plat I 26 per cent of moisture, as against 44, 40, and 35 per cent, respectively, for the previous year. There was no noticeable difference in the nitrogen-fixing powers of the soils for the two years. Carbon dioxid production was the same in soils from Plats I and VI but was greater in Plat VII than in the others. "The number of bacteria in Plat I . . . was, however, much lower than Plat VI, but was still higher than Plat VII. The results of nitrification in the case of Plat I were contrary to those obtained last year. The percentages of nitrogen transformed in the form of nitrate from the same amount of organic manure . . . after eight weeks' incubation were as follows: Plat I, 21,3 per cent; Plat VI, 53.4 per cent; and Plat VII, 46.9 per cent." Biological studies of bhatta soils containing about 69 per cent of stones and gravel show that this soil is quite efficient in the production of carbon dioxid and also in ammonification. The rate of nitrogen fixation is, however, about half of what takes place in black cotton soil. "Nitrification, though not as good as the black cotton soil, can still safely be classed as average... It was found that the growth of plants in bhatta soil was very much inferior to those from black cotton soil; and that the former had a very poor development of root nodules. This effect was not, however, so much noticed in the case of groundnut crop. Subsequent pot culture experiments on sann hemp alone have conclusively shown that inoculation of the bhatta soil with black cotton soil shows much improvement in the growth of the plants, and that inoculation combined with a dressing of til cake ... at sowing time gives most promising results."

Cultures of bacteria on sterilized soil, C. BARTHEL (Meddel. K. Vetensk. Akad. Nobelinst., 5 (1919), No. 20, pp. 13, pl. 1).—Studies are reported on the growth of pure cultures of different organisms introduced into garden soil rich in organic matter and containing some sand which was previously sterilized in the autoclave. The organisms tested were Azotobacter chroococcum, Bacterium radicicola, Streptococcus lactis, Bacterium casei, and Bacillus mycoïdes.

It was found that in most cases these organisms, when introduced in pure culture into the sterilized soil, grew and developed much more easily and better than in crude unsterilized soil. These results are considered to be of some significance from the soil fertility standpoint.

Nitrification in Egyptian soils, J. A. PRESCOTT (Jour. Agr. Sci. [England], 9 (1919), No. 3, pp. 216–236).—Two years' study on the biological conditions of the soil of an Egyptian farm, with special reference to nitrification, are reported. The soil was typical of the Nile alluvium.

It was found that in all cases the moisture content of the soil limited biological processes more than any other factor. "There was observed throughout the season in a cotton field a relatively large amount of nitrate, more than sufficient for the immediate needs of the cotton plant. The lack of response on the part of the Egyptian cotton crop to nitrogenous fertilizers may be accounted for in part, if not entirely, by the fact that nitrification in the soil is well ahead of the needs of the crop." There was no accumulation of nitrate in soil under wheat and maize.

It is thought that the period of winter fallow, during which the soil depends for its water only on the rainfall, may be a period of steady nitrification when the amount of rainfall is sufficiently high. The summer fallow soils immediately after removal of the winter crops were found to be biologically dormant. They were characterized by very low moisture content and by fairly high temperatures.

Pot experiments with wheat and maize showed that the root activities of a growing crop have some limiting effect on the production of nitrate in the soil In both cases the fallow pots accumulated appreciably more nitrate than the cropped pots.

The relationship between contraction and the percentage of colloidal clay (*West Indian Bul.*, 17 (1918), No. 2, pp. 113–118, fig. 1).—Studies on the amounts of internal pore space existing in blocks of 16 different soils which have been allowed to contract to the full extent and from which any residual water has been removed by subsequent drying to a constant weight at 110° C. are reported.

Comparison of these amounts with the observed value for linear shrinkage showed that a linear relationship appears to exist between the two values.

"By extrapolating the curve thus obtained, an approximation for the limiting value of the shrinkage in the case of pure colloidal clay is arrived at amounting to approximately 23 per cent. On this assumption it becomes possible to calculate the approximate content of colloidal material in any soil from a knowledge of the linear shrinkage. Results are adduced showing the values obtained for the shrinkage in the case of separated fine silt and clay fractions in the case of two soils of known shrinkage and physical composition, and compared with the values calculated from previous assumptions."

The influence of stones in soil on the growth of plants, T. PFEIFFER, W. SIMMERMACHER, and H. FRISKE (Landw. Vers. Sta., 93 (1919), No. 1-2, pp. 49-63, fig. 1).—Pot culture experiments with oats on a productive loam soil mixed with stones so that the pots contained 25, 50, 75, and 100 per cent of loam are reported.

It is concluded that a very high stone content in soil does not cause any considerable loss of energy through the root development of oats and similar crops. It was found that there was practically no difference in the available water and plant nutrients in the different soils, and the yield of dry matter varied only within the limits of error. It is further concluded that soil volume as such has no direct influence on plant growth.

Soils and manures (Bd. Agr. and Fisheries [London], Guides Small Hold., No. 6 (1919), pp. 30).—This pamphlet gives brief popular information on the subject for the benefit of service men intending to settle on the land.

Some experiments on sand hill land: Tillage, fertilizer, and crop adaptation, A. G. SMITH and O. O. CAMP (S. C. Dept. Agr., Com. and Indus., Bul. 63 (1918), pp. 20, fig. 1).—General soil development experiments are reported, the purpose of which was to determine the proper treatment and crops for coarse sandy soil, usually with yellow sandy subsoil.

It was found that deep breaking of sandy lands was generally more profitable than shallow breaking, although in some years shallow breaking gave the better results. Barnyard manure was more profitable when applied to cotton than to other crops. Manure drilled gave higher yields of cotton than manure broadcasted. In a comparison of acid phosphate, basic slag, and rock phosphate, with barnyard manure, acid phosphate and rock phosphate on the average gave practically the same results, while without manure, acid phosphate was the best. Rock phosphate did not compare so favorably with acid phosphate and basic slag the first year as it did the second and third years. Shallow cultivation gave higher yields of cotton than deep cultivation.

The influence of kind of soil and fertilization on nitrogen and ash content of crops, J. G. MASCHHAUPT (Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefsta. [Netherlands], No. 23 (1919), pp. 40-56).—Continuing previous experiments (E. S. R., 41, p. 422) with the same soils, crops, and fertilizer treatments, the same general results were found regarding the composition of crops. On swamp soil, the potato tubers had a high nitrogen content and a very low phosphoric-acid content. It is concluded that phosphoric-acid fertilizers are not particularly available to crops on drained swamp soil, although the availability was somewhat increased by addition of ammonium sulphate. Marked differences were observed in the composition of crop tops in these experiments from those in previous experiments, especially with reference to potash content.

It is generally concluded that the influence of fertilization on the composition of the ashes of plants can be judged with safety only when the harvested crops vary very little with reference to yield and growth status.

Manures in their relation to soils and crop production in the Central Provinces, D. CLOUSTON (Agr. Jour. India, 14 (1919), No. 1, pp. 101-106).—This is a summary of fertilizer experiments on alluvial wheat soils, black cotton soils, and lateritic rice soils.

It has been found on the rice soils that 10 lbs. of nitrogen per acre added as poudrette has given a greater increased return than the same amount of nitrogen added as cattle manure, and a still greater increase has been obtained from night soil. Additions of calcium cyanamid and of bone meal separately, and of bone meal in combination with sodium nitrate, have resulted in a loss. Bone meal combined with ammonium sulphate has generally given a small profit, as have also dried leaves and tank silt. Castor cake has given a small net profit in some cases and a loss in others.

"The only manures which have consistently given large acreage profits are cattle manure, night soil, and poudrette. The supply of night soil and poudrette is so small and the difficulty of getting sweepers to apply them so great that they are only of secondary importance as an economic factor in crop production. It therefore becomes evident that of the manures available in any quantity, cattle dung is the only one which really counts." Green manure is suggested as the best probable substitute for cattle manure, and experiments with sann-hemp as green manure on rice soils have proved profitable.

Experiments on cotton soils with urine earth "have shown that, in the year of application to jowar (*A. sorghum*) and cotton fields, the urine of a bullock for any definite period of time is equal in manurial value to its solid excreta for the same time." Green manuring is not considered a feasible proposition on this soil.

Soil deficiencies in India, with special reference to indigo.—Phosphorus and the future, H. E. ARMSTRONG (Jour. Roy. Soc. Arts, 67 (1919), No. 3471, pp. 446-460; abs. in Chem. Abs., 13 (1919), No. 16, p. 1892).—This is a general discussion on deficiency of phosphates in Indian soils with special reference to indigo soils.

In the soils examined phosphate was found to be deficient, while potash, calcium, nitrogen, and organic matter were present in relatively great excess. Additions of superphosphate and green hemp produced the best yields of indigo. It is pointed out that indican formation depends on a good available supply of phosphate, while an excess of nitrogen in the soil retards indican formation.

Fertilizers, J. G. McDONALD (*Rhodesia Munitions and Resources Com. Rpt.* 1918, pp. 35-41).—This is a short note on the value and proper use of fertilizer, with special reference to Rhodesian conditions.

Peat and its utilization, P. DE MONGOLFIER (La Tourbe et Son Utilisation. Paris: H. Dunod et E. Pinat, 1918, pp. [11]+179, figs. 23).—This book deals with the origin and physical and chemical properties of peat, describes the peat deposits of Europe and America, and discusses its commercial exploitation as fuel, source of gas, fertilizer carrier, etc., and its general agricultural value.

Experiments with night soil as manure, P. C. PATIL (Agr. Jour. India, 13 (1918), No. 2, pp. 281-286, pl. 1).—Experiments with night soil as a manure on sorghum, cotton, and rice show it to be profitable and in comparison with barnyard manure to have a considerably greater residual effect. "To ensure success the following conditions are required: (1) Before application of the manure the soil should be well harrowed, at least to a depth of 3 in., so that the soil to that depth is loose and soft; (2) the rainfall should be heavy in the first two months of the rainy season; and (3) the night soil should be applied in the dry season so that it will get dry in the soil as soon after application as possible, allowing thorough mixing with the soil and preventing the breeding of flies."

The pressing of sewage sludge, K. ALLEN (Trans. Amer. Soc. Munic. Impr., 24 (1917-18), No. 1, pp. 1-25, figs. 7).—This paper presents the main features

814

of the practice of sewage sludge pressing to obtain fertilizer material, fuel, etc. Dewatering sewage sludge by filter pressing with the plate type of press has been brought to a point where its efficiency and cost can be closely predicted. With fresh settled or precipitated sludge, the addition of from 0.5 to 3 per cent of lime, and a pressure of 70 or 80 lbs. per square inch, a firm, satisfactory cake can be produced.

Commercial oxidation of ammonia to nitric acid, C. L. PARSONS (Jour. Indus. and Engin. Chem., 11 (1919), No. 6, pp. 541-552, figs. 13; abs. in Chem. and Metall. Engin., 20 (1919), No. 10, pp. 502, 503, fig. 1).—This is a review of recent progress made in the oxidation of ammonia, together with a more detailed account of the investigational work which led to the development of the experimental plant built at Syracuse, N. Y., by the U. S. Bureau of Mines in cooperation with a commercial concern.

Further contribution regarding the physiological action of ammonium salts on plants, II, H. G. SöDERBAUM (Meddel. Centralanst. Försöksv. Jordbruksområdet, No. 178 (1918), pp. 12, fig. 1; also in K. Landtbr. Akad. Handl. och Tidskr., 57 (1918), No. 7-8, pp. 513-521, fig. 1; abs. in Chem. Abs., 13 (1919), No. 10, p. 1120).—Further pot experiments (E. S. R., 38, p. 121) are reported to determine the limits of the harmful effect of ammonium sulphate and sodium nitrate, alone and mixed, on oats, barley, vetch, and Italian rye grass on sand soil.

It was found that for oats the limiting amount of ammonia nitrogen was between 142 and 178 lbs. per acre, and for barley between 36 and 53 lbs. per acre. With rye grass no harmful effects were observed up to 178 lbs. per acre. With vetch the effect of ammonium sulphate was most pronounced, the smallest amounts used in any pot decreasing the plant growth. Vetch was also sensitive to sodium nitrate, but in less degree than to ammonium sulphate.

An afterwar fertilizer, ammonium nitrate, L. MALPEAUX (Vie Agr. et Rurale, 8 (1918), No. 45, pp. 335-339).—Tests of ammonium nitrate and ammonium sulphate on three different soils showed that the ammoniacal nitrogen of the ammonium nitrate is not so well retained by the soil as that of the sulphate, but that the nitrate contents of the soils were increased more by the ammonium nitrate. Ammonium nitrate gave about the same results in this respect as sodium nitrate.

In pot experiments with oats the best total results were obtained with ammonium sulphate. Ammonium nitrate gave slightly better results than sodium nitrate, although the weight of grain obtained with the latter was somewhat greater.

Plat experiments with oats, sugar beets, and potatoes using sodium nitrate, calcium nitrate, ammonium nitrate, ammonium sulphate, and cyanamid showed that calcium nitrate gave the best results for oats, followed closely by sodium nitrate. Ammonium nitrate and cyanamid gave about the same results with oats, which were only slightly less than with the two better fertilizers. All the fertilizers gave a marked increase over unfertilized soils. Ammonium nitrate gave the best results with sugar beets, but marked increases were obtained in all cases. With potatoes calcium nitrate gave the best results, which, however, were only slightly superior to those obtained with sodium nitrate and ammonium nitrate.

It is concluded that ammonium nitrate is a very active fertilizer and should be classed with sodium nitrate and ammonium sulphate in this respect.

It is further concluded from these experiments that the choice of a nitrogenous fertilizer should be governed by price, availability, and nature of the soil.

Influence of dicyandiamid on plant growth, E. JOHNSON (*Tidskr. Kemi*, 15 (1918), pp. 349-367, 369-393; abs. in Chem. Abs., 13 (1919), No. 12, p. 1354).-

Cropping experiments were conducted with three nitrogenous fertilizers called lime nitrogen and cyanamid, but consisting of mixtures of cyanamid, dicyandiamid, and urea, and with pure dicyandiamid.

The results obtained corresponded to the content of the fertilizers in urea and dicyandiamid and, allowing for the inhibitory influence of the dicyandiamid, followed the Mitscherlich law of minimum. A small percentage of dicyandiamid did not retard straw and grain yield and, with an increase of nitrogen in the fertilizer, there was a greater relative yield in grain than in straw. This was true for mixtures in which the dicyandiamid represented 35 per cent of the total nitrogen. Pure dicyandiamid did not increase crop growth and is considered possibly as injurious. It is thought that favorable influences attributed to dicyandiamid in previous work may have been due entirely to associated urea.

The biological determination of the relative availability of different nitrogenous organic manures in black cotton soil, F. J. PLYMEN and D. V. BAL (Agr. Jour. India, 14 (1919), No. 3, pp. 414-421).—Studies on the bacterial transformation of six common oil cakes and of an oil-free cake in black cotton soil of the Deccan are reported.

With the exception of the oil-free cake, karanja (*Pongamia glabra*) and cotton cakes appeared to be by far the most quickly available, and castor cake was not much inferior to them. Til cake (*Sesamum indicum*) was not quite so active, although the nitrogen ultimately nitrified compared favorably with that of other cakes. With the exception of mahua cake (*Bassia latifolia*), sarson cake (*Brassica napus*) was the slowest so far as nitrifiability in black cotton soil is concerned. The nitrogen in mahua cake was neither ammonified nor nitrified to any appreciable extent during a period of eight weeks.

The value of phosphate manures in India and the possibility of their manufacture on a larger scale, W. A. DAVIS (Agr. Research Inst. Pusa Bul. 81 (1918), pp. IV+28).—This is a report of a committee made up of a number of reports by individual members and others. Conclusions drawn by the committee from these reports are that not sufficient evidence is available to indicate definitely that any deterioration of the soil arising from depletion of phosphates has occurred generally throughout India, except in the case of the indigo soils of Bihar.

With reference to the effects of phosphatic fertilization in the different Provinces, the reports indicate that "in the indigo districts of Bihar such manuring is plainly beneficial.

"In Bengal and Assam, on the old alluvium, there is ample evidence that phosphatic manuring is of value and has given considerable increase with paddy (40 per cent), mustard, and other crops. On the old alluvium, lime is also deficient and is probably necessary to enable phosphates to produce their maximum effect. On the silt alluvium, evidence is variable and no general conclusion can be drawn. Pending further investigations on the tea garden soils evidence shows that phosphatic manures are of great value. Basic slag and basic superphosphates give the best results. Bone manures and mineral phosphate when applied to the soil have not given noticeable results, except indirectly, through green crops.

"In the United Provinces, in the eastern districts on opium soils, it is possible that phosphate manuring may be useful. There is no evidence of phosphate deficiency in other areas. In the Punjab, results appear to indicate that very little benefit is at present found in the use of phosphatic manures in most of the ordinary systems of agriculture adopted in that Province.

"In Burma, soils of the delta show great variations. In some areas the phosphate supply is ample, in others deficient. In general, however, it appears that phosphates will probably prove to be an essential manure in the great rice-growing areas of Burma.

"In Madras, experiments with phosphatic manuring have been chiefly made with paddy. Marked deficiency in available phosphate is chiefly noticeable in old paddy soils. All forms of phosphates have yielded marked results. On the laterite high lands chiefly devoted to planting crops, tea, coffee, and rubber, paying results have been obtained by the use of basic slag and basic superphosphates.

"In Bombay, the need for phosphate was most felt in the rice lands of the Konkan, both superphosphate and bone meal repaying the cost of application. Outside this area the scarcity of nitrogen and organic matter appears to be the limiting factor, except possibly in the case of leguminous crops, notably lucerne. In the case of cane, phosphate alone has given poor results, but when used as a manure on a preceding green dressing crop the subsequent yield of cane was increased. Early ripening and greater purity of juice were noticed.

"In the Central Provinces there appeared to be no indication of the need of phosphate in the black cotton soils. On the light soils of the Province it has proved valuable in the case of paddy, sann-hemp, and cane. Experiments have not gone far enough to indicate which form of phosphate is preferable. . .

"Taking India as a whole, there are sufficient supplies of phosphatic manures from all sources to meet the present demands, but there are isolated localities where the question of the supply of superphosphate in the immediate future appears to be important."

**Phosphate rock in 1918**, R. W. STONE (U. S. Geol. Survey, Min. Resources U. S., 1918, pt. 2, pp. II+199-222).—This report deals with the production and sale of phosphate rock in the United States and other countries during 1918, and with the distribution and character of deposits.

The phosphate rock marketed in the United States in 1918 amounted to 2,490,760 long tons, valued at \$8,214,463. As compared with the production in 1917, there was a decrease in quantity of 93,527 tons and an increase in value of \$443,379. The quantity mined in 1918 was 2,284,245 long tons, a decrease of 567,641 tons from the output of 1917.

The decrease in production was general. In Florida the decrease was 443.247 tons, or 19 per cent, with 28 plants in operation, 9 less than in 1917; in South Carolina 11,868 tons, or 26 per cent, with 3 producing plants, as in 1917; in Tennessee 108,160 tons, or 23.8 per cent, with 21 plants in operation, 2 less than in 1917; and in the Western States 4,479 tons, or 27 per cent, with 3 producers instead of 4.

**Triplite:** A possible source of phosphoric acid, A. E. V. ZEALLEY (*Rhodesia* Munitions and Resources Com. Rpt. 1918, pp. 41-43).—This is a brief note on the occurrence in Rhodesia of triplite, a fluor-phosphate of manganese and iron normally containing 30 to 35 per cent of phosphoric acid. It is said to be easily soluble in hydrochloric acid and readily fusible, and occurs in a deposit mined for the recovery of bismuth ore. Possibilities for the recovery of triplite as a by-product of this process are discussed.

On the manner of occurrence of potassium nitrate in Oregon, T. NATTRESS (Ann. Rpt. Mich. Acad. Sci., 20 (1918), pp. 57, 58).—This is a short note on the potassium nitrate deposits in the Lake Labortan region in Oregon.

Samples taken from the bluff surfaces contained potash, sodium nitrate, and potassium nitrate. Independent sampling done with consideration for the bulk contents of the rock strata showed an average content of from 4 to 6 per cent of potassium nitrate. "Weathering of the native rocks of the greater drainage area must be admitted to be the principal source of the supply and the explanation of the uniformity that prevails in the deposit."

Separation of potash salts, H. P. BASSETT (*Chem. and Mettall. Engin.*, 20 (1919), No. 2, pp. 76, 77).—The author discusses methods of separation of potash salts from lake brines, containing roughly equal amounts of potassium sulphate, sodium sulphate, and sodium carbonate, with a view to obtaining marketable products from the remaining salts. This is considered entirely feasible.

Potash production in Bussia (New York: Cent. War Indust. Com. Russia: Amer. Delegation [1918], pp. 6).—This report states that the main sources of Russian potash are the ashes of stalks of sunflowers. In 1911 the production was 26,465,580 lbs., and it is stated that at present the main regions of production are Northern Caucasia and the Saratov region. The estimated total annual production in Northern Caucasia during 1915 to 1917 was 30,000,000 to 35,000,000 lbs. of potash containing from 88 to 90 per cent of potassium carbonate, while the annual production for the same period in Saratov was from 5,000,000 to 7,000,000 lbs. of potash containing from 78 to 80 per cent of potassium carbonate. It is estimated that 10,000,000 lbs. of Russian potassium carbonate were imported into the United States during 1918.

Limestone action on acid soils, R. STEWART and F. A. WYATT (*Illinois Sta. Bul. 212, abs. (1919), pp. 7*).—This is an abstract of Bulletin 212 of the station (E. S. R., 40, p. 423).

# AGRICULTURAL BOTANY.

**Plant physiology**, R. C. KNIGHT (*Sci. Prog.* [London], 13 (1919), No. 52, pp. 561–566).—This is a review of recently published investigation and opinion bearing upon transpiration and related activities and conditions in plants.

Plant physiology, V. H. BLACKMAN (*Sci. Prog.* [London], 13 (1918), No. 49, pp. 49-53).—This is chiefly a review of the data reported by Coons (E. S. R., 34, p. 647), with interpretative comments.

Plasmolysis of epidermal cells in petals of tulip, A. GUILLIERMOND (Compt. Rend. Soc. Biol. [Paris], 81 (1918), No. 8, pp. 427-431, figs. 12).—Studies previously noted (E. S. R., 39, p. 734) as carried on with Iris germanica have been repeated with Tulipa suaveolens, which is in some respects even more favorable to the demonstration of certain structures and changes. The phenomena as detailed are said to be fairly comparable with those described in the previous account.

The activation of buds in the Compositæ, G. BOHN (*Compt. Rend. Soc. Biol.* [*Paris*], 81 (1918), No. 8, pp. 440-442).—It is claimed that forcing growth of buds by employment of any one or more of different factors (as etherization, etc.) may produce results of the most various kinds in different species. The operation of these factors may be dependent upon the characters of such factors, and independent of the quantity or quality of the nutriment placed at the disposal of the plants.

Bud formation of plant hypocotyls, F. R. CLARK (Ann. Rpt. Mich. Acad. Sci., 20 (1918), p. 146).—Seedlings of various kinds which do not usually produce buds along the internode of the hypocotyl were deprived of their tops just below the cotyledons, leaving only the internode of the hypocotyl above the ground. Practical regeneration of the top occured in Solanum dulcamara. The arrangement of the parts of the new top was similar to that of normal plants grown in the same pots.

Study of the artificial absorption of glucose by the mulberry tree through its aerial parts, C. Acqua (Ann. R. Scuola Sup. Agr. Portici, 2. ser., 14 (1916– 17), pp. 8, pl. 1, figs. 2).—Summarizing results of earlier studies (E. S. R., 36, p. 328) and describing later observations on the absorption of nutriment through aerial portions by the mulberry, the author concludes that in very small plants glucose solution produces distinct acceleration, the development including also morphological variations internally and externally. In somewhat older plants the differences produced are less striking, but are still distinct. In still older plants the differences produced are very slight. These observations are said to agree with those of Molliard (E. S. R., 35, p. 633) regarding the morphogenetic influence of sugar.

Behavior of plants in unventilated chambers, F. C. NEWCOMBE (Ann. Rpt. Mich. Acad. Sci., 20 (1918), pp. 145, 146).—During three years, laboratory tests have been made giving data bearing on the hypothesis that plants thrive best when well ventilated. The results of three series of experiments are given, leading to the conclusion that plants are not materially benefited by ventilation.

[The relations between temperature and the seasonal progress of vegetation], G. RITTER (Bot. Centbl., Beihefte, 35 (1917), 2. Abt., No. 2-3, pp. 568-577, fig. 1).—The author gives data obtained from observations on seasonal behavior of a number of plants in the vicinity of Bremen in regard to such phenomena as the appearance of blooms, leaves, ripe fruits, leaf coloration, and leaf fall. A study of correlations is considered to indicate a close correspondence between these phenomena and those of climate and of weather, more particularly during the earlier part of the growing season.

**Demonstration of methods for the study of stomatal action**, M. PENGELLY (*Ann. Rpt. Mich. Acad. Sci.*, 20 (1918), p. 154).—These methods were related to work employing, respectively, Darwin's porometer, the hygrometric paper tests, and direct examination with the microscope.

Conductivity as a measure of permeability, W. J. V. OSTERHOUT (Jour. Biol. Chem., 36 (1918), No. 3, pp. 485-487).—A study of a green alga (Ulva) and of a marine flowering plant (Zostera), both of which have cellulose walls, by the electrical conductivity method is said to show that this method measures permeability just as other methods do, but that the method herein used is more accurate and more convenient. This makes it possible to determine conductivity at shorter intervals, thereby detecting any rapid changes which may occur and determining the time curve with greater precision than is otherwise possible.

Note on the effect of diffusion upon the conductivity of living tissue, W. J. V. OSTERHOUT (*Jour. Biol. Chem.*, 36 (1918), No. 3, pp. 489, 490).—Having noted exceptions to the rule that electrolytes produce in living tissues either a rise in resistance followed by a fall, or merely a decrease in resistance, the author describes a case in which the effects noted are ascribed to diffusion.

A method of measuring the electrical conductivity of living tissues, W. J. V. OSTERHOUT (*Jour. Biol. Chem.*, 36 (1918), No. 3, pp. 557-568, figs. 8).— The author gives an account of a method employed in studies such as those above noted to determine the electrical conductivity of living tissues of organisms, claiming that under favorable conditions the results do not vary more than 1 per cent from the mean of the measurements.

A comparative study of permeability in plants, W. J. V. OSTERHOUT (*Jour. Gen. Physiol.*,  $1^{\circ}(1919)$ , No. 3, pp. 299–304, figs. 2).—Studies measuring permeability (as in those above noted) which were carried out with a brown alga (Laminaria), a green alga (Ulva), a red alga (Rhodymenia), and a flowering plant (Zostera), are said to have shown essential similarity in respect to the changes in permeability occurring in these plants.

The relation between the structures of some coniferous woods and their penetration by preservatives, P. C. KITCHIN (Ann. Rpt. Mich. Acad. Sci., 20 (1918), pp. 203-221, pls. 2).—This work, suggested by one of the conclusions

reached by Teesdale in work previously noted (E. S. R., 31, p. 743), is said to have shown that *Larix laricina* and *L. occidentalis*, while similar in most characters, are dissimilar in those structures most concerned in the passage of creosote into the wood. The similarity is thought to be due to differences in penetrable bordered pit areas. Additional data bearing upon work of Teesdale are given in the appendix to the main report.

Salt ratios in soil cultures, R. P. HIBBARD (Ann. Rpt. Mich. Acad. Sci., 20 (1918), pp. 147-150).—This is a brief account, with discussion of indications and bearings, regarding the work which has been previously noted (E. S. R., 39, p. 419).

[Mineral nutrient solution for maize], P. Mazé (Ann. Inst. Pasteur, 33 (1919), No. 3, pp. 139-173, figs. 8).—Work previously noted (E. S. R., 33, p. 522; 34, p. 525) has been followed up with studies on the nutritive requirements of maize.

It is claimed that boron, aluminum, fluorin, and iodin are indispensable to the development of maize in the same sense as are nitrogen, phosphorus, potassium, calcium, magnesium, sulphur, iron, chlorin, silicon, magnesium, and zinc, this fact raising the number of known elemental constituents to 18, including the more abundant ones carbon, hydrogen, and oxygen. It is thought that data obtained in this part of the work may give useful suggestions looking to more direct and practical work along these and closely related lines. The influence of organic matter, of aeration, and of the oxidation of iron are also systematically reported.

The utility of sodium in relation to growth is regarded as not yet established. It is thought that the facts here noted, with discussion, indicate the possibility of placing the elements which enter into nutritive solutions in two categories, one containing those elements which condition organization, the other, those which tend to prevent intoxication due to the accumulation of certain compounds formed during the stages of transformation into substances destined to become nutritive.

Plant ecology and its relation to agriculture, W. G. WATERMAN (*Trans. Ill.* Acad. Sci., 10 (1917), pp. 123-129).—This is a brief systematic discussion regarding the nature, content, and scope of general ecology, and of the special ecology of structural groups; also regarding the relation of ecology to agriculture, the nature of contributions to ecology with illustrations, and the proper place of ecology in agricultural study.

Dwarf shore floras, H. W. CLARK (*Trans. Ill. Acad. Sci.*, 10 (1917), pp. 145-159, pls. 4, figs. 2).—A list is given, with notes, of the species making up the dwarf flora as noted in October, 1914, along the shore of the Mississippi River near the Fisheries Biological Station at Fairport, Iowa.

The individual dwarfing of upland plants, although referred to shortness of their growing season as the principal cause, is thought to offer a complex and diversified problem assignable to several other causes, among these inhibition of root development by excess of soil moisture.

Notes of the introduced flora of the Douglas Lake region, H. A. GLEASON (Ann. Rpt. Mich. Acad. Sci., 20 (1918), p. 153).—It is stated that within a few miles of Douglas Lake, Mich., occur more than 100 species of introduced plants, their local distribution showing that they are almost completely dependent upon man for their dispersal and that they are unable to compete with the native plants under natural conditions. The fluctuations in the number of individuals from year to year suggest a close relation to climatic conditions. Areas occupied almost completely by introduced species soon develop into a closed association in which Poa pratensis is the dominant plant.

1919]

Notes on the Michigan flora, O. A. FARWELL (Ann. Rpt. Mich. Acad. Sci., 20 (1918), pp. 161–195).—This paper begins a series intended to give notes and discussion from time to time on rare or interesting Michigan plants. This series is practically a continuation of the contributions to the botany of Michigan begun in the Asa Gray Bulletin, which has been discontinued.

A botanical trip to Mexico, I-II, A. S. HITCHCOCK (Sci. Mo., 8 (1919), Nos. 2, pp. 129–145, figs. 19; 3, pp. 216–238, figs. 21).—Besides notes on topography, climate, rainfall, and temperature, the author gives in the first part of this contribution an account of botanical and agricultural observations in Mexico, including floral regions, range conditions, and forage crops. The second part deals with the common wild grasses of Mexico, more particularly with regard to such topographical features as coastal plains, plateaus, mountains, ponds, and marshes.

Note on inheritance in Phaseolus, W. E. BROTHERTON, JR. (Ann. Rpt. Mich. Acad. Sci., 20 (1918), p. 152).—Hybrids between three bush varieties of P. vulgaris and the scarlet runner, tall variety of P. multiflorus, gave in the  $F_1$  a decrease of 50 per cent in length of hypocotyl as compared with that of the maternal parent and an increase in length of epicotyl of 100 per cent as compared with that of the bush parent, but no change in the height of the hybrid. Long hypocotyl as found in the races of P. vulgaris is incompletely dominant to short hypocotyl as found in P. multiflorus.

It is suggested, therefore, that length of hypocotyl may afford a criterion of the classification of  $F_2$  segregates. It in considered incorrect to speak of hypogeal cotyledons as dominant to epigeal in this connection, since the position of the cotyledons in relation to the surface of the earth may depend largely on other than genetic factors. The essentially genetic factors are those which determine the length of the hypocotyl, rather than the position of the cotyledons in relation to the earth's surface.

A case of Mendelian segregation in Enothera pratincola, F. COBB and H. H. BARTLETT (Ann. Rpt. Mich. Acad. Sci., 20 (1918), p. 151).—The authors give details regarding results obtained from crossings between mutants appearing in the progeny of *E. pratincola* as previously noted (E. S. R., 35, p. 128).

Studies in the classification and nomenclature of the bacteria, VIII-X, R. E. BUCHANAN (Jour. Bact., 3 (1918), Nos. 4, pp. 403-406; 5, pp. 461-474; 6, pp. 541-545).—Three papers have been added following up those previously noted (E. S. R., 40, p. 521), dealing respectively with The Subgroups and Genera of the Actinomycetales, The Subgroups and Genera of the Thiobacteriales, and Subgroups and Genera of the Myxobacteriales and Spirochetales.

Comments on the evolution and classification of bacteria, R. S. BREED, H. J. CONN, and J. C. BAKER (*Jour. Bact.*, 3 (1918), No. 5, pp. 445-459).—This is a critical examination, with references, of the several groups of bacteria as proposed by the committee appointed by the Society of American Bacteriologists and consisting of Winslow et al. (E. S. R., 37, p. 819), and as suggested by other authors named (in connection with their contributions).

Bacteria which survive in fractional sterilization, E. ECKELMANN (*Centbl. Bakt.* [*etc.*], 2. *Abt.*, 48 (1918), No. 5–9, pp. 140–178, pls. 2, figs. 5).—The study here described of bacteria as regards their powers of resistance to sterilizing agents shows that bacteria resistant to such agents are to be found in many different situations, though the reasons for their absence in certain cases have not been determined.

Physiological relations seem to exist between species in widely separated regions. Germinability and resistance of spores were unimpaired in some cases cited, after 13 years of preservation in a dry condition. Difficulty of sterilization appears to be due largely in some cases to lateness or slowness in germination, though occasionally the production of new spores seems to be influential in this respect. The surest means to exterminate bacteria with temperatures not exceeding 100° C. is to subject the medium several times to high temperatures on successive days, with room temperature during the intervals. High degrees of resistance possessed by spores are due predominantly to impermeability of their membranes.

After repeated infection in liquid media (during two to five months) the spores lost the power of resistance due, apparently, to the increase of permeability of their membranes and their resulting too great readiness to germinate. After drying on soil, sand, or kaolin for a few weeks resistance may reappear in such spores. The species studied were aerobic, germinability being rapidly decreased by lowering the oxygen pressure and increased by restoration of the normal oxygen supply.

Studies on the proteolytic enzyms of soil fungi and Actinomycetes, S. A. WAKSMAN (*Jour. Bact.*, 3 (1918), No. 6, pp. 509-530).—Employing in the present investigation methods of isolation and description of soils identical with those used in a former contribution (E. S. R., 36, p. 214), the author has made a study of a number of organisms isolated from different soils, chiefly of *Aspergillus niger*.

It is stated that the proteolytic enzyms contained in the fungi studied appear to differ from known proteolytic enzyms of animal origin inasmuch as they have a greater range of optimum reaction and a lower temperature optimum. They are not precipitated by safranin. The exoenzyms can pass through a Pasteur-Chamberland filter. Their production of proteolytic exoand endoenzymos (as regards *A. niger*) is not affected by the sugar content of the medium. Both exo- and endoenzyms are produced by microorganisms on protein-containing and protein-free media. The age of the culture at which the most active enzyms are obtained depends on the organism itself, its rapidity of growth, and the nature of its waste products. Fibrin and crystalline eggalbumen are decomposed by both the exo- and endoenzyms. The fact that small quantities of ammonia are produced in the decomposition of peptone and case by the proteolytic enzyms of the microorganism suggests the presence of desamidases among the enzyms produced.

## FIELD CROPS.

Crop rotation and soil fertility, R. C. DONEGHUE (North Dakota Sta. Bul. 126 (1918), pp. 197-251, figs. 13).—The first part of this bulletin (pp. 197-216) deals with a study of cropping systems for the Red River Valley of North Dakota made during the 7-year period of 1910-1916, in an effort to determine the income that could be obtained when crops were placed in a rotation where the value of each crop could be fully realized. Various five and six year rotations have been followed, while observations have also been made on plats grown continuously to brome grass for 11 years, to wheat for 34 years, and to alfalfa for 5 years. The effect of manure on the various crops is also noted. The yields and estimated values of the crops are presented in tabular form and the results secured summarized as follows:

The black clay soil of the Red River Valley has deteriorated in fertility and crop producing capacity under a system of continuous cropping with wheat. Such land on the station farm contains approximately one-fourth to one-third less nitrogen and one-fifth less phosphorus than virgin soil of the same type. The yield during the last eight years has been 28 per cent less than during the first eight years of a 24-year period. A total application of 135 tons of manure per acre to brome grass during a period of 11 years produced an increase of 72 per cent in yield of hay, and of 22 per cent of nitrogen and 33 per cent of phosphorus in the surface 7 in. of soil. The increase in yield thus far obtained is estimated to be worth 60 cts, for each ton of manure applied.

Clover has produced a higher yield of hay than timothy, and the yields of succeeding crops of wheat and corn have been higher after clover. As an average of the 3 years, 1914–1916, in which clover and timothy were followed by wheat and corn the clover rotation is estimated to have produced a gross income of \$13.61 per acre more than the timothy rotation. Clover is also said to be a more profitable crop in the rotation than peas. In 1914 clover produced 3.22 tons more hay per acre than peas, and in 1915 wheat following clover yielded 6.9 bu, per acre more than that following peas.

The highest average income, \$29.01, was secured from a six-year rotation consisting of potatoes, wheat, barley, and alfalfa 3 years. Owing to the failure of alfalfa in 1910 and 1911 the average income on the duplicated plat of this rotation was only \$18. In the second ranking rotation, consisting of corn, wheat, barley, clover, and wheat, when two cuttings of clover were obtained the average annual gross income was \$24.49 per acre. On account of the better distribution of labor and the larger acreage of grain the latter rotation is deemed better suited to Red River Valley conditions.

Wheat, barley, timothy, brome grass, and potatoes responded to applications of farm manure, the average value of the increased yield being \$1.16 for each ton of manure during a period of 3 years. Clover, peas, and alfalfa have not responded to applications of manure.

It is estimated that the increase from one ton of rotted manure has been worth \$1.22 as an average of five plats, and the average increase on seven plats from one ton of fresh manure worth \$1.13. Considering the cost of the extra handling of rotted manure, it is regarded as more profitable to haul the manure directly from the barn to the field.

The second part of the bulletin (pp. 216–251) has to do with studies made in connection with a series of experiments previously described (E. S. R., 28, p. 338). These studies were planned in an effort to ascertain the effects of German millet, broom corn millet, corn, potatoes, and bare fallow on wheat grown in rotation with them, and also the influence of these crops upon the soil moisture and available nitrogen supply of succeeding wheat crops. Observations were made during the growing seasons of 1911–1913, inclusive, on the moisture and nitrate content of the soil at different stages in the growth of crops in various places in the rotation, and the data are presened in tabular form. The results secured may be summarized as follows:

German millet and broom corn millet improved the condition of the soil for wheat when the land was comparatively new and free from weeds. Where such a cropping system was followed continuously, however, the yield of wheat was reduced. In these experiments the second and third wheat crops following millet have frequently yielded more than the first crop where this cropping system had been practiced for 8 years or more, this being specially noticeable when the first wheat crop was preceded by a heavy crop of millet.

The growing of corn once in four years resulted in the maintenance of the yield of the first and second wheat crops following the corn, but the yield of the third crop decreased. The beneficial effects of the corn crop extended over a shorter time on old land than on new land, as indicated by the fact that the first wheat crop yielded 5.72 bu. more than the third crop in the last four years of the experiment while the preceding 4-year period it yielded but 1.95 bu. more.

158071°-No. 9-20-3

The effect of potatoes in the rotation was similar to that of corn. Fallowing also produced much the same effect, except that the first wheat crop yielded less and the third one more than when grown in a similar place in the rotation with corn or potatoes. There was a greater growth of straw when wheat was grown on fallow land than occurred on potato land, and more on potato land than on corn land. In specially favorable years more grain was produced with the greater growth of straw, but the results are held to indicate that ordinarily more grain is produced on corn land than on potato or fallow land for the conditions under which this work was carried on.

Soil moisture determinations in 1912 and 1913 showed that German millet and broom corn millet used similar amounts of water from the top 3 ft. of soil. More water was used in producing a bushel of wheat in the crop following millet than was used by the second, and more by the second than by the third crop of wheat following millet. Wheat was produced with less loss of water from the top 3 ft, of soil when it followed corn than when grown after millet. As an average of three crops, a bushel of wheat was produced with 18.4 tons less water than in the German millet rotation and 14.8 tons less than in the broom corn millet rotation. The first wheat crop following corn required less water than the second and the second slightly less than the third. More water was used from the top 3 ft, of soil for the production of a bushel of wheat when potatoes took the place of corn in the rotation, but less than was used in the millet rotations. The first wheat crop following the potatoes was produced with the least water, the amount increasing with each succeeding wheat crop. Wheat grown on fallow required more water for each bushel produced than when grown on corn or potato land, but less than when grown on millet ground if no account was taken of the loss during the year in which it was fallowed. As an average of two years this loss amounted to approximately 6 in. of rainfall.

The growing of millet seemed to favor the accumulation of nitrates more than the growing of wheat, but the heavy demands of the millet crop sometimes reduced the nitrate content of the soil to a low point. Nitrates accumulated more rapidly in corn, potato, and fallow land than where millet was grown. When measured by the amount of nitrogen used by the crop and the amount remaining in the soil in the form of nitrates, there was less available nitrogen produced in the wheat land the first year following millet than there was the second year. The amounts produced the third year following millet were practically the same as for the second season. The available nitrogen produced in soil growing the first crop of wheat after corn or potatoes was greater than when either the second or third crop was grown.

Finally it is concluded that, "for the black clay soil of the Red River Valley, the beneficial effect of corn and potatoes in the rotation is due largely to the greater amount of nitrogen made available during the growing season of succeeding crops and greater economy in the use of plant food and soil moisture. The better soil structure after a cultivated crop has been grown probably favors nitrification and permits a more complete and uniform distribution of the crop roots through the soil mass. The eradication of weeds is an important factor in the improvement of soil structure and the economy of plant food and soil moisture."

[Report of field crops work at the Hettinger, N. Dak. substation, 1913– 1918], -W. R. LANXON, A. J. OGAARD, and U. J. DOWNEY (North Dakota Sta. Bul. 130 (1919), pp. 9–12, 14–20, 21–23, 25–28, 36–49, 50–53, 55, 56).—This comprises a report on variety, rotation, and cultural tests with wheat, oats, barley, potatoes, flax, and corn, and field tests with buckwheat, alfalfa, sweet clover, red clover, brome grass, millet, Sudan grass, field peas, soy beans, chick-peas, kaoliang, emmer, hemp, and Dakota amber sorghum. The results secured with wheat are held to indicate that diversified farming is more profitable than where the farmer depends upon wheat alone. Under a system of mixed farming it is recommended that wheat be grown on disked corn land rather than on fallowed land. Kubanka No. 8 durum and Marquis Fife are regarded as the most dependable sorts for this region. Wheat proved to be more profitable than oats, although the latter is better adapted for growing after small grains in the rotation. Medium early varieties of oats are deemed best. Barley failed to produce as high a money return as either wheat or oats. Varieties of the two-rowed class of barley are regarded as best adapted to this locality. The best average results with flax are thought to be secured on virgin sod breaking, while plantings on brome grass breaking were scarcely profitable. Satisfactory results were secured on disked corn stubble. North Dakota No, 155 flax has given the best results.

Northwestern Dent corn is said to be the best sort for general purposes, while for hogging off Gehu and Dakota White flint were successfully grown. Spring plowing is deemed preferable to fall plowing for corn, while data have been secured which are held to indicate that cultivation to maintain a dust mulch is of less importance than for the removal of weeds.

The Early Ohio potato is regarded as the best general purpose sort, while Irish Cobbler has also given good results.

[Report of field crops work in Montserrat, 1917-1918], F. WATTS (*Imp. Dept. Agr. West Indies, Rpt. Agr. Dept., Montserrat, 1917-18, pp. 3-12, 15, 16, 19-28, 35-37, 38*).—This describes the continuation of work previously noted (E. S. R., 40, p. 228), embracing breeding, spinning, cultural, and fertilizer tests with cotton; variety tests with sugar cane; observations on the utilization of the ajowan plant (*Carum copticum*) and of American horsemint (*Monarda punctata*) as sources of thymol, and of *Datura metel* as a source of scopolamine; notes on peas, beans, peanuts, sweet potatoes, and yams; and information relative to the cotton and sugar industries.

[Report of field crops work at the St. Kitts-Nevis experiment stations, 1916-17 and 1917-18], F. WATTS (Imp. Dept. Agr. West Indies, Rpt. Agr. Dept. St. Kitts-Nevis, 1916-17, pp. 2-11, 13-16, 30-36, 37, 38; 1917-18, pp. 2-14, 16-18, 32-39, 40, 41, figs. 6).—These reports describe the progress of work conducted along the same general lines as previously noted (E. S. R., 38, p. 33), embracing variety and field tests with corn, yams, eddoes, beans, peas, sweet potatoes, peanuts, cassava, and castor bean. and manurial and seed selection tests with cotton. Information relative to the sugar and cotton industries is also included.

[The Woburn field experiments, 1918], J. A. VOELCKER (*Jour. Roy. Agr. Soc. England*, 79 (1918), pp. 263–276).—This describes the continuation of work along the same general lines as previously noted (E. S. R., 40, p. 824). The season of 1917–18 is said to have been rather unfavorable.

The maximum yield in the continuous wheat experiments, 28.3 bu. of grain and 2,447 lbs. of straw per acre, was secured from the plat receiving mineral manures and sulphate of ammonia with one ton of lime applied in 1905. The plat receiving rape dust equivalent to 25 lbs. of ammonia was next with 28.1 bu. of grain and 2,777 lbs. of straw. The average yield for the untreated checks amounted to 14 bu. of grain and 1,405 lbs. of straw. Mineral manures alone produced 14.6 bu. of grain and 1,603 lbs. of straw. Nitrate of soda failed to show any superiority over sulphate of ammonia, while farmyard manure was slightly inferior to rape dust. Phosphates without potash produced 15.5 bu. of grain and 1,418 lbs. of straw, while potash without phosphate produced 12.9 bu. of grain and 1,193 lbs. of straw. The highest yield in the continuous barley experiments was secured from the plat receiving farmyard manure and amounted to 35.1 bu. of grain and 2,238 lbs. of straw, followed by the plat receiving mineral manures and, in alternate years, nitrate of soda with a yield of 27 bu. of grain and 1,555 lbs. of straw. The average yield for the untreated checks was 8.6 bu. of grain and 587 lbs. of straw. Mineral manures alone failed to give any increase in yield although a slight increase was secured on the limed portion of the plat. Sulphate of ammonia alone again gave no weighable return, while the addition of large amounts of lime (4 tons) resulted in an increased yield. Nitrate of soda used alone at the rate of 2 cwt. (224 lbs.) per acre gave satisfactory results. Rape cake proved to be a failure with barley. Phosphate without potash produced 24.3 bu. of grain and 1,365 lbs. of straw and potash without phosphate 25.4 bu, of grain and 1,547 lbs. of straw.

Observations on the comparative effect upon barley yields of the unexhausted residues from so-called cake and corn feeding on the rotation plats showed a yield of 21.8 bu. of grain and 1,431 lbs. of straw for the corn-fed plat and 18.2 bu. of grain and 1,496 lbs. of straw for the cake-fed plat.

Wheat following green crops of tares, rape, and mustard which had been fed off produced at the rate of 12.2, 15.3, and 15.2 bu. of grain per acre, respectively.

In the improvement of old grassland, the best results were again secured from an application of 12 tons of manure per acre made in 1913 with a yield of 3,870 lbs. of hay, as compared with 3,668 lbs. for the untreated check. Various kinds of lime for grassland have been compared, the highest yield, 3,808 lbs. of hay per acre, being secured from Lias lime applied in 2-ton lots in 1910 and again in 1916. The untreated check produced 3,752 lbs. of hay. Comparing different forms of lime for grass, ground chalk gave the highest yield, 3,836 lbs. of hay, and the untreated check 3,360 lbs.

[Report of field crops work in Mysore, 1916–17], L. C. COLEMAN (*Rpt. Agr. Dept. Mysore, 1916–17, pp. 2–6*).—Variety, fertilizer, and cultural experiments with sugar cane are briefly described and field tests with miscellaneous crops noted.

[Report of field crops work in the United Provinces, India, 1918], B. C. BURT (*Rpt. Agr. Expt. Stas. Cent. Circle, United Provs.* [*India*], 1918, pp. 1-25, 32-34, 38, 39, 43-45, 50-59, 65-70, 74, 75).—This describes the continuation of work along the same general lines as previously noted (E. S. R., 40, p. 332).

Grain yields for 1919, E. B. STOOKEY (Washington Sta., West Wash. Sta. Mo. Bul., 7 (1919), No. 7, pp. 105, 106).—The yields of the leading varieties of barley, oats, and wheat grown at Puyallup during 1919 are given, together with their average yields for a period of years.

Barley yielded at the rate of from 23.38 bu. per acre for Beardless to 39.8 bu. for Hannchen for a 3-year period. Gray Winter oats sown in the fall produced 48.17 bu. for a 4-year average as compared with yields of spring varieties ranging from 49.77 bu. for Swedish Select to 60.6 bu. for Minnesota No. 281. The 4-year average yields of spring wheat ranged from 18.21 bu. per acre for Marquis to 22.42 bu. for Mexican Bluestem, and of winter wheat from 33.43 bu. for Little Club to 35.23 bu. for Red Russian. Red Russian seeded at the rate of 1.5, 2, and 2.5 bu. per acre produced at the rate of 31.25, 35.2, and 36.75 bu. per acre, respectively.

Statistical notes on cereals (Internatl. Inst. Agr. [Rome], Bur. Statis., Doc. Leaflets, 3 (1919), No. 6, pp. 88).—Statistical information is presented dealing with the yield, trade, consumption, prices, and rates of ocean freight for wheat, rye, barley, oats, corn, and rice throughout the world for the 1918 crops of the Northern Hemisphere and the 1918–19 crops of the Southern Hemisphere. Information is also given relative to legislative measures adopted in various countries concerning the production, trade, and consumption of cereals.

[Fiber plants of Brazil], M. P. CORRÊA (Fibras Texteis c Cellulose. Rio de Janeiro: Min. Agr., Indus. e Com., 1919, pp. XV+276, pls. 31, figs. 51).—This comprises a detailed account of textile fibers and of paper-making materials found in Brazil.

The agaves, A. BERGER (*Die Agaven. Jena: G. Fischer, 1915, pp. VII*+288, *figs. 81*).—This comprises a monograph on the agaves. Three subgenera, Manfreda, Littæa, and Euagave, are recognized, and 274 species described. A brief note on the cultivation of agaves is included.

Australian saltbush, R. McKEE (U. S. Dept. Agr. Bul. 617 (1919), pp. 12, figs. 4).—This comprises an account of the distribution, climatic and soil requirements, drought resistance, diseases, seeding, harvesting, and utilization of Australian saltbush (*Atriplex semibaccata*), said to have been introduced into the semiarid regions of the United States about 25 years ago.

Plantings failed in practically all cases except along the coast and in the San Joaquin and Imperial Valleys of California, and in the Salt River, Yuma, and Santa Cruz Valleys of Arizona. The plant was found to be tolerant of alkali and quite drought resistant, although not to the same extent as other species of Atriplex and other desert plants. While not so palatable as most forages, the crop is said to be readily eaten by sheep, goats, cattle, and horses when other feeds are scarce, having its greatest value as a succulent feed in late summer. It is also regarded as a suitable soiling crop, but of little value for hay.

The cultivation of barley in Chile, R. OPAZO G. (Cartilla Practica sobre Cultivo de la Cebada en Chile. Santiago de Chile: Serv. Agron. Rejion. i Ensenañza Agr. Ambulante, 1918, pp. 33, figs. 11).—Cultural methods and field practices employed in growing the crop are described.

The barley of Tripoli, E. DE CILLIS (*Agr. Colon.* [*Italy*], *13* (1919), *No. 8*, *pp.* 259-273, *figs. 3*).—Racial and cultural characteristics of Tripolitan barley are described.

**Buckwheat**, C. E. LEIGHTY (U. S. Dept. Agr., Farmers' Bul. 1062 (1919), pp. 24, figs. 6).—This publication comprises a discussion of the soil and climatic adaptations of the crop and the field practices and cultural methods employed in its production. The utilization of buckwheat is also described.

Selection of pseudo-starchy endosperm in maize, D. F. JONES (*Genetics*, 4 (1919), No. 4, pp. 364-393, pls. 8, fig. 1).—The appearance of amylaceous seeds in an extracted recessive progeny from a cross of starchy and sweet varieties of maize is held to indicate that an imperfect segregation or contamination of the two allelomorphs may have occurred, and led to selection experiments at the Connecticut State Experiment Station in an effort to recover both parental types.

Apparently pure sweet and pure starchy strains were obtained after five generations of selection in self-fertilized lines, which remained constant during four or five additional generations of self-fertilization and selection. The sweetand starchy-appearing selections behaved alike when crossed with ordinary starchy maize, segregating into starchy and sweet seeds in the  $F_2$  in the ratio of **3**:1. An examination of the starch grains of the two selections showed them to be quite similar and to lack full development as compared with starchy varieties. In chemical composition the starchy selection was found to be more like other starchy types, particularly in soluble and insoluble carbohydrates. Because of its behavior in inheritance, the nature of its starch grains, and the qualities of the seed, however, this starchy-appearing form of endosperm has been regarded as independent and genetically distinct from true starchiness and has been termed pseudo-starchy.

Crosses of pseudo-starchy and sweet gave indistinctly segregating seed populations in the  $F_2$  which showed little response to selection in the next generation, although in subsequent generations the parental patterns were recovered. The pseudo-starchy type was also recovered from the extracted sweet seeds of a cross of pseudo-starchy and true starchy. In both these crosses segregation became more distinct in later generations after the plants had been inbred. Two forms of segregation were observed, one giving a sharp mono-hybrid ratio of opaque and translucent seeds, and the other giving a less definite splitting in a 1:1 ratio, responding immediately to selection.

In interpreting the results the evidence is deemed sufficient to merit the assumption that endosperm and plant factors work together so that reciprocal crosses have slight immediate effect, and that the appearance of the seed in the  $F_2$  populations is not closely correlated with their genetic composition and hence with their behavior in later generations. Tentative factorial schemes are employed to illustrate ways by which these conditions may be brought about. It is stated that no evidence was found that imperfect segregation or contamination of factors occurred in the separation of the determiners of starchy and sweet endosperms in the original cross, the effects of selection being most logically attributed to the sorting out and rearrangement of hereditary factors.

[Cotton culture in French colonial possessions] (Assoc. Coton. Colon. Bul. 61 (1919), pp. 635-698, fig. 1).—This comprises an account of the industry in French West Africa, New Caledonia, the New Hebrides, Cambodge, Tahiti, and Guadeloupe.

Cawnpore-American cotton: An account of experiments in its improvement by pure line selection and of field trials, 1913–1917, B. C. BURT and N. HAIDER (Agr. Research Inst. Pusa Bul. 88 (1919), pp. 32, pls. 10, fig. 1).—Selection work, tests of new importations, observations on climatic conditions from season to season, and cultural experiments with so-called Cawnpore-American cotton are described. It is stated that the American cotton compares favorably in every respect with "desi" cotton, and that under suitable marketing conditions it is much more profitable.

Report of the Indian Cotton Committee (*Calcutta: Govt., 1919, [vols. 1], pp.* IX+264; [2] *pls.* 7).—This comprises a report of the committee appointed by the Governor General to examine into the agricultural and economic phases of long staple cotton production in India.

The first part of the report deals with the cultural problems and the possibilities of extending long staple cotton production in each Province. The second part includes a discussion of commercial questions and statistics, the establishment of a central cotton trade association in Bombay, and the formation of a central cotton committee to coordinate all work with cotton throughout India. The report is supplemented by two maps of India showing the distribution of the different kinds of cotton by districts and the relative importance of the crop; by irrigation maps of the Punjab, the United Provinces, and of Sind; and by two plans of a model ginning factory.

Inheritance of certain characters in the cowpea (Vigna sinensis), S. C.-HARLAND (*Jour. Genetics, 8 (1919), No. 2, pp. 101–132, fig. 1*).—The author describes observations on the mode of inheritance of factors affecting the flower color, the pattern of the seed coat, and the color of the seed coat pattern of *V. sinensis*, which may be summarized as follows:

The factor producing the type of flower color known as pale (almost white streaked with violet) has been designated L, and is said to exert a visible effect only in types with the Holstein and small eye patterns. It is also thought to be the factor mentioned by Spillman (E. S. R., 30, p. 636) as the one responsible for the production of anthocyanin in the stems and leaves.

The factor D, which exerted a visible effect only in the presence of L, converted the small eye pattern into the Watson pattern and the Holstein into the solid, at the same time changing the flower color to dark (deep reddish violet). Additional factors were recognized as follows:  $H_1$ , a factor which converted the small eye pattern into the Holstein pattern;  $H_2$ , which behaved in a manner similar to  $H_1$ ; B, a factor for black seed coat which also manifested itself in the production of a red tipped pod and a calyx and peduncle having more or less anthocyanin pigmentation; N, a factor for brown or buff color in the seed coat pattern; and M, a factor for dark maroon testa pattern.

In a cross between small eye and solid color the behavior of certain of the  $F_s$  families is held to indicate that both the Holstein factors were involved. The ratio of Holstein to no Holstein in the  $F_2$  was as 4.9:1, as compared with the expected ratio of 15:1. Linkage between the two Holstein factors is believed to account for the  $F_2$  results but not for those of the  $F_3$ . It is stated that no hypothesis can be suggested at the present time which will account for both the  $F_2$  and the  $F_3$ .

The following pairs of factors appeared to be inherited independently of each other: L and D, D and  $H_1$ , D and  $H_2$ ,  $H_1$  and  $H_2$ , and M and N.

Henequen in Yucatan, R. BARBA (El Henequen en Yucatan. Mexico: Sec. Agr. y Fomento, Dir. Agr., 1918, 3. ed., pp. 95+II, pls. 3).—This comprises a rather detailed account of sisal production in Yucatan.

A giant legume as a forage crop for Cuba, M. CALVINO (*Estac. Expt. Agron. Cuba Bol.* 43 (1919), pp. 29, figs. 7).—The production of Meibomia leiocarpa for forage is described.

**Production of late or main-crop** potatoes, W. STUART (U. S. Dept. Agr., Farmers' Bul. 1064 (1919), pp. 39, figs. 21).—Field practices and cultural methods employed in growing the crop are described. It is stated that approximately 85 per cent of the potatoes produced in the United States are grown as a late or main crop.

The industrial and nutritive value of the potato in Ireland, T. JOHNSON and C. BOYLE (*Dept. Agr. and Tech. Instr. Ireland Jour., 18* (1918), No. 4, pp. 443-471, figs. 7).—It is stated that the size of the starch grains varies with the size of the tuber, the largest being found on the outer and the inner side of the vascular ring. Starch content is greatest in the cortex, least in the inner pith. Moisture and total nitrogen increase from cortex to inner pith. Examination of the cut surface of a tuber indicates somewhat roughly, but serviceably, the probable composition. A thick cortical layer corresponds to a high starch content; a thin layer to a large proportion of crude protein. However, the unevenness in the thickness of the layers renders it necessary to use whole tubers (rather than sections) in analysis. Very large tubers are apt to be watery and lacking in starch. Soil and climate vary the composition of the tubers. High rainfall lowers starch content.

**Rice experiments** [in Trinidad], 1915–1918, J. DE VERTEULL and L. A. BRUNTON (*Bul. Dept. Agr. Trinidad and Tobago*, 18 (1919), No. 2, pp. 98–103).— This describes the results of variety, cultural, and seed selection tests with rice.

In the variety experiments, the average yields secured during the 5-year period of 1914–1918, inclusive, ranged from 17.73 barrels (2,127.6 lbs.) of paddy per acre for A. H. C. to 20.39 barrels for Jerrahan. Observations on varieties imported from Ceylon, India, Java, Formosa, British Guiana, and Louisiana are included. Increased yields ranging from 1.91 to 6.77 bags of paddy per acre were obtained from early (February) preparation of the land over late (June) preparation. The best results were secured with a planting distance of about 10 in., with from 2 to 4 plants per hole. A larger average number of tillers per plant and larger yields have been secured by single plant selection.

Cross-pollination of sugar cane, H. B. COWGILL (*Jour. Dept. Agr. and Labor Porto Rico, 3* (1919), No. 1, pp. 1-5).—This paper has already been noted from another source (E. S. R., 40, p. 241).

Varieties of sugar cane in Porto Rico, F. S. EARLE (Jour. Dept. Agr. and Labor Porto Rico, 3 (1919), No. 2, pp. 15-55).—This paper comprises a discussion of the cultural value and characteristics of sugar cane varieties grown in Porto Rico, together with brief botanical descriptions of a number of the varieties supplemented by a key for their identification.

Breeding timothy at Svalöf, H. WITTE (Jour. Heredity, 10 (1919), No. 7, pp. 291-299, figs. 7).—The author presents a brief account of the methods employed in timothy breeding at Svalöf, the numerous forms studied, and the results secured. Characters which have received attention with regard to variation and heredity include the length, thickness, and direction of growth of the stem; the number and length of internodes; the size and color of leaves; the length, thickness, shape, stiffness, and compactness of head; the size and color of glumes, the color of anthers, and the form, color, and size of seed; physiological characters such as hardiness and earliness; the quantity of aftergrowth and stooling ability; and disease and drought resistance. It is said to be practically impossible to secure perfectly constant strains of timothy, and in view of this fact the work of the plant breeder is believed to consist chiefly of the elimination of characters of purely theoretical interest in an effort to obtain the highest posssible uniformity in practical characters.

Characters deemed desirable for a timothy variety which is to be employed in a two-year meadow include tall, not too stout, erect, comparatively stiff stems with short top internodes and relatively long base internodes, vigorous, abundant stooling power, profusion of leaves, perfectly fresh at cutting, rich aftergrowth, hardiness, highest possible resistance to rust, convenient earliness, and good development during the second year. A desirable variety for perennial pasture, on the other hand, is described as one possessing vigorous stooling power, early and abundant aftergrowth after each grazing, hardiness, highest possible resistance to rust, and highly increased longevity. Good seed production is regarded as equally important as a high hay yield, the following characters being deemed essential for this purpose: Tall, stiff, compact, uninterrupted heads; big, plump, well-colored seeds, easily removed from empty glumes and with well-attached floral glumes; and a high degree of self-fertilization.

In trials with selected sorts of timothy made during the period of 1909–1918 two new strains have been developed and distributed, Primus and Gloria, which have produced approximately 12 and 20 per cent more green fodder per hectare, respectively, than ordinary Swedish timothy.

Inheritance of branching habit in tobacco, J. JOHNSON (Genetics, 4 (1919), No. 4, pp. 307-340, figs. 10).—Studies conducted at the Wisconsin Experiment Station are described in which observations were made on the inheritance of the branching or suckering habit of tobacco in a cross between a Cuban type having numerous large suckers and a Little Dutch strain possessing a few small suckers. The conclusions are based largely on counts and weights of suckers of the parental types and of succeeding generations made over a period of years under widely varying environmental conditions, as well as upon data secured when the parents and several succeeding generations of the cross were grown the same year under identical conditions. Data are also presented on correlations between the number of leaves and the number and weight of suckers, and on the inheritance of height of plants, number of nodes and leaves, flowering, and leaf size and shape. The results may be summarized as follows:

The branching or suckering habit of tobacco is a distinct characteristic and behaves as other inheritable characters, although subject to very considerable fluctuating variation, due to environmental conditions and to certain physiological factors. The  $F_1$  generation of the cross mentioned above was intermediate between the two parents for number of suckers, but somewhat above the intermediate condition for weight of suckers, thought to be due to the stimulus of heterozygosis. The reciprocal  $F_1$  generations behaved in an almost identical manner, and the variation was on the whole no more than that of the most variable parent, as shown by the standard deviation.

The  $F_2$  generation possessed a range of variation as great or greater than that of the combined range of the two parents. The standard deviation from the mean as regards the suckering habit was practically twice that of the average of the parents or of the  $F_1$ . The large majority of the  $F_2$  plants appeared to approach more nearly the Cuban type than the Little Dutch type, although the means more nearly resemble the intermediate condition found in the  $F_1$ .

Segregation in regard to the suckering habit was definitely shown in the  $F_3$  and succeeding generations, strains having been isolated which suckered even less profusely than the Little Dutch parent, while others were almost as prolific as the Cuban type, the large majority ranging between the two extremes. The standard deviations indicated that certain of these strains were no more variable than the parents and were probably breeding true for the suckering habit, while other strains carried as far as  $F_6$  have failed to show any signs of the homozygous condition. The production of few and small suckers appeared to be the recessive condition. The inheritance of the suckering habit is regarded as purely quantitative and not separable into satisfactory classes or ratios. The results are held to be comparable with those obtained by East, Hayes, and Emerson for various quantitative characters in tobacco, maize, and other plants, and it is believed the data should be interpreted in a similar way on the multiple factor hypothesis.

It is stated that random observations and systematically recorded data tend to show that no particular correlation exists between number, size, or shape of leaves and the number or size of suckers in the second generation of a cross between a large suckering and a small suckering type. While the production of a nonsuckering type of tobacco combined with the commercial practice of "topping" is regarded as probably impossible for purely physiological reasons, it is believed that by crossing and selection the production of relatively few and small suckerng strains of a certain type of leaf may be obtained. This may be of some commercial importance, although the combination of this character with the proper leaf shape and quality will be extremely difficult to obtain.

The combination and segregation of characters has also been demonstrated in this cross for such characters as height of plant, number of nodes and leaves, size and shape of leaves, and time of flowering. The occurrence of two abnormalities entirely foreign to the parents, one a morphological monstrosity and the other a "physiological weakness," are recorded as illustrating the occurrence of "new" characters in a variety cross under controlled conditions.

Flue-cured tobacco in Canada, D. D. DIGGES and H. A. FREEMAN (Canada Expt. Farms Bul. 38, 2. ser. (1919), pp. 44, figs. 7).—This publication comprises a general discussion of the production, harvesting, curing, and handling of flue-cured tobacco in Ontario by D. D. Digges (pp. 9-30), together with

observations on tobacco soils, rotations, and fertilizers (pp. 31-40) and on cooperative fertilizer tests (pp. 41-44) by H. A. Freeman.

Mechanical analyses are presented of 44 soils and subsoils now producing flue-cured tobacco in Canada, and the conclusion reached that the best soil for this type of tobacco is a loose, porous sand from 6 to 10 in. deep, underlaid by a sand to sandy loam subsoil with good natural drainage. Chemical analyses of a few of these soils are included and indicate a rather low state of fertility. Tests with commercial fertilizers are said to have given good results. The use of a complete fertilizer containing sulphate of potash, acid phosphate, and sulphate of ammonia or dried blood is recommended. The maintenance of fertility and the best conditions for growth are believed to be dependent upon a proper system of crop rotation. Turning under a clover crop just preceding planting to tobacco resulted in an inferior yield of poor quality. Observations on the proportion of stalk to leaf secured in Canada showed an average of 55.2 to 44.8. It is thought that a larger proportion of leaf could be secured, together with an improvement in quality, through earlier and lower topping.

The 1919 yields from ten wheat fields in "Egypt," C. G. HOPKINS ET AL. (*Illinois Sta. Circ. 236 (1919), folio*).—This circular reports the wheat harvest from 10 different experimental fields on which crop rotation systems and fertilizer experiments are being conducted.

[The cultivation of the greater yam (Dioscorea alata)], I. H. BURKILL (*Gardens' Bul. Straits Settlements, 2 (1919), No. 4, pp. 129–135*).—This comprises a progress report on cultural tests with *D. alata* conducted at the Singapore botanic gardens during 1918. See also a previous note (E. S. R., 40, p. 637).

The longevity of Bacillus radicicola on legume seeds, C. R. FELLERS (Soil Sci., 7 (1919), No. 3, pp. 217-232).—Bacteriological and vegetation experiments conducted at the New Jersey Experiment Stations are described in which an effort was made to ascertain the viability of *B. radicicola* on soy bean and alfalfa seed subjected to varying conditions of inoculation and held in storage for different lengths of time.

Evidence is presented to show that such seed inoculated with nodule infusion retained viable nodule-forming organisms on the seed coat for from six to nine months, while plants grown from these seeds possessed nodules on their roots. The soy bean and alfalfa organisms appeared to withstand about the same degree of desiccation. The shortest period of time (five minutes) that the seeds were kept in contact with the inoculant gave nearly as good results as longer periods. The use of gum tragacanth did not aid materially in prolonging the vitality of the bacteria, and the use of this material or similar substances is deemed inadvisable. Infected dry soil dusted upon moist seeds gave better results than sterile dry soil dusted upon moist inoculated seeds. Soil inoculation did not prove to be any more effective than inoculation with nodule infusion or commercial cultures. Commercial cultures gave as good results as nodule infusion.

In general the number of bacteria per seed and the number of nodules per plant were not closely correlated, it being apparent that only a few of the cells present on a seed were capable of nodule production. It is stated that this ratio may be as 1:1,000,000. It is also deemed probable that those organisms which resist desiccation longest possess the greatest infectibility. The greatest destruction of cells occurred within the first few hours after inoculation, after which they perished relatively more slowly and uniformly. The inoculation of soil in pots with a rich nodule infusion increased considerably the number of nodules produced per plant over that produced by inoculated seed alone.

While it is not recommended that inoculated seeds be stored for long periods of time before planting, a delay of several days or a month is believed to do no harm. There appeared to be little difference in the resistance to desiccation whether nodule infusion, commercial cultures, or soil is employed as the infecting agent.

Farm weeds of North Carolina and methods for their control, II, J. L. BUR-GESS and C. H. WALDRON (Bul. N. C. Dept. Agr., 40 (1919), No. 8, pp. 53, figs. 25).—In a further contribution to the subject (E. S. R., 38, p. 141), the authors describe and illustrate 25 important weeds found in the State, together with information relative to their eradication and control.

### HORTICULTURE.

The aerial fertilization of plants with carbon dioxid, M. B. CUMMINGS and C. H. JONES (Vermont Sta. Bul. 211 (1918), pp. 3-56, pls. 4).-A detailed account is given of experiments conducted to determine the general behavior of greenhouse plants aerially supplied with carbon dioxid in excess of that normally contained in the air. The trials were begun in 1909 and continued for seven years. Widely dissimilar types of plants were chosen, beans and peas representing the legumes; radishes and potatoes the root and tuber crops; lettuce, Swiss chard, and endive the foliage plants of the salad class; the strawberry of the fruit crops; and nasturtium and cyclamen of the flowering plants. The work for the earlier years consisted in learning methods of procedure. The data presented are based upon results secured from 1911 on. It was found impossible to supply an excess of carbon dioxid in closed receptacles which did not subject the plants to abnormal conditions of humidity and ventilation. Hence open cases were employed in all of the trials. The carbon dioxid was generated continuously, liberated slowly, and allowed to bathe the plants by dispersion. The results of the several trials are presented in tabular form and discussed. Earlier investigations along similar lines are briefly cited.

The early effect of an extra carbon dioxid dosage on beans was to stimulate the growth of the seedlings, thus producing larger plants. The later effect was to enhance the production of pods and beans and slightly to change the chemical composition of the plant by proportionally increasing the carbohydrate storage. Peas were similarly benefited. Roots responded less favorably than did most of the plants used in these trials. The results, however, were positive in all instances. Weight increments were distributed in roots and stems, but chiefly the former were affected. Treated roots and plants grew faster than the untreated ones, became edible sooner, and exhibited larger carbohydrate and smaller protein contents.

Potatoes, as a rule, grew more leaflets and more, heavier, and better tubers when dosed with carbon dioxid. Tuber formation did not begin earlier, but proceeded faster when once started. In one-fifth of the trials the untreated plants weighed less than did the treated ones. Swiss chard and endive responded to gas treatment by producing larger and heavier foliage and by maturing earlier. The trials with lettuce were less conclusive, but in a majority of instances the treatment seemed beneficial. The foliage of strawberry plants was more abundant and heavier, and the total weight and number of fruits far in excess of the production of untreated plants. Cyclamens either yielded more flowers or showed gains in weight of corms when extra carbon dioxid was furnished. Treated nasturtiums gained consistently when compared with untreated plants. The flowers blossomed earlier, were produced in greater profusion, and the total weight of the plants as well as the number and weight of the leaves were increased.

Summing up the results of the experiments, as a whole, excessive carbon dioxid dosage stimulates plant growth and consequently increases production, both of total crop weight and of food nutrients. Carbon dioxid appears to function much as does a commercial fertilizer and to be, to a greater or less extent, a limiting factor in plant growth. Plants can use advantageously more than normally occurs in the air. The chemical composition of plant life is slightly, though not materially, changed by the stimulation of carbon dioxid. The treated plants almost without exception show higher carbohydrate and lower protein contents than do those grown under normal conditions. The differences seldom exceed two or three per cent and are often less.

The optimum amount of carbon dioxid for use in open boxes where dispersion is continuous appears to be determined in the main by the plant which is under trial. Five tests were made with beans and nine with lettuce, the gaseous dosage varying in amounts from nil to 348 liters. Lettuce seemed to stand and profit by a daily bath in nearly 300 liters of carbon dioxid. The trials with beans were noted and classified, but the results indicate that the optimum is somewhat lower than for lettuce. Continuity of supply seems to be quite as important as its gross amount.

Is cooperative marketing of horticultural products applicable to Illinois conditions? J. W. LLOYD (Illinois Sta. Circ. 238 (1919), pp. 7).—A revision of a paper presented before the Illinois State Horticultural Society on December 19, 1917, in which the author concludes that fruits and vegetables grown in Illinois for distant markets can be successfully marketed through cooperative organizations of the growers.

Some economic aspects of fruit and vegetable storage, J. W. LLOYD (*Illinois Sta. Circ.* 237 (1919), pp. 8).—A revision of an address delivered before the Illinois State Horticultural Society on November 21, 1918, in which the author discusses the importance of storage, location of storage houses, size of towns that should store apples, storage for local consumption in producing regions, types of storage structures for apples, construction of an outdoor cellar, and storage of potatoes and root crops.

**Olneya** beans, O. F. Cook (*Jour. Heredity*, 10 (1919), No. 7, pp. 321-331, figs. 5).—The author gives an account of *Olneya tesota*, a leguminous tree of the southwestern desert region, and calls special attention to the possibilities of making practical food use of the natural supply of beans produced by these trees.

Studies on the biology and culture of superior mushrooms, G. BOYER (Mém. Soc. Sci. Phys. et Nat. Bordeaux, 7. ser., 2 (1918), pp. 233-344, pls. 4, figs. 20).—Part 1 of this work comprises a general exposition of germination and cultural experiments with various species of superior mushrooms. Part 2 contains an account of the author's work with morels, notably Morchella esculenta, and investigations on the genus Psalliota. The results of cultural experiments with various studied are also given. The more important mushrooms are considered, with reference to germination of the spores and early development of the mycelium, mycelium in its relation with its active or inert substrata, relation of the sporiferous apparatus with its mycelium and reciprocally, the development and method of growth of the mushrooms, methods of culture, fertilizing and manuring, decay and disappearance of mushrooms, and analytic composition. An extensive bibliography on mushrooms is appended.

**R**eport of plant industry, P. A. GLENN (Ann. Rpt. Dept. Agr. Ill., 1 (1918), pp. 15-22).—A report of nursery inspection work within the State for the year ended June 30, 1918.

Some important problems in pomology and their significance, H. P. GOULD (Ohio State Hort. Soc. Ann. Rpt., 52 (1919), pp. 20-28).—Among the problems discussed by the author are the maintenance of soil fertility, the selection of a management system adapted to the individual orchard, pruning, the improvement of fruits through bud selection, and the development of American-grown fruit stocks.

Fruit blossoming records, H. B. TERRY (So. African Fruit Grower and Smallhold., 6 (1919), No. 9, pp. 243, 245, 247).—A contribution from the Potchefstroom Agricultural Experiment Station, comprising a variety list of orchard fruits with dates of first and full bloom.

Fruit and fruit products of South Africa, R. A. DAVIS (So. African Jour. Indus., 2 (1919), No. 8, pp. 774-783).—This paper deals with the present status of the deciduous fruit industry in South Africa.

[Lists of fruits and ornamentals recommended for planting in Wisconsin] (Ann. Rpt. Wis. State Hort. Soc., 49 (1919), pp. 7-17).—Lists are given of orchard and small fruits, ornamental trees, shrubs, and perennial plants recommended for planting in Wisconsin, including also a list of shrubs all of which have been tested and found not sufficiently hardy for general planting.

The cost of building an orchard, V. H. DAVIS (*Ohio State Hort. Soc. Ann. Rpt.*, 50 (1917), *pp. 108–114*, *fig. 1*).—The author purchased a 145-acre farm and commenced to convert it into an orchard property in 1906. Annual cost data are given for all operations the first ten years, during which time 95 acres were planted to orchard and 25 acres were ready to be planted.

At the end of the 10-year period, the total expenditures were \$43,705.99, and the total sales \$9,592.29. An invoice was made at the end of this period, in which the total investment was figured at \$39.800, which after adding the total expense leaves a balance of \$5,686.30, the balance being dependent upon the value given the trees.

The outgo and income of a 10-acre apple orchard, U. P. HEDRICK (*Ohio State Hort. Soc. Ann. Rpt., 51 (1918), pp. 23-28).*—A summarized statement of data presented in New York State Station Bulletin 376 (E. S. R., 31, p. 46).

Some notes on the distance between trees in planting at the experiment station orchard, W. J. GREEN (Ohio State Hort. Soc. Ann. Rpt., 51 (1918), pp. 20-23).—In the spring of 1893 the variety apple orchard at the Ohio Experiment Station was planted, the trees being set 35 ft. apart each way. The author presents measurements taken January 15, 1918, showing the spread of branches for 31 varieties, and calls attention to the evils of overcrowding trees in an apple orchard.

Of the varieties listed, all but two had a spread of over 30 ft. in diameter, and 16 had a spread ranging from 35 to 40 ft.

Apple bud selection: Apple seedlings from selected trees, C. S. CRANDALL (*Illinois Sta. Bul. 211, abs. (1918), pp. 4*).—An abstract of Bulletin 211 of the station (E. S. R., 39, p. 844).

Apple grading laws.—Their value and requirements, H. C. HETZEL (Ohio State Hort. Soc. Ann. Rpt., 51 (1918), pp. 66–70, fig. 1).—A report on investigations conducted by the Bureau of Markets, U. S. Department of Agriculture, relative to the present status of apple-grading laws and practices in different States, with conclusions as to the value and requirements of apple-grading laws.

#### 1919]

The author concluded that properly enforced State laws were of much importance to the apple industry, and that a National law establishing one standard for all sections seemed highly desirable and practicable.

Controlling important fungus and insect enemies of the pear in the humid sections of the Pacific Northwest, D. F. FISHER and E. J. NEWCOMER (U. S. Dept. Agr., Farmers' Bul. 1056 (1919), pp. 34, figs. 18).—This describes the more important fungus and insect enemies of the pear in the region mentioned, and gives directions for combating them. It also tells how to prepare the spray materials needed and how to apply them. A spraying schedule, showing concisely when and with what to spray, is included.

**Pruning experiments**, F. S. CHAMBERS (*Proc. Amer. Cranberry Growers'* Assoc., 48 (1918), pp. 3-7, fig. 1).—An account is given of pruning experiments conducted with the Early Black cranberry at Whitesbog, N. J.

In December, 1915, six plats were pruned in different ways and six left as check plats. Heavy pruning produced a shorter and more satisfactory vine growth, slightly reduced the crop in 1916, but greatly increased it the following season. The greatest improvement in both vines and crop was produced by removing nearly all of the runners and leaving a good stand of uprights. The excessive pruning of vines resulted in only slight improvement. Pruning also apparently reduced the percentage of injury by frost and by fungus diseases.

Spoilage of cranberries after picking, C. L. SHEAR (*Wis. State Cranberry Growers' Assoc.* [*Proc.*], *31 (1918)*, *pp. 27–30*).—In this paper the author briefly calls attention to the results of studies conducted by the U. S. Department of Agriculture in cooperation with the Massachusetts Experiment Station, dealing particularly with the spoilage of cranberries by fungus rots or premature death of the fruit caused by rapid ripening or suffocation. It is pointed out that in order to lessen the amount of spoilage from these causes the cranberries should be cooled as quickly as possible after picking, stored in a cool, well-ventilated place, and handled carefully to avoid bruising. Ventilated packages should be used, especially for early shipments.

The reduction of cranberry losses between field and consumer, C. L. SHEAR, N. E. STEVENS, and R. B. WILCOX (*Proc. Amer. Cranberry Growers' Assoc.*, 48 (1918), pp. 7-10).—A contribution from the Bureau of Plant Industry, U. S. Department of Agriculture, in which the authors briefly consider the various operations to which cranberries are subjected in marketing them and the evidences of injury from bruising as shown by the keeping quality of the fruit.

"Reversion" and resistance to "big bud" in black currants, A. H. LEES (Univ. Bristol, Ann. Rpt. Agr. and Hort. Research Sta., 1918, pp. 25–28).—A summary of a study noted from another source (E. S. R., 41, p. 241).

**Baspberry** growing on small holdings, J. M. HODGE (*Jour. Bd. Agr.* [*London*], 26 (1919), No. 4, pp. 396-410, pls. 2).—An account of two colonies of raspberry growers established in Scotland several years ago, with special reference to the financial results attained by the average small holder in the colonies.

Report on the activity of the viticulture station at Auvernier for the year 1917-18, C. GODET (Ann. Agr. Suisse, 20 (1919), No. 23, pp. 1-55, figs. 6).—In addition to a report on routine operations, data are given on pruning, training, and intercropping experiments, as well as experiments in the control of mildew and Cochylis. Must analyses made at the station, together with analyses of the station wines, are also included.

Native fruits of North Dakota, L. R. WALDRON (*Minn. Hort.*, 47 (1919), No. 11, pp. 426-435, figs. 3).—The author calls attention to the practical importance for North Dakota of such fruits as the buffalo-berry, sand cherry, Missouri currant, and other wild fruits.

Applying the furrow manure in citrus groves, A. D. SHAMEL (*Cal. Citrogr.*, 5 (1919), No. 1, p. 4, figs. 4).—Some additional notes on methods of applying manures in furrows (E. S. R., 38, p. 845).

Report on the yield of coffee trees in the Surinam cultural garden during the year 1918, with comparative data for previous years, E. VAN DRENT (*Dept. Landb. Suriname Verslag. 1918, pp. 51-86*).—Yield data are given for several lots of trees of different varieties of coffee that were grown from selected trees. In many cases records are given for the four years, 1915–18.

Olive growing and oil pressing, A. OPAZO G. (Cartilla Práctica sobre el Cultivo del Olivo i Elaboracion del Accite. Santiago de Chile: Serv. Agron. Rejion. i Enseñanza Agr. Ambulante, 1918, pp. 63, figs. 28).—Practical instructions on olive culture and the manufacture of olive oil, with special reference to conditions in Chile.

Manual of practical olive culture, G. VITETTA (Manuale di Olivicoltura Practica. Casale Monferrato, Italy: Marescalchi Bros., [1914], pp. XVI+260, figs. 14).—The introductory part of this manual deals with the history and importance of olive culture, climatic and soil requirements, varieties, and the selection of varieties for starting new groves. The succeeding parts deal with the propagation of olives, planting, cultural details, insect pests, and diseases and their control.

The palms of the Philippine Islands, O. BECCARI (*Philippine Jour. Sci., 14* (1919), No. 3, pp. 295-362, pls. 3).—A descriptive account of the Philippine species of palms, including a conspectus of species of each genera.

A pineapple fertilizer experiment, P. GONZÁLES (Jour. Dept. Agr. and Labor Porto Rico, 3 (1919), No. 1, pp. 6-13, pls. 2).—A preliminary report on an experiment started by H. B. Cowgill at the Porto Rico Insular Experiment Station.

The experiment as here outlined consists of a trial of complete fertilizers of different compositions. The yield records for the first season are presented, and the results thus far secured indicate that nitrogen exerts the greatest influence on production, followed by potash. Heavy applications of acid phosphate appear to be injurious. Generally speaking, fertilizers have increased the yield as compared with no fertilizers, and there is some evidence in favor of organic as compared with inorganic fertilizers.

First report on fruit culture as practiced round about Tharushah (Sind) in Nawabshah District, M. U. F. BARAKZAI (Dept. Agr. Bombay Bul. 88 (1918), pp. 18).—This comprises notes on native methods of propagating and growing the mango, orange, and ber or jujube (Ziziphus jujuba), including suggestions for improvement in cultural methods.

A variety nut orchard (*Missouri Bot. Gard. Bul.*, 7 (1919), No. 8, pp. 129– 132).—A descriptive list is given of varieties of pecans, black walnuts, Persian walnuts, and hickory nuts included in the nut orchard at the Missouri Botanical Garden, St. Louis.

[Note on the condition of trees at the Hettinger substation, 1918], U. J. DOWNEY (North Dakota Sta. Bul. 130 (1919), p. 56).—Brief notes on the condition of shelter belts and ornamental and fruit trees growing at the substation in 1918 are given.

Commercial drug growing in the United States in 1918, W. W. STOCKBERGER (Jour. Amer. Pharm. Assoc., 8 (1919), No. 10, pp. 807–811).—A paper on this subject read before the scientific section of the American Pharmaceutical Association in November, 1919, in which the present cultural status in the United States of some of the more important drug plants is considered. Report of the director of forestry for the year 1918, R. H. CAMPBELL ET AL. (Dept. Int. Canada, Rpt. Dir. Forestry, 1918, pp. 70, figs. 13).—A report on the activities of the forestry branch of the Canadian Department of the Interior for the year 1917–18, with reference to forest protection, tree planting, operations of the forest reserves, forest surveys, and investigational work. Appended to this report are reports of the chief of the tree planting division, the superintendent of the forest products laboratories of Canada, and inspectors of the forest reserves for Manitoba, Saskatchewan, Alberta, and British Columbia.

The forests of British Columbia, H. N. WHITFORD and R. D. CRAIG (Ottawa: Comm. Conserv. Canada, 1918, pp. VIII+409, pls. 49).—A report on a survey of the forest resources of British Columbia, conducted under the direction of the Commission of Conservation of Canada. Part 1 discusses geographical relations, physiographic relations, climatic and soil relations, land tenure in British Columbia, forest administration on provincial lands, forest administration on Dominion lands, forest policy, forest exploitation, forest trees in British Columbia, and insect injuries to forests in British Columbia. Part 2 contains summarized data on the forest resources of British Columbia as a whole and detailed data on the forest resources of the several interior regions and the coastal belt of the Province. The text is accompanied by numerous illustrations and maps. Appended to the report are the timber-sale contract, volume tables for Douglas fir, cedar, and hemlock, and the British Columbia log scale.

**Reafforestation and the economic development of France**, P. DESCOMBES (*Mém. Soc. Sci. Phys. et Nat. Bordeaux*, 7. ser., 2 (1918), pp. 103-217, pl. 1, figs. 2).—A memoir on previous reafforestation policies in France, with a plea for a much broader development of both national and private reafforestation.

In part 1 the author discusses the denudation and decadence of the mountain regions, the overgrazing of pastures, and the genesis of the laws on the reafforestation of mountains. Part 2 deals with the forests of the plains, the forestry situation at the beginning of the nineteenth century, and the large public reafforestation projects undertaken during the nineteenth century.

Previous to the world war, the author concludes, France did not produce half of the construction wood needed for home consumption. He points out the importance of reafforestation to the economic development of the country, and suggests remedies with the view of stimulating private, as well as national, silviculture.

A forest policy for Australia, C. E. LANE-POOLE (*Sci. and Indus. [Aust.], t* (1919), Nos. 2, pp. 87-93, figs. 6; 3, pp. 152-161, figs. 10).—The author sketches the conditions that have brought about a serious forestry situation in Australia, recommends the adoption of a uniform forest policy for the whole country, and considers the essential features of such a policy.

Effect of changed conditions upon forestry, W. W. ASHE (Jour. Forestry, 17 (1919), No. 6. pp. 657-662).—The author points out that in view of the increase in stumpage value of low-grade timber in the Appalachians clean cutting is no longer necessary to secure an ample margin of profit. Low-grade trees may be reserved for price appreciation, small trees for accretion, and trees of the choicest species for seed trees. The motor truck and the portable band-mill have been used with sufficient success to indicate that, with a good system of roads, cuttings may be made over the same tract at frequent intervals without materially added cost. The conduct of investigations in serial fellings on private lands with auto trucks as motive power is advocated.

The development of a brush-disposal policy for the yellow-pine forests of the Southwest, H. H. CHAPMAN (*Jour. Forestry*, 17 (1919), No. 6, pp. 693– 702).—The author enumerates the factors that should be given consideration in formulating a practical brush-disposal policy, reviews previous brush-disposal practices employed, and presents the standard instructions for brush disposal on the National Forests of New Mexico and Arizona for yellow pine and Douglas fir types, except on Coconino and Tusayan forests. The article also includes Comments on Brush Disposal in the Southwestern District, by G. A. Pearson.

Making best use of idle lands in New York, J. W. STEPHEN (N. Y. State Col. Forestry, Syracuse Univ., Circ. 19 (1919), pp. 53, figs. 18).—This circular contains concise information on the starting and care of woodlands.

What is potential forest land? C. HOAR (*Jour. Forestry*, 17 (1919), No. 6, pp. 650-656).—The author tentatively defines potential forest land as "land suitable for the growth of tree species in stands . . . under natural conditions or such artificial conditions as are economically practicable." The policy pursued in eliminating lands from and adding lands to the National Forests is discussed, and more thorough investigation of various factors influencing land classification is advocated, with the view of securing definite knowledge relative to potential forest land.

The segregation of farm from forest land, P. S. LOVEJOY (Jour. Forestry, 17 (1919), No. 6, pp. 627-646).—The author attributes the failure to secure the development of a rational forest policy for the lands now waste and idle largely to the assumption that there is an inherent conflict between the forest and farm. He discusses the fallibility of this assumption, points out the importance of forestry to farming, critically reviews present methods of land classification, and advocates a comprehensive survey for separating forest from farm land that shall embrace topographic, geologic, geographic, agronomic, forest, and economic work.

New Indian species of forest importance, B. L. GUPTA (Indian Forester, 45 (1919), No. 7, pp. 388-392).—A list is given of 48 new Indian species of forest importance, showing their distribution.

Indian species of Carissa, H. H. HAINES (Indian Forester, 45 (1919), No. 7, pp. 375-388, pls. 4).—Descriptive notes with a key are given of the Indian species of Carissa, which yield Karaunda bark and Karaunda leaves, important sources of tannin.

Cultivation and tapping of Castilla rubber in the Philippines, V. C. ALDABA (*Philippine Agr.*,  $\gamma$  (1919), No. 9-10, pp. 274-307).—A contribution from the Philippine Experiment Station, comprising a study of the Castilla rubber industry in the Philippines, and based both on the author's practical experience and on available literature.

Consideration is given to the history, botany, and geographic distribution of Castilla, methods of culture, factors determining methods of culture, local method of culture, pests and diseases, seed bearing habit, light requirement and growth, variation in yield, improvement by selection, relation of planting distance to yield, tapping operations, and equipment. The text is accompanied by growth and yield data based upon measurements and tapping experiments conducted in local plantations, and the author presents conclusions relative to the best method of growing and tapping Castilla trees.

The distribution of walnut, W. H. LAMB (*Hardwood Rec.*, 47 (1919), No. 2, pp. 21, 22).—The great demand for American black walnut wood created by the war has caused special attention to be focused on this cabinet wood, and has led to many attempts to bring in substitutes which frequently have little merit because character and physical properties are lacking or because the

158071°-No. 9-20-4

available supply is limited. The author presents a complete analyses of species which might be brought in from foreign sources to be sold as, or with, black walnut.

Instructions for the planting and care of conifer trees in cooperative shelter belts (U. S. Dept. Agr., Bur. Plant Indus., 1919, pp. 3).—The instructions herein given are applicable to the semi-arid regions of the West.

Mechanical aids in stem analysis, E. C. PEGG (*Jour. Forestry*, 17 (1919), No. 6, pp. 682-685).—The author presents suggestions for lessening the labor connected with stem analysis, especially office computations. The suggestions are based on experience in cordwood and tie operations in the Ozark region of Southern Missouri.

Mensuration in France, D. BRUCE (Jour. Forestry, 17 (1919), No. 6, pp. 686-690).—Observations on forest mensuration practices in France.

Pathological marking rules for Idaho and Montana, J. R. WEIR and E. E. HUBEET (Jour. Forestry, 17 (1919), No. 6, pp. 666–681).—The paper presents the urgent need of forest sanitation in most of the timber sales conducted in Idaho and Montana, with special reference to the white-pine type of forest. An attempt is made to formulate marking rules which are intended to cover the removal of all infected trees upon the area which, if left, would act as a menace to the remaining or future stands. Special attention is drawn to the removal of infected trees below and above the specified diameter limits. The practical application of such rules to the various forest types of the region is discussed, together with methods and means of enforcing them. A bibliography of literature dealing with forest pathology is appended.

[Fire protection in Maine in 1918] (Dept. State Lands and Forestry [Maine] Bul. 2 (1918), pp. 5-45).—A report for 1918 on forest fires and fire protective measures for the year, both in the Maine forestry district and in other parts of the State not included in this district.

Report of the chief forest fire warden for the year 1918, G. H. WIRT (*Penn. Dept. Forestry Bul. 19* (1918), pp. 74, pls. 7).—A statement of the work of the Bureau of Forest Protection, including data on forest fires in Pennsylvania during 1918 with comparative data for the two previous years.

Forest fires in Canada, 1917 (Dept. Int. Canada, Forestry Branch Bul. 68 (1919), pp. 24, figs. 12).—A statistical report on the extent and causes of forest fires in the various Provinces in Canada in 1917.

Observations on some effects of fires in the chir (Pinus longifolia) forests of the West Almora Division, H. G. CHAMPION (Indian Forester, 45 (1919), No. 7, pp. 353-364, pl. 1).—The author presents observations on the effects of former and recent forest fires on stands of chir trees and other forest vegetation.

Pulp and paper, 1917 (Canada Census Indus., 1917, pt. 4, Sect. 4, pp. 52 + XI).—A statistical report on the pulp and paper industry in Canada for the calendar year 1917.

# DISEASES OF PLANTS.

The mode of dissemination of fungus and bacterial diseases of plants, M. W. GARDNER (Ann. Rpt. Mich. Acad. Sci., 20 (1918), pp. 359-423).—The bibliography appended to this discussion contains 220 titles.

[The unreliability of certain appearances in diagnosis of plant diseases], F. W. NEGER (*Centbl. Bakt.* [etc.], 2. Abt., 48 (1918), No. 5-9, pp. 178-181).— Examination of cases cited leads to the conclusion that in some plant diseases, abnormal phenomena, though they may be prominent, are in many cases unreliable as diagnostic features. They may not be directly related to the cause of the trouble, and in some cases are no more than post mortem phenomena, in the production of which such agencies as light may have been the main factors.

Michigan plant disease survey for 1917, G. H. COONS (Ann. Rpt. Mich. Acad. Sci., 20 (1918), pp. 425-450, pls. 10).—An account of Michigan plant diseases in their relations during 1917 is prefaced by the statement that the data are not yet at hand for the consideration of the fungi in the State in any manner comparable to what can be done in regard to the distribution of the higher forms. Only gross similarities can be pointed out.

It would seem that in large part the climate determines the fungus flora. Of the two factors, temperature and rainfall, the former seems to be operative in a broad way and the latter in a local way, influencing the annual prevalence. The plant diseases of Michigan are practically those of the other States of the same latitude.

Plant diseases [British Guiana], C. K. BANCROFT (*Rpt. Dept. Sci. and Agr. Brit. Guiana, 1917, pp. 50, 51*).—Leaf disease of Para rubber (*Melanopsammopsis ulei*) was not so prevalent as during the previous year. Where the winter condition of the trees occurs generally over the whole of the plantation at the same time, few of the trees showed the disease, which thus appears unable to endure the period of rest, requiring for survival a continuous supply of green trees. Indigenous rubber trees (*Hevea confusa*) in some parts furnish a basis for continual infection.

Bud rot of coconut still prevails in certain districts. Both mango and breadfruit are subject to ripe rot, which may be avoided by spraying with Bordeaux mixture just after the fruit sets and then again three or four weeks later. Witches' broom of cacao has declined during the past two years, yielding readily to Bordeaux mixture if the brooms are also removed. The rice plant so far appears resistant to disease. With the exception of smut (*Tilletia horrida*), the other known diseases of rice in the colony are blast (*Piricularia oryzw*) and stem rot (*Sclerotium oryzw*), which are present in negligible quantity. The most prevalent and only important disease of sugar cane is that due to *Marasmius sacchari*, which affects the roots. The only two citrus diseases of consequence are collar rot and citrus knot.

Investigations on diseases of plants and their treatment, O. GROVE (Jour. Bath and West and South. Counties Soc., 5. ser., 12 (1917–18), pp. 124–142, fig. 1).—A fruit blossom bacillus, affecting particularly blossoms and fruit spurs of pear trees, has been shown to be carried by insects. The organism has also been shown to be fairly common in the soil not earlier than April. It was found and studied in connection with roots of cabbage and other plants.

Damping-off and collar rot of tomatoes differ only in the stage at which the attack occurs. The fungus appears to be Phytophthora. The original source of infection is not known, though sterilization of infected soil prevents the disease.

Good results were obtained from the 1917 experiments on control of Rhizoctonia disease of asparagus. In studies of reversion of black currants the primary cause was found to be the interference of mites with normal terminal growth.

The work with Burgundy mixture so treated as to develop copper stearate appears to be the same as that described elsewhere by A. H. Lees (E. S. R., 40, p. 746).

Philippine economic-plant diseases, O. A. REINKING (*Philippine Jour. Sci.*, Sect. A, 13 (1918), Nos. 4, pp. 165-216, figs. 20; 5, pp. 217-274, pls. 22, figs. 23).— This compact account of Philippine plant diseases of economic importance takes up the hosts alphabetically, discussing the diseases and naming causal organisms where known. Fungus diseases are said to be found on practically all cultivated and wild plants in the Laguna Provinces, and they are thought to be numerous in other agricultural regions in the Islands. The great factors in the spread and destructiveness of fungi are lack of proper culture, of sanitation, of pruning, and of spraying, of which none is practically carried on in the Islands. While the list of diseases is by no means complete, many are due to fungus species supposedly new to science.

Notes are given on means and measures recommended for control of certain diseases.

Porto Rican fungi, old and new, F. L. STEVENS (*Trans. Ill. Acad. Sci., 10* (1917), pp. 162-218, figs. 13).—This is a detailed and somewhat systematic account of numerous fungi in Porto Rico, some of the species being regarded as new and some being apparently of economic interest.

Some new Porto Rican fungi, L. E. MILES (*Trans. Ill. Acad. Sci., 10 (1917), pp. 249–255, figs. 3*).—The species herein noted as collected in 1912–13, and since that time determined by persons named, are listed in connection with the hosts in relation with which they live as saprophytes or parasites, some of the fungi being possibly of economic importance.

The rusts of the Douglas Lake region, L. BONAR (Ann. Rpt. Mich. Acad. Sci., 20 (1918), pp. 277, 278).—A list of 40 rusts with their hosts is given as collected in the summer of 1917 within 4 or 5 miles of the University of Michigan Biological Station.

Notes on Cephaleuros virescens, R. HIGLEY (*Trans. Ill. Acad. Sci.*, 10 (1917), pp. 256–258).—This paper deals with gross details of *C. virescens*, which appears on 10 different hosts. Superficial characters make it possible, it is said, to divide the species into four distinct groups. The differences observed are supposed to be due to the resisting power of the several hosts.

Physiological characters as a means of distinguishing between the species of Penicillium, W. WÖLTJE (*Centbl. Bakt.* [etc.], 2. Abt., 48 (1918), No. 5-9, pp. 97-130, figs. 5).—This is a detailed account of study, with tabulation, of several species of Penicillium as regards physiological reaction to media of different characters, both physical and chemical.

Lime-sulphur sprays, V. VERMOREL and E. DANTONY (*Prog. Agr. et Vitic.* (*Ed. VEst-Centre*), 40 (1919), No. 7, pp. 152–154).—In view of the multiplicity of formulas for preparing lime-sulphur and the inconstancy and inconsistency of their effects, and in particular of the injury sometimes resulting from their use, experimentation has recently been carried out by the authors. The results are briefly detailed as regards substances found to exist in the solution or in the sediments in relation to temperature, time, proportion, dilution, surface exposure, and impurities.

Stem rust of grains and the barberry in Wisconsin, A. G. JOHNSON and J. G. DICKSON (*Wisconsin Sta. Bul. 304 (1919)*, pp. 16, figs. 15).—A popular description is given of the various rusts which occur on cereals, special attention being given to the black stem rust of wheat and the relation of the common barberry to its spread.

Take-all, the wheat growers' worst enemy, J. T. PRIDHAM (Agr. Gaz. N. S. Wales, 30 (1919), No. 2, pp. 77-79).—Observations during some years, and systematic counts made recently of wheat plants affected in each of several varieties named, show a serious degree of infection of wheat at the Cowra and other farms conducted by the Government. The results are serious in the aggregate, whether the disease be due to Ophiobolus herpotrichus, Cladosporium herbarum, Fusarium rubiginosum, or Mucor racemosus, or to a combination of these. Tabulated figures for a considerable number of wheat varieties show in each case the number of days required for the wheat to mature and the per-

centage of plants affected with take-all; also of those showing the presence of bunt, loose smut, and flag smut.

Phyllachora as the cause of a disease of corn, and a general consideration of the genus Phyllachora, N. E. DALBEY (*Trans. Ill. Acad. Sci., 10 (1917), pp.* 230-248, pl. 1, figs. 5).—An injurious disease of corn, supposedly not recorded previously for Porto Rico (where nearly every field examined showed infected leaves) is described as studied in connection with herbarium material collected in 1915 by Stevens.

A fungus, apparently *Scolecotrichum graminis*, was commonly present in discolorations somewhat similar to those which are associated with the disease in question. This fungus has been identified by the author as *P. graminis*.

Studies on tracheomycoses: Verticilliose of cucumber, H. A. A. VAN DER LEK (Meded. Landbouwhoogsch. [Wageningen], 15 (1918), No. 1, pp. 1-58, pls. 6).— This is a detailed account of the wilting disease of cucumber claimed to be due to Verticillium alboatrum.

Frost injury of potato tubers, J. E. KOTILA (Ann. Rpt. Mich. Acad. Sci., 20 (1918), pp. 451-460, pls. 2).—Experimentation is described as made for the purpose of determining the conditions for the various spottings and internal discolorations of potato tubers, also for determining the effects of chilling and freezing on germinability. Two methods for chilling and freezing tubers were tested, and are described.

The results as tabulated are considered to show that it is possible to reproduce various types of injury under controlled conditions. The necrosis type of injury developed in tubers chilled from 3 to 4 hours at -13 to  $-17^{\circ}$  C. if the tubers were afterwards kept at room temperature for five days. The darkening type of injury was produced in tubers kept with others for 24 hours at -5 to  $-17^{\circ}$ . Tubers kept for 5 hours or more at -13 to  $-17^{\circ}$  do not show so marked a discoloration as do those kept for 3 to 4 hours at the same temperature. No discoloration occurs in case of severe chilling or freezing. This fact is attributed to the more complete killing of the cells and to the bacterial activity. Chilling accelerates the action of tyrosinase, and also retards germination of tubers, sprouts being killed after exposure to -13 to  $-17^{\circ}$  for 4 hours.

Unknown corpuscles in diseased spinach roots, T. A. C. SCHOEVERS (*Meded.* Landbouwhoogsch. [Wageningen], 15 (1918), No. 2, pp. 75-84, pl. 1).—A disease on spinach roots is noted as invariably associated with the presence of intracellular bodies containing fat globules. These bodies, which appear at least in some cases to be motile, are thought to belong to the protozoa, and have been called, provisionally, X-organisms.

Sugar-cane varieties and froghopper blight in Trinidad, C. B. WILLIAMS (*Bul. Dept. Agr. Trinidad and Tobago, 18 (1919), No. 2, pp. 70–83*).—Based on field observations, published records, and replies to circulars sent to planters in 1912 and again in 1918, the susceptibility of a number of varieties of sugar cane to so-called froghopper blight is briefly indicated. It is stated that no variety of cane at present grown in Trinidad is immune to the disease, but that Uba and Badilla are the most resistant sorts, while a few recent introductions are deemed worthy of more extended trial.

The leaf mold of tomatoes caused by Cladosporium fulvum, W. K. MAKEM-SON (Ann. Rpt. Mich. Acad. Sci., 20 (1918), pp. 309-350, pls. 13, figs. 2).—The causation of the tomato leaf mold by C. fulvum has been shown by isolation, pure culture inoculation, and reisolation. Infection occurs by way of the stomata. Blooms are especially susceptible. The mycelium is found both within and between the cells. Conidia arise from a stroma-like formation extending through the stoma. Moisture favors growth. The approximate temperature conditions for growth are found to be, minimum 9°, optimum 20 to 25°, and maximum below 34° C. (93.2° F.) Strong, diffuse light is detrimental to spore and color formation. The organism withstands a considerable range of reaction. Translocation of starch is hindered in the infected leaves. The organism may be disseminated by air currents. While field inoculations succeed under normal conditions in the North, these do not appear to favor greatly the spread of the disease. The inoculation period requires usually 6 to 10 days, or longer under conditions of low humidity or temperature. The overwintering of the fungus is probably due to the longevity of the conidia, although growth as a saprophyte may also be a factor.

Bordeaux mixture is inefficient for control of leaf mold, as are also ammoniacal copper carbonate, potassium sulphid and sulphur dust. Commercial lime sulphur appears to be more effective as regards prevention of plant infection than self-boiled lime sulphur, but less effective in moist chamber experiments. Formaldehyde gas, while apparently effective in preventing spore germination, is expensive, owing to the quantity required. Fumigation with sulphur, as tested experimentally, appears to be an adequate means of killing spores of *C. fulvum* on trash and leaves.

The occurrence of Alternaria in a characteristic apple spot, and an apple rot caused by Gliocladium viride, F. J. MACINNES (*Trans. 111. Acad. Sci., 10* (1917), pp. 218-223).—The progress of a disease attacking immature apples sent from Harristown, Ill., for study is here noted and described, with an account of the fungi found in this connection. One of these shows no marked disagreement morphologically with A. tenuis. Two other species of Alternaria were found, one causing a core rot and one growing on the surface of the seed, but apparently causing no injury. A. fasciculata, regarded as a variety of A. tenuis, causes a spot not unlike the one affecting the fruit under investigation. It is not certain, however, that the "trouble is due to an Alternaria.

An apple rot caused by Gliocladium viride, F. J. MACINNES (*Trans. Ill.* Acad. Sci., 10 (1917), pp. 223-229, pls. 2, figs. 30).—A fungus found on petri dishes in which cultures had been made while isolating fungi from diseased apples produced, when inoculated on healthy fruit, a dry brown rot. A study was made of the organism, which may prove to belong near or within *G. viride*, though some differences are noted.

The longevity in the soil of the Sclerotinia causing the brown rot of stone fruits, J. B. POLLOCK (Ann. Rpt. Mich. Acad. Sci., 20 (1918), pp. 279, 280).— Facts are cited which are thought to show that Sclerotinia on mummied plums may persist in sclerotial form capable of producing ascocarps for at least 10 years, but that they can not persist indefinitely.

The control of brown rot of plums and plum pocket, E. C. STAKMAN and A. G. TOLAAS (*Minn. Hort.*, 46 (1918), No. 5, pp. 182–186, figs. 4).—Brown rot is said to have been reduced in experiments during recent years at the Minnesota Experiment Station from 35 per cent on unsprayed to 5 per cent on sprayed trees. Plum pocket has been reduced but not completely controlled. For either disease, Bordeaux mixture 3:4:50 or a commercial lime-sulphur 1:40 should be used at least three times (in connection with powdered lead arsenate) every year regardless of the appearance of the disease.

Sap acidity and disease resistance in grape varieties, M. D. ATTI (Ann. R. Scuola Sup. Agr. Portici, 2. ser., 14 (1916–17), pp. 24).—The author concludes his account of a study on grape varieties differing as regards locality of origin with the statement that a close relation may be demonstrated between sap acidity and resistance to disease.
Recent studies on the treatment of grape downy mildew, L. RAVAZ (*Prog.* Agr. et Vitic. [Ed. *VEst-Centre*), 40 (1919), No. 2, pp. 25-32).—Damage due to grape downy mildew during the year is said to have been comparatively slight. An account of the weather is given in this connection.

For a given percentage of copper, Burgundy mixture has the same fungicidal efficacy, whether mildly acid, mildly alkaline, or neutral. The scorching effect on the leaves caused by Burgundy mixture at 1 to 10 per cent, as here tabulated, shows a somewhat uniform increase of injury with strength. The effects due to causticity differ according to state or age of the foliage, earliness of the treatment, and concentration. The preparation, composition, and behavior of several mixtures intended to be fungicidal are described.

**Treatment of downy mildew**, A. MAZOTTA (*Prog. Agr. et Vitic.* (*Ed. VEst-Centre*), 40 (1919), No. 3, pp. 54–56).—In this article, which is said to have been translated from another source, it is stated that good results were obtained in tests with a treatment consisting of a commercial mixture consisting chiefly of sulphur and copper sulphate in different given proportions.

The action of polysulphid on Oïdium, J. CAPUS (*Prog. Agr. et Vitic.* (*Ed. VEst-Centre*), 39 (1918), No. 47, pp. 491, 492).—Employment of alkaline polysulphids at 0.5 per cent strength and an equal proportion of soap, both dissolved in water, gave satisfactory results as regards grape Oïdium. Favorable results from the use of this preparation in comparison with those from an insecticidal preparation are also noted. An account is given of the employment, as far back as 1853, of alkaline polysulphids against grape Oïdium.

Recent views regarding arricciamento (roncet) in grapevines, L. PETRI (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 27 (1918), II, No. 9-10, pp. 271-275, fig. 1).—Previous work (E. S. R., 28, p. 749; 29, p. 349; 31, p. 245) has been followed by this account of later study and observation regarding any causal influence of soil and climate in relation to grape roncet. The facts discussed are considered to show that roncet is probably due to the presence of a living organism.

**Distribution of Fusarium cubense**, the cause of banana wilt, E. W. BRANDES (*Ann. Rpt. Mich. Acad. Sci.*, 20 (1918), pp. 271-275).—The author sketches the history of banana wilt or Panama disease in various banana producing countries of America. It is claimed that this disease is due to *F. cubense*, of which the author has furnished previously an amplified technical description (E. S. R., 38, p. 757).

A study of susceptibility to this disease brings out the fact that in any particular country this disease attacks most severely, and sometimes exclusively, the variety most widely planted. This is said to be true in mixed plantings. Varieties which are not attacked, or which are slightly attacked in a given locality, may in some other locality suffer severely from banana wilt. The facts cited suggest biological specialization on the part of the organism.

The parasite enters the plant from the soil, failure resulting from all attempts by the author to inoculate portions above ground. The disease is also carried in the propagating rhizomes and in the water in the form of spores. Sterilization, though a problem of considerable difficulty, is claimed to be possible.

Banana wilt increases excessively within a month or so after the beginning, and increases to the end of the rainy period after which plants which are slightly attacked may improve and produce fruit.

Notes on the general treatment of fungus diseases, A. C. TUNSTALL (Indian Tea Assoc., Sci. Dept. Quart. Jour., No. 4 (1918), pp. 122-128).—The information and advice contained herein are concerned chiefly with tea culture. The Fusarium wilt of China aster, W. S. BEACH (Ann. Rpt. Mich. Acad. Sci., 20 (1918), pp. 282-308, pls. 4, figs. 13).—This is an account of the early history of the wilt disease of China aster and of studies thereon by the author. The causal organism is claimed to be a new variety of F. conglutinans, and is accordingly named F. conglutinans callistephi.

Growth and production of conida cease at  $14^{\circ}$ C. (57.2°F.). Spores are killed by exposure to 54.3° for about 10 minutes. The fungus is thought to be disseminated in seed or else in soils.

Control measures suggested are largely prophylactic and sanitary, but include also the development of resistant strains.

[Injury to coniferous forest trees near manufacturing plants] in the valley of the Arve, L. MANGIN (*Jour. Agr. Prat., n. ser., 32* (1919), Nos. 6, pp. 109– 111, figs. 3; 7, pp. 127–129, figs. 2).—An account is given of injury, primarily to foliage and affecting particularly conifers, some species severely, in the valley of the Arve following the increase, during the recent war, of activity in the manufacture of certain war materials.

Apparently, injury due to gas emanations from the works was brought about by their being carried after absorption into water droplets in the air during damp weather, and not by absorption of the gases directly. Root injury was noted in connection with *Trametes radiciperda*. Physiological causes of undetermined characters appear to be concerned in case of trees aged 20 to 25 years. Other investigations are considered necessary.

Tests with some chemicals against root nematodes, II, T. A. C. SCHOEVERS (*Meded. Landbouwhoogsch.* [*Wageningen*], 15 (1918), No. 2, pp. 85–88).—The author reports a continuation of studies (E. S. R., 38, p. 555) regarding the control of nematodes by soil treatment.

It is stated that in the pots of soil kept over winter from the previous year's experiment the nematodes had disappeared by spring, supposedly having been killed by the severe cold.

A new supply was obtained and these were employed in tests with 150 tomato plants put into infected soil, each of the 10 lots containing 15 plants and receiving treatment, except one kept as control. The degree of infection (reduced to percentage) ranged from zero for the lime-ammonium sulphate mixture and the formalin treatment up through naphthalin 14, carbolineum 22, quassia 33, sulphuric acid 39, caustic potash 45, benzine 48, and potassium sulphate 51 per cent, the control showing 52 per cent of infection.

#### ECONOMIC ZOOLOGY-ENTOMOLOGY.

The raptorial birds of Iowa, B. H. BAILEY (*Iowa Geol. Survey Bul.* 6 (1918), pp. 238, figs. 93).—This report deals with the birds of prey occurring in Iowa, of which 33 forms are recognized. References to the literature accompany the account of each form.

Notes on North American birds, IX, H. C. OBERHOLSER (Auk, 36 (1919), No. 4, pp. 556-559).

Notes on the races of Quiscalus quiscalus, H. C. OBERHOLSER (Auk, 36 (1919), No. 4, pp. 549-555).

The status of Larus hyperboreus barrovianus, H. C. OBERHOLSER (Proc. Biol. Soc. Wash., 32 (1919), pp. 173-175).

[Contributions on economic insects] (*Ztschr. Angew. Ent.*, 3 (1916), No. 1, pp. 196, pls. 6, figs. 46).—The papers here presented include the following:

The Development of the Sexes of the Honeybee (*Apis mellifica*), by E. Zander (pp. 1–74), which deals with (1) the postembryonal development of the reproductive organs, (2) of the drone, (3) of the queen, by F. Löschel, (4) of the worker, by K. Meier, and (5) with general concluding considerations, including bibliographies of 51, 5, 10, 6, and 35 titles, respectively; The Pine Spinning Sawfly (Luda hypotrophica) in Roggenburg Forest, by Parst (pp. 75-96); Contribution on the Biology and Anatomy of the Pine Spinning Sawfly (L. hypotrophica=Cephaleia abietis), by F. Scheidter (pp. 97-116); A Contribution on the Fly Problem, by A. Hase (pp. 117-123); The Biological Control of the Mulberry or West Indian Peach Scale (Diaspis pentagona), by J. Bolle (pp. 124-126); Fertilizing and Insect Attack, by L. Reh (pp. 127-133); Maybeetle Control in Bienwald (Rhine Province): A Model Example of Technical Insect Control, by K. Escherich (pp. 134-156); The Pteromalid Genus Platyterma of Walker (1834) and a New Species [P. ccksteini] reared by C. Eckstein in Germany from Lophyrus pini, by M. Wolff (pp. 157-171); The Control of Wood-boring Beetles (Anobium) in an Old Carving, by J. Bolle (pp. 172-178); Hulemvia coarctata, by R. Kleine (p. 179); and Notes on the Introduction of Sericulture into Germany Based upon a Personal Knowledge of the Biology of the Silkworm, by O. Maas (pp. 180-194).

Some plagues of our cultivated crops, R. ARANGO (Sec. Agr. Com. y Trab., Comision Sanid. Veg. Cuba, Bul. 2 (1919), pp. 94, pl. 1, figs. 43).—A descriptive account of some of the more important insect pests and diseases of cultivated crops in Cuba, including directions for their control.

Contribution on the Javanese mole crickets, W. ROEFKE (*Trcubia* [Dutch East Indics], 1 (1919), No. 2, pp. 90–97, fig. 1).—The author reports upon investigations of the mole crickets occurring in Java which represent two species, namely, Gryllotalpa hirsuta and G. africana.

[Thysanoptera of Florida], IV-V, J. R. WATSON (Fla. Buggist, 2 (1918), No. 3, pp. 97-102; 2 (1919), No. 4, pp. 116-119; 3 (1919), No. 1, pp. 2-5).—This continuation of the paper previously noted (E. S. R., 40, p. 353) lists additional species, making a total of 59. Six species are described as new and the genus Megalomerothrips is erected. Keys to the genera of Phlœothripidæ and to species of Trichothrips, Haplothrips (Anthrothrips of Uzel), and Frankliniella are included.

Hemiptera collected by the Yale Dominican expedition of 1913, E. H. GIB-SON (Proc. U. S. Natl. Mus., 55 (1919), pp. 275-277).

Notes on Gargaphia tiliæ, the linden lace bug, H. B. WEISS (*Proc. Biol. Soc. Wash.*, 32 (1919), pp. 165-168).—This is a report of observations made during the summers of 1918 and 1919 at Uhlerstown, Pa., where the linden lace bug was fairly abundant on lindens.

Eggs which are inserted in the lower leaf surface in clusters of from 60 or less to 300 hatch in about a week, and the combined nymphal stages require about three weeks, making a month from egg to adult. Adults of the first brood appear during the last of June and first of July, while the adults of the second generation hibernate and appear the following spring. Five nymphal stages are described.

Hyalopeplus smaragdinus n. sp., a new tea capsid in Java, W. ROEPKE (*Treubia* [Dutch East Indies], 1 (1919), No. 2, pp. 73-81, figs. 7).—The species here described was taken from a tea plantation in the vicinity of Soekaboemi, Java. Notes on the life history of the species are included.

The potato leaf hopper and the hopperburn that it causes, E. D. BALL (Wis. Dept. Agr. Bul. 23 (1919), pp. 76–102, figs. 25).—This is a detailed report of an investigation of *Empoasca mali* by the author, a brief preliminary account of which has been noted from another source (E. S. R., 40, p. 353).

The first report of the injury in Wisconsin, where serious loss resulted in 1917, is said to have been received just before the middle of July. Some of the worst fields were alrealy dried up and dead, while others were so severely injured as to have stopped growing. In some places beans adjoining the potato fields had already been damaged. Within a week reports of injury to potatoes by the leaf-hoppers had been received from practically all parts of the State and later from other States, including Montana, North Dakota, South Dakota, Minnesota, Michigan, and New York.

"The first sign of trouble is usually a triangular brown area at the tip of the leaf running back on the midrib. This is quickly followed by a progressive burning of the margin, usually from the tip backwards but occasionally in more or less triangular spots appearing along the margin, each one of these centered in a lateral veinlet. These increase in area and the burnt margin increases in width until nothing but a narrow strip along the midrib remains green, and in serious cases this weakens and dies and the leaf shrivels up."

Proof that the attack of the potato leaf-hopper ( $E.\ mali$ ) is responsible for producing hopperburn condition was obtained through cage experiments. It was found that dahlias are attacked in the same way and with the same effect produced on potatoes, its injury being quite serious in a number of localities. It has been found commonly on water sprouts and rapidly growing tips of box elder trees, and has been known to attack fast-growing shoots of apple stock in the nursery and rapid growing raspberry canes. This type of burning is not produced by any other known leaf-hopper or other insect, and this leaf hopper has not been found seriously injuring any plant in which the burning does not occur.

"To summarize the evidence then, it appears that leaf-hopper outbreaks have been followed in every case by hopperburn epidemics; that these outbreaks have occurred with little reference to temperature or moisture conditions; that the distribution of burning in the field and upon valeties has been entirely with reference to time of planting and the flights of the leaf-hopper, rather than to varieties or characteristic soil or moisture conditions; that no case of this type of burning has appeared in which the evidence of the leafhopper work was not present, and no leaf-hopper attack has been known without subsequent burning; that this insect produced this distinct and different type of injury on other plants; and finally, that in controlled experiments the injury has been reduced or prevented at will."

Studies indicate that most of the variation in susceptibility to attack by different varieties of potatoes was due to difference in the time that these plants developed sufficient foliage to furnish a place for egg deposition for the spring brood of adults. Observations indicate that a single leaf-hopper may seriously injure or even entirely destroy the margin of a leaf during its growing period.

The author has studied the effect of the grape leaf-hopper on grapes and woodbine, the rose leaf-hopper on roses and apple, and *E. unicolor* on apple (which he points out should be known as the apple leaf-hopper), and finds that these produce a similar injury, a characteristic white spotting which appears more markedly on the upper surface of the leaf, although the punctures are made from below. A comparison of box elder leaves attacked by the grape leaf-hopper with those attacked by the potato leaf-hopper affords a striking difference in the effect produced. It is thought possible that the difference in the method of feeding may account for the difference in effect, the grape leaf-hopper and the apple leaf-hopper (*E. unicolor*) puncturing the membranes of the leaf, while the potato leaf-hopper more commonly attacks the veins. The author considers it more probable that the affection is due to "some specific transmitted by the insect." The cage experiments showed that where two or three were present on each leaf it took only a few days to destroy a plant. In considering its biology the author compares that of the potato leaf-hopper with Typhlocyba rosx and E. unicolor.

Its natural enemies include an undetermined dryinid which parasitizes the egg, and a fungus (*Entomophthora spherosperma*) which destroys large numbers. As regards control measures the author recommends the application of blackleaf 40 at the rate of 1 part to 800 parts of water to which 5 parts of soap have been added. Since the nymphs feed entirely on the under surface of the leaves the spray nozzles should be set to direct the stream upward. The applications should be made as soon as the first burning appears on the leaves, that is, late in June or early in July. Arsenicals for the control of the Colorado potato beetle may be added to the mixture, or the whole, omitting the soap, may be added to Bordeaux. Where kerosene emulsion is used it should be as strong as safety to the foliage permits, 7 or 8 per cent of kerosene or 1 part of the stock emulsion in 8 parts of water having been found satisfactory.

An illustration is given of a drag board attachment which bends the plants, thus exposing the under surface of the leaves to the spray. A bibliography of 39 titles is appended.

The potato leaf hopper and its relation to the hopperburn, E. D. BALL (Jour. Econ. Ent., 12 (1919), No. 2, pp. 149-155, pl. 1, fig. 1).—A more detailed account is given in the paper above noted.

Report of a second collection of Nova Scotian eupterygid leaf hoppers, including descriptions of new varieties, W. L. MCATEE (*Canad. Ent.*, 51 (1919), *No. 10, pp. 225, 226*).

A study of the plant lice injuring the foliage and fruit of the apple, R. MATHESON (New York Cornell Sta. Mem. 24 (1919), pp. 683-762, pls. 23, figs. 10).—This is a report of studies at Ithaca, N. Y., of the life history and bionomics of the three species of plant lice that are frequently very injurious to the foliage and fruit of the apple, namely, the apple aphis (Aphis pomi), referred to by the author as the green apple aphis (pp. 686-718); the rosy apple aphis (A. sorbi) (pp. 718-750); and the European grain aphis ([Siphocoryne] Aphis avenæ) referred to as the grain, oat, or apple-bud aphis (A. savenæ) (pp. 750-758).

The apple aphis is the most common and widespread of the three, doing considerable injury every year, not only in bearing orchards but also in young orchards recently set and in nurseries. The greater amount of injury caused by this species is due to its remaining on the apple tree throughout the season, whereas the rosy apple aphis and the European grain aphis migrate in May, June, and early July to other host plants. In recent years the rosy apple aphis has also become very injurious and now does as much if not more damage in bearing orchards than does the apple aphis. The author concludes that all three species, now common on apple in all parts of the United States and Canada, are of European origin, having reached the United States in the first half of the nineteenth century. The failure to distinguish between the three species has led to much confusion in the literature even to the present day and this, as is pointed out by the author, is all the more noticeable since the three species differ so markedly in their life histories and the character of their injury to the foliage.

A somewhat detailed account of *A. pomi* was given in his memoirs by DeGeer who did not confuse it with the other two, but this account appears to have been overlooked until very recent years. The species was first clearly distinguished in this country by Pergande in 1904 (E. S. R., 16, p. 71), and a concise account of its life history was first presented by Smith in 1900 (E. S. R., 12, p. 268) under the name *A. mali.* Important accounts of its biology have been published by Brittain (E. S. R., 35, p. 853) and by Baker and Turner

(E. S. R., 34, p. 754). The food plants recorded by the author are apple, pear, American crab apple, mountain ash, hawthorn, and quince. Some varieties of apples are more susceptible than others, the author having found Twenty Ounce, Maiden Blush, King, Fall Pippin, Greening, and Baldwin to be the most susceptible to injury.

Investigations of the rosy apple aphis based upon rearings at Ithaca, N. Y., during the seasons of 1914, 1915, and 1916 are reported, with references to recent publications on the species by Brittain (E. S. R., 35, p. 853) and Baker and Turner (E. S. R., 36, p. 356). The author supports the view of Sanderson, who in 1901-2 (E. S. R., 14, p. 268; 15, p. 593) identified the American form as *A. sorbi* of Kaltenbach, thus differing with Baker and Turner who consider it to be a distinct form described by Fitch as *A. malifolia*. The fact that this species did not assume the status of an important apple pest in the United States until late in the nineteenth century is shown to be due to the fact that it must have an abundance of its summer host plants, the introduced European narrow-leaved and broad-leaved plantains (*Plantago lanceolato* and *P. major*), near at hand. The first real work on its bionomics was reported by Sanderson in 1901-2. More recent work has been reported by Britton in 1910, Brittain in 1915, and Baker and Turner in 1916.

Rearing experiments and field observations by the author show that P. lanceolata is the preferred summer host plant, and at Ithaca at least it is essential to the continued reproduction of the species during the summer. Breeding experiments on P. major were never successful for more than two or three generations, the line dying out sometimes very quickly, which results agree with those obtained by Baker and Turner, although Ross in 1915 and Brittain report very successful breeding experiments on P. major. The author points out that there is a remarkable parallelism between the spread of P. lanceolata and the spread and increase in destructiveness of A. sorbi.

The author's studies of the European grain aphis relate only to it upon the apple, its primary host. Studies of it on other hosts have been made by a number of writers, including those of Davis (E. S. R., 31, p. 753). At Ithaca only three generations are normally produced on the apple, and the winged migrants have practically all left by early June for summer host plants, which include a large number of grasses and cultivated grains. At Ithaca the fall migrants begin to appear on apple and hawthorn about the last week in September.

Data relating to the reproduction of *A. pomi* and *A. sorbi* are presented in detail in tabular form, and charts are given showing the reproductive capacity of the generations for 13 generations of *A. pomi* and 10 of *A. sorbi*. Illustrations in colors are given of the first instar of the stem mother, of the mature stem mother, the winged viviparous female, mature oviparous female, mature male, spring migrant, returned migrant, and mature oviparous female. The effect of the three species upon the apple tree and its fruit is pointed out.

A bibliography of 54 titles is appended.

Recent studies of the eggs of the three species by Peterson at the New Jersey Stations have been noted (E. S. R., 41, p. 253).

Miscellaneous aphid notes, I, J. J. DAVIS (Canad. Ent., 51 (1919), No. 10, pp. 228-234, figs. 6).—The genus Heteroneura is erected for Aphis setariæ, and two species are described as new, namely, A. cuscutæ and Macrosiphum ribiellum. A. cuscutæ was collected at Kaysville, Utah, on dodder (Cuscuta epithymum) growing on alfalfa.

Fitch's thorn leaf aphis, A. C. BAKER (Proc. Biol. Soc. Wash., 32 (1919), pp. 185, 186).—The author finds that Aphis cratagefolia of Fitch belongs to the

genus Anuraphis. *Aphis brevis* of Sanderson represents the same species and therefore becomes a synonym.

**Trench** fever, R. P. STRONG ET AL. (London: Henry Frowde and Hodder & Stoughton, 1918, pp. VIII+446, pls. 12, figs. 146).—A detailed report of the Commission Medical Research Committee, American Red Cross, of which a preliminary report has been previously noted (E. S. R., 39, p. 658).

Included in this report are the details of two groups of transmission experiments with *Pediculus humanus* (pp. 143–274). The authors' conclusions are that *P. humanus corporis* is capable of transmitting trench fever, not only when it passes directly from an infected man to a new host but also even to a third man, to whom it may be transferred two days later. The relative frequency of positive results in these experiments, which closely simulated natural conditions, indicates that this louse is an important agent in the spread of trench fever in France. It does not appear to transmit the infective quality to its offspring through the egg. "Lice were certainly rendered infective in 9.5 days and probably in 6 to 7 days by feeding them on a trench-fever patient from the latter part of the first to the seventh days of illness, inclusive, and then on a healthy man for about three days... There is evidence that, if the virus undergoes development in the louse, it requires 6 to 10 days to do so; there is a little evidence that suggests the minimum incubation period to be about four days. Lice may remain infected for at least 10 days and possibly 13.

"Lice may transmit trench fever under conditions in which the injection of the saliva appears to be a more prominent feature than the presence of a few minute granules of louse feces in the vicinity of the bitten areas during the feeding process. The incubation period of the disease produced under the conditions cited in [one case] was more protracted than in some of the other transmission experiments; after exposure twice a day for 21 days one man developed the disease in 27 days and the other in 38 days from the time of first being bitten.

"The exact rôle of the mouthparts in transmitting the virus is still undetermined. In four experiments, in which infective louse feces were rubbed into scarifications, the average period of incubation of the disease was 9 days, ranging between 7 and 10 days. From two experiments it would appear that the blood of recovered cases is not infective 100 days after onset of the disease."

Mosquitoes in relation to yellow fever, H. NOGUCHI (Jour. Expt. Med., 30 (1919), No. 4, pp. 401-410).—The experiments here reported show that symptoms and lesions closely resembling those of yellow fever in man can be induced in guinea pigs by the bite of female stegomyias ([Stegomyia] Aedes calopus) that have previously sucked the blood of a yellow fever patient or of an animal experimentally infected with Leptospira icteroides.

"With mosquitoes infected directly from a yellow fever patient the infectivity seems to become manifest after a longer period of incubation than with those infected with the animal blood. In the former, at least 12 days are said to be necessary before they become infectious, and this hypothesis seems to be borne out by the present experiment. On the other hand, the mosquitoes which were engorged with the infected blood of the guinea pig were found to be capable of transmitting the disease within 8 days after the feeding. This discrepancy may be explained by the fact that the number of leptospira existing in experimentally infected guinea pigs is far greater than that in human blood. The frequency with which positive transmission by the stegomyla was obtained in both instances was very small, indeed, in view of the number of mosquitoes employed. . . .

"Whether or not *L. icteroides* can survive and multiply only in the body of *S. calopus* and not in other varieties or genera is yet to be determined.

1919]

852

"Another interesting fact with regard to the extrinsic life of this organism is that it can multiply steadily at a temperature from 18 to 37° C. [64.4 to 98.6 F.] The optimum temperature at which it remains viable for many months is 26°. The climate in most of the tropical countries offers optimum conditions both for *L. icteroides* and for the mosquito, which carries and nourishes it."

Notes on Allograpta fracta (Diptera: Syrphidæ), W. M. DAVIDSON (*Canad. Ent.*, 51 (1919), No. 10, pp. 235-239, fig. 1).—These notes relate to the habits of a predaceous syrphus fly observed in the Imperial Valley in California in the spring and early summer of 1918.

The larvæ were specially beneficial to barley from March 15 to April 30, at which date most of the grain had ripened, and to corn during May and June. In fields in which they were specially abundant 25 per cent of the infested heads had larvæ working on the aphids. Experiments showed that a larva could, during its lifetime, eat all the aphids on from three to four heads of grain of average infestation. In one field of 20 acres, examined on a number of occasions, it appeared that *A. fracta* was responsible for an almost total destruction of barley aphids.

Larvæ of Eupodes volucris, Syrphus americanus, A. obliqua, and Catabomba pyrastri were present in the barley and corn fields, but in much smaller numbers than those of A. fracta.

In the Los Angeles district of southern California, A obliqua is very abundant and A. fracta comparatively scarce, whereas in the Imperial Valley the reverse holds true. In 1918 A. fracta was not reared from any other host than Aphis maidis, except that a single larva was taken attacking A. pseudobrassica.

A contribution to the knowledge of Brazilian Estridæ, A. LUTZ (*Mem. Inst. Oswaldo Cruz, 10 (1918), No. 2, Trans., pp. 118-137).*—A translation of the paper previously noted (E. S. R., 40, p. 458).

The prevention of blow-fly attacks on sheep by spraying, A. H. E. MC-DONALD (*Agr. Gaz. N. S. Wales, 30 (1919), No. 6, pp. 403-405, figs. 3).*—This is a brief statement of tests of dips, consisting of sheep-dip powder, a carbolic liquid dip, and a mixture containing arsenate of soda. While treated sheep were not absolutely protected from attacks by the sprays, the percentage of affected sheep was only 33 per cent against 54 per cent in the untreated group.

Experiments for the control of the grape root-worm, F. Z. HARTZELL (New York State Sta. Bul. 453 (1918), pp. 257-332, pls. 10, figs. 8).—This bulletin gives a brief account of the life history, habits, and economic importance of Fidia viticida (pp. 261-269) followed by a detailed account of control experiments conducted over a period of six seasons, much of which data is presented in tabular form.

The experiments have led the author to recommend two methods of control: (1) The application of molasses 2 gal., arsenate of lead 6 lbs., and water 100 gal., followed in about one week with an application of Bordeaux mixture (8:8:100) and arsenate of lead 6 lbs.; (2) two applications of Bordeaux mixture (8:8:100) and arsenate of lead 6 lbs., at an interval of about 10 days. The first system of treatment is specially recommended when the beetles are present in excessive numbers, while the second is advised for general vine-yard spraying when beetles are not abundant. "The addition of molasses destroys the adhesiveness of the arsenate of lead [E. S. R., 38, p. 858], thus necessitating the precaution of applying the material at a time when the weather conditions indicate that no rain is to be expected for several days. A supplementary treatment should be made in about one week with Bordeaux mixture and poison to protect vines from invading beetles. Two gal.

Two sprayings with Bordeaux mixture and arsenate of lead, thoroughly

applied at the proper time, have given effective control. The effectiveness of the spraying is more pronounced when the treatment is continued over several seasons. Failures to combat the beetle satisfactorily, are largely attributed to delay in making the applications, allowing too long an interval between the first and second applications, and lack of thoroughness due to poor spraying apparatus, dense foliage, or spraying in windy weather.

Investigations relating to this pest by Johnson and Hammar (E. S. R., 24, p. 165) and others have been previously noted.

Life history of the orchid pest (Crioceris subpolita Motsch?), S. LEEFMANS (*Treubia* [*Dutch East Indies*], 1 (1919), No. 2, pp. 82–89, pls. 3, figs. 5).—This paper relates to a species which was received from several localities, Padang (Sumatra), Buitenzorg, and Tjilatjap (Java), and was reared at Padang. Both the beetles and larvæ are destructive to various kinds of orchids by eating the flowers by preference and also the fruits and leaves if there are no flowers. The complete life cycle covers a period of from 25 to 31 days.

The quince curculio (Conotrachelus cratægi).—Methods of control in western New York, L. F. STRICKLAND and J. B. ACHILLES (N. Y. Dept. Farms and Markets, Div. Agr. Bul. 116 (1919), pp. 45, pls. 8, figs. 3).—Requests for assistance in eradicating the quince curculio in Niagara County, N. Y., the leading county in quince production in the eastern United States and where for many years it has not been uncommon for 80 to 90 per cent of the crop to be seriously injured by this pest, led to the studies here reported. Following a brief account of the life history of the species the details are reported of control experiments conducted in the years 1915, 1916, 1917, and 1918, respectively, a large part of which is given in tabular form.

Very satisfactory results were obtained from two applications in July of Bordeaux (3:3:50) or lime-sulphur (1:40), to which was added 3 lbs. of arsenate of lead to 50 gal. of spray. The first application was made as the adults began to feed, which varies from July 6 to 17, and the second about 5 days later, when oviposition took place. The spray should be so applied that both the upper and under surfaces of the fruit and foliage are covered. The spraying should be supplemented by the collection and removal of all drops and culls from the orchard before the larvæ have left the fruit for hibernation.

"The results of applying the spray at the two periods were excellent, the time the spray was applied being very important. The curculio larvæ in plat 1 were reduced from 69.16 per cent to 1.78 in 1915, 0.89 in 1916, 6.32 in 1917, and 0.32 in 1918. In plat 2 from the same infestation the curculio larvæ were reduced to 21.48, 0.95, 0.59, and 0.06 per cent in the same four years. In plat 3 from the original infestation the larvæ were reduced to 21.48 per cent in 1915, 0.18 in 1916, 0.04 in 1917, and to none in 1918. On the check trees the percentage of infestation of curculio larvæ was 69.16, 78.25, 69.23, and 2.77 from 1915 to 1918 inclusive, the small infestation of 1918 being credited to the unfavorable weather conditions at the time the larvæ left the fruit in October, 1917."

A list is given of nine references to the literature.

The life history of some social wasps in Java, W. ROEPKE (*Treubia* [Dutch East Indies], 1 (1919), Nos. 1, pp. 46-50, pl. 1; 2, pp. 61-67, pls. 2, fig. 1).—In the first paper the author deals with Polistes diabolicus, and in the second with P. javanicus.

Studies on the biology of Paracopidosomopsis, I-IV, J. T. PATTERSON (Biol. Bul. Mar. Biol. Lab. Woods Hole, 32 (1917), No. 5, pp. 291-305; 33 (1917), Nos. 1, pp. 38-50, pls. 2; 2, pp. 57-66, pls. 2; 35 (1918), No. 6, pp. 362-376, pls. 3).— This is a report largely of studies conducted at Austin, Tex., the first part of which consists of data on the sexes. The second, by the author and L. T. Porter, relates to spermatogenesis of males reared from unfertilized eggs; the third considers maturation and fertilization; and the fourth deals with the asexual larvæ.

The species used in the study was *Paracopidosomopsis floridanus* of Ashmead, which oviposits in the egg of the cabbage looper. Its egg develops in the body of the cabbage looper caterpillar, and by the time the caterpillar reaches the stage for pupation the larval parasites have consumed its entire contents and pupate within the skin of the host, which later hardens to form the mummified carcass. This form is said to be similar to the European chalcidid *Litomastix truncatellus* studied by Silvestri (E. S. R., 19, p. 57).

The author's studies indicate clearly that a fertilized female is capable of laying eggs from which individuals of both sexes develop, and that the unfertilized egg produces males only.

References to the literature are included in the first two papers.

Reference is made by the author to his previous observations on the development of *Copidosomo gelechiae*.<sup>1</sup>

# FOODS-HUMAN NUTRITION.

Nutrition in war and lessons to be learned from it, F. RHO (Ann. Ig. [Rome], 29 (1919), No. 5, pp. 269-276).—The author discusses the effect of a restricted diet in different countries during the war, emphasizing the fact that the decided reduction in calories and protein has not been productive of as much trouble as was to be expected. In conclusion he recommends that an effort be made to adopt a standard ration somewhere between the 2,000 calories and 70 gm. of protein of the war rations and the 3,500 calories and high protein of prewar times.

The practicability of feeding a scientifically balanced ration in Army camps, R. J. ANDERSON (*Amer. Jour. Physiol.*, 49 (1919), No. 4, pp. 523-530).— The author discusses certain important problems connected with the proper feeding of an army, and suggests the advisability of having an officer trained in the science of nutrition in every camp or division or of maintaining a separate department of nutrition or alimentation in connection with the War Department, with subordinate officers in the camps. The practicability is also suggested of having a uniform menu for a whole camp instead of separate menus for the different messes.

Average food consumption in the training camps of the United States Army, J. R. MURLIN and F. M. HILDEBRANDT (Amer. Jour. Physiol., 49 (1919), No. 4, pp. 531-556, figs. 11).—Statistical data on the food consumption in the training camps of the United States Army during the recent war, based on nutritional surveys made in 67 different camps including a total of 427 individual messes, are presented in the form of tables and graphs, and discussed under the headings of total consumption, food consumption by organizations, the effect of season on food consumption, the effect of length of time in camp, food consumption in the canteen, food consumption in the Army compared with other occupations, distribution of nutrients in the Army diet, percentage of calories supplied by chief components of the ration, and variety. An earlier report on the same subject has been previously noted from another source (E. S. R., 40, p. 68.)

Variations in strength and in the consumption of food by recruits and seasoned troops, P. E. Howe, C. C. MASON, and S. C. DINSMORE (Amer. Jour.

*Physiol.*, 49 (1919), No. 4, pp. 557-566).—Determinations are reported of the variations in strength and weight of approximately 40 men from each of 8 companies of recruits during 3 successive weeks. The food consumption during the same period was also determined. Most of the companies had been in camp only a few days and during the first 2 weeks of study were inoculated and vaccinated. The men of 4 of the companies represented seasoned troops in training from 5 to 6 months.

Every company of raw recruits, with one exception, showed an initial loss in weight averaging 1 lb., followed by the end of the third week by an average gain of 1 lb. over the original weight. There was also an initial loss in strength, with recovery practically completed by the third week.

The food consumption showed a wide variation which could not be correlated with the changes in strength and weight. The average food consumption of the seasoned troops was somewhat higher than that of recruits but showed as great variations.

Note on the acid-base balance of Army rations, N. R. BLATHERWICK (Amer. Jour. Physiol., 49 (1919), No. 4, pp. 567-572, fig. 1).—Tables are given of the acidbase balance of Army rations at a number of camps and at base hospitals connected with two of these camps. Some of the regular camp diets were strongly acid-forming, some about neutral, and others base-forming. There was a tendency, however, for the rations to be acid-forming in character. In the hospital dietaries, on the contrary, the base-forming elements were practically always in excess. The rations were in all cases found to contain more calcium, phosphorus, and iron than the usually accepted standards.

Investigations of the possible relationship of diet to disease were conducted at Camp Wheeler and Camp Devens. In the former, a rough parallelism was indicated between the duration of disease (measles, mumps, influenza, and pneumonia) and the amounts of meat supplied. In the latter no relationship was shown between the excess acid in the rations or the calorific intake and the influenza rate. The results obtained at Camp Wheeler are thought to suggest the possibility that an acid-forming diet consumed for long periods of time may lead to a greater susceptibility to diseases of the less infectious type.

Dried vegetables for Army use, S. C. PRESCOTT (Amer. Jour. Physiol., 49 (1919), No. 4, pp. 573-577).—This is a general discussion of the advantages in the military use of dried vegetables, with suggestions as to the best means to secure good products.

American military hospital dietaries, R. G. HOSKINS (Amer. Jour. Physiol., 49 (1919), No. 4. pp. 578-587, figs. 2).—In addition to a discussion of the problems of military hospital nutrition, which are treated in greater detail in a previous communication (E. S. R., 40, p. 866), tables are given and discussed of the quantitative data available on the actual food consumption in Army hospitals and medical organizations, of a detailed ration study at a base hospital for seven consecutive days, of the metabolism of an ambulance company, and of the average daily expenditure for certain foods for six months in the messes of the patients, detachments, officers, and nurses of a base hospital.

The average calorific consumption of different diets based on varying numbers of studies was as follows: Liquid diet (one study) 900 calories with normal distribution of protein, fat, and carbohydrate; light diets (two studies comprising 3,734 rations), 2,225 calories with 15 per cent protein and 29 per cent fat; regular diets (ten studies comprising 29,827 rations), 3,236 calories with 35 per cent fat and slightly low protein and carbohydrate content; sick officers' ward (one study comprising 137 rations), 3,570 calories with 39 per cent fat;

158071°-No. 9-20-5

hospital attendants and patients fed the same meals (four studies comprising 6,405 rations), 3,464 calories with normal fat, slightly low protein, and slightly high carbohydrate consumption; nonpatient groups (19 studies comprising 31,709 rations), 3,828 calories with approximately normal distribution of protein, fat, and carbohydrate; nurses' mess and officers' mess included in the above nonpatient group 2,859 and 3,695 calories, respectively.

Attention is called to the dietary idiosyncracies of medical officers, overconsumption, inadequate balance, and high wastage constituting the rule in such messes. This is further brought out in a table showing the average daily expenditure for certain items of food for six months in the different messes of a certain base hospital. The food items included meat, eggs, fresh milk, butter, fresh fruit, fresh vegetables, and canned milk. The daily expenditure for these items and the total daily expenditure per person were, respectively, as follows: Patients' mess 38.3 and 56.4 cts., detachments' mess 35.4 and 48.6, nurses' mess 32 and 46.1, and officers' mess 80 and 101 cts.

A preliminary study of the energy expenditure and food requirements of women workers, O. ROSENHEIM (Proc. Roy. Soc. (London], Ser. B, 91 (1919), No. B 635, pp. 44-61, fig. 1).—The investigation reported in this paper deals with women performing lathe work only. The general plan of the experiments was to determine by indirect calorimetry the energy expenditure of an average adult woman during 24 hours, divided into three approximately equal periods of sleep, work, and recreation. The determinations were made by the Douglas bag method as described by Cathcart (E. S. R., 41, p. 172), a fireman's smoke mask being used in most of the experiments in place of the usual valve, head, and mouthpiece. Statistical data are given of the results obtained with six normal subjects in periods of standard or basal metabolism, metabolism during nonworking hours, and metabolism during work, the latter being divided into light, medium hard, and hard work.

The average basal metabolism calculated by the DuBois formula was found to be 37.4 calories per hour per square meter of body surface, with a maximum variation from the mean of from -2.5 to +4 per cent. This is in close agreement with the figure of 37 calories (with  $\pm 10$  per cent maximum variation) given by Gephart and DuBois (E. S. R., 35, p. 370) as the average basal heat production of adult women between the ages of 20 to 50 years. The average resting metabolism was only slightly higher than the basal. The energy expenditure during horizontal walking at the rate of from 2.7 to 3.1 miles per hour varied considerably with the different subjects, due largely to their previous occupational training, the average for five subjects being 139.8 calories per hour per square meter of body surface. The results in general indicate that women expend practically the same amount of energy as men in moving horizontally 1 kg, of body weight through a distance of 1 meter.

The metabolism during work showed individual variations in work economy, particularly during hard work. The average increase in heat production over the standard was 72 per cent for light work, 109 per cent for medium hard work, and 181 per cent for hard work, as compared with 274 per cent for walking. These results indicate that the energy required for lathe work is relatively small.

The daily food requirements of women lathe workers as calculated from the data obtained varied from 2,400 to 2,800 calories. This is in absolute agreement with the recommendations made by Hill (E. S. R., 40, p. 865) for moderate munition work, as based on statistical inquiries.

In conclusion the author emphasizes the importance, in assessing the food requirements of women workers, of paying due consideration not only to the

quantitative but to the qualitative side, particularly to insure adequate amounts of the accessory factors or vitamins.

Gastric responses to foods (Amer. Jour. Physiol., 49 (1919), No. 2, pp. 174-232 254-270 fas. 94) -- Four papers are presented in continuation of the studies previously noted (E. S. R., 41, p. 467). The digestion of various forms of meat and eggs in the normal human subject was studied by the fractional method, the contents of the stomach being withdrawn at regular intervals and determinations made of free and total acid, pepsin, and amino nitrogen.

III. The response of the human stomach to beef and beef products. H. R. Fishback, C. A. Smith, O. Bergeim, R. A. Lichtenthaeler, M. E. Rehfuss, and P. B. Hawk (np. 174-203).—In this and the following studies it was found that all normal stomaches do not respond alike to the entrance of the same food, some responding very quickly and others slowly. The same difference was noted in the evacuation time. In consequence the subjects have been classified throughout the studies as having rapid- or slow-emptying stomachs.

The general results obtained in this study of the digestion of various forms of beef and beef products may be summarized as follows:

Roast beef and beef steaks appeared to be as readily digested if cooked rare as if medium or well done, rare roast beef apparently having a slight advantage in this respect. Roast beef was found to lie between the cheaper and tougher cuts of steak and sirloin and tenderloin steak in gastric response and evacuation time, the cheaper cuts of meat being handled more rapidly in the same individual than the more expensive cuts. Hamburger steak, stewed beef, boiled corn beef, dried beef, and beef bologna were handled by the stomach in the same length of time as roast beef, while calves' liver, beef tongue, and tripe required a slightly longer time and frankfurters and sweetbreads a shorter time.

For 100 gm, of the beef products tested, an average evacuation time of 2 hours and 35 minutes was obtained on subjects with stomachs of the rapidemptying type, and 3 hours and 25 minutes with the slow-emptying type. The maximum total acidity obtained, expressed in cubic centimeters of N/10 alkali required to neutralize 100 cc., was 184 and the average total acidity at the height of digestion 120. It is pointed out that these high acid values regularly shown by normal men necessitate a revision of the older ideas of hyperacidity.

The amino acid nitrogen values (which include ammonia) were moderately high at the beginning of digestion due to the ammonia of the meat, increased as digestion proceeded, and fell to a low level at the end of the digestion. Pepsin values were highest toward the end of digestion.

IV. The response of the stomach to pork and pork products, C. A. Smith, H. R. Fishback, O. Bergeim, M. E. Rehfuss, and P. B. Hawk (pp. 204-221).--For individuals with stomachs of the rapid-emptying type the general average evacuation time for pork products was 2 hours and 45 minutes, and for subjects of the slow-emptying type 3 hours and 40 minutes. The average total acidity at the height of digestion was 117. Liver and bacon required about the same period of gastric digestion as roast beef, pork sausage a slightly longer time, and roast pork, pork chops, scrapple, bacon and most forms of ham a still longer time. Ham sandwiches were more readily handled than most of the other pork products.

V. The response of the stomach to lamb and lamb products, H. R. Fishback, C. A. Smith, O. Bergeim, M. E. Rehfuss, and P. B. Hawk (pp. 222-232),-Lamb was found to require an average of 2 hours and 30 minutes to digest for the rapid-emptying type of stomach, and 3 hours and 20 minutes for the slowemptying type. The average total acidity at the height of digestion was 134. On the average, roast lamb remained in the stomach a few minutes longer

than roast beef, but not so long as roast pork. Stewed lamb required a somewhat longer period for digestion than roast lamb or lamb chops. Sheep brains left the stomach rather rapidly.

VI. Digestion in the normal human stomach of eggs prepared in different ways, R. J. Miller, H. L. Fowler, O. Bergeim, M. E. Rehfuss, and P. B. Hawk (pp. 254–270).—In addition to fresh eggs prepared in all the usual ways, tests were made with frozen and cold-storage eggs, duck and turkey eggs, the Chinese preserved duck egg called "pidan," and various combinations of eggs with other food materials.

In general eggs were distinguished from meat by the lower acidities which they provoked and by their more rapid evacuation. The average evacuation time for all egg preparations was for the first class 2 hours and 15 minutes and for the second class 3 hours and 5 minutes. The average of the highest acidities developed was 80 as compared with 120 for beef.

Raw egg white left the stomach much more rapidly than any other form of egg preparation, particularly when mixed with orange juice. The use of "orange albumin" in the diet of invalids would therefore appear to be supported from the standpoint of gastric digestion. Whole raw eggs were not handled so rapidly as either soft or hard cooked eggs. Eggs fried in the ordinary way and not turned left the stomach rather more rapidly than eggs cooked in any other way. Scrambled eggs and omelet required a somewhat longer time for digestion than hard or soft eggs and poached and shirred eggs.

Cold storage and mixed eggs could not be distinguished from fresh eggs as far as the response to the stomach was concerned. The eggs of the duck and turkey produced no difference in gastric response other than that caused by their greater bulk. "Pidan" gave rise to delayed and low acid responses and delayed evacuation.

Eggs and milk left the stomach a little more slowly than eggs alone, eggs with bread in about the same time as hard boiled eggs, bacon and eggs as rapidly as fried eggs alone, and frizzled beef with scrambled eggs as rapidly as scrambled eggs alone.

The influence of diet on teeth formation, M. MELLANBY (Lancet [London], 1918, II, No. 23, pp. 767-770, figs. 4).—In this preliminary paper experimental work with puppies is described in which the problem has been investigated of the factors involved in the development of sound teeth and of the growth of the jaws in relation to the size of the teeth.

The results obtained indicate that a deficiency of fat-soluble A in the diet is accompanied by abnormal development of the teeth. A diet containing in abundance articles with which the fat-soluble A is associated (cod liver oil, butter, etc.), allowed the development of sound teeth, while a diet otherwise adequate but deficient in fat-soluble A brought about delayed loss of deciduous teeth, delayed eruption of the permanent dentition, irregularity in position and overlapping, especially of the incisors, partial absence of or very defective enamel, and low calcium content. These results are thought not to be due to acute illness or malnutrition, as an improvement to the teeth was brought about by the addition of substances containing fat-soluble A, and the defective teeth appeared to be most pronounced in rapidly growing puppies.

Attention is called to the work of E. Mellanby on rickets previously noted (E. S. R., 41, p. 365), which puts on an experimental basis the intimate connection between this disease and hypoplasia of the teeth.

The effect of cow's milk and human milk upon smooth muscle, O. B. MEYER (*München. Med. Wchnschr.*, 66 (1919), No. 12, pp. 315-318, figs. 2).—In an attempt to determine whether the biological differences between cows' milk and

human milk might be attributed to the presence of adrenalin in different amounts, the effect of both kinds of milk upon smooth muscle was determined.

It was found that cow's milk produced a contraction in the muscle similar to that produced by a solution of adrenalin, and that human milk produced only a very slight contraction. While the resemblance to the adrenalin curve was quite marked, sufficient evidence was obtained to indicate that the contraction was not due to adrenalin. Further experiments, conducted with a view to determining the cause of the contraction established the fact that dialysed cow's milk, with the addition of 3 per cent of milk sugar, gave a curve with smooth muscle practically identical with that of human milk. This suggests the practicability of using dialysed cow's milk in infant feeding.

While the question of the cause of the effect of milk upon smooth muscle is still open, the author feels that further evidence is given by the experiments reported to support the view that the salts and milk sugar are partly responsible for the action.

Regeneration of blood serum proteins, W. J. KERE, S. H. HURWITZ, and G. H. WHIPPLE (*Amer. Jour. Physiol.*, 47 (1918), No. 3, pp. 356–392, fig. 1).—The results of a study of the regeneration and source of blood proteins, their fluctuation under abnormal conditions, and their function in the body economy are presented in the following papers:

I. Influence of fasting upon curve of protein regeneration following plasma depletion.—Dogs were used as experimental animals, and plasma depletion was effected by bleeding the animal from the artery and introducing into the vein red corpuscles washed and suspended in Locke's solution. By this method, the blood serum proteins, as measured by the refractometric method, could be reduced to a low level (33 per cent or even 20 per cent of normal).

The regeneration took place very slowly, whether food was administered or not, complete regeneration occupying from 7 to 14 days when the original depletion removed 50 per cent or more of the total serum proteins. The ability of the body to regenerate serum proteins while fasting and the lack of evidence of any constant fluctuation in serum proteins in association with periods of fasting or heavy protein feeding are thought to indicate that the serum proteins are not concerned as intermediary products between food protein and body tissue or parenchyma protein, and that their formation under certain circumstances may be attributed to the body proteins.

II. Influence of diet upon curve of protein regeneration following plasma depletion.—Experiments are reported which supplement those noted above by showing the effect of different diets upon serum protein regeneration.

The regeneration was found to be more rapid and complete upon a meat or mixed diet than in fasting, and more rapid upon a meat diet than a bread and milk diet. Following plasma depletion there was an average regeneration of 1 per cent of the total serum proteins within the next 24 hours, independent of food, shock, or infection. This is thought to represent the absolute maximum production under the greatest stimulus.

It is pointed out that regeneration of serum proteins on a meat diet after a 50 per cent depletion and regeneration of liver cell protoplasm after a 50 per cent necrosis both require from 5 to 7 days, suggesting that the body has the same difficulty in regenerating its serum proteins that it does in the construction of cell protein.

III. Liver injury alone: Liver injury and plasma depletion: The Eck fistula combined with plasma depletion.—In this paper experiments are reported which show that "liver injury tends to lessen the amount of circulating blood serum proteins, and the presence of liver injury tends to retard the regeneration of serum proteins after an initial plasma depletion. Furthermore, the Eck fistula liver appears to regenerate blood serum proteins more slowly than the normal or even the injured liver. The Eck fistula liver is smaller than normal, always presents evidence of degeneration (fat), and gives a subnormal functional test with tetrachlorphthalein."

This experimental evidence is thought to indicate that the liver is concerned in maintaining the normal level of the blood serum proteins, which is remarkably stable in widely varying conditions of health and disease.

An investigation of changes in the blood and urine resulting from fatigue, A. B. HASTINGS (Pub. Health Rpts. [U. S.], 34 (1919), No. 31, pp. 1682-1691, fig. 1).—The studies reported were made for the most part on the urine of men and the blood of dogs, although in a limited number of cases data were obtained on both the urine and blood of the same subject. Fatigue was induced in the animals by causing them to run in a revolving wheel, and later in a motor-driven treadmill. Data on the reaction of the urine of men at rest were obtained from men convalescing from minor surgical operations, and on fatigued subjects from men engaged in mechanical operations in an automobile factory, from men participating in a 12-mile Marathon race and a 6-day bicycle race and from a man on a 10-mile walk. The reactions of blood plasma and urine were determined electrometrically with a Clark electrode, and the reserve alkali of the blood plasma by the Van Slyke method for the determination of bound carbon dioxid. The character and amount of the food eaten were noted only in the case of the hospital patients. The general results obtained were summarized as follows:

Exercise produced a diminution of the bound carbon dioxid of the blood plasma which, however, did not progress to such a point that the reaction of the plasma was significantly altered. The rate of change of the bound carbon dioxid was a function of the rate and amount of exercise.

The urine of men engaged in manual labor tended to be of a slightly higher degree of acidity than that of men at rest. The urine of physically strong men was regularly slightly more acid after work than before, while that of physically weak men showed wide variations in reactions from day to day. Intense fatigue invariably resulted in an increase in the H-ion concentration of the urine.

Experimental scurvy in monkeys, A. HARDEN and S. S. ZILVA (Jour. Path. and Bact., 22 (1919), No. 3-4, pp. 246-251).—Three experiments are reported in which scurvy was induced in monkeys by the following diets: (1) Fresh beer, steamed wheat germ, and autoclaved bread, rice, and monkey nuts; (2) autoclaved rice, bread, and autoclaved milk; and (3) a diet similar to the first with the substitution of autoclaved milk for the beer.

In all cases an acute scorbutic condition developed in from three to four months, the symptoms in the first two cases being confirmed by the histological changes noted on autopsy. In the third experiment, the animal was cured in less than a week by the addition of lemon juice treated as described in a previous article (E. S. R., 40, p. 364).

An investigation of the antiscorbutic value of the raw juices of root vegetables, with a view to their adoption as an adjunct to the dietary of infants, H. CHICK and M. RHODES (*Lancet* [London], 1918, II, No. 23, pp. 774, 775).— By the usual feeding experiments with guinea pigs, the basal diet being oats and wheat bran ad libitum with 60 cc. of milk autoclaved at  $120^{\circ}$  C. for one hour, the authors have found raw swede juice to have antiscorbutic properties approximating in value to raw orange juice, protection from scurvy being attained with a daily ration of 2.5 cc. The raw juice of carrots was found to be inferior to that of swedes, 20 cc. being required to produce protection from scurvy. The juice of beet roots failed to prevent scurvy in the largest dose (20 cc.) that could be administered.

For purposes of comparison a table is given showing the relative antiscorbutic properties of the above-mentioned juices and of cooked potato, fresh raw cabbage leaves, fresh orange juice, and fresh grapes. The juice of grapes was found to have a value of only about one-tenth that of oranges.

A note on the value of germinated beans in the treatment of scurvy, and some points in prophylaxis, H. W. WHITSHIRE (Lancet [London], 1918, II, No. 24, pp. 811-813).—The author confirms the conclusions of Chick and Hume (E. S. R., 40, p. 868) as to the antiscorbutic value of germinated seeds, by reports of the successful use of germinated haricot beans in the treatment of scurvy in the Serbian army in 1917. The amount of antiscorbutic vitamin developed in the beans upon germination is thought to be equal to, if not greater than, that contained in fresh lemon juice. Even if no allowance be made for the food value of the beans, the cost of vitamins supplied by them is estimated at only 60 per cent of the cost when supplied by lemons.

Beer and scurvy, A. H. SMITH (*Lancet* [London], 1918, II, No. 24, pp. 813-815).—Conflicting reports from the literature of the value of beer in the prevention of scurvy are recorded briefly, and the explanation is advanced that the difference in results is due to the process of malting. With the elaboration and perfection of the malting and brewing processes the antiscorbutic vitamin, which was probably present in the earlier beers, having its source in the germinated grains, has been practically eliminated.

A historical inquiry into the efficacy of lime juice for the prevention and cure of scurvy, A. H. SMITH (Jour. Roy. Army Med. Corps, 32 (1919), Nos. 2, pp. 93-116; 3, pp. 188-208, fig. 1).—This is a more detailed report of the historical inquiry noted above.

The antiscorbutic properties of raw lean beef, R. A. DUTCHER, E. M. PIERson, and A. BIESTER (*Science*, *n. ser.*, 50 (1919), *No.* 1286, *pp.* 184, 185).—A preliminary report is given of feeding experiments with guinea pigs which indicate that raw lean beef does not possess antiscorbutic properties.

## ANIMAL PRODUCTION.

Mitosis and amitosis, E. G. CONKLIN (*Biol. Bul. Mar. Biol. Lab. Woods Hole*, 33 (1917), No. 6, pp. 396-436, pls. 10).—This is a discussion of purported cases of amitotic cell division to be found in the literature of cytology, supplemented by a study of the cleavage of the egg of the mollusk *Crepidula plana*. The author's point of view may be seen from the following statements:

"The modern revival of interest in amitosis is due to a reaction against the chromosome theory [of heredity]. If nuclear and cell divisions ever take place by amitosis in normally developing sex cells and embryonic cells it would deal a fatal blow to that theory. The occurrence of amitosis in fully differentiated tissue cells or in cells which do not undergo division would not affect the chromosome theory... There is not a single wholly conclusive case in which amitosis has been shown to occur in the division of normally differentiating cells. Therefore the attempts to disprove the chromosome theory in this way have failed."

Four types of modified mitosis which resemble amitosis are described.

Studies on cytolysins.—I, Some prenatal effects of lens antibodies, M. F. GUYER and E. A. SMITH (*Jour. Expt. Zool., 26 (1918), No. 1, pp. 65–82).*—Pregnant rabbits, injected with serum from chickens sensitized by previous injections of a suspension of rabbit crystalline lenses, and pregnant deer mice of the genus Peromyscus, injected with fowl serum similarly sensitized to the

proteins of Peromyscus lenses, produced young, a few of which had liquified instead of fibrous crystalline lenses. It is held that the lenses excited the production of specific antibodies in the fowl blood, and that these in turn attacked in utero the lenses of the young of the species used as antigen. The lenses of the mothers were not altered.

Observations on the relation between suckling and the rate of embryonic development in mice, W. B. KIEKHAM (*Jour. Expt. Zool.*, 27 (1918), No. 1, pp. 49-55).—The author reports experiments and embryological investigations showing that the delay which he had previously discovered (E. S. R., 40, p. 469) in the implantation of embryos in the uterus of female mice simultaneously pregnant and lactating is induced by full functional activity of the mammary gland. The extent of the delay seems not to be correlated with the size of the suckling litter. The influence of the gland varies markedly in different individuals.

The experimental production of hypotypical ovaries through underfeeding.—A contribution to the analysis of sterility, L. LOEB (*Biol. Bul. Mar. Biol. Lab. Woods Hole, 33 (1917), No. 2, pp. 91–115).*—In a series of experiments 26 sexually mature female guinea pigs received their accustomed feeds oats and green feed—in amounts not sufficient to maintain body weight for from 6 to 33 days. In most cases the weight decreased 25 to 35 per cent. Of 8 animals intended as controls, 1 lost 20 per cent of her weight in spite of abundant feed but the others maintained weight, ovulated normally, and 3 became pregnant. In 18 of the experimental animals and in the exceptional control the ovaries became definitely hypotypical—that is, atresia of follicles set in before the follicles reached normal size. In such animals ovulation is effectually prevented and the animals are sterile, at least temporarily. The uterus was found to be in a resting condition. The connective tissue of the ovary was more resistant to the experimental treatment than the granulosa cells.

The concrescence of follicles in the hypotypical ovary, L. LOEB (*Biol. Bul. Mar. Biol. Lab. Woods Hole, 33 (1917), No. 3, pp. 187–195).*—The author describes the ovaries of an underfed guinea pig, in which the hypotypical condition was so advanced that the connective tissue was affected and neighboring follicles became united. "The concrescence of ovarian follicles is analogous to the union of neighboring acini in the mammary gland and thyroid. It is a phenomenon which occurs probably in all or the majority of glandular structures."

The effect of alcohol on the reproductive tissues, A. H. ARLITT and H. G. WELLS (*Jour. Expt. Med.*, 26 (1917), No. 6, pp. 769–778, pls. 4).—Male and female white rats, mostly 6 to 9 months old, were given daily doses of ethyl alcohol with the food for a period of time and were then killed. Histological preparations were made of the reproductive and other tissues.

The treatment resulted in no apparent changes in the lungs, liver, kidneys, spleen, stomach, heart, or ovaries, but profound disturbances were found in the testes of 14 of the 15 males. The seminiferous tubules were reduced in size with compensatory edema of the intertubular tissue. Spermatozoa were absent in some cases, in others they were reduced in number or lacked tails, and in still others spermatids were numerous but apparently had been prevented from undergoing further transformation. Individual tubules of the same testis often showed considerable differences and individual differences between males were marked. The daily dosage varied from 0.25 to 2.25 cc. and the period of administration from 2 to 10 months, but it was found impossible to correlate the intensity of the histological changes with the severity of treatment.

Measurements, made by C. L. Chapin, of the diameter of the seminiferous tubules of each individual are recorded.

Further studies on the modification of the germ cells in mammals.—The effect of alcohol on treated guinea pigs and their descendants, C. R. STOCK-ARD and G. N. PAPANICOLAOU (Jour. Expt. Zool., 26 (1918), No. 1, pp. 119–226, figs. 8).—The authors present the results obtained during the sixth and seventh years of a study of the descendants of a number of guinea pigs that had been caused to inhale fumes of ethyl alcohol for an hour or more six days a week during periods of several months. The results of earlier years have been noted (E. R. S., 35, p. 65).

The report deals mostly with 594 progeny of alcoholic lines (four generations) and 233 of untreated lines, both stocks systematically mated to avoid inbreeding, but some information is also furnished concerning 302 individuals of inbred alcoholic stock and 41 untreated inbred animals. Since the previous report the mating technique has been improved through a study of the estrus cycle (E. R. S., 40, p. 467). Matings were made by placing a female in heat alone in a cage with a male. If a month later upon careful physical examination she was found to be pregnant, the mating was considered successful and the number of progeny produced was reckoned as of that date. The number of fetuses in utero was determined by palpation at intervals until parturition and a careful watch was kept for abortions. The young not accounted for at birth were assumed to have died and been absorbed in the manner discussed by Meyer (E. R. S., 40, p. 663). The accuracy of the palpation counts was checked by a number of autopsies of pregnant females.

The data from the noninbred stock are tabulated in three different ways according to (1) the number of generations since the most recent alcoholic ancestor without regard to the latter's sex, (2) whether the paternal or maternal stock or both were alcoholic, without distinguishing between generations except the immediate parents, and (3) whether the alcoholic ancestors were exclusively males, exclusively females, or of both sexes, likewise without discriminating between the more remote generations. The third method shows perhaps the most striking differences and is summarized below:

Character of mates.			Num-	Mat		Aver-	Voungl	Voung	Rela-	Pro- por-
Male.	Fcmale.	Mates' ancestors treated with alcohol.	ber of mat- ings made.	ings unsuc- cess- ful. <sup>1</sup>	Young <sup>1</sup> per suc- cessful mating.	weight of litter at birth.	in litters of 4 or 5.	alive 3 months after birth.	tive cor- rected death rate.	tion of deaths that were pre- natal.
Normal Alcoholic Normal Do Do Do	Normal Alcoholic Normal do	Nonedodo	88 34 35 72 33 86	Per ct. 4.5 23.5 5.7 19.4 3.0 12.8	$2.77 \\ 2.30 \\ 2.78 \\ 2.50 \\ 2.56 \\ 2.41$	Gm. 197.1 170.4 171.6 173.3 175.5 170.7	Per ct. 37 20 17 24 15 19	Per ct. 77.7 66.7 48.9 62.8 72.0 69.1	100 178 281 193 152 161	Per ct. 51.9 60.0 74.5 79.6 60.9 64.3

Condition of young from matings of guinea pigs exposed to alcohol or descended from alcoholic stock.

<sup>1</sup> One month after opportunity for copulation.

No litters of more than five young were observed in these experiments. Since the death rate was higher in large than in small litters, and since the proportion of large litters varied in the different groups of matings, it was necessary to eliminate as far as possible the influence of litter size from the mortality data. As used in the table, the relative corrected death rate of the young of a particular group expresses the observed death rate as a percentage of the

1919]

rate which the normal group would have exhibited had the distribution of litter sizes been the same as in the group under consideration.

That a high proportion of unsuccessful matings (indicative of early death of embryos or low fertility or both), a small sized litter, and a low litter weight are characteristic of both the matings with a treated male and those with alcoholic male ancestors is held to "prove the hereditary transmission of the defects arising from the treatment of the male animals." The general similarity of the two groups of young derived from alcoholized females indicates that "the treatment of female individuals also induces effects that are transmitted to later generations through the germ cells." The high mortality of the offspring of an alcoholized mother is attributed in part to the direct influence of the treatment. The authors consider the results secured by Cole and Davis<sup>1</sup> (who found that spermatozoa of treated rabbits were handicapped in a direct competition with normal spermatozoa), and by Arlitt and Wells (noted above) to be of significance in explaining the intensity and the racial persistence of the effects of alcoholizing male guinea pigs.

The ratio of males to females was 109.2:100 in young with fathers or other male ancestors treated, 86.5:100 in those with only female ancestors treated, and 123.6:100 when ancestors of both sexes had been treated. The ratio in the normal line was 113.2:100. These wide differences are discussed, but inasmuch as the normals showed an unusually high proportion of males no certain conclusions are drawn, although the possibility of higher prenatal mortality on the part of the females of alcoholic stock is pointed out.

About 2.52 per cent of the noninbred young of alcoholic stock and 3.31 per cent of the inbred alcoholics were conspicuously malformed in some particular (abnormally small eye on one side, cataract, opaque lenses, deformed limbs, etc.) or showed paralysis, gross tremors, and the like. In none of the untreated stock, inbred or not, were such defects noted.

In attempting to reconcile their results with those of Pearl on the domestic fowl (E. S. R., 40, p. 470), the authors are inclined to hold that many of the "infertile" eggs in Pearl's experiments contained embryos that died in early cleavage stages.

Studies on inbreeding.—I–IV, H. D. KING (Jour. Expt. Zool., 26 (1918), Nos. 1, pp. 1–54, figs. 14; 2, pp. 335–378, figs. 2; 27 (1918), No. 1, pp. 1–35, fig. 1; 29 (1919), No. 1, pp. 71–111, figs. 8).—The observations reported in these four papers cover 25 generations of inbred white rats reared at the Wistar Institute. The experiments were started with a litter consisting of two males and two females born in May, 1909. One of the females was called A and the other B; their inbred descendants are respectively designated the A and the B series. The plan required that A and B and every other female used for breeding should be mated twice with a brother from the same litter and then twice with an unrelated stock male. Young from the latter matings were not used to carry on the inbred line.

During the first six generations the diet consisted mostly of milk, bread, and corn, and many of the rats remained undersized, developed deformed teeth and other malformations, and produced small sized litters. These defects are not attributed to inbreeding, as they were also abundantly manifested by the rest of the rat colony. The diet was then changed to selected table refuse supplemented by ear corn or dog biscuit, and all evidence of malnutrition disappeared. Less marked nutritive disturbances were, however, again met with during the

<sup>&</sup>lt;sup>1</sup> The Effect of Alcohol on the Male Germ Cells studied by means of Double Matings, L. J. Cole and C. L. Davis. Abs. in Science n. ser., 39 (1914), No. 1004, pp. 476, 477.

last few generations, since table scraps became scarce and of low grade and no satisfactory substitute was found.

The animals produced in the first six generations were so few that practically all that lived were bred from. Beginning with the seventh, however, it was possible to inaugurate a system of selection which is described as follows: "In the A series of inbreds, which is called the 'male line,' all litters containing an excess of female young were always discarded; in the B series, the 'female line,' litters with an excess of male young were never reared. Unless the individuals in the litter were of normal size and vigorous at birth they were killed at once." Additional eliminations took place at the age of one month and at sexual maturity (3 months), all animals not meeting the requirements of normal weight, as given by Donaldson (E. S. R., 40, p. 546), and normal vigor being discarded.

The subtitles of the individual papers and the main topics treated therein follow:

I. The effects in inbreeding on the growth and variability in the body weight of the albino rat.—This paper summarizes (1) the adult body weights of 177 male and 137 female rats of generations 1 to 6, and (2) the systematic monthly weighings of 156 males and 169 females of generations 7 to 15 during the first 15 months of their lives. For this second set of measurements from 3 to 5 litters of each series were selected for study in each generation, the litters chosen being of medium size (5 to 8 young) and composed of individuals normal in size at birth. "There was no culling of the less desirable individuals, however, and all members of every litter were reared and weighed at the ages noted."

Inbred males belonging in generations 7 to 15 were heavier at all ages than stock albinos. In the adult state they were on the average, 18 per cent heavier than the general run of stock albinos and about 12 per cent heavier than males from a selected stock series reared under the same environmental conditions. Inbred females were, as a rule, slightly heavier at any given age than the females of the control series, but the difference between the two groups was much less marked. At the age of one year the average body weight of the inbred females was 3.7 per cent greater than that of the stock females. Some males of the seventh to ninth generation were the largest specimens of the albino rat on record.

The animals of the B series were somewhat heavier at all ages than those of corresponding sex in the A series. In both series the variability of the body weights—as measured by the coefficient of variation—was lower in the later than in the earlier generations.

II. The effects of inbreeding on the fertility and on the constitutional vigor of the albino rat.—Litter size, age at sexual maturity, fertility, mortality, and behavior are the topics considered in this paper.

The average number of young in a litter in the A series (1,752 litters) was 7.5 and in the B series (1,656 litters) 7.4. The average in a stock of noninbred albinos (424 litters) kept under the same environmental conditions was 6.7. These averages include the first four litters cast by each female or a lesser number in those cases where four were not secured. There were some changes in litter size in the inbred series as the experiment progressed. The average was 6.8 for generations 1 to 6, 7.2 for generations 7 to 10, 7.5 for generations 11 to 14, 7.7 for generations 15 to 18 and 19 to 22, and 7.4 for generations 23 to 25. Inbred females in giving birth to their first litters produced 6.9 young on the average. The second litters averaged 7.9, the third 7.8, and the fourth 7.3. The averages for the successive litters of the stock females were 6.2, 7.3, 6.5, and 6.7 young, respectively. In the earlier generations malnutrition delayed the time of puberty. In the latter generations considerably more than 25 per cent cast their first litter before the age of 90 days, while less than 10 per cent were more than 120 days old at the time of first parturition. Of the 594 females used for breeding, 68.5 per cent produced the required four litters. The majority of the others died of pneumonia. A few remained barren after one or two litters; postmortem examinations revealed inflamed ovaries or uterus in these cases. These facts are held to indicate that the inbreeding did not induce sterility. The mortality records indicate that the span of life was longer in the inbred animals than in ordinary stock.

The behavior of some of the inbred animals used in this experiment has been studied by A. W. Yerkes<sup>1</sup> and by N. Utsurikawa.<sup>2</sup> These investigators found that the inbred rats learned their way out of a maze more slowly than stock rats, and were more timid, more savage, and less active. It is suggested that perhaps nervousness is an hereditary trait that is intensified through inbreeding and that the nervousness of many pure bred domestic animals, notably race horses, is associated with the inbreeding (in a broad sense) frequently practiced by breeders of registered stock.

III. The effects of inbreeding, with selection, on the sex ratio of the albino rat.—The ratio of males to females among the 2,818 individuals of the 424 litters of stock animals used as controls was 104.6:100. The ratio among the 3,256 inbred animals in the six generations before selection began was 108.6:100. The young of the A series (male line) in generations 8 to 25 that were produced in first and second litters (sired by inbred males) showed a ratio of 122.3:100. Among young in the third and fourth litters of the A series females (sired by stock males) the ratio was 115.6:100. Breeding females of the B series (female line) in generations 8 to 25 produced male and female young in the proportion of 81.1:100 when mated to inbred males, and in the proportion of 91.1:100 when mated to stock males.

It is concluded that by selection the inbred rats have been separated into two distinct strains showing radically different sex ratios.

IV. A further study of the effects of inbreeding on the growth and variability in the body weight of the albino rat.—This paper completes study I by presenting the growth data for 296 males and 310 females of generation 16 to 25. These rats were not so heavy at any age period as those of the earlier generations, but they were much superior in weight to stock albinos reared under similar conditions of environment and nutrition. Variability did not tend to decrease with the advance of inbreeding. There were practically no differences in adult weights between the A and the B series.

By way of general conclusions, the author points out that selection for vigor is seemingly able to check any tendency for inbreeding to bring out undesirable latent traits, and that adverse housing and feeding conditions are capable of producing more detrimental effects on growth and fertility in the albino rat than is inbreeding.

A bibliography of nearly 200 titles on inbreeding, selection, sex ratios, and related topics is appended to the fourth study.

On a back cross in mice involving three allelomorphic pairs of characters, J. A. DETFELSEN and E. ROBERTS (*Genetics*, 3 (1918), No. 6, pp. 573-598).—To discover (1) any linkage that might exist between three dominant hereditary

<sup>&</sup>lt;sup>1</sup>Comparison of the Behavior of Stock and Inbred Albino Rats. Jour. Anim. Behavior, 6 (1916), No. 4, pp. 267-269, figs. 4.

<sup>&</sup>lt;sup>2</sup> Temperamental Differences between Outbred and Inbred Strains of the Albino Rat. Jour. Anim. Behavior, 7 (1917), No. 2, pp. 111-129.

factors in mice—those for agouti hair-pattern, dark eye-color, and black bodypigment—and (2) any selective mortality of particular zygotic types in early postnatal life, a number of mice heterozygous for all three factors were mated to triple recessives at the Illinois Experiment Station. Most of the data secured were from a group of 90  $F_1$  wild gray×pink-eyed brown females crossed back to pink-eyed brown males. These females produced 361 litters (comprising 2,259 individuals) in which all the young lived during the two weeks after birth that necessarily elapses before the eye- and body-colors of young mice can be determined, and 170 litters (811 individuals) in which some of the young died during this period.

No evidence of linkage was found—indeed, in the undepleted series, of the eight classes of young the two that would have been the noncrossover classes were least numerous. There was, however, an indication of selective mortality, for noticeably fewer nonagoutis than agoutis were found among the depleted litters, while the two kinds were substantially equal in number in the undepleted litters.

Fluctuations of sampling in a Mendelian population, J. A. DETLEFSEN (*Genetics*, 3 (1918), No. 6, pp. 599-607).—The data furnished by the 531 litters from the  $F_1$  females used in the experiment noted above were examined to see how closely the ratios in the individual litters approach the expected ratios. The statistical methods adopted are mainly those suggested by Harris (E. S. R., 29, p. 67). It is concluded that the observed deviations from expectation can properly be attributed to the chance fluctuations of random sampling.

A demonstration of the origin of two pairs of female identical twins from two ova of high storage metabolism, O. RIDDLE (Jour. Expt. Zool., 26 (1918), No. 2, pp. 227-254).—Two cases among ring doves are reported where an egg harbored two embryos which on dissection proved to be females. The eggs, which were laid by different birds, were very large but are held not to have been double yolked because (1) in one case the two-embryo condition was discovered early in incubation by candling and the relative position of the embryos could not be altered by rotation and shaking, and (2) in both cases the umbilici of each pair of fully formed embryos "had a practically common point of union on the [single, only partly absorbed] yolk-sac." The twins are termed identical because each pair is thought to have been derived from a single egg cell. The large size ("high storage metabolism") of the yolks is suggested as a factor in the separation of the blastomeres to form two embryos.

Genetic variability, twin hybrids and constant hybrids, in a case of balanced lethal factors, H. J. MULLER (*Genetics*, 3 (1918), No. 5, pp. 422-499, fig. 1).—On the basis of extended breeding investigations which he reports with beaded-wing drosophilas, the author recognizes a condition where heterozygosis is enforced by two opposed lethal factors in the same linkage group which are inhibited from crossing over by a third factor, and designates this condition as one of balanced lethal factors. He uses this as an explanation of the existence both of "pure" beaded-wing stock and of stock in which the beadedwing factor behaves like the factor for yellow in mice.

The author also points out that the factorial analysis of these flies has proceeded far enough so that various complicated and apparently non-Mendelian results, such as twin hybrids, constant hybrids, and the disappearance of dominant factors on crossing, can be made to order. If these cases occurred spontaneously the Mendelian mechanism at work might not be apparent, and the phenomena would be made much of by advocates of the theory of factor variability.

Fluctuations in a recessive Mendelian character and selection, E. ROBERTS (Jour. Expt. Zool., 27 (1918), No. 2, pp. 157-192, figs. 25).—Breeding experiments at the Illinois Experiment Station with vestigial-wing drosophilas (pomace flies) are reported.

Selection for 34 generations failed to increase the length of the wings. Vestigial-wing flies extracted from a cross with wild long-wing flies bore longer wings and wings of more varied shapes than the stock which had not been crossed. This result is attributed to modifying factors brought in by wild flies, and not to "contamination." For seven generations certain of the extracted stock were kept in an incubator where the temperature, though variable, averaged about 2° C. above the room temperature where the rest of the stock were kept. The incubator flies developed longer wings than the outside flies, and the effect was more marked in the males than in the females.

Selecting cattle for hornlessness, E. N. WENTWORTH (*Breeder's Gaz.*, 76 (1919), No. 17, pp. 849, 850).—The current view of geneticists as to the inheritance of the polled character in cattle is explained. It is pointed out that a long series of top crosses with polled animals does not ensure the "prepotency" of a polled sire.

Commercial feeding stuffs, quarterly report, January 1 to March 31, 1919, E. G. PROULX ET AL. (Indiana Sta. Bul. 230 (1919), pp. 63).—This is the first of the new series of quarterly reports of Indiana feeding stuffs, and tabulates the proximate composition of 982 samples analyzed during the first three months of 1919. The materials listed include alfalfa meal, buckwheat hulls and middlings, coconut oil meal, corn bran, corn feed meal, yellow corn feed meal, corn germ meal, corn gluten feed, hominy feed, yellow hominy feed, cottonseed cake, cottonseed feed, cottonseed meal, Kapok seed meal, linseed cake, linseed meal, oat middlings, palm kernel oil meal, peanut oil meal, rye middlings, velvet bean feed, wheat bran, wheat middlings, wheat shorts, red dog, white middlings, miscellaneous (mostly corn and oats) chop feeds, tankage, meat scrap, and mixed and proprietary stock, poultry, molasses, and condimental feeds and calf meals.

Inspection of feeding stuffs (New York State Sta. Bul. 455 (1918), pp. 15-186).—This is the report on the samples of feeding stuffs collected by the New York State Commissioner of Agriculture during 1918. The protein, fat, and fiber content of each sample is reported, together with the ingredients identified and in the case of animal by-products the phosphoric acid content. The materials analyzed include alfalfa meal, barley feed, barley middlings, barley hulls, brewers' dried grains, buckwheat middlings, coconut oil meal, corn bran, corn germ meal, corn gluten feed, corn meal, corn feed meal, hominy feed, yellow hominy feed, corn-and-cob meal, cottonseed meal, cottonseed feed, distillers' dried grains (corn), malt sprouts, dried yeast grains, dried beet pulp, linseed meal, unscreened flaxseed oil cake, oat hulls, oatmeal by-product, peanut oil feed, unhulled peanut oil feed, Spanish chestnuts, velvet bean feed, wheat bran, wheat middlings, red dog, wheat middlings and palm oil, wheat screenings, tankage, meat scrap, meat-and-bone scrap, beef scrap, fish meal, and various proprietary compounded chop, molasses, stock and poultry feeds, and calf meals.

**Poultry foods, J. C.** BRÜNNICH (*Queensland Agr. Jour., 11 (1919), No. 6, pp. 245, 246*).—Proximate analyses of market samples of Australian poultry feeds are summarized. The materials are meat-and-bone meal, pea meal, corn meal, bran, shorts, linseed meal (Meggit's), key meal, polly meal, and nine commercial mixed feeds. Besides the total ash determinations, the proportions of lime, phosphoric acid, and insoluble ash are tabulated. The market price of each feeding stuff is listed. An estimate of the actual monetary value of the ingredients of the mixed feeds indicates that the price asked for these is unduly high.

**Carrying capacity of ranges in western United States**, R. L. HENSEL (Ames Forester, 5 (1917), pp. 45-49).—Accessibility to water, topography, character of vegetation, prevalent diseases, local farming conditions, and extent of use are discussed as factors in determining the carrying capacity of a range.

The cattle industry of the Southeast, G. M. ROMMEL (*Producer*, 1 (1919), No. 6, pp. 9–12, figs. 5).—It is predicted that with the cattle tick eradicated the southern part of the United States, east of the Mississippi River, will become a very important cattle-growing region, partly because of an increasing demand for beef and partly because of the beneficial effect of the manure on the cotton crop.

The investigations of the Bureau of Animal Industry of the U. S. Department of Agriculture during the past 15 years (E. S. R., 41, p. 565) indicate in the author's opinion that the two most profitable methods of producing beef in the South are (1) to feed steers cottonseed meal on pasture, and (2) to feed calves for baby beef during the winter following weaning with a ration made up of silage, cottonseed meal, and other available feeds, but not corn except where the price is low.

Cattle industry, J. C. J. COOPE (Rhodesia Munitions and Resources Com. Rpt. 1918, pp. 45-55).—This article deals with the status of the beef cattle industry in Rhodesia. Available native feeding stuffs and common cattle diseases in the region are listed.

Some camel feeding experiments, H. E. CROSS (Agr. Research Inst. Pusa Bul. 77 (1918), pp. 8).—Experiments as to the amounts of various feeds that camels will consume are reported to show that the Indian Government's ration of 16 lbs. per day of a mixture of wheat and pea-straw is insufficient to maintain a camel.

**Domestication of animals in Peru**, O. F. COOK (*Jour. Heredity*, 10 (1919), No. 4, pp. 176–181, figs. 3).—Notes are given as to the degree to which the llama, the alpaca, the huanacu, the vicuña, and the guinea pig are under domestication in Peru, together with suggestions as to the part played by domestic animals in the highly developed agriculture of the prehistoric Peruvians.

Making money from hens, H. R. LEWIS (*Philadelphia and London: J. B. Lippincott Co., 1919, pp. 217, pls. 12*).—The scope of this book and the method of treatment are indicated by the following chapter headings: Chances with chickens; the riddle of the breeds; beginning with the incubator; beginning with the baby chick; critical days in the brooder; the secret of better chickens; the open-front poultry house; fuel for the egg factory; healthy hens; how to tell the good hen; the truth about the lighting problem. The "secret" of better chickens is to provide feeds rich in vitamins. Much of the material has appeared in somewhat different form in the series of leaflets known as Hints to Poultrymen, issued by the New Jersey Experiment Stations and noted from time to time.

Fall poultry problems, H. R. LEWIS (*New Jersey Stas. Hints to Poultrymen*, 7 (1919), No. 12, pp. 4).—The topics briefly discussed are the culling of the flock in the fall, the problems of sanitation, housing, and feeding during the fall and winter months, and the use of artificial illumination to stimulate egg production.

Feeding hens for egg production, H. M. LAMON and A. R. LEE (U. S. Dept. Agr., Farmers' Bul. 1067 (1919), pp. 15, figs. 5).—Information is summarized as to the composition of poultry feeding stuffs, suitable rations for laying hens, and methods of feeding. Rations are recommended on the basis of the experiments reported in Department Bulletin 561 (E. S. R., 37, p. 871).

Egg laying contests.—I, Sixth annual international egg-laying contest.— II, Report of the seventh competition and some five-year averages, W. F. KIRKPATRICK and L. E. CARD (*Connecticut Storrs Sta. Bul. 100 (1919)*, pp. 71, figs. 25).—This bulletin presents detailed reports of the annual egg-laying contests held at Storrs, Conn., in 1916–17 and 1917–18, and also averages the egg records, feed consumption, costs and profits of the third to seventh contests. Reports of the fifth and preceding competitions have been noted (E. S. R., 37, p. 368).

The simplified feed mixtures adopted for the fifth contest were used during the sixth and seventh and are regarded as very satisfactory. The feeds available for the seventh were of lower grade than those used in the sixth and the difference is reflected in a higher feed consumption per pound of eggs. In spite of the increased cost of feed in recent years, the difference between receipts and feed costs per dozen eggs has steadily increased in successive contests. Two charts present separately for the White Leghorns, Wyandottes, Plymouth Rocks, and Rhode Island Reds entered in the five most recent contests, the average egg production during each week of the year.

The best individual egg record in the seven years of the contests was made by a white Wyandotte which laid 308 eggs during the year 1917–18. It is stated that there are only two other trap-nest records of 300 or more eggs in all the egg-laying competitions in the United States and Canada.

Final report of the fourteenth egg-laying competition, C. Ports (Queensland Agr. Jour., n. ser., 9 (1918), No. 6, pp. 213-225, figs. 10).—This is a report on the annual Queensland Agricultural College egg-laying contest which closed March 31, 1918, and covers the same general ground as the report of the preceding contest already noted (E. S. R., 38, p. 173). A group of 6 birds was entered by each of 73 competitors. The egg records by months of each group and the annual production of the individual hens in 20 of the groups where the birds were housed separately are tabulated. The records by months of the latter hens may be found in the successive monthly issues of the Journal during the progress of the competition. The average weights per egg of the eggs laid in each group pen and by each single test hen are also recorded.

The average egg production was the lowest obtained during the 14 years of the contests, due partly to cold weather and excessive rainfall in the spring and partly to poor quality of the available feeding stuffs. It is stated that a good grade of shorts was unprocurable. The highest individual record was made, however, in the course of this contest, 334 eggs having been laid by a Black Orpington. Her eggs averaged 1.75 oz. per egg, which was below the minimum required for a prize.

Final report of the fifteenth egg-laying competition, Queensland Agricultural College (*Queensland Agr. Jour.*, 11 (1919), No. 5, pp. 183–194).—This contest was concluded March 31, 1919. The number of hens entered was 390, of which 240 were single tested. The records are tabulated as noted above for the preceding contest. Drought, a poor grade of wheat, and an unavoidable lack of green feed reduced the number of eggs secured and their average weight below what was expected on the basis of past performance.

A convenient method of indicating the time element in giving a hen's record, H. D. GOODALE (Jour. Amer. Assoc. Instr. and Invest. Poultry Husb., 5 (1919), No. 5, p. 37).—As a compact expression for a pullet's egg production from the date of first egg to the pause in egg laying during the second summer or fall, the author suggests a symbolic fraction with the number of eggs as the numerator and the number of days in the period as the denominator.

Fertility experiments, B. F. KAUPP (Jour. Amer. Assoc. Instr. and Invest. Poultry Husb., 5 (1919), No. 7, pp. 53, 54).—The cocks were removed from flocks of hens (13 different varieties) at the North Carolina Experiment Station. Egg fertility remained approximately normal for three days and then dropped steadily. No fertile eggs were secured after the eleventh day. When the cocks were returned, normal fertility was attained after five days. The detailed records of the White Leghorn flock are tabulated.

The results of single, one-day matings, J. H. MARTIN and W. S. ANDERSON (*Jour. Amer. Assoc. Instr. and Invest. Poultry Husb.*, 5 (1918), No. 3, pp. 22, 23).—A vigorous Single Comb White Leghorn cock was allowed to tread 34 hens in less than 9 hours. The hens had all been isolated from males for some time. Ten of the matings led to fertile eggs. The shortest interval between mating and the appearance of fertilized eggs was 29 hours 23 minutes. The longest interval was 6 days.

Note on the behavior of capons when brooding chicks, H. D. GOODALE (*Jour. Anim. Behavior*, 6 (1916), No. 4, pp. 319-324).—The brooding habits of 2 Rhode Island Red and 3 Brown Leghorn capons at the Massachusetts Experiment Station are described.

Both kinds cared for young chicks satisfactorily, led them about, scratched up feed for them, and called them by clucking. The marked differences between the two breeds with respect to the broodiness of hens was not reflected in the behavior of these capons, in fact the Leghorn capons were perhaps better caretakers than the Rhode Island Reds.

"Obviously, until more studies have been made of the behavior of fowls, the brooding instinct of the capon can not be cited as proof of the assumption of a female secondary sexual character by a castrated male."

**Concerning artificial lighting**, G. R. SHOUP (*Washington Sta.*, *West Wash. Sta.*, *Mo. Bul.*, **?** (1919), *No.* **?**, *pp. 106–110*).—Advice is given as to the handling of a poultry flock when artificial illumination is used in winter to increase egg production.

Cottonseed hulls, a sanitary and vermin-proof litter for poultry, M. B. TABENHAUS (Jour. Amer. Assoc. Instr. and Invest. Poultry Husb., 5 (1918), No. 3, pp. 23, 24).—The following advantages are claimed for cottonseed hulls as a litter in poultry houses: (1) Little dust is produced, (2) moisture does not penetrate it easily, and (3) droppings become covered with small particles of hulls and thus do not decompose readily and are not flattened out on the floor. The author's observations were made in Texas.

### DAIRY FARMING-DAIRYING.

Calf feeding experiments: Corn silage; whole milk dilutions, G. C. WHITE and J. A. KUELLING (Connecticut Storrs Sta. Bul. 102 (1919), pp. 91-136).— To study (1) the desirability of introducing corn silage into the ration of dairy calves early in life, (2) the results of substituting whole milk diluted with water for skim milk, and (3) the feeding of a commercial calf meal in conjunction with silage, 32 calves (dairy breeds, males and females) divided into 10 groups were put on experiment with the intention of feeding them for 180 days. The calves were mostly a week or so old when the experiments began. Those that were to get the silage were allowed it as soon as they would eat it. All calves received undiluted whole milk for the first 2 to 4 weeks according to circumstances. The normal amount of skim or diluted milk given daily was 14 lbs. per head. The following tabulation gives the details of the feeding

158071°-No. 9-20-6

and growth of the calves in the groups which were carried through the full period, except the calf-meal group:

Results from feeding silage or diluted whole milk or both to dairy calves from shortly after birth until about the age of 6 months.

<sup>1</sup> Limited.

Groups 1 to 4 were begun in May, 1915, and the others in 1916. The grain mixture in 1915 consisted of corn meal, crushed oats, and wheat bran (2:2:1). Group 5 received the same except that "hominy" was substituted for corn meal. "Hominy," ground oats, red dog, and blood meal (3:3:1:1) constituted the grain mixture given to groups 8 and 10. The blood meal was added because of the great dilution of milk in these groups compared with group 4. In the case of group 10, 2.5 parts of linseed meal replaced the one part of blood meal for 35 days toward the end of the experiment. The hay was composed of mixed grasses with some clover or alfalfa. The milk used in the dilutions contained about 5 per cent fat. The silage fed most of the time contained over 75 per cent moisture. Proximate analyses of 8 samples of silage are reported. Costs are computed on a 1915–1916 and on a December, 1917, basis of prices.

More or less scouring occurred in practically all groups, and it was particularly noticeable in group 2 which received silage, but no grain or hay. Feeding silage before the age of 2 or 3 months is not considered desirable because it widens the ration and increases the chance of scouring. In the later months the calves relished the silage, and often ate it before drinking their skim milk.

"The diluted whole milk groups proved more expensive than the skim milk groups, but gains were produced at a price low enough so that such a practice would prove practical on a whole milk market farm, since it eliminates the investment in a separator and the labor involved in separation." Of the diluted milk groups, group 10 (which also received silage) was the most satisfactory from the standpoint of gains and costs. Group 7 (diluted milk) was not continued on experiment because some of the feeds desired were not available. Group 9 consisted of 2 calves fed diluted milk in which some of the grain was mixed. The calves scoured badly and the experiment was discontinued. The ill-success is attributed in part to the method of feeding. "The usual coagulation by the rennin is probably interfered with."

The calves of group 6 received a proprietary calf meal with silage, grain and hay. After a few weeks all whole milk was withdrawn. No skim milk was fed. Four calves started and 2 completed the test. The average gains of the latter were 0.91 and 0.73 lbs. per day, respectively. Digestion troubles were encountered. Silage and calf meal is not considered a desirable mixture for young calves.

872

The feeding of oats to calves, J. HANLY (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 18 (1918), No. 3, pp. 306, 307).—The results of 6 different tests involving 42 calves, in which half the calves were fed crushed oats and the other half a prepared meal (corn meal, oat meal, and crushed flaxseed, 2:2:1), are summarized. Both groups received skim milk or buttermilk. The average daily gains per calf were 1.47 lbs. for the oats-fed lots and 1.39 lbs. for the meal-fed lots. In these experiments the meal was not steeped or cooked as in those previously noted (E. S. R., 37, p. 873). Like the oats it was mixed directly with the milk at the time of feeding.

A single test comparing whole oats with uncooked meal, each mixed with separator skim milk, is also reported. Throughout the trial, which lasted 127 days, the calves were grazed together on "medium pasture." The calves were 4 to 5 weeks old at the start and averaged 105 lbs. in weight. The average daily gain of the three oats-fed calves was 1.63 lbs. and of the three meal-fed calves 1.48 lbs.

A study of the relative reliability of official tests of dairy cows, W. W. YAPP (*Illinois Sta. Bul. 215, abs. (1919), pp. 4, figs. 3*).—The complete edition of this bulletin has been noted (E. S. R., 40, p. 773).

Dairying industry, J. C. J. COOPE (*Rhodesia Munitions and Resources Com. Rpt. 1918, pp. 30–35*).—Butter making in Rhodesia and the relation of dairy farming to soil fertility are discussed.

A system of Cheddar cheese manufacture suitable for Rhodesian farm conditions, J. C. J. Coope (*Rhodesia Munitions and Resources Com. Rpt. 1918, pp.* 26-29, 29a, 29b).—The Cheddar cheese process is considered the only one adapted to the warm climate of Rhodesia. The process of making cheese of the Cheddar type from whole milk under somewhat primitive farm conditions is outlined.

A study of the eye formation of Emmental cheese, W. M. CLARK (*Centbl.* Bakt. [etc.], 2. Abt., 47 (1917), No. 10-15, pp. 230-244, figs. 2).—Previously noted from another source (E. S. R., 37, p. 875).

## VETERINARY MEDICINE.

Annual report for 1918 of the principal of the Royal Veterinary College, J. McFADYEAN (*Jour. Roy. Agr. Soc. England*, 79 (1918), pp. 229-240, figs. 3).— This report deals with the occurrence of diseases of live stock during the year, including anthrax, glanders, sheep scab, hog cholera, foot-and-mouth disease, rabies, parasitic mange in horses, and abortion in mares.

The fifth and sixth reports of the director of veterinary research, A. THEILER (Rpts. Dir. Vet. Research, Union So. Africa, 5-6 (1918), pp. 812, figs. 72).—The papers here presented in these, the usual reports (E. S. R., 35, p. 678), are as follows: Acute Liver Atrophy and Parenchymatous Hepatitis in Horses, by A. Theiler (pp. 9–164); Itestinal Invagination, Intussusception, in Sheep (Reckziekte or Knopderm) (pp. 165–186) and The Occurrence of Dourine (Slapziekte) in South Africa, both by J. Walker (pp. 187-206); Anthrax in South Africa, by D. Kehoe (pp. 207-253); Investigations into Lamziekte in Cattle (pp. 255-320) and Preliminary Report on the Harmful Effects of "Steek" Grass on the General Health and Condition of Sheep (pp. 321-333), both by P. R. Viljoen; Contagious Abortion of Cattle in South Africa, by E. M. Robinson (pp. 335-373); Chemotherapy of Haemonchosis in Sheep, by F. Veglia (pp. 375-482); The Fate of Ingested and Injected Arsenic in Sheep, with Special Reference to Treatment of Haemonchosis (pp. 483-538) and The Microtitration of Arsenic (pp. 539–550), both by H. H. Green; The Effects of Arsenite of Soda Dipping Fluids on Working Oxen, by D. T. Mitchell (pp. 551591); Isolation and Description of a Bacterium Causing Oxidation of Arsenite to Arsenate in Cattle Dipping Baths (pp. 593–610) and Description of a Bacterium, Isolated from a Cattle Dipping Tank, which Reduces Arsenate to Arsenite (pp. 611–624), both by H. H. Green; Notes on the Species of Gastrophilus Found in South Africa, by G. A. H. Bedford (pp. 625–648); Notes on the Intoxication by Gastrophilus Larvæ, by G. van de W. de Kock (pp. 649–694); A New Nematode in Fowls, Having a Termite as an Intermediary Host [*Filaria* gallinarum n. sp.], by A. Theiler (pp. 695–707); Anoplura from South African Hosts (pp. 709–736) and New Culicine Larvæ from the Transvaal (pp. 737– 749), both by G. A. H. Bedford; and The Deficiency Aspect of Maize Products (pp. 751–774) and Upon the Quantitative Relationship between the Antineuritic Value of a Diet and the Onset of Polyneuritis (pp. 775–812), both by H. H.

**Report of the civil veterinary department, Assam, for the year 1918–19,** W. HARRIS (*Rpt. Civ. Vet. Dept. Assam, 1918–19, pp. 2+15+2).*—The usual report (E. S. R., 40, p. 380).

Annual report of the civil veterinary department, United Provinces, for the year ending March 31, 1919, E. W. OLIVER (Ann. Rpt. Civ. Vet. Dept. United Provs., 1919, pp. [6]+19).—The usual report (E. S. R., 40, p. 284).

A manual of bacteriology, R. T. HEWLETT (London: J. & A. Churchill, 1918, 6. ed., pp. X+769, pls. 31, figs. 69).—In the present edition of this manual of bacteriology, an earlier edition of which has been previously noted (E. S. R., 14, p. 491), the text has been revised throughout and much new material has been introduced, including considerable additions to the sections dealing with anaphylaxis, agglutination, and immunity. The chapter dealing with anaerobic organisms has been enlarged to include an account of the relation of this group of organisms to war injuries.

Heterolysins, II, A. SORDELLI and G. FISCHER (*Rev. Inst. Bact. [Argentina*], 2 (1919), No. 2, pp. 201-210).—Continuing the investigation previously noted (E. S. R., 40, p. 578), the authors have found heterolysins in the organs of the wild and domesticated guinea pigs and in guinea pig and chicken sarcomata. Rat sarcomata and carcinomata did not contain heterolysins.

The influence of desiccation on certain normal immune bodies, H. T. KARS-NER and K. R. COLLINS (*Jour. Infect. Diseases, 25 (1919), No. 5, pp. 427-432).*—A comparative study is reported of the effects on the normal antibodies in the blood of horses and goats of drying in the air, or in vacuo over sulphuric acid at room temperature, and freezing and drying over sulphuric acid in vacuo. The results obtained are summarized as follows:

"The normal antibodies in the serum of the horse and goat are gradually decreased by drying. The agglutinins and hemagglutinins are less affected by drying if the serum is frozen while desiccation is going on. The loss of titer in the nondialyzed serum takes place within the first ten days, while it is delayed in the dialyzed serum until after the twentieth day. The decrease of agglutinins in the dialyzed serum is uniform for all methods of drying until after two months, while in the nondialyzed serum the loss is greater in the serum that was not frozen and still greater in the serum dried in the air. The pH of dried serum is slightly greater than in the original serum, and as the loss of agglutinins becomes greater the difference is more marked. Dried serum dissolved and dried again shows definite changes in the formation of crystals."

Notes concerning the concentration of antitoxic sera, A. SORDELLI (*Rev. Inst. Bact.* [*Argentina*], 2 (1919), No. 2, pp. 211–214).—The author reports excellent results obtained in the concentration of antitoxic sera by the Homer method previously noted (E. S. R., 40, p. 287). Concentrations of the plasma

Green.

to one-fifth the original volume have been obtained which filtered easily, contained relatively little protein, and represented a loss of material not exceeding 10 per cent.

The production of antiserum for agglutination tests, F. H. K. REYNOLDS and J. F. HILL (Jour. Infect. Diseases, 25 (1919), No. 5, pp. 412, 413).—The authors have found that washing in sterile salt solution the killed suspensions of bacteria which are used for the production of immune serum rids the suspensions of certain toxic materials and facilitates the production of antiserum.

Phenolut, a colloidal cresol solution as a disinfectant, W. SCHÜRMANN (*Ztschr. Hyg. u. Infektionskrank.*, 84 (1917), No. 1, pp. 14-32).—The author describes a new colloidal cresol preparation "phenolut" which is said to contain no soap or resin, to have a cresol content of 40 per cent, and to form a clear 4 per cent solution in water. Tests of the comparative value of phenolut and lysol as disinfectants are reported, which indicate that the phenolut is as powerful a disinfectant as lysol.

Anaplasma marginale.—Jolly bodies in anemic blood; anaplasmatic forms of piroplasms, G. DI DOMIZIO (Clin. Vet. [Milan], Rass. Polizia Sanit. e Ig., 42 (1919), Nos. 7, pp. 203-220, figs. 2; 8, pp. 237-251; 9-10, pp. 292-311, pls. 2; abs. in Trop. Vet. Bul., 7 (1919), No. 3, pp. 152-155, pl. 1).—The author's conclusions are as follows:

"There exists among goats in the colony of Eritrea an intracorpuscular blood parasite which in all probability represents a species belonging to the genus Anaplasma (A. ovis). The researches and observations upon which various authors have based doubts upon the parasitic nature of anaplasms have maintained that they were nuclear fragments (Jolly bodies) or, on the other hand, stages in the life cycle of some piroplasms, do not detract from the value of Theiler's and Lignières's experiments, which demonstrated the existence of a new genus of parasite named by Theiler Anaplasma.

"The morphology described as characteristic of *A. marginale* (and its variety *centrale*) and of *A. argentinum*, as described by Theiler and Lignières, is distinguishable from that of the Jolly bodies found in anemic blood. The considerably higher percentage of the red corpuscles invaded with marginal points is of especial importance in this connection. These anaplasms are also distinguishable from the so-called anaplasm-like forms of piroplasms, inasmuch as a greater percentage of corpuscles is invaded with marginal points, and these points are quite spherical in form and each has sharply defined borders.

"Some authors in descriptions of alleged marginal points, examined singly, have pictured them as having irregular and indistinct borders (like those of the anaplasm-like forms of piroplasms), but the general aspect of true anaplasms leaves no room for doubt.

"Although Anaplasma has only been observed as a well-defined entity among bovines in South Africa and Argentina, the collective observations and researches of many authors appear to show that (a) these bodies exist not only in bovines but also in other animals, (b) very probably there exist several species or varieties of anaplasms not only in various species of animals but also in the same species of animal, (c) these various species or varieties, although conforming morphologically with typical Anaplasma, present slight differences in form."

A list of 58 references is appended.

The antigen of Bacillus anthracis, C. C. WARDEN and J. T. CONNELL (Jour. Infect. Diseases, 25 (1919), No. 5, pp. 399-411).—Following the methods previously employed in the study of fats as antigens (E. S. R., 40, p. 676), a tentative analysis of the fatty complex of the anthrax bacillus was made which indicated its composition to be approximately as follows: Caprylic acid 10, capric 25, oleic 60, and palmitic 5 per cent. A synthetic antigen prepared from the above proportions of purified acids and stabilized by the addition of a trace of egg lecithin, proved to be specific for *B. anthracis*. Guinea pigs and rabbits injected with large doses of the sterile artificial anthrax antigen regularly developed anthrax infection from anthrax spores of low virulence injected with the baled hay. Small doses of the antigen raised the resistance of the animals against infection with a highly virulent strain of anthrax organisms. Proteins isolated from anthrax bacilli did not act as antigens.

The Australian epidemics of an acute polioencephalomyelitis (X disease), J. B. CLELAND, A. W. CAMPBELL, and B. BRADLEY (*Rpt. Microbiol. Lab.* (*Govt. Bur. Microbiol.*) [*N. S. Wales*], 8 (1917), pp. 150–280, pls. 10).—This paper reports investigations of a severe disease with cerebral symptoms and with a mortality of about 70 per cent, which appeared in certain districts of New South Wales in the late summer and autumn of 1917 and again a little earlier in the year 1918. Outbreaks of a similar disease have occurred in the Goulburn Valley in Victoria, in Brisbane, and in Western Queensland, and in the Townsville district.

The authors' studies have led to the conclusion that the disease is a distinct clinical entity. The virus responsible for it is evidently closely related to that causing ordinary acute poliomyelitis, but is either specifically distinct or a more recent irritant apparently breeding true. It has been conveyed by intracerebral inoculations to monkeys, sheep, a calf, and a horse, but there is no evidence of its occurring in animals or of animals acting as a reservoir of the virus, or of the disease being conveyed by an intermediate host from human being to human being. The possibility of the occurrence of an intermediate (invertebrate) host of the virus is discussed.

Glycerinated rinderpest vaccine, C. KAKIZAKI (*Kitasato Arch. Expt. Med.* [*Tokyo*], 2 (1918), No. 1, pp. 59–66).—An investigation of the immunizing power of glycerinated rinderpest vaccine, prepared from defibrinated infected blood and from an emulsion of infected spleen, is reported.

The virulence of the glycerin blood extract was destroyed by standing for 20 days at a temperature of from 18 to  $22^{\circ}$  C. and for 80 days at temperatures lower than 15°, while that of glycerinated spleen required 60 days at temperatures of from 15 to  $29^{\circ}$  and more than 90 days at lower temperatures. Double vaccination with a total amount of from 20 to 30 cc. of the vaccine proved sufficient to protect the Korean cattle employed in the experiments from further infection by virulent blood.

Report of bacteriological investigation of tetanus carried out on behalf of the War Office Committee for the study of tetanus, W. J. TULLOCH (Jour. Hyg. [Cambridge], 18 (1919), No. 2, pp. 103-202, figs. 17).—This report deals with bacterial research on tetanus along the following lines: Inquiries into the occurrence of the various types of *Bacillus tetani* in the wounds of men suffering from tetanus and of those showing no evidence of the disease; experiments in vitro to determine whether immune sera, prepared by inoculation of whole cultures into animals, contain antibodies other than agglutining specific to the different types of the bacilli; experiments in vivo to examine the problem of infection with B. tetani as contrasted with intoxication due to absorption of the products of that organism; the influence which various surgical procedures exert upon infection of wounds due to anaerobic bacteria; attempts to diagnose tetanus and to determine the type of the infection by means of an agglutination reaction; a study of the possible relationship which may exist between the serological type of a tetanus bacillus and the hemagglutinating type of the individual from whom it was isolated; a discussion of two cases of abdominal

tetanus; and the results obtained in an examination of human feces to determine the prevalence of the various types of *B. tetani* in the human intestine.

From 20 per cent of wounds of men who showed no evidence of tetanus, B. *tetani* could be recovered at some period during the process of repair. Evidence was given which indicated that the serum prophylaxis in use until recently afforded more protection against Type I infections than it did against infections due to Type II or III. The experiments in vitro led to the conclusion that in whole cultures of B. tetani three antigens at least appear to exist: (1) The bacillary substance itself, the inoculation of which leads to the development of agglutining which are specific to the types; (2) an antiphagocytic antigen which is present in young unfiltered cultures, but if present at all is found only in small quantity in filtrates and which evokes the development of "opponing" which are specific to the types; and (3) a spasm-producing toxin. an antigen which is filterable and which in laboratory animals, at least, does not appear to be specific to the types. "These findings suggest that improvement might be looked for in serum prophylaxis and serum therapeutics from the employment of sera possessing antibacterial as well as antitoxic properties," The experiments in vivo led to the following conclusions:

The toxin of *B. welchii* and to a less extent that of *Vibrion septique* when used in sublethal doses produce sufficient devitalization of tissue to allow of the development of tetanus infection. Antitoxins to the products of these organisms protect animals against infection with *B. tetani* when such products are used as tissue debilitants.

The protection afforded by tetanus antitoxin can only be partial. The nature of the substance used to produce devitalization of tissues exerts a profound influence upon the development of tetanus spores in the tissues. Certain other relationships, the nature of which is at present not determined, appear to depress the infectivity or toxogenicity of certain strains of *B. tetani*. The experiments suggest, but do not prove, that while monovalent antitoxic sera exert no specific neutralizing influence on the spasm-producing toxin of any one type of tetanus they may exert a specific anti-infective influence. Equivocal results were obtained in the investigation of the relative value of antitoxic and antibacterial sera.

The antiseptic dressings examined were found to exert but little influence upon the anaerobic flora of wounds, but excision of the wound area, irrespective of the dressings employed in the treatment, exerted a beneficient influence.

It was found impossible to use the agglutination test as an aid to the diagnosis of tetanus, and no relationship was found to exist between the serological type of *B. tetanus* and the hemagglutinating type of the individual from whom it was isolated.

The growth of Bacillus tetani in the presence of tuberculin, F. MARINO (*Compt. Rend. Soc. Biol.* [*Paris*], 82 (1919), No. 22, pp. 821-824, 831, 832).— Three papers are presented.

**I.** Method for the determination of tuberculin (pp. 821, 822).—A method for the quantitative determination of tuberculin is described which depends upon the fact that *B. tetani* is very sensitive to tuberculin. The details of the process are as follows:

The culture to be tested is filtered, 10 cc. of the filtrate is inoculated with B, *tetani*, and the air in the tube exhausted. If the tetanus bacillus does not grow, the filtrate contains at least 1 mg. of tuberculin per cubic centimeter of the liquid. Under these conditions the exact strength of the tuberculin can be determined by putting in 10 test tubes gradually increasing amounts of from 1 to 10 cc. of the filtrate, making up the volume to 10 cc. with ordinary bouillon,

#### 1919]

and inoculating each tube with B. tetani and evacuating as before. The strength of the tuberculin can be calculated from the amount used in the first tube in which no growth takes place.

II. Determination of the antitoxic power of antituberculous serums (pp. 823, 824).—Using the method noted above for determining the strength of tuberculin, it was found that normal and antituberculous serums in general neutralize tuberculin to the same degree, but that occasionally the normal serum has a stronger neutralizing power than the specific serum. Three theories are suggested to account for this: (1) The antituberculous serum may contain free tuberculin, (2) the organism of immunized animals is weakened by injections of tuberculous cultures and no longer has the power of forming the same quantity of diastases as do normal animals, and (3) the organism under the prolonged toxic action of tuberculous cultures produces substances which have the property of weakening the diastases which attack and transform tuberculin.

III. [Comparison of human, bovine, and equine tubercle bacilli] (pp. 831, 832).— The amount of tuberculin in cultures of human and bovine tubercle bacilli was found by the tetanus bacillus test to be greater than that in cultures of the corresponding equine bacilli. The repeated passage of the equine bacilli through rabbits renders it as virulent and of as high a tuberculin content as human and bovine tubercle bacilli.

The author concludes that the tuberculin strength is always proportional to the virulence of the tubercle bacilli, and that human, bovine, and equine tubercle bacilli do not constitute different races of bacilli but different species of bacilli belonging to the same race.

Methods of detecting tuberculosis in cattle, J. J. LINTNER (Creamery and Milk Plant Mo., 8 (1919), No, 5, pp. 36, 37).

Accredited herds, F. TORRANCE (Agr. Gaz. Canada, 6 (1919), No. 11, pp. 953, 954).—The author presents regulations for the establishment and maintenance of tuberculosis-free accredited herds of cattle as fixed by an Order in Council dated September 20, 1919.

Bovine "aphticelle," BÉDEL (*Rev. Gén. Méd. Vét.*, 28 (1919), *No.* 325, *pp.* 12–17).—The author describes an affection of cattle from the evacuated district of France which differs from foot-and-mouth disease and is thought to represent a new disease.

Cattle fever ticks and methods of eradication, W. P. ELLENBERGER and R. M. CHAPIN (U. S. Dept. Agr., Farmers' Bul. 1057 (1919), pp. 32, figs. 5).—The first part of this publication (pp. 3–21), which deals with tick eradication, its progress and importance, life history of the tick, and methods of eradication, is based upon Farmers' Bulletin 498 by Graybill (E. S. R., 27, p. 579) and Bureau of Animal Industry Circular 207 by Graybill and Ellenberger (E. S. R., 28, p. 181), which it supersedes. The second part (pp. 21–32) contains information on arsenical dips by Chapin, and supersedes Farmers' Bulletin 603 (E. S. R., 31, p. 776) by the same author.

An epizootic caused by trypanosomes in cattle in French Guiana, M. LEGER and M. VIENNE (Bul. Soc. Path. Exot., 12 (1919), No. 5, pp. 258-266; abs. in Rev. Appl. Ent., Ser. B., 7 (1919), No. 9, p. 137).—The authors conclude that the trypanosome which infects cattle in the natural state, and cattle only, in French Guiana, is a new species for which the name Trypanosoma guyanense is proposed.

On the life history of the lungworm, Dictyocaulus filaria, in sheep, J. E. GUBERLET (*Jour. Amer. Vet. Med. Assoc.*, 55 (1919), No. 6, pp. 621-627).—This is a preliminary report of investigations conducted at the Oklahoma Experiment Station, in which the present status of knowledge of the parasite is reviewed.

The relative potency of tail bled and carotid bled antihog cholera serum, E. A. CAHILL (Jour. Amer. Vet. Med. Assoc., 56 (1919), No. 2, pp. 177-185).— This is the report of an investigation of the relative value as determined by potency tests of the following methods of bleeding for hog cholera serum: (1) Carotid bleeding preceded by 3 tail bleedings 7 days apart, all within a period of 38 days from the date of hyperimmunization; (2) carotid bleeding preceded by one tail bleeding 7 days apart, both bleedings within 17 to 21 days from the date of hyperimmunization; (3) carotid bleeding only in from 10 to 14 days after the date of hyperimmunization; and (4) tail bleeding 3 or 4 times within 38 days, after which the animals are injected with more antigen and subjected to a second series of bleedings.

The potency tests, which were conducted as prescribed by the Bureau of Animal Industry, U. S. Department of Agriculture, for the testing of hog cholera serum, indicated that there is apparently no difference in the relative potency of hog cholera serum obtained from any of the four bleedings described above, and that "the circulating blood of hogs properly hyperimmunized against hog cholera retains its potency without the injection of additional antigen for at least 38 days regardless of whether the animal is bled one, two, three, or four times."

The present status of hog cholera control, A. EICHHORN (Jour. Amer. Vet. Med. Assoc., 56 (1919), No. 1, pp. 51-59; also in Amer. Jour. Vet. Med., 14 (1919), No. 9, pp. 465-470).—This is a general discussion of hog cholera, its relation to other diseases of hogs, and measures for its control.

It is emphasized that while lesions produced by other organisms are new occurring with greater frequency in hogs, an effective and successful control of hog cholera would result in a very pronounced decrease in other infections. Vaccination, with a clear sterilized serum and virus free from all possible contamination, is considered by the author to be the foundation of the control of hog cholera.

An estimate of the number of cysts in a case of pork measles, M. C. HALL (*Jour. Amer. Vet. Med. Assoc.*, 56 (1919), No. 1, pp. 71, 72).—This is a brief account of a case of pork cysticercosis found in a young animal at the abattoir at Rosslyn, Va. The carcass, which with head and viscera removed weighed 56 lbs., was estimated to contain 190,470 cysts.

Horse sickness in the Belgian Kongo, R. VAN SACEGHEM (Bul. Soc. Path. Exot., 11 (1918), No. 5, pp. 423-432; abs. in Internatl. Inst. Agr. [Rome], Internatl. Rev. Sci. and Pract. Agr., 10 (1919), No. 1, p. 80).—The author found that "heartwater of sheep produces horse sickness but can not be transmitted to cattle. The virus of horse sickness gives feverish reactions in goats and sheep. The virus of horse sickness and that of heartwater appear to be two varieties of the same virus. Horse sickness was propagated at Sambi especially by Culicoides and Tabanus."

Joint-ill and its treatment with serum from the blood of the mother, MANN (*Ztschr. Veterinärk.*, 29 (1917), No. 3, pp. 65–81).—The author reports excellent results obtained in the treatment of joint-ill of foals with blood serum from the mother, and even better results in the use of the serum as a means of immunizing foals against the disease. As an immunizing agent the serum was injected intravenously in amounts of from 400 to 500 cc. or, if the animal was very restive, from 250 to 300 cc. was injected intravenously and a like amount subcutaneously in both sides of the neck.

Tables are given of 36 cases of joint-ill treated with serum and of 12 cases in which the serum was used for producing immunization. In the former 86.4 per cent of the animals recovered and in the latter there was no loss or injury, the disease developing in only 8.3 per cent of the cases and then in a light form which was cured in a short time.

The treatment of sarcoptic mange in the horse, M. A. VAN DEN EECKHOUT (Ann. Méd. Vét., 64 (1919), No. 3-4, pp. 112-115; abs. in Rev. Appl. Ent., Scr. B, 7 (1919), No. 8, p. 136).—In treating this parasite the author recommends the application of an ointment consisting of carbonate of soda, water, brown soap, sulphur, and creolin one part by volume of each. This is rubbed in by means of a hard brush so as to penetrate through the skin into the burrows, each treatment to continue for about 30 minutes, after which the horse should be well washed down with clean water and dried. The treatment should be repeated four times with intervals of 3 to 4 days.

Bacillary white diarrhea of young chicks.—VII, Ovarian infection of the adult fowl and transmission of the disease through the oviduct, L. F. RETT-GER, W. F. KIRKPATRICK, and L. E. CARD (*Connecticut Storrs Sta. Bul. 101* (1919), pp. 73–88).—In continuation of the investigation of bacillary white diarrhea previously noted (E. S. R., 37, p. 383), the problem of the prevention of the continued spread of ovarian infection through the breeding stock has been considered in the present study.

To determine whether the introduction of the organism of bacillary white diarrhea into the cloaca and oviduct of laying hens may lead to permanent ovarian infection, and to demonstrate whether the male plays the important rôle of transmitting the infection from infected to hitherto sound hens, two sets of experiments were conducted with adult fowls which had previously been found to be free from *Bacterium pullorum* infection. In the first experiment four groups of 18 well-matured Rhode Island Red pullets were housed permanently in separate thoroughly disinfected houses and treated as follows: One lot serving as check was left uninfected, while the other three lots consisted of 9 hens artificially infected, and 9 uninfected, one without male and the other two with males. The infection was produced by oviduct injections of from 0.5 to 1 cc. of a 24 to 48 hour broth culture of *B. pullorum*. A second inoculation of the same individuals was made one month later, following which three sets of agglutination tests were made. The birds were killed and examined five months after the first inoculation.

The second series of experiments was conducted along similar lines, three sets of 20 White Leghorn hens each being used, a check lot uninoculated, and two lots consisting of half inoculated and half uninoculated, one set without male and one with male added late in the experiment. The inoculation was made with a culture of *B. pullorum* similar to that of the first experiment but in this case diluted with an equal volume of physiological salt solution before measurement.

In the first series, practically all of the infected hens reacted promptly to the agglutination test, while with a single exception, none of the untreated lot reacted. In the second series, while the percentage of positive reactors was smaller than in the first, the relative number of permanently infected hens was much larger. The negative results of the agglutination tests and ovarian examination of hens of the check lot and of those associated with the inoculated hens are considered of significance as indicating that transmission of infection from hen to hen through infected litters and by ordinary association is rare. No definite conclusions could be drawn concerning the part played by the male in the transmission of the infected organism, but it is thought that this method of transmission can no longer be doubted.

In conclusion the authors advise that "as a practical means of preventing the spread of *B. pullorum* infection from hen to hen, and thus making the
disease as it affects adults stationary within the flock, males should not be allowed to run with the females except during the breeding season. The adoption of this policy can work no injury, and may contribute very much to the ultimate elimination of bacillary white diarrhea. A trial period of a year or two should suffice to enable us to determine the full value of the plan."

The chicken pox, roup, and canker problem in New Jersey, W. C. THOMPson (*New Jersey Stas. Hints to Poultrymen*, 7 (1919), *No. 11, pp. 4*).—The author discusses the status of these diseases in flocks in New Jersey, together with symptoms, effects, causes, treatment, and prevention.

On the life history of the chicken cestode, Hymenolepis carioca, J. E. GUBERLET (*Jour. Parasitol., 6 (1919), No. 1, pp. 35–38, pl. 1).*—This is a report of studies conducted at the Oklahoma Experiment Station in continuation of work previously noted (E. S. R., 35, p. 577).

The work has demonstrated experimentally that the stable fly may transmit this tapeworm (*H. carioca*) to chicks. "This thread-like worm, according to the above observations, seemed to be most numerous during the late summer and fall at the seasons of the year when *Stomoxys calcitrans* are very abundant. During the autumn this species of fly is less active, and consequently is more easily taken by chickens. Experimentally infesting chicks with *H. carioca* through feeding infested stable flies *S. calcitrans* under control conditions makes it evident that this species of fly may be the intermediate host of this species of chicken cestode." It is pointed out that three other of the six species of fowl tapeworms found in the United States have been demonstrated experimentally to be thus transmitted to chickens, namely, *D. proglottina* through the slug *Limax cinerus* by Grassi and Rovelli; *Choanotaenia infundibuliformis* through the common house fly by the author; and *D. cesticillus*, which has the house fly as its intermediate host, by Ackert, in 1918.

On the life history of Davainea tetragona, a fowl tapeworm, J. E. ACKERT (*Jour. Parasitol.*, 6 (1919), No. 1, pp. 28-34).—This is a report of studies conducted at the Kansas Experiment Station in continuation of previous work (E. S. R., 41, p. 685).

Flies that had been trapped in poultry yards infested with *D. tetragona* and other tapeworms were fed, many of them alive, to young chicks reared in a screened house. At the end of two months an examination of the chicks showed three to contain mature tapeworms, several with embryos. In 12 control chicks, the feed of which was free from animal tissue, no parasitic worms were found.

"Flies eat both onchospheres and egg masses of *D. tetragona*, and neither when ingested are lost by regurgitation or passed through the digestive tract unaltered. As common house flies from infected poultry yards constituted the only difference between the food given to the experimental chicks and that fed to the control chicks, evidently *D. tetragona* may be transmitted from one fowl to another by *M. domestica.*"

# RURAL ENGINEERING.

Geology and ground waters of the western part of San Diego County, Cal., A. J. ELLIS and C. H. LEE (U. S. Gel. Survey, Water-Supply Paper 446 (1919), pp. 321, pls. 47, figs. 18).—This report, prepared in cooperation with the State of California and the city of San Diego, deals with the geology and ground waters of that part of San Diego County, Cal., which is drained directly into the Pacific Ocean, and embraces an area of about 3,000 square miles.

The area consists of a mountainous highland area and a narrow belt along the shore characterized by broad, flat-topped sea terraces. The soil of all the valleys is composed of sand and silt derived mainly from the granite rocks of the highland area. In general, the water table in the major valleys has the slope and, to some extent, the form of the ground surface, although important differences exist. Observations on 122 wells showed four types of annual fluctuation of water table varying from an average of 7 to an average of 1.5 ft.

Tests of several wells are reported which show in general the dependence of yield on the character and thickness of the water-bearing material. "The specific capacity of the wells tested ranged from 6 to 45 gal. per minute per foot of drawdown. The smallest and largest yields were obtained from wells . . . only about two miles apart and which draw their water from gravels that are similar in character and thickness. . . . The tests indicate that wells sunk in the major valleys of San Diego County, penetrating a considerable depth of coarse sand or from 10 to 15 ft. of open gravel, such as lies at the bottom of the ancient river valleys, if properly perforated or equipped with strainers, may be expected to yield at least 20 gal. per minute per foot of drawdown."

The minor valleys of the coastal belt seldom exceed in area a few hundred acres. They are underlain and bordered by sedimentary rocks, and contain alluvium and other fill in their lower but not in their upper parts. The water table "lies farther beneath the surface than in the major valleys. In general shape and position, however, it corresponds to that in the major valleys, having little slope across the valleys but an appreciable slope downstream. Its fluctations within each year are similar to those in the major valleys of the coastal belt but of wider range. . .

"The quantity of ground water available in the minor valleys of the coastal belt is small, owing to the narrow width and shallow depth of the fill and the small run-off and short period of flow of the streams that traverse the valleys. Supplies adequate for domestic use can, however, be obtained in most of them. The safe yield of most of the wells is very small, because the run-off in dry years is almost negligible. The use of ground water for irrigation in these valleys must as a rule be restricted to lands on the floors of the valleys, but even with this restriction, the supply in many places will be insufficient to serve all the overlying land, particularly in dry years."

In the highland area the yield of wells in residuum or decomposed granite has been found to range from very small quantities to as much as 150 gal. per minute. "The largest yields are obtained from wells that penetrate residuum of considerable depth, that are provided with lateral tunnels and auger holes, and that are situated in valleys irrigated with water from an outside source. In general, it may be said that the specific capacity of the best wells in residuum is about 8 gal. a minute per foot of drawdown, that for many wells it is as low as 1 gal. per minute per foot of drawdown, and that for the poorest wells it is much less than 1 gal."

Analyses of waters from the three different sources in the area show "a wide range in mineral content in the waters within each of the three groups, and the average mineral content in all of them is rather high. . . . Rather highly mineralized sodium-chlorid waters, fairly satisfactory for use for domestic supplies and for irrigation, and very bad for use in boilers, are greatly predominant in San Diego County and may be regarded as typical for the area."

Tests of a number of pumping plants are also reported. "Centrifugal pumps ranged in efficiency from 34 per cent for a  $3\frac{1}{2}$ -in, pump to 76.5 per cent for a 6-in, pump, the efficiency increasing, other things being equal, with the size of the pump." Plant efficiency ranged from 26 per cent to 68.5 per cent, the smaller plants being the less efficient. The annual cost per acre-foot for the plants tested ranged from \$3.86 for a plant having a lift of 44.5 ft. and a discharge of 120 gal. per minute to \$14.69 for a plant having a lift of 97 ft. and a discharge of 116.5 gal. per minute.

Other general information bearing on the subject is given.

Surface water supply of Hawaii, July 1, 1917, to June 30, 1918 (U. S. Geol. Survey, Water-Supply Paper 485 (1919), pp. 172).—This report, prepared in cooperation with the Territory of Hawaii contains the results of measurements of flow of certain streams and ditches and records of rainfall in the Territory of Hawaii, made during the year ended June 30, 1918.

Surface water supply of the lower Mississippi River Basin, 1917 (U. S. Geol. Survey, Water-Supply Paper 457 (1919), pp. 35+XXXII, pls. 2).—This report presents the results of measurements of flow made on the Arkansas and Red River Basins during the year ended September 30, 1917. An appendix of gauging stations and publications relating to water resources is included.

Departures in canal design and location effect saving, E. N. BRYAN (*Engin.* News-Rec., 82 (1919), No. 1, pp. 48-50).—The author describes methods employed on the Waterford Irrigation District in California for effecting economy in canal design and construction, including minimum excavation, greater bottom width, omission of upper levee and change of location, use of full tunnel bore, provision of wasteways for cleansing pockets, location without use of the transit, and use of mass diagrams.

Why some irrigation canals and reservoirs leak, A. P. Davis (*Engin. News*-*Rec.*, 80 (1918), No. 14, pp. 663–665, fig. 1).—Experience of the U. S. Reclamation Service has shown that in numerous cases the admission of water into irrigation canals and reservoirs has disclosed the existence of subterranean cavities which cause settlements and cave-ins. Three notable examples of canal troubles and six with reservoirs are described. It is concluded that canal troubles may usually be remedied by puddling the cavities or by relocation.

"Remedies in the case of reservoirs are not so easy. Puddling is useless if the subterranean conditions are such that the seepage of water can get away and thus let the seepage continue. No reservoir in earth is of much value if it continuously seeps at the rate that water can pass vertically through puddled earth. The problem then is to avoid regions where subterranean conditions are such that the water can escape. A few rules of caution may be of value: (1) Avoid reservoirs adjacent to gypsum deposits and to limestone deposits which show evidence of caves. (2) Examine critically reservoirs in volcanic rock, as a few have failed in such locations. Coarse-grained sandstone seems to be an object of suspicion, and should be critically examined. (3) Natural depressions are treacherous and should be examined with care, and if they are near deep cañons or underlain with coarse material where water might readily escape no superficial tightness will avail to make them effective."

Algæ growths increase value of n in Kutter's formula, P. TAYLOR (Engin. News-Rec., 81 (1918), No. 4, pp. 179–181, flgs. 8).—Studies made by the U. S. Reclamation Service during 1912 to 1916 in the Tieton Irrigation Canal lined with reinforced concrete blocks indicated that algæ growths raised the factor n in Kutter's formula from 0.012 to 0.014.

The theory of underdrainage, W. J. SCHLICK (*Iowa Engin. Expt. Sta. Bul.* 50 (1918), pp. 57, pl. 1, figs. 8).—It is the purpose of this bulletin to present those principles which determine the efficiency of the operation of a well constructed underdrainage system, with particular reference to drainage conditions and requirements in the State of Iowa. "Only those phases of the whole study of soils and soil moisture that are essentially a part of drainage en-

gineering are discussed, and these are treated from a drainage standpoint. . . Some additional matter of a more strictly drainage engineering nature has been included so as to make a more complete presentation of the principles governing the design of underdrainage systems."

**Recommendations for farm drainage**, W. J. SCHLICK (*Iowa Engin. Expt. Sta. Bul. 51 (1918)*, *pp. 24, figs. 2*).—This bulletin is prepared for the general guidance of landowners and young drainage engineers, and is intended to give a good general knowledge of the main features of the farm drainage system.

Limestone rock asphalt produces good mortar, J. R. NASH (*Engin. News-Rec.*, 82 (1919), No. 19, p. 903).—Tests made at the University of Texas on mortar made from a natural limestone rock asphalt showed the mortar to be strong, light, and impermeable to water under 60 lbs. pressure for 48 hours. The aggregate contained approximately 10 per cent of asphalt, the remaining 90 per cent being a comparatively soft limestone. Tests of the same aggregate in concrete were not so satisfactory.

Saturation of concrete reduces strength and elasticity, M. B. LAGAARD (Engin. News-Rec., 81 (1918), No. 20, pp. 908–910, figs. 6).—Tests conducted at the University of Minnesota are reported using 1:2:4 trap rock concrete specimens, in which it was found that moisture present in concrete as a distinctly foreign element reduced its strength and modulus of elasticity, the effect being greater on the strength. The reduction in strength due to saturation by water which has been present in concrete from the time of casting was found in some cases to be more than sufficient to overcome the increase in strength due to better curing. It is concluded that the effect of saturation must be recognized in an analysis of test data, and the possibility of the resultant weakening of the concrete must be considered in design.

Compressing concrete increases its strength, F. P. McKIBBEN (*Engin. News-Rec.*, 81 (1918), No. 23, pp. 1031–1033, figs. 2).—Tests conducted at Lehigh University on the comparative compressive strengths of concrete columns of 1:2:4 concrete, in which half the number of specimens were compressed during molding under loads varying from 160 to 260 lbs. per square inch, are reported.

It was found that the compressed concrete weighed about 4 per cent more per cubic foot than the uncompressed concrete. For specimens 28 days old, the average compressive strength of the compressed concrete was 51 per cent greater than that of the uncompressed concrete. The increase in strength due to compressing increased considerably as the age of the specimen increased. The stress deformation curves for the compressed concrete specimens were much more nearly straight than the corresponding curves for the ordinary concrete specimens. The ultimate compressive strength for the compressed concrete 28 days old was 2,680 lbs, per square inch. The compressive strength increased as the molding compression increased. It is concluded that the strength of concrete can be materially increased by successive compression of layers.

Strength requirements for manilla rope (*Engin. News-Rec.*, 82 (1919), No. 20, pp. 958, 959).—Data showing the weight and strength of three-strand manilla rope, medium laid, as established by recent tests at the Bureau of Standards are reported, and are summarized in the following table:

### Weight and strength of manilla rope.

[Figures apply to three-strand rope, medium laid. and may show 95 per cent of the tabulated strength.]

[Figures apply to three-strand rope, medium laid. Four-strand rope may run up to 7 per cent heavier

Approximate diameter.	Cir- cum- fer- ence.	Approxi- mate gross weight of a 1,200-ft. coil.	Maxi- mum net weight per foot.	Mini- mum breaking strength.	Approximate diameter.	Cir- cum- fer- ence. Effect of artificial light on the growth and ripening of plants, J. L. R. HAYDEN and C. P. STEINMETZ (*Gen. Elect. Rev., 21 (1918), No. 3, pp. 232-236, figs. 5; abs. in Sci. Abs., Sect. B—Elect. Engin., 21 (1918), No. 245, pp. 189, 190).*—An experiment in an orchid house with beans is reported, in which gasfilled Mazda lamps were used as the source of light. Five 500-watt lamps were suspended in a row 36 in. above the ground and 17 in. apart and were kept burning day and night for 44 days, consuming 2.5 kw. Two lamps were kept burning 29 days longer. The hothouse temperature was raised 2° C. by the heat of the lamps. The power consumption over the bed was 55 watts per square foot and the intensity of illumination about 700 lumens per square foot of ground, thus approaching direct sunlight.

The rate of plant growth and development was nearly doubled over the plat receiving only daylight, but at high cost. It is thought that such artificial illumination might pay for itself when used for raising products temporarily of high value for special purposes.

Agricultural tractors, A. E. L. CHORLTON (Engineering [London], 105 (1918), No. 2714, pp. 7-10, figs. 12; abs. in Sci. Abs., Sect. B—Elect. Engin., 21 (1918), No. 245, pp. 175-177).—The work of an agricultural tractor is classified as road work, land work, and farmstead work. Considerable data bearing on these classifications are summarized and discussed.

The basic factors in road work are considered to be adhesion and resistance. Tests with steel and rubber tires on ordinary roads showed a maximum adhesion of 0.56 for steel and 0.6 for rubber tires. In designating a tractor for road work, it is concluded that the propulsive effort can not exceed 0.45 times the weight on the driving axle for steel tires and 0.5 for rubber tires. The data indicate (1) the desirability of providing enough engine power to permit the use of 4-share plows, (2) the value of a large flywheel effect to equalize the load, and (3) the advantage of using more efficient gearing. Fundamental values for the multipurpose tractor for English conditions are taken to be as follows: For road work, power requirement from 18 to 20 h. p., for land work 23 to 25 h. p., and for farmstead work 20 to 25 h. p. Other general features of design are discussed. The principles of the wheeled farm tractor, E. R. HEWITT (*Gas Engine*, 21 (1919), No. 6, pp. 182–185, figs. 3).—The results of a large number of laboratory and field experiments are summarized.

A series of laboratory tests on full-sized wheels which checked very well with work on the machine in the open showed that "(1) the maximum drawbar pull is a definite function of the weight per inch of width. Weights used varied from 10 to 200 lbs. per inch; the ratio of maximum possible drawbar pull to total weight on the wheel was constant for that range. This was found to be true whether the ground were wet or dry. (2) On sandy ground the drawbar pull available with a smooth metal wheel is about 30 per cent of the weight on the wheel. (3) On damp, sandy ground the maximum drawbar pull is greater, being about 43 per cent of the weight, and under some conditions even slightly higher. (4) Cleats increase the maximum drawbar pull only in so far as the soil resists shearing; that is, the cleat carries a section of the top soil and slides it against the soil below the edge of the cleat.

"Experiments indicated that this was practically independent of the depth of the cleat, depending solely on the shearing strength of the soil at the depth of the cleat edge. In some cases the shallower cleat pulled more than the deeper cleat because the roots in the sod were not cut off and advantage was taken of their shearing strength." In going uphill it was found that a cleat inclined forward at an angle improved conditions somewhat, as the cleat entered the soil almost horizontally, acting like a step and tending to lift the weight off the wheel. "An inclination of about 30° was found to be the most satisfactory on a 6-ft. wheel. This arrangement tends to self-clean to a great extent. Setting the cleats at an angle of 30° to the axis of the wheel also helps this cleaning effect by slipping action. The shearing strength of the soils tested appeared to vary from 5 lbs. per inch of width in dry molding sand to 75 lbs. in loam or sod."

Studies of propelling power requirements on hard macadam road, dry short clover, long grass sod on gravelly loam, and dry plowed land, in which a cart with 46-in. wheels with 8-in. flat tires was towed by a motor truck, showed that the drawbar pull increased rapidly with the weight per inch of width on a regular curve on all but the hard macadam road, where the increase was only slight. "If a tractor has too great weight per inch of width of wheel and gets on soft ground, as it must do in harrowing, etc., the power consumed in rolling friction becomes a large percentage of the total developed and the drawbar pull is proportionately decreased. There is every advantage in increasing the surface and reducing the weight. Tractors with a weight of over 200 lbs, per inch of width of wheels that are even 6 ft. in diameter become very inefficient on soft ground."

"By using antifriction bearings, good lubrication, and cut gears of good design, it is possible to reduce the frictional losses from the engine to the rim of the rear wheels to less than 16 per cent of the total power developed.... It was found that on good sod with short grass the efficiency of the machine was about 75 per cent, i. e., the drawbar horsepower divided by the engine horsepower was 0.75. On plowed ground, harrowing, or cross plowing, it was about 65 per cent, and never fell below that figure."

Average data of several years' laboratory tests of fuel efficiency and gear changes with a number of engines indicate that for an ordinary engine the load should not go below 60 per cent for maximum fuel economy. "On the best ones under good conditions a fuel economy of 0.66 lb. per horsepower-hour can be obtained at 50 per cent load. Tractor engines should not be used below this point over long periods. Another point to be noted is the absolute necessity of With reference to size of tractor, the author is not in favor of the small tractor as an economical investment but rather favors the use of horses for small farms instead. He is of the opinion that the machine should be as large as one man can operate easily and that can be run over roads, through gateways, and over bridges with 9 ft. overall width and 14,000 to 16,000 lbs. weight as the outside limits.

Controlled tests of tractor labor, E. RABATÉ (Vie Agr. et Rurale, 8 (1918), No. 2, pp. 27-29).—Plowing tests on light sandy and siliceous clay soils with eight tractor plowing outfits are reported. Test plats were 280 meters long by 40 meters wide. The tractors varied in power from 12 to 30 h. p. and in weight from about 2,800 to about 6,000 lbs. The plows consisted of from two to four bottoms.

The tests showed that better results were obtained with three plow bottoms than with two larger plow bottoms covering an equal width. The largest volume of soil was turned by a 20-h. p. tractor per unit of area plowed and per unit of fuel consumed. This outfit used a 3-bottom plow and worked to a depth of 19 cm. (7.5 in.). The next best results were given by two 16-h. p. tractors with 3 and 2-bottom plows, working to depths of 17.2 cm. and 18.5 cm., respectively. The most powerful tractor with a 4-bottom plow gave only medium results as regards fuel economy and volume of soil turned per unit area, but it stood second with reference to area plowed per hour.

Traction on bad roads or land, L. A. LEGROS (Jour. Inst. Mech. Engin. [London], 1918, Nos. 3, II, pp. 55-158, pls. 40, figs. 54; 4, II, pp. 159-194; abs. in Sci. Abs., Sect. B—Elect. Engin., 21 (1918), No. 246, p. 211).—This is a report of an extensive study and analysis of tractor and truck drives for hauling over roads and agricultural land.

With reference to the 4-wheel drive, it is concluded that "for the transport of goods over bad roads on gradients, varying from 1 in 15 on roads in which the tires sink 2 to 3 in. in depth to 1 in 5 on hard roads with bad surface, and for speeds varying from 1.5 miles per hour on grades to 12 miles per hour on fairly level roads, the 4-wheel drive tractor has great advantages over the ordinary 2-wheel drive tractor."

With reference to chain-track tractors, "it can be safely said that where a track can be found 7 ft. wide which does not present rocky obstacles over 10 in. high, whether over sand, ash, clay, marsh, snow, or ice, on the level, or on gradients up to 30 per cent, the chain-track tractor has proved itself capable of traveling and performing useful work beyond the capacity of animal haulage. For this reason the chain-track tractor may be expected to occupy a position of ever-increasing importance in the development of new countries, and in places where it is necessary to transport machinery and stores over roadless country many miles from the railway....

"One featue that is particularly remarkable is the small amount of power lost in compressing soft marshy land under the feet of the track-chains. A very visible alteration of the appearance of a marshy surface due to the prints made by the track feet may, for example, only involve an expenditure of power which is but slightly greater than that required for hard ground, whereas the effort involved in walking over the same soft surface may be many times greater than that of walking on the hard road."

Test of a disk pulverizer, C. CLAROU (*Prog. Agr. et Vitic.* (*Ed. l'Est-Centre*), 39 (1918), No. 15, pp. 343-350, figs. 3).—Several tests of a disk harrow with six disks for vineyard cultivation are summarized briefly, the general trend of

158071°-No. 9-20-7

opinion being that the implement promises to give good results. Traction tests showed that it required a greater tractive effort than the so-called vibrating or spring-toothed cultivator, and that the latter implement gave somewhat better results. It is thought that the disk harrow, while giving good results, is not entirely adapted for use on very heavy compact soils. Its traction requirements necessitate the use of two horses, which lowers its efficiency for vineyard cultivation.

Tests of mechanical cultivating apparatus, M. FERROUILLAT (*Vie Agr. et Rurale, 8 (1918), No. 40, pp. 251, 252).*—In connection with tests of a single 10-h. p. tractor on loose sandy vineyard soil, traction tests on a 3-bottom plow covering a width of about 30 in. and working at depths of from 5 to 6 in. showed a total average traction of from 221 to 322 kg. (487 to 708 lbs.). Tests of a double flexible toothed harrow covering a width of about 5 ft. and working at a depth of about 4 in. gave a total average traction of about 680 lbs. Other tests of special apparatus are noted.

Recent advances in the differentiation of lactose-fermenting (gas-producing) bacilli, with special reference to the examination of water and food products, D. R. Wood (*Jour. Hyg.* [*Cambridge*], 18 (1919), No. 1, pp. 46-58).— Investigations are reported which confirm studies by American bacteriologists and show that lactose-fermenting or gas-producing bacilli can be divided into two main types, distinguishable by the methyl red and Vosges-Proskauer reactions.

The methyl red—Vosges-Proskauer+type were found to be rare in human and animal feces, more common in surface water, milk, and sewage, and the predominant type in soil and grain, and to be more resistant than the methyl red+ Vosges-Proskauer—type. The methyl red type was found to predominate in four out of six samples of soil.

Organisms of the methyl red type were found in 66 samples of water out of a total of 200 containing lactose fermenters, and in 41 samples containing this type no evidence of recent contamination could be found. Twenty-nine of the 66 samples were from water sources of good repute, mostly public supplies. It is concluded that judgment of the water was liable to modification by the recognition of this organism.

"The presence of lactose fermenters of the 'M. R.—' 'V. P.+' type must be regarded with considerably less disfavor than the presence of 'M. R.+' 'V. P.—' organisms, and the application of tests for the recognition of these types is important. It is suggested that these tests should be included in all routine examinations of water and food products."

The deoxygenating effect of the effluent from the Miles acid process of sewage treatment, F. W. MOHLMAN (*Engin. and Contract., 50 (1918), No. 7, pp. 166, 167, fig. 1; also in Jour. Indus. and Engin. Chem., 11 (1919), No. 4, pp. 325-327, fig. 1).*—Experiments with the Miles acid process of sewage treatment led to the conclusion that the acid effluent from this process contains unoxidized sulphur dioxid which is oxidized at the expense of the dissolved oxygen in the water in which the effluent is diluted.

"The sulphur doxid may be oxidized before dilution by aeration for a short time with relatively small quantities of air. After this aeration the effluent will not de-aerate large volumes of diluting water."

# RURAL ECONOMICS.

Some after-the-war problems in agriculture, G. F. WARREN (*Jour. Farm Econ.*, 1 (1919), No. 1, pp. 12-23).—Problems of unemployment, police protection, education, labor, land ownership, food distribution, cooperation, equality of opportunity, substitution, and dissemination of manufacturing are touched upon to show the farmer's need for organization.

**Economic questions**, A. COSTA (Questões Economicas. Rio de Janeiro: Min. Agr., Indus., e Com., 1918, pp. X+374).—This is a study of the principal crops, the live-stock industry, finance, transportation facilities, cost of living, foreign trade and tariff policy, and related phases of the economic development of Brazil.

The appeal of the land, J. H. RICARD (L'Appel de la Terre. Paris: Payot & Co., 1919, pp. 399, pls. 8).—In this volume are collected contributions by the author, under the pseudonym of François Leterrien, published in the Paris Echo weekly between December 7, 1915, and January 2, 1918. Topics touched upon in these essays include the rôle of associations and private initiative, agricultural labor, cultivation by motor power, the increased food supply, management for agriculture, Government responsibility and intervention, the return to the land, and others.

The improvement of the Rhone and agriculture, L. BERNARD (*Vie Agr. et Rurale, 9 (1919), No. 38, pp. 201–203, figs. 2*).—The advantages to French agriculture that would result from certain improvements for the development of navigation, water power, and irrigation along the Rhone, proposed by the interdepartmental commission and recently considered at a special congress held June 1 and 2, 1919, at Grenoble are discussed here.

Give the land to the soldiers, E. BURON (Donnez des Terres aux Soldats. Paris: Éditions Bossard, 1919, pp. 188).—The author cites examples of the opportunities offered by Great Britain for soldier settlements at home and in her oversea dominions. He reviews old and recent legislation of France intended to bring about the assembling of parcelled holdings, and describes various lands of France which are or might be made available for distribution to soldiers as well as the steps to be followed in offering them for settlement.

The after-war settlement and employment of ex-service men in the oversea dominions, H. R. HAGGARD (London: The Saint Catherine Press, 1916, pp. 68).—This is the report of the author to the Royal Colonial Institute of a tour of England's oversea dominions, made early in 1916, to ascertain the facilities the various governments were prepared to give as regards land settlement and employment to British ex-service men who might wish to settle in them after the war.

Employment and natural resources, B. MACKAYE (Washington: U. S. Dept. Labor, 1919, pp. 144, pls. 10, figs. 10).—This is a consideration of possibilities of providing alternative and permanent employment on agricultural and forest lands of the United States. The original, actual, and potential utilization of the territory of the United States is geographically outlined, and the salient principles determining the success of land utilization by returned soldiers and the methods of applying them on agricultural and forest lands are discussed in detail. Principles applying to the use of agricultural soil relate to community cooperation, reclamation, ready-made farms, credit, limitation of farm areas, and land tenure.

Australian and other systems of land settlement are described, and Australian land legislation is frequently referred to as advanced and as having been developed to meet conditions similar to those on the American Continent. The question of payment charged for the use of land is taken up on the basis of the income to be derived from the farming industry.

The farm labor outlook for 1919, G. I. CHRISTIE (Jour. Farm Econ., 1 (1919), No. 1, pp. 8-11).—A forecast of the probable 1919 crop acreage, the demobilization of men from the Army, return of laborers from war manufacturing plants to the farm, demands for labor on public works, etc., is briefly considered. The work of the agricultural wages board in 1918, A. W. ASHBY (Jour. Roy. Agr. Soc. England, 79 (1918), pp. 138–156).—In these pages the work of the District Wages Committees and orders issued by the Agricultural Wages Board in England and Wales in 1918 are reported. In an appendix the minimum rates of wages in force March 1, 1918, are tabulated by counties, ages of workers, etc.

American negro slavery, U. B. PHILLIPS (New York and London: D. Appleton & Co., 1918, pp. XI+529, pl. 1).—This is a survey of the supply, employment, and control of negro labor as determined by the plantation régime, taken from historical and documentary sources, and from contemporary records of slaves, masters, and witnesses. The chapters included are the discovery and exploitation of Guinea, the maritime slave trade, the sugar islands, the tobacco colonies, the rice coast, the northern colonies, revolution and reaction, the closing of the African slave trade, the introduction of cotton and sugar, the westward movement, the domestic slave trade, the cotton régime, types of large plantations, plantation management, plantation labor, plantation life, plantation tendencies, economic views of slavery—a survey of the literature, business aspects of slavery, town slaves, free negroes, slave crime, and the force of the law.

Child-caring work in rural communities, H. I. CURRY (U. S. Dept. Labor, Children's Bur. Pub. 60 (1919), pp. 363-367).—In this address before the Children's Bureau Conferences in May and June, 1919, it is stated that the county is probably the best administrative unit for rural organization, but that a Statewide agency should be established for the placing out of children and possibly for other specialized work. The needs of rural communities for nursing and social service are discussed.

**R**ural population, E. A. GOLDENWEISER (U. S. Dept. Agr., Atlas Amer. Agr., pt. 9, Sect. 1 (1919), pp. 19, figs. 38).—This publication consists of graphs and maps of the United States with explanatory notes showing the geographic distribution and relative importance of urban and village population, the native white, foreign white, and negro stock of rural population, the proportion not attending school, illiteracy in the rural population, country of origin of foreign population, the rural population unable to speak English, and the increases and decreases in country population. This study also shows by State and county the country population in 1910 and 1900. The whole is based upon census figures for 1910. A list of selected references on rural population is given.

On absenteeism, G. F. DE LA ROSA (Bol. Agr. Téc. y Econ., 10 (1918), Nos. 118, pp. 870-878; 119, pp. 939-947; 120, pp. 1068-1078).—A discussion of the development and evils of, and the means of discouraging, absentee landlordism and the depopulation of rural districts of Spain.

A survey of the development of the Serbian (Southern Slav) Nation, G. DIOURITCH (Jour. Roy. Statis. Soc., 82 (1919), No. 3, pp. 293-342).—There is here published an address delivered before the Royal Statistical Society, on March 18, 1919, which is an economic and statistical study of the population; the land under cultivation; the foreign trade, particularly in foodstuffs; the mineral wealth; means of communication; and currency, banking, revenue, and public expenditure of Serbia, Serbian territories liberated in 1912, and Southern Slav peoples under the domination of Austria-Hungary.

It is shown that, in 1905, 87.37 per cent of the population of Serbia were agriculturalists; that 91.59 per cent of the 401,093 families in 1900 were proprietors; and that the area cultivated, especially plowed land, had increased considerably to the detriment of commons, grasslands, and forests. It is stated that the occupation of the people is even more exclusively agricultural

in the territory liberated from Turkey than in Serbia itself. Comparisons made illustrate the economic retardation resulting from Turkish domination and Austro-Hungarian economic control. The author outlines the means adopted by Austria-Hungary to exploit Southern Slav territory as a field for absorption of German and Austrian industrial production; also the Serbian losses in the war.

A study of agricultural colonization, D. TARUFFI (Ist. Agr. Colon. Ital., Relaz. e Monog. Agr. Colon., No. 5 (1915), pp. VII+268).—A detailed study is made of agricultural colonization programs at home and abroad followed by various European and non-European countries, also land-holding systems, encouragement of intensive cultivation, and other general problems connected with organization.

Jewish agricultural colonization in Palestine (Internatl. Inst. Agr. [Rome], Internatl. Rev. Agr. Econ., 10 (1919), No. 4, pp. 206-222).—A brief account of natural and economic conditions of the country and systems of land-holding, notes on the history of Jewish colonization in Palestine, and a report on the work of several colonizing companies through a period of years are given here.

[Onion growers' association and small holdings in Montserrat], F. WATTS (*Imp. Dept. Agr. West Indies, Rpt. Agr. Dept. Montserrat, 1917–18, pp. 30–34*).— These pages contain a report on the activity of the Montserrat Onion Growers' Association, notes on the boom in the sea island cotton and lime industries, and information showing the number of cultivators of small holdings.

Regulations of the Secretary of Agriculture under the United States Warehouse Act of August 11, 1916, as amended July 24, 1919.—Regulations for grain warehouses (U. S. Dept. Agr., Off. Sec. Circ. 141 (1919), pp. 46).— The rules and regulations for grain warehouses promulgated September 9, 1919, are presented. The amended text of the act (E. S. R., 38, p. 895) is included.

Suggestions regarding fall-sown crops, with notes on the live-stock situation, September, 1919 (U. S. Dept. Agr., Off. Sec. Circ. 142 (1919), pp. 27, fig. 1).—This is a study of the agricultural situation in this country and abroad and of the probable foreign trade of the United States with reference to fall-sown grains and to live stock.

In reviewing European wheat and rye requirements for 1919–20, reports by representatives of the U. S. Grain Corporation and of the U. S. Department of Agriculture who visited the principal countries of western and central Europe the past summer are noted, but the discussion is based principally upon data published by the International Institute of Agriculture. It is concluded that, assuming that monetary exchange rates will not be prohibitive, it seems probable that Europe will draw upon Canada, the United States, Argentina, and Australia to supply its cereal import requirements, as the four countries named are the only ones which have surpluses worth considering, and that apparently the United States will be justified in undertaking to produce an exportable surplus in 1920 of about 200,000,000 bu.

Study is made of the acreage sown, production, consumption, and exports for the last five years of the United States wheat crops, and of the acreage sown to winter wheat in each State for the crops of 1915 to 1919, inclusive, with the five-year average. The figures in the latter case show where the greatest expansion in wheat acreage was made in the last few years, and where growers should consider most seriously the question of readjustment of wheat acreage. The rye crops of the United States are shown in a similar way. Suggestions for preventing grain diseases, fall seeding of meadows and pastures, and restoring crop rotations which may have been interrupted by the

## 1919]

demand for increased grain crops during the War, and brief reports on the conditions of such winter-grown truck crops as potatoes, onions, and cabbage are given.

The figures given for the trend of factory production of dairy products indicate that between 1914 and 1918 the production of cheese decreased 25,000,000 lbs., and the condensed milk production doubled, it having increased from 875,000,000 lbs. to 1,675,000,000 lbs. With the latter increase has gone a considerable increase in our export of these products and it is predicted that, to supply their needs, the countries of Europe probably will continue to import dairy products, at least for a time. A chart illustrates the balance of trade in dairy products.

Tables give the number of cattle, hogs, and sheep before the war and in either 1918 or 1919 in 14 of the most important countries engaged in the international trade (imports and exports) in meat and meat products prior to the war, not taking into consideration the number of animals in what constituted the former Empires of Austria-Hungary and Russia or in the Balkan States, for which it has not been possible to obtain recent figures, also the number of pounds of beef, pork, mutton, and goat meat produced in this country, as estimated from the slaughter of animals for the past six calendar years and for the first six months (January to June, inclusive) of 1918 and 1919. It is estimated that during the five years before the war exports of meat and meat products from the United States averaged about 1,100,000,000 lbs. annually, of which pork and pork products constituted about 81 per cent. During 1915, 1916, and 1917 the average annual exports rose to above 1,800,000,000 lbs., of which pork and pork products constituted 76 per cent. In 1918 the exports of meat and meat products rose to 3,058,000,000 lbs., of which pork and pork products constituted 74 per cent. During the first six months of 1919 the export of meat and meat products amounted to 1,957,600,000 lbs., or 15 per cent more than during the first six months of 1918. Of this amount pork and pork products constituted 88 per cent. The conclusion is that our exports of meat will undoubtedly decrease somewhat in the future, but that the bulk of European imports of pork must continue to come from the United States.

Crop cycles in the United Kingdom and in the United States, H. L. MOORE (*Jour. Roy. Statis. Soc., 82 (1919), No. 3, pp. 373-389, figs. 8).*—This paper presents the methods employed in ascertaining the existence of periodicities which furnish evidence that the yield of the leading cereal crops in the United Kingdom tends to vary in well-defined cycles, and that, as far as the statistics of the two countries are comparable, the crop cycles in the United States tend to synchronize with those of the United Kingdom.

Crude figures for the yield per acre of wheat, barley, and oats from 1884 to 1914 in the United Kingdom, exclusive of the Isle of Man and Channel Islands, were converted into index numbers of which the base was the mean yield for the 10 years, 1890 to 1899. The curves platted and periodograms constructed are shown. In all cases the principal maxima are nearly at 1890, 1898, 1906, and 1914, and the secondary maxima are about midway between these years.

Study of the periodicity of rainfall in the Ohio and Mississippi River Basins, 1839 to 1910; the yield per acre of cotton in the United States, 1882 to 1914; and of crops of corn, wheat, barley, rye, buckwheat, potatoes, hay, and cotton in the United States gives finally 8-year cycles in which the maxima occur at about the same dates as those of the crops in the United Kingdom.

Returns of produce of crops in England and Wales with summaries for the United Kingdom (Bd. Agr. and Fisheries [London], Agr. Statis., 52 (1917), No. 2, pp. 37-58; 53 (1918), No. 2, pp. 33-56).—These reports continue information previously noted (E. S. R., 37, p. 392).

[Agricultural statistics of France] (Ann. Statis. [France], 35 (1916–1918), pp. 209–232).—Summary tables are given showing the areas sown and yields of wheat, rye, oats, barley, corn, potatoes, vines, rice, and cotton, and the numbers of live stock in France and in foreign countries during the period 1850–1918.

**Russia:** Its trade and commerce, edited by A. RAFFALOVICH (London: P. S. King & Son, Ltd., 1918, pp. IX+461).—Chapters on agriculture by J. J. Pelferoff, on poultry farming and fodder grass, and on the cultivation of cotton, flax, hemp, sugar beet, tobacco, wine, hops, and fruit by N. Malahovsky and A. Isenberg give statistics of production and exports of principal crops and live stock in Russia in the first 15 years of the twentieth century, with brief notes on land tenure and the development of the various agricultural industries and regions in which they are important. Mining and other industries are described, and discussions of internal transport trade, foreign trade, public finance by M. Bogolepoff, and money and credit are also included.

Agricultural and pastoral South Africa, F. D. MACDERMOTT (So. African Jour. Indus., 2 (1919), Nos. 5, pp. 419-435; 6, pp. 505-518).—The general cultural conditions in the different Provinces of the Union of South Africa are described. It is concluded that this region is preeminently a stock-raising country, that the weak spot in the agricultural outlook is that of the supply of breadstuffs, and that opportunities for further development lie in the production of mealies or maize, the cultivation of vineyards and citrus fruits, the production of wool and mohair, cotton and other fibers, and tobacco, and in the dairy industry. The commercial organization of the farm industries of the Union and the encouragement of land settlement are urged.

**Present** agricultural problems and colonization in Algeria, G. J. STOTZ (*Prog. Agr. et Vitic.* (*Ed. l'Est-Centre*), 39 (1918), No. 34, pp. 181–186).—Concluding the study previously noted (E. S. R., 40, p. 487), the author urges concentration of effort by European colonists upon the better land of the country, and organization for supplying capital, buying and selling, transportation, agricultural research, and education. A table is given showing the population, total area, and total productive area, also the production of crops and live stock per area in Australia, Argentina, Canada, the United States, and Algeria.

Estimates of area and yield of principal crops in India, 1916–1918 (*Dept. Statis.*, *India*, *Est. Area and Yield Princ. Crops India*, 1916–17, pp. 2–28; 1917–18, pp. 5–30).—Information previously noted (E. S. R., 39, p. 595) is continued for the later years.

# AGRICULTURAL EDUCATION.

Memorandum on the reconstruction of agricultural education in England and Wales, W. SOMERVILLE, P. H. FOULKES, and C. CROWTHER (*Newport, Salop, England: Agr. Ed. Assoc.* [1919], pp. 64).—In this memorandum the Agricultural Education Association of England formulates its views on agricultural education and research.

As regards elementary agricultural education and county work, it is recommended that a dividing line be drawn at the age of 16, the aim of continuation school education up to this age being the improvement of general education with English, arithmetic, and rural science as the essential subjects (with the addition of handicraft or gardening for boys, and domestic science, dressmaking, or dairy work for girls). After that age specific agricultural education courses should be provided for those who propose to stay on the farm. Twoyear classes devoted primarily to practical agriculture and horticulture (with a limitation of the centralization of such instruction) should be provided locally for those willing and able to carry their education beyond the continuation school age. Thereafter students fitted for higher instruction should be encouraged by scholarships or otherwise to proceed to a farm institute or possibly, in cases of outstanding ability, direct to the higher college. It is further recommended that provision be made for instruction in the best methods of performing the more highly skilled operations of the farm and allied work, that lectures and short courses to farmers, gardeners, and others, as well as field demonstration work, should be continued and extended, and that county educational staffs should be considerably augmented.

It is desired by the association that relatively short courses (with a standard course of between one and two years) be provided at farm institutes, and longer courses of not less than two years at the agricultural colleges. It is suggested that at the farm institute sound practical instruction should be the basis, while the 2-year (certificate) and 3-year (diploma) courses at the college would give a sound knowledge of the scientific principles underlying the practice and economics of agriculture and allied industries. The provision of scholarships tenable at the farm institutes is recommended to enable the more able students to pass to the college or university for more advanced courses. A farm suitable for teaching purposes is recommended for the farm institute. The farm at the college, in addition to serving for educational purposes, should be utilized as a central experimental farm for the Province.

The association is of the opinion that the university should be relieved of the duty of providing courses of a lower than university standard; further, that while a degree course based primarily on the history and economics of agriculture and the development of rural law and local institutions might serve better the needs of the working farmer taking a university course for its general educational rather than its technical value, the number of such students in attendance at present (except perhaps at the older universities) is not sufficient to warrant any radical departure from the existing type course based primarily on science. For students intending to go out as specialists in one of the sciences bearing on agriculture, it is recommended that an honors degree course in pure science should be followed by a post-graduate course in agriculture and agricultural science. The necessity for adequate facilities for research on the part of the university teaching staffs is emphasized, and it is insisted that the demands of administrative duties should not encroach unduly upon the time available for teaching and research.

As regards agricultural research, while increased financial provision is needed as the work develops, the present problem is considered the provision of trained men rather than of means. The organization of a definite research service is suggested, which would guarantee a satisfactory career and thus attract and retain the best men. The establishment of a national agricultural research committee to survey periodically the whole field of research and organize cooperative work on important problems, it is suggested, might be productive of great good.

The association qualifies farms for purposes of agricultural education as follows: Central experimental farms, attached to a research station and used entirely for purposes of experiment and research; institutional farms attached to a university, college, or other teaching institution and used partly for teaching purposes and partly for experiment; county experimental and demonstration farms, used for the duplication under different conditions of experiments carried out at the two preceding types of farms, and for the local demonstration of new crops, improved varieties, etc.; and illustration farms, run on strictly commercial lines, and intended to demonstrate in a given locality the possibilities of the system of farming deemed by the local advisory authority to be the best for the area in question. Attention is called to the great lack of well-trained teachers, advisers, and experts in dairying. The association criticizes the concentration of dairy education in the past on cheese and butter making, and points out that more attention should be paid to the production and management of milk for direct human consumption. It holds that horticulture can not be regarded as simply a branch of agriculture, and that the problem of the provision of horticultural education must hereafter be regarded as largely separate from that of the provision of agricultural education. It is found that more prominence should be given to poultry education in the curricula of colleges and farm institutes, and that the county work should be closely coordinated with it. A course of at least two years' duration preparing candidates for a national diploma in poultry keeping, or a poultry manager's certificate should be provided by the college, while the farm institute should provide shorter courses qualifying for a poultry worker's certificate. Special provision for research and experimental work in the subject is urgently needed.

The reconstruction of agricultural education (Jour. Bd. Agr. [London], 26 (1919), No. 3, pp. 300-304).—Extracts are given from the summary of recommendations in the memorandum noted above.

Allotments under the Agricultural Instruction Act (Agr. Gaz. Canada, 6 (1919), No. 10, pp. 865-869).—A brief summary is given of the purpose for which the grants for 1919-20, made under the Canadian Agricultural Instruction Act, are to be expended, together with statements of the appropriation to each Province. The total allotment of \$1,100,000 includes \$291,701.16 for agricultural colleges and schools, \$597,712.68 for instruction and demonstration, \$31,510 for women's work, \$154,076.16 for elementary agricultural education, and \$25,000 for veterinary colleges.

Government assistance to fairs and exhibitions (Agr. Gaz. Canada, 6 (1919), No. 9, pp. 816-821).—This is a series of articles dealing with government grants to fairs and exhibitions and the purposes for which they are expended in the Provinces of Nova Scotia, New Brunswick, Quebec, Ontario, Manitoba, Saskatchewan, Alberta, and British Columbia.

Vocational education [in New Brunswick], F. PEACOCK (Agr. Gaz. Canada, 6 (1919), No. 8, pp. 752, 753).—Steps taken under the vocational education act passed by the New Brunswick legislature in 1918 (E. S. R., 41, p. 195) are described. The policy of the board was to open only a few type vocational schools and departments during the first year, including a full-time county vocational school at Woodstock operating departments of agriculture, homemaking, commercial work, and motor mechanics.

[Extension teaching in farm management] (Jour. Farm Econ., 1 (1919), No. 2, pp. 44-73) .- The following papers read at the American Farm Management Association meeting in January, 1919, are included; Farm Management Demonstrations in New York State, 1919: A Demonstration for the Sixth Year: Income Tax and Farm Management; Demonstration Work on Cost of Production Records in Nebraska; Assistance Given in Summarizing Farm Records in Indiana; Farm Management Extension Work; Getting Farm Management to the Farmer; Teaching Farm Management Through Farm Accounting: Farm Management Demonstrations-Past, Present, and Future: Constructive Criticism of Extension and Demonstration Work in Farm Management; and Relationships Between Extension and Investigation Work in Farm Management. In these papers special attention is given to methods of teaching farm management, particularly in relation to the business of the farm and the farmer. Many historical facts concerning the development of farm management demonstrations, as well as suggestions with reference to the improvement of the present program, are included.

[Vol. 41

**Elementary chemistry of agriculture**, S. A. WOODHEAD (London: Macmillan & Co., Ltd., 1919, pp. VII+188, figs. 47).—This text deals with elementary principles and laboratory tests, the beginnings and development of a chemistry of agriculture, plants, soils, fertilizers, farm foods, milk and its products, and insecticides and fungicides. Each chapter begins with suggested experiments and is followed by review questions.

What is the value of the usual laboratory work given in general soils courses? P. E. KARRAKER (*Jour. Amer. Soc. Agron.*, 11 (1919), No. 6, pp. 253– 256).—It is the purpose of this paper "to express doubt as to the justifiable value to the students of the usual laboratory work in first or general soils courses as compared with other work which might be taken. In particular, it is desired to raise the question whether it would not be advisable to give this work as separate courses, thus giving opportunity for the securing of the subject matter without the laboratory work and requiring the latter only of men desiring to specialize in soils or closely related work."

Nature study and elementary agriculture (Agr. Gaz. Canada, 6 (1919), No. 9, pp. 836-839).—This is a series of brief articles dealing with nature study and elementary agriculture in the Provinces of Nova Scotia, New Brunswick, Saskatchewan, and Alberta.

In Nova Scotia nature study and elementary agriculture are not separated, agriculture being taught through nature study. In New Brunswick the subjects are combined in a nature study and agriculture course prescribed by the Board of Education. Schools are not obliged to have school gardens or home plats, but the Department of Agriculture offers grants for their establishment.

The course of study for the schools of Saskatchewan includes a course in nature study for grades one to six, and in agriculture for grades seven and eight. In the high schools and collegiate institutes the work is continued under the head of elementary science for the first two years and is compulsory, but in the third year it is known as agriculture and is an optional subject.

Under the Alberta organization nature study belongs characteristically to the first six grades of the common school, and may be said to persist as a method in the laboratory teaching of grades seven and eight. In the latter grades it is termed agriculture, and includes a knowledge of the essential laws and principles concretely established and understood.

The elements of animal biology, S. J. HOLMES (*Philadelphia: P. Blakiston's* Son & Co., 1919, pp. X+402, figs. 250).—This text, which is intended as an introduction to the elements of animal biology for the use of high-school students, comprises three parts, viz, the animal kingdom, consisting of a survey of the principal groups of animals; the elements of physiology, including chapters on the rôle of bacteria in causing disease, how diseases spread, and how they may be avoided; and general features and adaptations, such as evolution, heredity, eugenics, etc.

**Practical guide to agricultural home economics instruction**, L. ROUGIER, C. PERRET, and H. ASTIER (*Guide Pratique de l'Enseignement Ménager Agricole. Paris: J. B. Baillière & Sons, 1913, pp. 228, figs. 172*).—This book, which is designed especially for girls in rural districts, consists of two parts dealing, respectively, with the woman in the home and the woman on the farm. Part 1 includes chapters on the house, its furnishings, heating and lighting, and care; cooking; laundering; sewing; hygiene; prevention of disease; and care of the sick and of children. In part 2 chapters are devoted to the dairy cow; milk; butter and cheese; the utilization of by-products of milk, and the piggery; breeds of chickens and egg production; raising chicks, diseases; other fowls and rabbits; bees; the farm garden; and household accounts. Each chapter closes with review questions, problems, and references to literature. Food saving and sharing, E. M. TAPPAN ET AL. (Garden City, N. Y.: Doubleday, Page & Co., 1918, pp. X+102, figs. 13).—This book, prepared under the direction of the U. S. Food Administration in cooperation with the U. S. Department of Agriculture and the U. S. Bureau of Education, gives instruction on the wise selection of the different kinds of foods for their value in giving health and strength and in saving and sharing, and tells what this country did to provide food during the war and what is yet to be done.

Sewing and textiles, A. TURNER (New York and London: D. Appleton & Co., 1918, pp. [5]+246, figs. 64).—This text for graded and rural schools is designed especially for teachers who have had little training and experience. It contains detailed directions for making the various stitches, a needle book, a sewing book, garments, darning and patching, embroidery and fine needle work, the use of commercial patterns and principles of cutting and fitting, and the use and care of the sewing machine; studies of cotton, woolen, linen, and silk materials, including the evolution of weaving and spinning, history, growth and manufacture, properties of fiber, finish, judging and testing for quality, comparison of wearing qualities with price, etc.; laundry problems; and clothing—hygiene, functions, and budget. The material is arranged in sequence.

**R U S:** Rural uplook service, compiled by L. H. BAILEY (*Ithaca, N. Y.: Author, 1918, pp. 313*).—This register of 2,746 entries is described as "a preliminary attempt to register the rural leadership in the United States and Canada." It constitutes a rural Who's Who, and is based on replies received to requests sent out to 7,061 persons "regularly and prominently engaged in rural work as farmers, teachers, investigators, business men, ministers, lecturers, farm agents, authors, editors, rural organizers, administrators, if their efforts are such as to make them public characters."

# MISCELLANEOUS.

**Report of the Hettinger substation for the years 1913 to 1918, inclusive** (*North Dakota Sta. Bul. 130 (1919), pp. 3-56, figs. 6*).—This bulletin consists of reports for this substation for the years 1913 to 1918. The experimental data recorded are for the most part abstracted elsewhere in this issue.

Monthly bulletins of the Western Washington substation (*Washington Sta.*, West Wash. Sta. Mo. Bul., 7 (1919), Nos. 6, pp. 86–100, figs. 4; 7, pp. 102–116, fig. 1; 8, pp. 118–132, fig. 1).—These numbers contain two articles abstracted elsewhere in this issue, and brief articles as follows:

No. 6.—Future of Small Fruit Growing in Western Washington, by J. L. Stahl; Variations in Milk and Cream Tests, by L. E. Carter; Farm Crops for Fall Seeding, by E. B. Stookey; Sorting and Moving Flocks, by G. R. Shoup; Late Blight of Potatoes, by A. Frank; and Egg-laying Contest.

No. 7.—Summary of Small Fruits, by J. L. Stahl; Work of the Veterinary Department, by W. T. Johnson; What is Skim Milk Worth to the Farmer? by L. E. Carter; Potato Wart—A Dangerous Disease, by A. Frank; and Western Washington Egg-laying Contest.

No. 8.—Strawberries in Western Washington, by J. L. Stahl; How Can We Increase Crop Yields? by E. B. Stookey; Abnormal Milk and Cream, by L. E. Carter; Animal Proteins; A Controlling Factor in Egg Production, by G. R. Shoup; Poultry Mortality, by W. T. Johnson; Controlling Mountain Beavers, and Farmers' Winter School.

The history of the Agricultural Society of South Carolina, C. I. WALKER (*Charleston: Agr. Soc., S. C. [1919], pp. IX+168, pls. 15*).—An account is given of the establishment and accomplishments of this society, organized at Charleston, S. C., August 24, 1785.

# NOTES.

Arkansas University and Station.—Dr. Bradford Knapp, chief of extension work in the South, States Relations Service, U. S. Department of Agriculture, since 1911, has been appointed dean of the college of agriculture, director of the station, and chief of the department of rural economics. Martin Nelson has been appointed vice dean and vice director and chief of the department of agronomy.

California University.—A number of changes have been made in the plan of instruction of regular students in the college of agriculture, effective with the opening of 1920. Under the new plan fewer subjects will be required of all students, opportunity will be given for some work in agriculture each semester, and a closer relation will be established between the subject matter in the fundamental sciences and in agriculture. Among other changes, three new courses dealing in a broad way with general principles, one each in agronomy, animal husbandry, and horticulture have been added as electives. There will also be a new required course in botony, strongly emphasizing plant physiology, and changes will be made in the subject matter of the courses in zoology, agronomy, animal husbandry, and horticulture.

Georgia College and Station.—From practically no students ten years ago the college of agriculture has become the largest department of the university, with an enrollment of 450 long course students and a number in short courses.

A very successful tractor demonstration was held at the college November 5, 1919, under the auspices of the farm bureau of Clarke County. A boll weevil school is to be held January 20 to 30, comprising demonstrations of methods to fight the boll weevil.

T. E. Keitt has resigned as chemist and agronomist of the station, effective January 1.

Hawaii Federal Station.—C. W. Carpenter resigned as pathologist November 15, 1919, to become associate pathologist in the Hawaiian Sugar Planters' Station, where it is expected that he will continue his investigations on root rot diseases. J. E. Higgins, horticulturist, resigned December 25 to become professor of agronomy in the college of agriculture of the University of the Philippines.

Idaho University and Station.—Dr. W. M. Gibbs of the University of Wisconsin has been appointed professor of bacteriology and bacteriologist. C. H. Werkman has been appointed research assistant in bacteriology, and Ray F. Morgan instructor in dairy husbandry.

Kansas College.—Arrangements are being made for two 10-day short courses to be held in March, one in grain elevator accounting in cooperation with the Bureau of Markets, U. S. Department of Agriculture, and the other in grain marketing. C. W. Mullen, assistant professor of crops, has resigned to engage in agricultural journalism, and has been succeeded by J. W. Zahnley of the department of education.

Kentucky Station.—William Rodes, chemist, and A. E. Ewan, superintendent of experimental fields, resigned December 11 and December 13, 1919, respectively. The latter has been succeeded by S. C. Jones. Louisiana Stations.—W. R. Dodson, dean of the college of agriculture since 1909 and director of the stations since 1905, resigned January 1. He was succeeded by Dr. W. H. Dalrymple, who will also continue as professor of veterinary science and veterinarian.

Maryland Station.—Howard J. Winant has been appointed assistant in soil investigations.

**Massachusetts Station.**—Miss Esther S. Mixer, assistant chemist in the feed and dairy section, has resigned to accept a position in the Pennsylvania College, and has been succeeded by Miss Ethel M. Bradley.

Minnesota University and Station.—A contract has been entered into with the Anoka County Poor Farm for the use, by the station, of a portion of its land as a sandy-land experiment field. This tract adjoins one already in use as a peat-land experiment field, and a series of mutually contributory and complementary soil studies on the two types has been inaugurated.

The official testing of pure-bred cows for advanced registry has increased until 60 testers are now in the field.

The resignations are noted of R. M. Washburn as professor of dairy husbandry to engage in commercial work; F. W. Peck, as associate professor of farm management, who has been for several months connected with the farm cost-accounting studies of the Office of Farm Management, United States Department of Agriculture; and Benjamin Kienholz as instructor in agronomy. J. D. Black has been appointed professor and chief of the division of agricultural economics, vice W. W. Cumberland, whose leave of absence for service in Turkey as financial and economic adviser to the commission to negotiate peace between the Allies and Turkey has been continued for another year. J. R. Keithley, head of the dairy department of the North Dakota Station, has been appointed professor of dairy manufactures; Theodore Odland, instructor in agronomy and assistant agronomist; George A. Pond, assistant professor of farm management; C. G. Worsham, instructor in farm management; and D. L. Peterson, instructor in poultry husbandry.

Missouri University and Station.—The resignations are noted of T. J. Talbert as associate professor of horticulture; Ernest C. Pegg as assistant professor of forestry; Ralph L. Mason as extension instructor in poultry husbandry; and J. C. Hackleman as extension assistant professor of farm crops, the last named to assume charge of crops extension work at the University of Illinois. A. C. Dahlberg has been appointed assistant professor of dairy husbandry.

Nebraska University and Station.—Dr. E. M. Wilcox, plant pathologist and physiologist, has resigned, effective April 1, to become director of an experiment station to be established in San Domingo.

Nevada University and Station.—Dean C. S. Knight of the college of agriculture, also head of the department of agronomy in the college and station, has resigned to become secretary of the Reno Chamber of Commerce, effective June 30. Miss Hester Mayotte, secretary and librarian of the station, resigned January 31.

New Jersey College and Stations.—Arrangements have been made with the French Ministry of Agriculture for tests by the stations of eight lots of soil from the territory in the vicinity of Verdun, Rheims, Soissons, and Amiens. A comparison will be made of soil from fields not affected by shell fire with soil from fields badly torn by shells and shell fragments, with a view to determining whether the churning of the surface by shells and the temporary saturation with gas fumes has more or less permanently affected the cropproducing power of the land. William Rudolfs, of Wageningen, Holland, a graduate student in soils at the State Station, is to spend the greater part of the year in the Pasteur Institute in France, putting on a commercial basis the practice which has already been worked out in the laboratories for making rock phosphate available by the process of sulfofication. Howard F. Huber has resigned as assistant State leader of farm demonstration to go into commercial work, and has been succeeded by W. F. Knowles, formerly assistant State leader in boys' and girls' club work.

New Mexico College and Station.—President A. D. Crile and Joseph W. Rigney, assistant horticulturist, have resigned. The latter is to engage in farming, and has been succeeded by Sidney W. Wentworth.

A large live-stock dipping vat has been built on the college grounds for the use of farmers and stockmen at a small cost per head.

**Pennsylvania College and Station.**—A. L. Patrick has been appointed assistant professor of soil technology.

**Rhode Island Station.**—C. G. Bridge, assistant chemist, has resigned. Bertha M. Heath has been appointed assistant in animal breeding and pathology.

Tennessee University and Station.—Litigation extending over five years has been terminated by a compromise under which a bequest by the late B. R. Strong of \$65,000 and certain real estate to the university has been agreed to. Of this amount \$35,000 is to be used for farm purposes by the college of agriculture.

The cornerstone of the new agricultural building was laid November 1, 1919, and it is expected that the building will be ready for occupancy by the opening of the fall term. The cost will be approximately \$250,000.

S. H. Essary, associate professor of botany and mycologist of the station, has been appointed botanist.

Vermont University and Station.—An industrial fellowship has been established in the college of agriculture by the soil improvement committee of the National Fertilizer Association. The fellowship will provide \$1,500 per annum for three years for research in the station on the relation of fertilizers to the hastening of crop maturity. Lewis H. Flint, instructor in botany, has been designated for the fellowship.

Dr. A. K. Petersen, assistant professor of botany and botanist, has been appointed professor of botany and botanist in the Colorado College and Station.

Virginia College and Station.—The total enrollment of students is 789, the largest attendance in the history of the college.

M. E. Gardner has been appointed assistant horticulturist; E. R. Hodgson, superintendent of the Staunton County substation, vice R. H. Cook; and R. C. Thomas, formerly assistant botanist at the Ohio Station, assistant plant pathologist.

Washington College and Station.—Roy Larsen has been appointed assistant in horticulture in the station to investigate soil and cover crop management in the orchards of Chelan County, with headquarters at Wenatchee, beginning February 15. An appropriation of \$4,300 for the first year's work has been granted by the county commissioners.

The appointment is also noted of C. L. Vincent as instructor in horticulture, beginning January 5, vice E. S. Robertson, who will become extension specialist in horticulture.

Hypena humuli, studies, N.Y.Cornell, 161. Hyperglycemia, observations on, 364. Hyperimmunity, destructive, in rabbits, 186. Hyphantria cunea. (See Webworm, fall.) Hypochlorite solutionsassay of, 715. isotonic, for water sterilization, 583. (See also Dakin's solution.) Hypoderma bovis, life history, 280. Hypophysis in the rat as affected by inanition and refeeding, 270. Hyposoter fugitivus pacificus n.form, description, 261. Ice creamas factor in dairying, 774. bacteriological studies, Iowa, 279. colloid chemistry of, 310. inspection, Me., 171. Icerya purchasi. (See Cottony cushionscale.) Ichneumonoideafamilies and subfamiles, 360. new, 63, 261. Idaho-Station, report, 299. University and Station, notes, 199, 898. Idiocerus cognatus in New Jersey, 549. Ileum, H-ion concentration, 765. Ilex as source of caffein, 409. Illinois-Station, report, 198. University and Station, notes, 599. Immune bodies, normal, influence of desiccation on, 874. Immunityantistreptococcic, studies, 376. "destructive," in rabbits, 186. in plants, 656. production as affected by nutrition, 574. theories, 186. Immunizationstudies, 576. therapeutic, new prospects in, 187. (See also Anthrax, Hog cholera, etc.) Immunizing sera, anaphylactoid poisoning by, 185. Imperata spp. as paper-making material, 532, 732. Inbreedingeffect on growth curve in white mice, 766. studies, 267, 864. Indian meal moth on dried fruit, 665. Indiana Station, notes, 496. Indicatorbeet-extract, 112. papers, preparation and use, 11, 503. Indigoculture in India, 522, 529. from Lonchocarpus, 734. industry, 233. soils of India, 516, 814, 816. Infantscare of in rural Wisconsin, 794. feeding, 365, 561, 679, 859, 860. metabolism, 761.

#### INDEX OF SUBJECTS.

Infants-Continued. newborn, intestinal contents, 68. tomato juice for, 266. Infective agents, theory of invasion by, 777. Influenza, equine, notes, 580. (See also Pleuro-pneumonia.) Inheritance. (See Heredity.) Insectcausation of disease, steps for investigation, 456. powder, adulteration, U.S.D.A., 550. Insecticidal plants, list, 56. Insecticide from derris, tests, 661. Insecticidesinspection and analyses, Mich., 443; N.J., 43; N.Y.State, 237. notes, 354. tests, Wis., 661. (See also Sprays and specific forms.) Insectsabsence of complement in blood, 754. beneficial, distribution in Hawaii, 549. biology, formula of, 661. climatic law, 16. collection and preservation, 754. control by biological method, 754. control in New York, 245, 248. control, in relation to clean cultivation, 456. control, organization for, 250. economic, of United States and Canada, class-books, 56, foreign, protecting American crops against, 443. forest. (See Forest insects.) fungus parasites, 59. garden. (See Garden insects.) injuriousin British Guiana, 455. in Ceylon, 455. in Connecticut, Conn.State, 159. in Cuba, 847. in England, 755. in Florida, Fla., 455, 548. in France, 49, 59. in India, 354, 455. in Michigan, Mich., 660. in Minnesota, 57. in Montana, Mont., 57. in New Jersey, N.J., 57. in New Jersey nurseries, 549. in New York, 159. in North Carolina, N.C., 660. in Ontario, 549. in Queensland, 549. in Scotland, 549. in Seychelles, 59. in South Africa, 455, 549. in South Dakota, 58. in Tennessee, 754. in Uganda, 455. in West Indies, 59. to apples, corn, sugar cane, etc. (See Apples, Corn, Sugar cane,

etc.)

Insects-Continued. larvæ and pupæ, preservation, 56. life and seasonal cycles as affected by climate, N.J., 58. of British Guiana, treatise, 546. of stored grain and flour, 456, 463, 549. of stored grain as affected by humidity, N.J., 58. of wheat flour and wheat flour substitutes, 162. on imported nursery stock, 251. rôle in pollination, 330. scale. (See Scale insects.) soil-infesting, studies, N.J., 58. toxic action of volatile substances on, 456. use in medicine, 661. (See also specific insects.) Insurânce agricultural, in France, 793. agricultural, in Philippines, 793. farmers' mutual, U.S.D.A., 194. Internationalcatalogue of chemistry, 501. Research Council, 399. Intestinalcoccidium of the rabbit, new, 784. invagination in sheep, 873. parasites, remedies, 286, 480, 782. (See also specific parasites.) Intestines, H-ion concentration of ileum, 765. Intussusception in sheep, 873. Inulin, behavior in the animal body, 12, 764. Iodid, determination in mineral waters and brines, 12. Iodinbehavior and reactions in chronic infections, 781. compound of thyroid, isolation, 409. rôle in nutrition of maize, 820. Iodized chloroform in war surgery, 83. Iodometric studies, 504. Iodotannic test, red, studies, 207. Iowa-College, notes, 300, 398, 496, 700. Station, notes, 398, 700. Station, report, 299. Ipslongidens, notes, 758. spp. in Sweden, notes, 455. Irisleaf miner in New Jersey, 549. poisoning of calves, 782. root borer, notes, Conn.State, 159. Irondetermination, 711. salts as soil amendments, 326. sulphate sprays, fertilizing value, Hawaii, 138, 148. use in nutrient solutions, 430. Ironbarks of New South Wales, 744. Irrigable land in United States, U.S.D.A., 693.

#### 1919]

Irrigatedfield crops for hog pasturing, U.S.D.A., 72. lands, drainage, 786. Irrigationclimatic conditions controlling. U.S.D.A., 417. ditches, measurements of flow, 583. (See also Canals.) in Egypt, 483: in Nevada, Nev., 728. Utah, plant-food waters, 583. in supply from investigations, Ariz., 379. laterals, cypress lath for, 482. of lowland moor soils, 786. of orchards, 515. opportunities in Russia, 481. pipe, cement, Ariz., 288. porous-cone, for potted plants, 631, pumping for, 481, 785. pumping plant, small, Oreg., 688. reservoirs, leakage, 883. treatise, 481. water. (See Water.) (See also special crops.) Isosoma, revision, 667. Itonididinariæ, studies, 160. Jack bean, mineral constituents, translocation, 726. Jackdaw, food habits, 454. Jacks in Indiana, Ind., 178. Japanese cane. (See Sugar cane.) Jassoidea of Honduras, new species, 356. Jaundice, infectious, relation to rats, 85. Jellies, antiscorbutic, 470. Jewish Agricultural and Industrial Aid Society, report, 94. Johne's disease, studies, 84. Johnson grassas a weed, Iowa, 40. eradication, N.Mex., 139. Joint-ill of foals, 480, 879. Jolly bodies in anemic blood, 875. Jowar. (See Andropogon sorghum.) Juglans, abscission in, 134. Jujube, culture in Sind, 837. Juncus spp., analyses, Wyo., 333. Jutebaled, "heart damage," 451. culture in India, 522; 529. Kafir cornas dry-farm crop, Ariz., 29. as silage crop, Kans., 34. culture in South Africa, 528. effect on soil, Kans., 34. feeding value, 367; Kans., 71. fertilizer experiments, Kans., 33. growing with soy beans, Mo., 637. milling and baking tests, Kans., 64. silage and fodder, feeding value, 367. yields, Mo., 637. Kainitfertilizing value, Ala.College, 336. value in weed control, 538. Kala azar, studies, 781. Kale, nutritive value, 557.

Kaliosysphinga spp., notes, 759. Kansas-College, notes, 300, 497, 700, 898. Station, notes, 497. Station, report, 98. Kaoliangfield tests, N.Dak., 824. kernel-smut resistance, Kans., 48, Kaolin for tannin analyses, 805. Kapokculture in Ceylon, 529. seed meal, analyses, Ind., 564, 868. Karanja cake, fertilizing value, 816. Kauri forests, management, 46. Kelpdecolorizing carbon, La., 416. utilization, 508, 518. Kentucky-Station, notes, 497, 700, 898. University, notes, 497, 700. Kermes parasite, 164. Kerosene emulsion, insecticidal value, 162; Conn.State, 158. Kestrel, food habits, 454. Kid fat, digestibility, U.S.D.A., 65. Knopderm in sheep, 873. Kohl-rabiculture experiments, 737. weeding experiments, 737. Kokia spp. of Hawaii, 541. Labor saving in sugar beet fields, U.S.D.A., 337. (See also Agricultural labor.) Laboratory ware, palau and rhotanium, 11. Lachniella, genotype for, 757. Lachnodius phoradendri, synonymy, 757. Lachnosternalanceolata, studies, 166. spp., notes, 666. Lachnus, genotype for, 757. Lac-producing insects in United States, 457, 757. Lactalbumin, growth-promoting value, 465, 466. Lactation, relation to embryonic development, 862. Lactic aciddetermination, 112. in sour milk, N.Y.State, 201. Lactobacillus pentoaceticus n.sp., fermenting xylose, 614. Lactosedetermination in milk, 115, 505. growth-promoting value, 466. Ladybird beetlesfor aphis control, 62. storage experiments, 666. Læmophlæus minutus, notes, 759. Lake brines as source of potash, 518, 818. Lalang grass as a paper material, 532. Lamb and lamb products as food, gastric response to, 857. Lambsas affected by iodin feeding of ewes, Iowa, 286. feeding experiments, 771; Ind., 70; Kans., 71; Nebr., 770; Ohio, 568.

Lawn-grass mixtures, inspection, N.J., 40. Lambs-Continued. forage crops for, 368; Ohio, 177. growth as related to quantity and composition of ewe's milk, 176. self-feeders for, 772; Nebr., 770. shearing before marketing, Ind., 70. (See also Sheep.) Lamziekte in cattle, 873. Landacts, Irish, 293. classification, 839. classification in southern Minnesota, (See Agricultural credit.) credit. economics, outline for investigations, U.S.D.A., 292. grant colleges. (See Agricultural colleges.) holdings in India, regrouping, 491. plaster. (See Gypsum.) settlement for ex-service men, 193, 489. 591, 592, 792, 889. settlement in California, 91, 489; Cal., 91. settlement in Minnesota, Minn., 91. settlement in Oregon, 92. settlement in Queensland, 792. settlement in United States, 889. (See also Agricultural colonization and Small holdings.) tenure, ideal system, 292. tenure in France, 490, 791. tenure in Kansas, Kans., 791. tenure in Minnesota, Minn., 93. tenure in Nebraska, 387. tenure in Palestine, 891. tenure in Texas, 591. tenure problem, book on, 387. tenure, share-rent system, 592. tenure, studies, 891. Landsarable, in United States, U.S.D.A., 693. cut-over. (See Cut-over land.) forest. (See Forest land.) central Europe, laws affecting alienation, 693. in newly broken, clover and timothy for, Idaho, 226. sandy. (See Sand and Sandy.) swamp. (See Swamp.) washed, of Indiana, Ind., 130. waste, conversion into meadow, 231. Lapwing, food habits, 454. Larchfor wood-block pavement, 790. in Swedish forest economy, 345. rusts of, 353. wood, penetration by creosote, 820. Lard, storage holdings, U.S.D.A., 558. Laria (Bruchus) rufimana, control, 759. Larkspurs, toxicity, Wyo., 407. Larus hyperboreus barrovianus, status, 846. Lasioderma scrricorne. (See Cigarette beetle.) Laspeyresia molesta. (See Peach moth,

oriental.)

Leaddetermination, 413, 713. poisoning in waterfowl, U.S.D.A., 581. Lead arsenatefor codling moth control, 460. fungicidal value, Ill., 146. insecticidal value, Wis., 661. powdered v. paste, 160. triplumbic form, Mo., 650. use with Bordeaux, 533. use with lime-sulphur, Ill., 750. Leafcrumpler in South Dakota, 59. hoppers of genus Gypona, 456. hoppers of Nova Scotia, 849. Leatherchemistry of, progress, 614. determination of water-solubles in, 506. nitrification, 517. waste, utilization, 723. Leavesdried, fertilizing value, 814. effect on shoot formation, 526, 727. photosynthesis and respiration, 28. temperature, determining, 222. transpiration, device paralleling, U.S.D.A., 725. Lecanium prunastri in Pennsylvania, 164. Lecithin feeding of white mice, effects, 767, 768. Leeks, variety tests, 443. Legumesarborescent, of Hawaii, 344. effect on succeeding turnip crop, 231. for silage, Mo., 334. inoculation, 523, 832; Ga., 130; Mo., 335. (See also Nodule bacteria and Nodule production.) value on Indiana soils, Ind., 19. varieties for hay and pasture, 334. (See also Green manures and Alfalfa, Clover, etc.) Leguminosæ important for food and fodder. 729. Leidyopsis sphærica n.g. and n.sp., studies, 464. Leiomyza in North America, 62. Leishmania infantum, studies, 781. Lema trilineata, notes, Conn.State, 159. Lemonjuice, antiscorbutic value, 860. oil, index of adulteration, 715. stocks for oranges, 447. Lemonsbud curl or pinch at grafting union, 452.culture in South Africa, 540. fruiting habits, 651. Lenzites sepiaria on hemlock, 454. Lepidiota spp. on sugar cane, 354. Lepidoptera, economic, studies, 552, 757. Lepidopterous larvæ, preservation, 56. Lepidosaphesbeckii. (See Purple scale.) ulmi. (See Oyster-shell scale.)

Levulose, determination, 12. Licebiology, 552. destruction by dry cleaning, 255. investigations, 457, 458. on chickens, remedies, 662. reaction to bites of, 551. relation to trench fever, 851. relation to typhus, 552. treatise, 457. Life duration in the white mouse, studies, 767. Lightartificial, effect on egg production, N.J., 572, 869; Wash., 871. artificial, effect on plant growth, 885. measurements on heights and in forests, 330. (See also Sunlight.) Lignin, determination, 14. Lignum-vitæ, uses and supply, 244. Limax cinerus as carrier of Davainea, 881. Limeagricultural, analyses, N.J., 24. arsenate. (See Calcium arsenate.) chlorinated, as water disinfectant, 583. determination in white lead, 314. industry in Montserrat, 891. juice, antiscorbutic value, 470, 861. niter. (See Calcium nitrate.) nitrogen. (See Calcium cyanamid.) potash, fertilizing value, 724. requirement of soils. (See Soils.) Stassfurt-salt by-product, preparation, 724 weed-control value, 538. (See also Calcium.) Limes-Fomes parasite, 658.

sweet, as stocks, 447.

Limestoneaction on acid soils, Ill., 818. asphalt mortar, tests, 884. dealers, list, Iowa, 24. ground, for cotton and corn, Ark., 130. manganese content, 521. phosphate, of New Zealand, 326. various forms, comparison, 520. Lime-sulphur mixturesdilution, Ill., 146. fungicidal value, 657, 658. naphthalene, 657. preparation, 842. use, Mo., 356. use with lead arsenate, Ill., 750. Lime-tree borer of New South Wales, 555. Limicola platyrhyncha, proper name, 250. Limingeffect on potash solubility, 126. experiments, 228, 428, 520; Del., 136, 137; Mass., 21; Mo., 624; N.Dak., 124; R.I., 135. experiments on bog soils, 230. experiments on grassland, 826. experiments on moor soils, 212, 520. (See also special crops.) of Essex soils, 724. of Iowa soils, Iowa, 24. Linden lace bug, notes, 847. Linkage in maize, 436 Linseedmealanalyses, 868; Can., 565; Conn. State, 176; R.I., 564; N.Y. State, 868. and cake, analyses, Ind., 868; N. H., 68. and screenings, analyses, Ind., 564. feeding value, 569, 771; Ind., 70; Kans., 69; Mich., 74; Nebr., 770. for horses, Mass., 274. oil, production in Great Britain, 734. oil, use with Bordeaux, 355. Lipoidsas antigens, 477. determination, 116, 764. importance in nutrition, 559. in the blood in Tropics, 764. organ, origin of, 673. Lipovaccines, preparation, 377. Litter size, influence of male on, 268. "Little leaf" of fruit trees, studies, 452. Live stockdiseases. (See Animal diseases.) in Canada in 1917, Can., 594. industry in Dutch East Indies, 768. insurance, 793. laws in Maryland, 81. market reports, U.S.D.A., 672. marketing, cooperative, 593. patent medicines for, N.Dak., 673. production, climatic conditions controlling, U.S.D.A., 417. remedies, inspection, Conn.State, 176. situation in 1919, U.S.D.A., 891.

# 966

## INDEX OF SUBJECTS.

Macrosporium solani-

control, 51.

Live stock-Continued. statistics of France, 671. statistics of United Kingdom and France, U.S.D.A., 671. (See also Agricultural statistics.) (See also Animals, Cattle, Sheep, etc.) Liveratrophy in horses, 873. relation to blood protein, 859. Llama, domestication in Peru, 869. Locoweed disease, U.S.D.A., 582. Locustborer, control, U.S.D.A., 358. heart rot, notes, 752. tree and its allies, geologic history, 46. Locustscontrol, 455, 662. 17-year, Ohio, 163. (See also Grasshoppers.) Loganberry juice, analyses, U.S.D.A., 111. Lolium subulatum as pasture grass, 641. Lonchwa aristella, studies, 552, 553. Lonchocarpus cyanescens, indigo from, 734. Loranthaceæ, sap concentration, 632. Louisiana-Stations, notes, 498, 899. University, notes, 498. Louping-ill, studies, 578. Loxostege sticticalis, notes, Mont., 57. Lucern, (See Alfalfa,) Lucilia spp., relation to anthrax, La., 461. Lumberexport and our forests, U.S.D.A., 448. policy, national, U.S.D.A., 149. (See also Timber and Wood.) Luminescence of Pseudomonas luminescens, 222.Lunar tide in atmosphere, 211. Lungworms in sheep, 878. Lupinesabsorption of calcium salts, 221. germination as affected by organic substances, 523. Lyda hypotrophica, notes, 847. Lygus campestris, notes, 354. Lymphangitisbovine, studies, 782. contagious, treatment, 192. epizootic, studies, 579. ulcerous, studies, 87, 479, 579. ulcerous, treatment, 379. Lysin as product of hordein, 11. Macaroni wheat. (See Wheat, durum.) Machinery. (See Agricultural machinery.) Macrobasis murina, notes, 259. Macrodactylus subspinosus. (See Rose chafer.) Macronoctua onusta, notes, Conn.State, 159. Macrosiphumcynosbati, notes, Mich., 660. ribiellum n.sp., description, 850. solanifolii, notes, 160. solanifolii, remedies, 756. solanifolii, studies, Va.Truck, 662. spp. on vegetable crops, N.J., 255.

culture, 152. on tomato, 156. Madieæ, genera and species, studies, 330. Magnesiumand calcium ratio in soil as affected by wheat crop, N.Dak., 124. arsenate, solubility in carbon dioxid, 799. determination, 313. loss from soils, 214. salts as soil amendments, 326. soil, as affected by sulfofication and nitrification, 325. sulphate, effect on soil solubility, Mich., 512. v. high-calcium limestone, 520; Del., 137. Maguey as paper-making material, 732. Mahoganymicroscopic characteristics, 541. species, descriptive accounts, 541. Mahua cake, fertilizing value, 816. Maidism in guinea pigs, 562. Maine Station, report, 98. Maize. (See Corn.) Malacosoma americana. (See Tent caterpillar.) Malariacontrol, drainage for, 482. economic loss caused by, in irrigation district, 553. lessons on, 396. (See also Mosquitoes and Anopheles.) Malarial blood, fat content, 764. Maltextract, effect on calcium retention of infants, 561. green, antiscorbutic value, 561. sprouts, analyses, Ind., 564; N.Y.State, 868. Mammarydevelopment in a doe kid, 79. gland, relation to embryonic development, 862. gland, studies, 173, 174. secretion, physiology, 79. Mammitis, studies, Mich., 681. Manbasal metabolism, 760. energy exchange in, 563. Manganeseeffect on plant growth, Hawaii, 149. effect on wheat, and sources of, 521 of soil as affected by sulfofication and nitrification, 325. oxid crystals from Virginia, 420. salts as soil amendments, 326. salts, reaction of, 504. soils, - methods of handling, Hawaii, 138, 148. Mange, parasitic, 286.

(See also Horse mange and Sheep scab.)

1919]

[Vol. 41

Mangelsculture experiments, 229, 334; Can., 528 effect on following crop, R.I., 135. fertilizer experiments, 228, 229, 334; R.I., 135. field tests in Nova Scotia, 729. potash for, 629; Mass., 21. sodium for, R.I., 426. varieties, Idaho, 226; Nev., 228. variety tests, 334. Mango ripe rot, treatment, 841. Mangoesculture experiments, 650. culture in Sind, 837. Manila rope, strength requirements, 884. Manioc. (See Cassava.) Mannose yeast, 508. Manureammonification in soil, 20. and sulphur composts, effect on greensand potash, 799. application, N.Y.Cornell, 22. composition, 424. conservation, 322, 424. effect on azofication, 125. effect on soil bacteria, Del., 130; Ga., 130. effect on soil composition, 420. effect on toxicity of alkali salts, 322. fertilizing value, 424, 814, 825, 826; Ark., 130; Can., 516; Del., 136; Idaho, 225; Kans., 32, 33; Mass., 21; Mo., 624, 644; N.Dak., 139, 822; N.Mex., 139; N.Y.Cornell, 22; Nebr., 433. for greenhouse crops, Ill., 147. for manganese soils, Hawaii, 138. for permanent meadows, Mass., 21. fresh v. rotted, N.Dak., 139, 823. liquid, conservation in peat, 722. liquid, notes, 626. liquid, of bullocks, value, 814. liquid, preservation of nitrogen in, 20. liquid, studies, 721. production, conservation, and use, 322. residual effect on clover, 131. treatment with sodium arsenite, 625. use, guide for, 626. use on sand hill land, 813. Manuring, treatise, 21. Maplefrustum form factor, Vt., 47. scale, gloomy, notes, N.C., 660. Marasmiussacchari, notes, 841. sp. on sugar cane, 450. Mares, feed records, Can., 570. Margarinsfrom hardened fats, 362. methods of analysis, 412. nut, inspection and analyses, Conn. State, 170. Valenta test and Crismer number, 805. Margaropus annulatus. (See Cattle tick.) Marine salts, fertilizing value, 724.

Market reports, U.S.D.A., 672, 695. Marketingcooperative, 341, 593; Ill., 834. in North Carolina, N.C., 94, 294, 492, 695. in Texas, 591. Markets, municipal, 593. Marmalades and artificial marmalades, 66. Marsh gas, origin, 720. Martin roost in Washington City, 547. Maryland Station, notes, 100, 199, 700, 899. Massachusetts---College, notes, 199, 398, 498. Station, notes, 398, 498, 700, 899. Station, report, 98. Massospora cicadina, studies, 456. Mastitis. (See Mammitis.) Maternity in rural Wisconsin, 794. May beetlescontrol, 847. wingless, notes, 666. Mayetiola destructor. (See Hessian fly.) Meadow plant bug, Me., 162. Meadowsdrainage, 230. from waste land, 231. top-dressing experiments, Mass., 21. (See also Hay, Grass, and Grassland.) Mealy bugs, studies, 756. Meatand bone meal, analyses, 868; Ind., 564. and meat products, international trade, U.S.D.A., 892. drying, 362, 557, 807. estimation in sausages and meat pastes, 713, 714. hygiene, textbook, 81. industry in southern Brazil, 671. inspection in Norway, 280. market reports, U.S.D.A., 672. meals for hogs, Iowa, 272. methods of investigation and standards, 558. poisoning, toxic agent, 668, 808. powder, dried, 362. preservation, 263, 415. products, determination of water in, 799. scrap, analyses, Ind., 564, 868; N.H., 68; N.Y.State, 868. scrap for laying hens, Ind., 571. scrap, phosphoric-acid standard, 564. spoilage, 808. storage and shipping space, saving, 672. storage holdings, U.S.D.A., 558. (See also Beef, Pork, etc.) (See Culture media.) Media. Medicago falcata, culture in Alaska, Alaska, 31. Medicinal plants. (See Drug plants.) Medlar, stoneless, origin, 446. Megalomerothrips, new genus, erection, 847.

Meibomia leiocarpa as forage crop for Cuba, 829. Meigenia floralis, notes, 59. Melampsora pinitorqua, studies, 659. Melampsoræ, studies, 353. Melanconium sp. on butternut, 752. Melanophila spp., biological notes, 166. Melanoplusdifferentialis, control, Ariz., 355. spp., poison baits, 252. Melanopsammopsis ulei, notes, 841. Melanorrhæa usitata oleo-resin, 345. Melaphis minutus n.sp. from moss, 255. Melezitose in honey-dew honeys, 799. Melonaphis in New Jersey, N.J., 255. beetles, notes, N.C., 660. fly in Hawaii, Hawaii, 146. Mendeliandistribution, characters, theoretical 267, 268, 473. population, fluctuations of sampling in, 867. theory, exposition and critique, 726. Meningitis, cerebro-spinal, in the horse, 280, 480, 784. Meningococcus as affected by vitamins in animal tissue, 574. Mercuric acetate, oxidation of creatin by, 668 Mercurophen as a disinfectant, 283. Mercury, density of, 808. Merker grass, culture in Florida, Fla., 37. Merrillia, new genus of the Citreæ, 432. Mesaporus calandræ, notes, 759. Mesembryanthemum, gas interchange, 28. Mesquite, climax formations, 634. Metabolic laboratory, hospital, 68. Metabolismas affected by phlorizin, 68. as affected by rate of cooling 365, 563. basal, in man, 760. fat, relation to accessory substance, 559. mineral, of milch cows, 372. mineral, relation to protein require-ment, 558. of women workers, 761, 856. per calorie of technical work, 563. phosphorus and calcium, of milch cows, 678. protein, of Filipinos, 563. protein, studies, 171. Meteorologicalliterature, classification, U.S.D.A., 121.. observations-Alaska, 17; Mass., 17, 315, 509, 808; Me., 17; U.S.D.A., 120, 121, 417, 418, 509, 716, 808; Wyo., 315. at Hettinger, N.Dak., 809. in New South Wales, 509. in New Zealand, 718. in Philippines, 718. in Sweden, 809. tables, Smithsonian, 808.

1919]

Meteorologyintroductory, textbook, 15. papers on, 716; U.S.D.A., 120, 418, 716. (See also Climate, Rainfall, Temperature, Weather, etc.) Methyl alcoholin Gottlieb-Roese test, 311. production from alkali-sawdust fusion, 314. U.S.P. test for, 715. Methylguanidin, occurrence in meat, 668. Michigan-College, notes, 798. Station, quarterly bulletin, 98, 397, 598.Station, report, 698. Middlingsanalyses, N.H., 68. feeding value, Mich., 74. (See also Wheat, Oat, Rye, etc.) Mildew proofing of canvas, 551. Mildews, powderystudies, Mo., 654. treatment, 751. Milkadded water in, determination, 799, 804, 805. adulterated, detection, 208. antiscorbutic property, 266, 470. as a galactagogue, 80. as affected by gestation and stage of lactation, 679. bacteria, alkali-forming, U.S.D.A., 374. bacteria as affected by clarification, Mass., 278. bacteria, lactose-fermenting, 888. bacterial analysis, 372, 373, 573, 679, 776. bacterial count as affected by separator, 374, 375. boiled, curd of, 468. buffaloes', 680, 777. cans, washing, 373, 774, 775. cellular count, relation to udder infections, Mich., 578. certified, Drosophila in, 57. chemistry, progress in, 201. citric acid content, determination, 804. clarification, Mass., 278. coagulation in the stomach, 467. colloid chemistry of, 310. composition, calculating from cheese analysis, 805. composition, factors influencing, 679; Mo., 677. condensed, antiscorbutic property, 470. condensed, preparation, 81. condensed, production and international trade, U.S.D.A., 892. condensed, production during the war, 473. consumption in United States, 774. cost of production, Mo., 694; Ohio, 274.cost of production in Illinois, 573, 677.

[Vol. 41

Milk-Continued. dehydration, 557. dialysed, for infant feeding, 859. dried, antiscorbutic value, 266. effect on smooth muscle, 858. electrical conductivity, 804. electrometric titration, N.Y.State, 201. ewe's, 176. examination, 372, 373, 573, 679, 776, 804, 805. fat, Babcock test, Iowa, 279. fat, estimation in margarin, 412, fat, relation to solids-not-fat, 372. fat, Valenta test and Crismer number, 805. food value, Ill., 65. grading, 775. handling in city milk plants, 775. human, composition, 615, 802. human, effect on smooth muscle, 858. human, zinc content, 464. hygiene, textbook, 80. inspection, 372, 573, 775, 776. laws and regulations, 372, 373. marketing, 183, 184. methods of investigation and standards, 558. nonprotein nitrogenous constituents, 616, 802. pasteurization, 184, 775. pasteurized, antiscorbutic value, 266. pasteurized, coagulation in the stomach, 468. peroxidases in, 616. powder, antiscorbutic value, 470. powder, preparation, 81. preserved, lactose determination in, 505. price fixing, 193, 573, 574. price of protein in, 677. production and distribution in Great Britain, 184. production as affected by drugs, 181. production, cottonseed meal and peanut feed for, Tex., 78. production, feed consumed in, N.Y.Cornell, 180. refrigeration on southern farms, 374. samples, preservation, 573. samples, table for sorting, 804. sanitary production, 774, 775, 776. secretion as affected by milk injection, 80. secretion as affected by pituitrin injection, 79. secretion of a doe kid, 79. secretion, phosphorus and calcium metabolism in, 678. sediment tests, 775. skimmed. (See Skim milk.) sour, lactic acid in, N.Y.State, 201. stations, cooperative, 184. supply, control, 193, 372, 373, 775, 776. supply of a city, control, N.Y.State, 373. supply of New York, 372. supply of small town, control, 373. testing for freshness, 311. transportation, 372.

Milk-Continued. utensils, clean, importance of, 774, 775. utensils, sterilization, 372. zinc content, 464. Milkingmachine v. hand, Mich., 373. machines, studies, N.Y.State, 277, 278. Milletand Sudan grass, comparative yields, Nev., 227. as silage crop, 732. culture experiments, 333. culture in Alaska, Alaska, 31. culture in Burma, 529. effect on succeeding wheat crop, N. Dak., 823. field tests, N.Dak., 824. seed, analyses, Can., 565. v. Sudan grass for Ohio, Ohio, 234. variety tests, Idaho, 225. Milo maizeas dry-farm crop, Ariz., 29. chop, analyses, Ariz., 367. effect on soil, Kans., 34. for laying hens, N.Mex., 571. smut resistance, Kans., 48; Mo., 654. yields, Mo., 637. yields of forage, Ariz., 332. Mineolaindiginella. (See Leaf crumpler.) vaccinii. (See Cranberry fruit-worm.) Minnesota University and Station, notes, 700, 899. Miris dolabratus, account of, Me., 162. Mississippi-College, notes, 498. Station, notes, 100. Missouri-Station, report, 699. University and Station, notes, 100, 498, 599, 899. Mistletoesdistribution in Switzerland, 753. sap concentration, 632. Mites of stored grain and flour, 456, 463. Mitosis, studies, 861. Mohair, exports from South Africa, 772. Molassesbeet, desaccharification, 314. beet pulp. (See Beet pulp.) blackstrap, for sows, N.J., 73. carbon, preparation and value, La., 416. composition and calorific value, 507. feeds, analyses, Ind., 868; N.Y.State, 868. feeds, sugar content, Can., 565. Mole crickets of Java, 847. plows worked by horses, 586. Monarda punctata as source of thymol, 825. Mongoose in West Indies, 56. Monilia fructigena, notes, 53. Monohammus fistulator, notes, 555. Monolepta rosæ on maize, 57. Monomorium bicolor nitidiventre causing edema of eyelid, 463.

rubi. Raspberry | Monophadnoides (See sawfly.) Montana-College, notes, 100, 398. Station, notes, 398. Moor soilsbog, treatment, 230. drainage, 230, 687. effect on composition of crops, 422. fertilizer experiments, 519, 786. irrigation, 786. liming experiments, 212, 520. nitrification in, 212. reseeding frost-injured oats on, 734. (See also Peat soils.) Morchella esculenta, studies, 834. Morels, studies, 834. Morning-glory, wild, control, 537. Morphine, crystallography, 801. Mortarcement, bonding, U.S.D.A., 382. limestone-asphalt, 884. Mosquitoescontrol, 553, 666, 757; Conn.State, 159; N.J., 58. flight through water pipes, 461. in England, 358. in relation to yellow fever, 851. (See also Anopheles, Stegomyia, etc.) Moth beans, culture experiments, Tex., 36. Motortransportation, rural, U.S.D.A., 383. truck drives for bad roads, 887. truck traffic, efficiency of bituminous surfaces under, 688. trucks, braking tests, 586. trucks, impact tests on roads, U.S.D.A., 689. trucks, tests on concrete roads, 584. trucks, tire maintenance, 586. vehicles, gasoline consumption, relation to tractive resistance, 486. vehicles in United States, U.S.D.A., 383. Muckcrop diseases, studies, Mich., 654. soils of Ohio, Ohio, 212. Malberrybark disease, notes, 752. glucose absorption by aerial parts, 818. scale, biological control, 847. Mung beans, culture experiments, Tex., 36. (See Potassium Muriate of potash. chlorid.) Musca domestica. (See House fly.) Muscle, ammonia concentration in, 616. Mushroomsculture, 339. food value, 66. studies, 834. Muskeg, culture experiments, Minn., 387. Muskmelonsbreeding experiments, N.J., 43. culture, Mich., 147. Muskrat in Bohemia, 56.

Mustard--diseases, notes, 745. fertilizer experiments, 816. germination as affected by organic substances, 523. insects affecting, 455. pastured-off, effect on following crop, 826. wild, control by spraying, 537. yellow, seeding experiments, 230. Mustards, table, analyses, 263. Mutation injimson weed, 634. Œnothera, 431, 634, 821. Enothera, size characters, 224. (See also Variation.) Muttoncarcasses, space-saving method of preparing, 672. gastric response to, 857. production in United States, U.S.D.A., 892. Mycoderma sp. in banana must, 716. Mycosis of turkeys, 481. Myelophilus spp. in Sweden, notes, 455. Myosotis, variety tests, 242. Myxobacteriales, subgroups and genera, 821. Myxosporium valsoideum on plane, 353. Myzoides persicæ, control in Deli, 354. Myzomyia ludlowibiology, 460. relation to malaria, 553. Muzuspersice. (See Peach aphis, green.) ribis. (See Currant aphis.) Naartjes, culture in South Africa, 540. Napier grass, culture in Florida, Fla., 37. Nasturtium, aerial fertilization with carbon dioxid, Vt., 833. Natal grass, culture experiments, Ariz., 331. Nature studyand humaneness, syllabus, 494. civic, textbook, 598. course, Cal., 95, 597. in Canada, 896. textbook, 97. Nebraska-Station, report, 495. University and Station, notes, 498, 899. Necrobacillosis in swine, 87, 474, 777, 781, 783. Nectria sp. on birch, 752. Nematocampa limbata, studies, N.Y.Cornell. 161. Nematodesaffecting pea roots, 51. affecting rice, studies, 64. causing parasitic gastritis, 479. parasitizing turtles, 753. root, control, 660, 846; Fla., 548; N.J., 50. Neoechinirhynchidæ, synopsis, 464. Neotettix proavus, long-winged or caudate phase, 59.

Nephritis, diet used in treatment, 561. Nessler's solution, regeneration, 712. Nests, open and trap, Wash., 292. Neurotoma inconspicuain South Dakota, 59. studies, S.Dak., 251. Nevada----Station, report, 299. University and Station, notes, 899. New Hampshire College and Station, notes, 499. New Jersey-College and Stations, notes, 498, 899. Stations, report, 98. New Mexico-College, notes, 900. Station, notes, 398, 900. Station, report, 198. New York-Cornell Station, notes, 499. State Station, notes, 300, 700. State Station, report, 397. State Veterinary College, 696. Nezara viridulahibernation, Fla., 548. in citrus groves, 355. studies, 251. Nicotianarustica, aurea character, 440. tabacum, gigantism in, 440. Nicotiana, self-sterility, studies, 223, 431. Nicotinsolutions, strength of, 754. sulphate, insecticidal value, 160; Ill., 146. Night soil, fertilizing value, 814. Nigrospora panici, notes, 544. Nippon river fever. (See Tsutsugamushi.) Nisotra breweri, notes, 661. Niter cake for ammonia fixation, 516, Nitratecontent of soil as affected by various crops, N.Dak., 823. deposits of Amargosa Valley, 323. formation as affected by cultivation and weed growth, Kans., 33. Norwegian. (See Calcium nitrate.) of ammonia. (See Ammonium nitrate.) of lime. (See Calcium nitrate.) of potash. (See Potassium nitrate.) of soda. (See Sodium nitrate.) production in soil, studies, Mo., 623. Nitratesdetermination, 204. effect on soil solubility, Mich., 512. Nitrificationas affected by organic matter and lime, 319. as affected by phosphates, 721. as affected by sodium salts, 320. as criterion of fertility, 321. effect on rock phosphate, 324. effect on soil constituents, 324. in bhatta soils, 812. in Egyptain soils, 812. in embanked wheat soils of India, 811. in moor soils, 212.

Nitrification-Continued. in natural soils, 125. in wheat seed bed, Kans., 33. of leather, 517. of oil cake, 517, 816. studies, 421, 623, 720. Nitrite formation in solution, 623, Nitrites, determination, 204. Nitrobenzene, toxicity, N.Y.Cornell, 82. Nitrocelluloseexplosives, colloid chemistry, 801. from woodpulp, 14, Nitrogenabsorption by peat, 722. amino-acid, in gastric residuum, 764. assimilation as affected by sulphates, 427.assimilation, relation to cellulose decomposition, 632. atmospheric, solution by water, 321. compounds, production in Germany, 424. content of cacao soils as affected by shading, 213. content of crops as affected by soils and fertilizers, 422, 813. content of field soils, variations, 124. content of high-altitude grasses, Wyo., 333. content of rain and snow, 620; Can., 510. content of soil as affected by Kafir corn, Kans., 34. content of soil as affected by various salts. 326. determination, 504, 803. determination in blood, 13, 116, 617. determination in fertilizers, 228. determination in oils, 711. determination in soil, 124, 411. determination in urine, 414. distribution, determination, 712. fixation as affected by sodium salts, 320. fixation as criterion of fertility, 321. fixation, fertilizers from, 423. fixation, nonsymbiotic, 125, 721. fixation processes, 22, 111, 131, 218. fixed inorganic, production and consumption, 22. lime. (See Calcium cyanamid.) movement in soils, 214. nitrate and organic, relative availability, 627. of liquid manure, studies, 721. Nitrogenouscompounds, utilization in bacterial nutrition, 264. constituents of feeding stuffs, 367. refuse, utilization, 723. Nitrogenous fertilizersavailability, N.J., 22. comparison, 22, 218, 229, 424, 723, 814, 815, 825; Can., 516; Mass., 21. for corn and wheat, Del., 136. for orchards, Mo., 649, 650. mineral v. organic, N.C., 624

## INDEX OF SUBJECTS.

Nuts-Continued. Nitrogenous fertilizers-Continued. mining and manufacture, 423. organic-cake, bacterial transformation, 816. residual effect, N.C., 625. Oakuse in India, 323. world's supply, 424. Noctua fractilinea, notes, Mich., 660. Noctuid moth, control, 339. Nodulebacteria as affected by germination, Oat-735.bacteria as affected by sulphates, 427. production in bhatta soils, 812. production, notes, 522. (See also Bacillus radicicola and Legumes, inoculation.) North Carolina Station, report, 699. North Dakota-College, notes, 399, 499. Hettinger Substation, report, 897. Station, notes, 399. Station, report, 198. Nosema apis, diagnosis, 667. Nosema disease of bees, U.S.D.A., 359. Nucleus of leaf cells as center of oxidation, 221. Nummularia discreta, studies, 347. Nurseryinsects in New Jersey, 549. inspection, Conn.State, 158. Oatsinspection in Illinois, 835. inspection in New Jersey, 443. inspection law of South Dakota, 58. stock crown gall, studies, 545, 750; Iowa, 238, 249. stock, imported, insect pests on, 251. Nusa, Nearctic, notes, 62. Nut margarins, inspection and analyses, Conn.State, 170. Nutrientmedia. (See Culture media.) solutions as affected by added solids, 133. solutions as affected by adsorbing surfaces, 422. solutions at minimum concentration, root absorption from, 132. solutions for maize, 820. solutions, use of iron in, 430. Nutritionanimal, methods of experimentation, 366. fat-protein ratio in, 669. influence on immunity production, 574. of the rat, accessory factors in, 171. reduction of standard ration, 854. rôle of various food constituents in, 670. standard of adolescence, 669. studies with tadpoles, 468.
