TERMS OF SUBSCRIPTION. "THE BUILDER" is supplied gratis from the Office to residents in any part of the United Kingdom at the rate of 12s. per annum; 15s. for all parts of Europe, America, Australia, and New Zealand, 26s. per annum. To India, China, Ceylon, & 30s. per annum. Remittances payable to DOUGLAS FROST, Publisher, No. 46, Catherine-street, W.C.

Best Bath Stone, for Winter use. WESTWOOD GROUND, Box Ground, Combe Down, Corsham Down, & Summer Farleigh Down, &c. Dried. RANDELL, SAUNDERS, & CO., Limited, Corsham, Wilts. [ADVT.]

Box Ground Stone is the best for use in all exposed positions, being a well-known and tried Weather Stone. 50,000 ft. cube in stock. P I C T O R & S O N S, BOX, S.O., WILTS. [ADVT.]

Doubling Freestone. The stone from these quarries is known as the "Weather Beds," and is of a crystalline nature, and undoubtedly one of the most durable stones in England. It is of the same crystalline nature as the Chelchyn Stone, but finer in texture, and more suitable for fire-worked work. THE CHELYNCH STONE. THE BRAMBLEDITCH STONE. HAM HILL STONE.

Greater facilities have been provided for working these quarries, and the stone can be supplied in large quantities at short notice.

Prices, and every information given, on application to CHARLES TRASK & SONS, Norton-sub-Hamdon, near Ilminster, Somerset; London Agent—Mr. E. WILLIAMS, 16, Craven-street, Strand, W.C. [ADVT.]

Doubling Free Stone For prices, &c. apply to HAM HILL STONE, Quarry Owners, Stone and Lime Merchants, BLUE LIAS LIME, Stoke - under - Ham (Ground or Lamp), Ilminster. [ADVT.]

Ham Hill Stone! Ham Hill Stone! For Ham Hill Stone of best quality and workmanship, apply to JOHN HANN & SON, Quarry Owners, Montacute, Ilminster. Established 1837. Agents, MATTHEWS & GEARD, Alban Wharf, Regent's Park Basin, N.W. [ADVT.]

Asphalte.—The Sysel and Metallic Lava Asphalte Company (Mr. H. Glenn), Office, 35, Poultry, E.C.—The best and cheapest material for damp courses, railway arches, warehouses, floors, flat roofs, stables, cow-sheds, and mill-roofs, granaries, tin-rooms, and terraces. [ADVT.]

Asphalte. Sysel, Patent Metallic Lava, and White Asphaltes. M. STODART & CO. Office: No. 90, Cannon-street, E.C. [ADVT.]

EVERY DESCRIPTION OF SEASONED WOODS AND VENEERS IN EXTENSIVE QUANTITIES.

B. J. HUDSON & SONS, Millbank Sawmills, Grosvenor-road, S.W.; Whitfield-street, W.; And Store-street, London, W.C. Telephone No. 3,152, and Private Wire connecting Business Premises.

BANNER VENTILATORS.

The Strongest Exhaust Ventilators for all Buildings, Public Halls, Churches, Billiard-Rooms, &c.

HIGHEST PRIZES at all the most important Exhibitions.

BANNER SYSTEM OF SANITATION AND SANITARY APPLIANCES

WERE AWARDED AT THE

International Health Exhibition, 1884, One Gold Medal, Three Silver Medals, and One Bronze.

For further Particulars and Prices apply to

BANNER BROS. & CO. Sanitary and Ventilating Engineers, 11, BILLITER SQUARE, LONDON, E.C.

The Trade Guilds of Europe.

IN May, last year, a delegation from the Merchant Tailors' Exchange of Washington waited upon the Secretary of the State Department, to solicit its assistance in securing, through the Consular officers, information as to the conditions which prevail, and have prevailed for some time, between employers and employed in the several countries of Europe.

The principal points on which they desired information were, as to the existence of schools where boys may learn their trade, the laws by which they are governed, and if the system was successful; whether there are any guilds connected with the trade, and if so an account of the constitution, and the laws and regulations concerning apprenticeship. Before applying for the information it occurred to the Department that it would be equally valuable to the other trades.

Instructions were then sent to the various consuls to supply the required information, and that they might consider necessary for the full illustration of the conditions and relations which exist between the employers and employed in their districts.

The result is a volume of over 300 pages, containing full information on the various subjects. Taken together with the previous Report on Labour in Europe, which contains the rates of wages in all trades, hours of labour, cost of education, living, &c., and social habits, it presents as good a description of the state of the industrial classes of Europe as can be got. Some of the consuls, judging by the work, have made no reply; others say there are no such institutions in their district; others give a very brief description; but these cases are exceptions. Full information is given on guilds, trade-unions, apprenticeship, schools, technical education, customs and laws of trade, social habits, and other topics, and the works should be in the hands of all interested in industrial pursuits.

Among its contents are the trade regulations of the German empire; a valuable description of the Russian *artels*, or associative labouring societies; the rules of ten trade-unions of Scotland, including the masons, painters and joiners, and plumbers; and the conclusions of the second Report of the English Royal Commission on Technical Instruction, with the recommendations of the Commission. The Report from Leipsic is devoted to the history of guilds, and contains several inter-

esting features. None of the other Reports treat of the historical part of the subject.

According to Walford, trade guilds "existed in England at a very early date. There is good reason for supposing that in the tenth century there was an order of monks in the north of Germany whose chief occupation was commerce, and who probably encouraged and protected the guilds. These were known as the Grand Masters of the Teutonic orders. They founded a branch in London during the reign of Edward the Confessor, under the title of *Gildhalla Teutoniarum*. These merchant guilds are believed in many cases to have arisen quite independently of the towns wherein they were located; but in other cases they seem from the beginning to have been identified with the town and its corporate government. It seems clear that in early times the craftsmen were frequently members of the merchant guilds. The strict separation which at a later date existed between the merchant and the craftsmen did not then prevail, and probably only came about by degrees." But according to Brentano, the craftsmen to be admitted to the merchant guild had to be in possession of the full citizenship of the town, which implied the possession of land.

The men who in towns were citizens by the possession of town land were often also traders, and early formed for their protection a guild *mercatorium*, when the towns obtained charters; by their influence they obtained as one of its conditions that the men of the place should also have their guild merchant. Thus the citizens and the guild became identical, and what was guild law often became the law of the town. In great cities, where there were no merchant guilds, there the craftsmen early asserted their independence. Many craft guilds existed in Italy from the ninth to the twelfth century, the heads of which possessed a share in the government of the community. But in England and the North of Europe the guilds merchant, having become wealthy, excluded the handicraftsmen. From the union of these latter arose the craft guilds who gained the supremacy in the struggle for liberty. On the Continent the struggle was much more severe than in England, because the craft guilds were subject to greater oppression. In England the two guilds usually existed side by side until the increasing importance of the craft guilds and the decay of the merchant guilds led to their union, and so the craft guilds formed part of the constitution of the town.

The constitution of trade guilds was similar to that of others. They appointed a master and other officers, made ordinances and regulations for their government, the maintenance of their craft and its customs, including rules

against fraudulent workmanship, and the punishment of members infringing the rules; they assisted the members in sickness and adversity, settled all disputes, and had entire control of all matters relating to trade. At first craft guilds were voluntary associations; as they gradually increased in importance and power the terms of membership were altered, charters were conferred upon them confirming their privileges and rights, and no one was allowed to practise his trade who was not a member of the guild. The same causes which led to their rise also contributed to their fall. Growing up by their side was a poorer class who were excluded from citizenship; to these were added craftsmen who were not members of the guilds. In course of time they made their influence felt, and as they rose so the craft guilds decayed. The influence of the Reformation, the changed state of society, the growth of capitalists, the admission to the guilds of those who had little or no connexion with trade, slowly but surely led to their fall; and these societies, once so powerful, now where they exist do so only in name and for very different objects.

The consular report from Leipsic consists of a history of trade guilds founded on notes supplied by Mr. Mothes, an eminent Saxon architect, who is preparing an exhaustive work upon the guilds of the world.

It commences with a description of the early societies analogous to guilds, which are described as being founded through the endeavours of the toiling masses to free themselves from the galling yoke of oppression, gives an account of the Roman *collegia officina* down to the fall of the empire, and of the way in which they spread through those countries that were under Roman rule, and in a comparatively brief space gives a history of trade guilds in Germany down to their abolition in 1869, and of which we give some account, commencing with the conquest of Constantinople.

"When Theodoric the Great conquered that city he found some guilds existing there. The *singularium artium magistris* (masters of special arts) are mentioned often during the reign of the Ostrogoths. The title of *magister* was given to every full privileged member of a guild during those those days.

In 590, Thudolinde, Queen of Lombardy, gave certain privileges and rights to the *magistri Comacini* (stone-cutters) on the island of Comacina, in the lake of Como. This *magisterium* existed until the fall of Didier, and from 644 to 724 it was regulated by special laws. Besides the *magistri Comacini* there is evidence of the existence of the *magistri casarii* (house builders), and the *magistri Antelami* (carpenters of Antelamo). When Charlemagne invaded Lombardy he con-

firmed the privileges of the Lombard guilds, and gave to the *maçons* (masons) the rights enjoyed by the free Franks. Long before this Lombard artisans had emigrated to France and Holland, and carried the guild system with them, so that under the comparatively liberal government of Charlemagne they flourished better than for centuries. This is a different view to that taken by other writers, who assert that Charlemagne and his successors forbade the existence of guilds and societies, and decreed the severest punishments against those entering into such combinations.

The clericals and monks now began to engage in the various trades, and soon exercised great influence over the different branches. In 738, the *pes publicus* (the royal standard foot measure) of Liutpand did not satisfy the monks, so they established their own measure, which was called *pes de munitis* (monastic standard foot); and from 914 to 946 the Benedictines strove in vain to prohibit the masons of Lombardy from constructing convents and other religious institutions. At this point began an obstinate struggle of the guilds against the clerical workmen, and also against the serfs and bondmen employed by the nobility. The struggle was bitter, and was felt throughout the Continent. The efforts of the clericals to prevent the guilds from obtaining employment on religious structures did not succeed. In 924 Bishop Ulrich, of Liege, could not find enough architects among the clericals, and was, therefore, compelled to employ members of the guilds. Evidently the word "architect" is here used for or synonymous with "builder." In 1090 Manegold, the architect, was compelled to join a monastic order before he could secure the contract for building the convent at Marheek. In 1099 Bishop Conrad, of Utrecht, prevailed upon the son of the architect Pliher to betray the secrets of a guild. A short time afterwards the son was put to death by the father for his treason.

From this time to the end of the twelfth century various craft guilds were formed, and had increased so much in importance and power, and so strongly supported civil liberty, that from 1200 to 1219 the Emperor Frederick II. endeavoured to suppress them; but they still continued to exist, and in 1232 the Imperial restrictions were removed. During the struggle the guilds were severely treated. At Brunswick, in 1220, six guild-masters were hurned alive and six banished.

In 1230 the guilds of Magdeburg, which had grown powerful, were broken up by royal order, but they were soon re-established with greater privileges and rights. A similar case occurred in 1231 at Wurzburg.

In 1272 Radolph of Hapsburg recognised by decree the rights of the guilds to exist, and gave them the privilege of hearing arms.

During the thirteenth and fourteenth centuries Magdeburg was the scene of the fiercest struggles of the various guilds. In 1330 they secured several seats in the town council, but the next year they were deprived of their recently acquired privileges and the whole of the masters hurned alive. After years of oppression they again secured their rights, and took their places in the town council, and the influence thus gained was felt also in other districts, and helped to secure many advantages to the guilds of neighbouring provinces. Several masters of the guilds were admitted to the town council of Zurich in 1335, but only after a severe conflict.

From 1368 to 1372 members of the guilds are found in the town councils of Aix la Chapelle, Cologne, Dartmund, and Mayence. With the change in the external condition of the guilds occurred a change in their organisation.

It was not until 1150 that the guilds had any voice in the election of the masters. Previously to this the masters were chosen in the cities by the town councils and in the country by the hishops and princes, and at that time no one was allowed to be a member of the Strasburg guild who was not of free and legitimate birth and could prove his ancestry for four generations. Later, illegitimate persons were admitted to membership.

But in 1150 the members of the Strasburg

guilds had the right to reject the masters imposed upon them. In 1190 members of the guilds elected their own masters. Laws could only be enacted by the majority of the members, and candidates for membership admitted in a similar way.

But towards the end of the fourteenth century had come a change. The increase of prosperity had affected the masters of the guilds. The old Strasburg rule of not admitting illegitimate persons to the guilds was revived. Some of the guilds excluded the children of weavers, barbers, shepherds, millers, revenue and tax collectors, musicians, because they were not free born. The advance from fellow to master was rendered more difficult. The right of suffrage was taken away from the fellow. Formerly the candidate for admission to the guild had to execute a piece of work which had to be submitted to all the members. The rule was altered, and the masters assumed to themselves the right to judge the work submitted and to accept or reject any candidate they pleased. Each fellow who aspired to a mastership had to work one year in the place where he desired the mastership, and upon admission had to pay a certain sum of money. Disputes among either the fellows themselves, or between the fellows and the masters, were decided by the masters alone, and, not as formerly, by a committee of the two. Every member had to submit all his quarrels to the masters before applying to the civil or criminal courts for redress. This court within the guilds existed in some places as late as 1840. At this date in Hamburg the lodges of the masons and stone-cutters could inflict the punishment of death, and could not be interfered with by the criminal courts.

Most of the masons and stone-cutters united their lodges and formed a grand union organisation. This union, under the great lodge of Strasburg, comprised all the mason and stone-cutter guilds of England, France, Germany, Hungary, Italy, the Netherlands, Portugal, and Spain. The chief master, residing at Strasburg, in 1263 was subject to the authority of the Archbishop of Milan and of the Pope. No mention is made of the union of German building lodges in 1452.

At the Reformation, the fellows of the guilds were in a state of semi-serfdom. The troubled times which followed, especially the Thirty Years' War, destroyed, in a measure, the power of the guilds, and debased the standard of German handicraft work. The workmen found employment difficult, and entered the military service. When the Thirty Years' War ended, German handwork had sunk so low as to be the subject of ridicule. In 1520, Francis I. of France was obliged to send to Germany for gunsmiths, locksmiths, &c. One hundred years later, France excelled Germany in all kinds of handwork. After the peace of Westphalia, Germany had to depend upon French models in nearly all the branches of handwork. At this time the guilds had lost all their influence. Those of the masters that had seats in the Town Councils were rich persons, manufacturers and not handworkers. Two guilds only retained their ancient position, the Merchants' Guild and the *Universitas*. The other guilds still clung to the organisation adopted in the beginning of the fourteenth century. The little power they had left was exhausted in disputes with other guilds or with workmen who were not members of any.

The carpenters quarrelled with the joiners who made staircases; the joiners quarrelled with the carpenters who made doors; the glaziers quarrelled with the joiners and carpenters who made sashes out of soft wood; the joiners quarrelled with the glaziers who made sashes out of oak. The plumber was allowed to sell lamps, but not lamp-chimneys, globes, or wicks. The physician could prosecute the barber who prescribed a medicine, but the barber could not bring an action against a physician who bled or applied bandages. The *Universitas* would always sustain its members, among whom were the apothecary and physician. Either of them could prosecute the druggist, but he could not prosecute the apothecary.

In course of time the influence and power of the guilds sank even lower. The masterships became hereditary, the fellows thus lost hope and energy; the apprentice became mainly a domestic, and learned little of his trade. At the beginning of this century they were entirely demoralised and disorganised.

In 1815 thousands of German artisans had emigrated or gone into other pursuits. Great efforts were made to revive commerce, but nothing was done for handwork, which had deteriorated through the making of furniture, bronze articles, pottery, &c., by machinery.

In 1847 numbers of the members of the guilds joined political societies in the hope of bettering their condition. This naturally weakened what little influence the guilds had left.

When the revolution was suppressed in 1849, the workmen's unions were dissolved, but continued to secretly exist. At the same time, factories began to be extensively built, and seriously affected the condition of the handworker. Both masters and fellows of the guilds objected to the use of machinery. The former tried to compete with the factories by reducing the wages of the latter, who eventually resisted, and much trouble ensued.

The tendency of the age was towards the suppression of the guilds, and the establishment of general free trade. This took place in Saxony in 1860, and in Prussia in 1868. The guilds were partly dissolved, while the rest of them were restricted in such a way that they soon ceased to exist. A number of fellows established themselves as masters, but, being without either ability, education, or capital, they could not succeed and most of them became bankrupt. The workmen who did not become masters, having lost their guild connexions, gradually became Social Democrats and anarchists. Apprentices who were compelled to pass certain examinations before their time was out entered the masters of other masters as journeymen, no certificate of proficiency being required. Manufacturers took young boys as apprentices, and instructed them in a careless manner. Thus in a machine factory an apprentice was taught how to make rivets, and received a certificate as a locksmith. The tailor established as a builder, and the mason as a maker of implements.

At the present time there is a movement for the general revival of guilds. Laws to this end were enacted in 1878, 1880, and 1883; but these laws, while they impose certain duties on the guilds, do not give them any rights or privileges. Guilds under such circumstances are of no use, as no one will belong to a guild which is loaded with obligations and restrictions, but enjoys no privileges.

Their history in the remaining part of Europe is very similar. In France they existed from before the twelfth century, were re-arranged in 1673, and suppressed in 1791. They possessed halls, almshouses, and chapels, but not much real property. At their suppression the whole of their property was devoted to State purposes, but compensation was given, in some instances, to existing members.

In Belgium the guilds were suppressed, and their property confiscated in 1794. In the Netherlands the guilds were suppressed in 1798, and their property vested in commissioners. In 1820 this property was sold, and the proceeds applied to the relief of indigent members of the suppressed guilds and of the poor of the commune. In Switzerland some of the guilds have dissolved themselves, and either divided their property among their members or applied it to public purposes, particularly education; others exist under the name of *abbayes*, and possess considerable property. In Austro-Hungary the trade guilds were abolished, and their monopolies repealed in 1850. In their stead local bodies representing the masters and journeymen were established, apparently trade councils and tribunals of arbitration. The halls of the trade guilds were sold, and the proceeds given to the new associations. In Norway and Sweden the old trade corporations were dissolved in

1846. In Italy the ancient guilds were abolished with few exceptions in the present century before the union of the kingdoms. After the union, in 1878 and 1879, acts were passed abolishing all monopolies. In Spain many of the craft guilds still exist as benefit societies and trade councils. In Portugal the craft guilds were suppressed in 1834. In Russia trade guilds were introduced by Peter the Great in imitation of similar institutions in Germany. They had but little success, and after a fitful existence up to 1870, under certain conditions, trade was made free to all. In Turkey there are believed to be many institutions resembling the craft guilds of the Middle Ages.

In England the history of guilds is not so eventful as in many of the Continental nations. They were never much subjected to the tyranny of the ruling powers, and did not concern themselves with affairs of State; their struggle for freedom was for the right to participate in municipal affairs and to possess control of matters relating to their trades. The security against foreign invasion, the absence of power in the sovereign to enforce his decrees, and his having to rely upon the people's not having the means of resistance (for when resistance was arranged it was often successful), the aristocracy not being an exclusive caste, the parliamentary system in which the guilds were represented, all tended to diminish the jealousy between classes, and to give to the individual some sense of security. We meet in English history often complaints of exactions and oppressions, but these are comparative terms. What was termed oppression in England might in other countries be regarded as not deserving the same designation. The numerous contests in England that took place on the throne were in reality contests between a part of the people against the other, or were regarded by them with indifference; and, in the whole, they were pretty equally divided.

After victories there were the usual punishments, and cruelties were inflicted on the defeated party, but they were confined to those who took part with either side. Whoever succeeded, no change in the institutions of the country was made, and some historians assert that six weeks after the most violent conflict there was not a trace of it.

The history of guilds in England is the history of its municipal life, of which there is no better example than that of London. The earliest information we have of a craft guild in London was that of the weavers, who had a charter from Henry I., and which was confirmed by Henry II. From 1154 to 1189 there are records of eighteen guilds who were fined according to some authorities for existing without a charter, and, according to others, having neglected to pay the tax which all guilds were liable to. From then till the reign of Edward III. their existence is one continued struggle with the merchant guilds and citizens and each other. In the time of Edward II. was issued an ordinance that required every citizen to be a member of some guild, or mystery, and another ordinance of Edward III. transferred the right of election of corporate officers and members of Parliament from the ward representatives to trading companies. Their victory was now secured, and for many years the guilds possessed both the municipal and political power in the city.

What was the precise connexion between companies or guilds and the corporation is difficult to say. The ordinance of Edward II. required freemen of the City to be members of one or another of the companies. By the ordinance of 49 Edward III. the companies were nominated the members of Common Council, and the persons so nominated alone were to stand at elections. An ordinance of Richard II. restored the election of common councilmen to the wards, but corporate officers and representatives in Parliament were elected by a convention summoned by the Lord Mayor from the nominees of the companies. An Act of Common Council of Edward IV. appointed the election of aldermen, sheriffs, &c., to be in the Common

council, together with the masters and wardens of the companies. By 15 Edward IV. the masters and wardens were ordered to associate themselves with the honest men of their mysteries and come in their best liveries to the elections; that is, the franchise was restricted to the liverymen of the companies. We thus see the two bodies at one time united, at one time the companies electing the corporation, at another the corporation controlling the companies. Well may the City Livery Companies Commission say that it is no part of their duty to dissect this strange and composite constitution.

The view taken by the Commission is "that from about 1314 the guilds were a municipal committee of trade and manufactures. Soon after they became incorporated, and became, while retaining their position under the municipality, an institution in the nature of a State department for the superintendence of the trade and manufactures of London. By the commencement of the Tudor period they had become to a great extent an obsolete institution as regards trade superintendence. For a long time afterwards these bodies were an important element in the City. In the provinces the craft guilds have almost disappeared; but the guilds of London have continued in existence and have never been interfered with in any way by the Legislature with the exception of the Charity and Endowed Schools Commission. The condition in which they have existed for the last two centuries is that of societies, the only purposes of which have been benevolence and entertainments."

But the history of guilds, and especially of trade guilds, has yet to be written. The works upon the subject are nearly all for the purpose of supporting some theory, or taking some particular view,—antiquarian, democratic, or political. Attempts have been made to prove trade guilds to be benefit societies, clubs, monopolies, provident institutions, trade unions, &c., and for every page of historical matter or fact there are several of disquisition and speculation. The most complete work on guilds in English is the recent one of Walford, which contains much valuable and interesting information relative to the guilds of London and the provinces. There is much need of a work written from a social point of view, which would give the history of these societies, the nature and amount of the control they exercised over trade, the regulations they made, and their means and modes of enforcing them, and their relative position to the communities where they existed, which should be free from speculations as to their character, and not too much devoted to their municipal and political struggles. This information can now only be acquired by a tedious search through histories, general and local, articles on municipalities, reports of commissions, pamphlets, &c., at a great expenditure of patience and time.

THE LAW AS TO LINE OF FRONTAGE.

THE great value of the House of Lords as a Supreme Court of Appeal has been lately well exemplified by the manner in which they have ended the long-existing uncertainty in regard to the fixing of the general line of buildings in a street under Section 75 of the Metropolitan Management Amendment Act, 1862. Without quoting the whole of the section, it is enough to remind our readers that it enacts that no building "shall be erected beyond the general line of building in any street" without the consent of the Metropolitan Board of Works. Further on the same section says that "such general line of buildings is to be decided by the Superintending Architect of the Metropolitan Board of Works." If any one offends against this rule, by building beyond the line, then complaint is to be made to a magistrate, who may order the demolition of so much of the building as is beyond the "general line so fixed as aforesaid." One would have supposed that the enactment had been clear enough, and that all that the magistrate had

to do was to observe the line fixed by the Architect, and see if the building complained of goes beyond it. But by some legal ingenuity the point became confused, and in the last edition of Woolrych's "Metropolitan Building Acts" the law is thus stated:—"The certificate of the Superintending Architect is not absolutely conclusive, but the magistrate is entitled to judge for himself whether the line fixed by such certificate is, in fact, the general line of buildings in the street." Therefore the decision of a person skilled in regard to the superintendence of buildings, and quite impartial, has to be subject to the opinion of a person who, however competent he may be as a lawyer, cannot be considered to be so competent to decide what is the general line of buildings in a street as the Superintending Architect of the Metropolitan Board of Works. In 1864, in the case of *St. George's, Hanover-square, v. Sparrow*, we find the law as laid down in the above work first enunciated by the Court of Common Pleas. We are not now concerned with the reasons for that judgment, it is sufficient to state the result of it. But in 1867 came the case of *Banman v. The Vestry of St. Pancras*, when the Court of Queen's Bench took an opposite view. Here were two directly conflicting decisions; and then in 1871 came *Simpson v. Smith*, in which the Court of Common Pleas (differently constituted, indeed) adhered to the decision of the same Court in 1864. So matters remained till the case of *Spackman v. The Plumstead Board of Works*, in which Mr. Marsham, the police magistrate, decided that he himself must settle what was "the general line of buildings," and dismissed the summons, because, though the buildings went beyond the Architect's line, they did not go beyond what was the true line, in his opinion. This decision was reversed by the Queen's Bench Division, and their judgment has since been upheld by the Court of Appeal and by the House of Lords. Therefore, this most important question, which affects so many interests in the metropolis, is now set at rest once and for all. The only reason for astonishment is that the question could ever have been decided otherwise; the reasons in its favour are so overwhelming that it is a kind of puzzle how such able judges as decided to the contrary could have come to the conclusion which they did. "The words of the section," said Lord Watson in the House of Lords, "have one meaning, and one only, and upon these leading words which enact the prohibition, which constitute the offence, and which direct the remedy, there is no ambiguity whatever. They have a plain and ordinary meaning, and, as far as I see, they have no secondary meaning such as that suggested. The suggestion is that in the language which confers on the magistrate jurisdiction to try the complaint, you can find expression which may be amplified so as to override those other words enacting prohibition, defining the complaint and giving the remedy. And what are these words? 'If at the time and place appointed in such summons the said complaint shall be proved to the satisfaction of the justice.' Now, it is said that you may read these words as signifying that the justice is to re-try everything which has been decided before." Lord Watson then proceeded to point out that the previous plain words of the enactment could not be thus controlled. He concluded by the sensible observation that "a decision by a gentleman in the position of the Superintending Architect of the Metropolitan Board of Works is not likely to be less favourable to the interests of all parties concerned, nor is less likely to attain the ends of justice, than a series of decisions by a number of different district magistrates." Such has been the course, and such the conclusion, of this important phase of metropolitan building law.

Surveyorship.—On Tuesday last the Exeter Corporation of Guardians met to appoint a surveyor. On the voting being taken, of the nine candidates, Messrs. Wilkinson & Warren, of Exeter, architects and surveyors, received a majority of fourteen votes, and were declared elected.

NOTES.

E print elsewhere the memorial presented by the Institute of Architects to the First Commissioner of Works on Monday last in regard to the treatment of the site of the new War Offices, and the block-plan proposed by the Institute. The deputation made a case for their view which is quite unanswerable, except on the barest grounds of economy, and this seems to be the view taken by those outside the profession who have given attention to the matter. The *Pall Mall Gazette* observes:—

“The rival plan which the Royal Institute of British Architects submitted yesterday to the First Commissioner of Works for the new Admiralty and War Offices will not be adopted,* but will be interesting as another record of what London might have been if it cared to pay for appearances. The plan of the Architects is better than that of the Government at every possible point; it widens Whitehall, it prolongs the Mall, and it avoids dwarfing the Horse Guards.”

As we have repeatedly said, it is unworthy of such a country as England to build a great public building in a restricted and beggarly manner, and to lose an opportunity for permanently beautifying an important site in its capital, on mere monetary considerations. Those who attended the deputation, perhaps, carried away with them certain not very reassuring convictions as to the possible narrowing effect on the Ministerial mind of the interposition of the permanent irresponsible functionaries who have so much power of string-pulling in the direction of their own restricted ideas. We must congratulate the *Times* on showing signs of coming out of Egypt, that journal having actually devoted a leader to the recommendation of an artistic improvement formulated by a body of architects. After this, we may even hope that the *Times* will one day find out the truth about Lord Grimsthorpe and his attainments as an architectural artist.

THE debate on February 25 on the Tenure of Houses (Ireland) Bill cannot be passed over without notice. The object of the Bill was, shortly stated, to introduce fixity of tenure and fair rents to Irish towns. But the debate broadened out into one upon urban tenure in England and Scotland, and resulted in the promise of the Government to appoint a select committee to consider the question of leasehold tenure in towns. Therefore, the committee will certainly consider the question of leasehold enfranchisement. The cause and the result of the debate show that there exists a dissatisfaction with leasehold tenure in towns; we have never supposed that the dweller in towns would be content to see his brother in the country obtain compensation for improvements and not make an effort to obtain it for himself. The debate is a sign of the times; amid much that is unsound and unhealthy agitation, there is visible a wholesome tendency to make the lessee a permanent occupier at a fixed rent. “The certain rent in perpetuity which could never be raised,” as Mr. Macdonald, the late Conservative Lord Advocate, described the Scottish system, will, in all probability, be the solution at which we shall arrive in England, combined with a system of yearly tenancies. Be that as it may, this debate is a certain sign that things will not remain as they are.

LAST year we commented on the case of *Melliss v. The Shirley Local Board*, in which Mr. Justice Cave decided that the fact that Pym, one of the parties to the contract with the Local Board, was the surveyor of the Board, did not make the contract void, but merely rendered him liable to penalties under section 193 of the Public Health Act, 1873. The unanimous judgment of the Court of Appeal is published in the current month's number of the Law Reports. That judgment reverses Mr. Justice Cave's decision, and decides not only that the officer or servant of the local authority is liable to penalties under

* Our contemporary means that the House of Commons will not vote the money for it; but we hope better things.

section 193, but that the effect of his being interested in the contract is to render it void. There are no express words in section 193 making such a contract void, but the reasoning on which the Court of Appeal reached their conclusion is easily seen from Lord Esher's judgment. “This rule of interpretation has been laid down, that although a statute contains no express words making void a contract which it prohibits, yet, when it inflicts a penalty for the breach of the prohibition you must consider the whole Act as well as the particular enactment in question, and come to a decision whether the penalty is imposed with intent merely to deter persons from entering into the contract, or whether it is intended that the contract shall not be valid at law. It seems to me that the intention of the Legislature was that such a contract should not be entered into so as to be legally valid.” The result of this case, therefore, is a kind of double prohibition against servants of local authorities entering into contracts with their own masters,—firstly, the penalty; secondly, the invalidity of the contract. There can be little question that the judgment is in the right direction, and will put a stop once and for all to such contracts as were the cause of the litigation.

THE complaints of excessive railway charges are so numerous, and practical propositions for reform so few, that it is quite refreshing to have for consideration a suggestion of the latter description. Mr. Jefferis, C.E., an authority on railway matters in America, offers such a suggestion with every confidence in its merits, though he confesses that he does not anticipate a favourable reception for it. Our railway managers always declare that working expenses are at the lowest possible figure, but it is nevertheless in the “operating” department,—as Mr. Jefferis terms it,—that he considers reform is needed. His contention is that we are too conservative in our method of constructing rolling stock, and that the adoption of the “bogge truck” system would cause an immense saving. It is asserted that our carriages and wagons, being stiff and rigid in construction, create an amount of friction which would be greatly lessened by the lighter and more flexible “bogge” system, allowing of a great reduction in the amount of power required for haulage, and consequently in the working expenses. Many of our long passenger coaches are constructed on this principle, which undoubtedly facilitates their running, and lessens the amount of motive power necessary,—the benefit being, of course, principally apparent in traversing curves. The percentage of our working expenses to receipts is less than in America by some 8 per cent., but as they charge lower rates than we do, and pay so much more for labour and fuel, the difference should be greater than it is. The non-adoption of the system advocated is confidently ascribed to simple prejudice, but we can hardly think that there is no other obstacle in the way, as our managers have a reputation for studying economy in every direction, and they would hardly allow prejudice to hinder a beneficial reform. Anything which would allow of a reduction in rates should be hailed with satisfaction, for an increased amount of traffic would result, which would benefit both the shareholders and their customers.

FROM a recent report of the Peabody Trustees it appears that the average cost of the buildings erected by the trustees is 60*l.* 10*s.* 2*d.* per head, so that a family of four persons costs a capital sum of 242*l.* to house, which is a much larger amount than what is ordinarily expended by the speculating builder. As regards the acquisition of land, the trustees have been singularly fortunate, three sites, namely, those in Glasshouse-street, Bedford-bury, and Wild-street, having been sold to them by the Metropolitan Board of Works for a sum which leaves a clear loss of 235,808*l.* or more than a quarter of a million, to the ratepayers. Taking land and buildings together, a family of four persons costs 510*l.* to house. A warning note is struck in the statistics of the mortality among the inhabitants of these dwellings. In the year

1884 the deaths per thousand of the total population of the Peabody Buildings were 19.10, as compared with 20.34, which was the London rate; but in 1885 the death-rate in the dwellings was actually one decimal point above the general rate of mortality in London, the figures being 19.60 in the Peabody Buildings and 19.59 for the whole of the metropolis. It would seem from these facts that, while the death-rate of London has declined steadily since 1876, the death-rate in these model dwellings has increased since 1881, from 17.22 to 19.60 per thousand. It will be probably found that this increase is due to increased density of population, a point upon which we have frequently insisted.

THE Aberdeen Royal Infirmary, having been reported on by medical experts as structurally defective, and not at all equal to modern ideas, the managers recently employed Mr. H. Saxon Snell to suggest a scheme for remodelling and extending the present buildings. Mr. Snell, having visited Aberdeen, now recommends as the most economical method of utilising the present site and buildings to the best advantage:—(1) The erection of a new pavilion of four floors for surgical cases; the extension of the west wing of main building (three floors) for medical cases; and (3) an alteration of the present typhus-fever house, so as to adapt it as a post-mortem room, mortuary, pathological museum, and erysipelas wards. All other zymotic diseases are to be excluded from the Infirmary, and the accommodation after reconstruction would, besides

Plan of the Hospital.

the administrative department, be as follows:—Surgical cases, 100 beds; medical cases, 80 eye diseases, 16; venereal diseases, 16; erysipelas, 8; spare ward, 16,—total number of beds, 236. Mr. Snell estimates the total cost of these proposals (including other details which we cannot enter on) at 25,000*l.* The managers have no surplus funds for building, there being an adverse balance last year, and in fact, generally a deficit on each year's account,—a very usual circumstance with institutions depending on voluntary contributions. Mr. Snell's scheme is, we understand, likely to be objected to on medical grounds, and the proposal to construct an entirely new hospital on modern principles on a less

stricted site in the suburbs urged. The only objection seriously preferred against this is the difficulty of obtaining funds.

THE site for the erection of the new War Office and Admiralty buildings has been begun to be cleared, in spite of Lord Stratheden's appeal to the Government that nothing should be done until the result of the interview between the Royal Institute of British Architects and the First Commissioner of Works had been reported to the House of Commons. The houses in Spring Gardens Terrace facing the park have been partly demolished, and the quaint little gunner's house at the north-west angle of the Horse Guards Parade has been entirely removed. The other houses in Spring Gardens will shortly follow.

THE new western facade of the cathedral of St. Maria del Fiore, at Florence, is proposed to be further adorned by three bronze doors, and designs are invited, and three premiums are offered, viz., one of 4,000 francs (160*l.*) for the central door and two of 3,000 francs (120*l.*) for each of the two lateral doors. It is not stated whether the successful competitors will be entrusted with the carrying out of the work, nor what amount of money is proposed to be expended; and in default of this information foreign artists will perhaps do well to abstain from competing. The designs are to be sent in by the end of October next, and the premiated designs are to become the property of the promoters of the competition.

IN last week's *Athenæum* Mr. Magnússon suggests a very clever scheme for the planning of a library capable of indefinite extension of capacity, as required by the gradual increase in the number of books. His idea is to have a central circular reading-room with a dome and lighted by clear-story windows, and around this a range of book galleries in the form of a spiral, with lower halls, and lighted from above. The spiral gallery could be carried out as far as necessary for the requirements of storage when the library is first founded, and could be increased by the continuation of the spiral outwards as far as it might be found necessary to enlarge the space, without any more interference with the existing building than would be involved in pulling down the terminating cross wall of the spiral and rebuilding it at the end of the new extension. Communication between the spiral galleries and the central reading-room would be provided by eight passages radiating from the centre and piercing the spiral. Architecturally speaking, the termination of the spiral by a "blunt end" would always remain an awkward feature to the eye; but in every other respect the appearance of the whole externally might be made pleasing enough; and on practical grounds the idea is all worth attention, providing a simple and expensive means of enlarging the book galleries *ad libitum*, in proportion to the increase of the contents of the library. Architects ought to be grateful to Mr. Magnússon for a new idea.

ONE of the most difficult forms of thinking is to make a plan," said Mr. Goschen, in his admirable address at the Mansion House on "Hearing, Reading, and Thinking." His remarks were not addressed specially to architects, but no doubt architects among his audience, and they would recognise the truth and force of the dictum. True, it is true, assisted by the "pen and eraser" which Mr. Goschen himself finds such valuable aids to the process of thinking, and the great statesman finds indispensable. But the fact remains that the effort of thinking out a really good plan, one "with a backbone," as Mr. Goschen happily expresses it, addressed to a given end, and unswayed by accidental circumstances of detail, is an intellectual effort of no mean order, to which the public is quite insufficient weight.

FROM a letter we print in another column, addressed by the Leeds and Yorkshire Architectural Society to the Town Clerk of Sunderland in reference to the proposed Municipal Offices competition, it will be seen that there was ample reason for the criticism we have already made as to the arrangement of charging 5*l.* for the conditions without giving a word of information as to their probable nature. The Leeds and Yorkshire Architectural Society have paid the fee, or one of them has, and have found that architects have been invited to pay 5*l.* for ascertaining that they are to be mulcted of ten per cent. of their proper profit on the work, that no professional referee has been appointed, and that the time is too short. The Corporation may reconsider all these points; but unless they do, some men who may have been foolish enough to comply with the terms of the advertisement will unquestionably have "spent their money for that which is not bread."

MOULDINGS.*

BY GEORGE AITCHISON, A.R.A.

GRACEFUL, well-designed, and effective mouldings give the same distinction to a building that proper and well-chosen words do to language.

In grouping mouldings together care must be taken to make the divisions in harmonic proportions, to contrast the great with the small, the strongly-curved with flat surfaces, or with other mouldings whose curves are nearly flat, so that the group may be like a well-balanced and harmonious sentence.

A sentence is but a small piece of the whole work, and only helps to make up the impression to be conveyed, or the emotion to be raised; it is only a humble minister in reading a story that, if the plot is the only excellent thing in it, you probably read it but once—certainly but a few times; while, if the language be terse, harmonious, and expressive, though you may have learned the plot in your childhood, you read the work again and again with increasing zest.

In the poets, where rhythm, as well as choice words, always exist, we occasionally get those—

"Jewels five words long
That on the stretch'd forefinger of old Time
Sparkle for ever."

So in architecture we sometimes get a group of exquisite mouldings. We even now sometimes see a cast of Greek mouldings treated as one of the treasures of a house. Architects should feel the beauty of a moulding, as a master of language feels the beauty of a word.

R. Hall said, "I could think of that word 'tear' till I wept"; and when this sentence from his sermons was read to him, "Grace penetrates the soul as the sun penetrates the clouds," he said, "That is not mine; I never used a word in three syllables when there was a more expressive one in two; the word I used was 'pierces.'"

The only architects I know who must have had this feeling towards their mouldings are the Greeks.

If you consider the long continuance of the Doric order; that the only changes made in it were by delicate variations of the echinus, and in the proportion of the order, you must feel the love for exquisiteness that animated the architects and charmed the people of Greece. You feel that the Greek architects had the same admiration for their predecessors' master-pieces as Michelangelo had for the dome at Florence. "I will not make one like you, and better than you I cannot." We picture to ourselves Ictinus, who hoped to get the next temple to design, watching from dawn to eve the light come and go on the capitals of the Thesenn, and lying awake at night picturing to himself how he could improve the proportions, and get a more exquisite curve in the echinus.

If we want to excel the Greeks,—and I hope we do,—we must at least take the same pains. Dante tells us that "Excellence is not to be got by lying on a bed of down." Thanks to Professor Cockerell, Mr. Penrose, and John Pennethorne, we have the exact sections of some of the Greek mouldings, and they have shown us that when the architect had designed his mould-

ing, he took the trouble of getting the exact conic sections to make his mouldings perfect. Nothing can better show the difference of mental attitude between the Roman and Greek architects than their treatment of their mouldings; the latter felt that no trouble was too great to make their mouldings approach perfection; the Roman architects thought this striving for perfection not worth the trouble, and made their mouldings of segments of circles, determining to cover them with carved ornament if they were too faulty. The English architect is too apt to follow this had example, or even to do worse; he sometimes boasts of being able to draw mouldings with his eyes shut, or as fast as he can write, or he makes his youngest pupil or his office boy copy them from a book.

I have had one or two Greek, Roman, and Gothic mouldings run, to let you see the difference between them. You will notice, besides the shape, the extremely subtle methods by which the Greeks obtained their effects, and which are utterly wanting in Roman mouldings. The capital and necking of the Greek Doric are perhaps the best-known instances, and are certainly the most appreciated; the deep square ahaeus looks thick enough to bear the weight of the entablature, contrasts well with the large smooth convex surface of the circular echinus beneath, from which it is divided by the shadow of the re-entering curve, while the abacus makes the curved shadow that contrasts so well with the bright light beneath, gradually deepening into shade; the shade of the echinus is contrasted with the bright lines of the fillets below, intensified by the shadows between them, against which the elliptical flutings die; and a little below this juncture, one thin horizontal line of deep shadow repeats, and enforces those from the fillets above, and contrasts with the delicate shading of the vertical flutes.

In the use of the hawk's-bill moulding the bottom of the cyma, forming the lower part of it, is often brought in just beyond the upright face of the next member, so as to make a delicately-graduated shade finished by a sharp heck line; sometimes it is continued by a similar ogee below,—its section is then like a bracket in writing. Beneath the hawk's-bill there is sometimes a fillet; sometimes this fillet is bevelled outwards; sometimes there are two fillets; sometimes there is a bead beneath; but, whether this bead be bold or delicate, the whole group bears the mark of deep study.

The ogee may be found with a square or with a bevelled fillet under it; sometimes its lower half is sunk in beyond the upright face of the surface below; sometimes it has a head below it; but you can rarely find two of these mouldings alike. In short, no device was too slight, too eccentric, or too trivial, for a Greek architect to employ, if he thought it would contribute to the desired effect.

In the Doric entablature there is an absence of what we call mouldings,—the cymatum belongs to the pediment, and not to the cornice. In the cornice, frieze, and architrave the whole effect is got by flat surfaces, whose soffits are sometimes at right angles, are sometimes bevelled, and sometimes curved. At the Parthenon the only horizontal mouldings in the entablature are a little hawk's-bill moulding, and one sculptured head; but in all temples the entablature was but a framework for sculpture, in that there was plenty of curved surface; and the Greeks felt the need of severity to set off the sculpture; and they also felt how the curved outline and undulating surfaces of the sculpture set off the formal lines of the architecture.

The Doric temple is undoubtedly the most perfect piece of æsthetic architecture man has yet achieved; every device of architectural composition was lavished upon it. The outside of the building, too, was pure white, enriched by brilliant painting, and adorned with the highest forms of sculpture. Temples, too, were always placed on high ground when it was possible, and expedients were used to prevent the first near view from being directly in the front.

In the entablatures of the Ionic temples we get but little more moulding than in the Doric, and much less variety; for we have no mutules with their caps, gntæ, and bevelled soffits. In both varieties of temple the same aim is apparent, that is, to get a broad band of considerable projection to cast a deep shadow; this band is just softened under the top fillet by a

* A lecture delivered at the Royal Academy on the 25th ult.

little moulding to join it to the corona. In the Ionic the corona is crowned with an ovolo, or an ovolo and bead. The bed mould in the Doric is but the square mutule band; while in the Ionic it is an ogee and bead. The crowning member of the architrave in the Doric is but a wide fillet, while in the Ionic there is an ovolo and head beneath a narrow fillet, and sometimes the fillet itself is crowned by a small ogee.

In Doric temples, except that of Jupiter Olympius at Agrigentum, there are no bases to the columns; but in the Ionic there are not only beautiful bases of great variety of shape, but these base-mouldings are often carried round the cella of the temples, so that we see their effect on the straight as well as on the round.

In many instances the mouldings of the Ionic entablature and capitals are sculptured. Though this has been of advantage to us in showing the form of the ornament, which has perished in the Doric, where it was only painted, the sculpture breaks up the surface, and makes perfection of form in the mouldings less necessary than when the ornament was painted; but it appears that the Greeks were no less careful in the design of the original shapes of the mouldings, and in perfecting them by conic sections.

We once professed to admire Greek art, and even its most deadly opponents have never denied its perfection. Yet no one ever ventured to publish a full-sized section of a moulding until 1850, when Professor Cockerell gave two or three in his work on Egina, although J. Penethorne had taken them full-sized in wax, and Mr. Penrose had most elaborately measured them. Yet we have full-sized Gothic mouldings by the score, if not by the hundred, though no same person could ever compare them, for perfection, with the Greek. Greek mouldings were designed for bright sunshine, and the most brilliant people who ever lived have spared no pains, and no study, to bring them to perfection; besides, in the mouldings of the best buildings we have the accumulated experience of ages, for the Greeks would not sacrifice perfection to novelty.

Before speaking of Roman mouldings, I may mention that, in certain small buildings of peculiar design, the Greeks deviated completely from the proportions they allowed for regular temples; in short, they thought and felt. They did what was structurally and aesthetically necessary for the particular work they had in hand. In the Erechtheum, the entablature is about one-fourth of the height of the column above the base; while in the temple of Pandrosus, the little attached temple with the caryatides, the entablature was about two-fifths of the whole height of the figures. A certain thickness was wanted for the architrave, and a certain æsthetic weight, to compare well with the caryatides, so in this temple they omitted the frieze and made the cornice and architrave nearly equal in depth. To deepen the cornice they put below the ordinary bed-mould a deep dentil band and cap, below that a cavetto and bead, and then repeated the ogée and bead of the bed-mould at the bottom; thus you have a depth of two-thirds of what may be called the original cornice below it.

In the circular monument of Lysikrates, the only specimen we have of Greek Corinthian, the architrave had to be made deep, as it was on æsthetic grounds, to display a proportionate length of sculpture; so the cornice, instead of being one-fifth of the height of the entablature, is nearly the depth of the architrave; to eke out the cornice, a fillet and cyma are added under the bed-mould, then a dentil band and cap, and an ovolo and bead. These heavy cornices, designed for special purposes, commended themselves to the vulgar taste of the Romans, who generally had overpowering cornices, but they had no figure sculpture to consider.

Let me draw your attention to one particular instance of the barbarous taste of the Romans. They knew that the Greeks had sculpture in the metopes of their Doric temples; so in theirs they nailed up the skulls of the slaughtered bullocks with a fillet round the horns. Nature did not make bones to be seen, so they are always ghastly. What are we to think of people who chose bones as an ornament? Nothing can better show the blind reverence the urbane and hearty-loving Italians had for Roman antiquity than their copying this atrocity; nay, I have seen bullocks' skulls on the jambs of an Italian chimney-piece. I

have seen them, too, on the front of an English bank, but with more reason, as I suppose they were the monogram or rebus of the architect.

We criticise Roman mouldings under peculiar circumstances; they are the mouldings with which we are most familiar from constantly seeing them on buildings at home and abroad.

These mouldings were spread through Europe by the Italian architects of the Renaissance and their imitators. We cannot even greatly blame these architects, for they came when mankind had just been freed from their æsthetic and ecclesiastic chains, mainly through the study of the Roman writers.

The human mind began to feel itself free, and its gratitude was overflowing towards those by whom its fetters had been removed, and through whose means man could roam over new fields of study and delight. The tradition, too, of Rome's power and extent, and of Roman peace, must always have existed, and must have deeply impressed the citizens of the small Italian republics, always troubled by internal feuds, and dreading conquest by more powerful states.

The ruins of Rome's gigantic buildings were almost as impressive as its literature: that was not then known to be a feeble paraphrase of the Greek, and the remains of Greek sculpture that were constantly being found, added to the general respect. Mankind, overwhelmed at once by gratitude, by the traditions of greatness, and by finding in every branch of knowledge works they could not equal, are to be forgiven the enthusiasm they felt. Probably mankind were not then far wrong in thinking that their highest aspiration was to study and emulate the Romans for the time being, in spite of their gratitude being misplaced; but they little thought it would end, as far as learning and architecture are concerned, in binding them with worse fetters than those they were released from. Luckily we have just outlived this mistake of confounding the condit-pipe with the cool and refreshing water it brings to our lips; and are beginning to doubt if the worship of the hrazen wolf of Rome is the highest form of religion.

About Roman mouldings nothing need be said; they may mostly serve as a warning of what to avoid. We may safely say of anything purely Roman connected with the fine arts, that when they are not copies of Greek they are worthless, or worse. In anything connected with constancy and courage, with war and discipline, tactics and strategy; with those arts of diplomacy by which nations may be set by the ears; with those laws by which conquered nations may be kept down, the Roman works may be studied with advantage. The art of planning, by which known wants can be best provided for, and the science of construction, were never carried out better than by the Romans, and we may devote our time usefully to their consideration. Rome, too, was the emporium of the world, and much that would otherwise have been lost was in this way preserved; but the fine arts, that demand a high ideal, noble sentiments, and refined taste, could not possibly flourish amongst them.

You might as well expect a man to be a judge of fine claret, who drank a quart of raw spirits every day. The amusement of the Romans was looking on butchery; and they justified it as the proper means of perpetuating their ferocity. At the best they were ferocious peasants, and to the last this was their ideal type; at their worst they were voluptuaries, who had lost every virtue, even their courage. The Mediævals began a new epoch in architecture, as the Romans had begun a new epoch in construction. On the subject of construction the Romans began to ask themselves what was the use of the lintel, and eventually discarded it. The Mediævals began to ask themselves why they should use mouldings that did not show in their misty climates, and eventually took care that they should show, by deep cuttings and undercuttings.

As the climates in which they worked were so deficient in sunshine, there was too little distinction between the bright streak of light on shafts and their half shade, so they marked it with a projecting fillet, or curved the shaft to an arris.

In both cases the Romans and Mediævals made a great advance,—in fact, a doubly advance; they began new styles, and they tasted the charm of thinking to a point. This habit of thinking was not exhausted by the

solution of the one problem in hand, but remained with each man through life, and was constantly urging him on to make fresh advancement and new discoveries.

Here, at least, one may see an opportunity for the present generation of architects. They may think about their mouldings; they may make them as beautiful as Greek mouldings; and they may learn how to make them as effective in this misty climate as they were in sunny Greece. When once architects begin to think, there is no knowing where they may stop. We might even develop a new style.

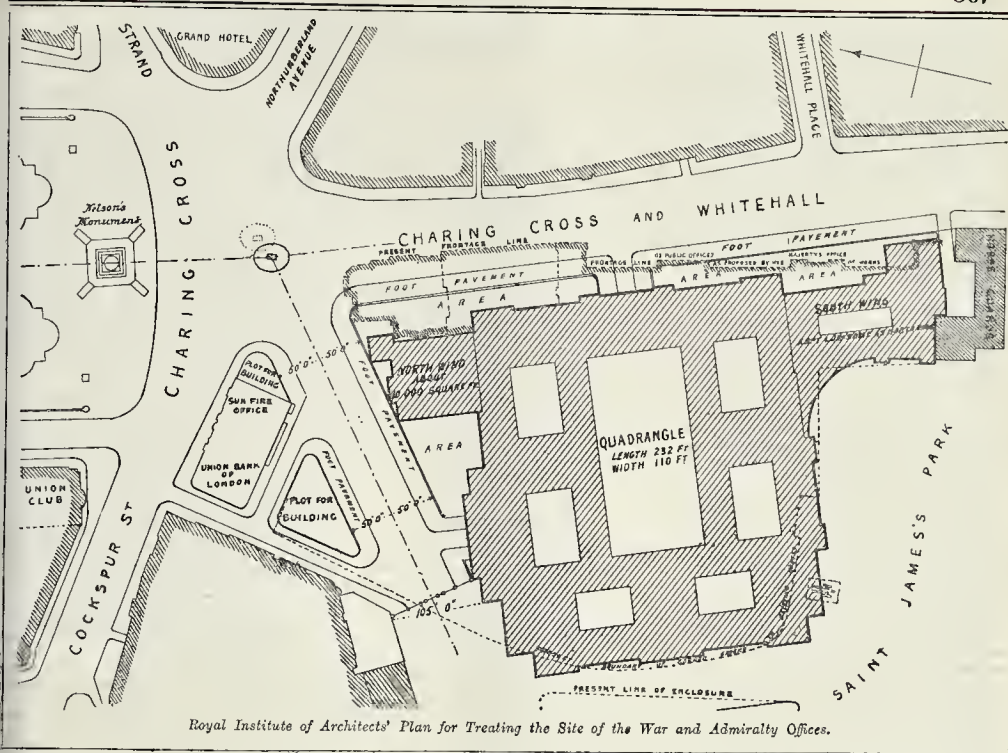

In the present day, for either invention is extinct in the civilised nations of the world, or we are pursuing a wrong method. If it be extinct, we cannot help ourselves, but we cannot be sure of it until we have tried a new method. Instead of saying "the Greeks were the most brilliant people the world has known, and had beautiful mouldings," or that "the Mediævals were the most logical and had effective mouldings, so I cannot do better than follow them," let each one say, "I want my mouldings to be beautiful; I do not want them to be copies of Greek or Mediæval, and I want them to tell their tale in my building. The Greeks had a sunny climate, and marble to work with. I have a misty climate, and stone or brick, how can I make my mouldings look as beautiful as theirs, and show as well as the Gothic mouldings?" Neither of these desires can be gratified at once. We must study the proportions we want, the curvatures of the mouldings, and the way of properly contrasting them; and then, from actual observation on the spot, try to learn by what devices we can make them tell the tale we want. Properly speaking, this is the art of the architect. A man may be a good planner, a good designer, and a good constructor, but he can hardly be an architect until he knows how to get the effects he wants, at the height or in the situation they occur.

Pheidias was a monumental sculptor, and competed for filling the pediment of the Parthenon. Pheidias's model was not chosen, but he demurred to the judge's award, on this ground, that the models were put on the ground, while the sculptor was to be placed 50 ft. above it. His objection was allowed, and when all the models were placed at the proper height, his model was adjudged to be the best.

Viollet-le-Duc makes a distinction between mouldings, viz. those which arise from a vague desire of man to ornament his dwellings or monuments, and those which have a definite signification, and are based on thought and logic. He says,—“The ancient Greeks were the first people who knew how to give to their mouldings a form derived from reasoning, applied to the object.” Two elements have to be considered in mouldings, their utility, and the sentiment their shape will produce. That which marks the mouldings of the five epochs of architecture, is the proper expression of the need they satisfy, and a distinction in their shape which attracts attention, which should engrave them on the memory. This distinction is derived from the sobriety of the means employed, in the choice of their curves, and a keen observation of the effect of light upon them. One may say of mouldings what has been said of style, “mouldings are architecture.”*

The Female School of Art.—The Marchioness of Salisbury distributed the annual prizes to the students of the Female School of Art in the Freemasons' Hall, Great Queen-street, on Tuesday afternoon. The Honorary Secretary read the report, in which it was stated that during the past year 156 students received instruction in the various branches of art taught in the school. In 1885, 2,263 works were forwarded to South Kensington for examination and rewards; of these, 957 were in the advanced section, and 1,306 in the elementary. The Marchioness of Salisbury then distributed the prizes. The Queen's Scholarship was awarded to Marion Ryder Henn; the Clothworkers' to Emma Ada Newcomb; the Atkinson to Hilda Lucy Bell; the Duchessa of Westminster's to Bertha Jeffreys; the Bright Medal to Helen Louise Condor; the Queen's Medal to Mary Harriett Fores; the Baroness Burdett-Conte's Scholarships to Ruth Harcus and Charlotte Maria Alston; and the Gilchrist Scholarship to Catherine Maria Howard.

* In our next we will give the remainder of the lecture, together with a number of sections of mouldings and illustrations of

Royal Institute of Architects' Plan for Treating the Site of the War and Admiralty Offices.

THE SITE FOR THE WAR OFFICES.

On Monday morning last a deputation from the Royal Institute of British Architects waited on the First Commissioner of Works, Lord Morley, to present a memorial in regard to the treatment of the site for the new War and Admiralty Offices. The members of the deputation were Mr. Ewan Christian (President of the Institute), Mr. Waterhouse, R.A., and Mr. Worthington (Vice-Presidents), Mr. J. Macvicar Anderson (Hon. Secretary); Sir J. McGarril Hogg, the Hon. Charles Gore, and Colonel Prendergast (Honorary Associates); Messrs. Jhas. Barry, F.S.A., Philip Hardwick, F.S.A., Lewis H. Isaacs, M.P., Banister Fletcher, M.P., David Brandon, F.S.A., Octavius Hansard, E.A. Training, G. Aitchison, A.R.A., H. H. Statham, E. C. Rohms, F.S.A., and Professor Roger Smith (Fellows); and Mr. W. H. White, Fellow and Secretary.

The deputation was introduced by the Earl of Wemyss, and received by the Earl of Morley, supported by the Hon. Levison Gower, M.P., and Mr. A. B. Mitford, C.B., Secretary to the Office of Works.

Mr. Macvicar Anderson, who spoke for the deputation, pointed out that, as this was a deputation from the Institute of Architects, they had invited only their own members to be present, and that they were not there to open any discussion as to the advisability of the Spring-gardens site in comparison with the other possible sites, but only to offer recommendations as to the treatment of that site, which had been selected by the Government. Mr. Anderson then read the memorial of the Institute, as follows:—

"We, the President and Council of the Royal Institute of British Architects, on behalf of the general body of members, beg leave to submit to your Lordship a respectful protest against the proposed treatment of the site in Spring-gardens for the new Admiralty and War Offices, as illustrated in the official block-plan which has been supplied us through the courtesy of the late First Commissioner, the objections to which we deem to be of serious nature as to justify us in pressing upon your Majesty's Government, before it be too late, the further consideration of the scheme. Your Lordship may not be aware that in June, 1882, when a Select Committee of the House of Commons was engaged in considering the scheme of the Spring-gardens site, the Council of the Royal

Institute of British Architects addressed a letter to the Right Hon. G. J. Shaw-Lefevre, at that time First Commissioner of Her Majesty's Works and Public Buildings, as well as Chairman of the Select Committee of the House of Commons on this special subject, in which they pointed out what appeared to them, judged from a public and an architectural point of view, to be defective and objectionable features in the scheme; and inasmuch as the soundness and accuracy of the views then urged, although not at the time officially admitted, have, in our opinion, received confirmation from subsequent action in furtherance of the scheme, we venture to re-open the question, and to request your Lordship's attention to the following considerations.

The occasion of erecting a great public building on the Spring-gardens site affords the opportunity,—which, if not now taken advantage of, can never recur,—of carrying out two public improvements of the first importance, namely, (1) the widening of Whitehall, and (2) the continuation and opening up of the Mall to Charing-cross. In no foreign capital, we believe, would such an obvious opportunity be neglected, and we beg leave to record our conviction that no scheme for the treatment of the site should be adopted which does not deal with these two points. That is to say:—

1. The inadequacy of the Whitehall thoroughfare at Charing-cross is patent. The width of the roadway increases considerably to the south, but the northern end is as the neck of the bottle through which the whole traffic from north, west, east, and south has to pass. Manifestly, if only on the score of meeting the requirements of the public, the contemplated removal of buildings on the west side of Whitehall and Charing-cross should be taken advantage of to throw back the frontage, and to allow of a similar width of roadway being continued northwards from the Horse Guards to Charing-cross. Apart, however, from the necessity of thus providing for the exigencies of the traffic, the widening of Whitehall and Charing-cross is essential in view of the erection of a monumental edifice on the western frontage. The unsatisfactory effect of placing lofty structures on the frontages of avenue wide thoroughfares is strikingly illustrated in Northumberland Avenue, and it is much to be desired that in the present instance a like result should not have to be deplored.

2. The continuation and opening up of The Mall to Charing-cross, with an architectural screen and gates, as at Hyde Park Corner, arranged on a central axis, terminating with the centre of Charles I.'s statue, and affording a vista both of the Strand and of St. James's Park, would be an improvement, the attractions of which are apparent to any one who studies the matter on the spot; so much so, that it is, to say the least, extraordinary that any scheme for the utilisation of Spring-

gardens for Government offices should have been considered, far less matured, without embracing it as an essential feature. It would be difficult to refer to any public improvement of equal importance which can be so easily carried out, or to one which would, we feel sure, meet with more general appreciation and approval.

To erect a building of great magnitude on the site in question without sufficiently providing, by the widening of Whitehall and Charing-cross, the space which is absolutely essential to the attainment of a satisfactory result,—a national monument, moreover, the principal frontage of which, according to the official scheme, will remain partially occupied by buildings of an inferior nature, such as shops and a tavern,—is, in our judgment, unworthy of the country. But if the site were treated with imperial consideration such as it deserves,—by removing the few buildings referred to, by sufficiently throwing back the Whitehall and Charing-cross frontage, and by opening up the Mall,—it would at once become worthy of the edifice proposed to be erected upon it.

In anticipation of a possible objection being raised, that the treatment of the site which we advocate would injuriously curtail the space required for the accommodation of the Admiralty and War Departments, we have prepared and beg leave to submit herewith a block-plan embodying our suggestions, which, after allowing for the widening of Whitehall and the opening of the Mall, provides a building area exceeding by about 9,600 square feet the area provided by the official plan. This is exclusive of the additional space, amounting to about 10,000 square feet, which would be available for an extension to the north were Drummond's bank to be removed. We possess no means of forming a judgment as to the sufficiency of this area for the purposes in view, but we conclude that we are justified in assuming that the official scheme provides accommodation sufficient to meet the requirements of the two Departments of State for which it has been devised.

The block-plan we submit is intended to be no more than an adaptation and expansion of the principle of the official plan, our object being not to suggest a plan for internal arrangement, but to show that the principle on which the official plan has been laid down can be adapted to the site, subject to the restrictions which we would impose in respect to Whitehall and the Mall.

Bearing this in view, we venture to point out that the internal courts, as shown on the official block-plan, appear to be inadequate in point of width in relation to the lofty buildings which are to surround them, and we would therefore suggest that a redistribution of the space allocated to open areas might be advantageously adopted, such as, with a slight increase of space, would admit of the courts

in question being made, as on the block-plan we submit, 50 ft. in width in place of only 25 ft., as on the official block-plan, and of an addition of 15 ft. being also made to the width of the quadrangle. About 6,000 square feet would remain available for increased accommodation upon each floor, and we would suggest that this additional space should be so disposed as to dispense with the necessity of erecting a lofty building immediately contiguous to the Horse Guards. Aesthetically, the gain would be immense to the Horse Guards, as well as to the general effect, were the wing of the new offices which would adjoin the former restricted to a moderate height. On the plan we submit we have projected the frontage of the building further to the west than was proposed by the official scheme, and to this we can see no objection, as the proposed building need not necessarily encroach upon the Park, nor occupy more than the space which is now enclosed as garden-ground attached to existing houses in Spring-gardens.

The scheme we promulgate involves the removal of the whole of the existing buildings between the present Admiralty and Drummond's Bank, and our block-plan of the new offices is so arranged as to admit of their completion without necessitating the dislodgment of Messrs. Drummond's, at least till such a time as other suitable premises can be provided for the accommodation of the latter.

In view of the circumstances that the Government are pledged,—as we understand,—not to disturb Messrs. Drummond in the possession of their present banking premises, and seeing that the area of 10,000 square feet, already referred to as being available for future extension in the nature of a wing to the north, is as nearly as possible identical with the area now occupied by Drummond's Bank, it would seem not unreasonable to suggest whether the area referred to might not be appropriated for the erection of new premises for Messrs. Drummond, which might be erected concurrently with the new offices, and be completed and ready for occupation before they were asked to vacate their present house. Such an arrangement would, we conceive, obviate all difficulty in regard to the acquisition and removal of Messrs. Drummond's present banking premises.

We respectfully beg leave to submit this scheme, in the interests of the general public as well as of the world of art, for the consideration of Her Majesty's Government, with the conviction that, while satisfactorily providing for two great and much-needed public improvements, namely, the widening of Whitehall and the opening-up of The Mall, it will secure a site worthy of the important buildings that are to occupy it, will provide an increased area available for the new offices, and afford the architects who have been already employed a better opportunity than they now possess of producing a national monument, such as may bear comparison with similar structures in foreign countries.

We have the honour to remain, on behalf of the general body of members of the Royal Institute of British Architects,

Your Lordship's most obedient servants,

EWAN CHRISTIAN, President.
ALFRED WATERHOUSE, { Vice-Presidents.
THOMAS WORTHINGTON, }
J. MACVICAR ANDERSON, Hon. Secretary.
WILLIAM H. WHITE, Secretary.

Royal Institute of British Architects,
9, Conduit-street, Hanover-square, London, W.,
22nd February, 1886.*

In the course of some conversation which followed, Lord Morley said he gathered from the memorial that the two points to which the Institute specially directed attention were the opportunity for widening Whitehall at that point (and the advisability of doing so on architectural grounds as well as those of public convenience, in order to enable the new building to be better seen), and for securing an opening from the Mall into Charing-cross. Mr. Charles Barry pointed out that the widening of the small internal courts of the proposed building, from 25 ft. to 50 ft., was considered by the deputation as a most important point on sanitary grounds. Room for doing this, without lessening the accommodation within the building, was obtained by the proposal to extend the limits of the site slightly westward into the Park, which would have little practical effect as an encroachment on the Park, but would add a considerable space to the internal area of the building. In regard to the question of lowering the new building towards the Horse Guards, Mr. Milford observed that the architects had not been aware originally of the interest which Londoners felt in the Horse Guards building, but that on being made aware of this, they had themselves moved their lofty tower from the position contiguous to the Horse Guards, which it occupied in the first design, to the position which it occupied in the amended design. A member of the deputation pointed out that one effect of leaving Drummond's Bank and other buildings

in front of a portion of the new buildings, which would be considerably higher, would be that the smoke from the chimneys of the lower buildings would be liable to enter the upper windows of the War Offices, as the perspective view exhibited in the room clearly showed. Mr. Anderson observed that Mr. Beresford Hope would have been present had he not been prevented by an important engagement, but he sent a letter supporting the views of the deputation, observing:—"The plan that you propose is unquestionably a better one than that of the Government. Should the latter one be proceeded with I can prophesy for it an eternity of unfavourable criticism and of regrets for a thoroughly bungled opportunity."

Mr. Christian recommended the First Commissioner to notice the bad effect of the lofty buildings crowded close to the street in Northumberland-avenue, which was apparent to every one, yet it was now proposed to erect buildings still more lofty close up to a thoroughfare not so wide as Northumberland-avenue.

The First Commissioner assured the deputation that, while necessarily unprepared to give any positive undertaking at the moment, the points which they had brought before him would have his very best consideration. Mr. Christian having expressed the thanks of the party to Lord Morley for his courteous reception of them, the deputation withdrew.

THE UNEXHIBITED SCULPTURES IN THE BRITISH MUSEUM.—III.

PROFESSOR NEWTON'S third and concluding lecture* on this subject was mainly devoted to the inscriptions contained on some of the numerous Roman sepulchral monuments stowed away in the basement of the Museum; but before describing and reading some of these inscriptions he referred to one or two specimens of sculptured sarcophagi, of which he exhibited drawings. One of these drawings represented the end of a sarcophagus found at Cyrene, on the north coast of Africa. He instanced this specimen as being a very suitable model for the decoration, by carving, of articles of furniture, &c. The design consisted of Cupids bearing festoons of flowers. These festoons, he had no doubt, were copies of the actual festoons which were used to deck the Roman tombs. The inscriptions on some of these sepulchral monuments were very curious, most of them relating to endowments left in trust to the survivors of the deceased on condition that they observed certain religious ceremonies at stated times. An interesting portion of the lecture was devoted to a description of the *columbaria*, or "pigeon-holes," which were formed in large numbers by co-operation between all sections of the people as the future resting-places of their ashes, which were enclosed in urns or small marble boxes. The management of these *columbaria* was described, the proprietary being analogous to the members of a modern provident burial club or society. After describing one or two more sculptured sarcophagi, one of which afforded a very interesting representation of the marriage of Cupid and Psyche, with evident attempts to portray the incidents described by Apuleius, the lecturer referred to the light which ancient cut gems were capable of throwing on the study of the myths and sculpture of the ancients, and in conclusion he said—"Now I have said what I had to say about these buried remains. In the vaults of the British Museum are all these things, which have been buried since the year 1852, and which are defaced and begrimed with dirt. They are utterly useless to anybody in their present position, and they cannot be seen without the aid of a lantern. Now, of course, I am bound to accept the decision of my generation, and, if it is the pleasure of the British public to leave these things where they are until the advent of another generation more sympathetic with regard to archaeology, I have nothing more to say. As you are aware I have ceased to be in any degree responsible for the present condition of these unhappy monuments, or for the exhibition of any other part of the magnificent collection of which I had the honour to take charge up to a very short time ago. The responsibility has entirely passed from me, but, if I may venture to say so, the responsibility has not passed from

the British public, and never will as long as the British Museum is national property. It is now some twenty-five years ago since I had the honour of giving a lecture on the Sculptures of the Mausoleum in this very theatre. Those sculptures were then in an unsightly shed, very much exposed to the weather. I made an appeal then, and pointed out that this is one of those things which is nobody's fault, because it is everybody's. Many years passed before my appeal was attended to, but by degrees we succeeded in absorbing into the Museum itself those sculptures and many others at that time in the sheds. Little by little we have received instalments of room for our national collection of sculptures, but this final act of bringing up the sculptures I have described from the darkness of the basement to the light of day, remains to be done. These sculptures are texts on which we may preach. They are themselves dumb except in so far as they appeal to the eye of the intelligent beholder. I feel convinced that if they could speak they would say, in plaintive tones,—

"Perhaps it was right to dissemble your love,
But why did you kick us downstairs?"

I would, then, earnestly entreat you to remember this: Governments in these days promise a good deal, and promise a good deal that they never fulfil; but if they are thoroughly convinced that the British public want a thing, they give it. I regret that I do not see at present any outward manifestation on the part of the British public that they care about what I consider to be a national disgrace so much as I think they ought to care about it.

BRICKWORK, AND THE LEANING TOWERS OF BOLOGNA*.

FROM letters which I have received with reference to my lecture I fear that its title may have misled some of you to look for an illustrated history or description of Italian brickwork in general, and of the "Leaning Towers of Bologna" in particular. I must, however, ask you to listen to a much more humble and unpretending discourse, which aims merely at putting into intelligible form a few notes which some years ago I made of these towers, as bearing upon the treatment of our own brickwork at the present day.

If I should repeat anything which you already know I hope, at any rate, it may not be altogether without some fresh feature of interest. If lessons are worth learning they are worth being brought forward in various forms and from various points of view.

Finding myself, then, at Bologna one fine September morning in the full enjoyment of a most enviable and acceptable holiday, I strolled away before breakfast towards those celebrated towers, and I thought I could not do better than take a "constitutional" to the top of the higher one and enjoy the view from such an isolated and commanding position at the height of some 300 ft. from the ground. I had, moreover, a desire to acquaint myself with the arrangements and construction of its interior, especially with reference to its staircase, the thickness of its walls, the diminution of its exterior dimensions, the description of bricks used, and the nature of the mortar and of the construction. I had no intention of making any special use of my investigations, but, having taken a few notes, I was urged by a friend to put them into shape, as likely to afford some little interest, if not instruction, to others also.

The Architectural Association immediately arose to my view in the long prospective, and having taken sketches of a few details, carefully to scale, I felt that I might be able the better to come before you. Most unfortunately on reaching Florence I irremediably lost my sketch-book, and together with it my hopes of being able to prepare anything worth producing. Nevertheless, on my return journey, the interval of an hour and a half between my trains afforded me the opportunity of renewing some of my notes of this tower, and taking again some dimensions of its sectional treatment. From the hurried nature of my second visit I am a little doubtful on one or two points, but I shall still venture to give you the leading features of this interesting structure, together with a few practical hints with reference to modern brickwork which its study suggested to me.

* For detailed reports of the first two lectures see *Builder*, pp. 296, 302, ante.

* A paper by Mr. William White, F.S.A., read before the Architectural Association on the 26th ult.

This tower,—the completed one,—was built in the year 1103, by Gherardo Asinelli, from whom it derives its name. The adjoining tower, built by the family of the Garisenda in the following year, probably never was completed. Intended to out-top the other, it is now but half its height, whilst its declination is between 19° and 20°, that of the other being only 13°. There were formerly endless doubts and disputes among tourists and guide-hooks, and the question is very often still asked at the present day, as to whether the towers were purposely built in this way, or whether they had subsided through defective foundations. Baderer says the tower of the Garisenda was built thus,—purposely on the slant. But their appearance, no less than contemporary history, seems conclusively to point to their subsidence taking place immediately after, and partly during the course of their erection. This certainly was the case at Pisa. In this campanile the declination is the greatest at the lower part, and thence to about two-thirds of its height it is gradually led back by a gentle curve towards the perpendicular. I say "towards" the perpendicular, for the upper part is still out of the line, so far as the eye can judge.

Signor Filopante, of Bologna, took accurate observations of the tower at Pisa, as well as of those of Bologna, and assured himself that a sufficient subsidence was still taking place to make it probable that they must eventually fall in a certain number of years, if it should still continue as he maintained it did. To my mind the probability is wholly against their falling, inasmuch as they must have fallen long ago had not the ratio of the subsidence been one of diminution rather than of increase, or even of a regular fixed quantity. The greater the divergence from the centre of gravity the more rapid would be the subsidence, other causes being equal, but here the ratio of subsidence seems to be less, at any rate so far as it has gone, and, therefore, it must be diminishing, or unless it had long ago nearly reached its bearings, it is not likely that more than its name would have now come down to posterity. It would not be surprising to hear that the tower of Pisa is still sinking, considering the way in which the water has been allowed to stand, from time to time, from 6 in. to 1 ft. in depth round the base on the lower side, and to soak away into the foundations.

It appears, indeed, like the Chapel of the Spinelli, to have sunk bodily into the earth, for its lowest stage stands now in a deep area sunk around it. In confirmation of the theory that their declination is from subsidence, rather than from intention, is the fact that a considerable part of the Tower of the Garisenda was taken down from fear of its declination becoming dangerous. Gally Knight says that the Asinelli Tower also was reduced in height by 156 ft. after the earthquake in 1449. Then, again, the idea of an intended inclination seems wholly improbable from the mere difficulty there must be in building safely to such a great height, with inclined and diminishing piers or plumbings, and on an inclined bed, to say nothing of the absurdity of supposing that the men of that day would not start the walling in level beds, even if they really had an intention of building out of the upright, which is an almost equal absurdity, although there may have been then, as now, remarkable men who would set aside common sense to strain after an affectation of originality. The name Asinelli may be interpreted as meaning "little asses." And if the theory of an intended inclination as attributed to them had proved to be the true one, the diminutive ought rather to be changed into the opposite. But this certainly would not be appropriate to the constructors of this interesting and remarkable monument. The experience of the builders of the Asinelli Tower appears to have been lost upon their successors in the following year as to the treatment of the foundation of the Tower of the Garisenda. They altogether failed to complete their work. There it stands, a crone and forlorn monument of honourable rivalry, we will hope, between the two families.

There is but little attempt in these towers at the ornamental treatment of detail in hrick-work which characterises so much of the Italian work, and adds so greatly to its beauty and interest. There is, however, in the Asinelli good and careful design and construction about the several parts, giving it an effect of satisfactory harmony and completeness.

We must now proceed to a short description of the building itself. The base of the tower is

Y: ASINELLI TOWER BOLOGNA 1/4 SCALE

about 51 ft. square, but nearly half of this is formed by an enclosing wall carrying a terrace at forty-three steps, or about 27 ft. from the ground, with a parapet hung out some feet over it, upon a deep moulded corbel course. At about 80 ft. above this is a battlemented set-off externally, and a paved floor. The tower then rises some 220 ft., diminishing upwards to the corbel course carrying the parapet, at the paved platform on which the cupola stands. The cupola is a bell-tower. It is about 8 ft. square, and is covered with an ogee roof. It has a large plain semicircular-headed heltry window, on each of its four sides. So much for its general aspect. We must now look a little more closely into the details of its construction.

We enter at the base by a narrow door, the head of which is formed partly by arching and partly by stone lintels, on massive corbels, through a wall 10 ft. thick, into a circular staircase of 6 ft. 10 in. diameter. Very few of the original steps of this staircase remain. There were about fifteen steps in the circuit, giving 17 in. in width next the wall, with a 12 in. newel and 7 1/2 in. rise. The newel staircase ceases at about the ninety-third step, or in about six circuits. The inside is then set off square, 9 ft. 3 in. each way, with walls reduced internally to 8 ft. 8 in. thick, the walls having been already reduced externally from 10 ft. at the base to 9 ft. 8 in. at the top of the newel staircase. This external reduction is by a set-off at the height of the forty-third step already spoken of. There is a small opening out on to the parapeted terrace. This terrace is carried on a small barrel vaulting and external wall, which does not seem to be otherwise connected with the main structure, to which it forms a surbase, and around which wide sheds were built early in the fifteenth century, in such a way as effectually to disguise the original design. Just below the cessation of the newel staircase comes the first window in the west front, and from its position with relation to the stairs, and to the windows over, in the north front, I concluded that the newel staircase was to have been carried up, but was abandoned. Remains of ten or twelve steps are still visible, broken off at the wall, where the well-hole begins. At about two-fifths of the height there is a plain groined vaulting, and paved floor opposite, the embattled exterior set-off seen in the perspective. At the top of the tower is a vault, with a twofold system of ribs, to carry the paved terrace and cupola over. To this I must recur presently. There must be some error in the height of this cupola as given by Murray at 38 ft. The portion rising behind the parapet cannot be more than 17 ft. or 18 ft., i.e., nearly three times the height of the 6-ft. door, from the terrace up to the spring of the copper-covered ogee roof with which it is capped, and this roof cannot be more than 9 ft. This would make it but 27 ft. at the most, and only 19 ft. above the 8 ft. parapet. Possibly the height may be taken to the top of the finial.

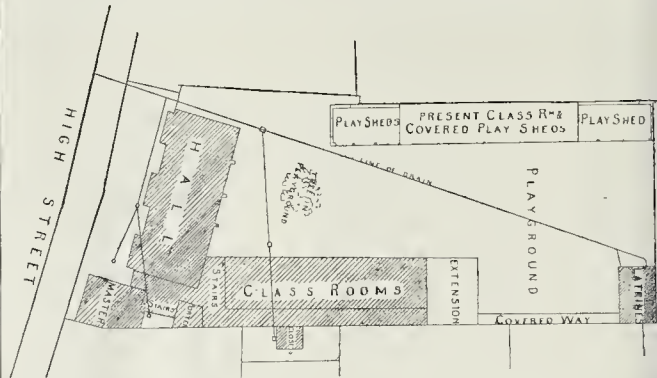

From the landing where the newel ceases, the ascent is now made by a rickety wooden staircase, in short flights against each wall of the square, with insufficient supports; the outer string having sunk some 3 in. below the wall-string all the way up. These steps rise about 7 in. I name this chiefly as affording a check,—very slight, it must be admitted,—to the respective heights of the stages and offsets by which I measured my section. But I cannot give accurately even the number of the steps. There is an old saying that "some people cannot count," and Murray numbers them at 429. This, at all events, cannot be correct. There is, however, a difficulty in counting these steps, there being a number of low quasi-steps, varying from 1 1/2 in. to 3 in. in height, which one hardly knows whether to count or not. And I had not the opportunity of checking my counting a second time. I lost my dinner as it was, and very nearly my train, which would have been almost as bad. But, in ascending, by adding together the number of steps in the stages, or points at which I made note of them, they come to 452, besides the cupola, which was locked. Whereas in descending I counted them through, to the vaulted stage 271, and to the ground 174, making in all 445, which is probably the more correct number, though still 16 more than given by Murray. Then as to the height in feet authorities differ. Of course, I could not measure this. But Murray gives it at 293 ft., and at 331 ft. to the top of the

lantern. I ought to say that, excepting the cupola, so far as I can calculate approximately by the steps, and also by the distance apart of the putlog holes, my dimensions work out to the same result within a few feet, although with such small units it is very easy to be a long way out. But it is only on this basis that I have been able to go, for the accompanying section. There are, in addition to the stages, but two material offsets on the inside. The manner in which they are made suggests the possibility of intermediate vaulted floors having been contemplated at these points. The others are only from 1 in. to 3 in. and at very irregular intervals from 10 ft. to 15 ft. apart. There are recesses left for large beams at most of them. There is nothing to show whether these were ever provided or not, but they were probably used for stages or landings for the steps or ladders. The heights of the stages of scaffolding outside seem to have been very regular. Above the set-off these were 4 ft. 9 in. apart, and below it 4 ft. 6 in. These holes were not filled up. Indeed in Italy they generally built from the interiors with scaffolding only hung out from the wall, and the holes were still left perhaps to facilitate further repairs. Their appearance is not so objectionable, as one might suppose, and in this case especially. I think they add a favourable feature to the work which would otherwise have nothing to relieve its massive plainness and monotony. It also affords to the eye better means of taking in the real height and scale of the building. The windows are small, being 17 in. wide and 4 ft. 3 in. high to the spring. The interior opening is 2 ft. 4 in. wide. The sills are weathered a little outwards and stepped to throw out the wet.

We come now to the vaulting of the flat roof. There are first two main ribs across laterally one and half brick wide by one brick deep; i. e., 16 in. by 11 in., and over these resting on them are diagonal ribs 11 in. by 11 in., filled in with brick vaulting, and covered with a paving of brick flat. The walls are, as we have seen, 5 ft. 11 in. thick above the battlement set-off, and at the top they are 3 ft. 2 in., so that they diminish above the extreme set-off to nearly one-half their thickness, and to less than one half of their thickness from above the basement. The 10 ft. wall at bottom is ten bricks thick, and the wall is three bricks at the top,—not of our 9 in. brick, but about 12 in., when laid as they are, with a wide mortar joint. Both quoins and faces are wonderfully true. The bricks are hard and the mortar sound, and though it has endured the heat of the storm for nearly 800 years, it would still put to shame most of the brickwork of the present day. I did not observe any system of bond in the work. So far as I could see, little or no attention seems to have been paid to it. Perhaps some one can enlighten us presently on this point. The irregularity in the size of the bricks would not be conducive of regularity in this respect. They are very irregular in form. But the average size would be 11 in. long and 13 in. to 23 in. thick. Five courses of bricks, with an equal number of joints, measure 1 ft. 1 in. Thus the mortar beds are $\frac{1}{2}$ in. thick, and the side joints are frequently much larger. Consequently every brick is wholly surrounded by mortar, which forms a compact mass throughout the structure, contrasting strongly with the fine thin joint with which bricks are lodged together at their edges after the fashionable mode now in use in England. Sooner or later we shall have to come to specifying our mortar joints to be not less than half or three quarters of an inch in thickness, instead of not more than one quarter. I have, indeed, for a long while specified the side joints to be wide enough to allow of their being fully filled with mortar. It necessitates good mortar and good construction. But of this we will speak further presently.*

Free Lectures at Carpenters' Hall.—The third of the present series of free lectures to artisans, under the auspices of the Carpenters' Company, was delivered on Wednesday evening last. The lecturer was professor Kerr, F.R.S.E., who chose as his subject, "A Course on the Philosophy of Building Materials," and impressed upon his hearers the great scope there was for the invention of artificial materials to correspond with the artificial purposes of building. A report of the lecture will appear in our next issue.

* The remainder is our next. A report of the discussion will be found on p. 358.

Block plan of Mr. Skipper's design for Cheltenham Grammar School.

Illustrations.

LIVERPOOL CATHEDRAL COMPETITION.

DESIGN BY MR. JAMES BROOKS.

THE two reproductions from Mr. Brooks's drawings which we give this week, showing the interior of the south choir aisle and the exterior of the south-east angle of the building, are very fine examples of the manner in which their designer has caught the true spirit of Gothic architecture. The broad masses of masonry in the buttresses of the exterior are especially fine and striking in effect, and recall Ruskin's expression about the characteristics of Medieval architecture—"Solid stone, broad sunshine, starless shade." The interior view shows on a larger scale than in the other drawings the manner of connecting the vaulting of the aisles with the main piers which rise past the springing of the aisle vaults.

DESIGN FOR A TOWN MANSION.

THIS design, the work of Mr. Gerald C. Horsley, was submitted in competition for the Gold Medal and Travelling Studentship at the Royal Academy schools last December, and we are informed upon the best authority that it only failed of success by a single vote. The author has been singularly successful, though at some sacrifice, we think, of external effect, in grappling with the real theme of the competition, namely, the thorough lighting of the interior for the display of works of art. The sculptured frieze is beautifully drawn, but is worthy of a more important place in the composition.

COMPETITION DESIGNS FOR CHELTENHAM GRAMMAR SCHOOL.

DESIGN BY F. A. POWELL AND J. HOWARD INCE, JOINT ARCHITECTS.

In this scheme the class-rooms, &c. are placed well away from the High-street, the school-hall being in front and of easy access either from the street, class-rooms, head-master's, or board-room. It, therefore, becomes the principal feature in the design, which is, as far as possible, in harmony with the old buildings and the traditions of the school.

The exterior is faced with Painswick stone, and relies for effect on simplicity and breadth of wall space.

It gives accommodation for 230 boys at an estimated cost of 5,328*l.*

DESIGN BY GEORGE J. SKIPPER, ARCHITECT, NORWICH.

The conditions of this competition prevented competitors from corresponding with the hon. secretary to ascertain, if needed, any explanation on the conditions or further knowledge of the Governors' views with regard to the proposed building, but the head-master at the present school very courteously gave any information in his power. The following were ruling points in preparing the design:—(a) A large assembly-hall set back at least 24 ft. from High-street; (b) the elevation to High-street to be specially considered; (c) so long as the

class-rooms, &c., at rear provided the necessary and proper provisions throughout for the various purposes their distribution would be capable of readjustment; (d) the caretaker's house quite an unimportant adjunct.

The accompanying plan shows the accommodation on the principal floor, and on the floor beneath are the lavatories, bath and cloak room, coal stores, heating apparatus and caretaker's house, which latter is located under the head-master's room, &c. On the first floor, over head-master's room, is the Governors' board-room, which is lighted partly by the semi-circular oriel window shown in the perspective view.

The buildings on either side of school shown in the perspective are from a sketch made of the spot, and in the grouping of the building special care was taken not to form a "gap" in the principal street of the town.

* We had added an elevation of the accepted design by Mr. H. Hall, but in deference to the wish of Mr. Hall, who thought his design would not be fairly judged by being shown in elevation along with others in perspective, we defer the illustration of it till the completion of the perspective view which Mr. Hall has in preparation.

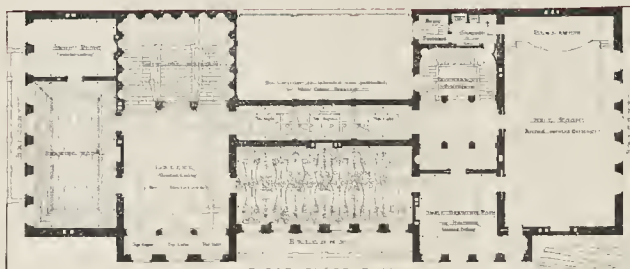

OBITUARY.

The late Mr. E. E. Cronk.—We regret to be of the death of Mr. E. E. Cronk, surveyor and land agent, of Sevenoaks, which occurred on the 18th ult. Mr. Cronk, who was sixty-five years of age at the time of his death, was Fellow of the Surveyors' Institution.

Herr Johann von Unruh, the well-known German railway contractor, died recently in Berlin, at the advanced age of 80. He deceased, who was born at Tilist, studied architecture at the Berlin Academy, and subsequently became a Governmental inspector in Breslau, as well as councillor at Gumbinn and Potsdam. He was elected director of several important industrial and manufacturing associations, and was the chief builder of the Upper Silesia railroads and the lines run from Potsdam to Wittenberg. He sat as deputy for Magdeburg in the two first Diets of the North German Confederation and in the Reichstag of the German Empire. Herr von Unruh was likewise the author of works on other subjects amongst them being "Sketches of the Modern History of Prussia" and "Experiences of the Last Three Years," the former of which appeared in 1849, and the latter in 1851.

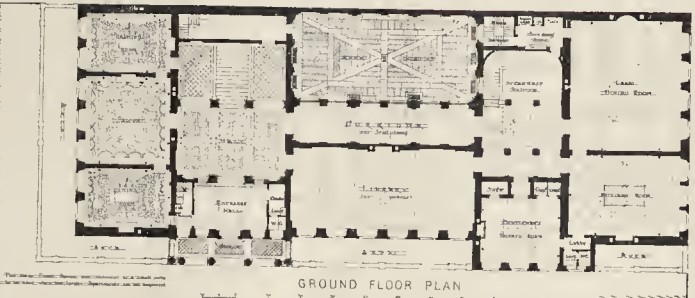

Fire Protection of the Metropolitan Suburbs.—Owing to the imperative need increased fire protection for the suburban districts of the metropolis, and the pressure brought to bear by the vestries concerned, the Metropolitan Board of Works, at their meeting on Friday last, decided to order three additional steam fire-engines from Messrs. Shand, Munn & Co. It is hoped that when the Bill before Parliament to provide for a higher brigade rate becomes law, an increase will be made in the number of fire-escapes in the lying districts.

ROYAL INSTITUTE OF BRITISH ARCHITECTS. MEDALS AND PRIZES, 1886.

At the meeting of the Royal Institute of British Architects on Monday evening last, consideration was given to the Council's recommendations as to the medals and prizes for the present year.

The Royal Gold Medal.—It was agreed to prove the Council's nomination of M. Charles Garnier, of Paris, as the recipient of this year's Royal Gold Medal.

The Soane Medallion (and, subject to the usual conditions, 50*l.*), for a design for a town church, was awarded to Mr. A. Needham Wilson, "Le temps mène tout à bien." In the same competition the following awards were made:—Medal of Merit and 10*l.* to Mr. J. H. Curry, "Ora et Labora"; a Medal of Merit to Mr. H. Bidlake, M.A.; and a Certificate of Honour to Mr. R. W. Schultz.

The Tate Prize of 30*l.*, for a design for a School of Medicine, was awarded to Mr. B. Priestley Rivers ("Medicine"). In the same competition a Medal of Merit was awarded to Mr. Alexander Paterson ("Doric"); and a Certificate of Honour to Mr. E. R. W. Leeson ("Spes").

The Grissell Gold Medal, for a design for a central octagon to a market, in iron, was awarded to Mr. A. R. Cox ("Student"), the only competitor.

The Institute Silver Medal and 25*l.* for assured Drawings.—1st, Mr. E. H. Sedding (Now or Never);—St. Magnus the Martyr, London Bridge, and Grantham Church, Lincolnshire. Medal of Merit, Mr. Arnold B. Tchell (The Marney Arms);—Layer Marney Towers, Essex. Another Medal of Merit to Mr. E. L. Conder ("Ars longa, vita brevis");—Long Melford Church, Suffolk. Certificate of Honour to Mr. S. H. Barnsley (Vale of Flowers);—Old Clove Abbey.

Institute Silver Medal and 25*l.* for an Essay on "Pediments and Gables" awarded to Mr. J. Waterhouse ("Summa sequor fastigia"). Medal of Merit to "More Majorum."

Next week we will offer a few observations on one of the drawings submitted in the various competitions.

THE NEW BUILDINGS OF THE LONDON SCHOOL BOARD. VISIT OF THE ARCHITECTURAL ASSOCIATION.

On the third Saturday afternoon visit of the Architectural Association was made on the 5th of February to the buildings of the School Board now being erected from the designs of Mr. Blomfield on the Thames Embankment.

The plan of the ground-floor is arranged with a large T-shaped room, which can be divided into screens, which are arranged to slide into a low wall, the top over the screen being closed by a revolving-shutter; beyond this room is a council-room. The first floor contains the library, which is a very lofty room, with arcaded openings into two aisles, and with a large room over the council-chamber. There are large book-stores in the basement, and several other rooms on the mezzanine floors for the school-room and caretaker's residence.

The work is perpendicular in style, the tracery external dressings being of Doubling stone, facing bricks being red, the columns and capitals to the arches are Portland stone. The base is formed of granolithic concrete. The walls are all of fireproof construction, and the work of the library roof has been treated with cyanite to render it fireproof. This is of hammer-bam construction. It is proposed to panel the walls of the lower hall with panelling from the old building in London. The ceiling of this room will be formed of panelling. The walls above the old panelling will be hung with Lincrusta, the walls of the council-room will be covered with Lincrusta, and all panelling. The walls of the passage and offices are faced with Burmantofts

glazed bricks. The beating is by means of hot-water-coils placed under the windows in recesses, with gratings opening to the air for the admission of fresh air.

The members passed from Stion College to the new offices of the London School Board. Mr. Bailey, the architect to the Board, kindly attended, and conducted the party over the building. The extension of the premises was carried out from the designs of Mr. Robson. The additions designed by Mr. Robson consist of six committee-rooms and other offices, approached by a new staircase, but in communication with the old building at every floor. The principal committee-room is decorated with a high dado of teak, the upper part of the walls being divided with plaster pilasters, the space between being papered with a dark red paper. The contrast between the teak and the white plaster looks somewhat abrupt, but the general effect of the room is good. The other committee-rooms are panelled, but the woodwork is mostly painted white. The furniture has been designed for each room.

IMPROVEMENTS AT MILAN.

The enlargement of the city of Milan by the proposed addition of a new suburb between the Piazza d'Armi and the Porta Magenta has been for some time under the consideration of the authorities, and several schemes have been proposed for laying out the ground beyond the terminus of the Milano-Erba Railway.

The Society of Architects of Milan appointed a sub-committee to consider the various plans suggested, and the report of the committee, together with a plan for the arrangement of the new suburb, and the proposed streets in connexion therewith, is published in the December number of the *Policenico*, the official journal of the Society. The following are the conclusions arrived at by the committee:—

"The Society is of opinion that the Municipality should purchase from Government the Castle and the Parade Ground (Piazza d'Armi) for the purpose of forming a grand public garden in this locality, crowned by the Arena, the Castle, and the Arch of Peace, surrounded by a fringe of buildings, public and residential, in extension of the contiguous Foro Bonaparte, which buildings should be the subject of special regulations in the interests of art."

That the largest possible space should be assigned to the garden, and that it should be laid out in such a manner as to show the three monuments to the best advantage, it being understood that the Castle shall be respected from an artistic and archaeological point of view.

That a new suburb be laid out to the west end of the present parade-ground, in direct communication with the public-gardens, and that the *carriero* be extended to the railway junction (Stazione di S. Sisto).

That a communication between the before-mentioned suburbs (i.e., the new suburb and the public garden), one to the east and the other to the west of the railway, with the central part of the city, be formed by means of two streets passing through the midst of each suburb, and converging in a piazza or open space, out of the south side of which two main streets conduct to the Piazza del Duomo, on the site of Via Mercanti and Via degli Orefici, this last street being straightened and widened.

That a grand avenue be formed through the western suburb, and be continued up to the railway station.

That in accordance with the Municipal plan the secondary streets in the western suburb should be arranged visually in line with the arena and the Arch of Peace, with symmetrically-arranged openings into the garden, and terminating in the Piazza Magenta, it being understood that the levels of these streets shall be so contrived as to pass over the North Milan Railway, which should be sufficiently lowered for that purpose."

ARCHITECTURAL SOCIETIES.

Birmingham Architectural Association.—The fifth ordinary meeting of the present session was held at Queen's College on Monday evening last. The Vice-President (Mr. John Cotton) was in the chair. Messrs. T. H. Nowell-Park and T. W. Baker were elected members of the Association. A paper was read by Mr. J. W. Tonks on "Mayoral Chains and Civic Insignia." The subject was treated historically, and the lecturer pointed out that the knowledge of heraldry and designing in gold and silver was not to be undervalued by the modern architect,—architects in Medieval times being goldsmiths in addition to their other vocations. At the close of the meeting a series of executed designs for

mayoral obains were exhibited. A vote of thanks, proposed by Mr. J. K. James, and supported by Messrs. H. H. McConall, T. W. F. Newton, J. Cotton, and Victor Scruton (hon. secretary), was unanimously accorded to Mr. Tonks, and after a response from that gentleman the meeting terminated.

Edinburgh Architectural Association.—The members of this Association paid a visit on Saturday last to Fettes College, and were conducted over the buildings by Dr. Rowand Anderson, architect to the Trustees. Dr. Rowand Anderson read a few notes on the founder and the college. The buildings, he said, formed the latest and most extensive buildings devoted to education by private request in that city of education; and now that the State was doing so much for education, they would probably be the last of their kind. The founder, Sir William Fettes, died in 1836. The trust funds at his death amounted to 166,000*l.* The funds were allowed to accumulate for some years, and in 1864 the contracts for the erection of the college were entered into, the architect being the late Mr. David Bryce. The college was opened for the reception of boys in 1870, and at intervals since then the various boarding-house and other buildings were erected. The buildings on the ground could accommodate two hundred pupils, fifty being foundationers. The architecture of the building is late French Gothic, as seen at the Royal Château of Blois on the Loire. In treating the interior no attempt had been made to be consistent with the art of the exterior. The drainage of the college, which it appeared is on a very complete system, was also described.

COMPETITIONS.

Cardiff Unitarian Church.—In a limited competition for the above church, which it is proposed to erect in Tredegarville, the designs of Mr. Edward H. Brnton, architect, Cardiff, were unanimously selected. The church will provide for 200 persons, and a Sunday school for about 100 children.

New Chapel and Mortuary, &c., at Wesley (York).—On February 1st, forty-three designs were submitted to the Burial Board for a new chapel and mortuary, lodge, and board-room, together with plans for laying out the site as a cemetery. Two premiums were offered of 20*l.* and 10*l.* respectively for the two best sets of plans. On the 27th ult. the Board made selection of the design under motto "Labor et Spes," by Mr. J. P. Pritchett, of Darlington, for the first premium; and "In Perpetuum," by Mr. Thos. Winn, of Leeds, for the second premium. It is expected that the chapel and lodge will cost about 1,600*l.*

The Tilbury Docks Arbitration Case.—The Court of Queen's Bench on Wednesday gave judgment in the matter of the arbitration between Messrs. Kirk & Randall, contractors, and the East and West India Dock Company, in reference to the contract for construction of a tidal basin and dock at Tilbury. Sir R. Webster, Q.C., Mr. Moulton, Q.C., and Mr. Cripps appeared as counsel for the contractors, to show cause against a rule obtained by the Company to revoke the submission to arbitration, or to give directions to the arbitrator, Sir Frederick Bramwell; while Sir Henry James, Q.C., Mr. Pollard, and Mr. K. Dight appeared for the Company, in support of the rule. The contract was entered into in July, 1882, and the works were stopped by the Company in July, 1884. Differences had arisen between the parties, and the arbitration clause of the contract was put in force. The contractors, after some 400,000*l.* had been spent on the works, made a claim for payments in excess of the contract price on the ground that in the deeper part of the excavations they had to deal with mud, instead of clay, indicated by certain borings by the company before the date of the contract. The Company, on the other hand, complained that the contractors did not put in the stipulated quantity of concrete per day, and the contractors replied that this could not be done in the altered circumstances. The Company objected to the reception of certain evidence by the arbitrator as going to an alteration of the contract, which would give the contractors about 150,000*l.* more than the contract price. The Court gave judgment for the contractors, but the learned Judges reserved their reasons.

ARCHITECTURAL ASSOCIATION.
BRICKWORK AND THE TOWERS OF BOLOGNA.

The tenth ordinary meeting of this Association for the present session was held on the 26th ult. at 9, Conduit-street, Mr. C. R. Pink (President) in the chair.

The following gentlemen were elected members, viz.:—Messrs. D. Geddes, A. H. Goodman, R. P. Sharp, F. E. Faithful, and H. E. Mallet. It was announced that arrangements had been made with Mr. Weedon, the water-colour artist, for a course of lessons, viz.,—two indoor lessons with copies, and six outdoor lessons on Saturday afternoons, to commence in the beginning of May. Applications to be made to Mr. Hilton Nash.

A vote of thanks was accorded to Messrs. George & Peto for permitting the members to visit the houses now being erected in Collingham-road, South Kensington.

Mr. William White, F.S.A., then read a paper entitled "Brickwork and the Towers of Bologna," of which we print the first portion on another page.

The Chairman, in inviting discussion, said that Mr. White had referred to the irregular shape of bricks, but it would be found that nearly all ancient brickwork was built of such bricks, not only in Italy but also in England. As an excellent example, he would mention the Holy Ghost Chapel at Basingstoke, where the bricks used were of varying widths, and tapered down ¼ in. at least in their lengths. There would be found, also, the thick joint which Mr. White had justly recommended. Doubtless many of those present had seen this chapel in passing through Basingstoke, but it would well repay any one who could alight at the station, and spend a short time in its inspection. The detail was of an excellent and remarkable character, reminding one of the French work of the time of Francis I., and was a good type of the development of Renaissance work, although its general lines were Medieval. In the present day, although of paramount importance, it was almost impossible to get perpendis flushed up. Mr. White had referred to the introduction of stucco at the beginning of the century. It was then fashionable to have houses treated in that way, and he thought people were often gulled into believing that stucco was as good as or better than stonework. He knew a stucco house in the South of England on which, it was said, 170,000L. had been spent, though even in the present day, he believed, it could have been built with Portland stone dressings, &c., for the money.

Mr. T. H. Watson said that a good many years ago he saw these towers, but at the time they did not suggest to his mind much of what Mr. White had laid before them. Indeed, he passed them by, and went on to see other buildings. Mr. White's paper had, however, interested him very much, and he would like to propose a vote of thanks. He (the speaker) had been somewhat surprised to find that the system adopted by the Romans in the use of brick was something quite different from what he at one time supposed. It was now found that the Roman construction was a concrete one, and where they used brick apparently structurally in arches, the bricks were about 2 ft. long, 1½ in. thick, and 5 in. broad, and were only veneered on the surface. Although one might see an arch running down with a deep soffit, the soffit was a mere veneer with a concrete mass cast in. Why they should have used bricks to such an extent was a matter for curious inquiry. The only solution that occurred to his mind was that the bricks were used to keep the concrete in place until it had set, and was able to support itself. It was evident that the Romans filled up the surface of the walls with bricks, put on much as tiles were now applied, and because it allowed them to carry up their walls in concrete more rapidly.

Mr. John Slater, B.A., remarked that a few years ago he spent a pleasant time at Bologna, the strongest impression left on his mind being the existence there of these two leaning towers, the effect of which from one point of view was most startling. After reading Mr. Street's book on the "Brick and Marble Architecture of Italy," he always felt inclined to keep to the windward of such towers. He was unable to go into the structural question of the towers, but as far as their appearance went, he did not think very much of them. They were, no doubt, very wonderful, but still the amount of

labour and expense might have been bestowed with much better effect in some other way. Mr. Watson, he believed, was wrong about the brick facing on the Roman walls. No doubt Roman walls were built of concrete, but many of them were not faced at all. In cases where the brick had been cut away, the remains of the marks of the boards forming the casing were still perfectly visible. Those gentlemen who a couple of years ago went through the tunnel of the District Railway, would remember that they could hardly believe the planks were not in position, the concrete having taken their impress to such an extent. An illustration in Palladio's first edition doubtless showed the manner in which the Romans built these concrete walls; and he believed it was entirely for appearance that these brick facings were given to them. The high position which brickwork occupied in Northern Italy was due to the very fine mortar, and the way in which it had been used. Those who could spend a few days in Bologna would see what could be done with carefully prepared brickwork, and he was never more surprised than when he saw the beautiful effects produced by the rubbed brickwork in the Bolognese palaces and churches. The cornices in some of the houses, too, were set in the most delicate manner, out of bricks, and the bond was carefully preserved. The effect produced by brick cornices was extremely striking, and although the general motif was the same, it was worked out in all sorts of ways. Mr. Slater also touched upon the variety of colours in the brickwork of Northern Italy, and mentioned the cloisters of the Church of San Zenone, at Verona, as one of the most beautiful examples of brickwork. He seconded the vote of thanks.

Mr. Stannus, in supporting the vote of thanks to Mr. White, said that he had a theory as to these towers. In the century in which they were built, each man who had his plot of ground within the walls of a town was anxious to exalt his own tower. There were many fends; and towns and families were riven by dissensions; it was, therefore, easy to understand each man's desire to have his tower higher than his neighbour's, which permitted him to treat his enemies to the polite attentions of boiling oil or melted lead. This sort of building went on to such an extent in Florence that the Republic passed a law that all towers should be regulated and cut down to a certain height, excepting, of course, that of the Palazzo Pubblico. With respect to the inclination of these two towers he believed that the foundations were more compressed between them, and that the ground outside being free, they had settled outward.

Mr. H. D. Appleton (hon. sec.) could not agree with Mr. Stannus's last remark. At the months of rivors the strata were often depressed by the weight of the detritus, and heavy buildings were believed to act in the same way. Would not the strata, then, if pressed down by the weight of the two towers, have caused them rather to lean together?

Mr. Randolph drew attention to the fine brick towers of the Netherlands, which he believed were at one time used for purposes of defence, and also as points of observation to see the arriving and departing ships. He did not agree that these towers were unornamental; they rather showed a breadth of treatment characteristic of the material used. The brickwork of towers like Lubeck was also very extraordinary.

Mr. H. W. Pratt said that his recollection of the tower was that its outside dimensions were the same at the bottom as at the top. Builders considered that the smaller tower was the only one in Italy built with the intention of making it overhang. Brickwork should not be treated as joinery.

Mr. Slater recommended any one interested in the question of brickwork towers to refer to Ruggè's "Baststein-Architektur des Italiens," in the library of the Institute of Architects.

The vote of thanks was then put, and was cordially received.

Mr. White, in his reply, remarked that the facing by the Romans might have been partly for a little bit of show construction, a little sham in the facing of arches and jambs, so as to make them appear solid and deep, when they were merely filled with concrete. They were doubtless also introduced for the effect of the colour which these little bits of brick would suggest. There was a good deal in what Mr. Stannus had said as to the origin of these towers.

CENTRAL ASSOCIATION OF MASTER
BUILDERS OF LONDON.

The fourteenth annual general meeting of the Central Association of Master Builders of London was held at the Offices, 31, Bedford-street, Strand, on the 24th ultimo, Mr. F. J. Dove in the chair.

The secretary, Mr. E. S. Henshaw, read the balance-sheet as audited, and it was resolved:—

"That the balance-sheet as audited read be adopted."

The secretary next read the following report:—

"The Committee have to state that during the past year, as anticipated in their previous report, a Bill to amend the Employers' Liability Act, 1880, was introduced in Parliament, against which this Association presented a petition so far as it affected the building trade, but its supporters not being able to obtain a second reading, as well as to renew their efforts during the present Session, Two Bills have been introduced, one by Messrs. Burt, Broadhurst, and others, having amongst its objects the doing away with any manual labour in case of injury; the other introduced by Messrs. O'Connor, Connors, and others, having in addition to the doing away with notice, many very important alterations, and being the definition in the principal Act, of men and all persons, including omnibus and tramway servants, which it is proposed shall include, besides the persons included in the definition in the principal Act, seamen and all persons, including omnibus and tramway servants, with the employer, either verbal or in writing, and whether the work be performed in the employers' workshops or elsewhere, and whether manual labour or not, and also repealing so much of the eighth section of the Act as defines the expression, 'person who has superintendence entrusted to him' as 'a person whose sole or principal duty is that of superintendence and who is not ordinarily engaged in manual labour.' Your Committee will continue, as heretofore, to watch and oppose generally the passing of these objectionable Bills, and will express their disapproval to the Metropolitan Board of Works the inconvenience to builders arising from tenders for their work not being opened in the presence of competitors, and were favoured with a very courteous reply, granting the concession asked for in the case of Fire Brigade Stations, and this, your Committee believe, has since been extended to Police Stations; they, however, regret to say that their representations to the Great Northern Railway Company were not attended with satisfactory results, but they will from time to time put pressure on all public bodies to adopt this system. Your Committee, however, desire to point out to the members of the Association the importance of protecting themselves against this objectionable system, and all the support which the Association can judiciously afford will be given in whatever case of complaint is brought to their notice by members.

The subject of the rejection of the lowest in favour of higher tenders has been the cause of consideration of your Committee, and amongst others the case of Mr. Krauss, whose tender for the construction of the Cardiff Corporation Waterworks, although the lowest, having been rejected by the Committee, was specially considered, and your Committee expressed to Mr. Krauss their willingness to bear half the expense of obtaining the highest Commissioner's opinion, if he thought it desirable. He, however, declining to do so, the opinion of Mr. Chitty Hannan and Mr. Maton, decided not to put the Association to the expense. Under these circumstances your Committee have thought it advisable to draw the attention of the Council of the Institute of Builders to the growing practice of non-acceptance of the lowest tender, and have asked them to take such measures in connexion with the Institutes of Architects and Engineers as they may deem advisable to prevent, if possible, a recurrence of such practices in future. They also brought pressure to bear on the Whitechapel Board of Works, which, although not successful in obtaining a decision in the particular case brought to their notice by Mr. G. S. Fritchard, was satisfactory, inasmuch as an apologetic letter was received for the action they had taken.

Your Committee, on the requisition of a member, held two meetings to consider the practicability of carrying out clause E of Rule 2 as to the keeping a register of foremen and others; a great diversity of opinion was expressed on the question, and it was thought desirable to shandon the subject for the present.

During the past year the action taken by the Plumbers' Company in granting certificates to qualified plumbers, has been under the consideration of the Committee, and the Company were communicated with, but up to the present no beneficial results have accrued. The Committee will be glad to have the benefit of your views on the subject, to what course may be thought best to adopt to enable the building trade to carry out similar arrangements, so that they may not be dependent on the Plumbers' Company. The Committee feel that it is a subject beset with great difficulties, and requires much thought and consideration, the movement being, in fact, the commencement of a system of self-help to every trade connected with building operations, and they are of opinion that the question is a very proper one for the Institute of Builders to deal with.

The Secretary, by order of the Committee, issued on the 9th January a circular asking for a Guarantee Fund to be raised for the purpose of assisting a member to prosecute an appeal, and as the Committee were advised by Mr. Maton, and through him Mr. Edwin Jones the Comptroller, that the case ought to be appealed against in the interest of the trade generally, it was decided to assist the member.

Having regard to the insufficiency of the accommodation at the offices in King-street, your Committee, after a conference held with the Builders' Accident Insurance Company, Limited, and the Institute of Builders, determined to relinquish their offices in King-street, and take furnished offices (consisting of a clerks' office, and the joint occupation of the secretary of the Board-room, and the position of the secretary of the Institute-room for general meetings) of the Builders' Accident Insurance, Limited, at a rental of 70L per annum, including all rates and other office expenses. They need not point out the advantages arising from having carried out an arrangement which would enable all those who are members of the several societies to have easy and convenient access to their respective

ices, which are all handsomely and comfortably furnished.
The Committee think it right again to ask your support or the Builders' Accident Insurance, Limited, a strictly mutual company started, as you are aware, in the interest of the trade, to protect employers against accidents to their workmen. During the past year the company has extended the risks undertaken to cover within certain limits accidents caused to or by employers' workmen, by their sub-contractors' workmen engaged with them without extra premium, and also to the public for an extra premium of 1s. per 10^l. expended in wages, as defined by the company's policy."

The Chairman having addressed the meeting upon the several matters referred to in the report, moved that the report as read be adopted.

The motion, having been seconded, was carried unanimously.

The secretary reported that the balloting list had been prepared in accordance with Rules xv. and xvi., and it was resolved:—

"That the Officers and Committee, as printed on the ballotting list forwarded to members, be elected for the ensuing year."

Moved by Mr. F. Adamson, and seconded by Mr. G. Williams:—

"That the thanks of this meeting be accorded to Mr. F. J. Dove for his services as President during the period he had been in office."

Carried unanimously.

The newly-elected members having taken office, the President, Mr. George Bart, J.P., took the chair, and introduced several matters of interest to the trade to the notice of the meeting, which having been fully discussed by several members from various points of view, the meeting was concluded by a vote of thanks to the chairman.

LONDON SANITARY PROTECTION ASSOCIATION.

At the fifth annual general meeting of this association, held last Saturday in their Offices, Adam-street, Adelphi, Mr. E. C. Robins, R.I.B.A., one of the vice-presidents, took the chair, in the unavoidable absence of the Duke of Argyll.

Mr. Robins read the report of the Council, which showed that the number of members on December 31st was 1,050,—an increase of 167 on the number on December 31st, 1884.

His report went on to give a long list of country mansions inspected by the engineers during the year, including Wynward Park and Seabam Hill, Durham; Saunmarey Hall, Guernsey; Weston, Dorset, and many others. Also a list of important buildings in London and neighbourhood, including the London Lock Hospital, Thomas's Hospital (part of), Grove Hall, Bow; Bethnal House Asylum, Bethnal Green; St. Catherine's Training College, Stenham; Cooper's Hill College, Staines; and all the masters' houses there.

In regard to this last, the report stated that had been inspected now for the second time, and that it was a source of gratification to the Council that so important a public body as the governing Body of Eton College had accepted the principle of periodic sanitary inspection, which the Council considered so necessary, and that the general character of the houses inspected was as insanitary as ever, only one cent. being found in perfect order, and one cent. (in addition) in fairly good order. In moving the adoption of the report the chairman said he wished to impress upon members, and through them upon intending members, that their system was one of practical utility.

Mr. Timothy Holmes, hon. treasurer, read his report showing receipts (including balance brought forward), 2,422^l., and expenditure, 9^l., leaving a balance of 473^l., against which there were outstanding claims to the amount of about 200^l.

Mr. Payne, of St. George's Hospital, in addressing the meeting upon the report, alluded to the death of Prof. Fleeming Jenkin, the inventor of this and all similar associations. He was a good engineer, and all his inventions were not only ingenious and scientific, but they worked.

Mr. Loch, of the Charity Organisation Society, in endorsing the adoption of the report, said he was hopeless for them to try and persuade labouring classes of the importance of having their houses in a good sanitary state, as the class above them showed the way, and that their houses in such a state and being them in it.

The report having been unanimously adopted, the meeting proceeded to the business of electing the Council for 1886, and the result of the ballot was declared to be that all the outgoing Members of Council were unanimously re-elected, with the addition to their number of Sir F. Bramwell, F.R.S., President of the Institution of Civil Engineers. Gen. Lord Chelmsford, who had previously been a member of Council, was elected a Vice-President.

SUNDERLAND MUNICIPAL BUILDINGS COMPETITION.

IN reference to this competition, the Leeds and Yorkshire Architectural Society have addressed the following letter to the Town Clerk of Sunderland:—

"PROPOSED MUNICIPAL BUILDINGS, SUNDERLAND.
Dear Sir,—I desire to acknowledge the receipt of particulars, 'Instructions to Competitors,' which have been laid before a general meeting of practising members of the above Society, when I was instructed to communicate to your Corporation the substance of the resolutions passed by the meeting, as follows:—

1. That the promoters of the competition be asked to state definitely if they will appoint a referee, as many competent architects, failing that provision, will be unable to compete, and, in the event of their deciding to do so, to publish at once the name of the selected assessor.

2. That the attention of the promoters be drawn to the advertisements in the papers, the terms of which require 5^l. to be deposited with the Corporation by any architect who may apply for the terms of the competition, and who must consequently forfeit that sum in case he decides not to enter the competition.

3. That promoters be asked if their wishes are correctly expressed in the paragraph which states (1) a half per cent. will be deducted from the architect's commission; and (2) that they will themselves undertake the quantities. With regard to the first point, the meeting expressed the opinion that the successful architect will be underpaid by a remuneration of 4 per cent. for all services to be rendered in carrying into execution a building of public importance, requiring so much study in detail.

4. That, in the opinion of the meeting, four sections are quite unnecessary for the purposes of the competition, a longitudinal and a transverse section often being sufficient, even for contract purposes.

5. That the short period between this and the 10th of April is insufficient to give proper study to the subject, and to prepare the necessary drawings, and that the promoters be asked to extend the time to a later date.

In conclusion, the members of this Society have been successful in obtaining nearly a dozen prizes for town-hall designs, and the above resolutions are the result of long experience of the subject referred to.—I have the honour to remain, your obedient servant,

GEO. BERTRAM BULMER, Hon. Sec.
To Fras. M. Bowse, esq., Town Clerk,
Corporation Offices, Sunderland."

BERNINI'S STAIRCASE AT THE VATICAN.

Sir,—In your note to my first Royal Academy lecture [p. 332] you treat the tapering staircase of the Vatican as a device of Bernini's for getting a greater perspective effect. He, no doubt, availed himself of it: a strong proof, in my opinion, of his genius, for thousands look up to it, to one who looks down.

Hemmed in as he was between the wall of the Vatican and St. Peter's, with only a truncated triangle to work on, his only alternative was to make a parallel staircase, with a wall thin at one end and thick at the other, wasting material and losing effect.

I used it as an illustration of how a man of genius could make a beauty out of a difficulty.

GEORGE ARCHISON.

NEW BYE-LAWS FOR CONCRETE BUILDINGS IN THE METROPOLIS.

Sir,—Mr. Goodwin's letter in your issue of the 13th ult. [p. 287], is so exhaustive on the conduct of the Metropolitan Board that little is left to say without referring back to letters published in your valuable journal of Nov. 14th, 1887, which some of your older readers will remember, but I think it advisable, with your kind permission, to refresh their memory, and for the instruction of younger men to publish again, simply to show that the Board condemn now what they not only granted, but

admitted, that Portland cement concrete is superior in strength to brickwork, &c.

[Letter from the "Builder," Nov. 16, 1887.]

"STRENGTH OF CONCRETE WALLS.

Determined to see for myself what had been accomplished with concrete, I visited the concrete houses at Gravesend, and, fortunately for my conviction, I arrived at the time of the examination by the Committee of the Metropolitan Board. I saw a 9-in. concrete wall battered with a 14 lb. sledge hammer. Mr. Vulliamy, the Architect of the Board, said that with about three such blows a hole would have been made through a 14-in. brick wall. I cannot say what number of blows were inflicted, but certainly the blows were struck vigorously, the only perceptible effect being a slight crushing of the stones on the surface of the concrete on the side hammered. Mr. Vulliamy tested the wall on the other side with a straight-edge, and declared that not the slightest effect was produced.

ROBERT WHITELEY,
Builder, Huddersfield."

My motive in asking your kind indulgence is to show by facts that a rubble masonry wall in mortar is quite a different thing from a rubble masonry wall in Portland cement, and I think, after thirty years' practical experience in superintending buildings in concrete or (more properly) Portland cement concrete and boulders of stone in all parts of the United Kingdom, also in Paris, Vienna, and Belgium, that, by this time I ought to be well acquainted with the adhesive qualities and tenacity of Portland cement. If two bricks or two rough bits of stone are joined together with Portland cement, you cannot separate them without breaking the stone or brick. The Board might as well say two deal boards jointed and glued together are not properly bonded or connected together. I have been summoned three times at the Southwark Police Court for not complying with the Building Act, at a great cost, and in every case had the Board, on which point I think the following resolutions, agreed to by the Board, must be, or ought to have been, conclusive.

[The "Builder," August 17th, 1873.]

"CONCRETE AND THE METROPOLITAN BOARD OF WORKS.

At the last meeting of the Board it was agreed that with reference to the two cases now before the committee of the erection, by Messrs. Tall & Co., of buildings in East-lane, Bernondsey, and Overhill-road, Dulwich, with walls of Portland cement concrete, without having obtained the licence of the Board for the use of that material, that Messrs. Tall & Co. be not pressed to accept a licence for the buildings erected under their patent, and further recommended that a printed circular be forwarded to the District Surveyors, informing them that the Board considered the buildings under this patent to be within the rules of the Building Act."

In conclusion, may I ask, after the Board agreed to this, where was the necessity of a licence? I was summoned before the magistrate at the Southwark Police-court because the walls were not properly bonded and put together. Mr. Biron, the present magistrate at Lambeth Police-court, was counsel for the Board; and, in examining the District Surveyor for Bernondsey, Mr. Biron asked him if the walls were properly bonded and put together. His answer was, they were all bonded. After many years the District Surveyors are of the same opinion; but why should I be exempt all these years from taking a licence more than Mr. Goodwin or other builders? I have never asked for any favour, and did not want any. I have built and superintended buildings of small and large dimensions, and never yet had any accident, and shall continue to construct the walls as I have always done. As to building to the Board from licence or the new by-laws, it is a matter of impossibility to erect a wall of moderate dimensions to remain sound. Mr. Goodwin has, he states, built warehouses and workmen's dwellings to the amount of 100,000^l.; but the only one he built according to the licence granted is a failure; in fact, he has for years built his walls according to my plan. I think the Board would be better employed in framing by-laws for brickwork, and give the District Surveyors more power over jerry buildings.

I will only add that Portland cement concrete dwellings can be built for the housing of the poor at 25 per cent. cheaper than brickwork, leaving a good profit for the builder. And further, if the Board pass their absurd by-laws to strangle concrete, it is my intention to trouble them to summon me again in a short time. With the assistance of kind friends I intend to bring the question of housing the poor so prominently before the public that there can be but one opinion as to the conduct of the Board, viz., that they are the main obstruction in solving the problem how to house the poor and find employment for the working classes.

Feb. 24, 1888. J. TALL.

The Proposed Tower Bridge.—As will be seen by an advertisement in another column, the Bridge House Estates Committee of the Corporation of London invite tenders for the construction of the lower portions of the abutments and two piers of the proposed bridge across the Thames at the Tower.

NEW PUBLIC OFFICES, WEST
HARTLEPOOL.

SIR.—In your issue of last week [p. 351], you give the result of this competition, and I observe by a local journal that the author of the selected plans adopted "F.R.I.B.A." as his motto. Now, I do not believe for a moment that the assessor in this case was influenced one iota by the motto, but, unfortunately, professional assessors are not always engaged, and such a motto may, or may not, influence unprofessional judges; at all events, I feel pretty sure that the use of the initials in question as a motto in competitions will be condemned by the profession generally, and a very large majority of members of the R.I.B.A.; and I hope we may not see them used again for a such purpose. A FELLOW.

** We entirely concur with our correspondent.

PLUMBERS' WORK.

SIR.—I shall feel obliged if you will favour me with a short space in your columns with respect to the registered plumber.

If we are qualified as such, I think there is need of a little alteration relating to builders' general foremen. In nine cases out of ten the foreman is a carpenter, who knows little or nothing of the art of plumbing. The plumber has to work under his instructions, often against his own better skill and abilities, or, as an alternative, lose his job, which does not pay us in these times. Now, if the architect or surveyor were to give his instructions to the plumber, I, and many of my fellow-workmen, know that many a job would be carried out cheaper and more satisfactorily to all concerned.

Take an instance: a job is ready for the plumbers, two or three are set on another fortnight, two or three more to different jobs in the building. No one is responsible except the general foreman, who is not a practical plumber; consequently the work goes wrong. We are all in a muddle, and the plumbing costs a great deal more than it ought to do.

What is the use of our being R.P.'s (registered plumbers) if we cannot exercise our abilities in the craft? If builders would think of it, they could not fail to see the bad arrangement, and would try to remedy it to their own interest and to the satisfaction of A PRACTICAL PLUMBER.

TRURO CATHEDRAL.

SIR.—Would you allow me to make an appeal in your paper for a special fund for the above buildings?

The work we are now doing, comprises the choir and retro-choir, with their aisles; the restored portions of the old St. Mary's Church, the lower stage of the clock tower, the two great transepts. The south porch and the baptistry are already contracted for, but unfortunately (on account of want of funds) the contract does not include the lower portion of the great central tower, which should properly come into this division of the work, to make the whole complete. It was hoped that before we reached this portion, the necessary funds would come in, but our walls are now up ready for the great transept roof; and at the meeting of the committee held last week, it was decided not to attempt the tower, but to carry the roof of the great transept and choir through. This is much to be deplored, as the architectural appearance of the present portion will be entirely spoiled, and the effect intended by the original design lost sight of, and also because the cost of erecting this portion of the tower hereafter will be greatly increased, besides the discomfit and annoyance which must be caused (however carefully the operation is performed) by removing the roof over the heads of the congregation, and erecting the permanent tower.

The Committee cannot appeal for funds for this work, as their hands are tied in the matter by their arrangements with the guarantors of the funds for the present contracts. I have therefore determined to make an appeal on my own responsibility, and entirely without the knowledge of the committee, trusting that surely there must be a sufficient number of persons interested in the work of the first English cathedral commenced since the Reformation to soon furnish the necessary amount when it is known that it is so urgently required.

The amount necessary to finish this portion of the Great Tower up to the level of the ridge of roofs of choir and transepts is 2,874*l.*; and this should be forthcoming at once, or otherwise the works will soon be too far advanced.

I shall be most happy to receive promises and subscriptions towards this; or, if preferred, I should think (though I have no authority for saying so) that they might be forwarded direct to the treasurer, Mr. A. T. Nix, Miners' Bank, Truro, if marked as specially for Great Central Tower.

ROBERT SWAIN,

Clerk of the Works, Cathedral, Truro.

A Pulpit of Caen stone and marble, with Portland steps, has been erected in Lillington Church by Messrs. Jones & Willis.

WOODWORK: BEAUFORT CASTLE,
BEAULY, N.B.

SIR.—It may interest Mr. Blashill and others to know that some of his suggestions in a recent lecture [p. 302, ante] have been carried out here at the erection of this castle.

When commencing, Lord Lovat (the proprietor) wished to use as much of the home-grown Scotch woods as practicable. Some of the doors are entirely of elm, panels 2 ft. 5 in. wide, both sides raised and fielded, the edge of the holding moulded, and to form the centre of the panel it was then veneered with elm-root, veneer cut ten to the inch; not only the doors, but the jambs of window and door openings have been treated in the same way; the effect is very good. This work has been finished about twelve months, and not any symptoms of shrinkage have yet appeared.

When the trees were cut down they were left in log for some months, then cut into plank, carefully stacked in the open air for three years, then converted into their present shape. Age of trees about 130 years.

The kitchen and servants' hall have open roofs of larch; the boarding (larch), 1½ in. thick, is wrought and V-jointed, is in 3 in. widths, and has been up three years with very little shrinkage. The entrance hall and corridor have panelled ceilings of larch; the chapel has a plain dado and doors; the main staircase, 31 ft. span, has hammer-beam roof; the gallery, 32 ft. span, has a flat ceiling, showing tie-beams (filled in between with plaster to form panels) with timber brackets at the wall, —size of tie-beam, 35 ft. 14 in. by 14 in., without sap. All these are of larch. Age of trees used, between sixty and seventy years.

As soon as possible after the larch trees were cut down, they were taken at once to the saw-mills, cut to size, and plunged direct into water, for six weeks attended to daily, then taken out and stacked ready for use, and up to the present time there is no perceptible shrinkage.

The floor of the gallery, and the floor, staircase, and dado of the entrance-hall, which have been prepared from Scotch oak, are scarcely so successful.

Lord Lovat wishes me to mention that the whole of this work, and all the carpentering (but not the joinery) has been carried out by the craftsmen of the estate under my direction. I may safely say the workmanship can scarcely be excelled.

A. CRUICKSHANK, M.C.W.A.,
Clerk of the Works.

The Student's Column.

FOUNDATIONS.—X.

IRON SCREW PILING.

THIS description of piling, which was introduced several years since for use in engineering works, and particularly for getting foundations in sand or loose earth, is capable of being made useful in the foundations of large buildings, but does not seem to have been much employed for that purpose. The screw, which forms the foot of the pile, consists of a blade from 2 ft. 6 in. to 3 ft. in diameter, and when fixed this blade has sufficient resistance to enable it to carry a very great load. Originally these piles were screwed into the ground by the use of long levers of tough wood, working in a capstan-head fixed on the pile itself, and turned by horse power; but it is better to work the levers by means of capstans fixed at a short distance and acting on levers fixed to the pile. The screw-piles may be sunk to a depth of 15 ft.

without much difficulty, unless they should meet with large stones, which greatly impede their action. A pile having a diameter of 9 in. or 10 in., with a screw measuring 2 ft. 6 in. across, will carry sixty or seventy tons. There are many cases in which it is not desirable to make extensive excavations in the ground on which a building is to be erected, where the soil would be troublesome or full of water, or where the building projects into a stream. In such cases screw-piles may be used, girders

being placed from pile to pile to carry the walls; or iron columns may be fixed on each pile so as to carry the upper parts of the building. Upon the whole, it seems likely that this method of providing foundations in an unsatisfactory soil may be made extensively useful both in diminishing the cost of the groundwork and in saving of time.

In pile foundations, more than in foundations of any other kind, it is important that there should be no settlement beyond what can be amply provided for beforehand. We have seen that in buildings of moderate size, such as the ordinary town houses of the Low Countries, the walls are so completely tied to the internal construction, that settlements may happen almost with impunity. But this will not be satisfactory in buildings of considerable magnitude or of an important architectural character. If through any want of care or judgment one pile fails to reach the solid stratum in which the rests are well fixed, it will yield to the weight, and a very serious fracture in the wall of the building or in the masonry of a pier will be the result. This mischief cannot very well be repaired; it can only be guarded against by the most careful observation of the effect of the blows of the ram upon each pile, so as to be sure that each has been so driven that it will safely carry its share of the load. The safe load must not be exceeded, and in making the calculation of the weight of the building, it must not be forgotten that, in such buildings as warehouses, which, more than any others, are likely to be built on piles, the loads placed on the floors are limited by nothing but the extent to which it is possible to pack the merchandise which they may be required to contain.

The preparation of foundations, otherwise than by simple piling, in the water of the sea and of rivers, is a subject quite distinct from that of foundations which may be executed by working above the level of the water. It involves the construction of coffer-dams, which are usually piled and puddled enclosures of the space in which the work is to be done, caissons or boxes in which the actual materials of the foundations are placed and sunk to the position which they are intended to occupy, and a great variety of cylinders and other contrivances for executing work exposed to the pressure of water and to the action of floods and tempests. Works of this kind have come to be considered as almost wholly in the province of the engineer, while the great bulk of the foundation works that have been dealt with in these papers are such as fall to the architect. They may, therefore, be properly kept distinct, and studied together with the special classes of superstructure which such foundations are intended to support.

There is no branch of the art of building that has made such beneficial progress during recent times as that of the making of foundations. Indeed, it may be said that in almost every other branch the tendency has been retrogressive. In the period of about half a century, during which an enormous impetus has been given to building, all available ingenuity has been exercised in many quarters to make the other departments of construction as unsatisfactory in regard of workmanship and materials as was possible, physically or legally. But the provision of a fairly good foundation is not only amply sufficient to preserve from failure the structures which are built with the care that was formerly more common than now, it will actually preserve the work of the indifferent builder from the fate that would have undertaken it in days before concrete foundations were known.

The student who has followed this subject carefully with a view to its practical and legitimate application, will not have failed to see how he may benefit by it. It is on the site, and beside the trench, and in the company of those whose life is spent in this work, and in the presence of failures which are the most instructive teachers, that he will find the best illustrations of true principles, and the most effectual correctives of false notions on this important department of his art.

A Cabmen's Shelter.—The thirty-eight shelter of the "Cabmen's Shelter Fund," the gift of Lady Charlotte Schreiber, placed on the cab-rank at Langham-place, will be formally declared open on Saturday next, the 6th inst., at 3 p.m., by the Right Hon. Sir Henry Layard, G.C.B.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

3,347, Sanitary Trap. J. S. Truss.

The body of the trap is box-like and provided with a cover and an outlet-pipe at the bottom. The inlet-pipe enters at the side and turns upward into the box, terminating in a valve-seat, on which a spindle-valve closes, the spindle being held in a fitting in the cover. The trap is cast in one piece with the inlet and outlet pipes. The form the core is also described in the specification.

8,175, Flooring Cramp. A. Dobbing.

The cramping-slide is pushed forward by an eccentric lever, a catch, which falls into notches, on the upper fore end of the slide. Two holding-catches support the slide also.

13,101, Fireproof Partitions. J. Rogers.

For temporarily closing the openings in fireproof partitions, hollow fireclay blocks with sunk handles, plain or corrugated, are employed. These blocks are carried and stacked in such positions as required, as, for instance, between double iron doors. They may have holes to permit the escape enclosed air on objection to heat.

13,380, Drying Bricks, &c. Barclay, Allison, and Barclay.

The bricks are burned by gas which passes from the kiln to another, and thence by flues to a shed for drying bricks before burning. The gases pass from a gas-chamber into a regenerator along a series of tubes, which are arranged in a parallel series, thence to a chamber at the bottom of the kiln into which they are discharged in horizontal tubes through suitable apertures. The products of combustion pass out at the bottom to a flue leading to the top of a second kiln, and so on being led to a firing-chamber before finally passing to the stack. Each kiln is connected to the gas-chamber and to the adjoining kilns, there being suitable valves and dampers so that the kiln or set of kilns may be cut off from the gas supply, while air may be used through to cool the contents. The drying-chambers may also be heated by gas brought directly from the producers.

14,514, Raising and Lowering Builders' materials, &c. W. Heatley and G. Hutbins.

A rope passes over a large grooved pulley at the upper part of the building, and under a smaller one below. The large pulley is on a shaft carried on bearings on suitable standards, and rotated usually by a worm-and-worm wheel. The worm shaft is provided with a catch to prevent running back, and the worm is provided at the ends with rollers, in which are rollers to reduce the end motion. The small pulley at the bottom can be raised or fixed in any position. In use, the articles to be raised are taken up by the rope at any point, the attachment being made by clutch pieces. These clutch pieces have inclined eyes, which grip the rope between their opposite edges, when a weight hung on the hook.

15,100, Flooring or Staging for Greenhouses-Treeton.

Perforated slabs, with V or circular grooves, are arranged at right angles to one another, and communicating with one another. They receive the water from the plants, and are provided at intervals with drain pipes.

16,918, Handles, Knockers, &c. J. Gordon.

Door-handles, knockers, &c., are made of cast or malleable iron, in two concave parts, with internal junctions. The edges are placed together, and then metal is poured inside, to connect them, and in a solid handle.

NEW APPLICATIONS FOR PATENTS.

Feb. 19.—2,419, J. Hoken, Fixing Door and other rods to Spindles.—2,427, W. Sanderson, Door and Latch Furniture.

Feb. 20.—2,482, W. Crow and W. Coley, Compound for Coating Wood, Stone, and other Materials.—2,483, T. Gray, Door Lock Handles.—2,489, Openshaw, Fastening Rain-water and other Pipes.—2,491, J. Simpson, Gullies.—2,497, R. Cole, Latching Cook or Tap.—2,498, W. Howie and R. Anderson, Window Frames and Sashes.—2,500, Kinell and Another, Opening Casements, Sashes, Ventilators, &c.—2,512, A. Doult, Fastenings for Iron Gates, &c.—2,518, A. Pocock and H. Colley, Metal Floorings or Horizontal Partitions Buildings, &c.

Feb. 22.—2,530, W. Welch, Hydraulic Cements.—2,531, W. Houghton, Water-closets.—2,543, E. B. Machin, for Cutting or Punching Tiles, &c.—2,547, J. Sample and W. Ward, using Knobs or Handles to Spindles.—2,551, A. Werts, Portable Dust-bins.—2,553, B. Hawes up, Automatic Feeding Apparatus for Sewing Machines.—2,563, A. PROVISIONAL SPECIFICATIONS ACCEPTED.

15,820, E. Pither, Door Shield or Finger Plate.—54, W. Hilder, Lowering and Raising Sliding Window Sashes.—440, S. Jenner, Chimney or Ventilating Shaft Top.—561, J. Stanley, Smoke-consuming Fireplaces.—794, A. Thomas, Automatic Flushing-tank.—829, J. Stüdder, Flushing Water-closet Pans.—1,496, T. Crampton, Electric Bells.—1,534, A. Clark, Combination Locks.—142, J. Brown, Transverse Ventilation of Sewers.—509, J. Jex Long, Open Fire Grates.—560, J. Wragg, Fastener for Window Shutters and Doors.—853, W. Fowler, Cisterns for Water-closets, &c.—883, S. Phillips and S. Wise, Indicator Lock.—923, H. Buchan, Water-closets.—990, J. Green and Others, Kitchen Ranges.—1,015, G. Wilkinson, Bakers' Ovens.—1,325, R. Hunter and W. Moffatt, Cooking Ranges.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to opposition for two months.

4,573, W. Leggett, Window and Door-Fastening Bars.—5,213, T. Pawcett and J. Pawcett, Pressing Bricks, Brickettes, and Tiles.—5,384, J. Evans, Union Joint or Couplings for Pipes.—10,183, W. Duffy, Wood Block Flooring.—12,525, W. Strymgar, Construction of Floorings, Roofs, &c.—13,769, H. Meisicke, Water Motors.—1,039, C. Veit, Door Locks.—4,164, W. Stobbs and E. White, Preventing Down-draught in Chimneys.—4,521, H. Yull, Waste Water Preventer.—5,027, J. Smith, Stench Traps.—5,636, S. Combs, Door Check.—5,684, T. Helliwell, Glazing.—5,956, W. Lester, Astragals for Roofs, Windows, &c.—1,133, A. Bergmann, Locks.—1,184, A. Boulton, Water Meters.

RECENT SALES OF PROPERTY.

ESTATE EXCHANGE REPORT.

Table listing recent sales of property, including items like 'By BRANCH & LEVINE and WALKER & RUNZ, Liverpool, Walton—The Liverpool Zoological Gardens, freehold area, 2 1/2 a. 3r. 3p. £19,500' and 'By REYNOLDS & BASON, Borough, Fenning-street—Ground-rent, 110l. a year, reversion in 72 years. 2,223'.

Table listing property sales, including 'Andover, near to—Freehold cottage, and 3a. 2r. 2sp. £389' and 'Binley, near St. Mary Bourne—Freehold residence, and 5a. 2r. 30p. 590'.

Table listing property sales, including 'Sevenoaks—The residence called "Heathfield," and 1 1/2 acre, 62 years, ground-rent 40s. £1,010'.

MEETINGS.

Table listing meetings, including 'SATURDAY, MARCH 6. Royal Institution.—The Rev. C. Taylor, D.D., on "The History of Geometry." 11. 3 p.m.' and 'MONDAY, MARCH 8. Royal Academy of Arts.—Lectures in Architecture: Mr. W. Watkins Lloyd will give "An Exposition of the Theory of Proportion in Architecture as understood and applied in detail by the Architect of the Parthenon." 8 p.m.'

Miscellaneous.

Architects' Benevolent Society.—The annual general meeting of the subscribers and donors of this Society will be held, at the above address, on Wednesday next, the 10th of March, at five o'clock. Steam Laundries.—Messrs. Scrivener & Co. have received instructions to proceed with the erection of the boundary walls of the second laundry Company of the London and Provincial Steam Laundry Company. The site is close to the Queen's Park Station, Kilburn. The buildings will be very extensive, and are to be commenced at once. The architect is Mr. Ernest Turner.

The Liverpool "Gordon" Working Lads' Institute.—The foundation-stone of this building, which will occupy a site a little to the north of the Stanley Hospital, has been laid by Mrs. Cliff. The building is being erected at the expense of Mr. William Cliff, in memory of his eldest son. The object of the institution is to provide a continuance of the Board School teaching of industrial training in the interest of boys who, having left school, are apprenticed to different trades and are in receipt of daily wages. Besides the educational advantages to be derived from it, social pleasures, gymnastic and other exercises, to elevate and train the mind and body will be provided. The institution will be conducted upon lines similar to the Whitechapel (London) Working Lads' Institute and other similar institutions. The principal entrance is from Stanley-road, and leads into a spacious vestibule, from which the main corridor leads, on the right to the social-room, 44 ft. by 20 ft., with kitchen opening therefrom, and a committee and secretary's room, and on the left to four large class-rooms for industrial and technical training, fitted with stoves, forges, benches, &c. From the main staircase or central hall access is gained to the gymnasium, 60 ft. by 13 ft., and a corridor leads therefrom to the bath-rooms, lavatories, &c., the heating of the building, as also for the baths, being arranged upon the basement-floor. The first floor contains a large lecture-hall and concert-hall, 79 ft. by 42 ft., and 31 ft. in height, with a polygonally-formed panelled roof. Chair accommodation is provided in this hall for 800 persons, exclusive of the orchestra, which will accommodate eighty more. The hall has also been arranged with a view to division into class-rooms, with light movable screens. The exterior elevations of the building, which is Flemish Renaissance in style, are broken with side and central gables, with stepped gables, parapets, and piers, the windows having tympana filled in with interlacing tracery, confined within variously shaped arches. The building will be constructed of red brick and terra cotta, interspersed with red sandstone dressings, the slates being Westmoreland greens. The entire works are being executed by Messrs. Morrison & Sons, of Wavertree, at a cost of about 5,000l., from designs by Mr. Walker, Dale-street.

The National Liberal Land Company (Limited).—The report and balance-sheet for the year 1885, to be presented to the sixth annual general meeting of the shareholders, at the Charing-cross Hotel, London, to-day (Friday, March 5), states that notwithstanding the continued severe difficulties experienced by all sellers of land in finding purchasers, the directors have been able, during the year, to realise from sales the sum of 40,487l. 11s. 6d. The purchases comprise a seaside estate at Rhyll, North Wales, and a valuable and important property at Highbury, a considerable portion of which latter has been re-sold at a handsome profit. The profit and loss account shows an available balance of 2,657l. 9s. 8d., and the directors recommend that, in addition to the interim dividend already paid for the half-year ending the 30th of June last, at the rate of 5 per cent. per annum, free of income-tax, a dividend at the same rate for the remaining half-year be declared and paid, and that the balance, subject to payment of directors' fees, be carried forward.

Guidford.—A memorial window has been placed in the west end of Christ Church, Waterden-road, presented by the late Mr. Pagan, of Oak Lodge, and commemorative of his wife and two children. It is in stained glass, and it illustrates the 11th chapter of Isaiah. The figure of Jesse is placed at the bottom of three central compartments, and from it start the root and stem referred to. The outer lights contain figures of angels. The genealogy of Christ is shown by the figures of David, Solomon, and others mentioned in the first chapter of St. Matthew, culminating in the figure of St. Mary and our Lord (the Incarnation), and His subsequent death. In the two pieces of tracery are figures of SS. Joseph and Joachim. The general treatment is after the style which prevailed in the latter part of the fourteenth century. The window has been designed and produced by Messrs. Lavers & Westlake, of London.

Bristol.—By an obvious misprint in our last issue, Mr. Bignell's Church, at Walthamstow, was described as having cost 800l. It should have been 8,000l.

Society of Engineers.—At a meeting of the Society of Engineers, held on Monday evening last in the Town-hall, Caxton-street, Westminster, Mr. Perry F. Narsey, President, in the chair, a paper was read on "The Roorkee Hydraulic Experiments," by Mr. E. S. Ballais, A.M. Inst. C.E. The paper was an examination and criticism of an extensive series of experiments on the flow of water in the Ganges Canal, made by Captain (now Major) Allan Cunningham, R.E., in the years 1874-79. The author, after stating that there were many important questions connected with the experiments to which attention had not yet been directed, proceeded to consider the method of velocity measurement. He enumerated the faults which the double float possesses, explained how it should be designed so as to minimise them, and argued that with the patterns of float used at Roorkee the amount of error must in many cases have been large, and that much better results would have been obtained by using floats of a different pattern, and probably better still by using current meters. Double floats were resorted to very rapid streams, but the idea that they were not suited to deep streams was shown to be erroneous. The rods used for measuring the mean velocity between the surface and the bed did not reach to the bed, and, therefore, would give results slightly in excess of the true mean velocities. He contended that rods and floats were not generally so good as current-meters. Referring to the distribution of the velocities in the cross-section of the stream, the author, after showing that the depression of the maximum velocity below the surface could not be due to the resistance of the air, adduced further evidence in support of the law discovered by the experimenter, that the ratios of the different velocities to one another are independent of the mean velocity in the stream. Another law propounded by the experimenter, namely, that the form of the transverse curve of velocities is independent of the depth of water, held good only in a rectangular channel.

Sounding by Potassium.—A very ingenious scheme for detecting the presence of sub-soil water has lately been devised by an American engineer, and is described by our Transatlantic contemporary the *American Engineering News*. In connection with some large public works at Boston it was desirable to test the effect that certain pumping operations would have on underground water. A number of small pipes were, therefore, driven into the ground into which the water would rise. The problem was to gauge the height of the water in the pipes in a simple and effective manner. A spring steel tape had attached to its extremity by a wire hook a small leaden weight. In the top of this there was a hole in which a cork was forced, and in the cork was fixed, in a vertical position, a needle, the point being upwards. The distances were so arranged that the point of the needle would be just on a level with the zero mark on the tape when the whole was allowed to hang in a vertical position. A small piece of metallic potassium was placed on the point of the needle, which would then be lowered by means of the tape into the pipe. Directly the potassium came in contact with the water it would ignite with a slight explosion, at which time the depth the tape had descended would be noted, thus giving the height the water had reached.

The Metals Exhibition at Rome.—The principal attraction just now at Rome is the Metals Exhibition, which is being held at the Palazzo di Belle Arti, situated in the Via Nazionale. Amongst the most important exhibits are two bronze statues, discovered in the Italian capital in the course of last year's explorations, one of these being the bronze Bacchus which was recovered from the bed of the river Tiber in September last. There is also an ancient lantern on view, brought from Venice, where it had been preserved. A magnificent pedestal, dating from the fifteenth century, with three steps supporting a column, is placed in a prominent position, and attracts much attention. The pedestal is encircled with carved leaves, chiselled in the metal, whilst a bird, representing an eagle with its wings spread out, is perched upon the extremity of the column, clasping a hook. A figure, which is intended to represent Emanuel Philibert of Savoy, is standing in the centre of the hall. It is attired in armour, consisting of polished steel inlaid with gold. The above are only a few of the many interesting works which this exhibition contains.

Royal School of Mines.—Professor Warrington Smyth, F.R.S., in continuing his lectures upon mining, in the theatre of the Geological Museum, Jermyn-street, considered the various systems adopted in the working of building stone. The pillar and bord or gallery is the most common, and dates from a very early period. It may be seen in the quarries of Egypt and Hindostan. The pillars there are rectangular, and sometimes, if the ground is not very firm, the openings are arched. The catacombs of Paris and Rome, and the caverns of Maestricht, have been wrought on a system not unlike this. Another remarkable instance, to be seen in our own country, is that of the quarries at Box, near Bath. In this case, the stone being strong, the angle of dip moderate, almost flat, and the character of the rock such as renders it capable of being cut with a saw, there is a degree of regularity such as is scarcely to be seen in any other workings. The headings or galleries are 25 ft. wide, and are crossed by others, leaving 12 ft. pillars between; the height of the stratum varies from 8 ft. to 20 ft. in the district. A very long-handled pick is used in these quarries, for the boring, and the rock is then cut away with a saw, the pillars being left permanently for support.

The Positivity of Building Materials.—Professor Recknagel has lately called the attention of German architects to the subject of the movement of the air in dwelling-houses, and to the fact, well known among English sanitarians, that air passes through the walls and ceilings. He asserts that the air passes upwards through the flooring with the same force as that with which it passes through the lowest part of the vertical partition of a room; while it penetrates the ceiling with the same force as that with which it passes through the upper portion of the upright wall. Statistics of Berlin mortality show that there is a higher death-rate amongst the persons living in the lowest and highest stories of houses than amongst the inhabitants of the intermediate floors; the dwellers in the loftiest rooms breathing air which has already passed through the lungs of those in the other portions of the house. During the colder seasons this is particularly the case. Professor Recknagel attributes, moreover, to the nature of the filling between the floors a certain share of the blame for the exceptional mortality of 28.2 per 1,000, which prevails in Berlin amongst the inhabitants of the stories higher than the fourth. As is remarked a contrary movement takes place, it is remarked that the residents on the first floor then breathe air which has passed through the lungs of the occupants of the garrets. In view of the evidently injurious consequences of dry-rot in the beams which separate one floor from another, it is urged by Herr Wagner, of Mayence, in the *Deutsche Bauzeitung*, that massive work in iron and stone, with a filling of slag-concrete, is the most suitable alternative mode of construction, the difference in expense not being out of proportion to the sanitary and other advantages thereby obtained.

The "Tale of Troy" and "Orestes."—The "Tale of Troy," as performed three years ago at Cromwell House, will be reproduced (in the English version) on the evening of May 27th, at the Prince's Hall, Piccadilly. The "Story of Orestes," an abridged translation of the *Orestean Trilogy* of Æschylus, which has been written by Professor Warr as a sequel to the former, will be represented on the preceding evening, May 26th, and also on the afternoon of May 28th, in the same place. The tableaux and scenery have been designed by Sir Frederick Leighton, bart., F.R.A., and Messrs. E. J. Poynter, R.A., G. F. Watts, R.A., and Walter Crane, and the music specially composed by Mr. Otto Goldschmidt, Mr. Malcolm Lawson, Dr. Monk, and Mr. Walter Parratt, who has undertaken the choral music for the new drama. The proceeds of the performances will be given as a contribution towards a University Endowment fund, with the object of enabling King's College and University College, London, to extend and cheapen the higher collegiate education, with a view to qualify them for the functions of a Teaching University.

The Plastic Decoration and Papier Mache Company, of Wellington-street, Strand (formerly Bielefeld's), have removed their factories from Staines to more commodious premises situated in Market-road, Caledonian-road, N. The offices still remain in Wellington-street.

Brick and Masonry Arches.—At the last meeting of the Liverpool Engineering Society, R. Coard S. Pain, Assoc. Inst. C. E., President, in the chair, a paper on "Brick and Masonry Arches" was read by Mr. A. Wharton Metcalfe. The author said his object in bringing the paper before the Society was to give and contrast the empirical and theoretical modes employed in the design of arches, and also by presenting certain tables derived from the general equation to the equilibrium curve to illustrate the great advantage of the latter mode. By means of these tables the construction of the true curve of an arch, when designing a bridge, became an easy matter. The author also considered briefly the mechanical and graphical means for drawing the linear arch, and gave tables derived from actual examples prepared in the office, and calculated from the general equation to the near arch. In dealing with such practical questions as the relative merits of brickwork and masonry in arches, and the systems of constructing the same, such as the ring and bonded methods, some valuable information was given, derived from the practice and experience of Mr. Charles Richardson, the engineer to the Severn tunnel. The recent developments of long submarine tunnels have lent additional importance to the question of the relative merits of bonded brickwork and of brickwork built in rings; this, and its bearing upon the curves of arches subjected to water pressure from without, was discussed. In conclusion, the importance of the subject was strongly urged, and more especially as the recent movement in favour of ironwork in the place of brickwork and masonry was considered to be hardly reasonable when the quality, hardness, and durability of bricks now made has been taken into consideration, as well as the economy resulting from their use.

A New Clock.—The parish church of Ivoston, Gloucester, by the liberality of Mr. Edward Bish, is about to be fitted with a turret clock by Mr. J. W. Benson, of Ludgate Hill. It has a copper dial of 4 ft. diameter, striking the hours and quarters, and is reported to be an exact timekeeper.

EAST GRINSTEAD.—For additions and alterations to Bramblehurst, and rebuilding stabling at Forest-row, Messrs. N. S. Joseph & Smithem, architects:—

Phillipson, London.....	£3,502 0 0
E. Conder, London.....	2,667 0 0
Manfield & Son, Farnbridge Well.....	2,663 0 0
Waters, Forest-row (accepted).....	2,049 0 0

FULHAM.—For rebuilding old malthouse, Stamford Bridge, Fulham, for Mr. J. Bowden:—

H. Smith.....	£1,278 0 0
Stone.....	1,260 0 0
W. H. Smith.....	1,212 0 0
J. Grover & Son.....	1,178 0 0
Prestige & Co. (accepted).....	1,070 0 0

GRAY'S (Essex).—For the completion of eight shops, High-street, Grays. Mr. J. H. Churchyard, surveyor, Bishopgate-street:—

H. J. Carter, Grays (accepted).....	£2,280 0 0
-------------------------------------	------------

GRAY'S (Essex).—For manager's house, for Messrs. Brooks, Shooldridge, & Co. Mr. E. C. Allam, architect:—

H. J. Carter, Grays (accepted).....	£864 0 0
-------------------------------------	----------

HIGHGATE.—For alterations and additions to St. Aloysius's School, Hornsey-lane. Mr. Albert Vicars, architect, Strand:—

T. Heath.....	£3,798 0 0
Grover & Son.....	3,684 0 0
Patman & Potheringham.....	3,473 0 0
Kelly & Son (accepted).....	3,375 0 0

ISLINGTON.—For the supply of six water-rans and two water-carts, for the Vestry of St. Mary, Islington, Mr. J. P. Barber, surveyor:—

E. H. Bayley, Newington-caneway.....	£278 0 0
J. & W. Rendall, Kingsland.....	280 0 0
Glover & Sons, Warwick.....	288 0 0
Bridges, Lagon Works.....	284 0 0
J. Smith & Son, Wolverhampton.....	259 5 0
East Yorkshire Cart and Wagon Company, Beverley (accepted).....	258 15 0

ISLINGTON.—For alterations and additions to the King's Arms, Liverpool-road, for Mr. W. L. Harris, Mr. H. Hardwicke Langton, architect. Quantities by Mr. F. H. A. Hardcastle.—

W. Smith & Son.....	£1,689	0	0
Fishler.....	1,445	0	0
Ridout.....	1,427	0	0
Langnead & Wey.....	1,425	0	0

Fifteenth-Century Italian Ornament.

VERY ONE who looks at pictures at all must often have been struck with the elaboration and delicacy of the ornamental designs represented on the hangings and costumes in the works of the early Italian painters. Decorative design has, in the history of most art-producing peoples, preceded the power of expressive and true delineation of the figure; it has sometimes, indeed, been carried to the highest point by nations, such as the Japanese, who have never attained the art of drawing the figure at all except in a grotesque fashion. And in the days when the great art of painting, which was the glory of the Renaissance in Italy, was gathering strength and experience and knowledge for its future triumphs; when the figure was still portrayed with a tentative and laborious striving, still stiff in the joints and conventional in attitude, though the face was often eloquent with pathetic expression of a somewhat restricted kind; at this time the pictures painted were exuberant in carefully worked-out ornament, rich diapers covering the dresses of the figures and the drapery which hung around, so that even pictures which present little of life or interest in the figures themselves became highly interesting and valuable on a merely decorative point of view. The signs thus illustrated are often not only highly elaborate and effective in themselves, but further intricacy is added to the working of them in the picture by the manner in which they are faithfully followed out by the artist through the folds and irregularly-twisted surfaces of the drapery on which they occur. It is perspective treatment, so to speak, of the sign, while it probably gave the artist an additional interest in his work, and added a problem of technique to the painting, is also a difficulty in the way of tracing and following the design, should the spectator be sufficiently interested in it to wish to do so.

It occurred to Mr. Sydney Vacher, the architect who has produced the book the title of which forms the heading to this article, that if the various ornamental designs found in early Italian paintings, or in our National Gallery alone, without counting the riches of sign galleries, were carefully copied, and in places where they were obscured by the folds of perspective of the simulated stuffs on which they were delineated, were drawn out like the map of the world on "Mercator's

projection," they would furnish a new set of hitherto unedited Renaissance ornaments, interesting both for their intrinsic beauty and the circumstances under which they were found. Mr. Vacher has spared no pains in order to carry out this idea in a worthy manner, and the large folio which shows the result of his labour is one of the most sumptuous books of ornament that has been brought out for some time past.* Perhaps the effort to produce a volume *de luxe* is rather too apparent, for some of the ornaments which are on a small scale and are simple repetitions of one detail are drawn out all over a large page in a manner which shows their effectiveness certainly, but which occupies more space than is at all required to exhibit the design and construction of the decoration; and the work would have been of more practical and general utility if the amount of design in it had been compressed into a smaller and less costly book. However, this is only from the point of view of the general student, who will probably have the opportunity of consulting and studying the volume in libraries; and, apart from this, we have every appreciation of large and beautifully got-up books on a subject of this kind; there are not too many of them in England, and a beautiful book is an artistic treasure in itself of no mean order.

In his preface, Mr. Vacher suggests a practical utility in the publication of these ornaments, as many of them would be very suitable for reproduction on ordinary stuffs, such as curtains and other hangings, in a cheap form, and as an improvement on many of the patterns that are in use for such textiles. None of these designs, the author believes, have been published before; and some of the best of them occur in paintings that are hung rather high in the National Gallery, and having been glazed for protection, are thereby still more disadvantageously placed for close study, and the beauty of their decorative detail is consequently overlooked, or almost invisible to the ordinary spectator.

The hangings from which these ornaments are taken are mostly used in the pictures as backgrounds to the figures, or sometimes as drapery on a throne or seat, extending down the back and into the floor in front of the seat. Mr. Vacher raises the question whether these decorations were invented by the painters who used them in their pictures, or painted them from actual brocades. He inclines to the latter theory, as the shadows and folds in many of them are painted as if from actual drapery. Some of them, however, we are inclined to think, were inventions; the task

* Fifteenth-Century Italian Ornament, chiefly taken from Brocades and Stuffs found in Pictures in the National Gallery. By Sydney Vacher, Architect. London: Bernard Quaritch, 1886.

would have been a very congenial one to the early Italian painters, so many of whom were decorators by profession, as much as painters of pictures. But where, as Mr. Vacher says, the patterns are carefully followed out in the deep folds of dresses and hangings, so that one has to look into the shadowed portion of the folds to trace out the combination of the design, it seems probable that they were painted from what was actually before the eye.

Of the thirty designs represented here in as many plates, not a single one illustrates that system of apparently natural growth and elusion of the idea of repetition which characterises so much of the later Renaissance ornament, and so much other fine ornament of different schools, and which has been carried to such a high point of perfection by Mr. Morris in many of his designs for textiles and wall papers. One or two, such as No. 10, from Crivelli's picture of the "Madonna and Child enthroned" (No. 807, National Gallery), or No. 11, from the same picture, present an appearance of intricacy at first sight, owing to the multiplicity of lines, but in reality they are seen to be based on the simplest geometrical arrangement. Some few of the designs given are merely powderings; a good many others are formed on a very simple basis, which Mr. Vacher describes as "a mesh formed of upward wavy lines drawn reverse ways, touching one another." Upon this simple theme, however, a great many variations can be played, as every ornamentist knows, especially with the help of colour. Others may be described as powderings, or repetitions of a small design filling a certain space, but placed so close as to cover the ground and fit into each other. These have an appearance of intricacy, but it is only a small but rather fully detailed design closely repeated.

The first two designs given are from Orcagna's "Coronation of the Virgin" (National Gallery, 569); the second is a repeating pattern of no very great character, but the first, in which bird-like conventional dragons (very like the dragons in Richard Doyle's pictures) are intermingled with a geometrical stem-and-leaf pattern in thin lines, is very delicate and effective, and just the thing to work in fine embroidery; it would require very patient work, however. The third design, from the same painting, a diaper of conventional flowers and groups of birds, gold on a purple ground, is much bolder in character, and looks, as Mr. Vacher says, very like an imitation of an actual textile. The expanded flowers, disks with rays, are very finely designed; the bird part of the pattern is rather feeble, and does not

blend well with the rest of the design. No. 4 is an example, from Fra Angelico, of another type of design, formed by the symmetrical spacing of sprigs of foliage not in themselves symmetrical. The effect of this is very pretty, though, regarded as design, it is disjointed and wanting in principle. A more vigorous and powerful design, on the same system, is given in Plate 30, a design in large conventional sprigs, very finely and broadly treated, from a drapery on the throne in the "Madonna and Child," by Vander Goeck (N. G., 774). The charm of the Fra Angelico example is in the graceful design of the separate sprig; there is no contrivance or thought in it. In the plate following this, No. 5, we have one of the finest designs in the collection, taken from Spinello Aretino's "St. John the Baptist" (681, N. G.), where it is continued over the ground on which the figures stand. This is an admirable arrangement of birds and conventional flowers in such a manner as to form a continuous design, each portion appearing designed for its position in relation to the rest; the details are of great delicacy. The design is printed in warm yellow and white, and looks very charming (Mr. Vacher suggests that this and the succeeding one are probably copied from silk tissues, and they look very like it), but for the sake of avoiding too many printings, in other words for economy, two other colours are omitted; for in the original, Mr. Vacher tells us, the dark parts of the birds are black, and the ground has a red enrichment. As we are told this frankly, there is, of course, no misleading; but it is a curious kind of omission to make (and it is made in regard to two or three other examples—always duly noted) in what is intended to be an edition *de luxe*. The first luxury in a book on ornament is to show the ornament with the highest possible correctness and effect; to restrict the chromo-printing is exactly the wrong sort of economy; and if there had been a little less expenditure on the size of the book, the paper, and the binding "by Birdsall, of Northampton" (which is highly creditable to that artist), there would have been enough saved to give the full number of printings requisite to show this and some other designs in their entirety. It strikes us as a singular misjudgment to bring out a costly book of ornament and to economise in the representation of the ornament itself, which is, after all, the ostensible *raison d'être* of the book. This only applies to a few of the plates, but it is impossible to pass the fact without comment.

The two most remarkable designs next in the book are the two very elaborate ones, Nos. 10 and 11, which we have already referred to, from Crivelli's "Madonna and Child" (N. G., 807). These show, as the author says, a very unusual form of ornament, little illustrated; No. 11 especially, formed entirely in white lines on a dull red ground, is an admirable design, and suggests a great deal of varied application of the same method. Plates 12 and 13, from two other Crivelli's (N. G., 724 and 739) are examples of ornament designed on the same principle, though not quite equal to No. 11. The fact of this special and unusual form of ornament recurring in Crivelli's pictures seems to us to indicate that it was his own special design, and not a copy of existing textiles or other ornaments. With the next plate we come on a series of a different class, large and open geometrical forms, filled in with very highly conventionalised foliage. Crivelli shines in this class also, which is a principle of ornament much more common, and prevalent in many modern wall-paper designs; one of his, white flowers on an arabesque pattern in two tints of red, is very fine and powerful. Another of Crivelli's, plate 15, black and dull yellow sprinkled with gold, may be noted as very effective. Another very fine one, of a much broader and bolder type, plate 21, is again by Crivelli, who, in fact, contributes a great deal of the artistic value of the book; this latter is from a Madonna (No. 788, N. G.). A very unusual and brilliant one from Matteo di Giovanni follows (plate 22), from the mantle of the Virgin in an "Assumption" (1,155, N. G.). The ground of this consists of a series of panels with scroll edges, in light

grey, so designed that the white inter-spaces form a complementary pattern of similar character; the centres of the grey spaces are filled with a very pretty flower seen on plan, the four cardinal petals symmetrical (we suspect meant to be in gold, but not so printed), the intermediate petals very playfully treated in three colours, varied *ad lib*, the arrangement following no fixed order. The author observes that there is a pattern very similar to this in the South Kensington Museum. The only two others we can mention are another very fine Crivelli ornament, black and yellow, the black predominating, from the "Madonna in Ecstasy" (906, N. G.), and a very original and artistic pattern from the coat of a figure in a picture ascribed to Durick Bonts (783, N. G.). This is an arrangement of unsymmetrical red sprigs on a white ground, with a broad five-pointed flower filling the spaces, the whole interlocked so as to form a symmetrical and continuous pattern.

We have to thank Mr. Vacher for a book which contains abundant material for suggestion to decorative artists, and which is in itself, despite the one defect we have alluded to, a charming work of art and a great ornament to an artistic library.

THE REVISED DRAFT CHARTER OF THE INSTITUTE.

THE proposed new Charter, as revised by the Committee, has now been circulated to members of the Institute, signed by twenty-six members of the Committee, and with a protest and an alternative draft signed by four dissentients. The nature of the alterations which have been made from the first draft is thus described in the preliminary remarks attached to the draft by the Committee:—

I. The clauses relating to the Council have been reduced in number, and simplified.

II. The control of general meetings has been specifically defined, and made absolute.

III. The proposed submission of new By-laws to the Privy Council has been rescinded.

IV. A provision respecting "Branches" of the Royal Institute has been added.

V. The power to hold Examinations has been extended to the Provinces, Colonies, Dependencies, &c.

VI. The preamble of the proposed Charter has been modified.

In regard to points I. and II., the absurd clause providing that the Charters should state who the first President and Council under it should be (Clause 25 of first draft) has been omitted; another (28) which gave the Council liberty at any meeting of at least five members, "to exercise all the powers of the Royal Institute," is struck out, as also the remarkable clause (35) to which we have before adverted, which rules that though the Council are subject to the control of the general meetings, any act previously done by them should not be invalidated by a subsequent resolution of a general meeting. It is not surprising that these two clauses should be struck out; the wonder is that they should ever have been seriously proposed. Taken together, they would have enabled any meeting of five out of the Council to have done whatever they pleased, without reference to the general body or the rest of the Council! The clause (32) which gave the Council power to apply funds in certain cases for the maintenance of Prizes, Medals, Studentships, &c., is also omitted and left to be dealt with by By-laws; and another clause relating to the application of funds has had the phrase "subject to the control of general meetings" inserted. Emendation IV. merely gives the power to frame by-laws in relation to "branches" of the Institute. On this head Mr. Holden suggests in a note that to the words, "the relations of the Royal Institute to such branches thereof as may be established within the United Kingdom, or its colonies, or its dependencies" should be added the words, "or to such other societies as may be already existing." This would leave the way open for any steps towards that federation or affiliation of provincial societies which in

some form may be possible and desirable. The modification in regard to the preamble consists in incorporating in it a paragraph which in the first draft formed part of clause 33, providing for the making of new by-laws and the management of the affairs of the Institute during what might be called the period of transition. In the preamble also the Gold Medal is defined as given "for the promotion of architecture," instead of "to such distinguished architect or man of science as may have," &c., &c. The sole merit of this alteration is brevity; otherwise it appears to us vague and ill-expressed. On whom or what is the medal to be conferred; and what is the meaning of "the promotion of architecture"? The paragraph was a great deal better as it stood before; it meant something definite then; it means nothing intelligible now.

The preamble of the Draft Charter is rather lengthy, but it is well to have the position clearly defined. The succeeding clauses as they now stand appear to us to be in the main satisfactory; there are, perhaps, still one or two points unnecessarily incorporated in the Charter with which by-laws might have dealt, such as the clause providing that every member should have a right to ask for a certificate of membership. This may or may not prove a necessary or a popular provision; it seems more a case for a by-law. Otherwise, we do not see that there is anything in the Charter as now proposed which is unsuitable.

The four dissentients referred to are Professor Kerr, Mr. Wyatt Papworth, Mr. Lacy W. Ridge, and Mr. Gough. They appear to be in rather "a temper" with the main body of the committee, and complain that they were called "delegates" and not "colleagues." The appointment of the members outside the Council certainly appeared to us to be made in the former sense. The draft was, at the meeting of November 30, returned to the Council for consideration, with the assistance of certain outside members appointed to represent each class of members in considering the revision. The minority object that a number of matters have been incorporated in the Draft Charter which ought to be dealt with under by-laws (in which we do not concur), and they then embody in their own draft the provision that members should have power to vote without personal attendance,—a matter which, of all others, ought to be left to an elastic by-law, inasmuch as it might prove very inconvenient or undesirable and to fix it for ever by a Charter would be most unwise. But whilst proposing to pin the Institute for ever to this detail, they are so cautious in other respects as to guard their provisions for the election and powers of the President by the saving parenthesis "if any," and the Vice-Presidents the same. What occult ideas they have as to the future possible constitution of the Institute which can render such an eccentric provision necessary, they know best; but, to our thinking, the very interpolation of such a provision shows that their alternative document is one which would be hardly worth while to take seriously.

Lectures for Sanitary Inspectors.—The Council of the Parkes Museum are making arrangements for a special series of lectures to inspectors of nuisances. The various subjects with which these officials ought to be acquainted will be dealt with in a course of twelve lectures, and the co-operation of several well-known authorities to deliver lectures in their own departments has already been secured. The course will be repeated twice a year to suit the requirements of persons preparing for the examinations of the Sanitary Institute of Great Britain, and will comprise all the subject scheduled for that examination. It is believed, however, that the course will have a further use in supplying the wants of acting inspectors and of other persons desirous of obtaining a practical acquaintance with the working of sanitary laws and regulations. The lectures will be given in the Parkes Museum, 744 Margaret-street, Regent-street, W., and members of the class will be granted the use of the reading-room and extensive library, a catalogue of which is on the point of completion. The dates of the lectures will be advertised shortly.

NOTES.

THE debate on Tuesday last on the payment of interest on capital during the construction of the Manchester Ship Canal resulted in a foregone conclusion. After the recommendation of the Board of Trade that the application should be allowed, it was scarcely possible to doubt what the result would be. We confess, too, that the motion to reject the Bill by one of the members for Liverpool, and the general character of the opposition, namely, to delay or harass the undertaking by a side blow, was scarcely calculated to draw many adherents to the side of Liverpool. We have always been sceptical as to the success of this undertaking, and the apparently absolute necessity which the promoters are in to be allowed to pay interest out of capital in order to enable them to raise the eight millions required, does not promise much for the success of the enterprise. We confess that it seems to us doubtful whether the payment of four per cent. interest during construction is sufficient to induce investors to lock up their money in a very speculative enterprise. Tramway companies and similar bodies promise investors six and seven per cent. during construction, which is obviously a different rate from four per cent., which can be obtained on investing in numerous investments, of which it may fairly be said that they are reasonably safe.

ON Tuesday night the House of Lords read the Code of Arbitration Bill a second time. It is always satisfactory to see a practical branch of law reduced into an intelligible shape, and there are so many laymen engaged the way or another in arbitrations that it will be advantageous to them to have the law relating to arbitrations in the same clear form as they are now able to peruse the law of bills of exchange and promissory notes. There is much sense in Lord Bramwell's observation that, when a layman is in any real difficulty about an arbitration, he will seek the advice of a lawyer, and not go to the code. But arbitrators and surveyors who have acted as arbitrators must have frequently wished to have the law presented to them in a clear, plain, and in a reasonable compass, even for their information on general procedure, and it is what the Code of Arbitration Law will do for them.

THE best point made in the address of Mr. Johnson, Secretary of the National Tug Harbour Society, on the occasion of the deputation to Mr. Mundella, on Wednesday, was in regard to the opportunity which such works, if undertaken without delay, would give for employing labour at present in full work on a large scale. We observe, however, that the deputation did not, according to the newspaper reports, make any specific suggestion as to points where harbours were not necessarily and immediately required. Bringing the subject into a practical form in regard to the employment of labour during present bad times, something more definite than a general recommendation to construct harbours was needed. The subject is undoubtedly of great practical importance,—we urged it before; but we doubt whether the society which has taken it up is very anxious or forcible in its advocacy. We join part of Mr. Mundella's reply, as being *per contra* of the subject:—

He was happy to be able to assure the deputation that the loss of life in the fishing industry on the coasts of the United Kingdom had diminished in the last few years, and it was a matter of great satisfaction to see that while the trade was increasing, the number of men employed in it was decreasing, a result with which it was attended with decreasing cost. The proposal of the speaker had referred to the relief of such works as were proposed would afford to the unemployed. But the expenditure of 3,000,000, annually on harbour works would only allow the employment of about 20,000 men, and, in order to employ 100,000 men, an expenditure of 15,000,000 would be necessary, and a million and a half more would be necessary. As to hereditarily on harbour works, England compared favourably with other countries, since we had had more done under this head than all the countries of Europe.*

ONE more scheme for the disposal of the sewage of the Lower Thames Valley has been issued. It is that of Messrs. Kinipple & Morris, M.M.C.E. In a report which they have submitted to several of the authorities in the Thames Valley, they describe what is designated a "divided" and a "combined" scheme. Under the former scheme the parishes of the Lower Thames are divided into three divisions as follows:—First division: Barnes, Mortlake, Kew, Richmond, Petersham, and Ham. The estimated cost of the works for this division is 199,614*l.*, with an annual expenditure of 11,410*l.*, equal to 9*d.* in the pound. The second division consists of Kingston, Surbiton, Maldon, Hook, Long Ditton, Thames Ditton, Esher, East and West Molesey, Teddington, Hampton, Hampton Wick, and Sunbury. The cost of this division is estimated at 277,430*l.*, with an estimated annual expenditure of 16,757*l.*, equal to 8*d.* in the pound. The third division includes Walton, Weybridge, Addlestone, Chertsey, Upper and Lower Halliford, and Shepperton. The estimated cost of this division is 55,411*l.*, with an annual expenditure of 3,227*l.*, equal to a rate of 4*d.* in the pound. It is not intended to make in each division a complete system of sewage disposal, with intercepting-pipes, pumping station, and precipitating-tanks. Each division, however, would have its own intercepting sewers and pumping station, from which the sewage from each division would be pumped to central precipitation works, where the whole of the unclarified sewage would be treated. The scheme proposes to filtrate the effluent water through land before it passes into the Thames at a point just below Teddington Lock, thus complying with the recommendations as to filtration made by the Royal Commission on Sewage Disposal. The site for the proposed precipitation works is on the River Wey, near the Basingstoke Canal; the directors of which, it is stated, are willing to take a certain sum for the absolute freehold right of the canal. The distinguishing feature of the combined scheme is that instead of three cast-iron main intercepting pipes there would be only one, conveying the whole of the sewage to the precipitation works. This combined scheme is estimated to cost 499,153*l.*, including the cost of the canal and the land. The annual expenses of maintenance would be 28,971*l.* On a rateable value of all the towns and districts included in the scheme of 926,241*l.*, a rate of 7*d.* in the pound would be sufficient for these annual expenses.

THE House of Commons have come to the same conclusion in regard to the proposed Bill for constituting the Metropolitan Board of Works a general opposing counsel against Water Supply Bills which we suggested two or three weeks ago,—that it is no part of the function of the Board to expend the ratepayers' money in such an object. The "Metropolitan Board of Works (Water Supply) Bill" was accordingly thrown out on the second reading by a majority of 130 against 76.

IT has been determined to erect a monument near the entrance to Prospect Park, Brooklyn, in honour of the soldiers who fell in the war of the Revolution, the Mexican War, and the last Civil War in the United States. The model which has been accepted is designed by Mr. Richard M. Hunt, and the sculptor who has been commissioned to execute the work is Mr. J. Q. A. Ward. The height of the monument, when completed, will be about 80 ft., and it will be constructed almost entirely of granite. The shaft forming the principal portion of the monument is to consist of two granite drums, not less than 16 ft. in diameter, standing together 32 ft. in height. There will be a base beneath them about 48 ft. in diameter, erected upon a circular platform 120 ft. in diameter. The latter is to be surrounded by a balustrade with four openings, approached from each direction of the compass by a flight of steps. The group surmounting the central shaft will represent an angel of peace, holding the olive branch in her hand and separating two combatants at her feet.

Beneath, on the exterior of the shaft, will be inscribed the names of the most important battles in which Brooklyn soldiers had distinguished themselves. On the base of the shaft will be bas-reliefs, illustrating the departure for, and return from, the war; and the work executed by women during the various battles, as well as the conflict between the *Monitor* and *Merrimac*. Four abutting pedestals, each supporting an equestrian figure, are to be placed around the base. These figures will represent Grant, Washington, Scott, and Jackson respectively. A series of four oblong pedestals, which are to support colossal figures, will stand on the chief platform, being partially enclosed by the balustrade. These figures are intended to represent a Zouave resting, with his rifle betwixt his knees; a sailor, holding a telescope in one hand and shading his eyes with the other; a dismounted cavalryman, kneeling on his saddle, his sabre broken, and armed with a pistol; lastly, an artilleryman, seated on a cannon, and grasping a rammer in one hand. It is calculated that the project will occupy at least five years to accomplish, whilst the cost is estimated at between 500,000 and 600,000 dollars.

WE have received a second "monograph of American Architecture" in the shape of a portfolio* of reproductions by the Helio-type Printing Company of a series of exterior and interior photographs of "the State Capitol, Hartford, Connecticut," of which Mr. Richard M. Upjohn is the architect. Plans of three floors are added. The building is a rich and costly one, and appears to have been worked out with care in all the details; but we do not find here the genius and originality which struck us so much in a former similar monograph of the Harvard Law Schools by Mr. Richardson. The style is Gothic, of an effective but unrefined type. Ornament is overdone and too lavishly introduced; and it is not "ornament of a meek and quiet spirit" by any means, but very self-asserting. Large, lumpy crockets stick out from little gables, giving them a ragged outline; windows are cut into heavy angular plate-tracery; shafts are placed standing far out from the walls on corbels, and with very big foliated capitals to carry statues which do not appear to be forthcoming. The design is what English Gothic architects (the best of them) would certainly regard as vulgar. If this is to be regarded as a typical modern Gothic design in the States, they have not caught the spirit of it in those regions yet. The plan is an effective one, but seems very lavish of space in entrance-halls and corridors, in comparison with the whole area of the building. As an example of recent American architecture, the design is very disappointing in comparison with its predecessor in the "monographs."

IN reference to the Sunderland Municipal Buildings competition the Secretary of the Northern Architectural Association has addressed the following letter to the Town Clerk of Sunderland:—

"Newcastle-on-Tyne, February 10th, 1886.

Sir,—The attention of the Northern Architectural Association has been called to an advertisement appearing in the daily press inviting plans for the new municipal buildings.

They would feel very much obliged if you will kindly inform them if a professional assessor is retained to adjudge the plans sent in.

I enclose a series of recommendations for regulating the conduct of architectural competitions, published by this Association, which have been sent to and adopted by other corporations under similar circumstances.

Perhaps you will be kind enough to lay it before the Town Council of Sunderland, and we hope they may see their way to adopt the recommendation in this case.—Yours faithfully,

FRANK W. RICH, Hon. Sec."

In view of the importance now attached by architects to the employment of professional advice in deciding competitions, and the fact that a large proportion of the profession have signed an undertaking not to compete except on the understanding that such advice will be

* Published by Messrs. Ticknor & Co. in Boston, and Messrs. Trubner in London.

obtained, we think it well to make public the fact that such a request has been made to the promoters of the Sunderland competition.

A GOOD deal is expected of Borough Surveyors in comparison with the salaries offered them. We have before us a circular from the Corporation of Eastbourne defining the qualifications and duties for candidates for this office under the borough. The surveyor must "be properly skilled and educated in the art or practice of building" (which is it, an "art" or a "practice"? Probably they mean "theory and practice"); he must hold a certificate from the Royal Institute of British Architects, or the Institution of Civil Engineers, or "the Institute of Sanitary Engineers" (*sic*), and "devote the whole of his time to the duties of his office, and not engage in any business, profession, or occupation, either for profit or otherwise"; and he is offered a salary of 156*l.* a year and an office (not a house). Not a brilliant prospect, certainly.

A CORRESPONDENT sends us one or two notes as to the results of competitions without the intervention of professional advisers in the case of two recent Board School competitions. In one case we find architect's estimate, 1,600*l.*; lowest tender, 3,670*l.*; total final cost, about 4,000*l.* In another case architect's estimate 4,500*l.* to 5,000*l.*; lowest tender, 8,840*l.*; total cost after sundry law expenses (we are not told what these amounted to), 10,130*l.* A very practical form of argument in favour of employing professional advice in the choice of plans.

THE Governors of the Charterhouse have appointed Mr. R. H. Carpenter, who is an old Carthusian, as architect for whatever alterations are necessary: an appointment which is a guarantee that there will be as little as possible destruction of the ancient work. Sir R. E. Webster will take charge in the House of Commons of the Bill in relation to the powers of sale and reconstruction sought by the Governors.

MR. SHAW LEFEVRE has endeavoured to throw whatever weight on such a subject may attach to his name against the Institute of Architects' scheme for improving the treatment of the site for the War and Admiralty Offices, in a letter to the *Times* of Friday last week. His objection, as stated, is solely on the ground of economy. His estimate of the increased expenditure which the Institute scheme would involve is very much over the mark, as Mr. Robins conclusively showed in a subsequent letter to the same journal. That Mr. Shaw-Lefevre is not alive to the architectural advantages to be gained might be expected from what he has shown us of his perceptions on that subject in connexion with this and other matters in which he unfortunately obtained far more of his own way than was for the architectural benefit of London. Any one who could deliberately support as adequate such a way of placing a great public building as that proposed by the Government for the War and Admiralty Offices must be very badly endowed with æsthetic sense. It is some satisfaction, however, to observe that Mr. Shaw-Lefevre's architectural lectures in the *Times* in favour of his own ideas are now apparently to go under his own name.

The Architect's Department, Metropolitan Board of Works.—At the meeting of the Metropolitan Board of Works on the 5th inst., the Clerk presented a communication from Mr. Vulliamy, the Superintending Architect, with reference to his absence from the office in consequence of the state of his health, requesting, in accordance with the Act, that during his absence Mr. Hobbs, the Assistant Architect, may be appointed as his Deputy in all matters connected with the Building Act Office, and Mr. Goddard, Surveyor and Valuer, in all other branches of the Department. This was agreed to. We regret very much to hear of Mr. Vulliamy's continued illness.

LETTER FROM PARIS.*

WILL the centenary exhibition be national or international? is the question now suggesting itself to the public and to the Government. The latter has opened some rather injudicious *pourparlers* on a matter which requires a prudence, tact, and adroitness of which French diplomacy, unfortunately, has no longer the secret. Some proposals, made late in the day, have been met by foreign Governments with a reserve which is not re-assuring. However it may turn out, it seems now to be understood in high quarters that the time for action has arrived; and M. Lockroy, the new Minister of Commerce, seems animated by abundance of zeal, of which we shall, no doubt, see the first result before long. Possibly by the time these lines appear, the Chamber may have already formulated the law to regulate all the financial questions in regard to the Exhibition of 1889. It is unnecessary to add that now the candidature of M. Antonin Proust for the duties of Commissary-General appears entirely put aside. That political sincere will be well replaced by an executive committee, in which M. Alphonse will be called on to occupy a prominent position, a fitting culmination of his active and useful career. A commission of control will be attached to that committee, and the municipality of Paris will be called upon to furnish a part of the guaranteed fund for the work, about eight million (francs) out of 40 millions; 12 millions will be granted by the State, and the rest furnished by a financial society. The matter is, therefore, entering on a new phase, and we shall, no doubt, have some further information to give in our next letter. It now only remains to say that a petition has been addressed to the Government by a great number of architects praying that the design and construction of the Exhibition may be open to competition. This request, signed by many well-known names, has been laid before the Ministry by M. Clémenceau. This question deserves serious consideration if the Exhibition is to have a character of grandeur and originality and to rise above the ordinary commonplace of exhibitions, and make us forget the had architectural taste of that of 1878.

To come from this great exhibition to smaller ones of immediate interest, that of the Water-Colour Painters is, as usual, the most brilliant and the most frequented of the smaller exhibitions which are rife at this time of year, though less so this year than on some previous occasions. This year there are some new recruits, whose talent does not make one forget the absence of so many old members. De Neuville is no more; Detaillé and Cazin do not exhibit; the infirmities of age have kept Eugene Isabey's pencil idle. But Lamy, the valiant octogenarian, is always there, younger and aliter than ever. We may note one or two of the new comers; M. Bontel de Monvel, who imitates pleasantly the style of modern English art; M.M. François Flameng, Gilbert, Morot, and Albert Besnard, an impressionist who employs all possible means, good or ill, to make us forget his academic origin. We might speak also of the exhibition of the *Mirlitons*, or that of the *Cercle Volney*, but not with many compliments. This art of the club has the serious fault of smothering a few fine works by real painters among the commonplace efforts of amateurs, who make art a pastime, who are applauded by a kind of fashion, and whose works remain at the same level year by year.

As to the "Union des Femmes Peintres et Sculpteurs," which holds its annual exhibition at the Palais d'Industrie, I prefer to pass over in silence an exhibition of utter insignificance, if one excepts the marine paintings of Madame Lavilletto, a good enough painting by Madame Annie Ayrton, and a pretty statue by Madame Léon Bertaux.

Formerly, when an eminent artist completed a work, he invited his friends to advise and criticise quietly in private before exposing it to the public. We have got beyond that now; the jaded palate requires a more sensational first exhibition. Thus we had the other day the "private view" exhibition of a sensational painting of the "death of a great composer," accompanied by a concert of sacred music intended to render more complete the nervous impression on the organism of the public. Under a carefully-prepared half-light the

spectators seemed to see the form of Mozart extended on a couch in the pallor of death, while from behind the canvass were heard the strains of his "Requiem." This carefully-arranged effect was too much for more than one fair "mondaine," whose lace handkerchiefs were moistened with their tears. Was it the music or the painting? This attempt has been succeeded, at the establishment of a well-known picture-dealer, by another on a larger scale, but not less carefully prepared. We advanced through a series of galleries to the Holy of Holies, where the work is unveiled to the pious gaze of the faithful in a mysterious and theatrical light. There will be further developments of this scenic contrivance, no doubt; and the good public runs after it with avidity. It is a suitable amusement for the Parisian "snob," whose name is legion, but it is a charlatanism unworthy of art. Munkacsy has no need of this kind of *mise en scène*, and why select it for his last work especially, which is certainly inferior to many preceding ones? The principal figure, that of Mozart, is poor and expressionless; the surrounding figures are mere commonplaces copied from models. The exaggerated praise lavished on this work only draws attention to the comparative failure of a painter whose real powers we admire too much to pretend any great admiration of this his latest effort.

We much prefer the modest exhibition of the works of a Viennese landscape-painter, M. Otto de Thoren, in the Rue de la Paix. There is here no pretension, but true artistic excellence, a genuine appreciation of nature, and some outdoor studies from animals executed with great truthfulness; and true art can stand on its own merits without the assistance of the picture-dealer's artifices of effect.

While the exhibition of the collected works of Baudry, which will open in April, is in preparation, there are several candidates for the succession to the post held by the great artist at the *Institut*. M. Puvis de Chavannes, who had been named as the successor, declines to come forward, and the contest remains between M.M. Henner, Gustave Moreau, Jules Lefevre, T. P. Laurens, and Jules Breton, of whom the latter has probably the best chance. M. Paul Dubois, the sculptor, we may here mention, has offered to execute gratuitously the monument to be erected to Baudry at Pere Lachaise, on a site granted by the municipality.

Our permanent museums, as has been observed, have been undergoing important alterations. The enlargement of the Musée de Clugny, where one of the courts has been transformed into a gallery for glass exhibits, is completed, and it is hoped that the new Luxembourg will be opened to the public this month. The placing of the works of art is nearly accomplished, and the exterior sculpture of the new façade is in process of completion, but the work has been very long in hand. The State adopts a cautious delay in matters of this kind; witness the Porte St. Martin, which has for whole months disappeared behind scaffolding, and of which the restoration has not yet commenced. M. Asbach has however, been commissioned to restore the statue of "The Rhine." That of "Holland," which has suffered so much, has been confided to M. Gaudex. M.M. Peziex and Desbois are to occupy themselves with the groups of lions, while M. Mattieu Meunier will undertake the bas-reliefs. All is ready, and the work might be very soon done. The Government might take example from the Railway Company "Do l'Ouest," which is pushing on the new works at the St. Lazare Station with great energy. There is here a large building yard in very full occupation; the buildings are rising fast, and the service to the suburbs should be open to the public at the end of this year. The architects have, nevertheless, encountered serious difficulties. As in the case of the construction of the Opera, there is a subterranean piece of water to contend against on the site of the ancient Grange de Batelière; deep pits had to be dug and foundations carried down, for which reason the façade to the Cour de Rome has been seven months in rising above the ground. However, now the Cour de Rome, St. Lazare will be soon demolished, the Rue d'Amsterdam widened, and passengers arriving from England will find, in the very heart of Paris, a vast and commodious station with a terminus hotel situated near the promenades, the theatres, and other main objects of interest in Paris.

* Deferred from last week for want of space.

The work at the Pont Neuf is being carried

on diligently. All the upper portions which have shown signs of weakness have now been removed, and the foundations are now being dealt with by the aid of caissons. Towards the end of the month the demolition will be complete, and the work of reconstruction will commence, which will probably occupy the rest of this year.

In the way of new constructions mention may be made of the barracks for the "sapeurs-pompier," which is to be inaugurated on the Boulevard Diderot. The organisation for fire-extinction in Paris, long in a very stationary condition, has recently been the object of much attention on the part of the administration, which has obtained from England, Holland, and the United States information as to the most recent improvements. The barrack building is a model of its class. In the principal building, intended for the officers, and the façade of which is adorned by a fine bas-relief by M. Roty, there is recorded, on a marble tablet, the list of firemen who died in the execution of their duty. This list already includes seventeen names, among them that of the sapeur Havard, who was burned in the conflagration of the Magasins du Printemps, and that of Colonel Troide-vanx, who perished in 1882, a victim to his devotion. Beside this is the telegraph-room communicating with all the postal telegraph stations. As soon as a fire is signalled, the telegraphist has only to press a button and the alarm-bells sound, the doors of the fire-engine houses open automatically, the gas is turned up at the same moment, and the engine is ready to start in one minute. There are special apparatus for enabling the men to slide from their dormitories into the engine-house, a high tower which serves for gymnastic exercises, and a basement with wells attached where the men are to go through a drill in the operations of fire-extinction and rescue of property. All the details have been carefully studied by the architect, M. Ronssé, who obtained the commission in a public competition, and has given his mind to the consideration of all requirements and all the recent improvements in connexion with the objects of his service.

The lust of the celebrated historian, Henri Martin, was recently inaugurated in the Mairie of Passy. It is the work of M. Marquet de Lassol, whose statue of Lamartine, now in the founder's hands, will also be erected towards the end of April. Without contesting the honour paid to the memory of Henri Martin, was going further than necessary to re-name after him the "Avenue de Trocadero," the title of which belonged properly to its situation, these changes of names cause a great deal of public inconvenience.

A few days before, a similar ceremony took place at the College of France in honour of laude Bernard; and in the last week of February was celebrated the centenary of Arago. The ultra-republican section of the municipal council declined to take part in this because Arago, when Mayor of Paris in 1848, refused to take any compact with the insurrection. It is to be hoped the council will be less severe in its views in regard to Admiral Courbet, whose statue it is proposed to erect in the Square ontholon. Nevertheless, if circumstances had given the gallant admiral a military command in 1871, there is no doubt he would have employed all the rigours of repression against the Communists. The execution of the monument to the admiral has been confided to MM. Dubre and Mercié, with the assistance of Pujol as architect. There is soon to take place also the inauguration of the funeral monument to Berlioz at Père Lachaise, and (in the Parc de Monsonis) that of the fine work by Mercié, entitled "Quand Môme," a reproduction of the original erected at Belfort. The artist is completing the model for the statue of Victor Massé, the composer, intended for Morbihan. It is a fine work and a striking one.

The same cannot be said of the greater part of the busts which adorn the Institut, and are intended to perpetuate the features of eminent men who have done honour to France. These are mostly below mediocrity, and the Académie des Beaux Arts has entrusted a committee of artists with the duty of weeding out those as unsatisfactory either in an artistic point of view or as likenesses. There have been fresh gaps in the artistic ranks since our last. We may record specially the death of M. Emile Lafon, pupil of Gros & Carpeaux, two of whose pictures are in the

Luxembourg, "Jesus disputing with the Doctors" and "John the Baptist recognising Jesus." Lafon was 68 years of age.

The sculptor Loison, who has also died recently, was about the same age. Born in 1820, he had followed with success the teaching of David d'Angers. Among his principal works may be cited "Phryne," "Daphnis," "Chloe," "Pandora," "History" (a marble group), the bust of Berryer which figures at the Institut, and various statues in stone at the churches of La Trinité, St. Ambroise, &c.

A RELIC OF WREN'S WORK: LONDON. THE COLLEGE OF PHYSICIANS.

"There stands a dome, majestic to the sight,
And sumptuous arches bear its oval height;
A golden globe, placed high with awful skill,
Seems to the distant sight a gilded pill."
Garth's Dispensary.

An enclosed and forgotten fragment of Wren's handiwork has lately been exposed to view. An extensive range of new buildings is in course of construction along the western side of Warwick-lane. The ground to be covered lies between Warwick-square and the hack of Newgate-street. Between this ground and Newgate Prison stand the foundries and show-rooms of Messrs. J. Tylor & Sons. Their principal block of workshops is conspicuous for its high tower, which soars above the prison shaft and the Holborn valley below. Immediately northwards of this block are the show-rooms and offices, embodying, in parts, all that is now left of the old College of Physicians. The eastern façade of this remaining fragment will soon be again lost to sight. The Royal College of Physicians derive their foundation from certain meetings which were held at his residence in Knight-riding-street, by Dr. Linsacre, physician to kings Henry VII. and Henry VIII., and the friend of Erasmus, Latimer, and Sir Thomas More. The members subsequently migrated from Linsacre's house, which they had inherited under his will, to more commodious premises by Amen-corner,—these ever memorable for the lectures that Harvey delivered therein upon his own great discovery, and for which he used some preparations that were religiously preserved after his death. Harvey, as did John Hunter in Leicester-fields, built for himself a museum adjoining to the site of the existing Stationers' Hall. But the college, the museum, and the earlier Stationers' Hall were destroyed by the Great Fire. The physicians, having assembled during the interval at their President's house, next went to the new College which Wren had built for them in Warwick-lane. These buildings (finally completed in 1689) included a hall, dining-room, lecture-theatre, and library; together with a large octagonal porch, entered from Warwick-lane, carrying the dome and its golden hall, which Garth commemorates in his "Dispensary." Pennant records that "on the summit of the centre" was fixed the bird of Æsculapius,—the admonishing cock. The amphitheatre gained well-deserved praise for its plan and proportions, both being admirably adapted to the purposes it should serve. The interior doubtless supplied to Hogarth a background of plate-iv. of "The Stages of Cruelty." According to D. Loggan's print of 1684, and certain invitation-tickets of later date, the court's western, and principal, side consisted of two lofty stories, surmounted by an attic-floor. Above the central pediment rose an octagon tower, in two stages. This tower, with columns at its angles, closely resembled that of Wren's existing church of St. Michael Paternoster Royal, on College Hill; whilst its lantern, carrying a vane, and the cock mentioned by Pennant, was like to that of Wren's church of St. Michael Bassishaw. The relic of which we speak presents, as viewed from the east, the two lofty stories, these being after the Classic model, and having no balustrade. Of its two orders the upper is Composite, the lower is Ionic. The pilasters, one above the other, support entablatures. In the middle intercolumniation were a niche, and the great doorway, gained by steps. The other corresponding spaces were pierced for windows. The upper range of single windows—high, narrow, and round-headed,—have unusually large and far-projecting ornamented keystones or hesses. The windows below are square: each of the several

* Originally sold in 1751, price 4s. the set. Hogarth had published, January 1st, 1760, the subjects of plates iii. and iv. from wooden blocks, on a larger scale.

pairs is separated, vertically, by a hanging festoon. The row which corresponds to them, to the west, forms, in part, a dividing wall, in Messrs. J. Tylor & Sons' premises. The fragment comprises three whole bays, or divisions, together with a fourth, which latter is broken. The broken division and the one next thereto are slightly in advance of the two others. King Charles II.'s statue occupied the niche over the door; Sir John Cutler's stood opposite to this in the western side of the Warwick-lane main entrance. These two statues, of heroic proportions, we last saw in the vestibule of the City Museum, Guildhall. Cutler's statue possesses a singular history. It was voted for, in 1680, by the Fellows, fervid with gratitude for what they conceived to be a magnificent gift by Cutler in aid of the new fabric. At the work's completion, they borrowed from him an additional sum. In 1699 Sir John's executors made a demand for 7,000*l.*, as including the recognised loan, and the pretended donation,—but set down for a debt in his own books,—with interest charged upon both amounts. In the result, Lord Radnor and one Mr. Boulter, the executors, accepted 2,000*l.* from the College, remitting the balance. In compliment to them, the Fellows did not disturb the statue, but marked their sense of Cutler's conduct by effacing the inscription which they had written beneath his figure:—

OMNIS CUTLERI CEDAT LABOR AMPHITHEATRO.

The library was furnished with books by Sir Thomas Mayerne, a native of Geneva, and physician to James I. and Charles I. The Marquess of Dorchester added to Mayerne's collection. The amiable Sir Samuel Garth caused Dryden's body to be conveyed to the College Hall. There it was honoured with a solemn performance of music, previously to the funeral, which was largely attended, in West Minster. On June 25th, 1825, Sir Henry Hallford, who had examined the remains of King Charles I. at St. George's Chapel, Windsor, *coram* the Prince Regent, delivered the customary Harveian oration, in Latin, to celebrate the opening on that day of the new buildings. These were erected by Sir R. Smirke, R.A., at the corner of Pall Mall East and Trafalgar-square. The amphitheatre, together with certain other parts of the old edifice, returned awhile to the uses of Newgate Meat Market. The entrance gateway and dome survived until about twenty years since. In the Grace Collection are two tickets, of dates 1721 and 1725, inviting Dr. Stukeley to a lecture and meeting respectively whereon the President, Thos. Parkins, asks his "Excellency" to attend "*cum pileo et togâ.*"

ARCHITECTS' BENEVOLENT SOCIETY. ANNUAL MEETING.

THE thirty-sixth annual general meeting of the subscribers and donors to this society was held on Wednesday afternoon last in the Meeting-room of the Royal Institute of British Architects, Conduit-street, Mr. Ewan Christian, President, in the chair.

Mr. W. H. White, the Honorary Secretary, read the annual report, which stated that the Council, during the last twelve months, had held five meetings, at which they had distributed the sum of 580*l.* 5s. among thirty-four persons,—identically the same number as in 1884-85,—and had paid one pension of 20*l.* The Council were glad to be able to state that the number of annual subscriptions to the Society had increased, though the amount received in donations (which were carried invariably to the capital account, and, in due course, invested) was less than it had been for the last six years, partly because of the absence of legacies such as those which were bequeathed to the Society in 1880, 1883, and 1884, by Mr. Edwin Nash, Mr. T. H. Wyatt, and Mr. David Mocatta. The contributions from Corporations or Societies had been few, namely, twenty guineas from the Worshipful Company of Carpenters (which was a renewal of their gift, to a similar amount, of the preceding year); ten guineas from the Architectural Association of London; ten guineas from the Nottingham Architectural Association; and, as in former years, the income of the small charitable fund pertaining to the Royal Institute of British Architects had been paid to the Society's account. A desire to see the funded property of the Society increased was still evinced by a few benefactors. At the present time it consisted of a sum of 4,200*l.*

London and North-Western Railway Four per Cent. Debenture Stock, and a sum of 1,500l. New Three per Cent. Stock, which together represented a total double that of a few years ago, the increase being mainly due to the initiation of Mr. George Godwin, F.R.S., and the exertions of the late Mr. T. H. Wyatt, aided by Mr. George Blair, the late Treasurer of the Society. Some months ago Mr. Godwin again urged upon the executive officers of the Society the paramount necessity of raising the Society's capital to 10,000l., and he offered to present 100l. to the fund with the view to twenty-five other donors each presenting or collecting a like amount. Professor Hayter Lewis, the present Treasurer of the Society, also offered a contribution of 100l., and he had accepted, at Mr. Godwin's wish, the difficult task of devising some scheme whereby the generous intention of the latter might be fulfilled. The time, however, was not favourable to such work,—to even a labour of love such as Mr. Godwin proposed,—and the Council were of opinion that it might be advisable to wait until the calamitous depression of trade and want of confidence in business affairs had passed away or abated. Since the last annual meeting, the honorary secretaries of other provincial societies had followed the excellent example of Mr. Holden, of Manchester, and had prepared circulars to the various architects in their several localities, pointing out the advantages of the Society and the pressing need of increasing its funds. At present the Council were not able to report as to the results of those efforts. The Society had a powerful claim on provincial architects, inasmuch as a large proportion of the applicants for relief were from the provinces. As an instance of this, out of nine applications considered by the Council that day, the majority were from country cases.

The income account and balance-sheet for the year ended 31st December, 1885, duly certified by the auditors (Messrs. George Scamell and Hugh McLachlan), were presented with the report. They showed that the total receipts during the year 1885 were 632l. 11s. 11d., including 64l. brought forward from last account, 206l. received in dividends, and 360l. received in subscriptions. The disbursements included payment of one pension, 20s.; 580l. paid to applicants for relief; and 28l. 9s. working expenses, leaving a balance to be carried forward of 3l. 17s. 11d. on income account, a balance of 36l. 15s. 8d. remaining at the bankers.

Professor Hayter Lewis, Honorary Treasurer, in moving the adoption of the report and balance-sheet, said it was to be regretted that the Society was not at present receiving so large a measure of support from provincial architects as could be wished, but in other respects he thought the Society might be congratulated on having maintained its position fairly well, and on its subscription showing a slight increase, notwithstanding that the present time of depression was seriously affecting the income of many charitable institutions.

Mr. E. N. Clifton seconded the motion.

The Chairman, before putting the motion to the meeting, said the most satisfactory feature of the report was the increase in the annual subscription, slight though it might be, for it betokened a continued and a lively interest in the work of the Society. It behoved every architect to do something to help so deserving a Society. However prosperous a man might be, however lucrative a practice he might enjoy, he or his family might come to want the aid which the Society could afford. He regretted to say that two recent applications for relief were on behalf of the families of men who had made way in their profession and had done a great deal of work. He was sorry to see that, while the architects of some provincial towns were doing their best to help the Society, there was one large town where there was always a great deal of work going on, and where architects were numerous, and yet the Society only received a solitary guinea from that town. That was not as it should be. After mentioning a suggestion that he made a few years ago to the Council of the Society,—to the effect that every architect who takes pupils should, so to speak, send titles of each premium to the Architects' Benevolent Society as some remuneration for being the means of introducing new members into the profession,—the chairman referred to Mr. Godwin's offer, mentioned in the report, and which he hoped would meet with adequate response.

The motion was then put, and carried unanimously.

A vote of thanks was passed to the retiring members of council, viz.—Messrs. T. G. Jackson, M.A., E. C. Robins, F.S.A., Prof. Roger Smith, Mr. Waterhouse, R.A., and Mr. E. N. Clifton; and to the auditors. To fill the vacancies caused by the retirement of members of council, and by the death of Mr. J. H. Good, the following gentlemen were unanimously elected, viz.—Messrs. T. M. Rickman, Geo. Scamell, Lewis H. Isaacs, M.P., W. Grellier, C. R. Pink (President, Architectural Association), and Banister Fletcher, M.P. In case any two of these gentlemen were unable to serve, Mr. W. M. Fawcett, of Cambridge, and Mr. Thomas Wells, were nominated as alternative members. The President, Hon. Treasurer, and Hon. Secretary were re-elected; and Messrs. C. F. Hayward, F.S.A., and W. Hilton Nash were elected auditors for the current year.

Thanks were voted to the Royal Institute of British Architects for office accommodation, &c.; to the Honorary Secretary; and to the Chairman. In the course of the proceedings it was pointed out by Mr. Scamell that the working expenses of the Society averaged less than three per cent. of its total receipts,—a result, he said, which probably could not be shown by any other charitable society.

STUDENTS' DRAWINGS AT THE INSTITUTE.

FOLLOWING upon a disappointing competition this year for the Pugin Studentship, which was by many attributed to a growing taste among students for other than purely Gothic art, comes an equally disappointing exhibition of drawings in connexion with the Tite Prize, which would seem to show that, if Gothic is beginning to be neglected, at least the purer Classic styles have not yet taken its place. We think that from several points of view it is to be regretted that the judges awarded the Tite Prize at all, unless it is to be understood that only in very rare cases indeed is it to be withheld. Besides depreciating the value of the prize to other winners in other years, who have sometimes received it, and it may be hoped will often receive it, for really first-rate work, it will seem to many at any rate of those who were not present at the meeting on Monday week to set the stamp of the Institute's approval upon a class of architectural design which can only be described, at best, as good commonplace.

Whatever may be said, however, of the architecture of the design "Medicine," by Mr. B. P. Shiras, of York, the plan is excellent, and shows not only considerable study and knowledge of the requirements of a medical school, but great care and no little skill in the arrangement of a rather complicated building; the elevation of the front looks better than the perspective, but we should like to see the central feature omitted.

"Spes," placed second, appeared to have good plans, but they were hung too high to be fairly seen; the detail is a little purer than that of "Medicine," but the design could hardly be judged by the terribly hurried ink perspective. "Doric," which was awarded a certificate of honour, showed a design in really good Italian style, pure in detail and correct in arrangement, but, unfortunately, the author had "come altogether to grief" in his plans. Among the rest we noticed "Hygeia's" clever effort in the Palladian style,—as to plan and grouping as well as detail,—a good and useful study, but unfinished, and without a chance of success in these days when Science is the master and would not put up with such a disaffected room as "Hygeia" provides, for any artistic consideration whatever.

The competition for the Soane Medallion was well up to the average; it is only a little surprising that with such an attractive subject more cannot be said. Mr. A. Needham Wilson, who takes the Medallion, has a very effective set of drawings, executed with great care both as regards drawing and the more important points of planning and design. As in all the other really good designs, the nave and chancel are of the same width. A heavy-looking but effective tower, which stands over the north chancel aisle on rather inadequate supports, is shown in sharp perspective, as seen in a narrow street, in a beautifully-executed drawing, which was carefully hung at Conduit-street with the

top of the nave on a level with the eye, or a little lower. It must be confessed that styles are rather unhappily mingled in this design,—most of the constructional, and many of the decorative, arches are of the blunt, stilted form peculiar to Early French work, while the tracery and canopies over the statues are of English fourteenth-century character. The design by Mr. J. H. Curry, placed second, is cleverly planned to make the most of the site. The most striking feature is the open cloister connecting the porch and transept on the street side. There is a central tower, and a morning chapel with a double curved end, which develops rather an ugly form in the roof. The drawing is effective.

Mr. Bidlake, who was awarded a medal of merit, has produced a design which shows certainly more knowledge and, probably, more power, than any of the others. We should much like to have seen what he could have done with more time and care. Mr. Schultz (certificate of honour) has attempted a central octagon plan and a design in a not very happy rendering of the late brick Gothic style of the North German or Dutch churches, with an "onion" dome. There were two other designs shown with central domes, neither of which calls for much remark. The design "Angelus" showed a fine open plan inside and an effectively piled up group outside, but we cannot commend its style and detail.

As is often the case, the competition for the Silver Medal for measured drawings produced the best work of its kind. Architectural drawing has now been brought to such perfection that, among the best draughtsmen, the choice of a good subject, and plenty of time to finish the drawings with due care, become very important elements of success, and but for these elements we believe the judges would this year have had a far harder task than fell to them. Mr. E. H. Sedding's drawings of St. Magnus, London Bridge, and of Cranham Church, Lincolnshire; Mr. A. B. Mitchell's of Laver Marney Towers, Essex; Mr. E. L. Conder's, of Long Melford Church; and Mr. S. H. Barnsley's of Old Clovee Abbey, are all first-rate specimens of drawing; but perhaps the detail of the Ionic capital of St. Magnus Church is quite the finest piece of work of the kind that has been yet seen at Conduit-street.

The Grissell Gold Medal only attracted one competitor, Mr. A. A. Cox, who has produced an octagonal iron roof, of somewhat novel construction, standing, as far as we could judge on a hasty view, on rather inadequate piers.

There is no doubt that Mr. Paul Waterhouse's and Mr. Oldrieve's essays well deserved the prizes awarded them.

FREE LECTURES TO ARTISANS AT CARPENTERS' HALL.

A GOSSIP ON THE PHILOSOPHY OF BUILDING MATERIALS.

THE third of the present series of free lectures to artisans under the auspices of the Carpenters' Company, was delivered on the 3rd inst., by Professor Kerr, F.R.I.B.A., and was entitled "A Gossip on the Philosophy of Building Materials."

Professor Kerr said he wished to take his hearers a little below the surface of things, even in so humble a matter as building materials, and to ask in the first instance how far they supposed Nature or Providence had undertaken to supply them with these materials? Many might answer on the contrary, to advance the doctrine that nature did not profess to supply them at all. One of his objects, therefore, was to satisfy his audience that enterprise in the direction of the invention of building materials was a thing to be considered with the utmost interest. A friend of his, very learned in the science of geology, found himself a few years ago in the company of a Scottish divine of the usual orthodox type, a pleasant man, but one with very confirmed opinions. The conversation having turned upon the antiquity of the globe, the geologist found the ecclesiastic was thoroughly satisfied that this earth was suddenly made out of nothing by an omnipotent power, exactly 4,004 years before the commencement of our era. The geologist, who held a very different opinion, asked the clergyman how he could account for the existence of the fossils found deep down in the stone. The reply was that they were not fossils at all, but that the devil had

put them there for the express purpose of deceiving people like the interrogator. Now he (the speaker) hoped they had got a little beyond that stage of belief, and he would first ask them to consider what stone was. Granite was a compound of broken grains of quartz, feldspar, and mica, which had somehow reached the surface of the globe boiling hot, so it might now be found not many miles below the floor of Carpenters' Hall. Sandstone, again, was a deposit of those grains which were washed down from the summits of the mountains by denudation, carried down the rivers, and deposited and compressed long ago. As to limestone, if they looked into the deep sea they would find the water charged to the full with myriads of little shells whose inhabitants had fulfilled their destiny and died, and which were falling through mile after mile of the depths of the ocean, and forming limestone at the bottom. These were materials which they were accustomed to say that nature had provided. He would take another case, that of timber. The tree was not grown for the purpose of furnishing timber, but in the luxuriance of vegetation lasting its day, dying when it had fulfilled its purpose, and being converted into coal. These were the natural materials, but he would take another, viz., brick. Nature did not supply them with brick, but only with mud or clay. How much more available a material was brick than stone! For instance, most of them knew what "bond" meant, and how brick fulfilled that condition. Terra-cotta and pottery were still more useful, so to speak, and altogether artificial. He would also refer to the most entirely and unreservedly artificial of all materials, viz., iron, and to artificial stone for grindstones, which beat everything else in its special line. The fact, therefore, was simply this, that natural materials had to be adapted, and those materials which were not so adapted had to be created; therefore, there was great scope for the invention of man in the legitimate enterprise of inventing artificial materials to correspond with the artificial purposes of building. The countries of the world might be divided into the two categories of stone and clay countries, and out of this arose the first great distinction in regard to building. In all probability brick was used before stone, except where stone walls of a very rude kind would necessarily be used in a stone country; but it was remarkable that the earliest known use of stone in anything like ordinary building was its use in enormous masses. Rude and rough small rubble stone might have been used at first, when better was not to be had, and when the skill of the workman was primitive indeed; but it was a remarkable thing that the most ancient remains of stone building were composed of stones of the largest size. This brought him to the distinction between Egypt and Assyria, as the representatives of the two rival civilisations of antiquity. Egypt was a stone country, Assyria a clay country, so that whereas the remains of Egyptian buildings were in existence at the present day, those of Assyria had wholly disappeared, except some pieces of sculpture which ad doubtless been brought from a distance. This also reminded him of the distinction between London and Paris. No one of his age could now pass through the streets of London without being struck by the enormous progress which had been made in building within the last thirty years. Still, though stone had been largely used, London could not attempt to vie with Paris. The existence of the beautiful one underneath the city of Paris might have added something to do with the peculiar grace and elegance of Parisian artistic sensibility. But in all events, there was a clear manifestation of the distinction between the clay basin of the Thames and the stone quarry of Paris. Turning to timber countries, it seemed probable that good building was in every case first manifested in timber. The Greek temples in their origin pointed distinctly to a timber origin, while Solomon's Temple appeared to have been mainly built of wood. One of the most remarkable peculiarities of ancient times was that of massed labour. The division of labour nowadays gave to every man his own province, and the result of combination was the production of such works as we were familiar with. But when we saw the great works of primitive antiquity, it was difficult at first to understand how such enormous masses of stone could have been moved and placed. The answer was always the same,—it was done by

massed labour. Turning to stone, he had already explained what granite, sandstone, and limestone were. Magnesian limestone was rendered partly crystalline by the accidental passage of a stream of volcanic heat in the formation of the stone, and that reminded him of the story of the stone used in the erection of the Houses of Parliament. For this purpose it was determined to employ the best stone to be found in the three kingdoms. Portland stone, as they knew, was a very good stone, but it had one remarkable and serious defect,—on one side it became blackened with the London soot, while on the other side it was blanched with wind and rain, the two effects being in most dismal contrast. It was therefore determined to discover a fitter material, and a Royal Commission was sent all over the three kingdoms to examine the different stones. They did their work well, and at Southwell, in Nottinghamshire, found a church of the Norman age, with its carvings as clean cut as if done the year before. This stone was carefully examined, and found to be the Mansfield Woodhouse stone, which the Commission determined should be used. No pains, however, were taken to inquire whether there was enough of it; so, by the time the basement had been built the supply of stone gave out. They next found the Anston stone, in the same neighbourhood, a stone partly made crystalline by a stream of heat passing through a certain portion of the quarry, the crystalline and non-crystalline stone being quite indistinguishable. This was quarried, and sent up to London. Mr. C. H. Smith, a well-known mason in Titchfield-street, was one of the commissioners, and was appointed to examine the stone as it arrived, but by reason of some difficulty in the matter of his remuneration, he naturally declined to serve. The consequence was that the stones came in without being checked, and the result was that those which were non-crystalline were the stones which had decayed. Out of this decay arose the idea of stone-preserved. A great many people were permitted to apply their nostrums to the face of the building, and it was well understood that the one object of a stone preservative was to keep out the wet. Let them consider for a moment where the Houses of Parliament stood. For the sake of being placed over a perfectly useless and purely traditional place, called St. Stephen's Chapel, the building was put on the bank of a dirty river, opposite the filthiest manufactories that could possibly be devised, generating gases directly destructive of stone. These gases were suspended over the river in the fogs, or blown straight against the beautifully carved surfaces, and carried with the wet into the stone, with the most lamentable results. If the moisture could be kept out, so would the destructive gases, and for this purpose some of the inventors used such things as hoiled oil and shellac, but none of them were good for anything. One invention, however, was brought out, which he was sorry had not been more successful in this country: he referred to Ransome's preservative, one of the most admirable of scientific contrivances. Ransome conceived the idea of forming silicate of lime inside the stone; he first washed it over with silicate of soda, and after allowing it to settle into the substance of the stone, he applied chloride of lime in the same way. A chemical combination was the result, silicate of lime being produced within the stone, and common salt thrown out in small quantity. Ransome's artificial stone was still more ingenious, because it was the practical application of the idea. Here any sand, provided it was clean, was mixed into a paste with silicate of soda. When made up and moulded under pressure, it was submitted to the action of chloride of lime; a cross-combination ensued, and without the application of heat or anything else, silicate of lime was formed within, so as to constitute the sand an artificial and perfect sandstone, the chloride of sodium being washed out. Thus was produced a perfect material wholly artificial, and even better than natural stone. Owing to our prejudices, however, Ransome's invention had not been a success in England, though he understood it had been more successful on the other side of the Atlantic. Our prejudices now were artistic, and we abhorred shams, but he could not help being sorry that so meritorious an inventor should have cause for complaint as to the reception of his brilliant invention. Dealing with brick, the first mention of anything like good bricks was in connexion

with the Tower of Babel. In early brick-work there was a rivalry between the sun-dried and the fire-burned brick. The sun-dried was similar to clay-lump, and was a very good material so long as the wet did not get at it. The bricks made by the Israelites in Egypt were sun-dried, the clay being mixed with just so much straw as would give bond to the bricks. In cutting a brick two things had to be considered; in the first place, it must be a soft brick, and, in the next place, the cutting would remove the protecting surface, thus rendering it a bad and rotten material. It also seemed a pity that so much ingenuity should be wasted for the mere whimsy of the moment, in the imitation of Dutch architecture, when we could do so much better with our own. In endeavouring to improve anything in this world, as regards the eye, a price had invariably to be paid in the disturbance of substantiality. The best brick facing was plain selected stocks, and the more they were chosen for beauty of effect, the more was this obtained at the sacrifice of substantiality. Glazed bricks were not liked for facing, but was it not possible to glaze or semi-glaze a brick or stone? Any one who could invent a glaze which would not require heat, but would still keep out the weather, would, he believed, make a fortune. Our brickwork was dirty, and we would not fall into the good French habit of giving the houses a wash down once a year. As to mortar, the earliest buildings of any magnitude were built of great masses of stone without mortar. The first mortar was tempered clay,—unburned brick and common clay making a good wall of its kind in the East. The next mortar seemed to have been burned brick and asphalt. The theory of lime mortar was that it consisted of lime and sand,—an artificial stone, like concrete, composed of sand with a minimum of lime and water. The sharper the sand, the better the mortar; the strength of the mortar was in the sand, and therefore the theory of perfect mortar was that it should be composed of grains firmly dovetailed together, with just enough of lime to fill the interstices, and no more. Mortar made without sand had no strength; and the question of the minimum of water was a vital one. The water had to dry out, thus leaving the spaces empty, so that the more water that was put in, the less solid was the artificial stone which the mortar constituted. Timber was a natural and very crude material, of fibrous and at the same time multitubular structure. This required to be seasoned. The tree was felled at a time when the sap was at its lowest, cut into logs, and kept in running water, so as to wash out the sap, which was albuminous. When this was done the tubes which contained the sap contracted, and so resulted the shrinkage of the timber. This was a material which, on the face of it, ought to be improved on, and nature insisted upon this being discovered sooner or later. Indeed, the purposes of building were wholly artificial, and no material was supplied upon the responsibility of nature, but upon the responsibility of man, who was expected to improve it in the course of ages. Iron, again, was a material as absolutely artificial as if it were had from another planet. To the ore (which looked very unlike a built girder) was added a flux which produced slag, the result being pig-iron, and here was artificiality of an extreme character already. The pig-iron was then re-melted and became cast-iron, a most valuable material of a granular texture, but at the same time somewhat treacherous, acquiring in the process of cooling accidental fractures and air-boles in the interior, which no amount of inspection short of testing would discover. Malleable iron was still more artificial, being re-fused and submitted to the blows of the hammer. The pig was a granular material, but when refined it seemed to lose this character, and under the roller or the hammer acquired fibre in the direction of the pressure, so that the identity of character with cast iron was entirely gone. By repeating the process the iron became more and more fibrous, until an iron tube could now be bent by the pliers into a spiral of 2 inches in diameter. Rolled iron was even more artificial, when they looked at a built girder, and considered that it was just as if it had been cut out of paper with a pair of scissors: they would agree that the extreme limit of artificial material had been reached by the persevering ingenuity of man. And here they would observe that the more the artificiality, the

the reliability of the material. The weak point of iron was its liability to rust. Iron oxidized like anything else by reason of its contact with air, and could only be protected by being galvanised or painted. Galvanising was originally done by what might be termed the electrical process, but was now accomplished by dipping into a bath of zinc. The reason for using zinc was that, though it oxidized, it was protected by its oxide. But the protective processes for iron were as yet imperfect, so that structures like the Crystal Palace or the Tabular Bridge over the Menni Straits, must be considered to be theoretically and practically weak. He believed, however, that, in the course of time, some application would be invented to protect iron effectually against the influences of our moist climate, and if so then it must have a great future before it for constructional works. The slag thrown off in smelting was also a material which promised great things in the hands of inventive ingenuity. Lastly, he would say a word about paint. Common oil-paint originally was a coating of white-lead and oil. A coat of paint was the formation of a film of carbonate of lead, to protect the wood or iron from the influence of the atmosphere. The oil,—the vehicle,—evaporated, leaving the carbonate of lead dry on the surface. The more pigment that was used the more was the white-lead weakened, pure white-lead being a strong and substantial coating. Professor Kerr, in conclusion, hoped he had succeeded in persuading his audience that there was much room for the exercise of ingenuity in the direction of artificialising building materials, and that nature did not undertake to find us in these materials, but, on the contrary, expected us to prepare our own.

The lecture was enlivened throughout by a variety of historical and anecdotal allusions.

On Wednesday evening last the fourth lecture of the series was delivered by Mr. T. Chaffell Clarke, F.R.I.B.A., his subject being "The Architecture of City Buildings." Mr. Alfred Preston, a member of the Court of the Carpenters' Company, presided, and the lecturer was listened to with marked attention, his remarks being frequently applauded. A report will appear in our next issue.

MOULDINGS.*

BY GEORGE AITCHISON, A.R.A.

In the Middle Ages the total size of every group of mouldings depended on the thickness of one course of stone. The architects altered the profile according to the size of the building, i.e., in large buildings the members were few and large, in small buildings they were many and small. This was opposed to the ancient system, where the module was adopted. One course might serve for a small Corinthian cornice; while the cornice to a large order might require several courses.

There are two main moulded members in a building, the cornice to throw off the wet, and the base moulding to spread the weight. Their shape must clearly explain their use to bring them within the pale of art. The Dorians did this most admirably; the top fillet was a drip-stone, the hawk's-bill was a drip-stone, and so was the corona; there was little reason for this in the sloping pediment, and they, therefore, crowned it with a cyma. The bottom of the column was large, and the steps acted as footings. The Ionians, living in Asia Minor, probably had less necessity to guard against rain, and had more sun; hence, in the Ionic, the crowning member of the cornice is mostly an ovolo. In this order the columns have bases.

But we must not lose sight of one thing, that though the corona may have a purely useful end,—that of protecting the face of the building from rain,—it has an equally important æsthetic end, that of producing a deep shadow where it was wanted, æsthetically to tie the building together, and to repeat and affirm the horizontal shadow from the lower edge of the architrave, broken by the capitals of the columns.

In the smallest thing connected with architecture we must always bear in mind that it is originally founded on construction, and cannot stray far from it if it is to satisfy the reason

* Continuation of a lecture delivered at the Royal Academy on the 25th ult. See p. 365, ante.

and the sentiment. We are far removed from Greek times, and have not even a tradition of their ways and thoughts in relation to architecture: so we can only try to resolve their problems by examination of their works and reflection upon them. Vitruvius, who hands us down something he learned from them, is a bad guide; he not only came late, when everything had fallen into rules, but he was using a wholly exotic art.

The Roman building material was rubble; the Greek material was marble. Of æsthetic architecture in its proper sense he was absolutely ignorant. He did not even know what it meant. When he had done his building he wanted to make it architectural, and for that purpose he considered he must stick on to it some sort of caricature of a Greek temple. English architects at the beginning of this century had much the same view. They built a square brick box, with holes for windows and doors, and plain projecting eaves and gutters; but they wanted it to be architectural: to achieve this they added a porch of Greek Doric or Ionic, in stone, wood, or plaster, and the thing was done. It is certain that Doric columns were derived from stone, and not from wood construction, as they get thinner as the Greeks learned more about stability. The architrave was probably stone, and the on-style, sy-style, dia-style, and arco-style were expressions of the bearing power of the stone,—in masons' words, "safe," "too thick," "rather thin," and "risky." The projection of the corona was to some extent governed by the thickness of the walls; it would have toppled over if the tailing had not been greater than the projection.

We modern architects are too much divorced from our materials, so that our mouldings are too apt to represent artistic rather than real needs. The early Mediæval architects were mostly masons, even so late as the building of the Ducal Palace at Venice. The architect, Bon, was called a stone-cutter (*tagliu pietra*). Carpentry, too, is extinct in England, and so are carpenters: excepting the hedge-carpenter, we have none,—they are all joiners,—and their maxim is never to work timber, but to case it. The Saracen architects did the same. Their beams are often round barks, with the square ends, and fretwork in thin casing. In consequence of this the architect loses all sense of constructive propriety in his mouldings,—their only propriety is æsthetic.

About 300 A.D. the Romans began to think about architecture, began to abolish lintels, and use arches; but they still adhered to the entablature, and put it over the arches. The Greek architects who worked in Syria also thought (I am by no means sure that Diocletian's architects were Romans, and not Greeks); the orders began to be lengthened out, to suit their position. Ionic pilasters may be found at the angles of the basilica at Chaga, running from top to bottom of the building, some 20 diameters high. The cap comes under the architrave, and in the middle of the pilaster is a moulding. But before this epoch in Europe the orders got turned into long shafts, with their caps under the cornice or architrave. In Syria the frieze had been discarded, the architrave had been moulded, and the cornice was a flat projecting stone, with a gutter in it. The Crusaders made acquaintance with these Syro-Roman or Syro-Greek buildings, and from them much of the Romanesque work was taken, and their methods and features were altered and improved upon when Gothic began. The cornice proper in Early Gothic first consisted of a drip-stone with a large quirked ogee beneath it, and the frieze was a hollow and head, filled with leaves. Eventually this sculptured frieze was omitted, and the cornice came to be but a drip-stone and hollow, the whole tendency being to use cornices merely as a narrow string, of the least possible importance.

It is in the archivolts and vaulting ribs, and in piers, that profusion of moulding is to be found; and it is by studying successive examples of them that we see the stages of alteration and improvement in the mouldings. In archivolts of the early part of the thirteenth century, a common form is a large torus, forming the bottom arch, flanked by a smaller quirked torus on each side; then the lower torus got a fillet or nose put on it to mark the centre; then the side toruses got their fillet; then the spaces between were hollowed; then subsidiary beads got put in, until at last the lower torus became a prism with hollowed sides, and the side ones were so hollowed out and

undercut that they became a sort of ogee. The setting out was, from first to last, on virtually the same geometrical form, a triangle of 45 deg. or 60 deg. And the mouldings alone were gradually altered, as more skill in construction was acquired, and greater lightness, elegance, and variety were demanded.

I do not intend to give you an archæologic history of Gothic mouldings, I merely want to point out that where the Mediæval architects perceived a defect they remedied it; where they saw an improvement might be made, they tried various means until they got the effect they wanted; not by capriciously abandoning their system, but by variations and improvements in the detail.

In spite of being trite, I will say that in horizontal mouldings, those that are concave rarely look well as supporters; an ovolo or ogee does best for that, and cymas or cavettos as crowning members. The Greeks felt this in their Ionic bases, and brought out the fillet of the scotia to the face of the torus above, so that it might have a solid bearing under it. Inside mouldings must be treated differently from those outside, as the light inside is diffused, and in certain places is below instead of above them, and they are lighted only by reflected light. I may also mention that in places that are only, or mainly, seen by artificial light, the mouldings may be designed as for sunlight; only care must be taken to ascertain the level of the light. An excellent group of mouldings, designed for a top light, may be lost or look ugly when the light comes from below. A little inquiry, thought, and care will prevent such untoward occurrences.

There are some effective groups of mouldings in some of the mirror and picture frames at Venice, mostly Milanese work; these groups begin with a small projection from the wall, carried on some distance, and then a bold, projecting moulding comes out, and from that the face recedes but slightly to the picture or glass; besides the differences of plane, effect was gained by the use of fillets of considerable projection chamfered on the edge. Much of the effect is also due to a peculiar ornamenting of the surfaces by undulation, and by carefully contrasting the different qualities of surface, some being left wholly plain.

Brick, soft stone, hard stone, and marble require different treatment in moulding. Brick requires a greater difference in treatment than stone or marble, particularly in the projection of the planes. With a 9-in. brick you can with difficulty get any considerable flat projecting surface.

Soft and hard woods must be moulded differently; very thin members break off in soft wood, and sharp edges get broken off or bruised.

Metal, too, requires different treatment from marble, stone, brick, or wood. You may get edges as sharp as you like in metal, but you cannot undercut, because the pattern will not draw.

We can never progress unless we resolve, think, strive, and learn. It is mainly to this end that I have given this lecture. We must resolve what effect we want; we must think how this effect can be got; and we must strive to make it as beautiful as possible. And when it is done, we must learn from our failures how to do it better next time. But this is not enough, for this only deals with individual experience, and what is wanted is aggregate experience.

From each architect, or each small group of architects devoting themselves to separate styles, the profession is a mere aggregation of individuals or of knots of men; lacks all the cohesion and discipline of an army, and cannot, as a body, benefit by experience. The successes or failures of the knots or the individuals only instruct the man or the group. A knot of imitators of Greek learn nothing by the success or failure of Mediæval imitators; this is well put by Fergusson:—

"The only one means by which man ever did anything great, either in the useful or fine arts, was by this aggregation of experiences. One man may be equal, either intellectually or bodily, to two or three of his fellow-men; but one can scarcely be equal to ten others, much less to a hundred or a thousand; and at all times it will be found that a thousand little steps of a thousand little men, if in advance of one another, will surpass the stride of the greatest intellectual giant the world ever saw; and it is only by steady perseverance onward that we can

really hope to accomplish anything great, or worthy of ourselves, or which shall be a benefit to those that come after us."

I do not want to make you vain, but I do desire to make you feel a due sense of your own worth, and that of the age in which you live. Are you not better than a ferocious Roman, a savage Norman, a half-barbarous Medieval or Mahomedan? In many respects you are superior to an ancient Greek. Why should you bow down before these people, and say "you are great and we are nothing; we can never hope to rival your work; we will humbly copy you?" Do you think, if your compeers in science and the useful arts had posed in this fashion, they would now "flash the lightning and weigh the sun"? No; we should have ballists instead of cannon; triremes instead of steam-driven ironclads; probably a flint and steel for getting fire, without even tinder or a brimstone match. We should have wick lamps or torches for our light instead of gas and electricity; scribes would copy our writing instead of giant cylinders driven by steam; and hand-loom would weave our cloth instead of Arkwright's machinery. Would Argand ever have made his lamp if he had believed the Romans unsurpassable? Should we have the steam-engine? Should we know the earth went round the sun? Would the law of gravitation have been found out? It should be as contemptible to copy an old building as an old book.

The great architectural ethnographer, James Fergusson, said of architecture:—"It possesses durability beyond almost any other of man's works,—except, perhaps, the lay of the poet,—and in this respect comes before us with a sort of pseudo-eternity, speaking to us of past times and people who have left no other record of their existence, and telling its tale with a distinctness and reality which, to my mind at least, no other art can match." Is it, then, not worth making an effort to re-create it, for we have no national architecture?

Savage hordes like the Goths, the Lombards, the Franks, the Normans, and the Saracens, managed to impress on their buildings sufficiently striking characteristics to enable us to say to which horde they are due. When they became partially civilised they produced Gothic in the West of Europe, and Mahomedan in Asia, Africa, and the East of Europe.

The masterpieces of both these styles excite even now our wonder and admiration. Neither the Mediaevals nor the Mahomedans were equal in civilisation to the Romans, and though no Gothic building covered a space equal to the Flavian Amphitheatre, nor was equal in permanence to the basilica of Maxentius, their tallest buildings exceeded the Pyramids in height. In every useful art, and in every science, we have not only left the Saracens and Mediaevals behind, but the Greeks and Romans as well; it seems, therefore, that it is not because we are altogether inferior to former peoples that they had architecture while we have none. This does not apply to England alone, but to France, Italy, Germany, Russia, Spain, Portugal, Sweden, Denmark, Norway, and America, and to the Americas, Australo-, Indo-, and Africo-English. It is simply because a new phase of humanity has supervened that we, as well as the other civilised nations, have building, but not architecture.

From the savage upwards, until, say the middle of the last century, no one ever made anything without an attempt, however rude, to give it some beauty of form. In the middle of the last century this desire ceased amongst civilised nations, possibly owing to the discoveries of science and the invention of machinery. Old traditions still hung about all arts,—they do even now; but, from a toasting-fork to a steam-engine, things began to be made for the end of use, and use only; and this new view applied to building, and does so still. A friend of mine remarked to the foreman at a cotton factory that it was very ugly. The reply was, "It perfectly answers the purpose of spinning calico in, and I don't know what more you want." This may be said to be the mental attitude of the bulk of civilised mankind. Whether what we call the improvement in taste is a real thing, or only a fashion, I cannot say; but before you can have any real architecture you must have the desire for it amongst the people and an effective demand. One of the most important factors in this is that the people who order a building must, when they see it completed, have a genuine love for it, and feel that it is not only more pleasing to them

than something else, but that it fulfils the desire for the particular beauty they want. The bulk of the people must feel thankful to the man who has done it, and be proud of him. I never heard that Messrs. Tyndal, Spencer, and Huxley were rich; they certainly have no official honours; but every English-speaking person in the world admires them, and is proud of their being English. The same feeling must be given to the architect. James Fergusson said we have no architecture, because we do not follow the method employed in old times of gradually improving on each thing done, and employing a vast number of able persons on it. This might be true, if we had anything to improve, but, as I said before, you cannot improve on nothing.

There is no lack of skill nowadays. You may get a Greek temple, sculpture, painting, and all, of nearly equal excellence to one of the days of Perikles; a Roman basilica, a Romanesque or a Gothic cathedral, an Italian palace, or a Swiss chalet; but you cannot get an original style, unless mankind want it, and when they really want it they will get it. So you must try and cultivate the public taste until you can produce a real want. Critics may carp, but that is the solution, and that is why savages, barbarians, and half-civilised people produced architecture that we now admire and copy,—and we cannot.

I believe, with our present knowledge and skill, we could take the truly British house,—a brick wall with holes in it,—and gradually form a new style out of it. I believe we could make a steam-engine beautiful, or one of the hideous abortions of the engineers, if mankind wanted it. I do not say that this generation could bring it to perfection, but they could make the first step.

Archimedes said he could move the earth if he had any fulcrum for his lever. We are in the same position: our fulcrum is the true love for a new species of beauty amongst mankind; and that we have not yet found, because it probably does not exist.

If you will go on perfecting yourselves in the knowledge of your art, in logically working out the problems before you, in making each necessary piece of your structure as true, as expressive, and as well-proportioned as possible, and in getting it ornamented with what you truly admire, you will be ready to meet the true taste when it does arise. If you neglect this all the recondite arts that are necessary to plan, construct, and put buildings into harmonic proportion will be lost, and will have to be laboriously disinterred from books and ruins, and will probably take a century or more. All I can hope is that a national taste may arise in your time.

The lecturer thanked those who had assisted him:—

Messrs. G. Jackson & Son for running the plaster mouldings.

Messrs. Bruciani & Co. for the cast from the Erechtheum.

The R. I. B. A. for lending him the Pugin drawings.

Professor Lewis for the diagram of the comparative forms of Doric capitals and Ionic Bases.

Professor R. Smith for diagrams of Gothic mouldings.

Signor G. Boni for the fac-similes of the mouldings of the Ducal Palaces at Venice and the drawing of the Loggetta.

Mr. Bidlake, Pugin Prizeman, for the loan of his drawings and Gothic mouldings.

Remodelled London.—At the Surveyors' Institution on Monday night, the discussion was renewed on the paper read a fortnight before by Mr. William Woodward, on remodelling London. The proposal was to deal with the metropolis as a whole in regard to its entrances, streets, squares, open spaces, and edifices, by schemes of improvement, some fifty in number, which would result in the formation of boulevards traversing the whole of the suburban districts, and communicating with each other, the formation of new streets running north and south, east and west, with avenues, circles, diagonal thoroughfares, isolating all churches, theatres, and public buildings, iron and glass covered arcades for shelter in wet weather, sites for new public buildings, recreation grounds, baths, gymnasia, and healthful accommodation for all classes of the population on a larger scale than exists at present, at an estimated cost of 67,000,000 sterling.

Illustrations.

TWO LONDON DOORWAYS. SCHOOL BOARD OFFICES.

THE new principal doorway to the enlarged offices of the School Board for London, from the designs of Mr. E. R. Robson, F.S.A., is a free rendering of what may be described as French Renaissance. The principal panel contains the Queen's head surmounted by a Crown, and has a ribbon bearing the inscription, "Elementary Education Act, 1870," alluding, of course, to the Queen's sign manual, which completed the Act which brought the Board into existence.

This panelling, together with the whole of the foliage and lettering, is by Mr. McCulloch.

The interior of the enlargement contains, in addition to the various business offices, a large committee-room panelled in walnut, the panels being carved by Mr. Ammonier.

Messrs. Higgs & Hill were the builders.

ROYAL INSTITUTE OF PAINTERS IN WATER-COLOURS.

The design of this door, in Piccadilly, by the same architect, may be described as a playful treatment of neo-Greek. Its difficulty, of course, consisted in being obliged to give way to the internal interests for light, and it is thus pierced at two points with large windows. Two unusually fine figures crown the same, which are by Mr. Verheyden, the sculptor, and are symbolic of water-colour painting. The foliage, lettering, &c., are by Mr. McCulloch. The busts along the façade of the building are the work of Mr. Onslow Ford. Messrs. Peto Bros. were the builders.

MEASURED DRAWINGS OF GRANTHAM CHURCH.

The parish church of Grantham is dedicated to a Norman saint (Bishop Wolfran), who died three hundred years before the Conquest.

The church, as it now stands, consists of one large parallelogram divided into three nearly equal widths, viz.,—the nave, north and south aisles, running the whole length of the building.

The oldest portions visible are the three nave transitional piers, exactly in the centre of the church; and the core of the piers at entrance to chancel.

The three arches over these three piers are later, and of much greater height in order to take both the original arch and clearstory window over (see arch-stones over these arches).

The very wide arch is late work, the extra width being given in order to give the utmost view to the rood-screen, of which stone foundations run the width of the chancel, rowel stairs being formed in the piers of either side. The church was then extended to its present length, and the whole north aisle up to the late north chancel aisle, the vestry being jammed on at the junction of both.

The north porch also is an addition, the wall being continued from the buttresses of one bay. The inner door is Early English, and probably came from the earlier west end.

The south side is much of one date, the latest work being eastward, over the Early English crypt.

TOWER AND SPIRE.

The tower was built in two stages. First stage, up to the chime chamber, terminating outside with the quatrefoil work. Soon after the upper part was built up to the base of the spire and finally finished with the magnificent spire, as Sir Gilbert Scott said, only second to that of Salisbury. The whole is of Ancastone stone. There is a splendid peal of ten bells, the framework of which sadly needs repair.

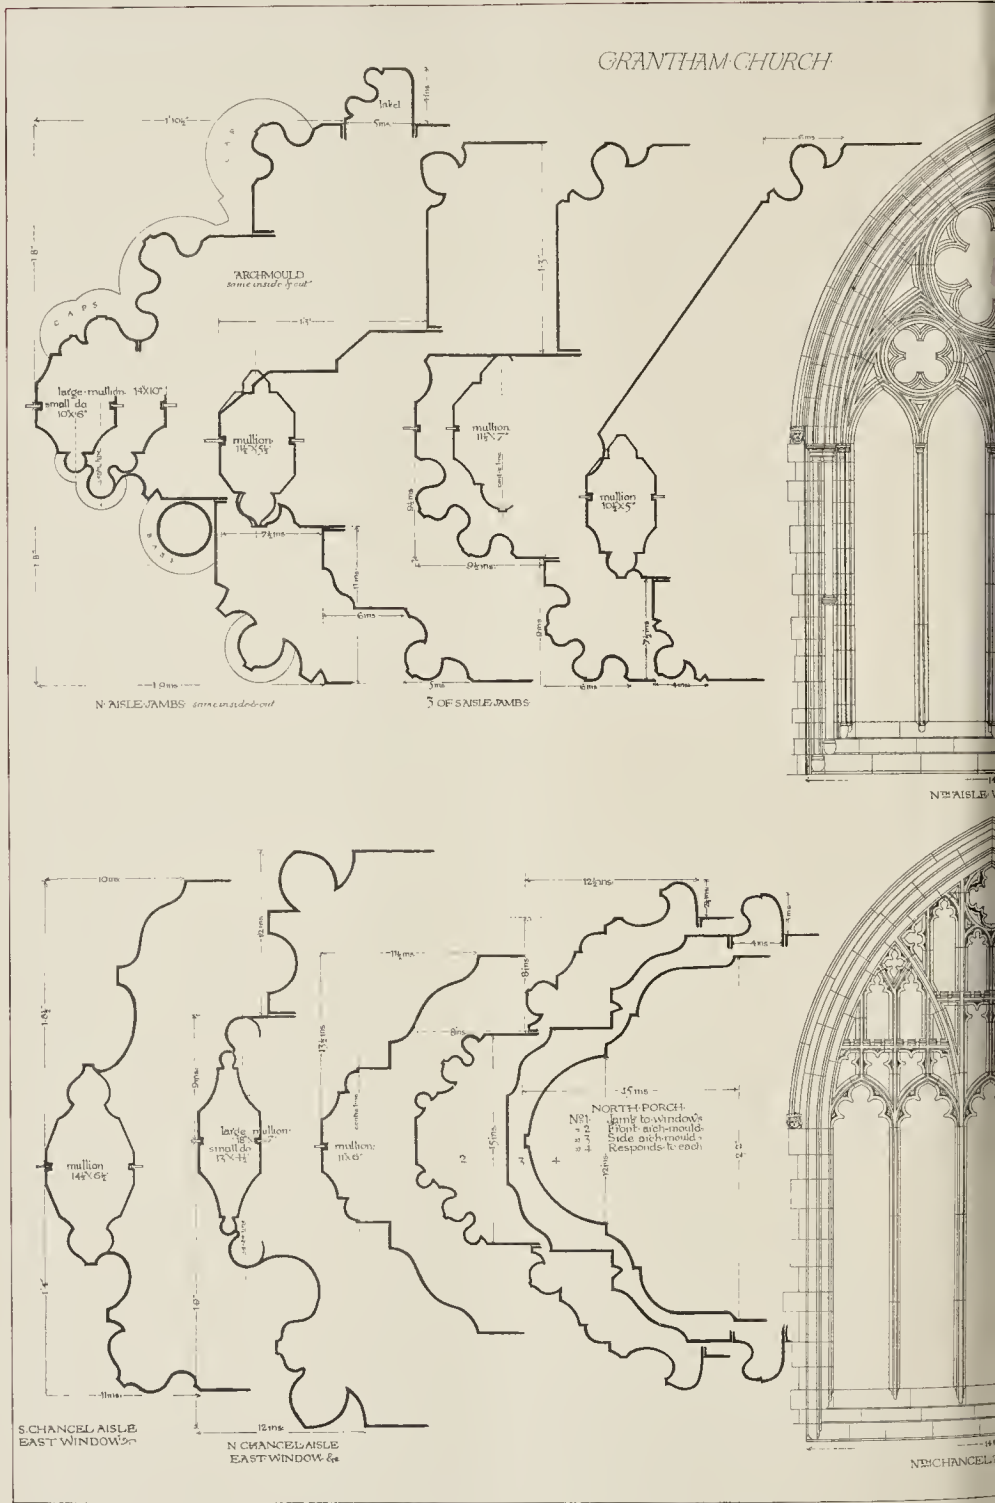

EDMUND H. SEDDING.

Hellenic Society.—This Society held its second meeting of the year, at 22, Albemarle street, on Thursday, when papers were read by Mr. A. S. Murray on "Antiquities from Lipari," and by Mr. Arthur J. Evans on "Terra-cotta from Tarentum."

Institute Prizes.—It was stated in error last week that Mr. Mitchell had received the "Medal of Merit" only for his measured drawings of "Layard Marney Towers." Two silver medals were awarded; the first, with five guineas, to Mr. E. H. Sedding; the second with five guineas, to Mr. Arnold B. Mitchell. Mr. A. A. Cox, not A. R. Cox, is the name of the winner of the Grissell Medal.

ARCHITECTURAL SOCIETIES.

Birmingham Architectural Association.—The sixth ordinary meeting of the current session was held at Queen's College on Tuesday evening last. The Vice-president (Mr. John Cotton) was in the chair. A paper was read by Mr. T. Amm on "Old Stained Glass," which was very ably illustrated by examples taken from various cathedrals and churches at home and abroad. In addition to the different phases of the mediæval art, the lecturer entered into the methods of modern manufacture, and made a statement to the effect that stained glass could be produced in this country to equal both in colour and form that of the Middle Ages. A lengthy and interesting discussion followed at the close of the lecture. A vote of thanks, proposed by Mr. W. Churchill, and supported by Messrs. T. W. P. Newton, J. Cotton, and Victor Scruton (hon. sec.), was heartily accorded to Mr. Amm for his paper, and after a response on that gentleman's part, the meeting terminated.

Leicester and Leicestershire Society of Architects.—On Wednesday, the 3rd inst., the President, Mr. Everard, entertained at dinner at his house, Woodville, near Leicester, the members of this Society. Thirty-two members, including pupils and assistants, responded to his invitation, and the Mayor of Leicester honoured the society by his presence. After the loyal toasts, (Colon) Millican responded for the Volunteers, proposed by Mr. Goodacre. The Mayor, Mr. R. T. replied for the town and trade of Leicester, proposed by Mr. W. Jackson. Mr. Everard proposed the toast of the evening, "Architecture at the Royal Institute," which was acknowledged by Mr. Goddard, and the Chairman's wish was then toasted with acclamation and social honours.

Northern Architectural Association.—The annual meeting of this Association was held in Old Castle, Newcastle-upon-Tyne, on the 1st inst., when the following additions were made to the roll of members:—Members, Messrs. W. S. Hicks, A. B. Plummer, and John H. Associate, Mr. James T. Cackett. Honorary Members, Wm. P. Brewis, J. A. Bryson, B. Dick, Alex. Drysdale, W. H. Dunn, jun., E. Hinton, C. J. Marshall, E. Rich, and G. Wilson. The election of officers for the ensuing session was also proceeded with, with the following result:—President, Mr. G. G. Hoskuis. Vice-presidents, Messrs. E. Shewbrooks, and Glover. Hon. Treasurer, Mr. W. L. Newbeck. Hon. Sec., Mr. F. W. Rich. Committee, Messrs. W. H. Dunn, J. H. Morton, J. Oswald, Thos. Reay, Wm. Livesey, W. Knowles, and C. E. Oliver. Auditors, Messrs. J. Cresswell and J. T. Cackett.

Edinburgh Architectural Association.—The monthly meeting of this Association was held on the 4th inst., Mr. G. Washington being president, in the chair. Mr. John Lachlan read his third paper on "Old Edinburgh Architects," going back to some of the eminent men who lived before the end of the century. Beginning with Sir Wm. Bruce, Gross and Balcaskie, in the time of James II., Mr. M'Lachlan referred to his local services in connexion with the Restoration, and to his appointment as Master of the Works and Architect to his Majesty. He had been brought up in the school where the Rev. Mr. Classicalism asserted its power, and his principal works were Holyrood Palace and the northern portion of Hopetoun House. Dealing with the Mylne family, Mr. M'Lachlan said they were Master Masons to many successive Kings of Scotland, and they were credited with many important buildings in the town. Having briefly sketched their work, he said that to Robert Mylne we owed the square and Mylne's-court, which were erected as a protest against the narrow lanes and alleys which were so characteristic of the burgh of previous centuries; the same architect and builder repaired the battlements of Edinburgh Castle after its siege by the Earl of Mar in 1685; while his grandson built the Blackfriars Bridge over the Thames, and the latter's brother William was architect and builder of the Edinburgh Bridge. The Adam family were also important in the history of Scottish architecture, William Adam, who lived in the beginning of the eighteenth century, and who, among other works, designed the wings of the Edinburgh House, Dumfries House, Floors Castle, Haddo House, and the old Edinburgh

Royal Infirmary. On the motion of Mr. Russell, a cordial vote of thanks was awarded to Mr. M'Lachlan for his interesting paper, and the Chairman expressed the hope that he would continue his efforts to give them some account of their professional ancestors.

ARCHÆOLOGICAL SOCIETIES.

British Archaeological Association.—At the meeting of this Association on the 3rd inst., Lieut.-Col. Adams, F.S.A., in the chair, the Rev. Canon Rontledge sent for exhibition a piece of Roman carving, probably one of the horns of an ancient altar, found built up in the walling of St. Martin's Church, Canterbury. It had been used as old material in later Roman times, for there are traces of mortar and pounce brick. Sir Henry Dryden sent a squeeze of the newly discovered Saxon stone at Moulton. It is covered with interlaced patterns with a grotesque animal. Mr. Loftus Brock, F.S.A., exhibited a collection of old views of demolished buildings formerly in the City of London, illustrative of the amount of information to be derived from their study. Mr. Romilly Allen, F.S.A. (Scot.), described a remarkable horn powder-flask of Danish workmanship, bearing a late date, 1697, the curious patterns which covered it being very similar in appearance to the very early work on crosses and in MSS. Mr. R. Blair, F.S.A., exhibited a fine collection of views and sketches of little-known antiquities in the north of England, among which were many Saxon interlaced crosses. The first paper was by Dr. A. Fryer on the "Divining Rod in Ancient and Modern Times." A paper was also read "On the Roman Villa at Box," by Mr. R. Mann. Some curious pavements have been discovered, one of which is remarkable for being all but exactly similar to another found in Gloucestershire. Mr. C. H. Compton stated that the remarkable sculptures found by Mr. Grover in the Aikyn Vault, under St. Paul's Chapel, Clapham (and which were described in *The Builder* for Jan. 2 inst, p. 60), had been brought above ground and were now safe in the disused mortuary.

Society of Antiquaries of Scotland.—At the monthly meeting of this society, held in Edinburgh on Monday afternoon, Dr. Arthur Mitchell in the chair, the first paper was a notice of two very fine Communion cups from Dalriada, Skye, by Professor Macpherson, Vice-President. In form and ornament they closely resemble a pair of cups in the Temple, London, and were supposed to have been presented to the parish by Sir Roderick Macleod, of Talisker. The Rev. Dr. Struthers and Mr. Law, of the Signet Library, followed with some remarks on the forms and uses of several of the vessels, especially the tall covered cup from St. John's Church, Perth, which Mr. Law considered to have been a pyx. The second paper was a notice by Mr. Cochran Patrick and Mr. Thomas Dickson, of Her Majesty's General Register House, on the discovery of the MS. Chartulary of the Monastery of Lindore, in Fife. The Chartulary, which is of the thirteenth century, and written on vellum, was discovered in the library at Caprington Castle, Ayrshire, and was exhibited to the Society by permission of Mr. Smith Cunningham, of Caprington. The third paper was a notice by Professor Duns of an idol human head from Ecuador, now presented to the Museum by Dr. R. H. Gunning. In the fourth paper Mr. Hutcheson gave an account of a stratum containing worked flints at Camphill, Broughty Ferry, which presented some very interesting features, and from which he had made a considerable collection of flakes and cores, which he exhibited to the society. The fifth paper was a notice by Dr. J. Jamieson of the discovery of a cist with an urn at Knockankelly, Arran.

Medals.—The Society of Medallists, under the Presidency of the Hon. C. W. Fremantle, Deputy Master of the Royal Mint, has determined to offer 20l. in prizes for medals to be competed for by students of this and other countries. Particulars can be obtained of Professor Legros, of the Slade School, University College, and of Mr. R. S. Poole and Mr. H. A. Grueber, at the British Museum. Medals for competition should be sent to the care of Mr. R. S. Poole, British Museum, on or before the 10th May next.

COMPETITIONS.

Paisley New Congregational Church.—A meeting of the congregation was held on the 3rd inst. to decide upon an architect for the new Church to be erected in School Wynd, the present church having been acquired by the Railway Company. Four Paisley and four Glasgow architects had been invited to compete, and the committee unanimously recommended one of the designs, which was adopted by the congregation. The author was found to be Mr. John B. Wilson, of Glasgow, and he was accordingly appointed architect. The building is to be proceeded with at once.

Blackburn Poor Law Offices.—A competition, limited to the architects of the Union, was lately instituted. The Guardians appointed Mr. James Hibbert, architect, Preston, to be professional referee, and to draw up the conditions of competition. Sixteen architects applied for conditions, and six sets of designs were sent in by the following:—Messrs. Stones & Gradwell, Mr. J. W. Bulcock, Mr. W. S. Varley, Mr. H. V. Wolstenholme, Mr. James Aspinall, and Mr. T. H. Duerden, all of Blackburn. On Mr. Hibbert's report the Guardians unanimously accepted the designs sent in by Messrs. Stones & Gradwell, Blackburn. The plans are on public view during this week in the present Board-room. It is intended to proceed at once with the work, which is estimated to cost between 8,000l. and 9,000l.

New Cemetery at Armley.—The Armley Burial Board recently offered two premiums of 20l. and 10l. for the best sets of plans of a chapel, mortuary, lodge, and board-room, proposed to be erected on the site recently purchased for a new cemetery for the township of Armley. Forty-three sets of plans were sent in; those prepared by Mr. J. P. Pritchett, of Darlington, and bearing the motto "Labor et spes," have been placed first; Mr. Thomas Winn, of Leeds, whose designs were premiated "In perpetuum," being awarded the second premium. The cost of the buildings is estimated at 1,600l.

Stretford Local Board Offices.—At the meeting of the Stretford Local Board last week, it was decided to employ Messrs. Mangnall & Littlewoods to carry out Mr. Gibbons's designs for this building. At a special meeting of the Board previously held, it was reported by the Chairman that Mr. John Gibbons, to whom had been awarded the first premium for his design for new offices, was an assistant in the City Surveyor's Office, and that Mr. C. M'Leod, who obtained the second premium, was an assistant in the office of Mr. W. T. Gunson, so that both of them were unable to carry out their designs. A protracted conversation took place as to the best course to take under these circumstances, and subsequently the Chairman and two of the councillors were requested to seek an interview with Mr. Gibbons and report to an early meeting. As the result of the interview with Mr. Gibbons, the Board decided to employ Messrs. Mangnall & Littlewoods, as before stated.

ROYAL ARCHITECTURAL MUSEUM AND SCHOOL OF ART.

The Council, in an address to the subscribers on the work of the Museum and School during last year, say that in most respects they are able to give an encouraging report, especially as to the progress of the School, which now forms a very important part of the whole very useful Institution, the valuable collection of the Museum giving a character to the School that it could not have without it, and the School forming a means of extending the sphere of usefulness of the Museum by bringing, as during last year, nearly 200 students to the building, many of whom came to draw or model from the casts contained in it. "This is the tenth year of the existence of the School as a regular School of Art under the Department of Science and Art. Nearly a thousand students have during that time been educated in art for longer or shorter periods, some of the students having been regularly in the School for over six years; over these not only has there been the influence of a systematic art education by very unusually talented masters, more especially the head-master, Mr. Frederick Brown, well known as one of the best teachers in London, but also of the continued presence of the unrivalled historical collection of works of art, ranging from the age of the Greeks to the present time. 386 works were sent up to the Department

many of which were from the casts in the Museum, including some excellent copies in clay by the modelling class, composed of carvers, masons, and a few young architectural students, whose studies of this character are of the greatest advantage to them."

With regard to the Museum itself, the Council say:—"The Museum was founded thirty-five years ago, and was supported at its foundation by annual subscriptions and donations alone; during the same ten years that the School has increased in funds and students, the subscription list, upon which the whole Institution still so much depends, has, principally from the deaths of subscribers or from the retirement of members of firms originally much interested in the Museum, decreased from 288. 18s. 7d. in the year 1876 to 150. 15s. 6d. in 1885." An appeal is made for new subscribers.

The annual public distribution of prizes will take place at the Museum, Tufton-street, Westminster, this (Friday) evening, March 12.

BRICKWORK, AND THE LEANING TOWERS OF BOLOGNA*.

HAVING now considered the construction, we come to the design and proportion of the tower externally. It is a work in which nothing is meagre or vulgar, nothing clumsy or top-heavy. There is no extravagant treatment. By a nice adjustment of parts a result has been arrived at which we may call bold and simple without being crude; light without being flimsy; massive without being cumbersome. I am sorry to be able to say so little about the basement story. But it affects the present outline but little. It is, in any case, effectually concealed by the houses from all points from which the whole could be properly taken in. If these houses were away, the value of its massive basement would no doubt be evident. The next stage is built with little or no diminution in its sides. It terminates in the embattled weathering or set-off, which forms a base high above the surrounding houses. The set-off being as much as 10 in., is strongly marked, although there is no abruptness in the lines by which it is effected. But your attention must be especially directed to the diminution of the shaft of the tower and to its relation to the overhanging parapet. It will be observed from the dimensions that the parapet overhangs beyond the line of the bottom of this shaft, but it is only by 2 in. that it does so. In the photograph it would appear to be almost within this line. But some allowance may perhaps be made for the further diminution caused by the height of the lines extending beyond the proper focus of the lens. The parapet, however, is still more than 14 in. within the plinth line. The square plain drip under the battlements projects 4 in., which might seem, at that height, almost lost. Indeed, with this exception, its only relief consists really in the plain arched corbel course which carries the parapet. There are no deep mouldings, no startling or difficult projection of string-course or of cornice. The parapet, it is true, projects nearly two-thirds of its thickness, but each battlement is backed by a buttress inside, of 16½ in. or 17 brick square, weathered off so as to thicken it out to the solid of the wall below. The height of the arched space below the string must be about 5 ft., or a trifle more, and the eplay of the corbel about 6 ft. 6 in., but I had no means of ascertaining those dimensions.

I know not if there be any tradition as to the original intent of these towers, whether they were built out of mere personal vanity, or for the perpetuation of a family name or a family feud. We will hope, however, that one chief object was that of adding a striking feature of an ornamental description to the city. It is certain that the general character of a place depends very greatly upon the style, magnitude, and outline of its permanent public buildings. It is probable that some amount of virtuous emulation led the representatives of the Garisenda family to follow the good example the following year. We can only regret that in some respects the endeavour met with so hapless a result. The height of the Garisenda Tower is said to be exactly 1 ft. more than half that of the Asinelli, but its declination from the perpendicular being in actual measurement half as much again as that of the

other, its proportionate inclination is nearly three times as great, and, if continued to the same height, the top of one side of the tower would, within a few feet, overhang the plinth on the opposite side. But the subsidence in each case is not on the square, but more nearly on one of the diagonals. The towers are planned at an angle with each other, and the subsidence is somewhat towards each other. The appearance of their divergence changes, therefore, with every step you take. To make a proper perspective from geometrical drawings would fairly tax any one's powers of simple geometrical perspective, and certainly the distorted bird's-eye perspective of the Garisenda Tower, as looked down upon from the Asinelli, is very singular.

But we must turn for a moment from the purely practical; for a friend blessed with a sentimental turn of mind has insisted on my giving you a quotation from the thirty-first canto of the "Inferno," as showing its early subsidence, and as illustrating its imposing impressiveness. This appears to have suggested to the poet a grand simile for his visit with Virgil to the tenth circle, "Guilt's Last Abyss." You must excuse my not giving it in the original, but I must give you the best I can. With very slight poetic licence, the passage may be rendered thus:—

"And then, at ease to lift me, stooping high
The big Anteus tower'd in his night,
As when one walks beneath Garisenda's height
His lofty battlement, athwart the sky
Suspended, seems through fleecy clouds to fly,
Declining fast, to crush the luckless sight,
That looks up spell-bound at the awful sight."

An examination of the foundations and surrounding soil would probably be an interesting and instructive subject of investigation if it could be made. I dare say there are men who would undertake to restore the towers to their upright position, by countersinking the higher side sufficiently to bring it down to the other. The foundation must itself, of course, be one solid mass. How far the footing spreads we have no means of knowing; but we do know how difficult it is to be sure of one's foundation on the slope of a hill of clay or of friable limestone.

I remember, many years ago, a builder telling me of a difficulty which he had surmounted in the erection of a chimney for some gasworks, by a singular and ingenious device. A chimney had been twice built, and twice it had failed. This builder then made himself responsible for its secure erection. The site was not far from the bank of an estuary, and the foundation was unequal and uncertain. The builder judged that if it must sink at all, it ought to be made, or at all events allowed, to sink equally; he therefore had a large block of granite, of several tons weight, roughly chaped into a pyramidal form. First of all this block was embedded, point downwards, at a reasonable depth, and from its upturned base was gathered out the walling to the extent required, so as to bring it still some feet below the ground at the proper base of the walls. The chimney was built, and although it subsided nearly 18 in., it sank so regularly as to keep its erect position as nearly as possible.

This brings us, in conclusion, to a more detailed discussion of our own modern brickwork. I am not now going into the various forms of bond, nor yet into the different descriptions of brickwork prevailing in various countries, localities, or ages. The size of the bricks has, as you know, varied enormously, as well as the mode of constructing them. Two centuries ago England produced some of the finest possible rubbed and gauged work. Some of this has been reproduced of late years. It is laid closely with joints of fine lime putty. But the fine facing has necessarily allowed of very little connexion with the rougher work behind it, except by the objectionable use of smaller bricks. Early in the present century it had become the custom to cover the brickwork with compo. From old letters it appears that much of this was done mainly from fashion. Even good old work was covered with compo equally with the poor rough work which this practice induced. The clean smooth surface was supposed to possess the merit and the beauty of fine dressed stone. It prevailed equally elsewhere. In England it is very fast disappearing. In Sweden the practice is deplorable. At Stockholm, last summer, I observed they are able really to produce grand effects in naked brickwork. They make this of a very rough description, having a ready resource in

the compo to give it a finish, and what they would call effect. In a handsome set of flats, I believe it was, drawing towards completion, there were manifest evidences of art and of skill in the treatment as well of the masses as of the details. The grouping and the gradating of the window spaces in the several stories, the arcadings, and the deeply-recessed windows gave light and shadow not to be found in any ordinary street in London. And life and spirit, too, were evident when you were just far enough away not to detect the offensive crudeness of the brickwork. With a little more care in the making and laying of the bricks, they would have been in advance of us. Yet they are content to reduce their work to a far lower level.

The character of much modern work is spoiled by the excessive thickness or height of the brick in proportion to its length and breadth. The actual size is of less consequence than the proportion. The size of our own bricks formerly was, of course, regulated very much by the tax on bricks, which was abolished about forty years ago, but from the effects of which we have not yet fully recovered. The brick was made of a maximum thickness and length. Its height is naturally a little under half its length. Its length is still practically regulated by Metropolitan and Local Building Acts and By-laws. Its length must be about 9 in. in order to work in with the thickness of walls usually described in Acts of Parliament. We have not yet arrived at 12 in. and 16½ in. as standard thicknesses for solid walls. Even if a new system be adopted occasionally for country houses the old proportions will necessarily be followed for all our ordinary urban or suburban structures. But we are now threatened with large terra-cotta facing bricks. They make a good face, but not a pleasant one. We are painfully conscious of their unpleasant repetitions, proportions, the marked uniformity of their size and colour, and of the structure of the wall made by them. It is probable that these will be available for buildings only on a large scale, where large ornamental detail can be introduced to relieve their pronounced monotony.

In strong and pleasant contrast with these is the thin brick which is now sometimes made, especially when a little time and money are available for their manufacture and use. But even ordinary brickwork must be more costly when a fine and thin joint is employed, and there can be no sufficient reason why this fine joint should be used rather than the thin brick for all ordinary purposes.

The great aim in ancient brickwork seems to have been to secure strength and mass. At the present day we aim at cheapness; and at a display of neatness of finish wherewith to disguise the economy. We are ashamed at the economy, which has become a painful necessity; and we are obliged to put the best possible face upon it.

In several particulars a very false economy has arisen from the mere following of ignorant fashion and tradition. I would speak with special reference to the construction of work almost universally in use. I mean as to the proper filling, or rather the not proper filling, of all the cross-joints and inside joints of the brickwork with mortar. At the present day each brick is carefully laid with only a small fillet of mortar next its outer edge. The bedding is sometimes done in like manner. This allows of a specious pretence of finishing up the unfilled joints, or portions of joints, from the top. But the more closely the bricks are laid the less is the possibility of the joint getting filled by such means. The finishing at best can come but about ¼ in. below the top bed. Very curiously such work is always supposed by the bricklayer to be firmer and better than if all the bed joints were properly filled in.

It is actually argued that, like a chair or table standing on three or four legs, so a brick the firmer for having support only at its edges instead of being solidly bedded and jointed into one homogeneous mass. The real result is a series of cavities or pockets in the walls in which the wet is drawn or is driven, and from which, perhaps, it takes weeks to dry, and the drying out at last into the building rather than out of it. The continuous vacuum in the walls is a direct vehicle for the accumulation of water for the saturation of the whole body of the wall. I have seen, on the south coast, rain bubbling through the inside end of the brick

* Continuation of a paper by Mr. William White, F.S.A., read before the Architectural Association on the 26th ult. See pp. 368, 353, ante.

ender in a 9-in. wall not yet covered with its
 upright tile weathering. Surely as regards the
 coping out of wet it must be evident that the
 greater the obstruction which can be pro-
 vided against the wind passing through the
 body of the wall the better. Then, again,
 or inner walls and partitions, these cavity-
 joints greatly tend to make a house noisy.
 They contribute a lot of little drams to
 make a great reverberation; and with the
 lightest shrinkage or settlement, which may
 indeed be induced by them, we have leaky
 chimneys and troublesome draughts. It is
 true the joints allow of a little economy in the
 quantity of mortar. But at what a loss! They
 allow of a neater, narrower joint being
 easily made; a little empty show at the
 greatest sacrifice of substance, and for the
 mere gratification of the bricklayer's whim in
 allowing his infernal fashion, his senseless
 addition. The inevitable result is a flimsy,
 noisy, draughty, damp, unsanitary
 house. Some clerks of works, and some
 builders, and even their foremen, will profess
 to see the fallacy of the custom. But, whether
 they see it or not, they rarely provide any
 efficient remedy for it. From a long experience
 can hardly believe that there is a bricklayer
 in England who has learned his trade in the
 usual way, but will stick to it, unless the reasons
 why it is wrong shall have been calmly and
 respectfully pointed out to him. The intelligent
 British workman, supposed to inherit and enjoy
 the traditional experience of centuries, will still
 be found to follow it, and if you should venture
 to be a little dogmatic in your opinion as to it,
 he will be ready to regard you as a horned
 idiot, ignorant of the first principles of his trade,
 and he will look at you as much as to say,
 "You, sir, may have your opinion on a matter
 which you know little about, but I am not
 going to change mine; not if I know it."
 How many of you have been told, or have
 read out for yourselves, the real origin and
 history of this custom? And how did it really
 originate? Formerly, every cranny of the wall
 was well filled; every brick was well sur-
 rounded with mortar, or else with grouting.
 It was with the grouting, indeed, that the evil
 at all had its rise. In the days of rougher
 work and wider joints, there was no diffi-
 culty in flushing up the work with mortar or
 with grout. The bond will not allow you to use
 mortar joints in the body of the wall than in the
 face, and as the finer work became the
 custom, and the joints were left unfilled, it
 became the custom to specify careful grouting
 every course. By degrees this degenerated
 to every third, fourth, or fifth course. This
 partial grouting being really of very little
 use, was still again reduced, but the narrow-
 ed joint was left, and it still remains to
 be a witness to the altered condition.
 These evils are but partially remedied by
 adoption of hollow external walls, to which
 really this base and hollow system has
 its rise. The treatment of hollow walls
 has been much controverted. A great
 deal is to be said in favour of making the
 cavity next the outside, as there is also of
 making it next the inside. Some of the evils
 caused may be remedied by filling the hollow
 with a damp-proof concrete, or by re-
 nouncing with cement against the outer face of
 the cavity. The cavity of air is considered
 to be a non-conductor; but if
 the cavity is to be filled with air super-
 saturated with moisture, or if streams of wet
 air drip down its interior, the benefit
 is worse than questionable.

It must draw to a close. If I have been
 able to bring before you anything fresh, or any-
 thing worth further discussion or consideration,
 I must thank our worthy President, at whose
 request I have come forward. I can
 assure that the subject may prove to be as
 interesting to you as it has been to myself.

10th Annual Exhibition of Meteorological Instruments.—Under the auspices of the Royal Meteorological Society, an exhibition of barometers, and of such new instruments as have been invented and first exhibited since the last exhibition, will be opened on Tuesday evening next on the premises of the Institution of Civil Engineers, 25, Great

THE DISPOSAL OF SEWAGE SLUDGE.

ASSOCIATION OF PUBLIC SANITARY INSPECTORS.

At the March meeting of this Association, held on Saturday last, at No. 1, Adam-street, Adelphi, a paper was read by Mr. W. Warner, C.E., of Nottingham, on "The Disposal of Sewage Sludge," Mr. Jerram, the Chairman of the Council, presiding.

Previously to the reading of the paper a proposal was unanimously adopted to support the memorial to the Local Government Board of Mr. Rees, late Sanitary Inspector at Guildford, for an inquiry into the circumstances of the dismissal of the memorialist without reason being assigned, after many years of faithful service. The Chairman pointed to the case as an illustration of the insecurity of the tenure of office of the sanitary inspector. Mr. Rees, at the age of 54, when too old to be eligible for a similar engagement elsewhere, had been suddenly discharged, apparently for no other reason than having ventured to bring to the notice of his Board infractions of the sanitary regulations by certain members of the Board itself.

Mr. Warner, after referring to the outset of his paper to an attempt to deal legislatively with the question of drainage as early as the reign of Henry III.; to the fanning of John Shakespeare, of Stratford-on-Avon, in 1552, for having a heap of refuse before his house in Henley-street; and to a paper on the subject of drainage by Sir Christopher Wren, in 1678, fixed upon the date 1855 as the commencement of the new sanitary epoch. In that year the last cesspool disappeared, and in 1858 the gigantic scheme of Sir Joseph Bazalgette was approved by Parliament, the works at the outfall of the main drainage system being opened by the Prince of Wales in 1865. The offensive and dangerous accumulations which soon afterwards manifested themselves at Barking Creek and Crossness disproved, as a Royal Commission had to admit, the theory that sewage could be at once got rid of by being discharged into a tidal river, and a great variety of inventions had been since produced for dealing with raw sewage. These inventions he divided into three classes, according to the three principles of action involved, viz., irrigation, filtration, and precipitation. Excellent results are obtained at Winchester from the irrigation process, and it is more or less successfully operating in Edinburgh, Carlisle, Nottingham, Leamington, Bedford, and some other towns; but the difficulty of finding agricultural land sufficient for a large city almost precludes the adoption of the irrigation principle in the metropolis, and various gigantic schemes for metropolitan sewage irrigation had come to nothing. The more costly filtration and precipitation processes have had to be resorted to in many towns, one of the most successful being in operation at Southampton. The method adopted there was illustrated by a large scale drawing of the works constructed from the plans of Mr. Bennett, C.E. The most important of the three principles was precipitation, in which the liquid sewage is deprived by precipitation of as great a proportion as possible of the solid matter it contains in solution and suspension, by the application of lime, animal charcoal, different alums and clays, ashes, blood, and other matters. The most conspicuous success had been achieved at Aylesbury with a solid product, native guano, found ready sale at 70s. per ton, and the effluent water was clearer and brighter than the drinking-water of many towns. Alum, clay, animal charcoal, and blood are used in the purifying process at Aylesbury. Good results with analogous processes are said to be obtained at Southampton, Ealing, Hertford, and Coventry. The most perfect of the precipitation schemes, that of Mr. Melliss, C.E., as carried out at Coventry, provides a bed of loamy soil where in vegetables and roots are planted, over which the effluent has to pass after filtration by chemical agents, before it can enter the ordinary water-course. The matter precipitated, termed "sewage sludge," still contains 90 per cent. of moisture, and to extract from 45,000 gallons of it the 2 cwt. of solids they contain is a matter which has employed the highest mechanical skill and inventive genius in the country, culminating in Messrs. Fryer & Allott's mechanical subsider. Bricks made at Leicester by Mr. Monson, and cement made at Burnley under General Scott's process, are illustrations

of other purposes for which the sludge is utilised. From the purely sanitary point of view, the "Destructor," in which the residuum is destroyed by fire, is the most to be recommended. The plan adopted at Ealing under Mr. Jones, C.E., is to pump the sludge into dams containing house refuse, and to burn both in the fiery furnace of a "Fryer's Destructor." The latest developments of mechanical invention have been devoted to a combination of the precipitation and the filtration principles. The invention of Bowing's filter press for yeast and other residues of breweries suggested forms of sewage filter presses which Messrs. Manlove, Allott, & Fryer, of Nottingham, have successfully produced. According to the calculations of Mr. D. K. Clarke, C.E., each of these presses will treat four times as much as the older forms of press, and twenty of them will suffice for the whole of the sludge of the metropolis, which amounts to 4,000 tons every day. Allott's sewage-sludge apparatus, recommended by Mr. Lacey, town surveyor of Brentford, after a careful inspection of all the processes in use, is expected to be in operation in a few days.

In the course of the discussion that followed the reading of the paper, further details of the process carried out at Southampton were given by Dr. Angell and Mr. Bennett, who had accepted an invitation to be present at the meeting for the purpose.

Dr. Angell said that during the past year their efforts at Southampton had been mainly directed to getting rid of lime in the purification process. The effluent produced by lime was extremely foetid and favourable to the development and the support of bacteria, which evolved the foulest forms of gas. The lime effluent passed through some very offensive phases, the trouble not being observed immediately on being discharged into the stream, but beginning three or four miles down the river. The materials substituted for lime at Southampton contained what was called occluded oxygen, and the results obtained had been almost marvellous. The filter presses were marvels of skill, but they did not turn out a substance which was of much use afterwards. The resultant cakes in the Southampton process were saleable at 15s. per ton, but unfortunately the time when they were most anxious to be rid of the stuff was just the time when the farmers were the least in want of it. They had to destroy 4,000 tons of it in the summer, and from a purely sanitary point of view he admitted that to burn it was the only proper way of dealing with the sludge.

Mr. Bennett, C.E., gave some explanations with regard to the details of the process adopted at Southampton. It was a combination of several systems. They employed the carbon process for precipitation, Shone's ejector, and finally the destructor.

The chairman and several inspectors took part in the discussion, and a vote of thanks was accorded to Mr. Warner and to Messrs. Angell and Bennett.

WOODWORK.

SIR,—I am very much interested in Mr. Cruickshank's letter [p. 390, ante] about the woodwork at Beaufort Castle. The few observations I was able to make in my lecture would teach little to those who have made a careful study of the subject, but,—thanks to the *Builder*,—they have penetrated far, and may increase the interest in the treatment of timber which the Carpenters' Company desire to promote.

Modern conditions tend to make the joiner into a machine. The best work he has a chance of doing in the matter of framing is to put together a door with flat narrow panels and heavy bevelled mouldings, and to bang it between jamb-linings and architraves of the most commonplace and mechanical-looking sort. Machinery can do most of this work, and anybody can do the rest. It can be done anywhere and brought over here, so that when the system has reached perfection our joiners will be little more than "fixers." Now there is a vast and little-trodden field for talent in the design and making of a door. What woods shall we use in the different parts and of what substance? How shall the panels be designed, how jointed, and with what mouldings round them? The treatment of the door-jambs will give rise to a dozen interesting questions. Few things are so constantly seen or give such solid satisfaction as a handsome door.

way, internal or external. I was once so struck with the appearance of a Dutchman's front door as to forget that I had rung his bell: so he caught me making a sketch of the panels, which were an inch thicker than stiles and rails, raised with a fine bold ogee curve instead of the ordinary splay, and with a nice moulding on the rising. I have drawn dozens of doors on the Continent and hardly recollect one without a raised panel. It is the same with our old panelled doors and such as are still made in old-fashioned places in this country. We can get the best of such work done here now, but the cost scares us.

It is in the village workshop and on large estates that young joiners and carpenters are most likely to find time and encouragement to perfect themselves in skill of hand and to become accomplished in the management of timber in every stage. Where they can get books and papers treating on such subjects, and particularly if they are within the influence of a class in connexion with the City and Guilds of London Institute, they may have all the advantages of Town training unalloyed. I should think also that a good deal of the money that is now being sent out of the country might find a temporary lodging in their pockets. I have just been shown some specimens of architectural carving in oak with the offer to have my own wood sent over to a small Swiss town to be carved to my own design and returned on reasonable terms. I never saw a "Crofter," but I have seen and admired a good number of Swiss village workmen, and I do not think there is anything so very particular about their brain or muscle that he need fear to try his skill against theirs.

THOS. BLASHILL.

SEWER VENTILATION.

Sir,—In a recent issue your contemporary, the *Lancet*, favoured the public with its opinions on this important subject.

After severely criticising the many foolish notions prevailing, the writer suggests that all sewers should be ventilated by 4-in. pipes, carried up "as perpendicular as possible," above the roofs of the adjacent houses. If it is intended to carry up the pipes from the centre of the streets, this, no doubt, would have an imposing appearance.

I quite agree with the *Lancet* that a great deal of ignorance prevails on the subject. In my humble opinion, sewer-ventilation, as generally spoken of, is all nonsense. Thorough aeration by surface-grates at frequent intervals, and a perfect system of flushing, has, in almost every case within a long and varied experience, prevented the generation of the gas altogether; and I contend that this is the only solution of the difficulty. If space permitted, I should be glad to give some practical illustrations, but will content myself by protesting against the system of keeping fresh air out of the sewers and attempting, by impossible pipes, to get rid of noxious sewer-gases, which ought never to be generated.

SANITARY ENGINEER.

March 4th, 1886.

PLUMBERS' WORK.

Sir,—Will you kindly allow me, as a general foreman, to reply to "A Practical Plumber" [p. 390, ante], whose experience of us must have been either very limited or unfortunate, and whose cool request for yet another trade privilege is so singularly ill-timed.

Your correspondent overlooks the fact that the trade to which an *efficient* general foreman has been brought up is but one of the many things that he has to know, and does know. General foremen, as a rule, are not plumbers, and although probably they cannot wipe joints nor make bends, they are capable of superintending plumbing, and certainly know when it is or is not efficiently executed.

I have known men who, after acting for a short time as plumbers' labourers, have by some means obtained work with the tools, and suddenly blossomed forth into full-blown and full-moneyed plumbers, while yet hardly knowing the right end of a trap. Is it to such a man that architects are to issue instructions, in preference to one who, in all probability, has, before becoming a general foreman, acted for several years as deputy foreman, and has therefore been thoroughly educated in the manifold duties required to be performed by him? Carry a "Practical Plumber's" impracticable suggestion to a logical issue, and its absurdity is at once apparent. If the general foreman is incapable of directing the plumbers, he is equally incapable of directing the men of any trade other than that at which he worked, and an architect must, on each of his jobs, act as the builder's general foreman.

If your correspondent would kindly condescend to emerge from the density of mystery in which plumbers from time immemorial have contrived to enwrap themselves and their trade, and to descend

from the lofty pinnacle from which they are accustomed to look down upon their fellow-workmen, and would answer the pertinent questions so ably put to them in your columns by "G. A. M. B.," he would do much good, and would considerably enlighten us.

I agree that plumbing generally costs more than it ought to do, but the remedy lies in a direction contrary to that which he indicates, and I propose, with your permission, to refer to this branch of the subject in your next issue.

G. W.

March 14th, 1886.

LADY ARTISTS.

Sir,—I notice a remark in your issue of Feb. 27 [p. 325], "Men and women who paint with real power are completely on a level now; there are no 'female disabilities' of any kind." This is not entirely accurate. The Society of Painters in Water-Colours (which you proceed to speak of) still maintains its rule that "no Lady Associate shall in any case become a full member." Surely it is time that this absurd anachronism should be reformed?

March 4th, 1886.

* * * We were certainly not aware of that; if it is correct, the sooner the Society alter such an absurd rule the better. The works of one lady, Mrs. Allingham, are among the chief attractions of their exhibitions, and those of the late Mrs. Angell were equally so.

The Student's Column.

OUR BUILDING STONES.—I.

THE importance of bringing science to bear on the selection of stones for our large public and private buildings is manifest to all who have had to deal practically with the subject. The questions that at first arise are as to what sciences are necessary, and what parts of them particularly apply to it.

The principal object of these articles is to supply material for the outline of a study of the causes which affect the decay of stone, in order that the student may be able to judge of the difference between good and bad building stone, and the selection of stone for particular purposes.

To begin with, after noticing briefly the action of the atmosphere on ancient buildings, we shall pass on to describe the various agents which attack and destroy stone. The artificial methods which have been employed to test the quality and durability of building stones will next be treated of, after which the use of the microscope will be explained in examining them.

A brief description of the common minerals found in the stones, together with their general characters and method of decaying, will be followed by an account of the origin, chemical composition, specific gravity, mode of decomposition, and other characters of some of the principal granites, sandstones, limestones, flags, and slates used in this country for building purposes. The more prominent stones used for ornament will also be described.

The next part will be devoted to the various ways of selecting stone for building, by pointing out where to look for defects and the means of detecting them. The position of the building with reference to the agents which particularly affect the locality, together with some remarks on the best modes of placing stone in building, in order to counteract those deleterious agencies, will then claim attention. The methods which have been employed in hardening stone artificially; and some account of the principal and tried artificial stones, their durability, adaptability for construction and uses as internal ornaments, will form the necessary theoretical part of the work.

Much of the work will, however, be theoretical. Without practice, necessarily, this theory is of little use, and although pointing out the manner in which the theory can be put into practice, the author cannot supply the practical part itself. This rests entirely with the student. No amount of reading can possibly teach anybody the mode of selecting building stones; pieces of the stones themselves must be obtained and studied. How and where to obtain samples of the stone will be pointed out when treating of the examination of stone.

BUILDINGS OF THE ANCIENT AND MEDIEVAL PERIOD.

The ordinary dwelling-houses of the ancient Britons were made of wood and thatched with grass. We learn from Diodorus Siculus, who wrote in the first century B.C. that the Britons

used to store their corn in excavations made in the ground; and this is fully borne out by the numerous remains of these underground repositories, found more particularly in Kent, Essex, and Wiltshire. There can be but little doubt that they also lived in these holes, at least during certain portions of the year, or during a time of danger.

If, however, we may judge from some of the monuments said to have been raised by the Druids, we find that these early people understood the art of working stone for building purposes to some extent.

Stonehenge is an example of this; the trilithons there bearing unmistakable signs of having been rudely shaped and fitted together. When we come to consider the very primitive tools which they must have used in the work, it is marvellous that they should have accomplished such a difficult task. If we may judge from the way in which their work is executed by uncivilised people in other parts of the world, the process must have taken a considerable time. The Sarsen stones from their nature are exceedingly durable. They are, no doubt, the remnants of a tertiary deposit and have resisted the action which caused their surrounding rock, when *in situ*, to decompose and disappear.

Roman masonry was principally of two kinds. The first consists of tiles or flat stones alternating with hands or layers of pebbles or small stones imbedded in mortar. The other variety consists of walls formed of square stones or ashlar, and the interior of rubble imbedded in mortar.

They seem to have discovered at an early period the means of counteracting the destructive action of the atmosphere on their mortar, for we find that after 2,000 years their mortar appears to have undergone little or no change. The Romans understood what does not seem to be comprehended by some modern builders, that, if the work is to be of a durable character, good mortar must be used. The remains of Roman architecture in Britain, however, show us that the workmanship in general was inferior to the buildings executed by them on the Continent. The stone, however, employed in building parts of the Roman Wall is of a very durable character, the peculiar tooling or broaching being quite distinct at the present time.

Many of the works attributed to the Saxons were partly constructed with Roman bricks and tiles. They appear to have tried to imitate Roman work on their capitals, though sculpture is seldom attempted on their doorways.

Illuminated Anglo-Saxon MSS. exhibit "the long and short work" and other distinctive features of the architecture of the period, of which there are examples at Earl's Barton Church, Northamptonshire; Scopning, Sussex; Repton, in Derbyshire; Jarrow, in Monk's Wearmouth; and in the crypts of Ripon and Hexham.

The principal object in view in speaking of the existing examples is to enable the student to see how the stone has lasted in these early buildings. It is necessary, of course, to ascertain which parts of the edifices refer to their respective periods. This, as will be seen, has to some extent been made easy by pointing out the particular parts of the buildings which refer to the period under consideration.

A very useful list of ancient buildings, with the state of their preservation, may be seen in Gwilt's "Encyclopaedia," pp. 470-478.

We have good evidence for believing that the architects of the Middle Ages exercised care in selecting the stone used in their subordinate edifices. Amongst other things, we know that Caen stone was brought from Normandy, held in high repute by them, and was largely employed. We may specially notice that it was used in the Temple Church, and parts of Winchester and Salisbury Cathedrals.

Stone derived either from Normandy or England was not uncommonly employed in Ireland, in structures of the eleventh and twelfth centuries.*

The art of stone-cutting appears to have reached its highest development at the commencement of the sixteenth century; works of this date exhibiting a perfect mastery of the subject.

About the beginning of the seventeenth century the celebrated Portland stone became known.

* Wilkinson's "Ancient Architecture of Ireland," pp. 84, 85.

to be generally used. The various important buildings constructed with this and other well-ried stones used in buildings of subsequent ate, will be treated of when the stones themselves are described.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

2,401, Ventilating Buildings, &c. G. F. Harrington. In arrangements for supplying fresh air to the spaces to be ventilated, self-revolving cowls provided with vanes to cause them to face the wind and may be of a swan-neck form, with vanes of about double the area of their throats. When employed to ventilate drains the cowls are made of a special shape. They are trapped with oil to prevent the escape of wind between them and air shafts, which lead to the spaces to be ventilated.

3,352, Supporting Window Sashes. F. Rowcroft. A wooden roller rests between the edge of the sash and a curved strip of metal pivoted at its upper end, and pressed toward the roller rises and allows it to slide freely, but when the sash is released the roller is pressed against it and holds it. The strength of the spring is adjusted by means of a clip.

11,425, Wood-planing Machines. J. Dent and J. Holt. Scrapers are formed from a thin plate of steel, and are clamped between metal plates. These scrapers are pressed against the rollers of the planing machine, and clean them while the machine is in work.

13,403, Manhole Cover for Drains. H. Colley. The cover has a bevelled edge, and is provided with an annular vertical projection, which drops into a cone filled with glycerine.

14,120, Door Furniture. J. Walker. In the form known as Mace's door furniture an improvement is introduced. A rose is stamped in a circular blank, and a central hole made in the edges of metal round the hole are raised up internally pressed down on the rim of the handle plate.

15,905, Closing Doors. R. S. Moss. Permanent magnets are used to close and keep doors, &c. A magnet is bedded in the jamb, and a piece of steel attached to the door, so that if the door be nearly closed the attraction of the magnet will shut it.

16,781, Window-sash Fastener. J. Walker. An arm turns on a pivot on the meeting rail of sash in the usual manner. A projection on its inside engages in a slot on the slide, and which is drawn across the joint when the arm is pulled over.

MEETINGS.

SATURDAY, MARCH 13. Architectural Association.—Visit to Houses now being erected in Kensington Court. Members to assemble at 8 p.m.

MONDAY, MARCH 15. Royal Institute of British Architects.—Mr. John B. Gass on "Some American Methods." 8 p.m. Society of Arts (Cantor Lectures).—Mr. Boverton Redwood on "Petroleum and its Products." II. 8 p.m. Victoria Institute.—p.m. Philosophical Society of Glasgow (Architectural Section).—(1) Paper by Mr. W. Cairns on "Plumbers' Work." (2) Annual Business Meeting.

TUESDAY, MARCH 16. Institution of Civil Engineers.—Discussion on Mr. Dugald Clerk's paper "On the Explosion of Homogeneous Gaseous Mixtures." (2, time permitting) These papers will be read on "The Economical Construction and Operation of Railways in newly-developed Countries, or where small returns are expected," by Mr. Robert Gordon, Mr. J. R. Mosse, and Mr. G. C. Cunningham. 8 p.m. Statistical Society.—7 45 p.m. Manchester Architectural Association.—Mr. John Holden on "The Duties and Requirements of an Architect's Practice." Nomination of Officers. 7 30 p.m.

WEDNESDAY, MARCH 17. Carpenters' Hall, London Wall.—Mr. John Slater, B.A., on "Concrete." 8 p.m. British Archaeological Association.—(1) Mr. W. de Gray Birch, F.S.A., on "The Legendary History of St. Nicholas of Myra." (2) "Notes on Haslemere," by Mr. Thomas Morgan, F.S.A. 8 p.m. Builders' Foremen and Clerks' Works' Institution.—Ordinary Meeting. 8 30 p.m. Society of Arts.—Mr. Vincent Robinson on "Eastern Carpets." 8 p.m. Royal Meteorological Society.—Mr. William Ellis will give "A Brief Historical Account of the Barometer," at 7 p.m., after which the members will adjourn to the Exhibition of Barometers and other Instruments, at 25, Great George-street.

THURSDAY, MARCH 18. Society of Antiquaries.—M. Galliard on "A Manufactory of Flint Implements at Beger, Gollansee," 8 30 p.m. St. Paul's Ecclesiological Society.—Mr. Charles Brown on "The Knights Templars." 7 30 p.m. Dundee Institute of Architecture.—Mr. W. Mackison on "Environment." 7 p.m. Edinburgh Architectural Association.—Mr. Hippolyte J. Blanc on "A Few Characteristics of Scottish Ecclesiastical Architecture." 8 30 p.m. York Architectural Association.—Mr. Walter G. Peaty on "Terra-cotta." 7 30 p.m.

FRIDAY, MARCH 19. Society of Medical Officers of Health.—Dr. Louis Parkes on "The Sanitary Condition of Poor Districts in the Metropolis, with special reference to their water-closet accommodation." 7 30 p.m. University College.—Professor C. T. Newton, C.B., on "Greek Myths illustrated by Fictile Vases and other Monuments." III. 4 p.m.

SATURDAY, MARCH 20. St. Paul's Ecclesiological Society.—Visit to the Charter-house. 3 15 p.m.

Miscellaneous.

The New London Hospital Medical College.—On Tuesday last the corner stone of the new buildings was laid by Mrs. William James Thompson the wife of the Chairman of the College Board. The college, which is being almost entirely rebuilt, is to be carried out in a free treatment of the Renaissance style, the architectural features being in red brick, the building generally being faced with yellow bricks. The building will, when the works are completed, be well fitted for the high position the college holds among medical schools, being attached to the largest general hospital in the kingdom. The library will be an especially fine room, and the extra cost of decorating it is borne by subscriptions from the staff and other friends of the college, and in future all prize-givings, &c., will take place therein. The building is being carried out from the designs of Mr. Rowland Plumbe, architect; and the builder is Mr. W. Goodman, of Hartham Works, Hartham-road, Holloway, N., who have just completed the new Nursing Home, which has been built by the hospital authorities to accommodate over 100 of the nurses and probationers. Mr. Thornhill, the surveyor to the hospital, is acting as clerk of the works.

Obituary.—Mr. G. Bouvier Goddard, an animal painter, whose numerous works have from time to time been favourably noticed in these columns, died at his residence, on Brook Green, Hammersmith, on Saturday, the 6th inst., after a short illness, due to exposure to this bitter weather. He will be remembered best by his large picture of Lord Wolverton's Bloodhounds, which was exhibited in the Royal Academy rooms in 1875, and his "Struggle for Existence," bought from the Academy walls by the trustees of the Liverpool Walker Fine Art Gallery. His later works, "Rescued" and "Love and War," showed him to have attained a mastery over the technique of his art which promised him a successful career as a painter of the special class of subjects to which he had devoted his talents. He was but fifty-two years of age at his decease.

The London Parcels Delivery Company's New Offices and Stables.—A new block of buildings for the London Parcels Delivery Company, consisting of offices, stables, and vans, has just been erected in Rolls-place, Fetter-lane, on a vacant plot of land immediately to the west of the new Birkbeck Institute. The Rolls-place frontage is about 40 ft. in length, the premises being carried to a depth of upwards of 100 ft. northward, in the direction of Bream's-buildings. They consist of a deep basement, together with ground and two upper floors. The ground-floor portion of the frontage is carried up by massive piers in blue Staffordshire brick, the upper storeys being faced with stock brick. About one half of the area of the ground-floor is intended for offices, and the remaining portion to the rear for the Company's vans, access being obtained by a central gateway. The first floor will be occupied as stables, whilst the second floor will be appropriated as fodder-stores. All the floors, from the basement upwards, are supported on iron columns; and, as a precaution against the outbreak of fire, every floor is fireproof, as well as the roof of the building. Mr. W. S. Witherington is the architect, and Messrs. Patman & Fotheringham are the contractors. The cost of the building will be about 6,000l.

Extensive New Suburban Building Undertakings.—Several extensive building projects are at present in course of development in the neighbourhood of Earlsfield, Garret-lane, Wandsworth. The Maxwell Farm Estate, belonging to Magdalen College, Oxford, containing 240 acres, extending from the boundary of the London and South-Western Railway on the north, to Burntwood-lane on the south, and stretching from its western boundary in Garret-lane to Trinity-road, and the high ground in the neighbourhood of Wandsworth County Prison, on the east side, is about to change its present agricultural character, the owners having decided to lay it out for building purposes. Between five and six miles of roads will be formed on the estate by the College authorities. It is estimated that the estate will admit of the erection of no less than 6,000 houses. On the north side of the railway an estate, having its frontage in Earlsfield-road, and stretching northwards in the direction of St. Anne's Hill and Wandsworth Old Town, has been purchased by the British Land Company, who have laid out several roads for the erection of upwards of 600 houses.

The War and Admiralty Office.—Referring to the memorial of the Institute on this subject (see *Builder* for last week, p. 367), the *Saturday Review* says:—"None too soon, hut, we should trust, not hopelessly too late, the Royal Institute of British Architects has bestirred itself in the discharge of duties for which it exists, and struck a blow to save London from a great architectural calamity. The question is not one of better or worse, but of the creation or rejection of that great main avenue of London, an avenue of varied interest and of unequalled historical association, of which the eastern terminus would be St. Paul's, then Fleet-street and the Strand, then Charing Cross, and then the leafy Mall and Buckingham Palace. All these familiar names and famous spots would be, were the scheme of the Institute to be adopted, brought into one street. Is this an occasion to palter and huckster?"

Woodworking Machinery.—Messrs. A. Ransome & Co., of Stanley Works, Chelsea, have sent us their new illustrated catalogue of patented and improved woodworking machinery manufactured by them. It consists of upwards of 200 pages, and is very fully illustrated. The letterpress descriptions are copious and clear, and the catalogue will certainly be of great assistance to intending purchasers and users of woodworking machines, which are now exceedingly numerous and varied in their powers. The catalogue will be found very useful for reference in builders' offices.

The Hyde Park Corner (New Streets) Bill.—In the House of Commons last week this Bill was read a second time and referred to a Select Committee. Mr. Leveson-Gower, in moving the second reading of the Bill, explained that the necessity for its introduction had been brought about by the changes which were made at Hyde Park-corner in 1883. Usually new streets were maintained by the parish in which they were situated, but in the present case difficulties arose.

Voussoir Arches.—At the Students' meeting of the Institution of Civil Engineers, held on Friday, 26th ult., Mr. W. H. Barlow, F.R.S., past-President, in the chair, Mr. H. A. Cutler read a paper on the "Stability of Voussoir Arches." The author asserted that the commonest method of the mathematical analysis of stresses, though more strictly accurate, is in most cases so complicated that the graphic method is preferred, not only for its simplicity and expedition of solution, but also for the readiness with which errors may be detected by it. The factor of safety required in practice so limits the application of theory that rigid accuracy in the determination of stresses is unnecessary. The tenacity of mortar being disregarded, the voussoir arch is not capable of resisting a bending moment, and may be considered as hinged at every bed joint in the arch ring. To investigate the stability of an arched structure by the graphic method, it is first necessary to find the correct curve of equilibrium for the dead load, or weight of the structure, and then assume the live load acting on one half the arch, while the remaining half is unloaded, and to construct a second curve, both of which should satisfy certain conditions. In voussoir arches, in almost all cases, both the dead and moving load may be considered as acting vertically. When the curve of equilibrium does not fall within the arch-ring a bending moment is produced, tending to increase the curvature of the arch lying inside the neutral line, and to diminish it if lying outside. Voussoir arches not being capable of resisting a bending moment, the condition to be fulfilled is that the curve of equilibrium must practically coincide with the neutral line. The arch would not collapse so long as the curve was everywhere within the depth of the arch-ring, but when close to the edge nearly all the strain is taken through a small portion of the voussoir. Prof. Rankine limited the curve of equilibrium to the middle third of the arch-ring, which may be accepted as a simple practical rule. The curve of equilibrium is found by fixing the points in the curve somewhere within the middle third, at the crown and springing. If the deviation of the curve from the neutral line be not within the limit at every other point, either the loading, the curve of the arch, or the depth of the voussoir must be altered.

The London Sewage Question.—At the meeting of the Metropolitan Board of Works this Friday, March 12th, the Works and General Purposes Committee will present a report detailing the several steps taken in connexion with the metropolitan sewage, and recommending that letters be founded upon the Report, be addressed to the Secretary of State and the British Local Board of Health in reply to their communications on the subject. Also recommending that the Engineer and Chemist be authorised to incur the working expenses necessary for the treatment by precipitation, &c., of nine millions of gallons of sewage daily at Crossness, such expenditure not to exceed the sum of 7,000l.; and that the necessary wooden tanks, &c., required for deodorising purposes be erected at various points on the lines of main sewers within the metropolis, at a cost of about 1,000l.—At the last meeting of the Board, Mr. Fardell called attention to the subject, on the ground of urgency, in view of the approaching summer; but for presuming to suggest that the Committee might at any rate report piecemeal, like some Royal and Parliamentary Commissions, he raised quite a hornet's nest about his ears, although, as a sympathiser suggested, his only desire was to "oil the wheels" of the Committee, and, consequently, to accelerate their motion. At the same meeting of the Board, the further consideration of the Report of the Special Purposes and Sanitary Committee on the Cleansing and Ventilation of Sewers, already noticed by us, was again deferred for a period of six weeks.

Relief to the Unemployed.—Owing to the prevailing distress Messrs. Perry & Co., builders, Tredegar Works, Bow, have inaugurated an unemployed relief fund, which is to last several weeks. Their employees have responded liberally to it, the firm adding their weekly contribution. A number of cases have been investigated by the committee appointed, the result being that relief is afforded expeditiously.

Sanitary Institute of Great Britain.—The Autumn Congress and Health Exhibition of this Institute will be held in the City of York in September next.

Royal School of Mines.—Professor Warrington Smyth, F.R.S., in concluding his lectures on mining, in the theatre of the Geological Museum, Jermyn-street, said, there can now be no doubt that the Newcastle roads, as the tramways were called, were in use long before the introduction of iron rails, wooden beams being employed; the wear and tear there soon caused them to lay an iron plate on the top. About the same time, Mr. Carr, of Sheffield, proposed various improvements in underground transport. Among these was the laying down of tram plates,—a simple iron plate with a flange to it,—which was so great an improvement that one horse could then draw several carriages. The rails were first of a very simple character, merely a bar of iron let into a slot; in these broad wheels run, but the wear is so considerable that where there is a large amount of material to be carried the rails approach to the kind in use on surface railways. Nothing, perhaps, is more frequently employed on mining railways than the bridge rail so familiar on the Great Western Railway; the T-headed rail and the double T-headed are also sometimes used; while another form often adopted is that of a T-rail, with a broad base, in which are a number of holes for spiking it down. These rails weigh 12 lb. to 15 lb. to the yard, or, where special strength is required, as much as 25 lb. A common gauge for underground mining railways is 2 ft., in other cases 18 in., while in others again, as in the ironstone mines of the North, where they work with large quantities of timber, it may be only 12 in. In conclusion, the lecturer took occasion to impress upon the students the necessity in all mining operations of a thorough knowledge of geology and mineralogy, by which, on the one hand, we learn to recognise what are the best districts in which to search for mineral, and on the other, to recognise the minerals themselves, as also those with which they are usually associated, and particularly in order to determine what is the relation between two sets of rocks.

Housing the Working Classes.—The nineteenth annual general meeting of the Artisans, Labourers', and General Dwelling Company, Limited, was held on Tuesday, 11th inst., Mr. Ernest Noel, M.P., presiding. The report showed that the rental for the year 1885 amounted to over 90,000l., the net revenue being 61,494l., out of which interest dividends upon the preference and ordinary capital amounting to 28,621l., had been paid. It was now proposed to pay a dividend of five per cent. on the ordinary share capital for the second month of the year, carrying over 4,000l. to the accounts reserve, and 1,141l. to next year's accounts. The increase of capital during the year had been 62,450l.; the total amount paid up to 31st of December was 1,234,310l., the authorised capital being 1,000,000l. in ordinary shares, and 750,000l. in preference shares 4 per cent. The completed estates of the company in London are Shaftesbury Park, S.W., at Queen's Park, W., comprising nearly 3,000 separate houses. At Noel Park, N., the new estate of the company, work had progressed so that at the close of the year 974 houses were completed, 680 being let and occupied. The estate when completed will comprise 2,600 houses. The directors have acquired a good site of over an acre in Lisson-grove for the purpose of erecting block-buildings as dwellings for the Industrial Classes. The report and accounts having been adopted, and the dividend of five per cent. declared, the retiring directors and auditors were re-elected, and a vote of thanks concluded the proceedings.

Tunbridge Wells Water Supply.—In the *Builder* for the 19th of December last, p. 81, we reported the completion of the new storage reservoir at Pembury, and printed the speech of the engineer (Mr. Brentnall) describing the work, in which there were some departures from ordinary practice in carrying out such undertakings. We are sorry to learn from the *Tunbridge Wells Gazette* that a month ago it was discovered that there was a leakage in the reservoir, and, on the reservoir being emptied, several cracks were found in the asphalt forming the bottom of the reservoir.

A Knighthood for an Engineer.—It is stated that the Queen has signified her intention to confer the honour of knighthood on Mr. Charles Douglas Fox, of Coombe Spring, Kingston-on-Thames, in connection with the engineering work of the Mersey Tunnel.

Gift to the Wolverhampton Art Gallery. The Wolverhampton Chronicle announces that a new gallery picture has been offered to the town through his Worship the Mayor, by Mr. Councilor Ross. It is the work of John Wilson, sen., R.S.A. The subject is a stormy sea seen from a wild shore near the Bass rock.

TIMBER (continued). Table with columns for item, quantity, and price. Items include Basso, Rio Bahia, Bor, Turkey, Sain, St. Domingo, Porto Rico, Walnut, Italian.

METALS. Table with columns for item, quantity, and price. Items include Iron-Pig in Scotland, Bar, Welsh in London, Sheets, single, in London, Hoops, Nail-roads, Copper, British, cke. and ingot, Best selected, Sheets, strong, India, Australian, Chili, bars.

YELLOW METALS. Table with columns for item, quantity, and price. Items include Lead-Pig, Spanish, English, com. brands, Sheet, English, Spelter, Silesian, special, Ordinary brands, Tin, Banca, Billiton, Straits, Australian, English ingots.

ZINC. Table with columns for item, quantity, and price. Item: English sheet.

OILS. Table with columns for item, quantity, and price. Items include Linseed, Cochin, Ceylon, Copra, Palm, Lagos, Palm-nut Kernel, Refined, English pale, Brown, Cottonseed, refined, Tallow and Oleine, Lubricating, U.S., Beffined, Turpentine, American, in casks, Tax-Stockholm, Archange.

CROYDON.—For additions to the Public Bath, for the Corporation of Croydon. Mr. Thos. Walker, Borough Engineer. Quantities by Mr. Robert Bidge, Katharine-street, Croydon: Gregory & Findley, Graves & Co., Holloway, Barton, Genny, Dickenson, Walker, Bryan, Page, Nield & Harper, Deacon, Smith & Balled, Sanders, Roberts, G. N. Wyatt & Co. (accepted).

Frinton.—For drainage in Field-road, Frinton, near Clacton-on-Sea. Mr. E. C. Homer, surveyor, London: Dixon & Co., N Waterman, W. G. Gillingham.

FULHAM.—For stables, &c., Star-lane, Fulham. Mr. B. J. Capell, architect: Scribner & Co., Holliday & Greenwood, W. Shurmer, Catmar, Jackson & Todd.

HADLEY WOOD.—For six houses on the Beech Hill Park Estate. Mr. Edwin T. Hall, architect, Moorgate-street: Foster & Dicksee, Rugby.

HIGHGATE.—For the erection of chancel end to St. Augustine's Church. Mr. J. D. Sedding, architect, Oxford-street. Quantities by Messrs. Nixon & Baven, Westminster: A. J. & J. Greenwood, Mowlin & Co., Bone, Dove, Stimpson & Co.

ISLINGTON.—For rebuilding Nos. 511 and 513, Liverpool-road, Islington, for Mr. F. Yardley, Messrs. George Carter & Son, architects, Holloway-road: Riches & Mount, Battersea, Parker, Peckham, Haines, Harrow, Garrud & Son, Hackney-road, Boreham, Bride-street.

ISLINGTON.—For the extension of shop and stables for Mr. J. Walkley, Elthorne-road, Messrs. George Carter & Son, architects, Holloway-road: Baker, Hornsey-rise, Beave, Norris & Luke (accepted).

LONDON.—For making certain alterations to No. 67, Leadenhall-street, City, for the Egyptian Cigarette and French Government Tobacco Company. Mr. H. I. Newton, architect, Queen Anne's-gate, S.W.: Cook, Godden, Bryman & Sons, Bryant (accepted).

LONDON.—For painting, repairs, &c., at the Public Baths and Washhouses, Endell-street, St. Giles', W.C. Mr. J. Waldram, surveyor. Quantities not supplied: Ansell, Hensman, Styles & Son, Sykes & Son, Munday & Son, J. Hicks, Gover & Son, J. B. Arford, Surveyor's estimate.

LONDON.—For the erection of a 2-h.p. "Otto" gas-engine, pumps, &c., at the Workhouse, Poland-street, W., for the Guardians of the Westminster Union. Mr. Jno. Waldram, engineer: Z. D. Berry & Sons, Crossley Bros. Limited, Merryweather & Co., Shand, Mason, & Co., Wilkinson (late Best & Co.) (Accepted).

LONDON.—For works at the City of London Brewery Mr. J. Jewhurst, architect: Langmead & Vay, Canning & Mullins, W. Shurmer, Wontner Smith, Burch & Co., Dixon & Co., Spencer & Co., Jackson & Todd.

LONDON.—For the erection of premises for the London and Provincial Banking Company. Mr. Horace Chester, architect: T. Boyce, C. G. Conroy, W. Shurmer, Paine Bros., J. Morter, Lawrence & Son, M. Taylor, W. Shepherd.

PRICES CURRENT OF MATERIALS. Table with columns for item, quantity, and price. Items include Ironheart, B.G., Oak, E.I., Spruce, U.S., Canada, Birch, Danstic, Canada, Pine, Canada, Yellow, White, Pine 1st, Pine 2nd, Spruce 1st, Spruce 2nd, Spruce 3rd, Pine 3rd, Pine 4th, Pine 5th, Pine 6th, Pine 7th, Pine 8th, Pine 9th, Pine 10th, Pine 11th, Pine 12th, Pine 13th, Pine 14th, Pine 15th, Pine 16th, Pine 17th, Pine 18th, Pine 19th, Pine 20th, Pine 21st, Pine 22nd, Pine 23rd, Pine 24th, Pine 25th, Pine 26th, Pine 27th, Pine 28th, Pine 29th, Pine 30th, Pine 31st, Pine 32nd, Pine 33rd, Pine 34th, Pine 35th, Pine 36th, Pine 37th, Pine 38th, Pine 39th, Pine 40th, Pine 41st, Pine 42nd, Pine 43rd, Pine 44th, Pine 45th, Pine 46th, Pine 47th, Pine 48th, Pine 49th, Pine 50th, Pine 51st, Pine 52nd, Pine 53rd, Pine 54th, Pine 55th, Pine 56th, Pine 57th, Pine 58th, Pine 59th, Pine 60th, Pine 61st, Pine 62nd, Pine 63rd, Pine 64th, Pine 65th, Pine 66th, Pine 67th, Pine 68th, Pine 69th, Pine 70th, Pine 71st, Pine 72nd, Pine 73rd, Pine 74th, Pine 75th, Pine 76th, Pine 77th, Pine 78th, Pine 79th, Pine 80th, Pine 81st, Pine 82nd, Pine 83rd, Pine 84th, Pine 85th, Pine 86th, Pine 87th, Pine 88th, Pine 89th, Pine 90th, Pine 91st, Pine 92nd, Pine 93rd, Pine 94th, Pine 95th, Pine 96th, Pine 97th, Pine 98th, Pine 99th, Pine 100th.

CONTRACTS AND PUBLIC APPOINTMENTS.

Epitome of Advertisements in this Number.

CONTRACTS. Table with columns: Nature of Work, or Materials; By whom required; Architect, Surveyor, or Engineer; Tenders to be delivered; Page. Items include Premises, Sewers, Paving and Concrete, Paving and Concrete, Cleaning and Dust Collecting, Contracts, Building Materials, Shop and Cambridge Heath, Billings Premises, Streets Works, Footway Pavements, Police Station, Bridge, Works, East Extension, Repairs, Sinking, Granite, Factory, and Six Houses.

PUBLIC APPOINTMENTS. Table with columns: Nature of Appointment; By whom Advertised; Salary; Applications to be in; Page. Items include Surveyor, Executive Engineer, and Surveyors.

TENDERS. Table with columns: Item; Amount; Name. Items include RUCKHURST HILL, CLAPTON, MLEY (Kent), A. A. Mitchell, Adcock, J. Arnaud & Son, and withdrawn.

LONDON.—For building a new dining saloon at the rear of 25, Chapel-street, Edgware-road, for Messrs. Beggins Bros. Mr. Robert Willey, architect, Ludgate-hill:—

Marks	694 0 0
Larter & Sons	82 0 0
Penny & Durrant	757 0 0
Turtle & Appleton	675 0 0
Jones & Sons (accepted)	580 0 0

LONDON.—For rebuilding No. 374, Euston-road, Mr. Robert Willey, architect, Ludgate-hill:—

Woodward	£1,600 0 0
Rhodes (accepted)	1,453 0 0

LONDON.—For works at the Marquis of Anglessa public-house, Devonshire-street, Lisson-grove. Mr. R. A. Lewcock, architect, Bishopsgate-street:—

Heath	Feasting, Counter, &c.	£266 0 0
Winn	Ousfitings	98 0 0

LONDON.—For works at the Jolly Butchers, 261, Old-street, E.C. Mr. R. A. Lewcock, architect, Bishopsgate-street:—

Worth's "History of Devonshire."

Worth's classes of publication are so entertaining as a county history,—so comprehensive, so various, embracing every subject that can interest reasonable man,—history, religion, politics, science, art, literature, folk-lore, superstition, and touching lightly upon all. The ear old folios of our learned forefathers, with their sweet credulity, their appetite for the marvellous, their complacent garrulity about their own times, their vehement patriotism and loyalty, and their ever-ready explanations of the inexplicable, have delighted generations of readers. Even now, in its modern and mutilated form, shorn of its peculiar charms, and filtered through the fine sieve of a sceptical generation, the county history holds a high place in our affections. With what a wide charity does it admit all subjects within its hospitable covers! How truly catholic is its range,—a vast trajectory, an infinite curve, reaching from yesterday to the "first syllable of recorded time" and beyond, to epochs social, inter-glacial, pre-glacial, too remote for the companionship of the halcyon imagination. British, Roman, Saxon, Danish, Norman hosts, in vast processions, march by in melancholy pomp; and warriors, in quick succession, cross the historic stage like phantoms of Macheth's vision. The ravages of war, the triumphs of peace, alternate alarm and elate us as we follow the equated record. Deeds of personal prowess for our chivalrous sympathies. The wit and wisdom of twenty generations are, for our edification, crystallised into proverbs. The mutter of the monk, the cry of the poor, and the sighs of hapless lovers, are audible in every age, and over all alike death, "pallid death," lies the inexorable doom. It is a book for every mood, and all occasions of study or leisure, yielding a generous return for invested time. The author is independent of rule and restriction. He may linger lovingly over his subject and present it to us with elaborate detail, or pass swiftly from point to point "with the motion of a pewterer's hammer." The aptness of his transitions does but give briskness to his narrative. He always has, moreover, the most interesting of all the counties as a field of his peculiar labours. In the present volume he deals with one which is "all but the

largest in the kingdom, which has afforded the earliest traces of man in these islands; which has never, from the dawn of recorded history, occupied a secondary place in the national life; which again and again in the hour of England's need has found the man" (who surely ought to be rewarded with a capital M); "whose worthies century by century claim the first rank in every class,—soldiers, sailors, lawyers, divines, inventors, poets, artists, explorers, statesmen, men of science. . . the history of such a county is the history of England," &c., &c. This is the true temper of your county historian; let us see how the author of this history of Devonshire, the land of deep valleys, has acquitted himself. In the first place, his hook is without a map, and this we take to be an inexcusable fault. We will waive the time-honoured engravings of the "principal seats," the coats of arms, remarkable inscriptions, &c., not without a sigh; but a map is absolutely essential to a well-regulated county history. Failing that, we should at least have such a description of the county as would enable the reader mentally to supply the omission. We are not possessed by any morbid craving for mere statistics; but we feel that we have a right to know the area of the district dealt with, its population, soil, main divisions, length of seaboard, its maritime and topographical features, &c., all of which might have been projected in a word-picture if not on a map. The flora, if not the fauna, of Devonshire, should certainly have a chapter to itself. The author has after much deliberation elected for an order "mainly topographical," taking separately such prominent places as Exeter, Plymouth, Tavistock, Crediton, and treating in separate sections of the history and peculiarities of each. In other words, his is not a history of the county as a whole, but of the individual lives of the chief places in it. The narrative loses in breadth and continuity by this treatment, which, moreover, involves a great amount of otherwise avoidable repetition. The whole work suffers somewhat from this fragmentary method of dealing with the subject. The architecture of the county, to wit, is not presented at one view, but in isolated references to individual examples, and those who desire to obtain a general idea of the special characteristics which differentiate the architecture of our principal western county will not find it in the present history. But they will pick up a good deal of desultory information on that and many other subjects,—stray facts about geology, genealogy, climate, historical vicissitudes, local customs, place-names, interspersed with biographical notices of famous Devonians of all times and conditions, from Ælfred,—if, indeed, he were a Devonshire man,—to Sir

John Bowring. The first and last chapters depart, however, from the general scheme: one gives in a connected form the early history of Devonshire, and the other its dialect and folk-lore; and these will, we venture to think, be read with greater interest than any of the others. The prominent facts connected with the early history of the county are its very partial occupation by the Romans, only one Roman station of note,—to wit, Exeter,—being within its confines; and the peaceful colonisation of the county by the Saxons who "annexed" it without conquering it, and finally ousted the Celtic population cuckoo-fashion, driving them westward, and re-settling the evacuated country somewhere between the year 710 and 823. "The constitution of Devon is," says Mr. Worth, "purely Saxon. Each of its hundreds has a Saxon name, and each of its municipalities originated in a Saxon community."

In the chapter on dialect and folk-lore the Devonshire speech is claimed to be "the true Classic English. The English of Alfred's time is the groundwork of modern English; in his day it was the polite, the courtly, the literary, in fact, the standard form of speech; and Alfred, a West countryman, spoke *most likely* in Devonshire style." Until 1100 the language of Alfred, or Ælfred, remained the only written English. It was to the accident that the great writers of the fourteenth century, the first to have their writings disseminated by the newly-invented printing-press, were Midland men that the fixed or book language varied from that of the Saxon king, Chaucer's "well of English undefiled" not having the true antique savour. Some compensation for the wrong thus done to the Western dialect was made when the heroes of Elizabeth's reign,—mostly West countrymen,—brought their local dialect to the court and again made it fashionable, "making its rugged sounds dear to all who valued stoutness of heart, and especially to the great queen herself." It appears to have been always the fact that in the really Classic English of Devonshire "everything is *he* except a Tom-cat, and that is a *she*." The true native dialect is now most marked in the Dartmoor district, although it may still be heard in Exeter; but along the Tamar it has been adulterated with Cornish idioms, and Plymouth, "the Cornishman's London," has further sophisticated the current speech by an alien Irish element. The etymology of the Devonshire place names is particularly interesting, and must be followed by the curious reader in the hook itself. Superstition has maintained a stronghold in the West, living animals having within memory been burned alive to avert the loss of others; puppies are still buried in a

A History of Devonshire, with Sketches of its Leading Cities. By R. N. Worth, F.G.S., &c. London: Elliot & Clark, 1886.

field to cleanse it of weeds; toads are cruelly destroyed as emissaries of Satan; and the sun is firmly believed to dance on Easter morning. Sir Francis Drake, the foremost of Devon's worthies, is reputed to have worked by magic, firing a cannon-ball through the earth to prevent his wife committing bigamy; and it is still believed that if you have the courage to call him by beat of his old drum he will promptly obey the call.

As usual, sad stories of the cruelties practised upon old women who were reputed witches re-appear,—the last execution of the kind but one in the kingdom taking place at Bideford in 1682; and the tragedy is darkened by the fact that the poor creatures almost invariably confessed their guilt, and gave circumstantial accounts of the devil's appearance to them "as a gentleman," "a lion," and so forth. Three of the most "old, decrepit, despicable, miserable creatures" that an eye-witness ever saw were hanged at Exeter as a consequence of their own confessions against themselves in 1695. And it is humiliating to find that, although the cruel laws against witchcraft have been repealed, and a poor woman may now be old and ugly without being hanged or burned for it, the belief in witches and their powers for evil is still strong in the West.

A large part of the work is naturally taken up with incidents connected with the civil wars and the Rebellion; and in those troublous times, by one misadventure and another, the old halls and mansions, which were numerous in the county, were either wholly destroyed or irremediably ruined.

They are not described at such a length as we could desire; but although little is said about them, they are evidently touched upon with competent knowledge of their characteristics, dates, and their proper places in the annals of our domestic art. Ford Ahhey, a remarkable example of monastic building adapted to domestic wants, partly, it is said, by Inigo Jones, and fresh in the memory of every one who has seen it, lovely in its partial decay, from the banks of the beautiful river Axe, has a little more attention bestowed upon it; but, as a rule, a sort of hasty guide-book reference is all that the author can afford.

With the anecdotes connected with the history of each town, the personal gossip, the local worthies, the strange customs, the survival of otherwise obsolete forms of land tenure, and the multitude of interesting facts bearing generally upon the county and its doings from time immemorial, we have no space to deal. We have much to thank the author for; but from our own particular point of view much is wanting to make his history perfect. It may be read as a critical commentary on earlier folios; but though it may usefully correct them in points wherein they were misdirected, it cannot be accepted entirely in substitution of those delightful, though perhaps desultory and somewhat inaccurate, treatises.

THE NEW RAILWAY BILL.

THE measure just introduced by Mr. Mundella dealing with railway and canal traffic is a bold and honest attempt to grapple with a question of great complexity and difficulty. This was recognised by all parties in the House, and the right hon. gentleman's effort is evidently better appreciated than any previous attempt in this direction. Of course, he had the benefit of the experience of his predecessors (which he acknowledged most fully), and, moreover, was aware of the objectionable features in previous measures which rendered them unacceptable. There is very much in the Bill that was to be found in that prepared by Mr. Chamberlain in 1884. Indeed, some points that provoked the greatest opposition on that occasion are incorporated here, though in a somewhat different form. Some are based upon the Reports of the different Committees which have from time to time investigated the subject; while in others,—in spite of the statement of Mr. Jeffers, C.E., quoted in our "Notes" of the 6th inst., that the opinions of Americans on such matters are unheeded on

account of prejudice,—Mr. Mundella admits that he is following precedents set by the legislation of the United States.

The first part of the Bill deals with the Railway Commission. The functions of this body were treated of at length in our issue of May 23rd last, when it was remarked that it had proved itself of sufficient value to be constituted a permanent tribunal. We are glad to see that this is provided for by the Bill, the Commission being made a permanent Court of Record. It is to be further strengthened by the appointment of a Judge of the High Court as Chief Commissioner. Although the general opinion of the House was that the judgments of the Commissioners had given satisfaction, Sir J. Pease complained that in some cases they had acted weakly. That some of their decisions have not been effective is due more to their uncertain tenure of office, and the liability of their decisions to reversal, than to any lack of ability to appreciate and adjudicate upon the causes brought before them. With a Judge as President, however, the decisions of the Court will have a force which should have the effect of precluding appeal, and thus simplifying the cases brought before it. Indeed, no appeal will be allowed except upon questions of law. Mr. Mundella hopes, however, to introduce a system of arbitration by which litigation may be, to a great extent, avoided. The proposal is to empower the Board of Trade to receive complaints from persons who consider that they are being treated in an oppressive or unreasonable manner, and, if they think there is reasonable ground for complaint, to call upon the railway company for an explanation. A competent person is to be appointed to confer with the complainants and the railway company, and endeavour to arrange an amicable settlement. Reports of such proceedings, with observations thereon, are to be submitted to Parliament, and would furnish valuable aid for further legislation. This idea is borrowed from the Americans, who have found it answer admirably. The publicity thus given to different complaints and to the arguments on both sides must be very useful to the public as well as to Parliament, and the system is guarded against abuse by the imposition of a small fee on receiving complaints. Sir R. Webster, while agreeing with the principle of negotiation, where practicable, expressed a certain amount of scepticism as to the probable efficacy of this arrangement; but, to the legal mind, perhaps, arbitration does not so readily commend itself as to others. Another useful provision is that giving a *locus standi* to councils, chambers, associations, &c. This clause is most comprehensive and valuable, especially as the decision of the Commissioners on this point allows of no appeal, and public bodies are allowed to apply corporate funds to any expense incurred in bringing cases before the Court.

The most important clause is that dealing with the rates and charges. It requires every railway company, within twelve months from the commencement of the Act, to submit to the Board of Trade revised specifications and schedules of their maximum rates and charges. Mr. Mundella showed that the Act of 1845 gave the House the right to demand this, and to exercise control over the rates, and impose such conditions as it may consider desirable. To meet the "terminals" difficulty,—the rock upon which so many attempts to settle the railway rate question has split,—it is provided that where such charges are proposed to be made, the circumstances and nature of the charge are to be fully stated. The Board of Trade will make the new classification and schedules public, and receive representations from any parties against the proposals. The Department will then undertake their final revision, and submit them to the House. Most of the railway companies have such classifications and schedules already prepared, and we may take it for granted that they will re-introduce those which the House declined to consider last year. The present measure is so far on the lines of that prepared by Mr. Chamberlain that it throws upon the companies the onus of bringing forward new classifications, &c.,

but, whereas he would refer them to the Railway Commissioners for revision, Mr. Mundella considers that the Board of Trade ought to undertake this work. Again, Mr. Chamberlain's plan for dealing with the terminals was to insert a clause worded as follows:—"It shall be lawful for a railway company to charge a reasonable sum for such terminal, subject, in case of dispute, to the sanction of the Commissioners who may prescribe the manner in which the scale of such terminals shall be published." Although it was further provided that "the provisions of this clause as to terminals shall not apply to any railway company until their revised classification and rates have been approved by Parliament," the traders naturally took fright at the indefinite power which (subject to costly appeal) the companies would thus possess with regard to terminals. In the present case they must first show that they may reasonably claim them, and give all details and particulars, and then take the decision of Parliament. There is plenty of time given for the preparation of these particulars, for the twelve months' grace dates from the 1st of October next.

The burning question of undue preference is dealt with as follows:—On proof of inequality in charges the burden of showing that it does not constitute any undue preference shall lie upon the railway company. The question is to be decided by the Commissioners, and they are to have power to take into consideration whether reduced charges are necessary for the purpose of securing the traffic in respect of which they are made. This is in recognition of the principle enunciated by the Committees of 1867 and 1872, who came to the conclusion that it is impossible to draw a hard-and-fast line as to equality in charges, as special circumstances frequently call for special rates, which do not operate to the prejudice of any person or class. Of course, if such prejudice is shown to result from this practice it will not be allowed to continue. It is quite as impracticable to make equal mileage rates binding under all circumstances, and it is provided that the companies may charge "group" rates, where it is found desirable. In this also the rights of the public are safe-guarded, for it will not be allowed where it would favour any particular person to the prejudice of another.

The remaining provisions of the Bill deal with statistics, methods of proceeding, definitions of terms, &c., and are of little public interest. As Mr. Mundella stated, it appeared that many of the grievances to which such prominence has recently been given could have been remedied by existing Acts, while others (as we recently took occasion to remark) could not be substantiated; but the present measure aims at simplifying proceedings by defining more clearly the rights and powers given to the companies. The favourable reception given to the first reading of this Bill augurs well for its success, though there will doubtless be objections raised to some of its provisions when it is considered in detail. A thoroughly satisfactory solution of the many vexed questions involved cannot be looked for in a single measure, but it seems calculated to do much towards settling some of the most pressing of them.

NOTES.

THE rejection of the vote of 50,000 odd by the House of Commons last week for the maintenance of the London Parks leaves them at present without any fund. This will, it seems, be met by a Bill handing the control over to the Metropolitan Board of Works of those which are not so-called Royal Parks, and enacting that the cost shall be defrayed from the rates, and obtaining a fresh vote for the Royal Parks. In theory there can be no doubt that London should pay for its own parks; there is no more reason why the country at large should pay for Battersea Park than for Sefton Park, at Liverpool. On the other hand, it must be admitted that the Metropolitan Board of Works have quite sufficient on their hands at present without the London

parks being added, and the ratepayers have far too little direct control over the expenditure of the Metropolitan Board of Works for it to be altogether satisfactory to see them entrusted with the collection and expenditure of the park funds. However, the House of Commons have so bid, and there is no more to be done except for Londoners to take care that whatever body looks after its parks in future they shall at once be watched over with care and intelligence and without extravagance as well as without cheseparing.

THE Metropolitan Board of Works cannot justly be accused of undue haste in their procedures for defecating the Thames. The treatment of 9,000,000 gallons a day, for which one of the reservoirs at Crossness is to be set aside, is, no doubt, an experiment on a large scale. But as far as the pollution of the river is concerned, the result of this treatment, supposing its success to be perfect, will only reduce the daily contamination by less than 6½ per cent. Further, assuming the satisfactory treatment of the 9,000,000 daily gallons, for which the sum of 8,000*l.* is allotted, to be such as to lead to the application of the same process to the 140,000,000 gallons of daily flow of sewage, the proportionate cost will be 125,000*l.* a year. Nor is this all. The Works and General Purposes Committee report with great truth that the dealing with the "sludge" is a matter of difficulty, because of the enormous volume of London sewage. If this product be formed at the same rate, in proportion to the volume of sewage, that obtains at Birmingham, it will amount to upwards of 4,000 tons a day. And the daily volume of the sewage is increasing by about 2½ million gallons per year. When we are told, with regard to this prodigious mass of semi-fluid, that "it could be pressed and burned or otherwise disposed of," and that there is every reason to believe that by the admixture of chemicals it would be deodorised, and the offensive appearance removed," it is clear that little is as yet certain except heavy cost. To redeem the Thames from the condition of a common sewer is, no doubt, an imperative necessity. But if this is done, as now appears to be contemplated, by the manufacture of a million and a half tons of sludge per annum, it may well be thought that the unfortunate experimenters are somewhere "between the devil and the deep sea."

THE debate on the taxation of ground-rents in the House of Commons on Tuesday last is not a particularly business-like performance. There was a general consensus of opinion that the ground landlord at present is improperly exempt from local burdens, and there was a good deal of wild talk. But no attempt was made to show how the ground landlord is to be rated, and but a very feeble one was made to the objection that if in future the landlord is rated he will ultimately make the occupier pay by extracting a higher rate. Mr. Moulton, who seconded the motion, answering the objection merely said that it was impossible any increase of taxation should be got out of the pockets of his tenants. It is when land is limited in extent in those cases where it is in request, people are obliged to pay current prices, and if in future ground landlords add to their rents the amount at which they are rated it necessarily follows that tenants must pay these increased rents. It may be that the Select Committee to which the question has been referred will find some way of dealing with the subject so that ground landlords and occupiers shall bear a more equal share of local burdens than is at present the case. Meanwhile, it is necessary to admit that though the taxation of ground-rents is desirable in principle it is not easy to reduce it to a practical form.

It is to be hoped that the question of labour statistics raised a short time ago by Mr. St. John's will not altogether be allowed to pass, for there can be no doubt but that an institution which laid itself out to give this kind of information would be of far greater benefit than would appear at first sight. The fact that so many countries have adopted the

system, more or less completely, is sufficient to show its practical utility, and it needs but little acquaintance with working-class affairs to see what a vast amount of knowledge might be brought to bear upon our own artisans. None are so insular as English operatives, or so firmly persuaded that they can do better work than those of any other nation; and it would be an admirable lesson if they could be made to see for themselves that the standard of perfection is approached much more nearly on the Continent than they appear to be aware; that Continental workpeople are contented to labour for much longer hours at a greatly lessened rate of pay; that much of the Continental, and all the American, machinery is as good, if not better, than our own; and that, in short, the English artisan has an incomparably easier time of it than most of his fellows abroad. The truth is that a good many of the difficulties that exist in labour matters are brought about by the workmen themselves; and if we examine dispassionately the past history of English labour it will be painfully evident how much loss of handicraft has been due to the men's intolerant and ill-advised haste in rectifying their supposed wrongs by strikes. The questions of emigration and plethora of labour are both of the last importance; and a well-devised organisation by which information on these points could be kept daily before all those who were interested, would be a wonderful smother of differences, both for masters and men. In default of such, the latter naturally fall an easy prey to the agitators, who make it their business to tell just as much or as little as may suit their purpose; or, in other words, to instruct their hearers in the way that is best suited to set class against class.

THE Metropolitan Board of Works have incurred the displeasure of the theatrical and music-hall managers in respect of the duty imposed upon them with reference to the inspection of theatres. It is only right to say that this duty, so necessary in the interests of the public safety, was not sought by the Board, but was forced upon them by the Select Committee on the Fire Brigade appointed in 1877. This Committee was originally deputed to inquire into the working of the Metropolitan Fire Brigade, but its scope was extended to include means available for preventing loss of life in theatres, and a great deal of evidence was taken upon this latter subject. The Committee reported "that no new theatre or large music-hall in the metropolis should be finally licensed until certified that in respect of position and structure it satisfies all due requirements for the protection against danger from fire [sic in original], and that the Metropolitan Board should be the certifying authority. That with respect to existing theatres and halls, the Metropolitan Board should have power to call upon the proprietors to remedy such structural defects as appear to the Board to be the cause of special danger, and to admit of being remedied by a moderate expenditure, option being allowed to the proprietors to refer the whole question to arbitration." In the ensuing session of Parliament the Board introduced a Bill giving effect to the recommendations of the Committee, and this Bill became law as "The Metropolis Management and Building Act Amendment Act, 1878." The Committee further recommended that the Lord Chamberlain and the Justices should make regulations for the management of theatres and music-halls, but no such regulations have been made. By a Bill now before Parliament, however, and of which the second reading was moved by Mr. E. Rider Cook on Wednesday, the Board are, at the instance of the Lord Chamberlain and the Home Office, seeking powers to make such further regulations as may be necessary for the safety of the public. Of course "vested interests" are up in arms at the proposal, but the figures cited by Mr. Cook as to the condition of things prevailing before the Board looked into the matter are the best evidence of the necessity of some effective controlling power. To quote only one set of figures, the Board, according to

Mr. Cook, found that forty-one theatres had, between them, only forty-two staircases and fifty-seven exits.

THE Vestry of Chelsea have issued a report on the recommendations of the Metropolitan Board of Works as to the cleansing and ventilation of sewers, which contains some very practical criticism. Among points in it we note that the Vestry consider the proposal to prohibit trade establishments, such as breweries, from sending hot water into the sewers, "would practically amount to a prohibition of the trade." In regard to flushing, they calculate that to daily flush the sewers of their district with any practical effect would require a minimum of 6,000,000 gallons per day. The recommendation that householders might be induced to flush the drains simultaneously at a stated time they dispose of, as we did, by saying that it is vain to expect to be able to compel such a united action. A by-law to that effect could not be enforced, and would only be attended to by a few of the wealthier residents. The same argument applies to the proposal that householders should deodorise (not "deoderise," gentlemen of the Vestry; consult your spelling-books) their sewage separately; they could not be compelled to do it, and the cost of deodorising piecemeal at so many points would amount to an enormous aggregate. On the question of street ventilators the Vestry do not commit themselves to any decided opinion; they seem rather desirous to disagree with no one. They conclude by the suggestion that "it would be advisable for the Vestry to request the Metropolitan Board of Works to place a sum of money at the disposal of its Special Purposes and Sanitary Committee, in order that they may by actual experiment and record of various systems of sewer ventilation be enabled to make such recommendations as will secure a solution of this very complex and difficult problem."

A CORRESPONDENT writes,— "As there appears to be an intention to propose building the new and larger House in one of the open courts adjacent to the present chamber, it is well to at once urge the objections to such a mistaken and retrograde act. In these days, the public voice demands proper sanitary arrangements in all buildings. Among these the provision of the means for the access of ample light and of pure air takes precedence. If the plan of the Select Committee of 1867, which has been ordered to be reprinted for the assistance of Members of Parliament in the consideration of this question, should be adopted and carried out, the excellent sanitary arrangements of the late Sir Charles Barry would be seriously interfered with, and I cannot imagine him, could he be consulted, sanctioning an act so damaging to his greatest architectural work. Of course, if a new House of Commons must be provided somewhere within the limits of the present Palace of the Legislature, local difficulties will of necessity create some disadvantages and inconveniences. The architect, whoever he may be, will not be working upon a *tabula rasa*. But I venture to think that the idea at the very outset of closing up open courts originally intended for the sole purpose of supplying light and air to a building of which they form a part, and which are not an inch too large for that purpose, is a bad one. To adopt it, even for so important an object as a new chamber, will be to begin upon a wrong principle and to invite future dis-appointment."

MR. J. HENRY MIDDLETON, M.A., Ex. Coll. Oxon, F.S.A., who has just been appointed to the Slade Professorship of Fine Art at Cambridge, is a son of the late Mr. John Middleton, F.R.I.B.A., of Cheltenham, and after leaving Sir Gilbert Scott's office, he was for some time in partnership with his father. Besides his architectural work, Mr. Middleton is known as a writer of authority on schools of painting, metal-work, pottery, mural decoration, ecclesiology, &c.; and articles on these and kindred subjects from his pen have appeared in the "Encyclopædia Britannica,"

and elsewhere, his latest and perhaps most important work being "Ancient Rome in 1885," published last year, and which we reviewed not long since. Mr. Middleton is at the present time the senior partner of the architectural firm of Middleton, Prothero, & Philoat, of Westminster, Cheltenham, and Newport, Monmouthshire.

An influential local committee has been formed to promote a fund for placing the Atkins monuments recently re-discovered in St. Paul's, Clapham, in some conspicuous and fitting place, and the end of the north transept of St. Paul's Chapel has been spoken of. This place has the great advantage of being close to the original position of the monuments, being, in fact, but a few feet from the vault where they were found, and which is most probably below the position which they occupied in the former old parish church of Clapham. Still there are great drawbacks, from the fact that the space is contracted and dark, while the presence of a row of small windows, which may not be interfered with, effectually prevents the re-erection of the architectural portion of the tombs, of which there are ample data for very exact recovery of the original designs. It will be better to have the figures visible, rather than to be hidden from public view again, but still it will be matter for regret if the committee should be unable to carry out this important part of what is necessary, instead of merely refixing the monuments on bases containing the original inscriptions, but without the architectural canopies, as is now proposed. We gave a detailed description of the figures in the *Builder* on the 2nd of January last, p. 60. We are glad to hear that the suggestion, made originally in these pages, to take down the Hever monument from the external wall of the church, where it is exposed to all weathers, and to refix it within the building, is likely to be carried out. We hope, too, that at the same time, the fragments of the monument of Bartholomew Clerke, Dean of Arches, which are actually in the heating-chamber, will also be brought into the church. These consist of two brass plates with inscriptions, and a single small kneeling figure, one of four which once adorned the monument, originally a characteristic composition of the time of Elizabeth.

DR. POLE'S letter on "Aerial Navigation," in the last number of *Nature*, is worth the attention of those who are interested in the subject. Dr. Pole is no visionary enthusiast, but one of the most clear-headed scientific men of the day, and he believes that the recent French experiments in balloon propulsion and steering, though only very partially successful so far, open up a distinct possibility of a future solution of the practical problem of air-ships.

IT is satisfactory to note that in spite of what has been said in some quarters as to the too severe demands made upon candidates for admission to Associateship of the Institute of Architects, in the conditions of the compulsory examination, no less than thirty-three candidates have applied for examination next week, and the Institute have had to make special provision to furnish accommodation for the candidates, by closing the Library to readers for three days next week. It is to be hoped the Institute may before long see its way to adopt Mr. Spiers's suggestion and acquire the Conduit-street galleries on the ground-floor for carrying on their increasing business.

THE exhibition of Mr. Holman Hunt's pictures at the room of the Fine Art Society has naturally attracted great public interest. It is impossible to look at this collection of works, showing immense labour and such serious purpose, without a regret that the artist's wonderful technical powers and unwearied labour are not supplemented by that *Je ne sais quoi* without which the breath of life cannot be breathed into a work of art. The sense of labour is never absent in looking at Mr. Hunt's work. Every detail is painted with the greatest care and minuteness, but seldom does the expression of the

work touch one with any force proportionate to the labour bestowed on it. Among those which reach their mark nearer than the rest are the wonderful piece of coast landscape and sunshine in the "Strayed Sheep," and the landscape in the "Hiring Shepherd," which can be looked into in all its details almost like actual nature. These works make one doubt whether Mr. Hunt's proper calling was not landscape. "Isabella and the Pot of Basil" is a fine work, only marred by the fact that the Isabella is so unlike any possible girl of the period assigned to the story. So much for painting ideal characters unwaveringly from a model. "The Awakened Conscience" is one of the figure-pictures that tells its story best and most directly. The "Light of the World" is one of the most remarkable pictures of its class, and has had a hold on the mind of the public such as the painter may well be proud of; but it is a work that will lose much of its hold when the kind of sentiment to which it appeals has passed away; and the same may be said of "The Shadow of Death," a much less complete and typical work, however. The "Light of the World," like Rossetti's poem "The Blessed Damozel," struck a new chord. The collection includes the "Scene from the 'Two Gentlemen of Verona'" (remarkable for the admirable portraying of Julia's anxiety at the impending discovery of her disguise); "Claudio and Isabella," in which Claudio looks quite mean enough for the proposal he made to his sister; a small duplicate of the "Christ and the Doctors," which is, perhaps, the artist's most successful work; and "The Scapgoat." The painter of these works will go down to posterity; but not in the first rank. Something is wanting. Genius has been described as "an infinite capacity for taking pains." Mr. Hunt's works give a decided negative to the definition. Painstaking almost amounting to genius is there; but it is not genius.

ARCHITECTURAL DRAWINGS AT THE ROYAL SCOTTISH ACADEMY.

WHILE there is no building of importance illustrated in this year's exhibition, the designs, although none of them displaying extraordinary ability, may be considered as fair specimens of the architectural outcome of the period.

Of designs for churches the most noteworthy is that of the Coats Memorial, at Paisley, by Mr. H. J. Blanc, which was successful in the competition, and which we fully described at the time. Mr. J. M. Dick Peddie submits an interior view of the chancel of St. Mary's Church, Haddington, restored. This church is of the same period, and probably designed by the same architect, as the later portions of St. Giles's, Edinburgh. It is, however, all of the one style, and is more graceful in its proportions and detail than the metropolitan example. The nave is still used as the parish church, but the chancel and transepts are in a state of utter ruin, and not likely ever to be restored as suggested by Mr. Peddie. The central tower (called "The Lamp of Lothian") when surmounted by its open crown, was probably the finest example of its kind. The church, which possesses a rich and characteristic west doorway, is illustrated in "Billing's Ecclesiastical Antiquities."

The front elevation of New Parish Church, Bo'ness, by R. Thornton Shiells & Thomson, showing a lofty hroached spire in the centre, flanked by octagonal-ended transepts beyond, which appear square-ended transepts, has a dignified aspect, but is somewhat commonplace as regards detail. The "Selected Design for New Church" (place not stated), by James Fairley, appears as an attempt to give importance to a small church by giving it all the features which may possibly be found in one of considerable dimensions, a mode of procedure very apt to impose upon a committee uninformed as to such matters.

The new spire, St. Paul's Parish Church, Galashiels, designed by Messrs. Hay & Henderson, occupies its position in a worthy manner. It has sufficient bulk for dignity and enough detail for picturesqueness. Mr. Thomas Leadhetter's Parish Church, near Linnethgow, is a fair example of an Early English church with spire, aisles, and transepts,

as conceived by a modern architect. Somewhat more pronounced is Mr. John A. Campbell's Free Church at Elie, Fifeshire, the spire of which is terminated by a small stone dome in a happy manner.

We have the usual contingent of mansions after the Scottish Baronial manner. Pitmedden, Aberdeenshire, has not suffered by the additions to it by Mr. Henry Worsdope, which show a thorough knowledge of the style. The House at Kilwinning, as designed by Mr. John James Burnet, is of a less ambitious type. The Tower of Lethendy, by Mr. Andrew Heiton, shows judicious selection and distribution of detail, and Kinlochmoiried, Invernesshire, by Mr. William Leiper, is equally felicitous, with rather more originality of treatment.

The latest phase of Scottish secular architecture is treated in a masterly manner by Mr. Sydney Mitchell, in the Hall at Well Court, Water of Leith. Well Court is a block of workmen's houses built for Mr. Findley of the *Scotsman*, and although quite new is a subject fit for the painter, both as regards composition and colour.

The central pavilion of the old Royal Infirmary of Edinburgh has been delineated in a worthy manner by R. Weir Schultz. It was designed by William Adams in the beginning of last century, and was destroyed a short time ago. Its destruction seemed inevitable, but we are pleased to observe that our suggestion as to the utilising of the fine old gateway on another site has been carried into effect.

The Parish Hall and Presbytery room, Hsmlton, by Mr. G. Washington Brown, is a modest and satisfactory building of Queen Anne type without any vagaries.

The street architecture of the new town of Edinburgh, notorious for its monotony, is now being relieved by the introduction of gables and elevations. One has sprung up adjoining the new premises of the Bank of Scotland in George-street. It is a strongly pronounced narrow front of Queen Anne type, with lank columns supporting nothing.

At the west end of Princes-street a lofty tenement has sprung up, having double bulbous gables, and towards the eastern end of that street a space has been cleared, upon which is to be erected new premises for the Edinburgh Café Company. These premises, designed by Mr. H. J. Blanc, will form a marked feature in the line of street as seen from the Mound. The gable in this instance is bounded by straight lines, the flanks of the elevation are broad and solid, and in the centre, above the shop-front, a wide millioned oriel is carried up through three stories, and a row of small square windows runs across at the springing of the gable. It is a most satisfactory manner of treating a narrow frontage. The Buccleuch Memorial and Science and Art School, Hawick, designed by Mr. James Fairley, jun., is a Classical structure upon a small scale, displaying a wealth of sculpture, which, if executed in a manner at all satisfactory, will form no inconsiderable item of the cost of carrying the design into execution. New Premises, South St. Andrew-street, Edinburgh, designed by Knox & Hutton, are just completed, and are effective in their way, but the style, a sort of Neo-Grec, is hard and unympathetic. Mr. Hamilton Beattie's premiated design for the Edinburgh International Industrial Exhibition is of an accepted character of these glass and iron structures appropriated to such exhibitions. There is a dome, of course, and it is of a pleasing contour; the rest is ridge and furrow, appropriately treated.

Mr. John Le Conte makes a speciality of the architecture of Old Edinburgh, his drawing of the Canongate Tolbooth with Moray House, &c., contains two of the most remarkable façades in the Old Town. Mr. Ruskin pronounced the Tolbooth to be the finest thing remaining intact in the city.

Proposed New West Front to Milan Cathedral.—We recently announced that it was proposed to rebuild the western front of Milan Cathedral, and that an International competition would be held for the purpose of selecting designs. By the courtesy of Signor Magrificio, the Secretary of the Milan Institute of Architects, we are informed that the particulars of the competition are not yet ready, but it is expected that they will be published shortly and so soon as we receive them we will lay translation before our readers.

CONCRETE.*

I HAVE to-night to ask your attention to the means to be adopted for rendering buildings stable, and securing good foundations. This question of foundations is perhaps the most essential of any with which persons connected with buildings have to deal, for if the foundation be faulty, the superstructure, even if it should stand, will certainly suffer. It will be totally useless for the architect to design or for the deft fingers of the mason to chisel out the most delicate window-tracery, the most graceful piers and columns, the most stately towers and domes; or for the artist to enrich these creations with the most brilliant efforts of his genius, unless the edifice be founded so that no cracks or settlements occur to deface the decorations. In some localities, as, for instance, where rock crops up close to the surface, a natural foundation is obtainable which cannot be improved upon, but in the majority of cases, and especially in London and its neighbourhood, it is almost impossible to find a good natural foundation without digging to a depth that is practically out of the question on the ground of expense. Hence, it is necessary to form artificial foundations, and the material principally used for these is concrete.

Although the use of concrete as a building material is of comparatively recent date in this country, it was known and extensively used by many of the nations of antiquity. There is ground for thinking that the Greeks were not unacquainted with its use, especially in the Italian colonies of Magna Græcia, and, as far distant as Mexico, in many of those curious pyramidal buildings which are the remains of an unknown civilisation, concrete foundations have been discovered. But when we come to those grand old builders the Romans, whose *par excellence*, the scientific constructors and engineers of ancient times, we find that they used concrete to an extent with which nothing that has as yet been done in modern times can compare. One reason for this was that the Romans found ready to their hand the best natural materials that exist in the whole world for making good concrete, viz., the Travertine, the pozzolana, which is a fine sandy earth of volcanic origin, and a beautiful clean, sharp sand. The use of concrete by the Romans dates back as far as the time of the Punic Wars (i.e., anterior to 509 B.C.), and no less than five kinds of concrete walls are described by Mr. Middleton, who has recently devoted a great deal of careful attention to the methods of construction of the Romans. In addition to using concrete for foundations they used it without any facing for walls, which were constructed very nearly as described in Mr. Tall's "Mr. Drake's patents, which were taken out several years ago. Wooden posts were fixed in a ground about 3 ft. apart, and boards were nailed horizontally to the posts, and then the intermediate space was filled in with concrete in a semi-fluid state, and, as soon as this had set, the boards were moved one stage higher, and the concrete formed one perfectly solid mass, and some of these early Roman walls are still so solid and hard still that quite recently it has been found necessary to destroy them with dynamite in the course of improvements that have been made. Even when the Roman walls appear to be of brick or marble as in every case a mere facing or covering, and the core of the wall is of concrete. They also largely used this material in constructing very extensive vaults supporting upper floors, staircases, ranges of seats, &c. Concrete also formed the basis of all the Roman roads, and in the early examples the blocks of stone laid on the concrete were much more closely jointed than was the case afterwards. There can be no doubt that the lasting durability of the Roman concrete was due, in addition to the excellence of materials, to the method in which it was made, and I shall refer again to the method of making concrete adopted by the Romans. The French have been very great users of concrete, or, as it is there called, since the year 1820, the material has been used in enormous quantities in docks at Toulon, Marseilles, and other places, and in the construction of the mole at Cherbourg and the breakwater at Cherbourg. In this country concrete was employed in very many cases, as for instance in the foundations

of Westminster Abbey and in the older portions of the substructure of St. Paul's; but its use died out, and for a long while the only method adopted for making stable artificial foundations was in had soils was pile-driving. Although Mr. Semple, of Dublin, in 1776, suggested the use of a mixture of sand, gravel, and quick lime for structural purposes, it was not till the beginning of this century that concrete was recognised as a building material. Colonel Pasley says that the first use of concrete for foundations was by Mr. Smirke at the Millbank Penitentiary in 1817, and there is a story that the discovery, or rather re-discovery, of the fact that lime would combine with gravel and form a sort of artificial stone, was a pure accident, owing to the upsetting of a large load of lime during the erection of Waterloo Bridge, when it was found that the loose gravelly bed of the river had been rendered hard and compact by the action of the lime.

Now what is concrete? It may be defined as an artificial stone, composed of a mixture of hard materials, such as ballast, flints, stone chippings, broken bricks, pottery, or iron slag, called the "aggregate," and a cementitious material called the "matrix," thoroughly combined together with a sufficient quantity of water. The value of the concrete depends almost entirely upon the quality of the cementitious material, whether lime or cement, and as it is most important that you should clearly understand the difference in the properties of various kinds of lime, I must make a short digression here in order to describe them.

You are, of course, all aware that lime is produced by burning limestones, and upon the constituents of the limestone depends the quality of the lime. First there are the rich limes produced from stones which are perfectly pure carbonate of lime, such as the upper and middle chalk formations and white statuary marble. Lime made from these stones is commonly called chalk lime, and is much used for mortar and concrete in country districts where chalk is plentiful. This lime when mixed with water commences to slack as it is called, i.e., it swells, hisses, gives off hot vapour, and falls into powder, and if it be then mixed with water it will always remain of the same consistency and never harden at all; and as it is soluble in fresh water, mortar made of chalk lime should never be used for external work, as the action of the weather will soon render the joints quite soft; and any one who has been present during the pulling down of buildings the mortar of which was composed of chalk lime will have noticed how easily the bricks are separated, and what a large amount of dust comes from the demolition. Then come the poor limes made from the argillaceous or clayey limestones, which contain, in addition to the carbonate of lime, various foreign substances, chiefly silica and alumina, and often a small quantity of oxide of iron. The existence of a small quantity of these foreign substances,—as in the Dorking, Halling, and Merstham limestones,—causes the lime made from them to show much less violent action when slacked, and enables it to set after slacking, but not under water. Next come the blue limes, which contain a greater quantity of silica and alumina, and produce what are called hydraulic limes, which will set and continue to harden under water; and after these come the so-called natural cement stones found in the London clay formations at Harwich, Sheppey, and the Isle of Wight, or imports of Yorkshire in the clays of the oolitic series. These contain even more silica and alumina, and from them used to be manufactured the Medina and Roman cements, which had the power of hardening under water very quickly. These cements enjoyed a high reputation for many years, but they are now almost entirely superseded by the artificial cements of which Portland is the type. You may take it roughly that rich limes contain over 90 per cent. of carbonate of lime; grey-stone limes, such as Dorking, about 80 per cent.; blue limes from 66 to 70 per cent.; and cements when to 50 per cent.

When it was a well-ascertained fact that for building purposes lime obtained from the limestones containing a considerable proportion of argillaceous earth was the best, the idea began to gain ground that an artificial cement could be manufactured by mixing chalk with various kinds of clay, and calcining the mixture. The first patent ever granted for the manufacture of an artificial cement of this kind,—called Portland cement from its resemblance when

set to Portland stone,—was taken out by a Mr. Aspden, in 1824 (who describes himself as of Leeds in the county of York, bricklayer), but the manufacture was not placed on a really scientific basis till Colonel Pasley carried out his elaborate series of experiments during the years 1826 to 1836. As so often happens with scientific discoveries, it appears to have been by pure accident that he discovered, after many failures, the superlatively good qualities of the alluvial clay or mud of the lower basins of the Thames and the Medway; this clay, which has been deposited in the tidal waters of these rivers, containing exactly the right proportions of silica and alumina for combining with the chalk. It would take too long to describe in detail the manufacture of Portland cement, but briefly it is this: the chalk and clay, in the proportion, as a rule, of about 70 per cent. of the former to 30 per cent. of the latter,—though these proportions vary with the nature of the chalk,—are ground under rollers and intimately mixed together with a great quantity of water until the mixture is of the consistency of thin paste, which is allowed to settle. The water is drawn off, and the residue is left to dry. This is then cut out in lumps and taken to the kilns, when it is burned at a high temperature, and it is very important that the whole of the mixture should be thoroughly burned. The effect of the burning is to drive off all the carbonic acid gas, and to leave the mixture in the form of clinkers. These are then carefully ground to a powder under millstones of such a degree of fineness that it will all pass through the meshes of a sieve having 625 holes to a square inch. The weight of the ground cement should be as nearly as possible 1 cwt. per struck bushel, and the specific gravity 3.00. The essential difference between lime and cement is that lime slacks with the addition of water, while cement does not. Lime powder after slacking will not set if mixed up with water, unless sand be added to it, while cement will set at once, and equally well in the water and the air. The property of setting quickly and setting under water makes Portland cement of the greatest value, and its use for concrete is extending every day.

Now with regard to the aggregate. This may consist of ballast, stone chippings, broken bricks, &c., but the latter should never form the whole substance of the aggregate, and care should be taken that the pieces are not too large. In the case of ballast, it is most important that it should be clean and free from any admixture of loam or earthy substance. And there is one other point to be remembered, which is, that the concrete will be much stronger for the admixture of a small quantity of sharp sand, which will fill up the interstices between the pebbles, &c., and will make a much more solid mass of the whole.

Having thus described the materials of which concrete is composed, I now come to the mixing process, and this is a matter which is far too often neglected. We all know the good old rule-of-thumb way in which ordinary builders' labourers mix up the concrete: a heap of ballast and broken bricks is piled up, a certain, or rather very uncertain, quantity of lime is poured out on it from a sack, the water is added according to the discretion of the mixer, and the mass is quickly turned over, and wheeled and shot into the trench, and a very superficial examination is often sufficient to show numerous nodules of unslacked lime after it has been thrown in. Now this is a most unscientific and improper way of preparing concrete: the great essential is that the lime should all be perfectly slacked during the mixing of the concrete before it is thrown into the trench, and that exact proportions should be maintained.

For ordinary foundation purposes, if what is called stone lime be used, two measures should be prepared, the cubical contents of the one being four times that of the other. The large measure should be filled with ordinary ballast, and turned out on a hoarded platform; to this should be added a small measure full of sand, and then a small measure full of lime: this will give the proportion of five parts ballast and sand and one of lime, and if this be well mixed and turned over after the water is added, which should be done gradually and in small quantities, it will make a very good concrete for ordinary purposes. If the ballast and sand, before the admixture of the lime, amount to a cubic yard, it will be found that about thirty gallons of water will be required to mix it thoroughly.

* By Mr. John Slater, B.A., being the fifth of the course of free lectures to artisans at Carpenters' delivered on Wednesday evening last.

This mixture should be then wheeled and thrown into the trenches,—not from a great height, as used to be considered essential, for, if so, the heavier particles tend to fall to the bottom first, and the mixture will not be so well amalgamated,—levelled, and rammed. The French method of making concrete, or *béton*, which is almost exactly the same as that adopted by the old Romans, is undoubtedly superior to ours. They invariably mix up the lime and sand to form good mortar first, and then mix in the pebbles with it. A heap of good stiff mortar is first prepared with a moderately hydraulic lime and sharp sand; a harrow full of pebbles, which have been washed, are then spread out on a platform; over it is spread a barrowful of mortar; then a second harrowful of stones, and then another of mortar, and the whole is turned over with spades and dragged backwards and forwards with rakes till the pebbles have become thoroughly enveloped in the mortar, and the whole mass is then thrown into the trenches. An extra precaution against deterioration of the concrete by contact with loamy earth is adopted in the best work by covering the bottom of the trench with another layer of sharp sand. The washing of the ballast is an excellent thing, as it tends to clear it from any earthy particles that may have become mixed with it. There can be no doubt that this is a far more scientific method of making concrete than the former; if the mortar is well made, you get the pebbles more thoroughly amalgamated, and you ensure that the lumps shall be thoroughly slacked before the concrete is spread; but it is also more expensive, and I should not consider it necessary to use this method in ordinary cases. But where the soil is very wet, or in any case where the stability of the foundation is of very great importance, I should always recommend the use of cement concrete. With ordinary care in mixing this, supposing the materials are of good quality, you know you can rely upon its setting quickly and forming a perfectly solid foundation, and you need be under no apprehension of having it spoiled by the inroad of water. The cost is more than that of lime concrete, but not so much more as the difference in cost of lime and cement, because you can use less cement proportionally. Six parts of ballast, one of sand, and one of Portland cement will make a concrete good enough for almost anything in the way of foundations. Care should be taken that not too much water is used. Faraday, the eminent chemist, said that in the production of concrete the great thing was the discreet and accurate use of water: if too much be used it will wash the cement away from the particles of the mass before it has time to become thoroughly indurated. If the trench in which the concrete is to be spread is not too deep,—that is, not above 18 in.,—my own opinion is that you will get a harder and more solid mass by filling it up at once to the full thickness, and not putting the concrete on in layers; but if you have to put the concrete 5 ft. thick, it must, of course, go on in layers. In any case, it will be much improved by being well rammed after levelling. In such a material as concrete there must be a large number of minute air spaces,—you can see them with the naked eyes in concrete that has set,—and the act of ramming will drive out much of the interstitial air and make the particles of the mixture more compact, and the denser such a material is the stronger it is. Numerous experiments have been made to ascertain the loss of bulk in making concrete. Professor Hayter Lewis found that 27 cubic feet of Thames ballast mixed with $\frac{1}{2}$ cubic feet of lime and 40 gallons of water, made exactly one cubic yard of concrete; and in some tests made by the Royal Engineers, it was found that 27 cubic feet of broken stones, 9 cubic feet of sand, $\frac{1}{2}$ of Portland cement, and 28 gallons of water exactly made a cubic yard. The difference between the two experiments may be accounted for entirely by the presence of the sand in the latter case, because the probability is that if a measure containing a cubic yard were filled with broken stones or ballast, it would still hold 8 or 9 cubic feet of fine sharp sand, because the pebbles will not lie close. It is sometimes stated that concrete expands after being mixed; if it does, it is because it has been improperly mixed, and any expansion that takes place after mixing can only cause some disintegration to take place.

Hitherto I have spoken of concrete as used

for foundations only, but there are many other purposes for which this material can be employed. I suppose it is not much more than twenty years ago that building materials and labour, being at a very high price and by no means of very high quality, the idea began to gain ground that concrete might be used for the walls of buildings. I have already alluded to the fact that the Romans used it for these purposes, and that, too, although they only had lime, whereas we have Portland cement. But the mixing of the pozzolana, which I have previously mentioned, with the lime gave it many of the characteristics of a cement.

The Italian architect Palladio, writing 300 years ago, gives a very good account of the Roman method of wall construction. He says: "The Ancients used to make walls called *reimpinta*, i.e., filled up with rugged stones, which is also called coffer-work, taking planks and planting them edgewise in two rows, distant from one another the thickness of the walls and filling the space between them with cement, stones of all sorts, earth and mortar mingled together, and so on from course to course." This method of using concrete for walls is called *monolithic*, the concrete being simply poured, in a semi-fluid state, into the position required, to which it is confined by boards, and it sets in that position, so that the whole of the wall is one compact homogeneous mass. Another method is to form slabs of concrete by casting it in moulds and allowing it to set there, and the slabs are then taken out of the moulds and carried to the place required and used in the ordinary way, just like bricks or stone. The former system, if only ordinary care be taken, makes undoubtedly the strongest work, as there are no joints, either vertical or horizontal, and, moreover, no skilled labour is required in this construction, ordinary labourers being able to mix the ingredients and fill in as required. Several systems of apparatus have been invented for confining the concrete to the requisite thickness of wall, and for shifting the moulding boards from one stage to another, and many of these are of somewhat complicated a character, but it is very doubtful if any material advantage is gained over the simple plan of nailing the boards to the upright posts and filling in between. Walls thus constructed are really stronger than brickwork, drier, and more cheaply built, but great care must be taken in the preparation of the concrete: the cement must be of the best, the aggregate must be broken to the proper size, and the whole thoroughly well mixed. If these precautions are taken, the thickness of the walls may be about 20 per cent. less than with brick.*

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

SOME AMERICAN METHODS OF CONSTRUCTION.

The seventh ordinary meeting of the present session was held on Monday last, Mr. Ewan Christian (President) in the chair.

Mr. J. Macvicar Anderson (Hon. Secretary) intimated that the Council proposed to close the library during Tuesday, Wednesday, Thursday, and Friday next week up to six p.m., but it would be open in the evening as usual. This was necessary on account of the number of applicants (thirty-three) desirous of submitting themselves to the obligatory Examination, and as the Council did not know how to accommodate them otherwise than by giving up the library for that purpose. As the Council believed a good many other applicants would present themselves in the course of the present year, it was proposed to hold another examination, possibly in November next. At the examination held towards the end of last month in Leeds, eight professional architects had been examined, but the result had not yet been made public.

A letter was also read from Gen. Posenby, stating that her Majesty had given her sanction to the selection of M. Charles Garnier as Royal Gold Medalist for the year.

Mr. R. Phené Spiers asked whether there was a possibility of the Council acquiring the use of the downstairs galleries at any future time. There had been considerable difficulty from time to time in finding space for the hanging of the drawings submitted for the various prizes, and he believed these diffi-

culties were likely to increase in the future. It had been intimated that in consequence of the large number of candidates for examination, the library would have to be given up on certain days, whilst the two magnificent galleries downstairs were, so to speak, in the hands of outsiders.

The President.—If the numbers increase as we have heard this evening, we may hope that we shall be able to take the additional galleries; but at present it is a question of finance, and we cannot venture to do it until we are in better circumstances. The next thing I have to announce is that a special general meeting, to consider the Charter, will be held on Monday, April 5th, at seven p.m.; and that, in case of any adjournment, it will be continued on the next day at eleven a.m., and so on until terminated. We hope, if possible, to bring this question of the Charter to an end, and to get the opinions of the members of the Institute upon it. We do not want to have any delay.

Mr. John B. Gass (Bolton), Graduate and Associate, and Holder of the Godwin Bursary and Medal for 1885, then read a paper on "Some American Methods," of which the following is an abstract:—

As holder of the Godwin Bursary, 1885, Mr. Gass visited many important cities in the United States and Canada, his tour extending over a period of three months. He found great practical benefit therefrom, and expressed his deep sense of obligation to Mr. Godwin, F.R.S., for his institution of the bursary, and to the many American architects and others for their courteous reception and willing assistance. The subjects treated on very fully in his paper, formed only a portion of his report. The most approved method of incombustible or fire-proof construction is a system of iron construction with hollow tile arches, the voussoirs having sides about 1 in. thick, and all the ironwork encased in ordinary or porous terra-cotta, specially made to suit positions, and plastered on top. Partitions or internal walls are made of hollow tiles which have good hearing power; a 5-inch hollow tile wall resists heat better than a 12-inch brick wall. Roofs are constructed of hollow tiles or porous terra-cotta slabs, supported by wrought-iron joists, and covered with various kinds of roofing. Underside of arches are made fire-resisting by wooden frames houses are made fire-resisting by terra-cotta slabs plastered on face. This is being extensively used, and has stood several tests. Ordinary brick arching in 4-ft. spans, resting on cross wrought-iron girders is still used, notwithstanding many disastrous failures. Concrete floors are occasionally used, in some cases as arching with corrugated iron soffit, in others with wrought-iron joists and flat soffit. Slow-burning or mill construction is in general use for all sorts of mercantile buildings, and affords excellent protection against fire spreading. Walls of brick, square columns of wood, not tapered, with cast-iron pinnets between wooden beams, plank floor 3 in. to 4 in. thick, with hardwood laths in joints, flooring of 1½ in. hardwood boards with laths, laid over two thicknesses of rosin-sized sheathing paper or ½ in. mortar. No painting, varnishing, or filling on woodwork for at least three years after the building is finished. Where special danger of fire exists, woodwork is encased with bright tin. Roofs with similar construction to floor, with outer covering of tin, asphalt, tar and gravel, cotton duck, &c. Double doors, with air space between, to prevent fire spreading; one door for closing in ordinary use, the other kept open in case of fire. These doors made of two thicknesses, tongued and grooved boards, covered with bright tin, or made of strong iron. Wire cloth lathing kept ½ in. from the woodwork and ironwork, and plastered on top, is used for fire protection, as also are "McCrirt" plaster, the basis of which is asbestos, and magnesite calcic, a saturated paper pulp. Brick walls to houses being generally furred with wood inside before plastering, "fire stops" of incombustible material are used at top and bottom on each floor to prevent fire spreading. In New York and other cities, outside fire-escapes are required on all tenement, flat, and apartment houses, office buildings, lodging houses, and factories; stand pipes, with nozzle to each floor, run up alongside the fire-escape. In great fires at Chicago and Boston, brick stores the best for walls, stone calined, limestone the best for walls, stone calined, limestone the best in many cases burned off, leaving the brick hacking standing one or two stories in height. Sandstones stood better than limestones.

* To be continued.

but granite disintegrated very rapidly; artificial stones suffered less damage than natural stones, and mortar stood better than bricks. Cast-iron columns failed very badly, bringing down whole buildings, and the failure of floors was generally from the exposed ironwork. Telegraph-poles got charred, but stood where buildings around were completely destroyed. In conversations with several chiefs of important fire-brigades, it was noted that the terra-cotta block system, with all iron encased, was thought by them to be the nearest approach to a perfectly fireproof building; brick arching for floors and ironwork exposed universally condemned; slow-burning construction, with floors made watertight, advocated for mercantile buildings; some place in the roof that could be made to serve as smoke-outlet should be provided in buildings of large size; one wood door, covered with tin, better as fire protection than one iron door; but two iron doors, with air-space between, better than two wood doors. The "fire-protection" apparatus for mill buildings is very complete, well arranged, and regularly inspected by the officials of the Mutual Fire Insurance Companies. In addition to other apparatus, sprinkler systems are in general use. These are formed by parallel lines of pipes, extending across the rooms, near the ceiling, and connected with a good water-supply. In valve-sprinklers, rows of perforated pipes are fixed in sections, in which the water can be turned by valves in case of fire. Automatic sprinklers are various forms of apparatus set in motion by the fire itself, at first breaking out, and are brought to bear directly on the place where the fire exists, and so arranged that when any one is in motion, the flow of the water sets an alarm-bell in motion. They are attached to the water-pipes at frequent intervals, and depend on their action on a solder fusible at a low temperature, ordinarily at from 150° to 170° Fahrenheit. The Grinnell sprinkler is the most largely adopted, and others in use are the Armeleo, Walworth, Victor, &c. From Mutual Insurance Company's returns, 1877 to 1885, in buildings protected by automatic sprinklers, there were 195 fires reported, with an average loss of 327 dollars per fire; in buildings not so protected, 553 fires, with an average loss of 1,794 dollars per fire. Ventilation and heating receive great attention in many parts of America; owing to the dryness of the atmosphere in the winter, and the greater evaporation from the body, it is necessary to keep a higher temperature in the rooms than is the case in England. At the Massachusetts Institute of Technology, Boston, there is a plenum fl. high, under the whole of the basement of building, into which fresh air, warmed or not as required, is put under pressure of $\frac{1}{2}$ in. water column. Air distributed from this to some through flues, 36 in. by 12 in., with steam boiler at the bottom of each, the temperature of the volume being regulated by the engineer on the basement. Inlets into rooms 8 ft. above the floor, and larger than the area of the flue, so as to ensure slow movement. Outlets have two apertures in the room, one 6 inches from the floor and the other close to the ceiling,—the former wholly used during hot season,—outlets discharge above the roof. The outlets are smaller than the inlets, so as to give pressure against the outside and prevent draughts. The whole system is under the control of the engineer, who maintains a temperature of about 65° in the rooms; he is furnished at evening with the weather prediction for the next twelve hours, and is responsible for the thermal condition of the building at the hour of opening, being under explicit orders as to steam and air supply for various conditions of weather. This system is successful and economical in working. At the Pittsburgh County building and other places fresh air is taken from the top of the tower, passes over steam coils and rough water washer, put under pressure by fans in large ducts, and conveyed through flues rooms, exhausted into chimney with smoke from boiler in centre. The systems adopted at the American Bank Note Building, State Hospital for Insane, Norristown, Pennsylvania; St. Ann Catholic Church, New York; and the Canadian Parliament Houses, Ottawa, were so described. The Baptist Church, Toronto, amphitheatrical in plan, and has roof sancer aped. In the winter fresh warmed air is admitted to the church at the highest point in the floor; the foul air is extracted from the lower level through trefoil openings in each end, and connected by small flues into the

main trunk in the basement, which is exhausted into large vent-flue, having the smoke-flue from hot-air stove in centre. There is roof ventilation for summer use. At McVicker's Theatre, Chicago, fresh air is taken from 60 ft. above ground, filtered, passes over steam coils in winter and ice-chamber in summer, forced into auditorium by fan through openings in ceiling. Extracted through openings in risers of floor and exhausted by means of fans. Air changed in auditorium every fifteen minutes. The system of down-current ventilation used with success, but not available where gas is burned. The extracts at floor level are ordinarily used in cold weather, however the warm air is admitted into rooms. Heating by indirect radiation often adopted for houses. The difficulties with, and objections to, steam heating are partially removed by the use of fractional valve. In the Canadian cities particularly, many steam-heating apparatus have been taken out and hot-water systems put in. In houses heated by hot-air, steel-plate furnaces are found the most satisfactory. There are open fire-places in the best houses. The Morse sun-rays' heater and ventilator is fixed outside the building, and acts when the sun is shining on the black and roughened outer covering. The progress of American architecture has been remarkable within the last few years, and though there is much that is bad, vulgar, and pretentious, it has begun to exhibit artistic and peculiar qualities of a very high order. The best specimens are scholarly and refined in detail, but adhere less slavishly to precedent than European work. New combinations are introduced, dictated by and growing out of the necessities of the building, without violating the character of the style. The best work is accordingly living and interesting, less the production of a dry-as-dust archaeology, and more in accordance with the true principles of all great architecture.

Mr. A. J. Gale (the first Godwin Bursary) proposed a vote of thanks to Mr. Gass. It was not at all an easy matter to go to America for the purpose of investigating its architecture, because there was so much to see, and a great deal of time was spent before the best examples were found. Mr. Gass was right in speaking of the help which American architects afforded to their English brethren who visited that continent, as they were gratified at their works being thus studied by Englishmen. He hoped this might not be the last occasion on which a Godwin Bursary went to America. The benefits arising from the reading of the paper and an inspection of the drawings on the walls could, however, be little compared with the benefit which such a Bursary conferred on its holder. He (the speaker) had not visited Canada, but he believed that the Canadian was not equal to the best American work. It was invidious to draw distinctions, but Mr. Richardson's work was universally good, and one of the most valuable things he was doing for the future of American architecture was his exertions in training men for the profession who would worthily succeed him.

Mr. John Slater, B.A., in seconding the vote of thanks, remarked that the members must have inspected the drawings and photographs on the walls with admiration, perhaps, in some few cases, not unmingled with a little awe. There was no doubt as to the value of the Bursary established by Mr. Godwin, who had foreseen the good architects would derive from finding out a little of the methods of American and Continental construction, and from learning that we in this country had no monopoly of excellence. The constructional methods of America seemed to show a boldness and breadth of aim, and a lack of conventionalism, which were really refreshing. Whether the lack of conventionalism in some of the artistic work was a subject for commendation must be a matter of opinion; but structurally, he believed, there could be no doubt about it. As to the fireproof system, the Americans were far ahead in that respect, and he could not help thinking that we might make our buildings far more fireproof than they were at no very great expense. The Americans also proceeded in a scientific manner with the question of the foundations, and in many cases they had to face greater difficulties than were met with in this country. In this connexion he should like to call attention to the excellent fireproof system which had been introduced by Mr. Lindsay, of the Paddington Ironworks, called "steel decking," which was being

used by Mr. Waterhouse at the National Liberal Club. It was impossible to read the professional journals of America, or the programmes of the various industrial universities and institutes of technology, without seeing what immense strides had been made in the matter of architectural education. Though a young nation, they had yet done infinitely more than our own in this respect. No doubt we had done a good deal, and the obligatory Examination was an instance of this, but we had not gone far enough, and this question of the education of students of architecture would have to be faced and fought out by the Institute in combination with other bodies. Mr. Slater then quoted the curriculum for an architectural student at the Massachusetts Institute of Technology, which was of a very comprehensive character, and contended that it was a disgrace that in England generally the architectural student had no such means of studying his profession as were available on the other side of the Atlantic. No greater benefit could accrue to the members of the Institute than to learn something of the methods of other countries, and to occasionally take stock, as it were, of their own deficiencies. With this object in view, he would venture to suggest that, as a number of honorary and corresponding members were on the roll of the Institute, some means should be adopted to make these gentlemen a little less honorary, and a little more corresponding. Great good would be done by getting them to give an occasional communication on the sort of work going on in their city, country, or district.

Mr. Alexander Payne asked if the drawings and photographs displayed on the screens could be kept up for some time?

The Secretary replied that the drawings would be on view all the week.

Mr. Rickman thought Mr. Gass had been wise in confining himself to a few results of his labours. In visiting Canada and the States one saw a very marked change from the architecture of this country. In the United States a class of buildings of our own date were to be seen, in connexion with which the architects had thrown aside survivalism, and had worked according to their own ideas. In spite of this, he found, when there, that he was not so shocked with the *biarrerie* of their appearance as he had anticipated.

Mr. Phené Spiers remarked that it might be interesting to say a few words as to the origin of much of the past architecture on the other side of the Atlantic. The American students had studied chiefly in France. Mr. Hunt, one of the oldest Corresponding Members of the Institute, was a student of the Ecole des Beaux Arts, where Mr. Richardson had also studied at the time when he (Mr. Spiers) was there. In 1837 or 1838 Professor Ware visited this country to study English art, and subsequently went to Paris to lay down a scheme of architectural education for an Institute at Boston. This system had been introduced into the Institute of Technology at Massachusetts, and was also being introduced into another Institute at New York. From time to time during the last twenty years he (Mr. Spiers) had received the visits of many of Professor Ware's most promising pupils. Feeling that the education he was able to give them was not sufficient, the Professor advised them to spend a few years in Paris, and on their way they had invariably called upon him for advice as to the course they should pursue when in the French capital. The style, therefore, which those who founded that school had taken as their starting-point, had been modelled on French ideas, such as would be found in the Library of St. Genevieve, in the building of the Ecole des Beaux Arts, in the Imperial Library, in the Stamp Office, and in various other buildings. If they bore this in mind, and looked at Mr. Richardson's drawings and photographs, they would see from whence he drew his inspiration. At the same time they would observe how the practical American had caused the Byzantine or Neo-Grec style to be so materially altered, that it became to a great extent an original series of conceptions. The Harvard Law School showed a great amount of originality and peculiar refinement, mixed with extreme breadth and boldness. It would have been impossible, he believed, for an English architect to have gone to the extent Mr. Richardson had gone, as he would have had numberless critics pointing out how he had sinned against the laws of ancient art.

Mr. Spiers concluded by saying that he looked forward with much interest to the future of American architecture.

Mr. Hugh McLachlan (second Godwin Bursar) said that both in America and in Germany the questions of heating and ventilation were more thoroughly considered than they were in England.

Mr. Dawson having made a few observations,

Professor Kerr remarked that he had visited America forty years ago, and he had always taken great interest in everything connected with that country. In the matter of architecture, there were two roads in which America might be expected to make very considerable progress; one was in respect to ingenious construction, and the other in what might be called originality of design. The whole population of America seemed to grasp the necessity for new inventions, and when an invention was brought to bearfully upon any requirement, it appeared to be done, not in the rough-and-ready way to which we were accustomed, but in a precise and practical manner, which showed the Anglo-Saxon intellect at its best, in that particular sphere. In this country we seemed to be too greatly trammelled with old traditions, and did not appear to get beyond the instruction received at school; but the Americans threw all that to the winds, and struck out for themselves, whenever occasion required, some new contrivance. Mr. Spiers had referred to the influence of France, but the Americans occupied a peculiar position in regard to architectural design. They were the English of the future. Design was a much more difficult thing to deal with than mechanical contrivance, because it seemed to march with the ages in an independent career of its own. When he was three forty years ago Trinity Church, New York, was just finished, and was considered a very fine building, and Grace Church, at the other end of Broadway, had been finished with a crocketed spire in cast-iron, painted to imitate granite. The then Editor of the *New York Herald* characterised this spire as being like a crocodile standing on its head, and this was the style of criticism which prevailed in England at the present day. Since then the Americans had made amazing progress, which, as Mr. Spiers had said, was largely due to French influence. The students came to London, got advice from Mr. Spiers, and saw what we were doing. Thus a sort of cosmopolitan style of architecture would gradually be evolved in America, where wealth was progressing more rapidly than in this country. The tendencies towards all the manifestations due to the profession of almost excessive capital were more fully exhibited there than here, and he believed their successors would find Teanastlanic architects not dealing in sham Gothic or Neo-Grec, but in a modern American style of their own.

The President, in closing the discussion, said it was a great satisfaction to him to hear such a paper as this. It showed how far-reaching and useful was Mr. George Godwin's idea in founding the Bursary. When he was in America he saw a very great deal of work which disgusted him, but the impression he derived was that a great revolution was going on in matters of art, and that a period of good work was coming on.

The vote of thanks was then put, and cordially received; and Mr. Cass having suitably replied,

The President adjourned the meeting to the 29th inst., when a business meeting will be held to receive a communication from the Council in respect to the report of the Departmental Action Committee, recently printed in the *Journal of Proceedings*.

Leeds.—Plans for the proposed completion of Emanuel Church, Leeds, at a cost of 1,200l., have just been unanimously adopted by the parishioners. One most important feature of the contemplated improvement, viz., the filling of the east window with Munich stained glass, has already been completed. The window consists of five lights, with a large rose above. The centre compartment represents the Good Shepherd; the other four compartments containing figures of the Evangelists,—their emblems being introduced in the lower panels and the pelican under the principal figure. The window has been presented by Miss Pegler in memory of her mother, the late Mrs. Charles Pegler, of Leeds; and has been designed and executed by Messrs. Mayer & Co.

ARCHITECTURAL PHOTOGRAPHS BY AMATEURS.*

If an architect thinks seriously of starting a camera, what sort of camera should he get? What process should he use? What outlay on apparatus? Cost in time of a negative, and a print, and outlay for materials? Additional weight of baggage in travelling? What are the average results obtained by people who cannot wait for the very favourable moments, and can only practise the art at intervals? Kind friends, by supplying a large show of suitable photographs and of transparencies for the lantern, and by stating facts, have enabled me to answer such questions.

Mr. J. L. Robinson, of Dublin, the hon. amateur photographer to the Architectural Association Excursion, has contributed over 800 illustrations of English architecture taken during the excursions to the A. A. Library; and, bound in volumes, they are in much request. The example is worthy of imitation. Mr. J. C. Stenning, Mr. J. Clerk, Q.C., Admiral Maitland, Mr. Gifford, Mr. Seymour Conway, Lieut. W. J. Little, Mr. J. Gale, Mr. R. L. Cox, Rev. F. C. Lambert, and others have also enabled me to exhibit specimens of the work of able amateurs.

For our present purpose we may regard photographs as shaded diagrams showing the existing condition of old buildings,—grand, picturesque, well preserved, in decay, or in ruins,—to be used as aids to the study of architecture, archaeology, and topography; or as giving the expression, surroundings, and details of modern buildings; records of works in progress, records of constructive appliances, of the curiosities of other days and of the novelties of our own; and we will not indulge in needless regret over the limitations, or in aspirations after the possibilities, of the art. In order to justify to some extent a fairly complete and proportionate sketch it will be well to assume unimaginable ignorance,—of a density which not one of us would perhaps be vain enough to own to. By this device the answers to the special questions, put on behalf of an architectural amateur trembling on the brink, may be given in an orderly way.

Processes.—At the present time the gelatinohromic process has the greatest number of admirers. The wet collodion process, which up to 1879 was that universally in use, has been laid by. The glass was, for that process, coated with collodion (gun-cotton dissolved in ether), containing a small amount of bromide of ammonium, and was then immersed in a solution of nitrate of silver, and the bromide converted into bromide of silver. The invisible lines adjoining the blue portion of the spectrum have the power of producing chemical change, and darkening the bromide of silver. Only these portions of any light, distinguished as actinic rays (*ἀκτινός, ἀκτινός* might be any ray, but some nomenclature is a necessity), produce permanent effect on the chemical condition of a negative. The highly-lighted portions of a scene reflect strong light and turn the corresponding portions of the negative black (sky and high lights), deep shadows remaining almost untoned. The operator usually prepared his plate just before using it, and fixed it at once. His fingers, of course, touched the nitrate of silver (lunar caustic), and when the light came upon them the coating turned black. Cyanide of potash was required to make the fingers fit to be seen. The photographer, who uses ready-prepared dry plates, congratulates himself on not requiring the services of that deadly drug. In using the wet collodion process for outdoor work, it was necessary to carry about a portable dark room, or dark tent, and the chemicals required for rendering the plates sensitive, and those for developing them. This cumbersome addition to the baggage led to the use of collodion dry plates. The early ones were those in which glutinous matter, such as beer, treacle, glycerine, coffee, tea, or tannin, was used to act on the silver. Later on, nitrate of silver was dissolved in bromised collodion; being allowed to set, it was then well washed to remove the free salts of silver, and dissolved in ether. The plates were coated with this preparation, dried, and used as the gelatine plates are now; but the sensitiveness being less, the exposure varied from one to ten minutes. These collodio-hromide plates were brought to

* A paper by Mr. S. Flint Clarkson, F.R.I.B.A., read before the members of the Architectural Association on the 12th inst.

great perfection by Colonel Stuart Wortley, and much used until gelatine plates were prepared.

The earlier attempts to use gelatine, by sensitising glass plates and paper coated with gelatine in the silver bath, were not satisfactory. The first attempt at the modern method was described by Dr. Maddox in 1817, and the process came into general use in 1879. Improvements have been steadily introduced during the six years last past; the art is a living art, and living at a great pace too. Gelatino-bromide dry plates are now manufactured in large numbers, and supplied ready for use; millions of "commercial dry plates," as they are called, are produced every year for home use and export; they are sent away by the ton. The glass is coated with a viscid solution of gelatine in which bromide of silver is held in a state of suspension; the sensitiveness of the plates,—as in the case of wet plates,—is in the bromide. Probably the majority of amateurs avoid the tedious labour of preparing their own plates. As, however, about two-thirds of the outlay for producing a finished photograph goes to providing the dry plate for the negative, enthusiasts do the work for themselves. They say, besides, that there are advantages beyond the money saving, in being taken behind the scenes, and getting knowledge of the nature of the plates which could not be obtained without this experience.

The glass commonly used is carefully selected crown glass, weighing about 15 oz. to the foot. The preparation of the solutions, which are to form the emulsion for a batch of plates, will take about three hours; the emulsion may then be left to set. On another day the soluble nitrates and bromide will be washed out by water, leaving only the insoluble bromide and iodide of silver in the emulsion. The emulsion being melted, filtered, hotted, and stirred, three to five hours may be agreeably spent, finishing up with the cookery. The holding process may, however, be modified by using Professor Eder's method, in which the emulsion is not heated beyond 150°. This method is now almost universally applied, and shortens the time a good deal. The coating of the plates with the liquid is done with great rapidity; the emulsion stiffens upon the glass, and does not run off or move. After the plates have been put into a drying-box, arranged so as to allow plenty of dry fresh air to pass over them, they will be ready for use in from half a day to a couple of days. They will improve in many ways after being kept some time,—notably they will have no tendency to frilling which frequently happens with very new plates. The idea of any actinic light reaching the sensitive film is full of terrors. A second's exposure to a naked gaslight, even at the distance of several feet, produces a strong impression, which appears as fog in a negative. Ruby glasses, the deepest shade is used in the dark room. Camera and lens tubes are lined with black velvet, and black cloth is put over the camera during exposure. Kept carefully in the dark and the dry, the plates will last for a long time,—perhaps, under favourable conditions, for ever,—but it is unnecessary to try the experiment.

The sensitiveness of the plates varying considerably, they are classed as ordinary, rapid, and instantaneous. It is supposed that the reason why gelatine plates are so much more sensitive than collodion is that the sensitive salts are in a finer state of division. The sensitiveness is at any rate increased as the division is carried still further by additional cooking of the emulsion. It is usual to indicate the sensitiveness of dry plates by a comparison with wet collodion plates. It is supposed that everybody has used wet collodion; though it has been less and less used for six years, which experts seem to look upon as several lifetimes,—an interesting example of survival. Ordinary plates have from twice to thirty times the sensitiveness of wet collodion plates; about ten or twelve times is recommended for ordinary work. Instantaneous plates are charged for at the rate of about one-fifth more than ordinary plates. For sea-pieces,—not found in the direct path of an architect,—of an amateur,—an exposure of 1-200th part of a second is sufficient. The Oxford and Cambridge boat-race, with all the crowd on the bank and river, needs a very sensitive plate and short exposure. For trotting horses in various positions the exposure is put at 1-2000th part of a second. Such short

exposures require special lenses which admit more light than those used for ordinary work. The time of exposure of a succession of plates, all prepared with the same emulsion, will be varied to suit the hour, and the brightness, or the reverse, of the day. Experienced people know, without the labour of thinking, whether 150th part of a second, or three seconds will be required for a special subject on a bright day; or whether it should be three or five seconds on a grey day; five or ten seconds on a dull one; ten minutes or half an hour in the inside of a building. The camera may be left to itself, by an eager well-occupied student, if the light is deficient, and the image is consequently coming on at an easy rate. It is satisfactory to know that, in such circumstances, two, three, or five minutes more or less exposure make practically no difference, as the plate may be developed so as to make the best of what proves to be an under or an over exposure.

The cost of the 150 plates, from which successful prints were obtained illustrating the buildings visited in the Banbury excursion, allowing 10 per cent. in addition for damages, would be 3l. 5s. Prepared cleverly, instead of being bought, they would come to about one-third of this amount, but the large expenditure of time has been hinted at above.

Prophetic persons state that the paper processes will in time supersede all others,—at any rate, for amateur work in the open,—on account of ease in carrying and in manipulation, no risk of breakage, rapidity of printing, and reduction of first cost. I have felt that to deal with the gelatine process, and to leave remarks in the paper processes to others, would be my safest course. Notwithstanding all the advantages claimed for paper, dry plates are more largely used every year. It is said that the army of amateurs using dry plates has become, within a few years, as large as it was twenty years ago, when the collodion process first became popular. To film-carriers or roll-holders have as yet inspired such general confidence as the gelatine plates, and there is, apparently, a suspicion that uncertainties in the manufacture of papers occur rather frequently.

Cost.—A camera, 7½ in. by 4½ in., a Ross's symmetrical view lens with diaphragm on the system recommended by the Photographic Society, and three double backs or dark slides,—to take in all six sensitive plates,—should be required by an amateur when he is about to begin actual work in earnest. For these, with tripod, level, and other necessities, about 11l. will be required: on the chemicals and other apparatus for dealing with negatives and for printing at least 3l. must be expended in addition. "Quarter-plate," 4½ in. by 3½ in., is sometimes recommended for the first start, just in order to get the hand in; but 5 in. by 4 in. is better. The first cost of this should be about

This meagre outfit is a minimum; but taken for in order that the first trials may be made with freedom; without any idea, at least, of possessions have made it difficult to go on. More lenses will be wanted for careful work afterwards. Instructions to beginners are given by arrangement with makers of apparatus, and there is a class at the Polytechnic. When the amateur starts on his first expedition, hoping, perhaps, rather than believing, that a slender store of knowledge will prove sufficient for the occasion,—his expenditure, if he is taken to a 7½ in. by 4½ in. camera and has carefree, will have amounted to about 17l. Leaving on one side first cost of apparatus, only the costs out of pocket for plates and chemicals,—a 5 in. by 4 in. negative will cost out 3d. by the time it is varnished and can be shown in the light of day. The first print will cost about 1½d. For 10 in. by 8 in. the estimated negative may be put at 1s., and the first print at 3d. [The six small photographs reproduced in the *Builder* this week are from 5 in. by 4 in. prints, and the larger one from 10 in. by 8 in.]

It is not unusual, for people with many irons in the fire, to finish off the negative, take a final print, and then entrust further reproductions to others. For six years the members of the Architectural Association have been supplied with admirable prints at a charge of 6d.: 10 in. by 8 in., and 3d. for 5 in. by 4 in.,—at a very low price as such things go, to assist a student's time and a working profit are, of course, included in these prices; and a hard-working amateur, who is liberal in gifts to his

friends, may be satisfied to take over these with his other rewards.

Notes as to Baggage.—For the Banbury excursion this session, four dozen 10 in. by 8 in. plates and ten dozen 5 in. by 4 in. plates were required. Two dry-plate cameras, dark slides and changing boxes, tripod, level, lantern, and the fourteen dozen of plates increased the ordinary traveller's baggage by about 65 lb. The risk of breakage of the plates,—if there is a steady hand, and if proper boxes, cases, &c., are used, may be very small,—during six annual excursions no important negative has been injured before the arrival at home. Still, glass is fragile,—and losses have happened in afterwork done in quasi-comfort in the dark room at home, and thereafter in rooms not dark. The 10 in. by 8 in. camera weighs 12 lb. with changing-box, tripod, and six plates,—twelve plates for it weigh about 7 lb. The 5 in. by 4 in. camera with six plates weighs only 7 lb.; it is not infrequently looked upon as a suitable companion for a day's walk among the mountains. A dozen 5 in. by 4 in. plates weigh about 2 lb. If the resolve has been made that six 10 in. by 8 in. and eighteen 5 in. by 4 in. negatives shall be obtained within the day, it is necessary to start with 20 lb. of baggage; that is, two leather cases containing the cameras and changing-boxes,—the tripod, contrived to fold into a length of about 2 ft., may serve as a handy bâton.

Completing Negatives.—The ingenious automatic changing-box is a little luxury which, when holding a dozen plates, costs about 4l. 10s. A plate may be transferred from the box to the camera and hack again, without the possibility of light affecting it or any plate in the box. From the dark slides of the changing-boxes the plates are transferred at the dead of night into packages by the light of a ruby lamp, and fresh films are put in ready for the toils of the morrow. Guiding minds do not recommend developing plates on a journey. They will be just the same at the end of the journey if kept safe from damp and light.

When home and leisure are reached, and the eager desire felt to behold and permit others to behold the fruit of the labours, the negatives must be developed, perhaps intensified or reduced, fixed, washed, and dried,—before a trial print can be taken. Varnishing is not absolutely necessary, but there is greater risk of injury without it. After a good print has been obtained the negative is warmed, coated with varnish, warmed once more, and when cool again it is ready for the printing. Not reckoning time spent in doctoring, adding to or diminishing density, and supposing that a hatch of negatives are treated at the same time, it is considered that each negative requires from ten to fifteen minutes of special attention, between the time of taking it out of the dark slide and putting the sensitised paper upon the varnished negative.

The negative, when the descent of the shutter left it in darkness, had received all the details in light and dark, but too faint to be visible,—the developing solution brings the latent image into sight, and in doing so changes the condition of the silver which has been acted upon by the light, making it insoluble in solvents which dissolve bromide of silver. If, for instance, a gelatine plate is exposed and not developed, but treated with hyposulphate of soda, all the silver salt will be dissolved, and a film of colourless gelatine will be left on the glass. The solution being poured upon the plate, and made to cover the whole of it, the first faint darkening will commence in about a quarter of a minute,—in about two minutes the whole plate (in a good negative) will be darkened, except those parts which represent blackness in the scene. It must remain till it appears denser than it is eventually to be, and practised skill can alone determine how long that must be. Of the two developing processes which are used for gelatine plates, the ferrous oxalate is considered the best for beginners, on account of its extreme simplicity and good results. More may be made of an inferior plate by the other process,—the time consumed will be about the same for each.

Development brings out the qualities of a plate which are required for printing; and fixing keeps it in the state to which it has been brought. After rinsing so as to get rid of the developer and stop that process from continuing, five minutes or so must be spent in an alum bath so as to harden the gelatine. Rinsing clears away alum from the surface, and the fixing solution is then used to take away such

portions of the sensitive salt of silver as were not acted upon by the light, and by the developing solution. After their removal the plate can be brought into the light of common day without injury or risk of change. Washing for at least half an hour in running water, or frequent changes of water, will be necessary in order to get rid of the hyposulphate of soda, used to get rid of the superfluous silver.

Printing.—A sensitive film is put upon paper; this paper is laid upon the negative; and the light strikes through the negative, and acts upon the film on the paper, in the same way as the light acted upon the film on the glass. The dark portions of the negative transmit little of the light, and thus there are light parts in the print; and vice versa. The preparation of the ready sensitised paper, which is so largely used, is at present a trade secret. In view of its cheapness, few amateurs now go to the trouble of preparing their own paper. It is sold ready for use at 13s. 6d. per quire; the cost of the paper for a 10 in. by 8 in. print is thus 2½d.; for 5 in. by 4 in., ½d. The paper will keep good for a considerable length of time, either before printing or between printing and toning. Superior results are gained by very experienced photographers who sensitise their own paper; but they are obliged to print and fix on the same day on which they prepare the paper, as it turns brown in twenty-four hours.

In printing, the negative is placed in a pressure frame over a piece of the sensitised paper; the frame is so made that half the print can be examined, and the other half remain in contact with the negative, so that no change in the relative positions can take place. When the light has passed through and left a perfect impression on the paper, the negative is removed. The print is then washed in water, changed twice or three times. In order to give a more agreeable tone than the red of the print at this stage, an exceedingly thin film of gold,—as thin as a soap-bubble,—is deposited upon it, from the "toning-bath," composed of chloride of gold and acetate of soda. The tint depends on the length of time passed in the bath: a print passes from red to brown, then to purple, blue, and ends in a dull, flat, slate colour. It is usually advisable to remove the prints from the bath while the shadows are still a very warm brown, the half-tones just becoming purple or violet. After the toning, washing in water gets rid of the toning solution in the paper; if this is not done the toning goes on. A solution of hyposulphate of soda does for the print what a similar solution does for the negative,—that is, removes the silver which has not been acted upon by light, and thus fixes the print. After complete washing the hyposulphate is got rid of. It is the criminal responsible for the decay of so many admirable prints. Many ghostly shapes, becoming dimmer every year, had their time of pleasant force; for years the fixing solution has been, as a work of pure supererogation, destroying the silver.

Some architects have skill in attending to their ordinary work, and to the printing of photographs at the same time. A space on a wide desk, between a large window and a drawing-board, may be covered with pressure-frames by a Caesar-like person; and no time will be lost, nor any interest suffer. Each print will require about five minutes of special attention, from putting it on the negative to clipping it round,—sometimes more, for, with a dense negative and dull weather, it may take even two days before a good print is obtained.

Silver printing has been, and is, more largely used than any other process,—though there are others which have staunch advocates. Platinotype is said to be gaining ground. The results are permanent, the effect that of a good pencil drawing,—the surface of the paper dull, not glazed, and it is more easy to carry out than silver printing. On the other hand, it is more expensive, and an inferior negative will not yield a passable print.

Beginners are not likely to try the rapid printing papers, as they call for so much special knowledge in timing the exposures.

Fixed Prints.—A frame of these prints has been presented to the Association. A print on paper is floated in a warm solution of gelatine, then placed face downwards on clean glass, and pressed into contact in all parts with a squeegee or the hand. The surface becomes very fine: when dry they are trimmed, sized, and painted over on the back with oil colour or coated with black varnish. Treating a 10 in. by 8 in. print in this way will cost 6d. to 1s.

Transparencies are printed from negatives on ordinary dry plates. An exposure of from five seconds to a minute, according to the density of the negative, is given at a distance of 3 ft. from a gasburner,—all other light being excluded. They must be slowly developed, and fixed with fresh solution. An ordinary transparency for 3½ in. by 3¼ in., printed from a negative, requires an outlay of about 3d. The wet collodion process is also largely used for transparencies, as gelatine is apt, unless very skilfully used, to give a more or less yellow tint, and impede the transmission of light through the glass.

Miscellaneous.—General maxims,—such as those which mention the virtues of patience, of keeping on learning, and of being amiable under failures,—are by common consent of the utmost value, especially to beginners in photography. An amateur will find that plenty of the discipline, which is the purpose of life and its occupations, is likely to come in his way. The sun will not shine for a whole day,—or, when the watch is not vigilant for a moment, will open a joint in a changing-box, and adorn each interesting negative with one or more comet-like forms,—or do some other playful deed. A plate with a view on it will be used again with strange results; the nacoated side of another plate will be turned towards the lens. A whole set of dry plates will prove, in an unexplained way, useless; and perhaps he will refuse to be comforted, although he prepared them himself. Chemical, green or red fog will appear on one or another of another set of plates; with, for variety, blistering, frilling, spots, streaks, scatchings, yellow veil, yellow fog, or halation. Prints which he has given away in the pride of his heart will turn up from time to time; and, each time in ghastlier pallor, accuse him of perfunctory washing.

The early days will, however, pass away with a decent rapidity. There are few things more pleasing than to observe the affectionate friendship between a capable old hand and his camera, tripod, and plates, all proved thoroughly during long practice; the instrument might be praised,—in verse,—for seeming as eager as its master. This facility,—acquired with much difficulty, and so easily lost,—appears to some people very dangerous; they assert that, instead of remaining a good servant, the art often succeeds in bringing its master into subjection. Used as helps to study, and for the rapid collection of information for reference, there can be little risk. If a student sketches and means none the less, and photographs as well, he has gained the service of additional hands and eyes. These remarks have been strictly limited to showing the cost in time and money of acquiring and making use of the services of such additional members.

The ethox light was used for the lantern by which the photographic slides were exhibited. Gas-bags, pressure-boards, weights, &c., always bulky and unsightly, and very often inconvenient to the spectators, were thus entirely dispensed with. Being under pressure of 600 lb. to the square inch, or forty atmospheres, sufficient oxygen gas is stored in an iron bottle only ¼ in. diameter and 2 ft. 2 in. long. A regulator, invented by Messrs. Oakley & Beard, of 202, Grange-road, S.E., was screwed upon the bottle so as to obtain the proper consuming pressure, and a portion of the gas passed direct to the jet, and another portion passed over ether, saturated with it, and then carried to the jet. The method of supplying gas to the jet proved very efficient,—the light being as steady as any before seen.

[Of the discussion which followed we will give a brief report in our next.]

Proposed New Clubhouse at Swansea.—The Conservatives of Swansea town and district have formed a limited company for the purpose of providing a clubhouse for the members of the party. Negotiations are nearly completed for the purchase of a suitable site,—45, Wind-street, which is freehold property,—upon which it is proposed to erect the clubhouse. Plans for the erection of the building, which have been prepared by Mr. T. P. Martin, architect, have been approved of.

Surveyorship, Fulham.—On Thursday, the 11th inst., Mr. F. W. J. Palmer, Assistant Surveyor to the town of Folkestone, was appointed Assistant Surveyor to the newly-formed Vestry of Fulham. There were 137 candidates for the appointment.

EXAMINATION HALL FOR THE COLLEGES OF PHYSICIANS AND SURGEONS.

THIS building (of which we this week give view and plans) is to be erected by the Royal Colleges of Physicians and Surgeons of London, and will afford accommodation for the examination of six hundred medical students at one time. It is on the Duchy of Lancaster land, and faces the Victoria Embankment Gardens. It will be in the Italian style of architecture, and built of red brick and Portland stone. The basement is spacious, and contains rooms for mensura, caretakers, &c. On the ground-floor are clerks' and secretary's offices, and waiting-room and examiners' room, and three large examination-rooms. On the first floor, one large examination-room, 100 ft. by 30 ft., capable of being divided in half; and also two other examination-rooms, each 60 ft. by 21 ft. The second floor has similar accommodation, and on the third floor are two large chemical examination-rooms and two anatomical examination-rooms. Lifts and other accommodation are provided on each side of the building.

Portions of the old Savoy Palace walls were discovered in excavating, and some old tiles and other articles have been discovered, and are deposited in the Duchy of Lancaster office.

The Queen has graciously offered to lay the foundation-stone on the 24th inst., which will be on the south end of the east wing, and will be of white Balmorall granite, with these words on it, gilt:—

VICTORIA,
QUEEN OF GREAT BRITAIN AND IRELAND,
EMPERESS OF INDIA,
LAD WITH HER OWN HAND
THIS FOUNDATION STONE,
24TH MARCH, 1886.

The trowel will be silver gilt, the mallet and level made from the old oak of the Savoy Palace.

The new building occupies the front portion of the land, and on the back the future extension is proposed to take place.

The architect is Mr. Stephen Salter, and the builders Messrs. Higge & Hill, of South Lambeth. The amount of the contract is 25,070.

BIRMINGHAM ASSIZE COURTS. SKETCH COMPETITION DESIGNS.

ONE of the two sketch designs given this week was one of those submitted by Mr. John P. Seddon, of London, and Mr. John Coates Carter, of Cardiff, under the notices "Castor," "Castor and Pollux," and "Pollux." It resembles generally that of Mr. Waterhouse in the disposition of the courts. Internal areas are given in sufficient abundance to provide every room and each corridor with windows at the usual levels, as well as top lighting by skylights, so that every portion of the building would be supplied with air and light. Each court has the whole of the rooms required in connexion with it in convenient proximity, and those appropriated for witnesses immediately wanted, are, in each case, exactly opposite the doorway to the court by which they would have to enter. Those for the jury are upon the other side of the court in each case, as is desirable. There are separate entrances for the Bar and Judges, and a grand central entrance from Corporation-street for the public having business in the courts, and another distinct one for the common public, giving access to the galleries of the courts only.

J. P. S.

The other design, by Mr. H. H. Statham, is planned on the principle of classifying the various rooms in groups so that each corridor may have its own speciality. The magistrates' rooms and the officers and witnesses connected with their courts are all arranged on the right of the hall, the magistrates' executive departments being entirely combined around their special corridor. The third court is similarly treated on the left of the hall. At the top of the hall the right-hand passage gives access to the Criminal Court corridor, the left hand to the Civil Court corridor and to solicitors' rooms, the barristers holding the cross corridor at the top. The consultation-rooms are arranged and numbered along a "Consultation-room Corridor" on the left of the plan, so that the room named for an appointment could be at once found. The steps at the top of the hall lead to the level of

the judges' retiring-rooms and the sheriffs' room, which is placed between them, the offices of the Clerk of Indictments and Clerk of the Crown being close to the foot of this stair. The judges are provided with a perfectly distinct entrance and private corridor on the first-floor level, entering from the higher level at Newton-street and descending a few steps to the intermediate level of their rooms. The rooms for witnesses immediately wanted opened directly into the Courts.

It was proposed to carry on ventilation and heating simultaneously, by mechanical propulsion of air through chambers intermediate between the ground-floor and the basement rooms, and in the large courts by basement passages; the air propelled by fans through water-sprays, and then through canvas sieves (removable and washable) and through the floors or through tubes (in winter) by steam pipes placed in the air-chambers. Air extracts from the top of all courts and one-story rooms. The areas from which the air was drawn to be lined with glazed brick, and the air-ducts lined with cement to a smooth face; the whole system of air supply to be capable of easy and efficient cleansing. The extract from the central hall to be by an upcast shaft in the circular turret, the lower part of which contains a staircase.

A novelty in the arrangements is the suggestion of lifts from the prisoners' cells to the docks of the courts: a plan certainly not convenient than sending police and prisoners up a narrow winding staircase, and taking up much less room. An attempt has been made at a special external treatment of the prison cell block, giving it a bastion-like character.

H. H. S.

COMPTON WINYATES.

WE give this week seven illustrations of the charming house at Compton Winyates,* reproduced from photographs taken by Mr. J. Robinson, of Dublin, the well-known architect who has for about eighteen years used photography as a help in studies of architecture. The photographs were among the large number shown by Mr. S. Flint Clarkson at the meeting of the Architectural Association, when he read the paper printed elsewhere in this number.

Compton Winyates is the best accepted form of the name,—though Winyates, Winyate, or other spellings are used occasionally,—it belonged to the Marquis of Northampton, and is at the present time used as a residence by Lord William Compton. Situated in one of the most westerly of the hollows in the high ground about a mile to the west of the division between Oxfordshire and Warwickshire, Camden, and no doubt the people of his time wrote of it as "Compton-in-the-Hole," to distinguish it from several other Comptons heabouts. The high ground is, in fact, part of the line of hills, which some people call the northern extension of the Cotswolds. A tourist, with a liking for roads along hills might begin at Edgehill, the scene of the battle of 1642, which is about five miles north of Compton Winyates, and work down in a south-westerly and leisurely way by Brailles, the Rollerich Stones, and then by the true Cotswolds of Gloucestershire, through the middle of that county from Chipping Campden to Bath. In the early part of his journey would look down on the streams which go feed the Warwickshire Avon and would find at another Avon,—that which divides Somerset from Gloucestershire.

The waters from the quick slopes round Compton are received in a piece of water in the house, and go thence in a little stream, through the Stour, and then into the Avon, a mile or two from Stratford. The lowest point in the rising ground round "the hole" is thus, of course, on the west,—the side from which the house is approached.

The distance from a railway station keeps down the number of visitors. Kington is the nearest, and it is said to be about nine miles by cross-roads through "the Feldon" to the west of the hills. Camden, writing before 1607, put down pleasant words, which in old translation recall in our time the motto

* We gave two or three sketches from this house at the time of the last Architectural Association excursion; these photographs give more varied illustrations of it. Mr. Clarkson had selected them as those which wished published to illustrate his paper on "Architectural Photographs by Amateurs," they will be in place here.

of joyous days. He found the Feldon (the part of Warwickshire south of the Avon), "a champain country, whose fertile fields of corn and verdant pastures yield a most delightful prospect from the top of Edgehill." If, however, the larger roads and a prospect are preferred, it must be fully a dozen miles from Kineton station to the house.

The post-Restoration church is a little further down the hollow than the house,—to the north-west of it. The old church is said to have been destroyed by Parliamentary soldiers in 1646. The house was garriaged by them, as its owner was a zealous partisan of Charles. The present church was commenced in 1663; and the date, 1666, on a pipe-head, may point to its completion. We gave in our last volume (vol. xlix., p. 237) some extracts from old account-books showing that the cost of the building started in 1663 was about 300l., and may mention here that on pp. 237, 332, 337 of that volume are some notes and illustrations as to the house also. The church has two equal naves,—the arcade between them abutting on the eastern wall, and the altar being placed under the point where it abuts. An intention to deviate from ordinary plans has been suggested; but instances, such as Caythorpe, a church on the Cliff-road, south of Lincoln, may be quoted as telling against this. Caythorpe is almost entirely of geometrical date, and has also a double nave, the easternmost arch abutting against the central tower, above the apex of the west crossing arch, and the westernmost arch hitting the centre of the gable of the west front; for at Caythorpe one span covers the two equal naves. At Compton the arcade abuts at the west end on the centre of the tower arch, and is carried on a combination of key-stone and corbel. The date and many oddities of detail make the building piquant; but candour might lead to the confession that there is not much that is architecturally interesting.

Of the house, however, candid visitors always tell a different tale; and it has been known to make so favourable an impression as to distance all competitors of its age and size. Situation, history, and colour may do a good deal, but there are good grouping and detail as well,—so that everything is in its favour. The plan consists of a small quadrangle;—the buildings round it being,—the offices on the left on entering, the hall opposite the entrance porch, and rooms and chapel on the right. Henry VIII., when he visited Compton, was lodged in the rooms on the right of the quadrangle.

Shields on the doorway of the entrance porch,—now reached across the site of the filled-up moat,—give approximately the date of the erection,—that is, somewhere about 1513; for the pomegranate of Aragon, the castles of Castile, the rose and portcullis of the Tudors appear side by side. Sir William Compton, from boyhood the friend and companion of Henry VIII., built the house, and since he lived in it not many alterations have been made. He used brick of a rich red very liberally for walls and chimneys,—diapering some surfaces with a few black headers; stone he used more sparingly in windows and doors, and for quoins and copings. Stone slates with thick ragged edges cover the roofs. One of the stone-paved paths crossing the court leads to the entrance to the hall,—a simple doorway, not very much more prominent than that on the left, which leads into the offices. The founder, it is stated, pulled down a castellated house at Fulbrooke, also in Warwickshire, and carried off the materials to Compton. Fulbrooke is between Stratford and Warwick,—perhaps fifteen miles from Compton, so that the situation of the places offers no obstacle to the credibility of the story. The fact that Fulbrooke Park was the place, as people used to say, from which Shakespeare removed Justice Shallow's deer, has nothing to do with the story of the bay windows and other materials, which to be of any use must have been taken away at least seventy years previously.

The bay window is in the usual position at the dais end of the hall. The stonework is earlier in character of detail than in the parts adjoining; and, although the general effect is very pleasing, some parts have a look of not being specially prepared for the place which they occupy. The little arcade above the heads of the window-lights,—a feature which has been repeated at Wroxton Ashley, and in other recent work,—has, for instance, a shield and other ornamentation in one division only,

but that division is not over the central mullion. There is besides no reply to its rich detail elsewhere in the quadrangle; the line of the top of its parapet is carried along by a simple stone coping, but none of the other lines are continued. The other windows just by in the hall have cinquefoiled heads, but those in the hay are plain four-centred. The oak roof of the hall is also said to have come from Fulbrooke; and there is certainly an enigmatical look in it also, especially about the spacing and the feet of the wall-pieces. The wood screen across the hall at the end next the offices is a rich and notable piece of work,—some of the carving full of skill and spirit.

Canonbury Tower also belongs to the Marquis of Northampton, and was made to contribute some years ago to the adornment of Compton. A large oak chimney-piece was brought hither, and some other fittings. Sir Digby Wyatt directed these works, and put the hay window on the staircase which shows on the right of the large view, and is, particularly from the staircase side, a most pleasing addition. Among the pretty things on the outside of the building, the two gables with timber work, one on each side of the porch, in the entrance front, merit a high place, having a good deal of design in them in the cornices, bargeboards, and the little bracketed windows. The designer was, happily, not afraid of a good-sized piece of brick wall. There is a satisfactory breadth in the walls under these gables and elsewhere, and, consequently, an easy restful look; but the happy man was not oppressed by the cry for very ample lighting of all rooms and spaces, as the modern architect very properly is.

The brick chimneys, in every variety from plain octagon to rather wild and unalike involved forms, are among the noteworthy features; they may be compared with those at Hampton Court, Cheney, East Barsham, &c. The chapel, the plaster ceilings, carving, tapestry hangings, and so on, would deserve notice if we were attempting a complete account, instead of simply putting together a few remarks apropos of the illustrations.

FREE LECTURES TO ARTISANS AT CARPENTERS' HALL.

THE ARCHITECTURE OF CITY BUILDINGS.

THIS was the subject of the fourth lecture of this course, which was delivered on the 10th inst. by Mr. T. Chatfield Clarke, F.R.I.B.A.

Mr. Chatfield Clarke commenced by drawing a contrast between the City of London of today and the City as it existed in the time of Henry II. After glancing at the lost opportunity which was presented by the Great Fire of 1666 for laying out the City on some such comprehensive plan as that prepared by Wren, he came to a much more modern period, viz., about fifty years ago, when two great improvements were made in the City, the formation of Moorgate-street and King William-street in connexion with the approaches to the new London Bridge, of the architecture of which streets it could only be said that it was tame and uninteresting in character. After mentioning St. Paul's Cathedral, the Bank of England, and the Mansion House, many of the halls of the City companies, and several of Wren's churches, as monuments which were worthy of any city in the world, the lecturer proceeded to refer to the great changes which the street and other improvements of the last forty or forty-five years have wrought in the aspect of the City. Cannon-street was one of the first of the great arteries which cut through the City, the buildings on the south side being wholly new. The formation of the Holborn Viaduct and its approaches, the erection of the new Victoria-street, together with the widening of many of the most important of the City thoroughfares, and, last of all, the formation of the new thoroughfare through Eastcheap, constituted a series of undertakings on a large scale which had given much opportunity for architectural development. One special feature had been adopted, notably in the Mincing-lane and Mark-lane neighbourhoods, that of utilising the frontages of old houses, often the former residences as well as counting-houses of merchant-princes, rebuilding them, but marrying them to a lot of back land, and forming alleys or passages through to an adjacent street, by such means giving much value to back land; for nothing was more noteworthy of the trade of the City than the clinging of certain trades or markets to a very limited

area, giving special value to the property there and determining its use and adaptation with great particularity. It was true that owing to the narrowness of the streets, which, again, was due to the great value of land, many a worthy and excellent building was insufficiently seen; but, nevertheless, they were not scamped on that account or pinched in the character of the design or the material with which they were executed. What could not be seen was as worthy as what was seen. One cause which had contributed much to good building in the City was to be found in the fact that the value of the ground bore a much higher proportion to the value of the whole site than did the building to be put upon it. Lamentable as it was to find that it had been necessary to destroy many a sound and well-built building, occupied in earlier times by a noble family and later by a merchant-prince, the ground had become so valuable,—special sites reaching 45l. per foot super,—that the cost of replacing the building with one economical in its development of the space and complete in its lighting, with numerous floors and every disposition for business could not be avoided. The problem of a street building consisted in the adaptability of the buildings to the wants, the climate, and the surroundings of the particular business to be carried on. Now, to combine the needs of buildings with the simple principles of design, such as providing such a sufficiency of structural strength as not to make the building apparently weak in the lower portion, while not sacrificing light in that portion where it was most abundant, to let openings follow out of solution, &c. was a problem not always easy of solution. The treatment of the design, however simple, and in whatever style, should bear the relation not only of the scale of the whole to the parts, but a subordination of the less features to the ruling lines of the whole. Prominently in City buildings, there were several principal classes, such as banks, insurance offices, warehouses, shops, and offices, each class having its special requirements, which there were some factors common to all. The lecturer named a great many of the principal buildings of these types which have been erected of late years in the City, generally with commendation, pointing out that in some instances good designs had been marred by the exigencies of the law of light. We regret that we have not space to devote to this part of the paper. In conclusion, he observed that he had shown that within the limits of a square mile or upwards there was an amount of really good modern design worthy of the study of all who were interested in the art of architecture. The question that arose in his mind was, Does the amount of work, carefully and conscientiously thought-out, receive at the hands of the public that amount of recognition that it ought to do if not, why not? It could not be denied that it had almost been the fashion of late years, in certain circles and journals, to decry the works of modern architects as wanting in fitness, as ill-adapted to their uses, or, as having been in many cases carried out without a conscientious regard either to cost or to the details of modern wants. Now he took the liberty boldly to deny in the main that there was any shadow of justification for such charges. Admitting some unfortunate exceptions, he contended that an examination of the immense amount of building work executed in the City of London alone would give the easiest refutation to such statements. If we compared from one moment the healthiness, the fitness, and the general disposition of modern premises with those in which our forefathers lived and worked, and if we looked at the careful and economical disposition of the place, the use of materials, and the desire to adopt the scientific classes of construction of iron and otherwise, we should see that there was no comparison between the old and new; and, with wide knowledge of men in the architecture of the past, we should find that they were earnestly desirous of carrying out their work with a sole regard to the interests of their clients, and in many cases (though not adequately compensated) with a strict eye to the financial results of their works, and with a regard to their bearing on the health and happiness of the community. Of course, the public at large, who, as a rule, generous recognised the merits of any distinguished designer, had not always at hand the means of knowing how crippled he might have been, and how difficult it was to get assented

plans and designs which, to be fully understood at first, must be judged of only by those who had technical knowledge of drawings; but in the end, a conscientious single eye to the interests of the client or the public would be generously recognised and appreciated, and the passing mood or fashion of decrying the labours of those who were often working under limitations not understood was probably one of those evanescent forms of shallow criticism which would die out. Nevertheless, the student of architectural art will be warned that the sacrifice of utility to style, the choice of such style where wholly inappropriate to the class or position of the building, and any want of care in the estimates, carelessness in the construction or superintendence, would justly not only bring on the head dissatisfaction and loss, but would not keep alive in the public mind a conviction that it was better to get on without an architect, and to trust themselves guided by the building contractor. It should be the aim of every young practitioner especially, by his talent, and energy, to dispel such an illusion and to raise the character of the profession of which he was a member. The contractor's final word was one of satisfaction that that ancient guild was taking up the thread of the work of art-education, so fit and right in connexion with the Company, and by such means establishing in the minds of a great public those claims of fitness and ability to do most useful work in our great community.

On Wednesday evening last the fifth lecture of the series was given by Mr. John Slater, B.A., on the subject "Concrete." The portion of this will be found on another page.

ARCHITECTURAL SOCIETIES.

Manchester Architectural Association.—At a general meeting of this Association, on the 13th inst., Mr. L. Booth, President, in the chair, Mr. John Holden, President of the Manchester Society of Architects, read a paper on "The Duties and Requirements of an Architect's profession." He said that as the standard of education rose in respect to the general public, would it rise with the architectural profession. He then detailed and described many of the practical questions upon which architects are often consulted, and said it had always been his opinion that the architect was the proper person to take out the quantities for his own works. Such a course was of great advantage to the owner and also to the builder. Many plans in London offices completed their articles, without knowing anything about quantities, but he was glad to say was not the case in Manchester. In conclusion, he said he looked forward to the time when the Fellowship of the Institute would be considered one of the aims of an architect's life. The Institute, from its origin and from the number of its members, ought of necessity exercise very great influence on the profession throughout the country. If non-Metropolitan Fellows were to be bound by its regulations, they should have some voice in framing or making the same. A discussion followed, in which Messrs. Mea, Talbot, Colley, Hodgson, Mould, and the chairman took part.

Royal Institute of the Architects of Ireland.—The usual monthly Council meeting of the Institute, held on the 1st inst., Mr. J. R. Carroll, in the chair (also present, Messrs. J. J. Callaghan, Wm. Mitchell, S. Synes, Hon. Secy., Albert E. Murray, hon. secretary), after the general business was concluded, it was decided that a deputation from the Institute should wait on the Lord-Lieutenant, and present a letter with an address of welcome, Messrs. J. R. Carroll, T. Drew, and Albert E. Murray, hon. secretary, to form a sub-committee to draw up an address, which was duly presented on the 1st inst. The address contained the following passage:—

It is a source of great satisfaction to the architects of this country to observe that successive Governments have an increasing disposition to employ the best talent available to design important public buildings, rather than by a system of departmental centralisation to lose the advantages to be obtained from varied working in different schools of thought. We can, in pride and satisfaction, point to some public edifices in this city, erected under the former system, not unworthy of any country, and to an important work now being executed on which, it is believed, will not be less deserving praise.

Lord-Lieutenant, in his reply, accepted the title of vice-patron of the Institute.

THE DISPOSAL OF THE METROPOLITAN SEWAGE.

An important report on this subject was presented to the Metropolitan Board of Works at its meeting on the 12th inst. The following are the principal passages:—

"Immediately after the publication of the first Report of the Royal Commission on Sewage Discharge, the Board instructed their Engineer and Chemist to institute a series of experiments for the purpose of ascertaining the best method of complying with the recommendations of the Commission, and voted the sum of 1,000*l.* for the purpose of those experiments, to assist in which Dr. Dupré, F.R.S., was retained.

As a preliminary measure, the Chemist to the Board, Mr. Dibdin, and Dr. Dupré commenced a series of experiments in their respective laboratories, and arrived at certain definite conclusions which served as a guide to the trials subsequently made at the Western Pumping Station, Pimlico. At this place apparatus was erected for the treatment of successive quantities of 1,000 gallons of sewage, which was subsequently arranged for the larger quantities of 100,000 and 250,000 gallons.

These larger experiments were conducted for about three months, and demonstrated that chemical precipitation of the solid matters held in suspension can be effected by the addition of various re-agents, but that no practical advantage accrued from the addition to the sewage of more precipitating matters than are really necessary for facilitating the natural tendency of the solids to deposit: the effect of adding large quantities of chemicals ensuring only a more perfect clarification without materially affecting the soluble constituents of the sewage.

This primary point having been determined, attention was next given to the collection and disposal of the sludge. Although at first sight this appeared to be a tolerably simple matter, the enormous quantity of London sewage rendered it imperative that more precise data should be obtained as to the quantity to be dealt with per day, its adaptability for transit, pressing, and ultimate disposal.

The evidence given before the Commission was of so conflicting a character that it was felt that nothing short of a prolonged series of experiments on a tolerably large scale, extending over some months, and including day and night, would afford the information necessary before working plans could be drawn up for the erection of plant for treating the whole of the sewage.

The Board therefore voted a sum of 5,000*l.* in November, 1884, for the erection of works at the Crossness Outfall for the treatment of one million gallons of sewage daily, and the pressing of the sludge obtained therefrom. These works were accordingly erected, and while special attention was directed to the sludge, numerous experiments were made with regard to the chemicals employed for precipitation. The results of these have confirmed those first arrived at, viz., that the sewage can be sufficiently clarified by the addition of 3.7 grains of lime and 1.0 grain of proto-sulphate of iron to each gallon of sewage, and by subsidence in settling-tanks during a period of from one to two hours. In addition to the removal of the solids, the grosser odours of the sewage are destroyed, and the foul and offensive appearance removed.

The accompanying reports of four very eminent chemists (one of whom was a member of the Royal Commission on the Metropolitan Sewage Discharge) are a sufficient guarantee as to the satisfactory condition of the effluent after the above treatment of the sewage.

The two reports are as follow:—

October 27, 1885.
To the Sub-Committee on Sewage Disposal of the Metropolitan Board of Works.

Gentlemen,—In response to the question submitted to me for consideration through Mr. Dibdin, whether the treatment of metropolitan sewage with lime and sulphate of iron, in the proportion of 3.7 grains of the former to one gallon of the latter to each gallon of sewage, furnishes an effluent of such a character that we could recommend its discharge into the river at all states of the tide, we have, in the first place, to express our regrets that the shortness of time within which it is desired to receive from us an expression of opinion has not allowed of our making such a comprehensive examination of the matter as its importance would have rendered desirable.

We have, however, witnessed at Crossness the treatment of the sewage in the manner indicated, and have made certain experiments with effluents obtained thereby, and we now submit the following statements on the subject:—

1. We are of opinion that the discharge into the river of such an effluent as is obtained by the treatment in question, and after such subsidence of the solid matters as

is practically attainable, would be a very great gain over the discharge of untreated sewage, and that the treatment done, apart from its precipitating action, exert a distinct purifying effect upon the liquid part of the sewage. We consider, however, that the effluent produced by the proposed treatment retains a sufficiently unpleasant odour to prohibit its being discharged into the river during warm weather at all states of the tide.

2. As regards the mere production of a fairly clear effluent our present impression is that little, if any, additional advantage would accrue either from an increase in the proportions of the chemicals specified or from a resort to other chemicals which would act merely as precipitants.

3. We have reason to believe, however, from what we have seen in the way of experiment, that the addition of manganate of soda and sulphuric acid, or of other suitable oxidising agent to the fairly clear effluent obtained by the treatment with lime and sulphate of iron would so far deodorise and purify that as to allow of its being afterwards discharged into the river, throughout the year, at all states of the tide.

4. It is a question whether this supplementary treatment of the said effluent by an oxidising agent may not be dispensed with during the winter months.—We are, &c.,

(Signed) F. A. ABEL,
WM. ODLING,
ALEX. W. WILLIAMSON,
A. DUTRE.

December 19, 1885.
To the Sub-Committee on Sewage Disposal of the Metropolitan Board of Works.

Gentlemen,—In our report of the 27th October we expressed the following opinion, viz:—

1. That the discharge into the river of an effluent obtained by the treatment of sewage with lime and sulphate of iron in the proportion of 3.7 grains of the former and one grain of the latter to each gallon of the sewage, and by such subsidence of the solid matter as is practically attainable, would be a very great gain over the discharge of untreated sewage; but that such an effluent retains a sufficiently unpleasant odour to prohibit its being discharged into the river during warm weather at all states of the tide.

2. That so far as regards the mere production of a fairly clear effluent, little, if any, additional advantage would accrue either from an increase in the proportions of the chemicals specified or from a resort to other chemicals, which would act merely as precipitants.

3. That we have reason to believe that the addition of manganate of soda and sulphuric acid, or of other suitable oxidising agent, to the fairly clear effluent obtained in the manner described, would so far deodorise and purify that effluent as to allow of its being afterwards discharged into the river throughout the year at all states of the tide.

4. That it was a question whether this supplementary treatment of the effluent might not be dispensed with during the winter months.

We have nothing additional to observe with regard to statements 1 and 2, but with reference to 4, we have to state that additional observations made by us since the submission of our report have led us to the conclusion that the concurrence during a considerable part of the year of the comparatively low temperature, both of the sewage and of the river into which it is discharged, with the greater dilution of the sewage, renders a supplementary treatment of the fairly clear effluent obtained by the addition of lime and sulphate of iron unnecessary during the periods of such concurrence.

With a view to enable us to speak more definitely on the subject dealt with in statement 3, we have instituted a number of experiments, not only with samples of average sewage, but also with samples representing exceptionally offensive conditions: we have, moreover, carried out our experiments not merely at the ordinary temperature, but also under exceptionally severe conditions as regards maintenance of the sewage and the effluents at elevated temperatures and in confined spaces.

The results of these experiments have led us to the conclusion that, in cases when the supplementary treatment by an oxidising agent of the effluent obtained by the use of lime and sulphate of iron is necessary, the addition of manganate of soda in some proportion ranging between 0.5 grain and 1.5 grain of the crude commercial manganate to one gallon of the effluent, together with sulphuric acid in a proportion corresponding to about one-third of that of the crude manganate used, suffices to deodorise and purify the effluent to such an extent as to render its discharge into the river objectionable at all states of the tide.

We therefore recommend:—

1. That the sewage be treated throughout the year with lime and sulphate of iron, in the proportions of 3.7 grains of lime to 1 grain of sulphate of iron (green vitriol) to each gallon of sewage.

2. That whenever it should be found that the fairly clear effluent obtained by that treatment is to any appreciable extent offensive, manganate of soda be added to the effluent in such proportions as are found to be necessary to deprive it of its offensive smell, these proportions to range between 0.5 grain and 1.5 grain (inclusive) of the crude commercial manganate, with sulphuric acid (commercial oil of vitriol), in quantity equal to about one-third of the crude manganate added.—We are, &c.,

(Signed) F. A. ABEL,
ALEX. W. WILLIAMSON,
WILLIAM ODLING,
A. DUTRE.

For the purpose of pressing the sludge obtained, a 30-inch press was procured from Messrs. Johnson & Co., of Stratford. During the seven months that this has been at work it has pressed 1,787 tons of sludge, which yielded 523 tons of 'cake.' In addition to the sludge thus treated, 1,408 tons have been experimented upon by various means, for the purpose of ascertaining the possibility of getting the sludge into a solid condition without the expense of thus pressing it. The result showed that this had been done to a certain extent; but the time required to make it solid would, during the summer months, render this method objectionable.

One hundred tons of sewage-cake have been burned in a Hoffman's furnace, at the brick works of Messrs. Hughes & Co., at Pluckley

Kent, and about 200 tons have been burned in various ways at Crossness. The result showed that, while there is but little difficulty in effecting the desired object, the expense of carrying on the system without nuisance would be prohibitory. It, therefore, became obvious that some other method of disposing of the cake, if the sludge is pressed, or of getting rid of the wet sludge, must be adopted, and if it is not removed from the works by farmers and others for manurial purposes the alternatives evidently are, either raising up low-lying land with the cake, or of taking the sludge or cake out to sea, provided that the contradictory evidence on these points could only be met, as before, by direct experiment. The Board, therefore, ordered that one of the compartments of the reservoir at Crossness should be arranged for the treatment of eight million gallons of sewage daily (the one-million gallon works being continued simultaneously) and that the sludge thus resulting from the treatment of nine million gallons of sewage should be used for the purpose of settling many doubtful questions as to its treatment and ultimate disposal. These works are now completed, and will be in operation in a few days. In the meantime, as many conflicting estimates of the cost of carrying the sludge out to sea have been submitted to the Board, advertisements were inserted in the leading daily newspapers inviting plans and estimates for a vessel suitable for that purpose, and in order to induce the leading firms of shipbuilders to compete, the Board offered a premium of 500*l.* for the best proposal in the event of the tender not being accepted. These plans have now been received and are under the consideration of the Board.

As soon as the eight million gallons experiment is at work, advertisements will be issued offering the pressed or unpressed sludge to all persons who may desire it, free of cost,—the object being to ascertain to what extent the sludge may be disposed of by this means.

The Royal Commission recommended that in the event of the sewage being treated by chemical precipitation at the present outfalls, the effluent should be filtered by passing it through land before being discharged into the river. The object of this was evidently to insure the removal of all odour from the effluent, and the possibility of 'secondary fermentation,' as it is called. The great cost attending such a method, and the difficulty of finding suitable land for the purpose in the neighbourhood of the outfalls, induced the Board to ascertain whether the desired object could not be effected by direct treatment of the effluent by means of an oxidising agent which, while effecting immediate deodorisation of the slight sewage odour remaining after the chemical or precipitation, should, at the same time, prevent the redevelopment of offensive gases. This agent has been found in permanganic acid, a substance widely used on a small scale, but hitherto not considered available for sewage treatment on a large scale. The operations of the Board, however, have not been confined merely to the application of chemicals, but also to their production on a large scale, with the result that while manganate of soda, the actual agent in the production of permanganic acid at the commencement of the Board's operations could be obtained only in limited quantities at 40*l.* per ton, it can now be purchased in practically unlimited quantities at 11*l.* per ton.

The application of this material in conjunction with sulphuric acid has met with such success, not only in London but elsewhere, that the necessity for land filtration no longer exists; and thus the great objection to the treatment of the sewage, and the discharge of the effluent at the present outfalls, is overcome.

The deodorisation of the sewage as a temporary measure, pending the construction of permanent works for its treatment by precipitation, has been systematically carried on. At first this was accomplished by means of chloride of lime, that substance being the only one obtainable in sufficient quantities at the time. Manganate of soda and sulphuric acid were subsequently used. In order to obtain the former of these in sufficient quantity at a low price, the Board found it necessary to construct chemical works and manufacture it themselves, with the result of reducing the cost as above stated. During the past summer these chemicals were the only ones used, and were found to be thoroughly effective.

For the purpose of preventing any nuisance within the metropolis arising from the discharge of offensive gases from sewer ventilators, the Board authorised the application of manganate of soda and sulphuric acid to the sewage as it flowed through the main sewers. Accordingly thirteen stations were arranged at the following places, viz.:—Bedford Park, Willesden, Fimlico, Westminster, Bayswater, Holloway, Old Ford, the Tower, Deptford, and Battersea.

The first of these came into operation on July 23rd, and the remainder as rapidly as possible. These stations are now being considerably augmented, and thus, while the evolution of sewer gas will be prevented within the metropolis from sewers under the Board's authority, more complete control will also be obtained over the storm overflows.

Provision has been made for the supply of 3,000 tons of manganate of soda, and 1,000 tons of sulphuric acid. Of this quantity 1,000 tons of manganate are now in stock, and the remainder is under contract for delivery by July, deliveries commencing at once. Should these quantities prove insufficient, by reason of another exceptional season, there will be no difficulty in providing as much more as may be required, either by manufacturing or purchasing it.

The plan of deodorising the sewage within the metropolis is proposed, not only as a temporary measure, but also as a permanent scheme for preventing the sewer gas nuisance, and will, therefore, ensure, during the summer months, the arrival of the sewage at the outfalls in a deodorised condition, and thus materially assist in the production of an effluent of a far better character than would otherwise be obtainable.

The contract drawings for the enlargement of the Barking reservoir, and arranging it for precipitation and purification works, are in a forward condition, and the contracts may be let in the course of the ensuing summer, and the works completed and ready to come into full operation for the summer of 1888; in the meantime, the deodorising works already described will prevent any nuisance from arising at this outfall.

Nine million gallons of sewage per day will be precipitated at Crossness throughout the coming summer, and the remainder will be deodorised, as on the north side, until the process of precipitation has been extended to the whole of the sewage discharged at this outfall.

The sludge arising from the precipitated sewage is being pressed into 'cake,' and given to agriculturists gratuitously to utilise upon their lands, and, if possible, to develop a demand for its use; and sludge that may not be so disposed of will be sent in lighters out to sea, both in the liquid and in the cake condition, in order to ascertain the cost and effect of this mode of getting rid of it.

The Board have now under consideration the twenty-three designs sent in by shipbuilders in reply to the invitation issued by the Board, and will shortly be in a position to determine what course they will adopt with respect to them.

Your committee submit the above facts for the information of the Board, and beg to recommend: That letters founded upon this report be addressed to the Secretary of State and the Erith Local Board of Health, in reply to their communications on the subject."

The report was received, and ordered to be printed and circulated, its consideration being postponed for a fortnight.

German Renaissance.—So much importance is often attached by the unskilled public to names as indicative of architectural or pictorial styles that the exposition lately given by Dr. Lehfeld at Berlin deserves mention as elucidating the above subject. According to his view, much is now described as *German Renaissance*, which should more properly be styled *Baroque*. While the Renaissance period in Italy extended from 1420 to about 1540, the movement only displayed itself in Germany about 1500, and was concentrated in the period between then and 1560. A distinction was drawn by the lecturer between the Renaissance works built in Germany by Italians, and those designed by native architects. The introduction of Renaissance styles into Germany was due not only to architecture, but also to painting and engraving; the pictorial treatment of many German Renaissance works being thus explained as well as the occurrence of ideas drawn from metal work, &c. In North and South Germany true Renaissance work has a like character of graceful simplicity.

ARCHITECTURAL ASSOCIATION VISITS.

The fourth Saturday afternoon visit of this Association for the present session was made on Saturday last to the houses in Kensington court which are being erected from the designs of Mr. Stevenson.

The houses now in course of erection are principally facing the street which runs parallel to the High-street, the roadway having been raised some 8 ft. from the original level; the angle house, which is very ingeniously planned, with a small frontage to each street, has the dining-room on the floor below the entrance hall, which is, however, still well above the level of the street at the back; this lower ground-floor comprises in addition the kitchen and offices. The hall floor comprises, in addition to the large ball, two reception-rooms. There are two floors above this. The other houses are arranged with large halls in the centre of the block. The external elevations are faced with red brick, some with buff terra-cotta dressings, others with gauged brick. All the houses have lifts which pass through the principal floors, and which are worked by hydraulic power, which is supplied by the Hydraulic Power Company, who have a station on the estate. The lifts are made with an arrangement whereby the door opening into the lift cannot be opened unless the cage is opposite the door. At the back of the estate the stables have been built. These are arranged with the coach-houses on the ground-floor; the stables are on the first floor, approached by an inclined plane with a rise of 1 in 3; and above these, the coachmen's living rooms, which have a separate gallery and staircase to reach them from the ground, and also a staircase from them to the stable level.

PROPOSED UNITED ARTS CLUB.

Sir,—Will you allow me, through the medium of your valuable columns, to draw the attention of professional men to the fact that a circular will, in the course of a few days, be issued relative to the above? The Club will be founded on principles comprising all the accessories pertaining to institutions of a similar nature, and will provide accommodations specially suitable to the requirements of professional men.

All architects, painters, sculptors, and engineers in the United Kingdom will be eligible. By thus bringing together the various members of the kindred professions, it is hoped to promote more social intercourse than at present exists between them.

The annual subscription will be placed at the lowest possible figure, so as to enable the young members to participate in the benefits offered.

A. LOWTHER FORRESTER,

Hon. Sec. (pro. tem.).

No. 19, York Buildings, Adelphi, W.C.

SEWER VENTILATION.

Sir,—“Sanitary Engineer” on p. 424 in your last issue, asks me to be as far as I can in sewerage sanitation as he is in his grammar. I say:—“Thorough aeration . . . and a perfect system of flushing has prevented the generation of the gas altogether.” Now, I do not believe it. These will diminish the production of the gas as dilute it, but not prevent it altogether. Moreover, it is not only the “gas” that has to be guarded against, but disease germs floating in the “gas” in the atmosphere of the sewer; hence the objections made by many people to surface-gratings of the streets as blow-offs, and especially in close crowded thoroughfares. The *Lancet* in advocating high-level outlet ventilating pipes for sewer ventilation is simply recommending a sensible plan, one which would be of great benefit in many places where the street-gratings are dangerous. I have suggested this often for years back.

W. P. BUCHANAN.

. Where are the pipes to go, so as not to either an eyesore and obstruction, or a concentration danger to individual houses? That is the question,—or one of the questions,—in connexion with the subject.

Buxton.—At a recent meeting of the Directors of the Buxton Improvement Commissioners, it was decided to recommend that the capital of the company be increased by 4,000*l.* for the purpose of erecting an assembly-room adapted to the requirements of a theatre. It was also decided to accept an offer from the Duke of Devonshire of part of the Serpentine to be added to the Pavilion Gardens as a recreation-ground for juveniles, &c.

The Student's Column.

OUR BUILDING STONES.—II. THE GENERAL CHARACTERS OF ROCKS.

THE word "rock" does not necessarily imply that the substance is of a solid, rocky material, although rocks used for building purposes are generally so. Geologists apply the word to gravel, clay, sand, and mud...

Our large cities in considerable quantities, but more especially so in the manufacturing districts, where its presence is governed more or less by the nature and magnitude of the manufactory.

The same thing applies to a certain extent to hydrochloric acid. We should find that this acid occurred largely in a free state in towns; but it exists in the sea-air as chlorides, principally as chloride of sodium, common salt.

Nitric Acid also occurs in small quantities in rain-water.

We have seen that rain-water in descending through the air takes up a certain quantity of it, and that carbonic acid is largely present in rain-water. Any stone containing carbonate of lime is attacked by this acid.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

7,674, Sharpening and Setting Saws. L. Martiner.

The saw is supported by a holder which can be raised or lowered, and is sharpened by a file fixed in a holder, to which a reciprocating motion is imparted by a crank and connecting-rod.

9,762, Cattle Drinking-Troughs. R. Pringle.

The orifice of the inlet-pipe from the main is directed upwards and protected by a shield presenting its convexity to the inflow to direct the water upwards, thus obtaining a surface flow of water and a "tranquil bed."

9,846, Excavator. J. F. Sang.

Two or more rotary disc cutters and a plough are mounted in the fore part of the main framing, and serve to cut and direct the earth into a receptacle through which the endless series of the elevator buckets work.

12,136, Cellars, &c. P. Schaar.

The vessels containing the beer, &c., are formed of masonry, glass, earthenware, concrete, or a similar material, and may be lined, if required, with cement and the like.

13,350, Kilns and Stoves. J. C. Wehh.

The kilns are placed one above another, and the flues arranged so that the gases pass round the top and sides before passing beneath the floor.

13,651, Portable Load Gauge. H. Adair.

The apparatus is used for gauging the height and weight of loads. It consists of a folding post of adjustable length, with a hinged gauge arm and a hinged foot, and is placed beside the wagon or conveyance.

14,892, Fireplace. Winfield, Evered, and Underhill.

A mantel register stove is converted into a cooking stove by the addition of an oven and boiler. The oven is fitted to the fire, and is surrounded by a flue through which the products of combustion pass to the chimney, a perforated damper regulating the draught.

THE CHEMICAL ACTION OF RAIN AND AIR ON STONE.

Having given a few of the more important features which characterise rocks generally, we now proceed to discuss the action of rain and air on them in so far as it concerns the decay or preservation, as the case may be, of the rock.

The normal condition of the atmosphere is considered to be a mechanical mixture of nearly equal volumes of nitrogen and one of oxygen to every small proportions of water vapour, carbonic acid, and still smaller quantities of ozone and ammonia.

In addition to these, or vapours, gases, and solid particles are present. It is with the vapour which, when condensed, forms rain, hail, and snow, that we are now particularly to deal.

An analysis of rain-water will show us that sulphuric acid frequently occurs in the air of

Edinburgh Architectural Association.—Visit to Niddrie Marischall.

Miscellaneous.

Surrey Archaeological Society.—The annual general meeting of this society, to receive the report of the Council, to elect officers for the ensuing year, and for general business, will be held at the Whitgift Hospital, High-street, Croydon, on Wednesday next, the 24th inst., after which Dr. Alfred Carpenter and Mr. J. R. Trower will offer some remarks on the history and nature of the foundation of the Whitgift Hospital. Mr. S. W. Kershaw, M.A., F.S.A., will also read a paper entitled "Notes and Annals of the Hospital;" and Mr. Henry Berney, A.R.I.B.A., will describe the paintings in the Chapel of the Hospital.

The New Unitarian Hall in Essex-street. In the *Builder* of the 27th ult. appeared an article on the historical associations connected with Essex-street Chapel, Strand, which is now being converted into a public hall for the general use of the Unitarian body. The structural alterations include, externally, the Essex-street frontage, which has been designed in the Italian style, faced with cement. Arched windows have been opened out, and the frontage has been relieved with handsome pilasters and cornices. The entrance to the office portion of the re-arranged structure is at the north angle, and is in Portland stone, with ornamental iron gates. Internally, the area of the chapel,—which was on the first floor,—is being converted into a public hall, 50 ft. by 40 ft., with a large recess for an organ, and over the east end there will be a gallery capable of accommodating 200 persons, the entire capacity of the hall being equal to an audience of 600. Besides the hall there are several retiring-rooms. The hall is approached from the ground-floor by a handsome stone staircase. On the ground-floor what was the old house as the residence of the ministers, together with several other apartments, have been converted into offices for the various Unitarian book societies. A shop for the sale of books has been provided, whilst adjacent are large apartments for storage purposes. On this floor there are also several committee-rooms, together with a library, likewise a council-chamber, lighted by a skylight, and fitted with pitch-pine dado and fittings. As already stated, Messrs. T. Chatfield Clarke & Son are the architects, and Mr. J. T. Chappell, of Pimlico, is the contractor. The cost of reconstructing the building will be about 6,000l.

The First Theatre in Brighton.—"The History of the Theatres of Brighton," with brief biographical notes of the principal performers from 1774 to 1855, written and collated by Henry C. Porter, twenty-four years dramatic critic at Brighton, will be issued shortly. The author says:—"The first theatre that Brighton could boast of was in North-street, and approached through a garden that abutted upon the main thoroughfare from Church Hill to the Steine. The building was of wood, with brick hasement, and underneath the house was a vault dug out of the chalk bank, in which it is said smuggled spirits used to be kept, as opposite the building were uncultivated fields and narrow bridge paths that merged into the greater Lane at the rear. The early wooden theatre was partly concealed by a high wooden boarding, and there was also another entrance from the back in Duke-street. The house was sustained by massive oak beams, and the stage was with its back to the west, rather declining towards the row of oil lamps and the circle of lamps that served to illuminate the shrine of Thespia. The structure was erected in the spring of 1774 by Samuel Paine, a bricklayer, who resided in a cottage close at hand, and followed that vocation. The first tenant was Roger Johnstone, a property-man from Covent Garden, who inaugurated the initial season on Tuesday, August 30, 1774, with Garrick's farce 'Letho, or Æsop in the Shades,' preceded by Colman's 'Jealous Wife.'"

The Unemployed.—The employees at the different Government Works in London, being invited by the heads of the firm of Messrs. Perry & Co., Government Contractors, to assist in forming a fund for the relief of the distressed workmen, responded by at once forming a committee of the several foremen, or their representative, of each district, and raising weekly subscriptions from the men under their charge (for a period of six weeks, if necessary), the mechanics subscribing one shilling and labourers sixpence each week. This has been so heartily taken up by the workmen that the committee were able, at their last meeting, to consider and give relief to twenty-five applicants, these being in all cases workmen who have been engaged upon Government works from time to time and well known to the foreman, who is responsible to the committee and vouchers for their being duly entitled to such relief. The firm sent the treasurer a handsome donation of 10l., which enabled the committee to grant to each of the twenty-five applicants the sum of 1l. each.

The Tite Prize.—Mr. Leeson writes to point out that his design "Spes" was placed third, not second, in the Institute list, the second being "Doric." The place of the two was inadvertently transposed in our remarks on the drawings.

Lightning Conductors in Germany.—The Liebeck Insurance Association has been taking steps to facilitate the adoption by its policy-holders of these important preservatives against disaster, by reducing its rates for insuring buildings thus protected on arranging easy terms of payment with a Berlin firm which supplies them. The importance of this question to the office referred to may be estimated from the fact that scarcely one-twelfth of the cases of damage from lightning occur in towns or villages, and the rural nature of the district in which its risks lie renders it peculiarly liable to losses from this cause. It is stated that buildings with soft roofing are struck two and a half times oftener than those with hard roofing, and are twenty times more liable to become ignited than the latter.

OXFORD—For the supply and erection of iron Gothic roof, and columns and gables, &c., for the Anthropological Museum, Oxford:—

Gardner, Anderson, & Clarke	£1,047 0 0
-----------------------------	------------

RAMSGATE—For certain alterations to fixtures and shop-front, at No. 49, High-street, Ramsgate, for Mr. G. Wellies, Mr. B. L. Elgar, architect:—

W. H. Fort	£125 0 0
B. J. Cowell	115 0 0
H. Miller	114 0 0
W. W. Martin	112 0 0
J. Elgar (accepted)	110 0 0

SILLOTH—For the supply and erection of the whole of the cast-iron columns and other cast-iron work, for new grain warehouses, for the North British Railway Company:—

Gardner, Anderson, & Clarke	£1,906 0 0
-----------------------------	------------

STAINES—For alterations to Mr. Cox's shop, High-street. Mr. Ralph Pitt, architect, Staines:—

Baker, Staines (accepted)	£200 0 0
---------------------------	----------

STRATFORD—For works in connexion with new counting-house, Broadway, Stratford, for Mr. J. R. Roberts. Mr. Kingsley Cole, architect. Messrs. Batam & Co., surveyors, Mount-street, Grosvenor-square:—

G. J. Hosking, Upton-lane	£765 0 0
Williams & Son, Thornhill-square	757 0 0
Macey & Sons, Strand	695 0 0
Wall Bros., Kenilworth	625 0 0
J. Morter, Stratford	591 0 0
Falmer & Co., Old Gravel-lane	545 0 0

WALTHAM ST. LAWRENCE—For alterations and additions to The Grange, Waltham St. Lawrence, for Mr. H. Franklyn, Messrs. Cooper & Sons, architects, Maidenhead:—

C. W. Cox	£555 0 0
Hann & Co., Windsor	449 0 0
Silver & Sons, Maidenhead	417 0 0
Bottrill, Reading	416 10 0
Margetts, Reading	359 0 0

WEST WICKHAM (Kent)—For the completion of two shops at West Wickham, Kent. Mr. G. St. Pierre Harris, architect, Basinghall-street, Messrs. Baxter, Payne, & Lepper, surveyors:—

Crosley	£139 0 0
Lay	135 0 0
Taylor & Son	113 0 0
Jones	101 0 0

WEST WICKHAM (Kent)—For the completion of five houses at West Wickham, Kent. Mr. G. St. Pierre Harris, architect, Messrs. Baxter, Payne, & Lepper, surveyors:—

Jones	£391 0 0
Taylor & Son	291 0 0

WEYBRIDGE—For proposed residence and stables at St. George Hill, Weybridge, for Miss Milligan, Mr. G. A. Wright, architect, Westminster-chambers:—

Brown, Weybridge	£4,281 8 8
Adkins, Surbiton	4,077 10 0
Holloway, Battersea	4,064 0 0
Ward, Portsmouth	3,912 0 0
Bottrill, Beading	3,860 0 0
Woods, Weybridge	3,825 0 0

SPECIAL NOTICE—Lists of Tenders frequently reach us too late for insertion. They should be delivered at our office, 46, Catherine-street, W.C., not later than Four p.m. on THURSDAYS.

TO CORRESPONDENTS.

Registered Telegraphic Address, "THE BUILDER, LONDON."

J. C. B.—R. A. H.—H. H.—W. J. E. H. should be glad to see the plans of the concrete building referred to.—J. R. W.—C. E. T.—E. L. F.—E. J. L.—L. G. R.—G. W. (next week)—J. C. (amount should be sent).—W. W. Miller.

All statements of facts, lists of tenders, &c., must be accompanied by the name and address of the sender, not necessarily for publication. We are compelled to decline pointing out books and giving addresses.

Note.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.

We cannot undertake to return rejected communications.

Letters or communications (beyond mere news-items) which have been duplicated for other journals, are NOT DESIRED.

All communications regarding Library and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

PUBLISHER'S NOTICES.

Registered Telegraphic Address, "THE BUILDER, LONDON."

CHARGES FOR ADVERTISEMENTS.

SITUATIONS VACANT, PARTNERSHIPS, APPRENTICESHIPS, TRADE, AND GENERAL ADVERTISEMENTS.

Six lines (about fifty words) or under 4s. 6d.

Each additional line (about ten words) 0s. 6d.

For full list of Special Advertisements, also for special advertisements on front page, Competitions, Contracts, Sales by Auction, &c., may be obtained on application to the Publisher.

SITUATIONS WANTED.

FOUR Lines (about THIRTY words) or under 2s. 6d.

Each additional line (about ten words) 0s. 6d.

PREPAYMENT IS ABSOLUTELY NECESSARY.

* Stamps must not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable at the Post-office, Covent-garden, W.C. to DOUGLAS FOURDRINER, Publisher.

Advertisements for the current week's issue must reach the Office before THREE o'clock p.m. on THURSDAY.

The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to advertisements, and strongly recommends that the letter OFFICERS ONLY should be sent.

SPECIAL—ALTERATIONS IN STANDING ADVERTISEMENTS OR ORDERS TO DISCONTINUE same, must reach the Office before TEN o'clock on WEDNESDAY morning.

PERSONS Advertising in "The Builder," may have Replies addressed to the Office, 46, Catherine-street, Covent Garden, W.C. free of charge. Letters will be forwarded if addressed envelopes are sent, together with sufficient stamps to cover the postage.

TERMS OF SUBSCRIPTION.

"THE BUILDER" is supplied minor from the Office to readers in any part of the United Kingdom at the rate of 1s. per annum. To all parts of Europe, America, Australia, and New Zealand, 25s. per annum. To India, China, Ceylon, &c. 35s. per annum. Remittances payable to DOUGLAS FOURDRINER, Publisher, No. 46, Catherine-street, W.C.

The Reconstruction and Sanitation of Central London.

WHEN a certain eminent historian was inditing the opening chapters of his projected work, he was disturbed, it is said, by a street row under his windows, the merits of which he could by no ingenuity of questioning discover. And his inability to determine the rights of a quarrel which happened under his own observation not unnaturally disheartened him in his task of unriddling the quarrels of all the world; for history, as it was then understood, is little else than a record of quarrels.

We have just now at our doors an opportunity of improving Whitehall, for which all things are ripe, about the importance of which are assured, and which, once neglected, will never, in all human probability, recur. If we do not bring ourselves to spend a few hundred thousand pounds in so desirable a work, what chance is there of our spending a few hundred millions on the reconstruction of Central London, the need of which is not so pressing, the merits of which are not so obvious, while attendant difficulties are incomparably greater? "A question not to be asked." And there is but little or no chance of our embarking upon a scheme of such unexampled and unrivaled magnitude, what good is to be had from its serious discussion? And yet such a project has recently occurred to many minds, and that which must, we hope, be accepted as the result of the best thought upon the subject, has been embodied in a volume of selected essays,* prepared in response to the offer of a large money prize. By three essays out of the twenty-seven which have been printed, and these are ably illustrated by plans and sketches, the subject divides itself into three parts,—the first, the alignment, reconstruction of destroyed streets, and the best manner of re-housing the distressed poor. And each section falls naturally into two main divisions,—What is well to do? And by what means it is to be accomplished? Each part of the subject is treated by special difficulties of varying degrees of intensity. It is easy to take a topographical map of London and lay upon it any number of desirable routes, and to suggest for facility of intercommunication and

conducive to architectural magnificence. It is easy also to clear away in imagination the congested centres of the great city, marking them out by washes of colour, and re-arranging their surfaces in symmetrically-figured building blocks, with open spaces and breathing-grounds, and all sorts of pleasant ameliorations. But it is difficult to determine with any approach to certainty what description of new building shall most suitably replace the old as being really adapted to the needs of the poor; and more difficult still to devise a financial scheme by which operations on such a scale can be conducted with a reasonable prospect of commercial success,—the only sure basis. The promoters of the scheme start with the postulate that property must steadily increase in value indefinitely where the population is constantly growing and the occupied area is fixed, and that future value so assured may be discounted for present purposes. No very close estimates are given, nor are they possible without such preliminary valuations of the districts to be dealt with as would involve a very large outlay of capital. It is proposed that the huge work shall be undertaken in sections, with the sanction of a special Act of Parliament, by a company or trust having some such title as "The Consolidated Central London Reconstruction Company" (which sounds to our ears a little too much like the sort of institution which we meet with in the works of Charles Dickens), subscribed by capitalists in shares of from 1,000*l.* to 10,000*l.* each, and guaranteed in part by the hypothecation of the coal and wine duties, and in part by a charge upon the local rates. The works would be carried out by contractors selected by competition, and under the direction of a special Works department composed of a staff of solicitors, architects, engineers, and surveyors. The essayists confess themselves appalled at the extent of the operations involved, which would demand an outlay equal in amount to the whole of the National Debt. Mr. Westgarth endorses their verdict as to its impracticability, but thinks that what cannot be undertaken in whole may still be accomplished in part. This is, in fact, what is being done by private enterprise, by philanthropic effort, and by the public bodies charged with these special duties.

The Metropolitan Board of Works have undertaken, upon a comparatively limited scale, similar works to those proposed to be entrusted to this imaginary department. They have laid out new streets, and cleared away old neighbourhoods. They have created superior frontages, and let the abutting plots on building leases; and they have, as it appears to one of the essayists more critical than his fellows, done all this unwisely, and not too well. What

security have we that where the Board has failed the company would succeed, or that they would do well in the future what their predecessors have done ill in the past? That with ampler powers and a wider discretion, they will achieve more fortunate results? None. The larger the scheme the greater the opportunities of error, and the more widespread the possible disaster.

The facts as to the present condition of Central London adduced by the essayists are sadly interesting; but they are not new. London is overcrowded; its thoroughfares are yearly growing less and less equal to the pressure of the periodic ebb and flow of the vast human tide which courses through them. The dwellings of the very poor are as bad as they can be,—a scandal to a Christian State. We have preached from these texts for half a century, and have lost no opportunity of enforcing their lessons.

It is, in fact, on the social and economic side of the great problem to which the essayists have addressed themselves that the real difficulty lies. Consider for a moment, and by way of example, the condition of the poor sempstresses of the East end of London, numbering a quarter of a million souls, recruited annually from our rural population. While every other form of labour has been receiving an enlarged remuneration theirs has fallen. Their position is sensibly worse than it was when Hood's piteous "song" stung the public conscience into transient remorse. By working fifteen hours,—when they are so "fortunate" as to obtain continuous work,—they can earn a shilling! And it is taken for granted that no improvement in this respect is to be so much as hoped for. They live in lonely garrets and die of broken hearts, or they seek in shame the means of existence which their utmost efforts cannot honestly procure. How is it proposed to deal with the case of such a class as this? It is proposed to erect vast piles of buildings in which these poor women can live as it were in communities,—under the administration of capable managers,—that they shall occupy cell-like apartments surrounding a common dining-hall. The suggestion of a "reading-room" for those weary eyes reads like mockery. It is calculated that by wise management, a rigorous economy in all things,—warming the building by hot water and regulating the dietary upon scientific principles,—it may be possible for each poor needlewoman to obtain lodging, food, light, and warmth, for 4*s.* 6*d.* per week, leaving 1*s.* 6*d.* for clothing and sundries, always assuming that she is fully employed and never ill. It is almost certain that such a scheme would break down from a hundred causes, and that an existence so conditioned would not resist the temptations of a great city, the

* Essays on the Street Alignment, Reconstruction, and Re-housing of Central London, and on the Re-housing of the Poor Classes, to which Prizes, offered by William Arthur, were awarded by the Society of Arts, 1885. London: George Bell & Sons.

attractions of the glittering street, and the bright warmth and gaiety of the music-hall or gin-palace.

There is just one drop of comfort to be sucked out of these essays. One of them gives a useful table of the proportion of open spaces to the population in European and American towns, and shows that London is not the worst off in this regard. Thus, while Paris has 1 acre of park to every 13 inhabitants, Vienna 1 to 100, Chicago 1 to 200, Philadelphia 1 to 300, Brooklyn 1 to 639, New York 1 to 1,363, London has 1 acre of open space to every 353 inhabitants. It is unhappily true that where the population is most dense the open spaces are most contracted, and that central London has only 1 acre of recreation-ground for every 1,000 inhabitants, being but a shade better off than New York. But in that city the evil is working its remedy, and large tracts are being purchased, at enormous cost, for its better sanitation. Here is a possible field for philanthropic effort, the results of which can be in no wise doubtful. It is very doubtful wisdom to house our poor in vast barnack-like structures, which must, from the very nature of their occupation, deteriorate in a hygienic sense, and in the long run become centres of disease. But there is no doubt about the wisdom of seizing every opportunity of buying up less valuable sites in the congested districts, and keeping them, if possible, free from buildings. Even the jaded needlewoman could sometimes find an hour to breathe the purer air which such open spaces would afford, and to refresh herself with the sight of flowers, and, may be, the songs of birds,—sad reminiscences of the country life from which she was too early torn. Something in this direction is not beyond the power of organised beneficence; it would not tend to pauperise the recipients of benefits which would re-act with salutary force upon the community at large; and it could be carried out piecemeal without any "staff" or "department" whatever.

There was once, and once only, an opportunity of reconstructing Central London on a comprehensive and sufficient plan, and the man of all others best fitted for the work was at hand. That opportunity was lost, and will never return. The very excellence of our modern building forbids the notion that a widely-devastating fire will give another. When the chance of laying out the capital on lines adequate to its necessities. Something in the right direction has already been done, and more is in progress, and we must be content with the prudent use of each opportunity as it arises, rather than look to projects which break with their own weight. To some such conclusion Mr. Westgarth has himself been reluctantly driven; for in an introductory chapter, which is the most thoughtful portion of the work, he sorrowfully admits that towards the housing of the very poorest classes,—which was his chief, and, indeed, his sole aim,—absolutely nothing has been done by these essays. It is evident that he has been moved to a consideration of the subject by an ardent sympathy with human suffering, and one can but regret the insurmountable difficulties which lie in his way.

Health Exhibition, York.—An important meeting was held in the city of York on the 17th inst., convened by the Lord Mayor, to consider the arrangements to be made for the Sanitary Congress and Health Exhibition to be held in the city in September next by the Sanitary Institute of Great Britain. Dr. Alfred Carpenter, Mr. Rogers Field, M. Inst. C.E., Mr. Ernest Turner, F.R.I.B.A., and Mr. E. White Wallis, secretary, attended as a deputation from the Institute, and spoke of the satisfactory results which had followed the previous Congresses of the Institute. The building selected by the local committee for the Exhibition is the most suitable that has ever been placed at the disposal of the Institute; and from the way in which the preliminary arrangements have already been made there is every reason to believe that the Congress and Exhibition in this city, in which so many successful meetings of this kind have been held, will have a large result in the progress of sanitary science. The Congress will commence on September 21st, and the Exhibition will remain open one month.

BUILDINGS ENTITLED TO LIGHT WITHIN THE PRESCRIPTION ACT.

THE question as to what erections can be the subject matter of a claim in respect of a right to light within the meaning of the second section of the Prescription Act (2 & 3 William IV., c. 71) becomes very important in these days, when spaces within towns are of so much more value than was formerly the case. Thus it might be of great importance to obtain as soon as possible a right in respect of some space of ground occupied by a building, and at the same time it might not be desired to erect thereon "any dwelling-house" or "workshop," which are the two words which appear with distinctness in the section in question. Something, then, in order to gain a statutory right must be placed on the ground, and it must fall within the category of "other building," which is the sequel to "dwelling-house" or "workshop" in the Act to which we have referred. It is equally also of importance that a person who is building on a servient tenement should be able to know whether he will obscure the light of a "building" which can acquire a statutory right.

To know what erection can acquire a right such a person naturally turns to the Prescription Act, and there finds the words which we have quoted. In regard to the two first there can be no doubt, but the words "other building" are apt to be puzzling, since nowhere in the Act does any definition appear of them.

Before we attempt to consider them it is, in passing, worth while to notice that a house not actually complete can obtain a right to light. That was decided, once for all, in *Courtauld v. Legh* (Roscoe's "Digest of the Law of Light," second edition, p. 5), where the house was not painted or papered, nor was it decorated, nor were the internal fittings completed. A person bought it in this state, and after putting it into a habitable condition lived there for ten years, when a neighbour obscured his light, and the judges decided that mere occupation was not necessary to found a statutory right, and that a house, so long as it is structurally complete, can obtain the right. This was a very important decision, because it affects those numberless houses which are erected by speculative builders, and which often stand empty, and, so far as painting, &c., goes, unfinished for several years. We confess that occupation of premises appears to us to be an element which the Legislature might well have considered necessary in order to give a dominant tenement the right to light. It is, perhaps, the more curious that occupation has not been considered necessary, because it has been held that the use of the premises may affect the question of the right,—that is to say, that if a person has enjoyed a strong light for some rather unusual purpose, such as examining jewelry or sampling silk, he is entitled to have this extraordinary amount unobscured. Thus occupation here directly affects the right, whereas in regard to a right to light in the first instance, it has been held to be an immaterial element. This is one example of the need for some legislative consideration of the whole subject. It is somewhat surprising that the words "other building" have been almost absolutely free from litigation. It is true that the word "building" has been considered in connexion with the Reform Act of 1832, when a wooden structure with boarded sides and a thatched roof, supported by wooden pillars let into the ground with a padlocked door, and used as a place for storing potatoes, was held to fall within the words "other building," following the words "house, warehouse, counting-house, shop" in Section 27. Also the words have been considered in regard to the Metropolitan Building Act, but there they had to be construed strictly in regard to the object of the statute. It was left for Mr. Justice Chitty in the recent case of *Harris v. De Pinna*, of which the full report will be found in the *Law Times* Reports for March 13th, 1886 (for it has not yet appeared in the *Law Reports*) to give an authoritative decision in the words of the Prescription Act. What the erection was may be best shown by quoting the description of the

judge's premising that it was a structure for the storage of timber. "It has beyond question certain elements of permanence and stability. There are large upright balks of timber, and there are cross-beams. There are besides floors; above that in some parts, at any rate, there are coverings which serve as a roof, but not merely as a roof, but serve for the purpose of stacking timber on the top. These coverings have a double use,—the protection of the timber, which is below from the effect of the water, and also the use for storing other and additional timber on the top. In this place the timber is stacked, is stored, is dried, exhibited for sale and sold, and the plaintiffs say that beyond all question light is a matter of importance to them." The three sides were open, and there were no windows in the ordinary sense of the word, the apertures being the spaces left between the upright and the cross beams. The reasons which induced Mr. Justice Chitty to hold that this was not a building within the meaning of the Prescription Act were, so to say, general considerations of its character. "Would any ordinary man, with a reasonable knowledge of the English language, passing this structure, speak of it as a building?" A question which he himself answered in the negative. If he said it had been a glass structure completely, or for the greater part enclosed, then it would be a building within the Act. Again, he asked, was this a structure which a reasonable man would be on his guard against obtaining the right to light, and this also he answered in the negative. The result is that we fail to obtain any precise definition of the word "building," but we perhaps may say that it must be a permanent structure, completely enclosed, and one which is, in ordinary parlance, a building. These elements will cause the inclusion of most things in the shape of sheds, outhouses, and so forth; but they should exclude such things as the old-fashioned Dutch barns, spaces covered by galvanised iron roofs supported by posts and pillars, and open at the sides. Yet in every case it must be a question of fact, though from what has here been stated there are some considerations which clearly assist at a solution of the question.

NOTES.

THE memorial to Mr. Street, which was unveiled by the Lord Chancellor on Wednesday in the central hall of the Law Courts, we cannot consider as a very satisfactory work except as regards its general effect architecturally, which is good, and combines well with the surrounding architectural details. Admiring, as we do, Mr. Armistead's great abilities as the sculptor of many fine works, we cannot regard his statue of the late architect as a good likeness, nor as a very happily designed figure. The frieze below, representing handicrafts connected with building, is only partially successful; the best figures are the smith wielding his hammer, which he does with considerable energy, and the figure of the architect studying his plan, which is unfortunately very much hidden from view on the return side of the frieze where it is in the shadow of one of the projecting piers of the ball. The Lord Chancellor spoke with truth and eloquence in regard to the "patient and loving attention" which Mr. Street gave to his great building; we know he attended to all the architectural details personally with a minuteness which is unusual in the case of so large a work; and in regard to the architectural treatment, he was unquestionably very seriously hampered by the economics of a certain well-remembered *Empire* Commissioner of Works. Among those present at the ceremony were Mr. Beresford-Hop M.P., Mr. Blomfield (the architect for the memorial), Mr. Armistead, Mr. Pearson, St. John Millais, Mr. G. Godwin, and Mr. Justice Kay, Mr. Justice Grantham, Mr. Justice Chitty, and others.

AS soon as the London season begins, as Rotten-row, "the ride, where gaily flows the human tide," as Mr. Arnold has it, is all;

tain with riders, the necessity for some communication between it and the ride on the north side of the Park becomes apparent. The easant mile by the Bayswater-road is so isolated from the southern rides that the latter become crowded to excess. It is true that during the season a strip of gravel is laid down between Hyde Park Corner and the Marble Arch. But what is required is a permanent level between these two points, so that there may be a continuous ride from Princes-gate to the north-east corner of Kensington-gardens. All that is required is to make a ride between the Marble Arch and Hyde Park Corner similar to that in front of the Knightsbridge Barracks, of about the same breadth. This would obviously necessitate the throwing back for a few yards of the footpath, but when completed it would add much to the usefulness of Hyde Park as a place for equestrian exercise, and add to the gaiety and life of the north side. If a few thousands of pounds from the Mansion House fund had been spent on this work it would have given work to many and added to the value of Hyde Park.

THE department of classical antiquities in the Louvre has recently received a very valuable addition,—one, too, which bears significance to the important work done by the Ecole Française established at Athens, and may well cause the English archaeologist to sigh for a day when the British Museum may receive like additions from excavations made by the long-looked-for British School at Athens. Tanagra terra-cottas have long fetched almost fabulous prices in the European market. About 1876, when these figures began to get scarce, it occurred to some ingenious dealer to open out new sources of profit by the sale of terra-cotta figures supposed to have come from Athens. The majority of these were whole or partial forgeries, but a few figures were indeed beyond doubt to the district of Myrina, in the Troad, and Pergamon. M. Waddington took the matter, and permission was secured to excavate on a large scale on the estate of M. Baltazzi, at Myrina, near Smyrna. The excavations were begun in 1880, and in 1881 the find was already a large one. By the courtesy of the director of the school, M. Waddington then inspected the "find" of the past year, and noted especially a large number of finely-modelled Sirens, bearing traces of purple and some figures of Eros. According to the terms of the excavation, one-third of the discoveries went to the Turkish Government and are now in the Tchintz-Kiosk museum; a second third to the French School; the third to M. Baltazzi, who, with rare generosity, has waived his claim "in favour of the French School. Out of about nine hundred vases, bronzes, &c., which thus fell to the school, four hundred of the finest specimens have been sent to the Louvre, and are now in process of arrangement. It remains to say briefly wherein the peculiar value of these figures consists.

WITH very few exceptions the Myrina terra-cottas belong to the Alexandrian or Greco-Roman times; but certain marked general differences remain, which render the Asia Minor terra-cottas specially notable. It will be remembered that the subjects of the Tanagra terra-cottas belong to subjects of private life, draped women reclining, sitting, standing, reclining; figures of mythological import are rare, nude figures being hardly so. At Myrina it is just the contrary, mythology predominates. Aphrodite, Eros, the Siren, Nike, Herakles are frequent figures seated or lying down are very numerous. Further, at Tanagra no one has been known to trace any replica of a well-known vase. At Myrina several instances have been found where both the draped (Coan) and the nude (Cnidian) Aphrodite of Praxiteles distinctly echoed, and a number of figures reproduce the Herakles type of Lysippus. Myrina the artist's name is frequently on the reverse of the terra-cotta; at Tanagra never. At Tanagra the figures are only ever exceed 10 in. in height, at Myrina they are as high as 3 ft. The Myrina figures

have also this further special claim on our interest that frequently they are arranged in elaborate groups, which recall, both in composition and execution, the style of the Pergamene artists. In a word, the Tanagra figures are in style finer; those of Myrina, both as to subject and connexion with the history of art, undoubtedly more instructive.

IN a paper read before the Leeds and Yorkshire Architectural Society on the 8th of this month, on "The Neglect of Architecture," Mr. G. Aitchison drew the following contrast between the Government method of dealing with great architectural works in the Renaissance in Italy and in the present day in England:—

"In 1295 the Florentine Republic, a little city with a small territory, and mainly dependent on its woollen manufacturers, determined to rebuild its cathedral. Vasari tells us that the instructions were that it should be built 'so that for size and magnificence nothing more could be desired either for the heavy workmanship, or the skill of the men.' It was ordered to be executed outside with polished marble, and with as many cornices, pilasters, columns, inlaid work of leaves, figures, and other things, as we see at this day. He also tells us, in the 'Life of F. Brunelleschi,' that the republic, by means of its merchants in various countries, paid the expenses of the most famous architects of France, Germany, England, and Spain, to come to Florence, in 1420, and give them advice on the method of doming the choir of the cathedral.

England is not a little town, with a small industry, but is supposed to be the richest country in the world; and is the centre of an empire on which the sun never sets. We have lately had a competition for a vast public building, in which the defences of the empire are to be organised. The instructions were, that convenience of arrangement was alone to be considered. Any one might compete, and Government promised to do its best to conceal his folly, but it bargained that whoever gained the competition should have no claim to the ordinary starvation pay, but should take a lump sum for all present and future work."

The argument is clinched by a further contrast between the treatment of Sir Charles Barry, paid 1,600*l.* a year, and that grudgingly, for exclusive attention to the greatest building of modern times, worried so that he thought of giving up the work, and his drawings appropriated without payment, and the treatment of Bernini, "whose whole voyage from Rome to Paris was a series of triumphs; who was fairly paid by Louis XIV. for the time he was in France and on his journey; and on leaving was presented with 50,000 crowns and given a pension of 2,000 crowns a year and 500 for his son. When he died and left 400,000 crowns, Queen Christina remarked on this, for the Pope's benefit, 'Had he served me, I should have been ashamed he left so little.'"

THE Council of the Liverpool Architectural Society have circulated the following comment on the matter of federation of architectural societies:—

"With reference to the circular letter and sheet of queries on the subject of architectural federation, which has been issued by the Society of Architects to all practising architects throughout the Kingdom, the Council of the Liverpool Architectural Society think it right to remind the members of the Society that the subject is now engaging the attention of the Royal Institute of British Architects, and that it will be shortly dealt with in their amended by-laws. The Institute should alone deal with this important subject, being the only chartered body of architects in the Kingdom."

We think the Council of the Liverpool Society have taken a very proper view of the matter. We have received a circular embodying a resolution to much the same effect from the Nottingham Architectural Association.

SOME notice of the important work begun last year, and still in process, at Orvieto, has appeared in the Roman *Notizie d. Scavi* (1885, p. 33), but we have deferred our account of the discoveries until a personal inspection of the treasure-trove was possible. The excavations have been carried on at the foot of the rock on which Orvieto stands, in the necropolis known as Cannicella, and a structure has been laid bare which Sig. Gamurrini, who reports the excavations, thinks may be dated at the

end of the fourth or beginning of the third century B.C. The tombs of the necropolis were, he thinks, already built when the Etruscans raised a wall to support, as it seems, the ground immediately above, and built a sanctuary, where they established the cult of Venus Primitiva, a goddess whose worship must have been similar to that of Astarte. This sanctuary was decorated with terra-cotta reliefs and statuettes. It was probably destroyed in the siege of Volsinii (Orvieto) by the Romans, B.C. 264. This date is borne out by the character of the architectural and sculptural remains. Happily, also, some coins have been discovered, all dating previously to B.C. 264. By the kindness of Sig. Mancini, who now superintends the work, we were able to inspect the large quantity of miscellaneous "roba" yielded by the sanctuary and neighbouring tombs. We did so the more gladly because the objects found are already on sale; a few months, or even a few weeks, will see them scattered to the four winds of Europe. Perhaps the most interesting of the painted vases discovered was a *pelike*, with a representation of the slaying of Astyanax by Neoptolemos. The vase is, unhappily, in a ruinous condition, but Signor Mancini expressed the hope that many of the missing fragments might be found by further search. On the obverse side we have the usual type of the warrior hurling the child against the altar, but to the altar there clings, not, as usual, the white-haired Priam, but a hardened, middle-aged man. The scene is extended to the reverse of the vase. On it are depicted a white-haired man running towards the scene of the slaughter, behind him an altar, and, on the other side of it, a woman clutching her hair in desperation. It will be seen that a familiar type is treated after a somewhat unconventional fashion. Next in interest we may mention a small black-figured *kylix* with a very delicate finely-drawn representation of a man hunting a hare. The hare-hunt is such an important archaic type that every new instance is of value. In another *kylix*, of fine drawing, we have the scene of the sacrifice of a hare occupying the centre of the vase. Another vase represents in a curious manner a stag-hunt; the stag is being driven into nets, which are rudely but quite distinctly depicted. A hunter is waiting at the other side of the net to despatch the prey with a spear. Lastly, a large *lebes* had been found, in the mouth of which five racing galleys are painted, in vertical position, so arranged that when the vessel was full of wine the ships should seem to be floating. This seems to have been a favourite conceit with the ancients. Two vessels of the same kind may be seen in the Louvre. The excavations are still in process, so that any day may add to results already important.

THE Fifth Volume of the "Architectural Association Sketch-book," which is just completed, fully keeps up the high standard of previous volumes, and is a mine of interesting and picturesque work illustrated in admirable drawings. Among the most interesting we may mention sketches (reproduced from water-colour originals) of the nave of Tewkesbury and of S. Sauveur Caen, by Mr. W. R. Lethaby; a sketch of figures from two pictures by Schiavoni, by Mr. Sydney Vacher; bridges at Verona and towers at Genoa, by Mr. Marvin; the old Hotel de Ville, Orleans, by Mr. Oakeshott; Bishop West's Chapel, Ely Cathedral, by Mr. W. G. B. Lewis; Langton Church Baptistery, by Mr. E. W. Paul; and old metal-work in the South Kensington Museum, by Mr. C. E. Tuttle. These seemed among the most interesting and the most artistic drawings, in the course of a general look through the subjects; but there is not a drawing in the book that has not interest and more or less merit of draughtsmanship.

FROM a circular forwarded to us, we are given to understand that "an attempt is about to be made under distinguished auspices to revolutionise the cab system of London,

which is admitted to be in many respects unworthy of the greatest city in the world. It is intended to place upon the streets of the City and West End three thousand new cabs, built upon the best principles, and with some novel improvements. A number of these vehicles will be in the form of open Victorias, so that when weather permits the Londoner will be able to enjoy the luxury of a pleasure-drive in the parks or suburbs in a handsome and convenient equipage. It is intended to take sixpenny fares, and tips and extortion will be abolished, as the drivers will be paid by wages and a commission.* If superior vehicles are to be provided at lower fares than at present, it is not very easy to see how the new venture is to pay. A better form of hired vehicle for pleasure drives would certainly be a boon to ladies. For ordinary purposes of getting about quickly, the London Hansom is not to be complained of, however, and the legal fare is very low for the work done; nor have we met with "extortion" save in very rare instances. For the London "four-wheeler," however, there is nothing to be said, and if it is against this quadruped (or quadrupete) that the new movement is directed, may it prosper.

MONUMENTS COMMEMORATIVE OF THE SIEGE OF PARIS.

In 1871, immediately after the disasters which cost France five milliards and two provinces, and many of the best and noblest of her lives, the Conseil-Général of the Seine decided to open a public competition of designs for monuments to commemorate the principal combats in the vicinity of the city.

The most eminent architects and sculptors hastened to respond to the invitation. Among 130 competitors we may mention M.M. Boitté, Davion, Boileau, Chipiez, Vaudremer, Deslinières, Etex, Ronillard, Lheureux, Gerhardt, Corroyer, Villeminot, Salleron, Comesson, Magne, Henard, Carrier-Belleuse, &c. The following year a jury, among whom were M.M. Guillaume, Ch. Garnier, Duc, Baltard, and Alphand, decided on this very remarkable competition, which, like all large competitions of the kind, showed a good many eccentricities, among others a stone skeleton with a Prussian helmet on its skull. M. Bruneau obtained the commission for the monument for Chatillon, M. Marcel Deslinières for that of Bourget, the monument of Haij was entrusted to M. Mellet; that of Champigny to M. Vaudremer; and that of Buzenval to M. Chipiez. Of three of these we give illustrations, and a general description of them may be of some interest.

Leaving Paris with Fort Montrouge on our right, and Fort Bicêtre on our left, by a somewhat circuitous route (for the communes just outlying Paris are very badly served in the way of convenience of transit), we reach Bourg-la-Reine. There a neighbouring road leads to the slope of the hill, on which stands M. Mellet's monument in memory of the battle of the 27th of November, 1870. This is a stone erection, resting on a base of cyclopean rusticated masonry. On the upper portion is a mass in the form of a sarcophagus, surmounted by a monumental stone, with two pediments, on one of which is sculptured a sword, on the other the words "Paris à ses défenseurs," and the name and date of the battle.

At Chevilly, a little commune about a mile distant, which on the previous 30th of September had been the scene of a sanguinary combat, in which the 35th Regiment of the Line had suffered cruelly, the survivors of the fight have erected to the memory of their comrades an obelisk in black marble, terminated by a white marble urn.

Returning to Bourg-la-Reine to get to Chatillon, where M. Bruneau's work is erected, we pass Bagnex, where, on the 13th of October, the Comte de Dampierre, commanding the mobiles of the Aube, was killed at the head of his troops. To commemorate that day, the Commune, in a little place which bears the name of that brave soldier, erected a circular sarsbase carrying an octagonal pyramid surmounted by a cross. Four faces are decorated with commemorative inscriptions and warlike emblems. The sarsbase is crowned by battlements, and four funeral steles occupy its extremities. The effect is pretensions and the general outline wanting in that simplicity of

line which gives a character of grandeur to a monument. One of the steles, higher than the rest, serves as a support to a bust of the Comte de Dampierre, a remarkable work by M. Marquet de Vasselot. Not far off, on a tablet let into the wall of a house, is an inscription indicating the place where the commander was killed.

We are now arrived on the woody plain of Châtillon, from whence there is an extensive view. At our feet is the fort of Vanves; further, the villages of Issy, Vanves, and Malakoff, and in the background Paris and its fortifications. On the height whence the Prussian batteries bombarded for a month the quarters on the left bank, rises a monument in the form of an obelisk, occupying the centre of the circular space surrounded by a grille. On one of the faces is sculptured a palm combined with an antique shield bearing the inscription, "1870, Châtillon," and below, on the stone, the words, "Paris à ses Défenseurs." On the base of the obelisk are reproduced the arms of the city, and the motto, "Fluctuat nec mergitur."

Châtillon is our last halting-place in that part of the suburban zone, and we now quit the department of the Seine, to find, at the gates of St. Cloud, the monument of Buzenval. Châtillon and Buzenval are almost the extreme limits of that interrupted fight which went on for 130 days. This monument, of great simplicity, is, as we have said, the work of M. Chipiez. On a rectangular sarsbase is a stone stele on which is graven the date of the battle of Buzenval. With the stele is joined a plaster supporting a torn laurel crown, emblematic of the brave but vain resistance of the besieged. Not far off, in the cemetery of Montreuil, is a rectangular pyramid to the memory of those who fell on January 19, 1871. After having crossed the Seine by the Pont de Neuilly, we find, at the turn of the Courbevoie, the monument which the Conseil Général of the Seine has dedicated to the memory of the national defence. On the pedestal (once occupied by the statue of Napoleon I.) is a figure of a woman in a military cloak, and whose head, of a rather masculine style of beauty, is crowned with battlements (see illustration). She leans against a broken cannon, her right hand grasping a sword, the other holding a standard as if to protect with its folds a soldier lying at her feet. The dying man, whose countenance is more or less a portrait of Henri Regnault, who perished at Buzenval, endeavours, with failing hand, to get at a last cartridge. This monument was the subject of a special competition in 1879, when the prize fell to M. Barrias. By a touching contrast, behind the principal group, which faces the position occupied by the enemy, the artist has sculptured a lovely little girl cowering terrified beneath the cannon, personifying the sufferings of the inhabitants during the long siege. This figure is hidden from view in the illustration.

By the Brussels road we arrive at Bourget, situated at the extreme limit of the department. It was here that there took place the furious combats of October 28th and December 16th, 1870, an episode of which was popularised by the engravings from De Neville's picture. This fight is commemorated by two monuments. That by M. Deslinières, chosen in the Municipal competition, is entirely constructed of grey granite. It is erected on the Place de la Mairie at Bourget, and consists of a square base carrying a pedestal of which the upper part presents a frieze decorated with triglyphs (see illustration). The metopes enclose laurel crowns, and a square pyramid terminates the monument, of which one face shows a broken sword carved in relief, with the following inscription:—

BOURGET
XXX OCT. XXI DEC.
MDCCLXX
ILS SONT MORTS
POUR DÉFENDRE
LA PATRIE.
L'ÉPÉE DE LA FRANCE,
BRISÉE DANS LEURS
VAILLANTES MAINS,
SERA FORGÉE
DE NOUVEAU PAR LEURS
DESCENDANTS.*

The monument is of an architectural simplicity much more eloquent than the complicated and

* We cannot suppress a passing note of admiration for the fine artistic perception and the delicious feeling shown in this monument and its brief inscription. It is worthy of a country which, more than any other, has combined the qualities of the artist and the soldier.—Ed.

mannered ornamentation of the second monument, the author of which we do not know, which has been raised at the end of the main street, by private subscription.

Not far from Bourget we remark in the middle of a field a large pyramid decorated with a cross. It has been erected, in virtue of a stipulation in the treaty of Paris, to the memory of the German soldiers who fell in the war. Nor must we forget in our route the monument erected on the territory of Epinay in memory of the soldiers killed on September 30, 1870, and who are buried at the foot of that little monument.

The heights of Arron and Chennevière, whence we look down the panorama of the Marne Valley, have also their monumental souvenirs of the war. On the plateau at Arron is a very simple rectangular pyramid of great simplicity; at Chennevière is the funeral monument of Franqueti, commander of the *déclaireurs de la Seine*.

We are now at Champigny, where the fight was carried on for two long days. At the end of the war every rising of the ground concealed a dead body. On this field of melancholy fertility two great mounds have been raised, covering each 2,000 or 3,000 soldiers. Further towards Villiers-sur-Marne every field and garden has its graves; the plateau became a vast-cemetery. We remember still, in 1871, deciphering with difficulty, on a wooden cross, coarsely shaped, this singular inscription:—" Ici repose ma main gauche élevée par un éclat d'obus le 1er Décembre, 1870. Carloti, Sergent-Major au 121^e de ligne." On another cross, the simple words, "Regretté par ses comrades"; on another further on, "Priez pour vos frères d'armes." All these poor corpses are now collected in a vast crypt constructed by M. Rivière, architect to the Government, behind the monument by M. Vaudremer. This square crypt comprises a set of subterranean galleries with a chapel adjoining them. On tablets of marble between the piers are inscribed the numbers of the French regiments whose soldiers repose side by side with the German soldiers' remains.

The principal façade, where two wrought-iron doors give access, is in rusticated masonry with courses of granite. On a large tablet of marble is the following inscription:—" Monument élevé par l'État à la mémoire des soldats morts pendant le siège de Paris: Bataille de Champigny (Loi des tombes militaires, 4 Avril 1873)." The other portion of the monument to which we ascend by two flights of granite steps in the wall, is the first in date. It is composed of a quadrangular *cyppus* on a large spreading base, and crowned by a capital the angles of which are decorated with large leaves. The spaces between the leaves are occupied by two heads, symbolising "France" and "War." They are the work of M. Chapu (see illustration). On the principal face are carved the words, "Défense de Paris," and on a shield is a relief of a Roman soldier falling, with his sword broken in his hand; a large palm passes behind this. Beneath this is the inscription:—" Champigny, 30 Novembre -- 2 Décembre 1870." On the opposite side is the Paris motto again:—" Fluctuat nec mergitur," accompanying the ship emblematic of Paris.

Here ends our peregrination, unless we wish to go as far as Vincennes, where is the monument of another siege of Paris; we mean the bronze statue of General Dumesnil, the work of Rochet, to whom we owe the colossal Charles Magne on the *place* adjoining Notre Dame. This statue, which commemorates the defence of the Donjon de Vincennes in 1814, stands of a short obelisk in red granite, constructed after the design of M. Ch. Garnier. But it is pleasanter to remain at Champigny, where the war has left no permanent traces, where six months after the end of the war life had come already gay with Parisian strollers and "bals champêtres." The ruins have now disappeared; gay and coquetish villas have replaced the blackened houses and garing walls. Everywhere the trace of bullets has been effaced, and holes made by shot filled up, as here, as elsewhere all around the great city, only some funeral stones, piously visited every year,* recall the sufferings of besieged Paris and the places where her defenders fell.

R. B. FENWICK.

* It is the custom with many Parisians to make a kind of pilgrimage round these monuments every winter, and this was *proprio* of that occasion that the above record was written early in January, but the appearance of the illustrations had to be postponed owing to the Liverpool Cathedral designs taking up all our space.

"ARCHITECTURAL PHOTOGRAPHS BY AMATEURS."
ARCHITECTURAL ASSOCIATION.

In the discussion which followed the reading of Mr. S. Flint Clarkson's paper on this subject see *Builder*, p. 436, ante).
The Chairman (Mr. C. R. Pink, President) complimented Mr. Clarkson upon his excellent paper, and its accompanying illustrations. Unobtrusively there was some danger that photography, in the hands of the architectural student, might militate in some ways against good and careful sketching. Some of them might remember the very obvious pun of Thomas Landseer, the engraver, that photography was indeed "a foe to graphic art!" At the same time, he was happy to say that photography had not been a source of much danger to the members of the Association, when he considered the amount of sketching done by them, which not only annually increased in quantity, but improved also, he thought, in quality.

Mr. J. C. Stenning said that with any process was next to impossible to obtain satisfactory results from exteriors without good sunlight and shadows. The operator should never work with the sun at his back or in front of him, fitness of picture being the inevitable consequence in one case, and a blurred and wretched result in the other. As a guide to the hours most suitable for different points of the compass in taking exteriors, on a summer's day, he might mention, soon after sunrise for the north portion, later on for the north-east, towards midday for the east, just before or after midday for the south, midday for the south-east and north-west, afternoon for the west, evening for the north-west, and last of all north again. It is a good maxim to have the sun shining upon the direction of either shoulder, so as to capture both sunlight and shadow on the building, and thus obtain relief and contrast. For his reason morning and afternoon were the best periods of the day for exterior work. Interiors, as a rule, could be taken best when the light was most active, say about midday. An overcast, but not dull day, was very favourable for rendering pictures of interiors soft and harmonious, and the reflected light from snow is useful, as it lightened up the ceiling. The exposure must vary according to the distance the operator stands from the building, being less or further off, as a greater amount of light is reflected on the plate; while, when close, exposure must be increased. The colour of the building must be considered; few would be the same exposure to an exterior of Westminster Abbey as to that of Salisbury Cathedral. These might be taken as samples of good bad for reflecting light, though there might be others more extreme, such as parts of St. Paul's for darkness, and Milan Cathedral for brightness. The colour of the stone or brick, if vividly red or yellow, rendered a little more exposure necessary, and grey and weathered subjects were deceptive, being less reflecting than was apparently the case. With subjects giving great contrasts, such as light ivy with masses of ivy, or a doorway with deep shadows, a full exposure, and weak development were necessary. Details of architecture when much weather-worn should be under a side light; the exposure being, if thing, a trifle under, with fairly strong development, so as to obtain contrast. In this case camera should be placed, if possible, at an oblique angle to that from which the light came. Interior work was much easier than exterior work, the most suitable lens, using rapid plates, was of Wratten and Wainwright, in the nave of the cathedrals ten minutes' exposure would be sufficient; but in the choir, owing to the use of glass, the dark wood of the stalls, &c., exposure of half an hour to one hour would be too much. It was best to err on the side of over-exposure for interiors, and, in fact, rather try to over-expose. A lens of short focal length was preferable for use, and the series of lenses were not adapted, except for small angle, to architectural work, on account of the small angle. The portable symmetrical lens of Ross, worked to maximum size of 3, or the wide angle rectilinear of Dallmeyer, best to a size less than advertised, would give best results. Landscape or single combination lenses must not be used, in consequence of optical distortion, the only exception being a view from a distance included a building which came near the centre of the plate.

In confined situations it was necessary to use a lens embracing a very wide angle, or one of short focus. The result, however, was not to be compared with that produced by a proper lens for the subject, as the untrue proportions were so marked, the foreground being exaggerated, and the distance reduced. A full outfit for an 8½ in. by 6¼ in. camera by a first-rate maker would cost from 30s., and for a 12 in. by 10 in. from 50s. to 60s., chemicals included, but not prepared plates, which cost from 10s. to 18s. per dozen for ordinary rapidity, and more for rapid and instantaneous. Apparatus could be obtained second-hand under these figures, but the purchase should be entrusted to some one *au fait* at such matters.

Mr. J. A. Gotch proposed a vote of thanks to Mr. Clarkson and to the several exhibitors, viz., Mr. J. C. Stenning, Mr. J. Clerk, Q.C., Admiral Maitland, Mr. Gifford, Rev. F. C. Lambert, Lieutenant Little, Mr. Seymour Conway, Mr. J. L. Robinson, and others, for lending photographs and slides, and to Mr. J. Gale for the loan of slides, and directing the lantern illustrations.

Mr. Leonard Stokes seconded the vote of thanks, and considered that any one who could not afford to give plenty of time to photography had better let it alone. It was the sort of thing that could not be done well without a great many failures, and a pretty considerable outlay. No doubt when at one's fingers' ends it was a very valuable thing to be able to take good views, but even then a small pony-trap was almost necessary if one carried large plates. There was also a good deal of time taken up in the developing, printing, and so on.

The vote of thanks was then carried by acclamation, and the proceedings terminated.

THE ASSOCIATION OF PUBLIC SANITARY INSPECTORS.

The Council's "Report on Impending Changes in Sanitary Law," as affecting initial procedure, and the powers, responsibilities, emoluments, and status of sanitary inspectors, was adopted at a special meeting of the Association, held on the 19th instant. The Report is as follows:—

"The Council beg to report that they have considered the impending changes in sanitary law, and are of opinion that much public benefit may result from a statement of their knowledge of the law which they are called upon to administer, and their opinion on required changes therein.

The Council having much experience as executive officers in operations under the various sanitary enactments, and in view of their probable amendment or consolidation, desire to state that they have proved the said laws to be unnecessarily complicated, to be unreliable in administration, and in no wise calculated to encourage zealous officers in efforts to secure prompt abatement of insanitary conditions.

The Council endorse the recommendations contained in the Memorandum to the Report of the Royal Commission on the Housing of the Working Classes, by E. Dwyer Gray, esq., M.P., in so far as follows:—

1. 'That the sanitary officers should only be removed by the Local Authority for misconduct or neglect of duty' (and, we would add, proved incompetence).
2. 'That sanitary officers should be held more directly responsible for the abatement of nuisances.' And we add, they should be required to initiate proceedings on their own responsibility on behalf of the Local Authority for the abatement of nuisances, by serving notices requiring all necessary works to be done for such purpose; such notices to be reported to the Local Authority and approved or otherwise.
3. 'That the powers of the Local Authority should be made more simple, stringent, and summary; powers should be given for the abatement of nuisances by the sanitary officers,' that 'the procedure is dilatory and cumbersome,' and 'that in many instances after the case is worked up with much labour by the sanitary officer the offender is let off by the magistrate with a caution or nominal penalty.' We also agree with Mr. Gray that 'a minimum as well as a maximum penalty should be provided for sanitary offences; and the minimum should be largely increased in all cases of a repetition of offences by the same person in respect to the same premises.'

The Council consider it desirable in the present position of Parliamentary affairs to limit the scope of this report primarily to a formal declaration that sanitary inspectors are placed

in positions of great responsibility, armed with totally inadequate powers to efficiently respond to the expectations and requirements of the public. Secondly, to a confirmation of evidence given to the Royal Commission on the Housing of the Working Classes, in so far as relates to the present defective condition of the law, which is here done. And thirdly, to set forth what our experience has proved to be the most essential amendments required in sanitary law to secure efficient administration, as follows:—

1. That the powers, responsibilities, and emoluments of sanitary inspectors should be largely increased.
2. That a minimum rate of salary for sanitary inspectors should be enacted, and that it be legal for Local Authorities to make provision for superannuation or compensation, similar to the provisions made under the Poor Law and Metropolitan Local Management Acts.
3. That sanitary inspectors should be duly qualified, and only be removable from their appointment for proved misconduct or incompetence.
4. It should be enacted that sanitary inspectors shall initiate proceedings on behalf of the Local Authority for the abatement of nuisances by serving notices requiring all necessary works to be done for that purpose. All such notices to be read to and approved, or otherwise, by the Local Authority, or Committee appointed for such purpose, who shall, if satisfied thereon, order proceedings to be taken against the offenders.
5. It should be enacted, that any person failing or refusing to comply with the notice requiring abatement of nuisance (the nuisance being proved to the satisfaction of the court), shall, if he fail to satisfy the court that he has used all due diligence to carry out the necessary works, forfeit, and pay to the Local Authority a sum not exceeding £—, and also a further sum not exceeding £—, per day during default."

CONCRETE.*

The Metropolitan Board of Works, after long deliberation, have at length announced their intention of recognising the use of concrete as a building material for walls in London, and to place the following restrictions on its use, viz., that the proportions shall be one part of cement, two of sand, and three of coarser materials, which may be ballast, gravel, broken bricks or stone, or furnace clinkers, but the coarser materials are to be broken small enough to go through a 2-in. ring. The walls are to be of the same thickness as brick walls, and to be carried up between parallel frames, and the District Surveyors are to see that the regulations are properly carried out. I think these regulations too strict as to the thickness of the walls, and as to the proportion of cement, particularly as extensive ranges of buildings have been put up in Southwark, where the cement was gauged eight to one. I rather pity the District Surveyors in their work of supervision, but the Board seem to have missed the most important point of all, viz., the quality of the cement; and they certainly ought to give their officers power to test this, for, as I have pointed out, serious consequences will ensue if this be not of the best kind.

The second or block system has, however, some advantages: no particular building apparatus is required; any imperfections in the concrete can be discovered before it is used; the blocks can be made of any required section and of any size; and permanent joints can be given to the blocks by mixing various mineral colouring matters with the aggregate in the moulds. But for laying these blocks just as much skilled labour is required as in the case with bricks or stone, and, of course, mortar or cement must be used to bed the blocks in; in fact, this is merely using artificial blocks of stone instead of natural ones. But this artificial stone is really concrete, and as such it possesses virtues which may be sought in vain in any of the natural building stones, and therefore no lecture on concrete would be complete without a reference to the artificial concrete blocks, which are very extensively used at the present time. I believe the first artificial stone which was used in this country was Ransome's, which was patented in

* Continuation of the lecture by Mr. John Slater, B.A., being the fifth of the present course of free lectures to artisans at Carpenters' Hall, delivered on Wednesday evening, the 17th inst. (See p. 434, ante.)

1844 or 1845. This consisted of a mixture of sand, silicate of soda, powdered flints, and a little clay, which was worked up to the consistency of putty, pressed into moulds, dried and burned, and this burning, in my judgment, takes this material out of the category of concrete stones. Some years later, however, Mr. Ransome found that by dipping the moulded mixture into a bath of chloride of calcium the burning could be dispensed with, and a series of experiments made in 1861 by Professor Frankland showed most conclusively that Ransome's patent concrete stone, when only a fortnight old, was equal to the best of the natural stones. Soon after Mr. Ransome's first patent, in 1847, Mr. Buckwell obtained a patent for "Granitic Brescia Stone," which, I believe, was used in 1851 in the Hyde Park Exhibition. This was essentially a concrete, as it consisted of fragments of suitable stone broken into small pieces and mixed with cement with a small quantity of water, not more than enough to bring it to a damp state; this was put into a mould and powerfully compressed with a percussive action, additional materials being added until the requisite thickness of block was obtained. The block was thus rendered very dense and compact, and this artificial stone was used for water-tanks,—than which no severer test can be applied of the qualities of an artificial stone. At the present day the artificial stone which is most used is the well-known Victoria stone, the patent for which was originally obtained by a Mr. Highton. The aggregate of which this stone is composed is ground Leicestershire syenite, a species of granite containing hornblende instead of mica, and lacking quartz, which is thoroughly washed so that no earthy particles remain, and an ingenious machine has been patented for doing the washing business. After being washed the aggregate is carefully mixed with a certain quantity of Portland cement of the very best quality, and is placed in iron-lined wooden moulds which are filled to the top, but no pressure is applied; after the concrete is set it is taken from the moulds and placed in a bath of liquid silicate of soda, and after ten days' immersion the block becomes so thoroughly impregnated with silica that nothing but the strongest acids will free it again. The stone thus becomes intensely hard and quite impervious to weather action; in fact, its hardness increases with time. This property makes it invaluable for copings, sills, paving, &c., and it has another advantage over ordinary stone that heads and sills can be cast in as long lengths as are desired, thus avoiding joints. It is used also for sinks and other such purposes. The silica used in the manufacture of this stone is obtained from the Farnham stone found under the Surrey chalk beds, which is boiled in coppers with caustic soda.

One of the most enterprising modern pioneers in concrete building was the late Mr. W. H. Lascelles, of Bankhill-row, who was a most sanguine believer in the future of this material. Mr. Lascelles actually built cottages which were not only habitable, but comfortable, the walls of which were only 1½ in. thick, formed of slabs of cement concrete,—the outer side cast in imitation of brick or tiles, and the inner side left rough for plastering. These very thin walls appear to have kept out the weather perfectly, but moisture condensed on the inner face, so Mr. Lascelles improved upon his original idea by having a double casing of slabs with a cavity between. He also formed floors of concrete, window-frames, and roofs, but the latter did not turn out very successful, as there was always a certain amount of shrinkage. This system did away almost entirely with the use of wood, and consequently the houses so built were as near being fireproof as possible.

Mr. Lascelles's concrete is composed of four parts of powdered coals and one part of cement mixed together in a mill, with a small quantity of water, and cast in moulds without pressure, and by mixing metallic oxides in the form of powder with the cement the concrete is coloured any desired tint. Very excellent specimens of nullioned windows, chimney caps, heads and sills, strings, copings, panels, and overmantels are made in this material, and are largely used as a substitute for stone, and it is much cheaper than stone, but I am bound to say I have seen cases where the colour has not been retained as it ought to be, and I am informed that this is caused by the workmen giving the slabs a top dressing of coloured cement after they come out of the moulds. Of course this should never be

done, as the colour should really penetrate some depth into the mass of concrete. For standing a London damp and smoky atmosphere, there can be no doubt of the great superiority of this concrete to almost any natural stone. Messrs. Lascelles also make a very good wall on what is termed Potter's patent. In this a casing of concrete slabs, of which one face is fine, is put up and ordinary concrete filled in between just as in the way I described with the wooden framework; but as the slabs are intended to remain they are formed with a key, so that when the core of concrete sets it is quite impossible for the skin of slabs to move. Among the numerous purposes for which this material is used may be mentioned silos, water-tanks, sewer-pipes, columns, &c.

It would occupy too much time were I to attempt a description of all the methods of concrete construction that have been invented, such as Tall's, Drake's, and others, but the most recent of these,—the system patented by Messrs. West,—has various novel features about it which deserve attention. This, like Potter's system, is a slab construction filled in with rough concrete, but the form of the slabs is ingeniously arranged so that no temporary tie or external support is required during building. The slab itself is made of concrete cast in a mould, so that on one side is a finished face, plain or ornamental as the case may be, and on the other a sunk panel about half the thickness of the slab itself, with its edges undercut, so that when in position, and the mass of semi-liquid concrete is poured in, the slabs are securely keyed to the general mass. Dovetail mortise-holes are also formed on the top and bottom edges of the slabs, in order that when laid they may be kept in their proper place by simply pouring into these holes some quick-setting cement. There is also a narrow groove along the edges of the slab, which, when filled with cement, acts as a joggle joint, keeping the slabs together. An inner and outer casing of slabs is thus set up, and the plastic concrete poured in, filling up the sunk panels, and making with the slabs a perfectly solid wall.

For openings, jambs are moulded having recesses or dovetail holes, into which the fluid concrete may penetrate, so that they can be thus keyed to the general mass of the wall. The slabs are made either rectangular or hexagonal on plan, and as they are all cast in a mould, there is, of course, not the slightest difficulty in arranging for circular work, splayed angles, or anything of that kind. There has always been considerable difficulty in arranging for moulded or enriched string-courses or projections with concrete, and this difficulty is proposed to be overcome by casting the moulding first and then applying it to the slabs while they are in a plastic state, the moulding thus becoming part of the slab, which is then fixed in the required position. The moulds for casting these slabs are made of metal and lined with india-rubber. Similar slabs can be moulded with curves for constructing domes, and ceiling-slabs can be made with rebates, so that they can be supported on the joists or girders. This system of concrete building is certainly the most scientific and the most complete that has yet been invented, and I have no doubt whatever that a building thus erected would be perfectly dry and very strong; but I am somewhat disposed to think that the system is a little too complicated to be cheap, as the labour required for properly setting the slabs in place and cementing them together would nearly equal that required for a stone wall. The inventors have, however, shown so much skill in maturing their designs and providing for all difficulties, that it is quite possible they may soon be able to point to actual works carried out on this principle and to give accurate details of cost, which I am not able to do now. A very ingenious travelling scaffold and concrete elevator have also been invented by Messrs. West, which obviate the necessity of erecting a scaffold all round the work, and require no pullog holes to be left, and undoubtedly some such arrangement as this has been a great desideratum as an auxiliary to concrete construction. There can be little doubt that this system of concrete building would be of most material use in the construction of farm buildings, cottages, &c., in country districts far removed from railways, as the slabs are light and portable, and the material for the filling can generally be obtained on the spot.

For paving purposes, concrete is, of course,

excellently adapted, but it is very difficult to get ordinary workmen to lay a concrete floor properly. What they like is to lay the concrete and let it get hard, and then finish off the top with a thin coating of neat cement. This looks very well when it is first done, but sooner or later the thin coating begins to flake off or crack and looks very bad. The proper way is to break up the materials of the concrete to small size, and then, in laying it, to trowel it off on the top as smooth as possible, so that it is all one mass and no layers exist. Portland cement should always be used, and, if ordinary care be taken, there is no reason why a labourer should not lay an excellent concrete floor. There are many patents for concrete paving, of which I may mention Drake's granitic concrete and Macleod's granitic, which has been largely used in the North of England for warehouses, stables, &c. It is not cast in blocks, but laid *in situ*, and it can be made to take somewhat of a polish if desired. This forms an extremely hard impervious pavement, and it looks very well, but I really believe the whole secret of the excellence of these patent systems of paving lies in the careful manipulation of the materials and the sparing use of water. I may state here that for engine-beds concrete is, in many respects, far superior to stone, and it is not liable to chip and crack, and it is very much less expensive.

I now come to the last division of my subject, and that is the use of concrete for vaults and in fireproof construction. Every one is acquainted with the fact that an ordinary arch exerts a thrust which has to be counteracted, or it would soon push out its abutments. A concrete arch, however, after it has set forms a complete homogeneous mass, and exerts only a dead weight on its supports. The Romans were aware of this and constructed the boldest and most extensive vaults of concrete as in the Baths of Caracalla and the House of the Vestals lately excavated. They were careful, moreover, to make the concrete used for these purposes of lighter materials than that employed for wells or pavements. The great dome of the Pantheon was constructed entirely of concrete of varying thickness, and the walls supporting this enormous mass were 20 ft. thick. In the House of the Vestals the whole of one of the upper floors, about 20 ft. in span, consisted entirely of a great slab of concrete 14 in. thick, merely supported by corbels projecting from the walls, and in the Baths of Caracalla there are still extensive remains of large concrete vaults. We in this country have not yet obtained satisfactory evidence of the safe span and thickness of a concrete vault, but the material is very largely used to form small arches for fireproof floors. It is quite impossible to treat the very important question of fireproof buildings fully at the age end of a lecture, but whatever system of fireproofing he adopted, concrete will prove to be the most important element in it. Whereas the opinion used to be held that iron girders and columns as supports to a building were sufficient to make it fireproof, we have been taught by sad and costly experience that this is very far indeed from being the case. In the United States and in France they are much more particular than we are in this matter, and in the former country it is laid down as an incontrovertible maxim "that no building can be fireproof unless all constructional ironwork be protected," and no better material can be found as a protective than concrete. Stone is utterly valueless in this respect, as it will crack when heated, and give way without any warning whatever. Fox & Barrett's system consists in filling in concrete between wrought-iron joists the concrete being supported on fillets of wood placed about ¼ in. apart, and resting on the bottom flange of the iron joists, the undersides of the wood fillets being plastered. Either the concrete is carried up the requisite height and forms the floor, or if a wooden floor is required small joists cut to a dovetail section are imbedded in the concrete and the floor-board nailed to them. Dennett's system is almost exclusively a concrete construction, consisting of concrete arches supported next the walls of projecting courses, and by rolled iron joists at intermediate points. In this system gypsum mixed with the Portland cement to form the matrix, as experiments have shown that the substance can be heated to whiteness, and the suddenly cooled without being injuriously affected. In Horublow's system the iron girders are surrounded by concrete, an

enclosed in a fire-clay casing supporting fire-clay arches. Even concrete arches supported on triangular-shaped wooden joists, form a floor which is very largely fireproof. If iron columns are used, a temporary wooden casing should be erected round them, leaving a space of about 2 in., which should be entirely filled up with Portland cement concrete, and if a fine face is desired this can easily be obtained by cementing the concrete. Messrs. Lindsay have patented two systems which comprise the use of steel decking, as it is called, and concrete arches, the girders being entirely covered with concrete both at top and bottom. The concrete used by this firm is very light; it is called pumice concrete, and is composed of washed coke-ore and sand mixed dry, and Portland cement of the very best quality. It is, of course, self-evident that if you get sufficient adhesion and transverse strength to support the mass of concrete in for upper floors or vaults, the better, as so much less weight is thrown upon the supporting walls or columns. The steel decking for this kind of floor is of peculiar shape, and the system is a novel one, and appears to me likely to prove of great value for buildings of considerable size, where girders are a necessity for supporting upper floors. These girders may be described as truncated quadrilateral triangles, set alternately on their bases, and the truncated vertices riveted together at their sides, and forming a series of hollows and elevations. They are constructed of rolled steel about $\frac{1}{2}$ in. in thickness, and their depth need not be much more than half that required for an iron girder. When the weights required to be supported are not very heavy, a combination of these steel girders, with ordinary rolled joists can be adopted. The iron joists can be placed about 14 ft. apart, and from the steel skewbacks riveted to the joists the arches of concrete can be turned on centreing. There is a possibility with concrete floors that will withstand ordinary strain, that the sudden fall of anything like a huge iron safe might break through the floor, and in order to avoid any risk of this kind Mr. Lindsay runs steel wires through the joists, the whole length of the floor, before the concrete is filled in. These are about 1 in. apart, and are strong enough to hold up an exceptional weight that may by accident come upon the floor. In addition, these steel wires form a sort of nucleus round which the concrete sets. The total weight, girders and all, of these latter floors is considerably less than that of any other system of fireproof construction, and they are also extraordinarily strong. At one of the latest tests of these rough-girders, where the thickness of metal was 5-16ths of an inch only, a load of 15 tons was applied in the centre of a 10-ft. bearing without causing fracture. And this test was in confirmation of previous ones, so that I believe these girders will supply a long-felt want. They are being used largely in the construction of the new National Liberal Club by Mr. Waterhouse.

I have now endeavoured to bring before you some of the purposes for which this common material, concrete, is adapted. Its use is extending daily, and in that extended use lies a danger which it behoves us all to guard against: whether we are employing it for floors, for pavings, for walls, for vaults, for architectural enrichment, or what not, it cannot be too strongly insisted upon that sampling of every kind must be avoided; that the quality of the Portland cement used in its manufacture must be of the very best; and that no labour in manipulation must be spared, or inferior materials be used, or carelessness in working, the results are sure to be disastrous, and grave discredit will be thrown upon a most useful building material. The object is a sternly practical one, and it has been impossible to illustrate it by elaborate and beautiful drawings, but at least we can learn one lesson from it, and that is the great, incalculable value of thoroughness in all the work which we have to undertake. As I commenced by referring to the Roman builders, so would conclude by pointing to them again as a model for us. Depend upon it, when they were building the walls of those edifices which are still the wonder of the world, they gave no thought to what posterity would think of them; they simply did their work in the best way they knew of, and spared no pains to make it good, and if we imitate them on this, we shall all, whether architect, builder, or artisan, have the

satisfaction of feeling that we have done some bit of good work, and although it is not given to us all to be great artists, and to which the world with noble buildings, we can at least put our whole heart into everything we undertake, and we shall thereby display the truest genius which has been described as an infinite capacity for taking pains.

ROYAL METEOROLOGICAL SOCIETY.

THERE were some interesting points about the annual exhibition of instruments which was held in the Library of the Institution of Civil Engineers, Great George-street, Westminster, last week (16th and 17th inst.). Perhaps the most interesting of the exhibits, not strictly meteorological, and having at the same time a sanitary importance, was Mr. Baldwin Latham's earth hygrometer. The question of the hygro-metric condition of the ground as compared with the air in a certain district, is one which is not at present understood; but Mr. Latham has been investigating the matter, and believes that he will be able to establish relations which will contribute to the solution of a question having an important sanitary bearing. During the ten years he has been in charge of the drainage works of Croydon he has been preparing calculations made upon observations obtained there. He is satisfied that his instrument will afford trustworthy results. It consists of three perforated cylinders, lined with fine wire gauze. Each is filled with earth from the locality to be tested; but they occupy different positions,—one being suspended in the air, one immediately below the surface of the ground, and the third 12 in. lower. A lever is appointed to each cylinder, on the opposite side of which is a counter-weight. Acting separately, each cylinder records its observations in the form of a diagram upon a small cylinder driven by clockwork. The percentage of moisture which the earth in every case contains at any one time is seen at once by a glance at the index.

Among the instruments, new, or not previously exhibited, we noticed Jordan's improved photographic sunshine recorder, which consists of a cylindrical box, in which a slip of prepared paper is fixed. The sensitised paper receives the sunlight which is admitted into the box by two small apertures, upon which a distinct mark is obtained. Mr. Jordan, who is the Keeper of Mining Records at the Home Office, secured, at the eleventh hour, but not without considerable trouble, a place for his instrument at the recent Inventions Exhibition, where it afterwards obtained an award. There were several new forms of anemometer, the most interesting being one exhibited by Mr. W. H. Dines, in which the axle is driven by a pair of small windmill sails. A registering dial records the number of revolutions, and the instrument is so arranged as to give any required number of revolutions per mile. Several improved surveying aneroids were exhibited. Though these instruments are practically reliable in taking a rough surface survey, and, indeed, exceeding useful in obtaining the section of an extensive piece of rough and difficult country, they are utterly useless for surveying purposes underground. We suspect it is due to the ever-varying conditions of air-currents in such situations; but it is a fact, nevertheless, that they almost invariably read too deep in metal mines and not deep enough in colleries. In a Welsh mine, a recent experiment discovered discrepancies varying from 50 ft. to 45 ft. from the correct depths in the indications of several aneroids used. Possibly improvements will ultimately obviate these objections.

The usual monthly meeting of the Royal Meteorological Society was held on Wednesday in last week, at the Institution of Civil Engineers. The President (Mr. W. Ellis, F.R.S.) gave an historical sketch of the barometer. After remarking on the accidental nature of the discovery of the instrument, in the year 1643, in its best form, in ignorance for some time of its value for purposes of meteorological inquiry, he gave a brief account of many early kinds of barometers, the first endeavour being in consequence of difficulties experienced with the ordinary mercurial form to enlarge the scale of variation, attempts which in general introduced other errors and inconveniences. The desire to experiment on elevated positions induced the construction of an early form of

portable barometer, one such, with cistern completely closed, leaving the air to communicate through the pores of the wood, having been made above 200 years ago. The President further described various points in the arrangement of the Ramsden, Gay Lussac, and other barometers, including also mention of some modern patterns of long-range barometers, standard barometers, and such barometers as are more commonly used. The practice of driving out air from the mercury by heating or boiling appears to have been in use early in the last century. Engraved plates indicating the weather to be expected with different heights of the mercury have been longer used, at least as early as 1688. As regards correction for temperature, Le Duc, in the last century, adopted a temperature corresponding to 54.5 deg. Fahr. as that to which to make reduction, because corresponding nearly to the average of observations, such reductions being now made to the natural zero 32 deg. Fahr. Reference was made to the employment of water (as in the well-known Royal Society barometer) and other liquids instead of mercury; also to various kinds of floating and other barometers not at all or not entirely mercurial, and to metallic barometers. The President concluded his account with a sketch of the history of recording barometers or barographs, including a notice of the application of photography and electricity to recording purposes. At the conclusion of the President's address the meeting was adjourned to afford the fellows and their friends an opportunity of inspecting the valuable and interesting exhibition of barometers referred to above.

UNIVERSITY COLLEGE, LIVERPOOL: NEW CHEMICAL LABORATORIES.

THE new chemical laboratories in connexion with University College, Liverpool, were opened on Saturday last by Sir Lyon Playfair, M.P., who delivered an interesting address on the occasion.

The buildings, which have been erected from designs by and under the superintendence of Mr. Alfred Waterhouse, R.A., occupy the western confines of the college site, and are placed in immediate and convenient connexion with the Medical School block. The west front, containing the principal entrance, which is surmounted by the water-tower, faces direct upon Brownlow-street; while the eastern elevation looks out upon the college grounds. The most characteristic feature in the building is the large pentagonal apse, which looks southwards and forms the containing wall of the large lecture and practical theatres, which have been designed expressly with a view to lecturing requirements. The polygonal angles are relieved with buttresses running up the entire height of the building, and terminating in ornamental headpieces in terra cotta. The lower theatre is lighted with dual windows introduced in each of the five polygonal facets, while corresponding ornamental arcading is introduced in the exterior facets of the upper theatre, which (to facilitate artificial darkening) is in part lighted from the roof. This outer polygonal apse is flat roofed, backed by the gable roof, which is carried the full length from side to side of the interior portion of the theatre. The main front in Brownlow-street is enriched by the entrance porch and tower, which intervene between the large lecturing-theatre annexe and the body of the building, which contains the various supplementary laboratories, museums, and class-rooms, while the tower itself is occupied by the main staircase and minor rooms. The central portion of the building is designed in three gables facing the street, and is built in three stories. Near one end of this rises the bold and lofty chimney, rendered necessary by the elaborate furnace and ventilation arrangements, which are very complete. The entire design will be eventually completed by the erection of two large laboratories for qualitative and quantitative analysis, placed side by side, and extending from the north end of the present building to Dover-street. Until their erection the north wall will retain its present blank unfinished aspect.

The practical theatre is specially arranged for a large class of students to follow by actual experiment on their own part the demonstrations given by the lecturer, whose table is placed in the middle of the room a few feet away from the back wall and between the

frances. The students' working benches are fifty-two in number, and are arranged in six concentric rows rising one above another. These rows form segments of circles described from the lecturer's position as a centre. It is hoped that by this arrangement the acquisition of a knowledge of elementary practical chemistry will be greatly facilitated and rendered more thorough. The containing wall of the room opposite the lecturer is itself polygonal. The theatre is lighted by three Bower gas-lights, which have been fitted up by Mr. A. Bucknall, of Renshaw-street.

The structure has been carried out under two contracts,—one for the excavation and foundation works, which was undertaken by Messrs. Wm. Tomkinson & Sons, of Liverpool; and a second, embracing the remainder of the work, which was executed by Messrs. Jones & Sons, also of this city. The greater part of the fittings was entrusted to Mr. T. Urson, of Liverpool, under a separate contract. The works have been carried out from first to last under the careful supervision of Mr. A. G. Cook, M.C.W.A., to whom the College is much indebted for his constant vigilance and assiduity as clerk of the works.

BUILDERS' CLERKS' BENEVOLENT INSTITUTION. ANNUAL DINNER.

The eighth annual dinner of the members and friends of this excellent charity was held on Tuesday evening last in the Venetian Saloon of the Holborn Restaurant, when 240 gentlemen sat down to table. Mr. George Howard Trollope (Trollope & Sons), President of the Institution, in the chair. After dinner, the Chairman proposed the health of the Queen, referring to the important ceremony which her Majesty was to perform on the morrow (Wednesday last), viz., the laying of the foundation-stone of the new Examination Hall of the Colleges of Physicians and Surgeons, which was described and illustrated in our last.

In proposing the toast of the evening, "The Builders' Clerks' Benevolent Institution," the Chairman expressed the gratification it afforded him to see so many old and valued friends of the Institution present to lend him their support on behalf of so admirable a charity as that whose cause he pleaded. The Institution was founded in 1866, for the purpose of granting pensions to decayed and necessitous builders' clerks and their widows, for the maintenance of the orphans of builders' clerks, and for the granting of temporary relief in times of illness or lack of employment, or under other circumstances. The Institution had now been in existence for twenty years, and consequently it would next year attain its majority. Since its foundation twenty-two pensioners had been elected on its funds, the number on the list at the present time being fifteen. During the first twelve years of the Institution's existence the pensions allowed were 20*l.* a year to males and 15*l.* a year to females, but in the year 1878, under the active presidency of their good friend, Mr. Rider, the pensions had been increased to 25*l.* for males and 20*l.* for females. From very small beginnings the Society had gradually extended its operations with the result that last year it disbursed no less than 350*l.* in pensions and relief.* The work of the Institution was carried on with an exceedingly small outlay for working expenses, and in that respect he believed it would compare most advantageously with any other institution of the kind. At the same time, the Committee of the Institution would be able to dispose of a much larger sum in aid of the necessitous (were funds provided) without any appreciable increase in working expenses, and he trusted that the Committee would be afforded the opportunity of doing so. The regular income from annual subscriptions and from dividends was not sufficient to meet the demands on the charity, and, therefore, they were to some extent dependent upon donations received at the annual dinners. Fortunately the Institution stood very well at present with regard to its Orphan Fund, and, therefore, he asked intending donors on that occasion to devote their gifts, as far as possible, to the Relief Fund, upon which, owing to the present depression, they had, and were likely to have, many claims. He trusted that builders'

* For further particulars respecting the financial position of the Institution see report of the annual meeting given in the *Builder* for Feb. 27 last, p. 364.

clerks generally would join the Institution, for there were undoubtedly many who had not yet realised the advantages resulting from membership. In conclusion, the Chairman quoted some remarks on the claims of the charity made in a recent "Note" in the *Builder* (p. 328, ante), and the toast was received with much enthusiasm.

Mr. Howard Colls, in proposing "The Architects and Surveyors," said that the architects and surveyors were no doubt at one with the builders in hoping for better times. As a proof of that, he might mention that a short time ago he had the pleasure of hearing a paper read by a young architect at a meeting of the Surveyors' Institution, advocating the rebuilding of a great part of London, the scheme including the formation of about sixty miles of new streets, at a cost of about a million a mile! As builders they would all be glad to welcome the realisation of such a project. But Mr. Woodward's paper had been much criticised, one well-known architect, Mr. Blashill, going so far as to say that it would be cheaper to move London altogether than to rebuild it. However, leaving that subject, he might say that there were some architects and surveyors who were liked by the builders, and some who were not liked. He could only say that the builders wished long life and prosperity to those architects and surveyors whom they liked, while they hoped that those whom they did not like would learn to imitate those whom they did like. With the toast he coupled the names of Mr. Stonor and Mr. Mullett, the latter one of the founders of the Institution, who both responded.

Mr. Koe, in a humorous speech, proposed "The Builders," within which denomination, he said, he did not include certain ingenious gentlemen who were able, out of "airy nothings" to build "local habitations" sufficiently cobwebby in their nature to serve as residences for Ariel; nor the acute and exacting gentlemen who were supposed to have such very keen eyes for "extras" and percentages; nor the gentlemen who were popularly supposed to make it the express purpose of their lives to build in the interests of doctors learned in typhoid fever; nor those other faithful representatives of the building trade who, in certain quarters, were represented to be perpetually engaged in concocting schemes for the "degradation of the working man," in regard to which it ought in fairness to be said that, in spite of his "degradation," the working man seemed quite able to maintain his position as "boss of the show." No; to his mind, the typical representatives of "The Builders" were to be found in such men as the President of the Institution; as Mr. Greenwood, their President last year; or as other of their past Presidents, such as, to name only a few, Mr. Stanley George Bird, Mr. Howard Colls, or Mr. Joseph Randall (of the firm of Kirk & Randall), and others. With the toast he coupled the name of Mr. Randall.

Mr. Randall having briefly replied, Mr. Edwin Brooks (treasurer) proposed "The Past-Presidents," referring to the great services rendered by the brothers Lawrence, Mr. George Plucknett, Mr. Taprell Holland, Mr. Thomas Stirling, Mr. Stanley Bird, and Mr. Benjamin Colls; and, amongst Presidents in more recent years, by Mr. Howard Colls, Mr. Joseph Randall, and Mr. Greenwood.

Mr. Randall responded.

Mr. Greenwood proposed "The President," and Mr. Trollope, in responding, referred to the fact that his father was President of the Institution in 1875.

The toast of "The Visitors" was next proposed by the President, coupled with the names of Mr. Stanton William Preston, Clerk of the Carpenters' Company, who, in responding, spoke of the educational and philanthropic work which that Company had engaged in of late years, special mention being made of the courses of lectures given by the Company last year and this year.

During the evening, subscriptions and donations to the amount of 326*l.* were announced.

Mr. Wheatley, the Secretary, will be glad to afford further information as to the work of the Institution. The office is at 21, New Bridge-street, E.C.

Oldbury.—A proposal is on foot for erecting a Free Library building at Oldbury, but the Ratepayers' Association threatens hostility to the project unless it is carried out by public subscription.

PAGODAS IN BURMAH.

From an interesting paper entitled "Burmah, the Eastern Country and the Race of the Brahmas," recently read by Mr. J. George Scott before the Indian Section of the Society of Arts, we extract the following particulars with regard to the pagodas which abound in the country:—

"The number of pagodas in the country altogether extraordinary. There is no village so poor but that it has its neatly-kept shrine, with the remains of others mouldering away round about it. No hill is so steep and rocky, or so covered with jungle, as to prevent the glittering gold or snow-white spire rising up to guard the place from ghouls and sprites, and remind the surrounding people of the Saviour Lord, the teacher of Nirvana and the law. The banks of the Irrawaddy are lined with them, from the source to the northern hills. The number of them at Pagan, an ancient capital, renders it one of the most remarkable sacred cities in the world. A Burmese proverb says there are 9,999. Whether that is true or not, they cover an area of nearly sixteen square miles, and are of every order of architecture and in every stage of decay, some with cloisters and chapels, and ante-chapels, as fine as many a cathedral, and built in the form of the cross; others with the light grace of the minaret; others again rounded like the Hindoo dome; some that suggest the bamboo-modelled pagodas of China; others a mere Border 'peel'; finally the ordinary half-shelled solid mass, characteristic of Burmah itself; some gilt and white-plastered, as fresh as if new built; others mere heaps of crumbling bricks. The most picturesque group is, however, at a point of the river a few miles below Mandalay. The Irrawaddy here makes a grand sweep to the westward. On the left, as one ascends, are the bare, rocky Sa-gaing hills, on the right the well-forested banks at Ava and Amarapura, rising here and there into knolls and little hills with rocky faces to the river front. All three towns, Ava, Amarapura, and Sa-gaing, if now they can be called towns, are ancient capitals. Hence the abundance of religious buildings. On the Sa-gaing hills, stairways, some of them over a mile long, wind up the steep slopes to the pagodas on the tops, the steps in some places hewn out of the rocky hill-sides, in others laid with square blocks of alabaster. The shrines are not merely on the hill-tops. Down on the cramped space at the base are many more conspicuous among them being the huge solid cupola of the Pumpkin Pagoda. On every practicable spot of the ascent there are more or more mere bell-shaped masses of bricks, some mounted by the invariable umbrella, glittering with gold-leaf, and musical with scores of little bells, hung from the concentric circles, rising one above another in lessening size. Opposite, more pagodas rise up in massive dignity on the river bank, or show their slender spires further back against the green boughs of gigantic trees. The sight, with the background of the huge dark Shan hills to the eastward, is striking and beautiful in the extreme.

There is good reason for this multiplication of fanes. No work of merit is so richly paid as the building of a pagoda. The pagoda-founder is regarded as a saint on earth, and when he dies he obtains the last release; for him there are no more deaths. The man who sets up a row of water-pots on a dusty road does well; he who raises a sacred post, who builds a rest-house, presents an image or a bell or founds a monastery, gains much merit, an ensues a happy transmigration when he passes away; but the Payah-tagah is snatched from the three calamities, his merit outweigh the demerits, and he attains the holiest rest. It may be remarked that it is of no avail to repair a previous dedication, unless it be on of the great world-shrines at Rangoon, Pegu, Prome, or Mandalay. In the case of ordinary pagodas, the merit of the repair goes not to the restorer, but to the founder. Pagodas are built over relics of the Buddha, or models of them; over the sacred eight utensils of a mendicant; or imitations of these, and over copies of the sacred books."

Cambridge.—Prince Albert Victor of Wales recently opened the new buildings of the Cambridge University Union Society, which have been erected from the plans of Mr. Alfred Waterhouse, R.A., at a cost of between 9,000 and 10,000.

ARCHITECTURAL SOCIETIES.

Birmingham Architectural Association.—The seventh ordinary meeting of the current session was held on Tuesday evening last in the Library at Queen's College, when a paper was read by Mr. H. H. McConnell on the "Transition in Architecture from Gothic to Renaissance in England." In the course of a very able chronological paper Mr. McConnell clearly showed, with the help of a large number of his own drawings, the cause of the Transition, and spoke of the work done by the many architects during the period. A vote of thanks, proposed by Mr. W. H. Kendrick, and supported by Messrs. A. Reading, E. Wood, J. Jotton (Vice-President), and T. W. F. Newton, was heartily accorded to Mr. McConnell, who briefly responded.

York Architectural Association.—At the meeting of this Association held on the 18th inst. Mr. Walter G. Penty read a paper on "Terracotta as a Building Material." Terracotta, he said, was simply a superior kind of brick, as both were manufactured from the same material, viz., clay; only the one, terracotta, was brought to a higher state of perfection. The lecturer described in an interesting manner how terracotta was manufactured, and referred to its cheapness, durability, and artistic excellence. It was, he remarked, much deprecated by stonemasons, as they viewed it from a standpoint of rivalry to stone, but he asserted that it was impossible for terracotta to be a formidable rival to stone, as the latter exceeded it in dignity. A discussion ensued, in which the chairman, and Messrs. Parker, Yeoman, and the honorary secretary (Mr. Benson) took part.

ARCHÆOLOGICAL SOCIETIES.

British Archaeological Association.—At the meeting on March 17, Mr. G. R. Wright, F.S.A., in the chair, the discovery of a remarkable historic monument at Langley Burrell was announced. It consists of a mound having a circular platform, paved and elevated, surrounded by a ditch, long lines of embankment radiating from the centre. The entrance faces the east, and the mound has the appearance of having been a place of sacrifice. A detailed inscription will be laid before a future meeting. Mr. McIntyre North exhibited a drawing of the curious red brick arches found during some excavation works on the site of the Duke of Norfolk's Palace, in the Borough, Southwark. Mr. Earle Way described some recent discoveries at St. Margaret's Hill, Southwark. Mr. Woodhouse exhibited a fine series of London medals, illustrative of many buildings which have passed away. Mr. Loftus Brock, F.S.A., described a collection of the gun money coins of James II., struck prior to the battle of the Boyne, showing some singular reductions in size. The King's Exchequer declined. Colonel Rams, F.S.A., in describing a visit to the ruins found at Clapham, expressed his opinion that all the sculptures were the work of the artist, and that the work was superior to the usual class of monumental figures produced at the close of the seventeenth century. A paper was then read by Mr. W. De Gray Birch, F.S.A., on the Legendary History of St. Nicholas Myra.

Deford Architectural and Historical Society.—The first of three "walks" of the members of this society took place recently, when a numerous party, by special permission of the authorities, visited the Castle Mound and the site, in the city. Mr. James Parker gave a party a short history of the object of the moon's visit. The second "walk," which was arranged should be round the City Walls of New College took place, however, on the 13th inst., when the party was again under the able contorship of Mr. James Parker, who explained courses they were to take, and had already en, by maps, which greatly assisted the ters in forming an idea of the direction the walk took. Inside the Holywell entrance Parker gave an interesting account of the prominent features of the old walls, and several interesting particulars as to the laws relating New College to keep the walls in repair, which he read from a copy of the original receipt.

Essex Archaeological Society.—The annual meeting of this society was held on the 18th inst. in the Barbican of Lewes Castle. The chairman (the Rev. P. de Putron), moved a

vote of condolence with the family of the late Earl of Chichester in their bereavement, and expressing the loss the society had sustained in the death of their president. Mr. Crosskey then presented the annual report, and mentioned that Domesday Book would be issued within about a fortnight, and the volume for 1886 would be issued to members in about a month afterwards. The accounts were next presented and passed. Mr. Griffith proposed the election of the Rev. Chancellor Parish as joint secretary with Mr. F. Barchard, in the place of the late Rev. W. Purcell, and this was agreed to, the Chairman remarking that they were very much indebted to Mr. Parish for his services in connexion with Domesday Book. Mr. Latter Parsons, of Lewes, and Mr. Clayton, of North-street, Brighton, were elected members of the Committee. Some discussion then occurred as to the place of holding the annual excursion. After various suggestions had been made the matter was referred for decision to the Committee.

OBITUARY.

Mr. Alfred Burges, C.E., F.S.A.—This well-known engineer died at Worthing on the 12th inst., in his 90th year. He was articulated by his father,—a man of humble condition, but who could afford a premium for his son,—to the leading civil engineer of his day, James Walker. The pupil soon became the partner; and a life prolonged far beyond the ordinary human span, a colossal fortune, and the survival of his son, William Burges, the distinguished architect, alike attest to the more than ordinary character of the subject of our notice. Alfred Burges, without the same advantages of education, had many of the tastes and proclivities of his son William; he was a careful and tasteful draughtsman, and took especial interest in archaeology and antiquities. He was well known on the various works of the Trinity Corporation, especially additions to lighthouse buildings, &c.; and was constant in his supervision of the most successful wet dock works in the Port of London, the Commercial Docks, and on the Commercial-road tramways and causeways to the East and West India Docks, also on the Barking and Essex roads, the bridges on which, in many cases, were re-erected or widened by his firm. The Essex Sewers Commissioners and the Bedford Level Commissioners were also largely advised by him. The Leeds and Selby Railway, the Hull and Selby Railway works, the Junction Dock at Hull, and numerous metropolitan and provincial docks and harbor works in England and Scotland, were improvised by him. It is only necessary to note the names of the chief assistants who passed through the office of Walker & Burges to identify the position in his profession that the junior partner of the firm occupied. They were as follows, viz.:—J. W. Bazalgette, G. P. Bidder, M. A. Borthwick, W. B. Bray, J. Cooper, G. S. Dalrymple, T. Deane, E. Druce, A. Drysdale, J. Hartley, J. Hawkshaw, J. Herbert, D. P. Hewitt, W. H. Holland, J. R. McLean, J. McConnochie, Major Newsome, R. E. J. Ormiston, W. Parkes, F. Pollock, J. B. Redman, T. M. Smith, R. Townshend, J. S. Tucker, among others. They all are, or were, corporate members of the Institution of Civil Engineers, but nearly two-thirds have long since joined the great majority.

A New Building Undertaking at Brockley.—The Bridge House Farm Estate at Brockley, containing an area of about fifty acres, was some time since purchased by a company of capitalists, who have constructed roads on the estate from 50 ft. to 60 ft. in width, and several houses in the "Queen Anne" style have already been erected. The erection of a public hall is contemplated, whilst a site has been reserved for the erection of a church. On an elevated portion of the site the owners have also founded what has been designated the West Kent Grammar School, and a portion of the building, consisting of the central block, has already been erected. It is intended to add two wings, together with a chapel in connexion with the school. The school buildings, when completed, will be three stories in height, and a prominent feature will be a central tower. Mr. C. Evans, of Post's-corner, Westminster, is the architect.

Illustrations.

ST. JAMES'S CHURCH, MARSH-LANE, BOOTLE, NEAR LIVERPOOL.

THIS church, the interior of which we this week illustrate (from a water-colour drawing by Mr. Brewer, exhibited last year in the Academy), was described at length in our columns at the time of its opening last February. It will be sufficient now to say that it is designed in the style of the Early Decorated period, dating about the middle of the thirteenth century, and consists in plan of nave and aisles, with tower and entrance at the south-west corner; a baptistery at the end of the north aisle; chancel and side chapels, with stone-vaulted ceilings; and a range of confessionals adjoining the tower and south aisle. The principal dimensions are as follow:—Total internal length from east to west, 148 ft.; chancel, 31 ft.; total breadth across aisles within 64 ft.; breadth of nave, 29 ft.; height of nave from floor to cornice, 50 ft.; height of nave from floor to ceiling in centre, 64 ft.; height of aisles from floor to cornice, 25 ft. There is sitting accommodation for 1,000 people, the seats being of pitch pine. The building is executed in local red sandstone, and the floors are laid with 2-inch pitch-pine flooring; the chancel steps and footpaces of encaustic tiles by Messrs. Carter, Johnson, & Co., of Worcester. The heating is by low pressure hot-water pipes, supplied by Mr. C. Seward, of Preston, due care having been given to the subject of ventilation. The plans and details of the church and presbytery have been prepared by Mr. Charles Hadfield, of the firm of M. E. Hadfield & Son, Sheffield, under whose frequent personal supervision the work has been carried out by Messrs. G. Woods & Son, of Bootle. Mr. Haworth was clerk of the works, and Mr. Bishop-foreman.

The illustration is reproduced from Mr. Brewer's drawing by Messrs. Goupil's process.

INDUSTRIAL DWELLINGS TO BE ERECTED IN SILVER PLACE AND INGESTRE PLACE.

THESE plans, by Mr. H. H. Collins, were selected, in a limited competition (as previously mentioned in our columns), instituted by the Vestry of the parish of St. James, Westminster. The primary object of the Vestry was to appropriate a trust fund in the erection of comfortable habitations for those least able to help themselves, namely, widows, with one or more children, and women earning precarious livelihoods.

The land covers an area of about 3,000 ft., and is held on a long lease from the Saffron Estate. The site is not only limited in area for the accommodation required, but is dominated by ancient lights and other difficulties, and express conditions were laid down as to the height to which the proposed buildings were to be carried, and 70 to 75 per cent. of the rooms were to be single-room tenements, the desire being to assist a class of very poor persons.

The building is planned so that a great majority of the rooms can be converted almost indefinitely into one, two, or three room tenements, and as the majority of the occupants will be widows there is no necessity for providing for any increase of family. Twenty-three single-room tenements are provided, of various sizes, to suit the means of all classes, both with regard to dimensions and rent.

The rooms compare favorably with the Peabody Buildings and other model dwellings, the living-rooms being, on an average, 12 ft. 6 in. by 11 ft. 6 in., and the bedrooms 11 ft. 6 in. by 10 ft. 3 in., and all about 9 ft. in height.

The buildings in the rear are low in elevation, and the window openings of the present buildings command a right of light over the same, so that the yards, &c., will, practically, always be ensured the same light as the new buildings are arranged for.

The basement contains a small washhouse, with washing troughs and coppers, so that the inmates can wash small articles of clothing; the public baths being close by, there is no occasion for providing an ordinary laundry, and, of course, no laundry business will be allowed to be carried on in the premises. There is also a workroom for the use of sewing-machines, &c., well lighted and heated.

The endeavour has been to make the archi-

tectural features pleasing, but not ornate, so that "monotony and ugliness," which Miss Octavia Hill says the working classes so much complain of, is avoided; the desire has been to make it as homely in appearance as possible. The elevations will be constructed of picked stocks neatly pointed, with red brick and terracotta string courses and dressings.

To each window is provided a light iron balcony, so as to encourage a taste for window gardening and to render the rooms pleasant and cheerful. All the approaches are kept light and cheerful, dark corners being in every instance avoided.

The floors are all fireproof, and the sculleries and w.c.'s are paved with white asphalt. The divisional walls have glazed brick dados, 5 ft. high, the upper portions being painted with enamelled silicate paint. Each room has rails and hooks for hanging up clothes, cupboards being avoided as much as possible on account of the dirt which they too often enclose. In each living-room there is a cottage range with oven, having a special arrangement so as to deliver warm pure air into the room, and every room has a fireplace; and each living-room has a food cupboard with coal bunker underneath properly ventilated, *vide* detail. All the windows are made with deep bottom rails, being an inexpensive mode of providing ventilation, and there are, in addition, foul-air exits.

The sanitary arrangements have been most carefully considered. Mr. George Godwin has pointed out long ago that "the position of the water-closets, &c., is a great danger, not merely for moral, but for physical contamination," the whole question depending upon supervision and personal responsibility. It is evident that the more this supervision can be localised the more the danger is minimised. Thus, in the plan care has been taken, in the first place, for economical reasons, to place the whole of the water-closets as much as possible together, and to so distribute their use that those for the single-room tenements are confined to not more than three tenants, who would be responsible for keeping them clean and sweet; any delinquent being thus easily traced, while each tenant of a double-tenement has a separate and distinct water-closet for the condition of which she will be held personally responsible.

All water-closets are well lighted and ventilated, and placed externally to the building, the windows having the upper parts permanently fixed open as hoppers. The windows over the internal sinks are treated in the same way.

The drainage arrangements are set out in the sanitary sheet. It will be seen that there is an absolute disconnection from the main sewer, a thorough flow of air through all the pipes, an easy means of access for cleansing, and an absolute disconnection from the drainage arrangements and the different tenements. Doulton's last patented closets, without riser and with lifting seats, are provided. The scilp-pipes are open at their feet and heads, and have a current of air continually permeating them. The branch pipes of the water-closets are also ventilated so as to prevent siphonage. All waste-pipes from sinks are trapped and carried into the open-air, discharging into heads of rain-water pipes, these latter emptying over Bellman & Ivey's trapped gullies. The potable water is entirely distinct from that used for water-closets, elop sinks, &c., each water-closet having a water-waste preventer placed over the same. The cisterns will be placed on the flat roof, easily accessible and so arranged as to prevent their being affected by frost or being invaded by dirt or vermin.

All soil, rain-water, and other pipes are carried externally to the building. Dust shoots are provided off the corridors in the open-air, and have no connexion in any way with the rooms. They are carried up beyond the eaves of the building and are thoroughly ventilated. They discharge into galvanised iron dust-bins, which can be easily cleansed by the dustmen.

Care has been exercised to obtain a good means of escape from fire either by the staircase or on to the fireproof flat roof.

The building contains twenty-one single-room tenements and twelve double-room tenements, exclusive of carekeepers' accommodation.

MONUMENTS COMMEMORATIVE OF THE SIEGE OF PARIS.

For some account of the three monuments illustrated, see article on p. 466 of this number.

Font Cover, Congresbury Church.

PRESBYTERIAN CHURCH, HIGHGATE.

This building is recently begun, and will occupy a commanding position at the top of the hill, where Hornsey-lane meets Cromwell-avenue. The plans provide for a galleried church to seat 730, whilst behind is a two-storied building having vestries, session room, ladies' room, &c., on the ground-floor, with a large hall over. There are three staircases to galleries and hall. Externally, the materials are Kentish rag, with Bath dressings; and the contract has been let to Messrs. T. Wontner Smith & Son, of Essex-road, at 6,700l., which will include hall, vestries, church, and spire complete. The architects are Messrs. Potts, Sulman, & Hennings, of 1, Paruiva's Inn, whose designs were selected in a limited competition.

DESIGN FOR A MUSEUM AND LIBRARY FOR A SMALL COUNTRY TOWN.

This pretty little design obtained the prize for the best design produced last year in the upper division of the Architectural School of the Royal Academy, which, considering the high standard of the work generally, was no small achievement. Its author, Mr. E. Gny Dawber, says that he intended the roofs to be covered with red tiles, and the whole front to be of lightish buff terra-cotta, with irregular bands of the same material darkened in the fanae.

The New Examination Hall for the Colleges of Physicians and Surgeons.

The foundation-stone of this building was laid by Her Majesty the Queen on Wednesday. We published a view and plans of the building in our last. We are asked to mention that the facing bricks are being supplied by Messrs. Thomas Lawrence & Son, of Bracknell, being of the variety known in the trade as the "T.L.B." bricks.

FONT COVER, CONGRESBURY CHURCH.

The font-cover here given is the only Jacobean work left in the church. It is octagonal in form, and apparently of earlier date than the pyramidal top being slightly earlier than the panels below. These panels are carved to much spirit, as are also the plasters at angles, all of them being of different designs. There is some good fifteenth-century scrol-work in the church.

Labourers' Wages in New South Wales.

We extract the following from the sheet "Australian Information for British Journalists" issued from time to time by the Immigrants Office at Sydney:—"The immigrants who landed at Sydney from the steam-ship *Pat* were a number of single men accustomed to routine of agricultural life. These readily found employment, the rates of wages being as follows:—Gardener for Rockdale, 35s. per week; dairymen for Randwick, 16s. and 18s. per week respectively; and two dairymen for Botany per week each; farm labourers for Queanbeyan, Liverpool, and Jamberoo, 40l., 30l., and 35l. annum respectively; two ordinary labourers Liverpool, 30l. each per annum; an ordinary gardener for the Gordon District, near Sydney, 40l. per annum; in all cases with board lodging. A generally useful man, to do druggery, was engaged for Wagga Wagga, at 30l. per annum; and an assistant baker, at 39l. annum, with board, for East Maitland. Immigrants were distributed over the colonies in the following directions:—North: Glen Ingle, Newcastle, Gunnedah, Wallend, and East Maitland. South: Wollongong, Moss Vale, Murrumbidgee, Albury, Jamberoo, Liverpool, Box Hill, Cootamundra, Wagga Wagga, Goulburn, Queanbeyan. West: Lithgow, Orange, Nyngan. These are places where steady, industrious men have excellent chances of success, and none others should think of emigrating."

Roman Mosaic at Berlin.

A ROMAN MOSAIC PAVEMENT AT BERLIN.

The circumstances under which the mosaic here illustrated found its way to Berlin are somewhat singular. It was discovered in 1810, the pulling down of a fifteenth-century dwelling-house in Trèves, about 7 ft. below the level of the street. The Prefect of the town rewarded an announcement of the discovery in Paris, but no notice being taken, the owner of the house was allowed to do as he pleased with it. He built a wall across it, as shown in the illustration. The right-hand and smaller part of the mosaic was taken up, and the larger part of it was placed in the Trèves Museum, where the two picture panels (on the right over which the wall was built) are still to be seen, although the remaining fragments have gradually crumbled away, or, as it is asserted, found their way into the pockets of artists. The left-hand and larger half was covered over again, and not re-opened until 1864, when the house was bought from the son of the previous owner. It was then thrown open to the public, and finally offered for sale. It was bought by a firm of Berlin architects (Messrs. He & Stegmüller), and placed *pro tem.* in the Royal National Gallery; it still remains the private property of the architects above named.

The pavement is believed to date from the end of the century of our era, and, judging from the character discovered upon some of the detached tesserae, it is conjectured to have been the work of Greek artificers. A wide band of light blue upon a dark ground forms the outer border of the pavement, which measures about 18 ft. by 15 ft. 6 in. The inner space is divided into two oblong side panels and a square centre, the inner covered with an ornamental design of a frequent in Roman work; the latter surrounded by a second and richer border, and containing four eight-pointed stars formed by interlacing lines, in and between which are inserted figure designs,—animals, with a background of landscape, birds, or vases. The ornamentation of these designs is remarkably correct and forcible, and the colouring rich and nonious.

The ground is composed of a yellowish limestone, except in the outer border, in the side panels, and in the border of the centre, where it is of dark blue-grey marble. Lines of different varieties give the more important colours of the interlacing lines (yellow red), and of the pictorial compositions, which contain a good deal of bright green blue.

The mosaic, that is, the portion of it which escaped destruction, is in a state of excellent preservation, although, when discovered, it had sunk considerably from its original position (probably owing to the falling in of a hypocaust below it), and was broken in several places.

Portsea.—The Church of Holy Trinity, Portsmouth, has just received a Munich stained-glass window representing the Adoration of the Kings. The window is by Messrs. Mayer & Co., Munich and London.

STONE-SAWING AND MOSAIC MANUFACTURE.

An action at law involving some interesting and important points respecting the sawing of stone and the manufacture of mosaics has recently been determined, after a long and almost tedious hearing, by Mr. Justice Grantham, sitting without a jury in the Court of Queen's Bench. For the first time, we believe, an attempt has been made to apply machinery to the purpose of producing the tesserae for mosaic decorations, and, as it happens, the prompt first consequence has been litigation of a costly and protracted nature. The suit was initiated by Messrs. Hall & Co., of the Burley Engine Works, near Leeds, to recover something between 800l. and 900l. from Messrs. Burke & Co., of Newman-street, London, Paris, and elsewhere, for certain stone-working machinery supplied to the order of Mr. Burke. And in response, Messrs. Burke & Co. preferred a claim of over 4,000l. against the plaintiffs for breach of contract and consequent loss. The defendant, for the manufacture of mosaics, forms an amalgam of the waste pieces of marble and plaster of Paris. The admixture, becoming a solid block, is sawn into slices by horizontal saws. It is then further split into fingers or strips, and is finally cut into squares or tesserae, the plaster of Paris in the end separating from the marble. By this process the material for mosaics are obtained with greater ease and speed than has been possible under the old methods, and at the same time a great saving is effected by the consumption of scraps and bits of stone which otherwise might be simply waste. According to the story disclosed in court, Mr. Burke visited the plaintiffs' works at Burley, and ordered certain horizontal saws, working on the pendulum principle, his reason for choosing that principle being that he required to place several machines within a small space. The plaintiffs had not a machine of this kind in stock, and in fact had not made any of that kind, but the defendant supplied drawings, showing the arrangement he desired, and from those designs the plaintiffs constructed the machinery which subsequently formed the ground of action. On being put to test after erection, the machines failed, the pendulum, saw-frame, and intermediate gearing being broken. Thereupon Mr. Burke refused to accept and pay for the machinery, his contention being that it was improperly constructed, the worm-gearing for working the sand-box being wrongly set out, and the pendulum, cross-heads, and saw-frame being made of cast-iron instead of wrought-iron. In the meantime he had discovered some Belgian machines which he considered better for his purpose; and this strengthened his objection to keep Messrs. Hall's machines. The trial occupied eleven sittings of the court; and a large number of witnesses were examined on each side. Among the exhibits were some mosaics about 2,000 years old, produced for comparison with those of modern machine-made specimens. Mr. Forbes, Q.C., and Mr. Edge were the plaintiffs' counsel, Mr. Lockwood, Q.C., and Mr. Hilbury representing the defendant. Although a great deal of evidence was given upon the merits of the machines, the real issue

eventually turned upon the question whether, as Mr. Burke had supplied the plaintiffs with drawings from which to work out his idea, the latter were simply acting as his servants for the time being, and were, therefore, not liable for the failure of the machinery. On the merits of the machinery the consideration arose whether a machine supplied for sawing stone (as these were) could be expected to be capable of cutting marble and granite; and upon this point Mr. Powis Bale, Mr. Turner (of Rodley, near Leeds), Mr. Roberts (of Bradford), and other experts, maintained that machines for sawing such hard substances as marble and granite must be made specially strong, and were distinct from frames required to saw building stone. Another point advanced by the plaintiffs was that the very limited space allowed for the machinery told seriously against its chance of efficient working; and Mr. Powis Bale, the chief witness for Hall & Co., held that for this mosaic marble-cutting process the crank principle, and not the pendulum principle, ought to have been adopted. The machinery was, however, made upon the defendant's own instructions, and in the end the Judge decided that by supplying the drawings Mr. Burke had relieved the plaintiffs from liability, and must take the consequences himself. He further took the view that by confining the plaintiffs to a too-restricted space the defendant had necessitated such a cramping of details as to increase the danger of breakage; and that Mr. Burke had, against the advice of the plaintiffs, adopted the wrong principle, this being shown by his having subsequently bought Belgian machines, working on the crank principle. Judgment was therefore given for Hall & Co., both on the counter-claim and on the original claim, with costs; although some slight reduction was made in the items, and the plaintiffs were ordered to remove a rubbing-bed found to be out of truth in one of the machines set up in London. In preparation for the action, several professional gentlemen on both sides visited Paris to witness trials of the machinery in question set up in that city.

PLUMBERS' WORK.

STR.—"A Practical Plumber" asserts (p. 390, ante) that plumbing generally costs more than it ought to do, and proposes as a remedy that the responsibility for the plumbers' work should be taken away from the general foreman. I mentioned in your issue for March 13th (p. 424) that although his assertion is correct, the remedy lies in a direction contrary to that which he indicates.

I say, without fear of contradiction, that upon a building there is no man whose presence is a more unmitigated nuisance than the man who is not under the direction and control of the general foreman. He requires more attendance, more "making-good" after, does more damage to other work, and causes more accidents, than all the other trades put together.

My contention is, that if the plumbers' work is to be brought out at a reasonable price cost, the general foreman must have absolute control over every plumber employed, and that the detail of the work should be settled upon, and the specification placed in his hands, at a much earlier stage of the work than is now generally the case.

It frequently occurs that when a building is about to be erected, a lump sum of money is provided in the quantities for the plumbing, or at least for the internal plumbing, and there the matter rests until the roof is on. Much money is then wasted, and the cost of the plumbers' work materially increased, by having, in order to get courses for the pipes, to cut chases and holes which might easily have been left in the brickwork as the job was carried up, by altering joists and trimmers to get traps and fittings in position, and in doing other work at a heavy cost, which would have been done for comparatively little had it been taken in hand as the work progressed.

As these operations rarely tend to increase the stability, or diminish the cost, of the structure, this course of procedure constitutes, within my experience, a very serious evil; and I would therefore suggest that, when a job is about to be carried out, before a single brick is laid, the whole scheme and arrangement of the plumbing should be thoroughly considered and definitely decided upon, and a clear specification drawn up. A duplicate set of plans and sections should be obtained, and the courses of the pipes and positions of the fittings carefully drawn upon them. Thus fortified, the general foreman would be enabled to arrange for the due execution of the work in a proper and straight forward manner, the cost would be the lowest possible, and the work would probably be carried on even to the satisfaction of "A Practical Plumber."

G. W.

SEWER VENTILATION.

SIR.—The question put by you on p. 458 of your last issue,—"Where are the pipes to go, so as not to be either an eyesore or obstruction, or a concentrated danger to individual houses?"—is most legitimate. As to the eyesore objection, the plumber and architect should be able to settle that between them. If round pipes be objected to, use strong square ones. This objection has been overcome in other cases, and can be again. As to concentrated danger to individual houses, a good deal of that is imaginary if the outlet is placed high and above the chimneys. If the law were once passed that it must be done, it could be done, and people would get used to seeing sewer blow-offs just as they are with smoke blow-offs. W. P. BUCHAN.

AN APPEAL.

SIR,—May I ask the favour of space in your columns to appeal to the building trade on behalf of one who has been and is amongst its most respected members?

He was the founder of one charitable institution connected with the trade, and a liberal supporter of all the others.

He is the son of a late well-known builder, and for many years has filled responsible positions in several large firms. In 1868 he started in business for himself, but, unfortunately, in 1879 became involved in a law-suit, and although only a small amount was in dispute, it lasted five years, and eventually resulted in the loss of his all for costs.

It is proposed to raise a fund for the benefit of those depending on him for support. His age (under sixty) precludes him from seeking the aid of those institutions with which he has had so much to do, even if he could bring himself to such a step. The case is well known to Mr. Alfred Mansfield, of South-street, Grosvenor-square, and to Mr. Grover, of Wilton-square, Islington, N. As to what form the assistance shall take depends mainly on the amount received. I shall be glad to give all information if any of my brother builders will write to me.

STANLEY G. BIRD,
President of the Institute of Builders.
25A, Upper George-street, W.

A QUESTION OF SLATING.

SIR,—Can any of your numerous readers inform me if it is usual in letting slating of houses by the square, the owner finding time to point with, and the cutting of the slates to the building, and allowing the master slaters or contractors all the advantages in the measurement of slating, for the owner to deduct for skylights and chimney-stacks?

SLATER.

A TAX ON BEAUTY.

SIR.—Architects and builders and their employes will do well to watch with care the present movement for the readjustment of local taxation. In the debate on Tuesday, Mr. Thorold Rogers seriously proposed a tax on costly houses, not because they let well, but because they do not. The proposition actually is that capital irrevocably spent in high-class workmanship and materials should be permanently taxed, and Mr. Rogers carried his preliminary motion.

The injury that any such practice would inflict on the architectural profession, the destitution it would cause among the employes of builders, and the general folly of the whole idea, are my reasons for asking you to warn your readers. WM. MUIR.

PROVINCIAL NEWS.

Chadwell Heath (Essex).—A new Congregational hall was opened here last week to serve as a chapel and Sunday school. The building has been erected by Mr. Dowling, of Romford, from plans prepared by Mr. E. C. Allam, architect, Romford. The total cost of the building and furniture is between 400l. and 500l.

Chilworth (Surrey).—The Chilworth Gunpowder Mills, which are stated to be the oldest gunpowder works in England, having been established in the time of Queen Elizabeth, have just been enlarged and extended under the supervision of Director-General J. N. Heidermann.

Derby.—The Spring Exhibition now open in the Derby Corporation Art Gallery is described in the local *Advertiser* as one of the best ever held there. It includes a loan collection of works by well-known masters.

Grimsby.—A committee appointed by the Board of Guardians for the Caistor Union to consider the desirability of building a union workhouse at Grimsby have decided to recommend that the Parliamentary borough of Grimsby should constitute a separate union, with its workhouse at Grimsby.

Hedon (Yorks).—The *Hull Times* states that a new race-course, and the necessary buildings in connexion therewith, are being completed at Hedon, under the auspices of the East Riding Club and Race-course Company.

Hull.—The work of erecting some new almshouses has been stopped by the Charity Trustees, at the desire of the Town Council, who propose an alternative site.

Mildenhall (Suffolk).—It is proposed to build a new public hall here, at a cost of about 700l.

Newark.—The chief corner-stone of the Church Mission-room in New Town, Newark, was laid on the 18th inst. The room will seat, when completed, about 300 people. There will also be a schoolroom attached, which will front Newton-street. The cost is to be 620l. Mr. Crossland is the builder, and Mr. Geo. Shepherd is the architect.

Nottingham.—The line of the new thoroughfare in Wheeler-gate is now clearly defined. Workmen are busy laying down wood pavement upon a solid bed of concrete at the Hounds-gate end of the new street, and the roadway up towards the Market-place is being rapidly prepared for paving. Already the foundations and basement of extensive premises abutting upon the new street line have been built, but no steps have been taken towards removing the buildings fronting South Parade, which are included in the improvement scheme.

Preston (Lancashire).—A new club-house for the Reform Club, Preston, is being erected in Chapel-street. Mr. David Grant, of Preston, is the architect.

Southampton.—A new font has just been presented by Mrs. Humphreys, of Southampton, to the church of St. Laurence, in that town, in memory of her daughter Rosalind. The design consists of an angel in a kneeling position, upholding a shell which forms the basin. The font, which has been executed in Sicilian marble, is the work of Mr. W. C. May, the sculptor.

Speen (Newbury).—A new parochial room is being built at Speen, at the cost of the Misses Majendie, on a site presented by Sir Richard Sinton. Mr. S. Gambier Parry is the architect.

Wednesbury.—The Wednesbury Local Board have made the disagreeable discovery that the cost of the sewerage scheme in which they are embarked will exceed the engineer's estimate by 5,844l., the total cost being now set down at 35,964l., instead of 30,120l., the sum originally computed. Of this increase, however, 3,607l. is entirely due to unexpected requirements of the Local Government Board to meet objections of property-owners to the outfall works being constructed near to their properties, and 606l. 10s. in respect of the diversion of the sewer from ground broken by mining operations to a safer bed, whilst the balance, 1,630l., including commissions, arises from excess of contract price over the engineer's estimate. Thus, provoking as is the increase, the bulk of it arises from no fault of the Board, but from the pressure of rate payers through the Local Government Board, and, if it permanently obviates the anticipated nuisance from the outfall works it will, after all, not be money ill spent. — *Staffordshire Advertiser.*

CHURCH-BUILDING NEWS.

Cauldon.—The parish church of Cauldon, Staffordshire, has just been re-opened, after restoration under the supervision of Mr. J. R. Naylor, architect, Derby. The principal works now carried out include a new south porch of Stanton stone; open benches of red deal, with pitch-pine ends; floor of Minton's encaustic tiles; a new font of Stanton stone; a pulpit, with base, of the same, surmounted by a superstructure of pitch-pine; and a lectern of pitch-pine. The church is warmed with Porritt's heating apparatus. The work has been carried out by Messrs. Knowles & Son, of Brassington, Derbyshire.

Coleford.—A new south transept has been added to St. John's Church, Coleford, Gloucestershire, and it was opened on February 25th. Mr. Sydney Gambier Parry, of London, was the architect; and Messrs. Wall & Hook, of Brimscombe, Gloucestershire, the contractors.

Fareham.—A new parish church is about to be erected here, from designs by Mr. A. V. Bloomfield, M.A.

Farnborough, Kent.—The chance of Farnborough Church, which has been in a dangerous state for some years on account of the nature

of the site, has been rebuilt, with additions by the diocesan architect, Mr. J. Clarke, F.S.A., and was re-opened on the 26th ultimo. An organ chamber has been added. The lines of the old chancel have been followed, and the details preserved. Mr. E. Vaughan, of Maidstone, was the contractor.

Little Wigborough, Essex.—The church of St. Nicholas, Little Wigborough, is one of the churches destroyed, or nearly so, by the earthquake which occurred on the 22nd April, 1884. The whole of the church was shattered, and has to be nearly rebuilt, including the tower. Such parts of the old walls as could be preserved have been restored with the windows and old details. New open seats have been added instead of the former square pews, the chancel floor laid with ancient encaustic tiles by Messrs. Godwin, and proper choir seats introduced. The plans were prepared by Mr. Joseph Clarke, F.S.A., diocesan architect, and the work well carried out under his superintendence by Mr. George Dobson, of Colchester. The church was re-opened on the 4th inst.

Oldbury-on-Severn.—The parish church of Oldbury-on-Severn has been re-opened, after restoration under the superintendence of Mr. F. S. Waller, architect, Gloucester. Mr. Gyde, of Brimscombe, was the contractor, and the total cost of the works has been 1,600l. The church has been new-roofed, an entire new floor has been laid, and the old-fashioned high pews have been removed, open seats of pitch-pine being substituted. The two arcades were found to be in a very defective condition, and the freestone of which they consisted was covered to the thickness of $\frac{1}{2}$ in. with whitewash. The font has been removed, and an old one which formerly belonged to the church has taken its place. A reredos, provided at the expense of Dr. Bonpre, of Salisbury, has been placed in the chancel. It consists of three panels, the one at each end representing the Alpha and Omega, the centre one containing a floriated cross, the whole being from the designs of the architect. The old pulpit has been removed, and one of similar design to the Perpendicular portions of the church substituted. This, as well as the reredos, is composed of Painswick stone, with panels of alabaster. The whole of the carving has been executed by Mr. Henry Frith, of Gloucester.

Taunton.—There have been some material additions made to St. James's Church, Taunton, under the direction of Mr. E. B. Ferrey, architect, and on the 17th inst. Mr. Henry Davis, builder, of Billefield, Taunton, presented to the church a handsome altar, substantially made of oak, from designs by Mr. Ferrey. The front of the altar is composed of five bays. In the centre bay, against a carved and gilded diapered background, stands a plain oak cross.

Thirsk.—The parish church was restored internally a few years ago, but from the designs of the late Mr. Street, R.A., but from want of funds the work was stopped before the fine south porch, and the external stone work generally, were in any way repaired. An effort is now being made to raise funds for the restoration of the porch, which is of considerable size, and has over it a parvise or upper chamber to which access is only gained with much difficulty by a small doorway high up in the wall of the south aisle. The work now proposed embraces a new staircase to the parvise, a suitable oak ceiling to the porch, re-leading and repairing the old oak roof, the removal of whitewash and general repairs to the stonework, and fitting the parvise as a clergy vestry, the church being at present without one. Plans for these works have been prepared by Mr. C. Hodgson Fowler, F.S.A., of Durham.

DISSENTING CHURCH-BUILDING NEWS.

Birkdale.—The memorial stones of a new extension to Brighton-road Wesleyan Chapel, Birkdale, Southport, have been laid. The extension consists of four vestries and an infants' room fitted with a gallery, the whole being separated from each other and from the main building by movable partitions. The total outlay in connexion with the addition is estimated at 650l. Mr. H. E. Peach is the architect, and Messrs. Sarginson & Anderson, of Birkdale, the contractors.

Bollington.—A new Wesleyan Chapel has been opened at Bollington, near Macclesfield. It will seat 700 persons, and is Early Gothic style. The total cost has been about 5,000l.

d the contract has been carried out by Messrs. Ill & Bradburn, of Macclesfield, the architects being Messrs. Waddington & Son, of Manchester and Burnley. The plumbing work has been done by Mr. Westwood, of Macclesfield; and the hot-water apparatus was fixed by Mr. Harlow.

Liverpool.—The memorial stones of a Wesleyan Chapel have just been laid in West Derby, Tue-Brook, Liverpool. The style of architecture will be Early English Gothic. The building will be faced with Yorkshire pitched parapets and Stourton stone dressings. Accommodation will be provided for 766 worshippers. The plans have been prepared by Messrs. Samuel Hurst & G. E. Bolshaw, architects, Southport, and the works are being carried out under their supervision. The sole contractor is Mr. Edward Burns, joiner and glazier, Danby-street, Liverpool.

Wirksworth.—A new Baptist Chapel here has been opened for service. It is capable of seating 300 adults, and has in addition a good school-room and five class-rooms. The cost, including purchase of site, heating apparatus, erection of organ, is estimated at 2,700l. J. Wallis Clappam, of London, is the architect, and Messrs. J. Walker & Sons, of Wirksworth, were the contractors; Mr. Axe, of Leamington, supplying the woodwork; Mr. Parker, of Cromford, the gasfitting, plumbing work, and heating apparatus; and Mr. Haslam, of Derby, the ironwork.

The Student's Column.

OUR BUILDING STONES.—III.

ANY of the most important building stones consist chiefly of carbonate of lime and carbonate of magnesia in equal proportions. Such a stone is usually injured by the sulphuric acid in rain air. If the stone be crystalline it is generally good and durable; if, on the contrary, it should be amorphous,—that is, having indeterminate form,—it very readily decays, even the crystalline form is more or less attacked in a large city. We may here remark, that the action of acids in their combined state is very much less than when they are free. This is especially the case with sulphuric acid. The matter whether the stone is crystalline or the action of this acid, in a large city, arising either as free sulphuric acid or as a salt of ammonia, is just the same, on the carbonate of magnesia. The sulphuric acid attacks the carbonic acid, and forms with the magnesia, a sulphate which is soluble in water, and results in the decay of the stone.

The mortar of walls may often be observed to be slowly swelling out and dropping off, owing to the conversion of the lime contained in it into sulphate by the action of sulphuric acid in the air.

It has lately been proved that in the atmosphere of a large town, with abundant coal, and rain, inscriptions on marble become illegible in half a century. It will be obvious, however, that much depends on the kind of stone. Lichens of lime, potash, and soda are also killed by the impurities of rain-water. Mosses, lichens, &c., by keeping the surfaces always moist, provide means for the continuous action of water. Moreover, when these stones decay they supply organic acids, which play an important part in the decomposition of rocks. There can be no doubt that a great deal of the decomposition of rocks, which has been attributed to the action of carbonic acid is due in the first place to the action of organic acids, but that these organic compounds of such an unstable character eventually pass into carbonic acid, and thus their initial action is lost sight of. Their action as destroyers of building stone would not be very great in a town where the lichens did not grow, but in the country are often covered by

the power of these acids when they are in contact, from a chemical point of view, is very great. They even dissolve silica.

The prominence of oxygen in rain water, and its readiness to unite with any substance that

Dr. Angus Smith's "Air and Rain" (1872), p. 444, citat. "Proc. Roy. Soc. Edin." (1878-80), p. 518. Consult A. A. Julien, "Amer. Assoc.," 1879, p. 32.

can contain more of it, causes oxidation to be a conspicuous feature in the decay of building stones. Thus, any stone containing an appreciable quantity of ferrous or manganese oxides will rapidly become discoloured.

The white spots and veining found amongst red sandstones detract much from their value when appearances are considered. The red colour of the stone is due to the presence of ferric oxide, which, reduced by decaying organic matter (derived from the soil and atmosphere by rain) to ferrous oxide, is usually removed in solution as an organic salt or carbonate. When the deoxidation takes place round a fragment of plant or animal it usually extends as a circular spot; when water containing the organic matter permeates along a joint or other divisional plane, the decoloration follows that line.*

From what has already been said it is evident that a stone that may be of a durable character in the pure country air may be of no value in a large city. The carbonic, sulphuric, nitric, and hydrochloric acids all conspire to rot the stone. It is, therefore, important for the student to know what to look for to counteract these deleterious agents. This becomes more urgent as our towns are growing into cities, where, for the most part, all our important edifices are erected.

One of the first things, then, is to learn something about the action of climate on stone, or "weathering," as it is called. We have sketched an outline of the more salient features of the action of air and rain on stone, but it is to be hoped that the practice the student must have to properly understand the subject will enable him to fill in this outline and more or less complete it. We have learned that it is an essential point to know the chemical composition of a stone, but we have also mentioned cases where this knowledge has been of little use. We must again urge that too much importance is not to be attached to the chemical composition of a stone, apart from other considerations. For instance, two rocks, which give almost precisely the same chemical composition, in every respect resemble one another in outward appearance, have both been laid properly, and under similar conditions, yet, as a matter of experience, have been found to weather very differently. A chemical analysis gives the aggregate composition of the stone, and we should thus know how much lime, or silica, or magnesia, &c., it contained, but it does not tell us how they are combined in any particular part of the stone, and we know that, as in the case of chalk and statuary marble, where the chemical composition might be identical, their resistance to weathering, respectively, is quite different. It is evident, therefore, that an insight into the structure of stones will place us on a better footing in guiding us as to their selection for building purposes. For this reason we shall appeal to the microscope to aid us.

Attempts have been made to produce artificially the action of rain and air on stone, as well as to estimate its purity. We may as well state at once that it is impossible to imitate in the laboratory the influence of climate in causing stones to decay, with any degree of accuracy. It is true that approximate results may be arrived at, which are exceedingly useful, but the element of time, which in all cases is necessary, cannot be successfully coped with.

Solutions of very weak hydrochloric or sulphuric acid have been made in which pieces of the stone under examination have been placed and left for several days. It is said that the action of these acids on the stone shows roughly whether it is capable of being durable or not in the atmosphere of a large town.

The purity of a limestone may be roughly estimated by chipping a piece off a block, and putting it in weak hydrochloric acid. If much impurity is present, it will be shown by an insoluble residue, which will remain behind. The acid may attack some of the impurities, but the proportion of non-calcareous matter so attacked is usually extremely small.

Mr. C. H. Smith proposed a test in which several damp pieces of the stone might be placed in a glass about one-third full of water. After a lapse of half an hour they should be agitated, and if the water then has a milky appearance, it shows that the stone is not thoroughly crystalline, but contains some earthy matter. If the water is very milky, it shows that the stone is not very durable.

* Geikie, "Text Book of Geol." (1862), p. 332.

ABSORPTION OF WATER BY STONE AND ITS DESTRUCTIVE EFFECTS.

The quantity of water a stone is capable of absorbing has material influence in determining its comparative durability.

All stones that have been examined contain interstitial or "quarry" water. It is not in chemical combination with the various minerals which constitute the rock, but is merely retained in their pores. A great deal of this water evaporates when the stone has been subjected to the influence of the atmosphere, and it is for this reason that stones used for building purposes should be well dried or "seasoned" before being made use of. If they be dried artificially it should be done very gradually indeed, for the heat will not penetrate to a sufficient depth to obtain the desired effect if the stone is too quickly heated.

Moreover, the heat when applied rapidly forms a cake or crust on the surface of the stone, which disintegrates when exposed for any length of time to the atmosphere, as will be seen later on. By far the most satisfactory and cheapest method is to let the atmosphere do the work, unaided by artificial heat. It is as well to somewhat protect the stones from the rain by putting them in an open shed.

A peculiarity connected with certain free-working limestones is that they become in some degree harder on their surfaces by exposure to the weather. This is said to arise from a slight decomposition taking place, which will remove most of the softer particles and leave the hardest and most durable to act as a protection to the remainder.

We find by experiment, exactly as might be inferred that the more water a stone absorbs the less durable it is; this must, therefore, be borne in mind when dealing with other considerations which affect its durability.

A simple method of finding how much water stones absorb is to dry them thoroughly, and then carefully weigh them with a spring balance. Then immerse the specimens in water for a day, after which they should be taken out and re-weighed. The additional weight shows the amount absorbed. This amount may be increased by exhausting the air from the specimens before immersion. When water freezes it expands, and in expanding produces a tremendous pressure on the material which contains it. To give examples of this: bomb-shells and cannon filled with water, and hermetically sealed, have been burst in strong frosts, by the expansion of the freezing water within them. In winter weather, as plumbers are well aware of, water-pipes are frequently burst, in a similar manner.

When a stone, therefore, contains much water, the water in freezing forces the particles composing it, asunder. Consequently, when a thaw comes, the particles having lost their original cohesion are easily removed from the stone, which thus rapidly decays. Experiments have shown that the more a rock is weathered the more water it absorbs. So that when a stone has commenced to decay it will increase in a greater proportion as the decay of the stone proceeds.

Many experiments have been made to imitate the action of frost on stone. The following is one which has been much used in this country.

Brard's Method.—The absorbent power of a stone, or the quantity of water absorbed on exposure of the surface to water, may be determined either with or without the use of the air-pump. On this absorption in some stones almost the whole weathering depends, while in the case of others it is but an indifferent guide.

In order to determine the real extent of damage resulting from absorption an ingenious method was contrived by a French engineer (M. Brard). The method is based on the idea that the expansion produced during the efflorescence of crystallisation of certain soluble salts on the evaporation of water from a saturated solution of such salts absorbed by the stone will resemble in its effects the expansion of the rain-water absorbed when the material is subjected to those changes of temperature, near the freezing point, to which much of the destruction of building material in our climate is generally owing. To determine the durability of a stone, therefore, a block is taken of convenient size (2-in. cubes are the most convenient) and boiled

* Guide to the Mus. of Franc. Geol. (1877), p. 38. † See further on this subject, Delessé, "Bull. Soc. Géol. France," 2me sér. xix. (1881-2), p. 65. ‡ Ansted, "Phys. Geog. and Geol." (Orr's Circ. of the Soc.), 1856, pp. 205-8.

for half an hour in a saturated solution of *Glauber's salts* (sulphate of soda), consisting of about a pound of salt to a quart of water. When taken out the clock is suspended by a thread over the vessel in which it was boiled, and within twenty-four hours it will be found to be covered with crystals. As soon as this is the case, it is dipped in the same water in which it was boiled, and the dipping must be repeated at intervals as often as the crystals appear during a period of four days. By each dipping the portions of stone forced out by the crystallisation will be left in the liquid; and at the conclusion of the experiment all the fragments of stone at the bottom of the water are collected and carefully weighed. It is considered that in the time mentioned (four days) the stone will have been so much disintegrated at and near the surface, by the forcing out and washing away of particles in consequence of the successive crystallisation of the salt, as to enable us to form an idea as to its relative durability. In the case of some limestones the quantity of stone lost may amount to as much as 20 grains, the original 2-inch cube in its dry state having weighed from 10 oz. to 12 oz. In other limestones the loss has not amounted to more than a tenth of a grain. The latter would be estimated to be ten times as durable as the former. In sandstones there is occasionally no result, and probably no very great dependence can be placed on the method, except in calcareous rocks, or at least in those which owe their compactness to a calcareous cement.

The late Mr. C. H. Smith showed that this process differs somewhat from the action of frost, because the crystallisation of *Glauber's salt* is unaccompanied by expansion, such as is produced by the freezing of water.

Another process of testing the action of frost is to freeze the specimens after moistening them with distilled water. This mode of experimenting is said to have the advantage over other processes in producing both the chemical and mechanical actions on the stone which naturally result from atmospheric humidity and a freezing temperature.*

Each cube subjected to freezing should be carefully weighed and enclosed in a thin metallic box, furnished with a suitable covering, and the whole series of boxes containing the specimens placed within a larger vessel of thin metal, which is surrounded by a freezing mixture. Care must, of course, be taken that all the particles detached from each cube by the freezing should remain in its own box. After about thirty repetitions of the freezing process, the specimens should be re-weighed to see how much they have suffered from the treatment.

Books.

Laxton's Builders' Price Book for 1886. Originally compiled by WILLIAM LAXTON Sixty-ninth Edition. London: Kelly & Co., and Simpkin, Marshall, & Co. 1886.

THIS work adds to its bulk every year, and the present edition has many additions to its predecessors. Many of the faults we found in the last edition remain unrectified; much of the excavator's work is low in price, and much of the bricklayer's high.

There is an item on page 22 of brickwork in half place and half stocks, and another of one-third place and two-thirds stocks; surely this word "place" is an error, and should be "grissels"; place bricks are not allowed to be used according to one of the clauses of the most recent of the Metropolitan Buildings Acts; they are miserably soft bricks, and certainly under no circumstances should be mixed with stocks, while grissels are reasonably well-burned.

Most of the prices remain unaltered from last year's edition; the day-work labour is low, as low as some of the prices are high. Wilkinson's pavings are varied in price, see page 69.

The later editions of this Price Book give many very useful memoranda for each trade, many explanatory notes, and much useful information, as to the methods of making cements, measuring work, &c., that former editions did not give; and each year adds to these notes, certainly the most complete and most useful ever given in any book of the kind.

* Dobson, "Rudiments of Masonry and Stonecutting," 1873, Appendix, p. 131.

In the *Plasterer*, page 79, the "labour only" (added in this edition) and the labour and materials, are set side by side; the price set down for ganging is high, while many of the prices for labour only are low for good work, this addition, though of prices for labour only, is a welcome one; but it should be stated, we think, to whom this list of "labour only" applies: are they the prices the builder should pay his workmen, or do they bear profits for the builder to receive?

In the *Carpenter*, page 103, fir timber, no labour, is given at 2s. 6d. per foot cube, while the next item of lintels, wood bricks, plates, and sleepers, is given at 2s. 8d., i.e., 2d. per foot cube for labour, cutting to sizes, and fixing (worth at least 4d., including profit), and the fir framed in floors is priced at a further increase of 2d. per foot cube, worth at least 3d. to 4d. as a low price. The roofs and partitions should not be classed together, the roofs are worth 2d. more than floors, and the partitions 2d. more than these; workmen will ask 10d. per foot cube for frame partitions, and then there is sawing waste, nails, and profit to add. Turning back to page 91 we find the prices given there for carcassing (i.e., for labour only in it) are 25s. to 30s. per load of 50 ft., this is 6½d. to 8½d. per foot cube,—not enough.

The notes on sanitary work and drainage are very full and explicit, and have several new traps, interceptors, &c., added, notably the "Kanon" and Bannor's Covers, for inspection shafts; and again, "ventilation" has its share of attention, and a very complete list of ventilators of almost every kind.

In the *Painter*, special paints are treated by a list of prices given for extra colours, the prices of the ordinary being set down at the same as common colours.

The book, however, in spite of some deficiencies, is a very full and useful one, and has evidently had a vast amount of labour spent on it to make it what it must be admitted to be, the best of its kind.

Precautions to be adopted on Introducing the Electric Light. By KILLINGWORTH HEDGES. London and New York: E. & F. N. Spon.

THESE appear to be strong grounds for the opinion that electric lighting is on the eve of considerable development in this country, as Mr. Mundella has stated his conviction that material modifications will have to be made in the Electric Lighting Act, 1882, which, though framed with the best intentions, has well-nigh strangled a new industry at its birth. If this development should take place on any large scale there is a risk that the work of carrying out installations may occasionally be placed in inexperienced hands, and the author of this little treatise has done well in republishing, with additions, the article which appeared in this journal six months ago (October 24, 1885, p. 569). Mr. Hedges points out clearly the risks that are inseparable from slovenly work and incompetent handling, and gives clear directions for carrying the main and branch conductors and the lamp wires, and for calculating the sizes of the various leads according to the number of lights to be worked. He insists very properly that some regular system should be followed, so that it should always be known which is the positive and which the negative wire,—in other words, which wire leads from the machine to the lamps, and which is the return. In addition, however, to showing this by mere position, i.e., by placing the positive wire on the left side of the negative if vertical, and under it if horizontal, we should strongly recommend that the insulating covering should be of different colours on the two wires, and thus any accidental displacement would not be of consequence. The author devotes considerable space to the subject of fusable cut-outs, an excellent form of which he has invented; but we rather doubt whether they would be quite so useful as he imagines in saving lamps, for, if too sensitive (that is, if fusable by a current slightly in excess of the normal current which the lamp is made for), the probability is that after a short time the cut-outs would fuse with less current, and the lamps would be unnecessarily extinguished. As to the main cut-outs, we quite agree with the author that 40 per cent. extra current is not too low a margin to provide for. Practical rules and instructions are given for working the dynamos, laying the wires, fixing the lamps, &c.; also the Phoenix Fire

Office Rules and the American Insurance Regulations, all of which are good and deserve careful attention. We cannot, however, congratulate Mr. Hedges on his clearness in some of the calculations which he gives. For instance, we are told, in connexion with the use of turbines for providing the motive-power for dynamos, that "from the following table the H.P., speed and quantity of water used by turbines working under various heads can be calculated." The table consists of columns of figures, of which the following is a specimen:—

Diam.	H.P.	Speed.	Gallons.
6	·0205	222	·35

and we think this about as perplexing a collection of figures as we ever saw, the fact being that these figures are simply constants by the use of which the desired information as to speed, &c., can be obtained by elaborate calculations. It is unfortunate that the proof sheets have not been more carefully revised, as there are a number of errors which might easily have been avoided. Where has the author ever seen a gas-burner that uses 500 cubic feet per hour?

Wages and Earnings of the Working Classes. Report to Sir Arthur Bass, M.P., by LEONZ LEVI, F.S.S., F.S.A. London: John Murray, 1885.

THIS book of 150 pages is so full of statistics that at first a person may be repelled from taking it up. But, in truth, statistics are often more eloquent and striking than many words, and the surest way to obtain a clear insight into the condition of our working classes is to peruse leisurely from time to time a few pages of this book. Any person of ordinary intelligence can then form his own conclusions. It is impossible to notice this book as if it were an ordinary piece of writing; it is only possible to extract some conclusions, and to recommend our readers to study it carefully. *Prima facie*, there can be no doubt that the working-classes are better off than they were twenty years ago: this is evident from the fact that they "are in receipt of 30 per cent. more in 1884 than they were receiving in 1857, or, in other words, that if the total weekly receipts of a family from all sources in 1857 amounted to 24s., now they reach at least 32s. a week." In addition, we have to bear in mind that every article of consumption except meat is now cheaper, and, indeed, when the statistics of this year come to be taken, it is not unlikely that meat will be found to have dropped considerably in price. Against an increase in wages, and a decrease in the price of necessities may be set an increased cost of locomotion and rent in our large towns, but not sufficient to counterbalance the advantages from wages or prices. It should be observed, however, that we have no statistics for the year 1885, and, therefore, it does not follow that Professor Levi's results are applicable to this present time. On the other hand, some fall in the rate of wages has certainly not brought them to anything like their former level, and it seems probable that had wages and prices been now as they were in 1857 the present distress would have been far more widespread and formidable than it is. Taking, for example, bricklayers' wages in Manchester, we find that in 1850 they were 26s. a week; in 1860, 30s.; in 1870, 32s.; in 1877, 43s. 1½d.; in 1883, 38s. 7d. These figures show that, even allowing for a drop at the present time, bricklayers in Manchester, at least, are better off now than they were in 1870, though not so flourishing as in 1877.

François Boucher. Par ANDRÉ MICHEL. Paris: J. Rouam, 1886.

THIS is one of a series of small books on "artistes célèbres," and forms a very good and interesting monograph on the gay, facile, and licentious painter who expressed so truly in his art the spirit of that thoughtless and corrupt French society which laughed and intrigued almost on the very verge of the Revolution. It is prefaced by a brief memoir and portrait, and illustrated by more than forty engravings giving many of the most characteristic and graceful of Boucher's designs, keeping clear of the class of work in which he pandered to the taste of the indolent which regarded the "good society" of the time, for whom he painted. The artist's history of the painter is given in considerable detail, and the critical remarks on his work are marked by excellent judgment and impartiality, doing justice to Boucher's real powers without condoning his faults, artistic and moral.

RECENT PATENTS.

8,251, Cupboard Turn. W. and W. G. Saville.

The spindle is square in section, and has a screw-cut on it. A nut is first screwed on, then the square, which is formed with a square shoulder, is passed on, and, finally, a lock-nut is screwed on.

15,805, Ventilators. G. S. Buchanan.

A series of cylindrical or slightly conical concentric tubes, with expanded mouths, are arranged above a gas pendant. The outer tubes being of finished length, and the whole terminating in a conical opening, communicating with the exhaustive. A spirally-coiled sheet of metal may be used in place of the concentric tubes if desired.

15,857, Surfacing Compound. A. Hoxter (varia).

A planed or planished surface of wood, metal, or other material is coated with a composition of boiled seed oil, a sicative, and oil of turpentine. After drying, the surface is gone over with a filling material, varnish, &c. The surface may be polished or it has hardened.

16,023, Sanitary Trap. T. Durran.

A dip-tube is screwed into the body of the trap, the joint being made air-tight by the seating of an lined flange on the top of the tube. The pipe is fixed internally in the form of a spiral to give the waste water a rotary motion for the purpose of making the trap self-cleansing. The outlet has a hinged-piece, upon which a check valve is seated to prevent the back-flow of sewer-gas.

6,792, Slating Roofs. G. Ross.

The slates are laid as in open bond slating, but with all slates reduced into the spaces occurring in a bond under the points of the larger slates. Nails by which the slates are fixed may be made to pass through a notch in the heads of one in the course below, and thus prevent the error from shifting sideways. The alternate courses are, according to another method, laid as in close bond, and the remaining courses in open bond, making the slates fill the open spaces. These smaller slates may be of different colour or variously shaped, and are thus utilised for the purpose of ornamentation.

6,821, Sash-bar Cramp. Herbert & Colley.

A screw working in a hole through one end of an angled or other shaped frame of a sash or window-piece, which is guided by the sides of the hole.

By S. R. BENT. Tottenham Court-road—No. 192, term 10 years, ground-rent 75l. 420. Camden Town—14 and 95, Camden-square, 64 years, ground-rent 8l. 570. Harlesden—3, Park-road, 90 years, ground-rent 8l. 6s. 600.

MARCH 19. By W. & F. HORTON. Haverstock Hill—Freehold Ground-rents of 32l. per annum, reversion in 66 years 685.

By H. STAINES. St. George's East—33 to 39 odd, Cornwall-street, 6 years, ground-rent 8l. 10s. 145. Cambridge Heath—An Improved Rental of 39l. per annum, term 17 years 340.

MEETINGS.

FRIDAY, MARCH 27. Architectural Association.—Visit to the Royal Courts of Justice. Members to assemble in the Great Hall at 3 p.m. Edinburgh Architectural Association.—Visit to Niddrie Marshes. Monday, March 29. Royal Institute of British Architects.—Business Meeting. 8 p.m. Estate Exchange.—Annual Meeting of Members. 3 p.m. Society of Arts (Contor Lecture).—Mr. Bouverton Redwood on "Petroleum and its Products." IV. 8 p.m. Liverpool Architectural Society.—Mr. B. B. Preston on "The Ancient University and City of St. Andrews." 7 p.m.

THURSDAY, APRIL 2. Society of Arts (Indian Section).—Mr. James Gibbs, C.S.I., on "The History of Archæology in India." 8 p.m. Junior Engineering Society.—Mr. G. F. Harris, F.G.S., on "The Relation of Geology to Engineering." 7 45 p.m. SATURDAY, APRIL 3. Association of Public Sanitary Inspectors.—Dr. Alfred Carpenter on "Sanitary Legislation." 6 p.m. Society of Arts (Special Lecture).—Professor George Forbes on "Electricity." 3 p.m.

WEDNESDAY, MARCH 31. Carpenters' Hall, London Wall.—Mr. James Doulton on "Terra Cotta." 8 p.m. Builders' Foremen and Clerks of Works' Institution.—Quarterly Meeting of Directors. 8 30 p.m.

THURSDAY, APRIL 1. Purkes Museum of Hygiene.—Dr. Louis Parkes on "London Ventries, and the Administration of Sanitary Law in the Metropolis." 8 p.m. Society of Antiquaries.—8 30 p.m. Royal Archaeological Institute.—4 p.m. Edinburgh Architectural Association.—Mr. H. M. Wardrop on "Architectural Sculpture." 8 30 p.m.

FRIDAY, APRIL 2. Society of Arts (Indian Section).—Mr. James Gibbs, C.S.I., on "The History of Archæology in India." 8 p.m. Junior Engineering Society.—Mr. G. F. Harris, F.G.S., on "The Relation of Geology to Engineering." 7 45 p.m. SATURDAY, APRIL 3. Association of Public Sanitary Inspectors.—Dr. Alfred Carpenter on "Sanitary Legislation." 6 p.m. Society of Arts (Special Lecture).—Professor George Forbes on "Electricity." 3 p.m.

Miscellaneous.

The Proposed Bridge at Teddington.—A Local Government Board Inquiry was opened in the Assembly Rooms, Teddington, on Saturday week last, by Major-General De Courcy, in reference to the application of the Teddington Local Board for sanction to borrow the sum of 1,500l. towards the construction of a foot-bridge across the Thames at Teddington. Mr. Walton, instructed by Mr. Prall, appeared on behalf of the Board; and Mr. Cohen represented a number of ratepayers, who objected to the construction of the foot-bridge. Mr. Walton urged the need for the bridge, which would open up communication between the two sides of the river at that point, and increase the attractiveness of a wide district. The Local Government Board had received memorials from 6,000 inhabitants in favour of the bridge, and many persons had promised to contribute liberally to the cost of it. Some of the materials of the old bridge at Hammer-smith would be utilised in the construction of the proposed bridge. The Thames Conservancy approved of the scheme. The loan was only to defray the cost of the portion of the bridge which would be in the parish of Teddington. The plans had been prepared by Mr. George Pooley, and a contract had been provisionally entered into with Messrs. Dixon to construct the bridge at a cost of 2,000l. Evidence in favour of the proposal having been called, the inquiry was adjourned till Tuesday last, when Mr. Cohen called Mr. Arthur Payne, who gave evidence in opposition to the bridge, which he stated would bring no place but Ham nearer Teddington. He had examined the agreements, and he believed that if the bridge were swept away the Local Board would be liable for all damages. The foundations were to be only 4ft. below the bed of the river; but he should not like to erect the bridge on the proposed site without a foundation 20 ft. below the bed of the river. He thought there was a risk in having the bridge only 13 ft. high, as proposed; and that a heavily-laden barge coming in contact with the lattice-work of the bridge would damage it considerably. In fact, if the bridge were constructed according to the proposed plans, great risk would be run. It was not a fact that London clay was exceptionally free from any susceptibility to scouring. Old Westminster and Blackfriars Bridges were instances of failure in the construction, owing to scouring. If piles were driven down near the lattice-work it would prevent damage being done by the debris brought down by a flood; it would also withstand the scouring. The inquiry was resumed on a subsequent day, when the evidence in opposition of the scheme was concluded. The report of the Local Government Board on the application for the loan will be issued in due course.

Bartholdi's Statue of Liberty in America.—For some time past the enormous pedestal on which M. Bartholdi's statue of "Liberty Enlightening the World" is to be placed has been in process of preparation, and, according to contract, will be completed on the 1st of April. The American Government proposes, however, to defer the official inauguration of the monument until the 3rd of September next, being the anniversary of the day of the signature of the treaty which established the independence of the United States.

Old Glasgow.—Messrs. David Bryer & Sons announce the forthcoming publication of a set of sketches of "Quaint Bits still existing in Glasgow," drawn by Mr. David Small, with descriptive letter-press by Mr. A. H. Millar, F.S.A.

The Metropolitan Board and the Sewage Question.—Commenting on the proposals of the Metropolitan Board for dealing with the Metropolitan sewage (for which see last week's *Builder*, pp. 457-8), the *Lancet* says:—"As to the disposal of the effluent we quite agree that it must be disinfected somehow before it goes into the river. At present the sewage must be treated at the existing outfalls, for the danger of the present system is urgent, and some chemical disinfectant must, therefore, be used. Whether permanganic acid is the best we cannot say, possibly it is. But, although it is inapplicable at Barking and Crossness, land irrigation is a better means of purifying sewage-effluent than any chemical disinfection; and, when the sewage goes down to Sea Reach, as we trust it will before many years are past, the final purification will probably be done by the soil, and an almost perfectly pure effluent thrown into the river. The committee are, indeed, so enamoured of their permanganate disinfection that they have quite given up the idea of moving from their present outfalls. They say, on the authority of the chemists who advise them, that 'the necessity for land filtration no longer exists, and thus the great objection to the treatment of the sewage and the discharge of the effluent at the present outfalls is overcome.' To this we most strongly demur. We are more than ever convinced that the sewage of all London ought not, even after chemical treatment, to be thrown into the river at Barking and Crossness; and we decline to receive on this point the assurance of certainty from chemists who, three years ago, were equally sure that no important injury was done to the river by the raw sewage. We are sorry that the Board persists in this obstinate resistance to the recommendations of the Royal Commission. They have been forced into their present action, after a hard fight, by the pressure of scientific and public opinion, and now, instead of giving in gracefully and obeying the wish of the nation, they contest every inch of ground in their retreat."

The Free Lectures to Artisans at Carpenters' Hall.—We print on another page the conclusion of Mr. John Slater's admirable lecture on concrete, of which we published the first portion last week. On Wednesday evening last the sixth lecture of the course was given, when Mr. H. H. Statham treated of "The Fine Art Aspect of Woodwork." We will give a report of this lecture in our next.

Buildings in Countries liable to Earthquakes.—*Nature* gives a brief account of a paper read by Professor Milne at the last meeting of the Seismological Society of Tokio, describing the results obtained from a seismic survey of the ground in the neighbourhood of his house. Some experiments were also made with a view to discover the best method of constructing buildings which would stand earthquake shocks with least damage. The practical conclusion of the investigation was that there were three ways by which residents could escape from very much of the motion which disturbs an ordinary building. These were (1) by a seismic survey they might select a site where there was relatively little motion; (2) they might build up from the bottom of a pit, which might be utilised as a cellar, the walls of the houses not touching the sides of the pit; (3) when obliged to build on soft ground, when a pit could be excavated, a light one-storied building of wood or iron might be rested on a layer of cast-iron shot.

Art Needlework.—A paper by Miss Higgin, for long well known in connexion with the Royal School of Art Needlework, on "The Revival of Decorative Needlework," will be a leading feature in the *Art Journal* for April. The paper will be illustrated with designs for embroidery by Walter Crane, Wm. Morris, Geo. Aitchison, A.R.A., Selwyn Image, and Mrs. Wardle, of Leek.

Petroleum.—We are asked to mention that the representative collection of specimens and apparatus used in illustrating the Cantor lectures on "Petroleum and its Products," which are now in course of delivery at the Society of Arts, in the Adelphi, by Mr. Boverton Redwood, will remain open to inspection in the Society rooms during the ensuing fortnight. After Monday next the collection will include all the principal forms of oil lamps and stoves for burning this mineral oil. Any person interested in petroleum manufacture can obtain admission by applying to the Secretary of the Society of Arts.

The New Buildings around Spitalfields Market.—A large number of new buildings, containing shops, with residences above, are at present in course of erection at Spitalfields Market, which is intended to be entirely surrounded by buildings of this character, erected at the cost of the lessee of the market. The buildings, when completed, will have frontages to Commercial-street, Brushfield-street, and Lamb-street, each about 300 ft. long. The most advanced portions of the buildings are those in progress in Lamb-street. The whole of the property on the west side of that street from Crispin-street to Commercial-street, will be cleared away for the new market buildings. Altogether, when finished, there will be nearly one hundred of these shops and houses, all of which are intended to be occupied for market purposes in connexion of the area of the market proper, which they enclose. The buildings, which throughout will be uniform in their external architectural appearance, contain three stories above the ground-floor, in addition to a basement. The shop portions on the ground-floor are faced with red and blue glazed brick piers, and the upper floors with red brick, the first and second floors containing bay windows. The elevations are surmounted by gables faced with cement, enclosing the attic or dormer floor. There are iron balconies at the foot of the first and second floors. There will be spacious approaches to the interior of the market proper from each of the three street frontages. Mr. Sherrin, of Finsbury-square, is the architect; and Messrs. Harris & Wardrop, of Limehouse, are the contractors. Mr. D. Macdonald is foreman of the works.

The Teak Forests of Upper Burma.—An agitation is being stirred up in various quarters against the monopoly which the Bombay-Burma Trading Company is supposed to enjoy in regard to the teak forests in Upper Burma. The Allahabad paper, for instance, has lost no opportunity of raising its voice against the conditions at present governing the exportation of timber from the Upper to the Lower Province, and now we find that the "Moulmein community" is preparing a memorial to the Viceroy urging that forest leases should be cancelled, and that the forests should be worked directly by Government. The attitude of Moulmein is intelligible enough. It is itself the centre of a large teak district, and any narrowing of the limits of competition would, of course, be to its interests. Any restriction of the kind contemplated by the Moulmein community, however, would have the immediate effect of inordinately running up the price of teak, and driving people to employ iron where wood now is used. It has also been a frequent complaint at Moulmein that the Bombay-Burma Trading Company has made it a practice to export under-sized timber. On the contrary, we think it may safely be said that the company has consistently opposed the denudation of the forests. If the company held a short lease, say for four or five years, there might be some inducement to cut down trees indiscriminately; but when the terms of the lease gave it possession for forty or fifty years, it would be a sheer disregard of its best interests to export under-sized timber.—*Bombay Gazette.*

Clocks.—A large church clock has just been erected at Tichmarsh, Northants, by Messrs. John Smith & Sons, of Derby. It strikes the hours and chimes the Cambridge quarters. It is fitted with all modern improvements, and the wheels are machine-cut so as to be perfectly accurate and smooth. The same firm have also just completed a large clock at West Bromwich, which strikes the hours, and shows time upon four large dials, which are illuminated at night. Automatic apparatus is provided for turning the gas up and down.

Works in Dublin.—The *Freeman's Journal* reports that, in anticipation of the payment of the first instalment of a Government loan of 100,000*l.*, extensive paving works have been commenced in the city. A large water-main is about to be laid along the South Circular-road, with a view to increase the water supply in the south-western districts of the metropolis. The Corporation has just agreed to a contract with Messrs. Hammond for the erection of a block of artisans' dwellings at Barnack-street and Tighe-street, for a sum of 9,000*l.* It is probable that the City Engineer will shortly set about the completion of the new street from Blackhall-place to Barrack-street.

Plymouth.—An addition of great decorative importance has been made to the interior of St. Peter's Church, Plymouth. There are three lancet lights over the sanctuary arch, which, from necessity, were originally filled with plain cathedral glass. These lancet lights have now been filled with very rich glass, almost mosaic in character. The general design has been carefully and thoroughly carried out by the well-known artists in stained glass, Messrs. Clayton & Bell, of Regent-street, London. The central light represents the opening of the Books as described in the Revelations. The highest portion of the window portrays the throned Deity under a rich canopy; in the centre is St. Michael with drawn sword; and angels in kneeling posture, with trumpets, fill up the lower part. In the heads of the side lights are the two supporting angels of Justice, and the remaining portion is occupied by the twelve apostles, each holding an emblem, sitting on thrones as assessors. The windows have been given in memory of the late Mr. Thomas Merrill Vicary, who was the vicar's churchwarden for no less than thirty-six years. The central light was given by Mrs. Vicary, and the two side-lights by numerous friends. The plaster space between the sanctuary arch and the sills of the window seems now to call more loudly for mural decoration, and a design for this has been made by Mr. E. A. Fellowes Frynne, the subject being the Church Triumphant.—The chapel of the Plymouth, Devonport, and Stonehouse Cemetery has just received a three-light Munich stained-glass window representing the Raising of Lazarus. The work has been designed and carried out by Messrs. Mayer & Co., of Munich and London.

Wellingborough Church Steeple.—The *Northampton Herald* reports that a few days ago Mr. J. T. Parker, one of the churchwardens of Wellingborough, communicated with the firm of Wright & Parker, of Oldham, who are doing some work near Finedon in connexion with the Glendon ironworks chimney, and that subsequently one of the men employed by the firm made the ascent to the weather-cock by means of a series of ladders placed on the west side of the steeple. They were expeditiously fixed one above another by means of hooks, blocks, and ropes, the whole process not occupying more than a couple of hours. The man found the top of the southern pinnacle to be loose. The height of the spire is 105 ft., and it is hexagonal in form. In 1844 it was found necessary to take off the top of the spire in consequence of its dilapidated state. It had been braced with iron at some earlier date, but the stone had fallen away and the top became dangerous. The work was entrusted to Mr. John Herberth, of Ramdys, who had done similar work at Ramdys and other churches, and he took the top of the spire off several yards down, and replaced it with its present top.

The London Hydraulic Power Company.—We are informed that Mr. J. Stannah is constructing hydraulic machinery, to be worked by the above power, for Messrs. Grosvenor & Chater, of 68, Cannon-street; Messrs. W. & J. R. Hunter, of 56, Moorgate-street; and Messrs. Crowden & Garrod, of 62, Southwark-street. For lifting purposes the use of the above power is rapidly extending.

CONTRACTS AND PUBLIC APPOINTMENTS.

Epitoms of Advertisements in this Number.

Table of Contracts and Public Appointments with columns: Nature of Work, By whom required, Architect, Surveyor, or Engineer, Tenders to be delivered, Page.

Table of Public Appointments with columns: Nature of Appointment, By whom Advertised, Salary, Applications to be in, Page.

TENDERS.

Table of Tenders for various construction projects including Bromley (Kent), Durham, Goring (Oxon), and Lwiche.

GREAT CLACTON (near Colchester). For residence and stables. Mr. Alfred Broad, architect, Croydou.

HEMEL HEMPSTEAD. For the erection of new slaughter-house and stabling, for Mr. John Youngman, Lower Marlowes, Hemel Hempstead.

HENDON. For erecting a pair of semi-detached villas in Finchley-lane, Hendon. Mr. William Ranger, architect, Finchbury-pavement.

HEREFORD. For alterations, &c., at the Imperial Tavern, Hereford, for Messrs. Watkins & Son, Mr. W. W. Robinson, architect, King-street, Hereford.

ISLINGTON. For new warehouse, shop-front alterations, &c., at Nos. 379 and 381, Hornsey-road, Islington, for Mr. H. J. Kimbell, Mr. John E. Sears, architect.

LEATHERHEAD. For new house and warehouses, for Mr. G. Hutchinson, corn merchant, &c., Mr. W. G. Shearburn, architect, Dorking.

LONDON. For the erection and completion of new factory, arrangements, at No. 11, Upper Brook-street.

LONDON. For rebuilding premises, No. 33, Friday-street, corner of Queen Victoria-street, E.C., for Mr. Abraham Barnett, Mr. Banister Fletcher, M.P., architect.

LONDON.—For the erection of workshops in rear of No. 195, Green-street, Bethnal Green, E., for Mr. Thompson. Mr. C. E. Jackson, architect:—

Willing	£450 0 0
Edwards	318 0 0
Ames	287 0 0
Malevald	248 0 0
Brooks	230 0 0
Everard	216 0 0
Consell Bros. (accepted)	208 0 0

LONDON.—For rebuilding No. 1, Broad-street (corner of Berwick-street), Golden-square, for Mr. W. Bender. Messrs. Burden & Milnes, architects:—

Jerrard	£1,876 0 0
Brand & Gould	1,797 0 0
Scrivener & Co. (accepted)	1,769 0 0

LONDON.—For alterations and repairs at 30 and 31, Beech-street, Barbican. Mr. Delissa Joseph, architect:—

T. Fryer, Kingsland	£380 0 0
Holmes & Belcham	264 0 0
W. Heath (accepted)	257 0 0

LONDON.—For alterations at Nos. 229 and 232, Camden-road, for Mr. E. Barras. Mr. C. E. Collins, architect:—

Dearing & Son (accepted)	£260 0 0
--------------------------------	----------

LONDON.—For repairs and alterations to No. 44, Baker-street, for Mr. H. Bingley. Mr. G. Jackson, surveyor:—

Smith	£455 13 8
Wall	424 0 0
Brass	291 0 0
Leyermann	269 0 0

LONDON.—For building residential chambers and shops at No. 23, Panton-street and No. 26, Oxendon-street, W. Mr. T. Milbourn, architect. Quantities supplied:—

J. O. Richardson, Peckham (accepted)	£3,979 0 0
--	------------

LONDON.—For building warehouses at No. 24, Heron-street, Walworth, S.E., for Messrs. Creighton, Mitchell, & Co. Mr. Banister Fletcher, M.P., architect:—

E. G. Greenwood (accepted)	£290 0 0
----------------------------------	----------

LUTON.—For new residence, warehouse, &c. for Messrs. Oakley Bros. Mr. W. J. Pearson, architect. Quantities not supplied:—

R. Ford	£295 0 0
D. Dunham & Son	888 0 0
Slough Bros.	873 0 0
D. Parkins	838 0 0
C. Wright	824 0 0
Smart Bros.	800 0 0
J. Spinfeld	790 0 0
Nyville Bros.	764 0 0
Cox Bros.	749 0 0
J. Saunders (accepted)	668 0 0

LUTON.—For villa-residence, Dunstable-road, for Mr. E. Deacon. Mr. W. J. Pearson, architect. Quantities not supplied:—

D. Parkins	£1,659 0 0
D. Dunham & Son	1,498 0 0
Smart Bros.	1,475 0 0
Nyville Bros.	1,460 0 0
Slough Bros.	1,391 0 0
A. Lissman	1,385 0 0
Cox Bros. (accepted)	1,240 0 0

MARTOCK (Somerset).—For Ham Hill stone for the Wesleyan Chapel, Martock:—

C. Trask & Sons	£473 0 0
J. Trask & Co.	404 0 0
S. & J. Staple (accepted)	365 0 0

PADDINGTON.—For rebuilding the Masons' Arms, Harrow-road. Messrs. Raymond & Webbe, architects. Quantities by Messrs. Bairstone Bros.:—

Oldray	£2,220 0 0
Green	2,099 0 0
Saley & Son	1,998 0 0
Hitchin	1,987 0 0
Walker	1,893 0 0

RICHMOND (Surrey).—For ironfounder's work. Mr. Walter Brooks, Assoc.-Mem. Inst. C.E., Town Surveyor:—

Franklin & Son, Richmond	15 per cent. off.
J. & G. Peirce, Richmond	25 " "
R. H. & J. Pearson, Notting-hill	25 " "
F. Bird & Co., 11, Gt. Castle-street, Regent-street	27 1/2 " "
Reynolds & Co., Richmond	32 1/2 " "

RICHMOND (Surrey).—For ironmongery. Mr. Walter Brooks, Assoc.-Mem. Inst. C.E., Town Surveyor:—

R. H. & J. Pearson, Notting-hill	62 1/2 to 10 per cent. off schedule prices.
Reynolds & Co., Richmond	32 " "
J. & G. Peirce, Richmond	25 " "
Bird & Co., Regent-street, London	27 1/2 " "
Franklin & Sons, Richmond	12 " "

TENDRING (near Colchester).—For alterations and additions to the Live and Let Live, for Messrs. T. Daniell & Sons, West Bergholt (proprietor finding all bricks and tiles). Mr. J. W. Sturt, architect, Colchester:—

Hazel, Benninghams	£284 0 0
Fade, Kirby Cross	255 0 0
Wilkinson, Clacton-on-Sea (accepted)	237 0 0

WALLINGFORD.—For erecting St. Leonard's rectory-house, Wallingford. Mr. A. J. Style, architect, Westminster-chambers. Quantities by Mr. E. Dudley, 19, Queen Anne's Gate:—

Holly & Butler	£2,035 0 0
Silver & Son	1,893 0 0
Symm & Co.	1,877 0 0
A. D. Add	1,777 0 0
Brasher & Son	1,731 5 0
G. Cooper & Co.	1,725 10 0
S. Elliott	1,672 0 0
Bush	1,641 0 0
Higgs & Son	1,650 0 0

WALLINGFORD.—For erecting St. Leonard's rectory-house, Wallingford. Mr. A. J. Style, architect, Westminster-chambers. Quantities by Mr. E. Dudley, 19, Queen Anne's Gate:—

Holly & Butler	£2,035 0 0
Silver & Son	1,893 0 0
Symm & Co.	1,877 0 0
A. D. Add	1,777 0 0
Brasher & Son	1,731 5 0

Layer Marney Towers, Essex.

AYER MARNEY HALL is, perhaps, as good an example as exists of the English mansion at the time when it was passing from the castellated to the domestic stage.

It seems to possess a little of the fortified manor-house, and yet retains the leading idea of a great gateway and flanking towers so usual in buildings of the preceding reigns. Layer Marney, however, is so perfect as Oxburgh in Norfolk, which is a little earlier in date and is the finest example of its date we have left. The contrast between the two is noteworthy, and deserves careful attention, as illustrating the advance which had been made to meet the growing needs of the time. The general plan of Oxburgh exhibits much the same arrangement as Layer Marney, and has the advantage of being complete, or nearly so. The great gate tower gives access to the quadrangle, measuring 118 ft. by 80 ft., round which the principal rooms are grouped. The south side was pulled down in 1588, and this portion included the great hall. Fortunately, we have a hall of much the same description at Hengrave, in Suffolk, and so are enabled to form a correct judgment of the whole. The entrance gateway is flanked by octagonal turrets, rising to a height of 80 ft. out of the moat, somewhat similar in design to those at Layer Marney, but with a difference, which should be noted, that in the latter all the eight stories, including the ground-floor, are pierced with windows in each of the octagon, but at Oxburgh the light is admitted by loopholes only on the ground-floor; and in one of the towers this treatment is continued for the whole height. The arch has been further strengthened by a bridge over the moat already referred to, this important means of defence is absent at Layer Marney. Nor is it likely that a better ever existed here, for there is no trace of such an arrangement, and the nature of the ground is such that it would have been almost impossible to construct one. One point of resemblance between the two buildings is that observed, and that is, that the windows in the great rooms over the entrance court, command a view over the courtyard, besides looking inwards to the court. This was gradually becoming a common practice, but is never to be found in the earlier castles, where the large windows only looked into the internal quadrangle, and is an indication of the lateness of the work. The

unmachicolated parapet over the entrance at Oxburgh is a feature wanting at Layer Marney, and its absence serves as a good example of the manner in which the builders were gradually freeing themselves from old customs which had no longer any useful purpose.

Layer Marney Hall takes its name from the ancient family of Marney, or, as spelled variously in old manuscripts Mareny, Marigni, Marny, Marigny, and Marini. The last seems to be the most ancient, for Hugo de Marini had the Prebend of Totenhall in the Church of St. Paul's, London, and was Dean of that church from about 1160 to 1181. Dugdale, in his Baronage, says:—"The first mention I find of the family is in 2 E. III, but a further mention beside that already stated occurs; for under Richard I. Werry de Marinis was excused by a writ from paying scutage." There are several other notices of the family; as, for instance, William de Mareny had to pay a fine of twenty marks to King Henry III. for having married a lady who was the king's ward. Another entry states that "William de Mariny, by payment of x libr., obtained licenses for granting to a laic a tenure in Leirmarney, with the advowson of the church there." This was temp. Ed. III. In Burke's "Roll of Battle Abbey," the name of Marny is stated to be one of those who came over with William the Conqueror, but Domesday Book says nothing about any grant of lands at Layer Marney or elsewhere, at the general distribution; but it is known that in the year 1166 William de Marney held a knight's fee under Henry de Essex. In all probability the family came over soon after the Conquest, and received a grant of lands; for the king would naturally be anxious to surround himself with foreign friends in order to strengthen his authority.

The member of the Marney family with whose name the present building is associated is Henry, the first Lord Marney, of whose life the Essex Archaeological Society (Vol. iii., "Proceedings") has published the following interesting particulars:—"Lord Henry Marney, numerous and splendid as were the honours which he acquired, started in life as plain Henry Marney, Esquire, and belonged to a class described by Henry VIII. as 'scant well-horne gentlemen, of no great lands.' He inherited the paternal property, but this, probably, in the king's eyes was 'scant' compared with the large holdings of some noblemen in those days, and with the noble domains and large acres afterwards conferred on Henry Marney by the king himself, on the Duke of Buckingham's forfeiture. Henry Marney stands recorded amongst 'English Worthies' and amongst the 'Noted Sheriffs' of Essex, but his first entrance on the path of court

advancement appears to have been when he assumed some office in the household of Margaret, Countess of Richmond, mother of Henry VII. That he discharged with credit the duties of his office is apparent from the fact that the Countess appointed him one of her executors, and the early partiality with which he was viewed by Prince Henry, afterwards Henry VIII., is evinced by the youth's request to his father, Henry VII., that Henry Marney might be made a Privy Councillor. The appointment was repeated by Henry VIII. himself when he succeeded to the throne; and both before and after the favourite was employed by his patron on various confidential services. The following is a list of honours and appointments conferred on Henry Marney:—

1. Previous to the accession of Henry VIII.—Sheriff of Essex; Chancellor of the Duchy of Lancaster; Officer of the Countess of Richmond's household; Privy Councillor to Henry VII.

2. After the accession of Henry VIII.—Privy Councillor to Henry VIII. (a distinct appointment); Knight of the Garter; Lord Privy Seal; Captain of the Body Guard; Baron, by title of Lord Marney.

Henry Marney served frequently as a soldier in the civil contests under Henry VII. Under Henry VIII. he served repeatedly in France, especially in the campaign including the "Battle of the Spurs," in which the king was present in person. He seems to have had a glorious quarrel with Cardinal Wolsey. This was before he was made a Baron. One would like to know how he contrived to survive the Cardinal's wrath in those ticklish times, and to win the peerage in spite of hostile influences.

Lloyd, in his "State Worthies," says:—"Sir Henry Marney was one of young Henry's first Council, who loved his person well, and his prosperity better; and impartially advised him for his good, and modestly contested with him against his harm; that council that was hand as well as head, and could perform as well as advise; this was the searching judgment that discovered Buonviso, the Lucchese, his letters to the French king betraying our designs as soon as thought on, and instructing him for prevention before our king was ready for the attempt. Industry and thrift overrules princes; this personage has no time to transcribe intelligence, but what he borrowed from his sleep; nor money to buy it, but what he saved out of his allowance; yet he understood more than any one prince of Europe, and was more consulted than any one statesman. His judgment was solidly safe, rather than that which was superficially plausible; as one who was a stranger to the wisdom of the latter age (as Sir Francis Bacon describ-

it), which is rather fine deliveries and shifts from inconveniences than solid and grounded courses for advantage. His foresight was large, and his spirit larger; he considered all circumstances that occurred to him; judged what he considered, and spoke what he judged, with that resolution as to his opinion, that argued he understood the matter in question, with that modesty to his superiors that showed he understood himself. He would say that he that could not with the cam-leon change colour with the air he lived in, must with the cam-leon live only upon air."

Such was Lord Henry Marney, a man in high Court favour, yet with none of the meannesses commonly incidental to Court life; learned, even amongst his contemporaries, which included such names as Wolsey, Erasmus, and Michelangelo. Can it be a matter of surprise that, living as he did, in an age of the revival of literature and art, he should endeavour to erect a building which should remain a monument to his greatness and an example of the splendour of the times?

A reference to the plan will at once suggest the leading idea on which the building was arranged. The principal courtyard was entered under the great gate tower, which still stands, and this formed the means of access to the chief apartments, which were grouped around it. Of these only the south-western wing remains, with a few fragments of walls and foundations, just sufficient to indicate the site once occupied by the whole. The secondary courtyard is more perfect, standing in very much the same state as when first erected. The north and south sides are long, low buildings of brick, in good preservation. The eastern end is occupied by the great barn; while the remaining side is entirely open, and presents no appearance of ever having been intended to be enclosed. The third and last feature in the general grouping is the church, which certainly ought not to be omitted in a description of the Towers, for it almost seems to form a part of the buildings themselves. Not only is the greater portion of the work of the same date; but the history of the church is so interwoven with the history of the Towers that a description of the one necessarily involves constant reference to the other. Take, for instance, the north aisle, which consists entirely of the Marney Chapel, begun by Henry, first Lord Marney, and continued by John, his son. This contains the elaborate and beautiful tombs which they had directed in their wills should be erected to their memory. To these further reference will be made. The north-eastern corner of this chapel is indicated on the general site plan.

The magnificent gate-house claims primary notice. (See lithographic illustration.) It rises to a height of about 70 ft. from the ground, and forms an imposing object when viewed from the south where the country is open. Standing on a slight eminence, it commands a fine view over the estuary of the Blackwater and the surrounding country, while on the horizon the sea may be plainly distinguished. This gatehouse consists, as will be seen from the drawings, of a central block of three stories in height, flanked on either side by two octagonal towers on the south, and two square turrets on the north, each divided up into eight stories. In the principal front, which faces south, each of these floors is lighted by windows in three faces of the octagon. These towers are again flanked by smaller semi-octagonal turrets some 7 ft. less in height than the principal ones, but the use to which these were put is not quite clear, though it is not unlikely that they were merely added for ornamental purposes in order to give more breadth and apparent solidity. The great four-centred archway on the ground-floor gave access to the courtyard within, and over this are the two principal rooms, lighted both back and front by large five-light windows with transoms. In the north-western turret is a fine wooden newel staircase, from which all the rooms are approached. On the first principal landing of this staircase is a door of communication with the only perfect part of the courtyard buildings still remaining. Here it may be well to state the

results of a careful examination as to how much of the building was really completed in accordance with the original scheme. Various opinions have been expressed on this point, some contending that the whole building was finished, and has since fallen into decay and ruin, leaving but few remains behind; others hold that the building was never completed except that portion which still stands, and that this is in the state finally intended by its designers, and, in support of their argument, point to the toothings which are evidently as first built. The foundations and fragments that are to be found scattered about the site, they attribute to a former building. A third theory is that these scattered fragments are remains of Lord Marney's work, but that the building was never very far advanced, either because of want of funds, or owing to the owner's absence abroad; hence, what little had been done disappeared in the course of a few years, leaving the hock now existing, because that was the only portion which had been finished. This last opinion seems to be much nearer the truth than the former ones, but even this does not appear to be the whole truth. There can be no doubt whatever that a previous manor-house stood upon the site, as many references are made to it and to its owners, but no fragments of any kind of this building are left. The whole of the remains

alone has to be dealt with. An examination of this elevation and a comparison with the adjoining tower will certainly suggest the idea of its being unfinished. The mean-looking eaves gutter over the terra-cotta mullioned windows, and the poor lath-and-plastered gable, as a finish to the solid brick walling and elaborate work of the lower floors, bear no resemblance to the rich parapet and cornice of the gate-house. Either the work was intended to be finished the same height as at present, or another story was to be added. The former can hardly have been the case, for all the materials were at hand ready for completion; the terra-cotta moulds had been made and the work simply required casting. That the same moulds would have been used is extremely probable, for the windows, which are terra-cotta, are similar throughout. Is the idea, therefore, of another story being part of the original design tenable? As has been already mentioned, there is communication from the staircase in the south-western turret, with the dwelling-house on the first floor, and there is evidently a hocked-up doorway on the ground level. On the second floor a recess is found to occur in the west wall of the landing of this staircase, and an examination of the external wall clearly shows that a doorway had been intended on this floor also, but had, like that on the ground-floor, been hocked up. Of

Block Plan of Layer Marney.

discovered are of brick, but of bricks precisely the same in material, colour, size, and method of laying as the still perfect portions of the towers. It must be remembered also that the art of brickwork had only in recent times been re-introduced into this country. From the time of the Romans it was but seldom used, and even when this was the case, it was only in small quantities. One of the earliest, if not quite the earliest, specimens of the revival of this method of building of any considerable extent is at Caister Hall, in Norfolk, the date being about 1420, only some eighty years previously to the erection of Layer Marney Hall, and from that time instances of its use multiplied rapidly. But it would be difficult to imagine that the manor-house at Layer Marney had been rebuilt at this period in that material, only to be pulled down to make way for Lord Marney's building, about the date of which, 1506, there is no question. It may fairly be concluded, then, that the whole of the remains now in existence are the work of Lord Marney. But here a further question arises as to whether those portions we have left are complete as was originally intended. This has hitherto been assumed to be the case,—but the conclusion hardly appears to be borne out by facts. It is evident that the gate-house is complete, so that the western dwelling-house wing

course, in the present dilapidated state of the building, it would not do to make too much out of such an occurrence, but when these things are pieced together they appear to supply exactly the clue which was wanting in order to explain the present apparently unfinished condition, and the conclusion seems a reasonable one that another story was intended to be added, and that the present roof was merely a temporary expedient, for preserving from decay that part of the building which was in advance of the rest, from some cause or other the work was stopped.

The terra-cotta work, which is so plentifully used, deserves remark, for it exhibits a very early example of the influence of the Italian Renaissance on the architecture of this country. When burned, the clay is of a rich buff colour and has a very pleasing effect in contrast with the red brickwork, which forms the general body of the walling. It is of even texture and the blocks vary in length from 8 in. to 1 ft. 3 in., and have been carefully modelled. The detail is a little mixed, for though the egg-and-tongue and the guilloche ornament are distinctly Classic features, as are also the dolphins which crown the cornice, the trefoil cuspings beneath can hardly be included under this head. An explanation of this mixture is to be found in the employment of Italian

workmen on the building; these, doubtless, were entrusted with the more ornamental details. Coming from Italy, they would be familiar with the style which was fast becoming the fashion in England at the time, and, therefore, only the plain parts of the work would be left to the local workmen. Presuming this to be the case, it may help to clear away doubt as to the date of the buildings which surround the secondary wing, or retainers' courtyard. It has generally been supposed that this portion is slightly earlier than the great gate-house and the remains of the house adjoining; and the reason given is that the work is more English in appearance, and contains none of the Classic terra-cotta work so conspicuous in the larger buildings. It is true such may be the case, but the materials and the mode of execution in this portion differ in no wise from other parts,

panels corresponds exactly with that on the towers, while the material is precisely the same; and it is remarkable that the well-known sedilia in Wymondham Church, Norfolk, are evidently designed and executed by the same man, as the work here also is the same as at Layer Marney. The view given will explain better than any description. The general arrangement was carefully carried out in accordance with the will of its owner, and it only needs to be added that the material throughout, with the exception of the figure and the slab upon which the figure rests (which are of black marble), is the buff-coloured terra-cotta used elsewhere. Little skill, however, has been shown in its erection, for, strange to say, in the main cornice the egg-and-tongue pattern can be observed peacefully reposing upside down, seemingly quite unconscious of the incongruity of such an arrangement.

invisible. Many of these chimneys (some of which are engraved by Parker) were standing in 1854, but were shaken down in the earthquake which occurred in the Eastern Counties on the 22nd of April in that year. Layer Marney Towers appear to have been quite in the centre of the disturbance and suffered a good deal, many of the roofs being injured and scarcely noticeable fissures in the walls became alarmingly apparent. These do not seem to affect the real stability of the pile, but are very unsightly and will tend to hasten the decay and ruin which seem inevitable. It is a pity that such should be the case, but the outlay needed to restore the Towers to anything like a sound and habitable condition would be so large that the chance of the work ever being done appears remote indeed; but that this would repay the trouble and expense involved there cannot be two opinions.

The interior arrangements have been so modernised that it is almost impossible to discover the purposes to which the rooms were put, except in the long, low ranges of farm buildings which form the north and south sides of the retainers' courtyard. The lower floor has been built for stables, while the apartments on the upper floor Parker describes as "dormitories," and this was evidently the use to which they were put. A detail of the interesting roof to these rooms is given, and a perspective view of the same will be found in Parker's "Domestic Architecture." The timbers of this roof are solid, and well framed together with large oak pins; the principals are carried some way down the walls, so as to relieve them as far as possible of thrust; and this end is further attained by iron tie-rods at the floor-level, and the termination of these has been made a feature in the elevations. A reference should be made to the remarkable brass in memory of John, the second Lord Marney, and his wife and her first husband. This brass is in the chancel of the church at Little Horkeley, and was placed there in accordance with the will of the lady. She survived Lord John, and died in 1549, directing that her effigy should be placed between those of her husbands,—Lord John on her right hand, and Mr. Thomas Finderne on her left, and that they should have their full coats of arms. Evidently the good lady was not a little proud of her husbands, and wished posterity to see with what distinguished families she had been allied. The drawing of this brass is taken from an engraving in the Suckling Papers.

It will be interesting, in concluding these remarks, to extract a few passages from the wills of the two owners of the Towers,—Lord Henry Marney and his son John,—which are published very fully in the Transactions of the Essex Archeological Society, vol. iv. The will of the former is dated 22nd May, 1523. After many directions about prayers to be said

Next order to the Dame Brigette Marney late the wyffe of John lord Marney and Sometyme wyffe to Mr Thomas Fynderne Blewrey and she dyed the xxx day of September in the year of our late God my cccc lxxij

The Marney Brasses, Little Horkeley.

as can be discovered; while points of difference would in all likelihood occur in buildings erected at different periods, even where they were only parts of one whole. That both were built at the same time may be decided, however, with the more English appearance when we consider that the number of foreign workmen employed would be limited at the time of the introduction of the style, and these would certainly concentrate all their energies on the principal court-leaving the less important buildings to the care of workmen, who could, and in this probably did, carry out their portion in any in which they had been brought up. It can be no doubt but that the same hand modelled the terra-cotta work for the buildings was employed on the elaborate beautiful tomb belonging to Lord Henry Marney in the church adjoining, which is still in a fair state of preservation, though broken in places. The design of some of the

The brickwork is of a deep red colour, diapered all over the building with diagonal patterns of blue vitrified bricks which break the wall surface in a not unpleasing manner. The courses rise four in 10½ in. and have joints measuring as much as 5-8ths in. in width. In the moulded portions of the work the same dimensions are retained, and this, on a close inspection, presents a coarse and rugged surface, which, however it may have looked when first built, now harmonises well with the ruinous conditions of the Towers. This effect of dilapidation and decay is increased by the plaster (which, in many places, had been used to imitate stone quoins) peeling off, exposing a veritable sham, which, until lately, the old builders had been deemed incapable of resorting to. Unfortunately but two of the beautiful cut brick chimneys, which were once such an ornament, now remain; and these are so hidden away up at the top of the Towers as to be almost

The Marney Arms.

for himself and his forefathers, together with directions as to his burial, he goes on to say,— "Also I will that there be a convenient herse made aboute in the church according to my degree, wth my armes and other things belonging unto me as by myn executors shalbe thought convenient, and my body to be conveyed as shortly as may be. . . . First I will

that with the profits of all my said landes that the chapel which I have begon adjoyning to to the chauncell of the parishe church of leyer Marney forsaide be new maide and fully fynysshed according to the same proporcions in length, bredith, and heith as it is bogon, with a substancial flat Roofe of Tymber, and also with the profit of my said landes that myn executors cawse to be made a Tombe of marbull to be sett in the wall betwixt the chauncell and the said chapell, which wall I will it be newe, and to be vawted over w^t marbull and workmenly wrought w^t suche works as shalbe thought convenient by my executors, and my Image to be made of hlack marbull or Towch [touchstone] w^t everything convenient and appurteyning to the same, and to be leyde and sett upon the said Tombe, and I will that two Images of laton [brass] be made w^t the pyctours of my two wife w^t ther cote armers upon them, that is to say Thomasyn, and she to lie on my right side, and Elizabeth, she to lye on my left side upon the same Tombe." Proved 15th June, 1623.

The will of Lord John, who succeeded his father, but survived him little more than a year, is of even greater interest to the antiquary, but treats of many matters which it would be out of place to quote here. "IN THE NAME OF GOD, AMEN, the tenth daye of the moneth of Marche. In the yere of our Lorde God a Thousand fyve hundred twenty and four, in the fyfteenth yere of the Reigne of our Sovereigne lorde Kinge Henry the eight, I John Marney Knyghte, Lord Marney of Marney in the countie of Essex being whole of mind &c. . . . bequeth my soule to the blessed Trinitie, to our lady Saint Mary to Saint John the Baptist and to all the holy company of hevyn, and my body to be buried in the newe Ile in the north side of the parishe church of leyer Marney in the middles of the said Ile, directly agensst the myddes of the newe chapell, six foote from the petition betwene the chapell and the Ile, in a vawte of bryke to be made so large that two bodies may be leyd therein, over the which vawte I will there be a Tombe sett and made of suche stone as my father's is made of, yf it may be gotten, or ells of graye marull, the which Tombe I wol shalbe eighte foote long and fyve foote brode and four foote high, and to be wrought in every condicion as my father's Tombe is, except the vawte over and above my father's saide Tombe, and the armes about the Tombe I will to be changed after the device of the harode (Herald), and round aboute my said Tombe I will there be made a grate of waynscott, and at every corner of the same grate a principall pyler w^t a white lybard upon the top thereof [these lyhards or leopards have now been removed and are affixed to the corners of the pews in the nave of the church], and upon which Tombe I will have an Image for myself of the same stone that my said Tombe like unto my said father's tombe shalbe made, yf it may be gotten, or ells of freestone, my said Image lying upon the midds thereof porteryd w^t my cote armor, with my helme and creste at the hede and a white leopard at the feet, and on either side of my said Image I will myn executors ley oon Image of brasse for every of my two wyves, Dame Crystian and Dame Brygett. The Image of my wife, Dame Brygitt, is to be laid on my right hande and the other of my lefte hande, and bothe the said Images to be pyktyrd with ther cote armors, and at the west ende of the said Tombe I will there be made an awter where I will have a preest synging for me perpetually after such ordences and devices as here in this my present will hereafter I have shewed and declared."

The remaining tomb in the church is of a much earlier description, somewhat plainer than those just described, constructed of a very beautiful marble resembling alabaster and panelled round with quatrefoils containing shields. The whole tomb has indications of rich-coloured decoration, and is supposed to be the one erected in accordance with the will of Sir William Marney dated 1414.*

* We will give some further illustrations of this interesting house in our next.

NOTES.

A GREAT difference of opinion as to the value of Mr. Mundella's Railway Bill appears to exist among those who would be affected by it. The agricultural interest are very dissatisfied with the clauses relating to undue preference, many going so far as to denounce the whole measure. Representatives of other industries express equal irritation at the facilities afforded for appeal,—though, of course, they would have the same privilege in this respect as their opponents, and the *locus standi* clauses will, to a certain extent, place them upon a more equal footing in point of strength. The railway companies, on the other hand, view the Bill with the greatest apprehension and alarm, and are making every preparation to oppose it. In the circulars issued by the directors calling upon the shareholders for their assistance, the rates clauses are represented as amounting to nothing short of confiscation; and the effect of the *locus standi* clause is also exaggerated and misrepresented. In a resolution passed last week by the Metropolitan Company, it is stated that the Bill is calculated most seriously to injure the companies, "with a view possibly to ultimate purchase." Such assertions as these as to the effect of the Bill upon railway property,—in which, of course, many in the House are interested, besides those actually connected with railway management,—may cause numbers to hesitate before declaring in its favour; while, on the other hand, many are pledged to their constituents to support it. As regards the Government, it does not seem at all likely that the dissatisfied attitude assumed by various parties will deter them from pressing the measure, though they will doubtless be willing to adopt such amendments as would remove objections without lessening its value. Indeed, Mr. Mundella has received several deputations from both sides, and will probably somewhat modify his proposals. The *Standard* of Saturday last, in a temperate review of the measure and the objections raised to it, remarks that the alarm which it is exciting is altogether unnecessary and unwarranted. This observation is certainly justifiable as regards the circulars of the London and North-Western and Midland, the former of which, especially, is calculated to thoroughly frighten timid and uninformed shareholders.

IN another column we print an important report on the Metropolitan Sewage Question, adopted by the Metropolitan Board of Works at its last meeting. The adoption of the report was moved by Mr. F. H. Fowler, deputy chairman of the Board, who made a long speech recapitulating the history of the subject, and the motion was seconded by Mr. Selway, who truly observed that the subject was the most important one with which the Board had been called upon to deal since the question of devising a comprehensive sewerage scheme for the Metropolis first came before it. The method of treating the sewage now recommended by the Committee would, he believed, he found successful. A brighter effluent could no doubt, he said, be obtained by a larger use of chemicals, but its increased brilliancy would not be of sufficient value to counterbalance the increased quantity of the sludge which would result from the use of greater quantities of chemicals. The nature and extent of the problem to be solved may be judged from some figures quoted by Mr. Selway. He said that London sends down its sewage outfalls 150,000,000 gallons of sewage per day, yielding, after precipitation, no less than 3,000 tons of sludge, which, after being subjected to great pressure by mechanical means, could only be reduced to 850 tons per day. Mr. John Jones, another member of the Board, while not opposing the adoption of the report, criticised the action of the Board, and contrasted the admissions of the reports now made public with its strenuous denials, made only a few years ago, that the discharge of the metropolitan sewage into the Thames caused any nuisance. These denials, he pointed out, had been persisted in as long as possible, at the

expense and to the detriment of the ratepayers, and though the Board and two of the chemists who advised it had recanted their views, there was, he thought, reason to fear that the suggested expedients would not be found to be all that could be desired. A suggestion made in the course of the discussion was that the pressed sludge might, for some years to come, be used to raise the level of the many thousands of acres on the Kent and Essex shores of the river which are lower than the level of high-water, and which are at present protected against flooding by raised banks or walls of earthwork.

THE case of Barlow v. The Kensington Vestry which was last week decided by the House of Lords, has gone from Court to Court with varying results. Our readers must by this time be pretty well aware of the case, as we have commented on it from time to time. In the first instance Vice-Chancellor Bacon decided in favour of the plaintiff, a police magistrate having previously been of a contrary opinion. Then the Court of Appeal gave judgment in favour of the Vestry, and now the House of Lords has reversed that judgment. The question turned upon whether or not a corner house, partly in De Vere-gardens and partly in Kensington-road, with its entrance in that thoroughfare, was beyond the general line of buildings in De Vere-gardens. As a matter of fact the inside of the house, so far as it was in De Vere-gardens, extended 7 ft. beyond the front of the other houses in that street; that is to say, it extended to the pavement, whereas the other houses had an area of 7 ft. in width between them and the pavement. The Superintending Architect of the Board of Works called in his certificate "a house in Kensington-road, at the corner of De Vere-gardens." The Lord Chancellor has decided that the house is in the Kensington-road for the purposes of the Metropolis Local Management Act, 1862, the Court of Appeal having held that it was both in De Vere gardens and the Kensington-road. But the Lord Chancellor carefully guarded himself against laying down the proposition that a corner house cannot be, for the purposes of the Act, in two streets, "each case must be decided on its own merits, having regard to all the circumstances." It seems clear, therefore, that a corner house such as the one in question with its front in one street, must usually be regarded as being in that street, and that that it may project beyond the general line of what may be called the side street. This seems to be the practical result of this long litigation, with which we may have occasion to deal finally, and *in extenso* on a future occasion.

SIR FRANCIS BOLTON has just issued his Report of the water supplied by the several metropolitan water companies during the month of February last. He states that the highest flood state of the river at West Molesey during the month was 4 ft. 5 in. above summer level mark, and the lowest 10 in. above that mark, the rainfall at West Molesey being 0.44 in. during the month. He continues to lament the absence of a fixed standard of filtration, and considers that the gelatin examination will be of assistance in establishing some such standard to be arrived at. The results of this examination, contained in a letter addressed to the Local Government Board by Dr. Percy F. Frankland, are interesting. The following is the statement:—

Name of Supply.	Number of colonies obtained from 1 cubic centimetre of water.
Thames:—	
Thames water (unfiltered).....	15,800
Chelsea.....	305
New River.....	80
West Middlesex.....	254
Southwark.....	203
Grand Junction.....	265
Lambeth.....	265
Lea:—	
Lea water (unfiltered).....	20,600
New River.....	74
East London.....	252
Deep Wells:—	
Kent (taken direct from the well).....	5
Kent supply.....	149

In his letter Dr. Frankland points out that

samples of unfiltered river water, taken for comparison, were obtained at Hampton and Chingford respectively, remarking that the number of micro-organisms found in the unfiltered river waters was only about half as great as the number found in the water collected during the previous month, and in nearly all cases the filtered waters exhibited a similar reduction. There is, however, little or no change in the condition of the East London and Chelsea waters in regard to micro-organisms (these companies have the greatest storage capacity), a fact which Dr. Frankland attributes to the probability of the water in their reservoirs having been taken from the rivers when they were in a less favourable condition. It will be noticed that the water taken direct from the well in the case of the Kent supply is remarkably free from micro-organisms.

AN American sanitary journal gives a description of Heysinger's apparatus for cremating the remains of the dead. Where this apparatus is used, it is proposed to proceed with burial in the usual way, "thus avoiding any shock to the feelings of friends who have dread of cremation as usually performed," the funeral rites are proceeded with as in ordinary burial, and the grave filled up. Then the cremating apparatus is brought to the grave, and the body burned in its resting-place. The way in which this is done, or proposed to be done (for we do not gather that the method has yet been practically applied), is, briefly, as follows:—The ordinary wooden coffin, containing the remains, is placed in a terra-cotta case, with tight-fitting lid. This case is just large enough to receive the coffin and to leave an air-space all round the latter, as or projections on the bottom of the case being for the coffin to rest upon. A terra-cotta flue or pipe is fixed at each end of the case, and these rise to within a short distance of the surface of the ground, being covered with caps when the operation has been completed. The crematory furnace is portable, and is attached to the flues just mentioned, so as to drive a double current of the incandescent gases and air into the terra-cotta case, where consuming the body, the products of combustion being led under the grate of the furnace, the process being continued until a thermometer shows that no more aqueous gases are passing. Fans or blowers are proposed to be used for driving the gases through. If this method be practicable, and that at a moderate cost, which seems somewhat doubtful, it may be an impetus to the use of cremation, inasmuch as it may satisfy popular prejudices in favour of burial while combining the sanitary advantages of cremation. We shall be curious to hear more of this invention.

APPRECIATIVE reference is made in the last number to hand of the Chicago *Sanitary* of the efforts which are being made in that country for the registration of efficient plumbers. Many advocates of the work which has been so vigorously taken in hand by the Municipal Company of Plumbers, at the instigation of Mr. George Shaw, the Master, have taken American precedents in support of the plan of the Company, and as far as we can ascertain, registration has been carried out for a few years past with very satisfactory results in America. Sometimes, it appears, mere pretenses seek to get their names inscribed on the register, but without success. An amusing incident is described in the journal before mentioned. It is that of a so-called "practical plumber" who had associated himself with a hardware and implement company "carrying on business in a town in Kansas, and who sought to join the local Plumbers' Association. A committee was appointed to wait upon the applicant and to inquire into his eligibility for membership, with the result detailed in a long list of questions and answers, from which we give the following specimens:—

Q.—How is a trap ventilated? A.—Never let it air.
Q.—What are the different patterns of traps commonly used? A.—Do not remember.

Q.—What is a lead safe? A.—A pan under a water-closet to catch leaks.
Q.—Is there a pipe leading from the safe usually? A.—Yes, going direct to the sewer.
Q.—Are you sure you are a practical plumber? A.—Oh yes.

It is not to be wondered at that before the examiners had put many more questions they dismissed the candidate with "That is all." In their report the committee say that the man who gave these answers is a fair sample of the "practical plumber" found in the "tin-shops and hardware stores" of Kansas, yet, say the reporters, such men have the "unadulterated gall" (whatever that may be) to apply for membership to the Master Plumbers' Association. We learn that in the end "the applicant was most respectfully told to stick to bell-hanging."

THE case of De Souza v. the Trustees of the British Museum, decided last week, is of importance to those in charge of public libraries. It is unnecessary to comment on the facts, but two things are apparent from the judgment of Mr. Justice Chitty. The first is that before a reader can properly be excluded from the use of the library for alleged misconduct he should be put in a position to answer any charges which may be made against him. The second is that though the governing body should be judicial in considering the charges, they are not bound to do more than specify them to the person complained of in an ordinary clear manner, so that if he desires he may be in a position to refute them. This seems, after all, only to be plain common sense; but it will assist those who manage libraries, reading-rooms, and similar institutions to have the law laid down from the Bench.

THE Exhibition of Fine Arts now open at Rome includes in the section "Metal-work" a department of special interest,—*i.e.*, a room devoted to such ancient bronzes as have been recently excavated, or as represent points of special note as regards subject or technique. The centre of the room is fittingly occupied by a now famous colossal statue, of the finding of which we some months ago gave an account. At the left-hand of the end of the room stands the scarcely less famous statue of a nude athlete, which gains much in effect by its present erect position. Near this last statue is the beautiful bronze Bacchus found on the 20th of last September very near the island of San Bartolommeo, in the Tiber. Ovid mentions a temple of Faunus on this island, and it seems possible that the statue may once have stood within its precincts. We are glad that the statue is now exhibited in a popular exhibition, as it gives a chance to the general public of becoming acquainted with a very fine and delicate specimen of ancient work in remarkably good preservation. The figure is perfect but for a fracture above the right ankle. The thyrsos held in the left arm was found in three pieces, and has been put together. Considering that the statue was found by the workman feet uppermost, it is extraordinary that the head should be in such perfect preservation. The god is crowned with ivy, and wears the headgear of a woman; two long locks (attached separately) fall on his shoulders, the lips are inlaid with brass, and the eyes made of marmo palomhino. Behind the left knee there is clearly to be seen the impress of a coin, which numismatists decide to be an aureus of the first century of the Empire. This figure of Bacchus may safely be attributed to the best Greco-Roman times. Besides these three famous statues there are a series of smaller exhibits. Prince Maffeo shows two interesting statues, one of a Roman Senator dressed in the toga, in the attitude of an orator; a second, of Etruscan style, representing a somewhat archaic type of a god holding a cornucopia. From Civita Vecchia is a curious piece of bronze, once apparently forming the coating of a galley, and shaped at the end into a female head of archaic style. It was fished up out of the sea, and is now the property of Signor Ardit. Count Spinelli, whose excavations on his estate at Acerra have yielded such valuable results,

also exhibits a case of bronzes, and a third case contains objects found in the excavations of 1873 at the Monte della Giustizia, among which the most remarkable is a double lamp of great beauty. It is chased all over with very rich decorations, and on the cover stands a graceful figure of a Lar. The exhibition includes a large collection of reproductions of ancient bronzes. The example here set of bringing first-rate antiques before the public is doubly profitable. It encourages popular interest in local excavations, and it gives the modern craftsman the opportunity of comparing his own technique with that of Classical times.

THE loan collection of drawings at the Gallery of the Society of Painters in Water-colours unfortunately closes on Saturday this week, and we presume that preparations for the annual exhibition in May render it useless to hope for any further extension of the time. The exhibition has formed a kind of summary of the water-colour art of the early part of this century, and is most interesting in a historical sense, as well as in regard to the beauty of many of the works. Among other things, the spectator was reminded of the fine things done in the old broad and rather colourless style by Havell, whose name has dropped out of general recollection, while that of Girtin, whom Havell at his best certainly equalled, has survived. Perhaps Girtin was partly drawn along the path of fame by the greater glory of Turner, who in his early days was more or less linked with Girtin in talk and criticism. Girtin is pretty well represented, also David Cox (in quality if not in quantity). Some of Mrs. Angell's exquisite flower and bird paintings are there, also flower and bird paintings not much inferior to hers, by a predecessor,—Rosenberg; also, in the way of still life, F. Walker's splendid study of "Mushrooms." The water-colour replica of the "Harbour of Refuge" is also in the collection. Other well-known names, old and recent, are well represented. The attendance at the exhibition appears to have been nothing like what its high interest would have led one to expect.

THE French Gallery in Pall-mall, which opened on Monday, is not so interesting as it usually is. The collection contains two works of Meissonnier, into which the artist has not put much effort, but which exhibit that wonderful ease and thoroughness in portraying the whole attitude, costume, and character of a single figure, which has become a kind of second nature with him. These are "Le Sommeil" (46) and "Le Funere" (50), the latter a figure of which we seem to read the whole history and character, but it is a very common-place one. Seiler's "On the March" (10), is a painting Meissonnier might almost have signed, a small group of military men in a tavern, finished with wonderful delicacy. The same painter's "A Rare Proof" (47), and "Writing his Leader" (48), should be noted. Oeder's "Approaching Storm" (34) is a powerful landscape with a good deal of individuality of style. "The Traitor Tracked" (53), a Servian subject of P. Joannitis, is one of the best figure paintings in regard to point and expression; the expostulatory and yet weak and unnerve manner of "the traitor" is very well given. The painting by Israels (63) is a smaller edition of one of his finest and most pathetic works, the widow watching by her dead husband's coffin, which has been seen in the same gallery, and on the fine and pathetic quality of which we commented at the time, though we cannot now recall the title under which it was then exhibited. The larger picture is in a private collection in London. Heffner's "Repose" (60) is one of the finest efforts in his impressive but rather artificial manner. "Princes of the Church" (13), two aged dignitaries descending from the Sanctuary, by Aug. Hohnberg, shows some very brilliant painting of architectural and decorative detail, which is its chief interest, though the figures are good and characteristic. "Prayer" is a small but good specimen of Gérôme's work (135), an

interior of a mosque with figures in the act of worship. "The Evening Hymn," an interior with two figures of girls seen against a window (130), by W. Firlie, is an expressive painting. Krümer's large work with many figures (119), "He that is without sin among you," &c., contains fine points, especially in the expression and action of some of the subordinate figures who look on; but the Christ is weak and theatrical.

THE exhibition at Messrs. Tooth's Gallery in the Haymarket contains no very remarkable work except Sir John Millais's picture of "Bubbles," which we have already noticed. There is a good work of Mr. Faed's, "Alone" (8), and a clever but very ugly picture by Eisenhut of "A Tartar School in Baku" (60). Mr. Boughton's "Forget-me-not" (62), a life-size three-quarter length of a handsome girl, is a pleasing work. Others, by Messrs. Waterlow, Gallegos, Heffner (a fine example), Davis, De Blaas, Pasini, &c., are worth looking at.

THE "on view" of the late Mr. Graham's pictures at Christie's this week has afforded an opportunity of seeing together many works by some remarkable modern English painters which will not be so fully and collectively represented again for many a year to come. There were a great number of Mr. Burne-Jones's works, including the "Six Days of Creation," the first (and most beautiful) edition of "Venus's Mirror," that modern Giorgione the "Chant d'Amour," and a good many others. There was a room full of Rossettis, including that strangely pathetic early work, "Found"; pity the painter did not pursue this path of truth and nature more, instead of giving his powers to producing impossible feminine animals with preternaturally long necks and large lips. There was F. Walker's "Bathers," where the figures of two London youths among the crowd are treated with almost Greek style and dignity, and yet are natural, and his "Vagrants," with the powerful figure of the woman with folded arms, and the smoke drifting across her figure, which once seen can never be forgotten. There was Sir John Millais's "Blind Girl," about which such paper warfare ensued a quarter of a century ago, and which we still think "will not do"; and his "Vale of Rest," which is a fine poem in its sombre feeling and rich evening light, and is a work that is not likely to lose in position as time goes on. The same can hardly be said of "Apple Blossoms," the figures in which are absolutely alarming. Among other works of interest we noticed some landscapes by Mr. Legros, with which we were not familiar, and which have a rare merit of their own, in their fine and poetic composition, and soft aerial tones. The occasion was one of remarkable interest to lovers of pictures, and that it was felt to be so the crowd in the rooms fully attested. It will be curious to see for what sort of prices the Rossettis and the early pictures by Sir J. Millais will go at the sale. "The Vale of Rest" is certain to command its value, but of some others, and of the Rossettis, we feel somewhat doubtful. Among the spectators in the Rossetti room there was a good deal more criticism (sometimes rising to sarcasm) than enthusiasm.

NO more charming exhibition has ever been seen in the rooms of the Society of Fine Arts than the collection of works by Mrs. Allingham, under the title "Surrey Cottages." Everyone knows the general character of her work, but one must see a number of examples together (there are sixty-six at the gallery) to realise how various, how complete, and how true both to nature and art are these little transcripts of bits of English scenery, with their homes and inhabitants. The drawings are broadly grouped under the heading of Spring, Summer, Autumn, and Winter (only a few of the latter, however). The elements of the scenes are much alike: a bit of garden or a part of a meadow, with wood rising behind it, an old, half timber, half brick, thatched house, and two or three figures; but the variety within this restricted path is

wonderful, and not less the thoroughness with which every portion of the work is finished, yet without a touch of hardness. The composition of the little scenes is a model of that kind of art which is so carefully considered as to seem quite natural and spontaneously; the figures, however small, are never without a little point or history; the mother looks out after her children going to school; a neighbour calls over the gate to the mistress of the house; a child comes out to give a penny to the fiddler, watched by the others over the wall; the action and expression of each is complete in itself, but they all fall into their places as part of the scene. We had begun to mark some special favourites in the catalogue, but it would have ended in marking them all. All who love the spirit of English rural scenery, and who can appreciate art that is unobtrusive, modest in its aims, but true to the backbone, should visit this collection, which sends one away with the mind full of pleasant images and associations.

LETTER FROM PARIS.

On the 28th of January last, M. Paul Haag, Engineer-in-chief of Roads and Bridges, delivered an interesting lecture before the Société Centrale des Architectes on the great works in Paris, the undertaking of which was, according to him, intimately connected with the construction of a high-level metropolitan railway. In our February letter we briefly alluded to this project, mentioning the general objection felt in Paris to the idea of a city railway on the surface, which would cause, it was thought, vibration dangerous to buildings, fill the streets with smoke, &c. On the other hand, it is extremely difficult to establish an underground railway below the sewer levels in a city like Paris, where the houses are both very lofty and very deeply cellared, and where the space under the streets, what with water, gas, sewerage, and networks of telegraphic and telephonic wires, is as complicated with passages as the basement of a theatre.

Accordingly, both with the public and the Government, there seems to be a turn in favour of M. Haag's high-level idea, which has already been carried out successfully in New York, Vienna, and Berlin; and although no decision has yet been come to, we may take the opportunity to sketch in a general way the principal features of a project which has considerable chance of being accomplished, and which, as it involves no subterranean excavation, may be carried out in time to help the extra traffic of the '80 exhibition.

The leading idea of M. Haag is to make his Metropolitan Railway not an isolated system, but the complement of the suburban system and the uniting of the great lines which penetrate into Paris. It is important to add that, though serving the central part of the city, the railway is to interfere with no important building in any way, and will respect the artistic physiognomy of Paris. A new road would be opened from west to east of the City, 42 metres wide, on the centre of which will be placed the metal viaduct, 12 metres wide, with an ordinary roadway of 15 metres on each side of it. This main road, which will serve in its course the Boulevards, the theatres, the Halles Centrales, the Hôtel des Postes, and the Hôtel de Ville, will branch at its extremities to join the great lines and the suburban railway, crossing the Seine at the Halle aux Vins, with no necessity for tunnels except at the Pantheon and the Trocadéro. Without entering on any discussion of a project, the attractive side of which is obvious, but which has given rise to criticisms too lengthy to formulate, we may say that M. Haag calculates the expense at 400 million francs, with a net receipt of 17 or 18 millions from the rent of stores and shops bordering the railroad. That is the state of the question submitted to the Government. It is to be hoped it will be satisfactorily entered on, and do something to amend the stagnation in labour from which we have been suffering.

The above-named lecture was one example only of the importance and interest of the meetings of the Société Centrale. The other day M. Hielard read a paper on the future Bourse de Commerce, and its financial aspect; and next M. Vielcastel has given us some information on the art of the far East. In a few days, M. Marius Vachon will discourse to us

on national Russian art; and M. Georges Berger, Commissioner of the Foreign Sections in the Exhibition of 1878, will exhibit in turn the plan of the future exhibition, with the statement of the financial combinations calculated to ensure its success without falling heavily on the taxpayer. We may here observe, in regard to the Société Centrale, that the conference of this year will take for its chief extension *extra muros* the town of Troyes, a selection which will probably draw a large number to join in a visit to a place of such special architectural and historical interest. The works of M. Guilbert Martin, to whom may be credited the revival of mosaic art in France, will also be visited. He has created at St. Denis a school of mosaic, and he carried out the mosaic work at the Pantheon, after the design of Hébert, and also the decoration of the Darn staircase at the Louvre. This latter includes eight cupolas executed in enamel, after the designs of M. Leneveu.

On April 7th the artists elect the jury for the Salon of 1886. In the mean time the jury of admission, presided over by M. Bongereon, is working without cessation at the task of choosing from among the 5,000 pictures sent to the Palais d'Industrie the 2,500 which the regulations admit.

There is another exhibition, of which we shall have to give account, and which is announced under the most favourable auspices, that of the works of Paul Baudry, at the Ecole des Beaux Arts, which the Mobilier National is decorating for the occasion with fine tapestries. This, which will remain open during the months of April and May, includes 170 original pictures, twenty-three copies, and 170 drawings. The receipts are intended, as already mentioned, to go towards erecting a monument to Baudry in Père Lachaise. The subscriptions for this object already amount to nearly 40,000 francs.

Since our last letter the Académie des Beaux Arts has proceeded to fill up the place of the deceased painter; and though, in the order of presentation, M. Emile Lévy was in the first rank, it is M. Jules Breton who has been victorious, after four votings. This success falls in happily with that attained in America by a work of the same artist, at the Morgan sale. This is a subject of melancholy reflection to Parisian painters, who are not accustomed to such strokes of fortune, for the sales at the Salle Dronot have fallen far below their former success, and the artists are the first to suffer under the general stagnation which reigns here. Under these circumstances it is necessary to stimulate public attention by successive exhibitions, which do not always attain their end. That of the Water-Colour Society has been much less successful than in former years; and the same with the exhibition of Black and White installed in a rather makeshift manner in the sheds of the Tuileries. There are some remarkable drawings there, but they are exceptional points in an ocean of common-places which look like the works of pupils in the primary schools. Let us hope better for the exhibition of Pastels (a very brilliant one last year), which will open in the Galerie Petit on April 2nd.

The Académie des Beaux Arts has had to decide recently on the competition for the architectural prize founded by Achille Leclère. The subject was a museum on a private property. M. Conil Lacoste, pupil of M. Gignat, had obtained the prize, while "honourable mention" was accorded, *ex æquo*, to MM. Delestre and Baudein, pupils of M. Gnadet. The Académie has also decided on the first competition for the "Grand Prix de Rome" (architectural section). The jury had to examine forty-eight sets of drawings. Ten young architects have been admitted into residence for the final competition. These are:—M. M. Defrasse, pupil of M. André; Louvet, pupil of M. M. Louvet and André; Delemer, pupil of M. André; Sordais, pupil of M. M. Daumet and Gerhardt; Leroy, pupil of M. M. Coqart and Gerhardt; Dehuc, pupil of M. Gnadet; Conil Lacoste, pupil of M. Gignat; Leslika, pupil of M. Gignat; Despradelle, pupil of M. Pascal; and Gaston Cousin, pupil of M. M. Coqart and Gerhardt.

Meddling a little too promiscuously in politics the Conseil Municipal is at the same time occupied about some interesting and useful public works. They may be justly reproached, certainly, with giving a dangerous degree of moral support to those engaged in the Decazville strike; but they have certainly given an impulse to some public works which the Govern-

ment has not ventured to initiate. Thus the Council has again moved, and this time with apparent chance of success, for that suppression of the fortifications which has been twice refused. The new Ministry of War shows itself, in principle, favourable enough to that suppression; they have had consultations with M. Alphonse on the subject, and unless a fresh Ministerial crisis supervenes, it seems likely that his ideas will be carried out. The circle of fortifications being about 36 kilomètres, a commencement would be made by demolishing the portion between Auteuil and the Porte de Roineville, about 18 kilomètres in extent; at least, this would be the best course. Here the Municipality would have no private property to buy up, as in the usual road-making projects; they would, on the contrary, have the right of sale of the sites reclaimed from the fortification zone, after a space of about 72 mètres had been reserved for a double boulevard planted with trees, on each side of the city boundary railing. Later on, after the entire suppression of the fortifications, the double boulevard, bordered by gardens and villas, would create around Paris a great sanitary avenue from the Bois de Vincennes to the Bois de Boulogne, the two reservoirs of pure air at the two extremities of the city.

In combining this operation with that of the Metropolitan Railway, we shall, perhaps, solve the problem of cheap lodgings, accompanied by sanitary conditions. In the very heart of Paris also all is prepared for the indispensable prolongation of the Rue du Louvre, which, with the new Bourse de Commerce, will quickly do away with all the conglomeration of narrow unhealthy houses left in the centre of Paris. On the side the Government is seriously occupied about completely isolating the Opera Comique theatre, and giving it a new and fine façade towards the Boulevard des Italiens. This project, which will cost about three million francs, is to do away with the danger from fire which has often threatened the edifice. It is to be hoped the Government will not be so dilatory in this matter as about the restoration of the Porte St. Denis.

The Municipal Council, in spite of its activity in other directions, seems determined to do nothing about the continuation of the Boulevard Haussmann, perhaps from a hatred of the name of the "reactionary" initiator of the scheme, though the ostensible pretext is economy, and the adjournment of operations which are described as *de luxe*. Meantime the suburban communes, which have not the same reasons for economising, continue to embellish their districts with monumental edifices of the Mairies. A competition is to be opened at Muresnes for the building of a Hôtel de Ville, and in the course of the year three new Mairies will be inaugurated, at Boigny, Arcueil, and Pantin. The latter will be made the object of one important artistic decoration. The ways and means are also under consideration for reconstructing the Mairies of Vincennes, Levallois, Perret, and Charenton,—a considerable aggregate of work. The same energy will have to be shown within the city before we can quote Paris the proverb, "Quand le bâtiment va, tout va."

The Government ought to take some steps about the ruins of old buildings as well as the building of new, and clear away, at least before approaching exhibition, the walls blackened by communal petroleum which still rear themselves on the Quai d'Orsay. The unhappy idea has been mooted, indeed, of establishing here a Museum of Decorative Art so long announced. But the members of the Union Centrale, who seem to inhabit a region of pure utopianism, have at last been made to comprehend that the proper treatment for such a museum would be in the industrial quarters and among the art-workmen whose benefit it is intended. The quarter called "Du Marais," and especially the ancient Hôtel Thoiry formerly occupied by the Ecole Centrale (and described in the *Builder* last year), could be a convenient and suitable neighbourhood, but nothing will be done yet. It takes me, you see, in such an atmosphere of routine and indifference, to get up anything like a rival to South Kensington.

Every year the Fête Nationale gives occasion for the inauguration of a statue, making part of the programme of the day. This year it will be Diderot who will have the honour to exhibit in bronze effigy to the Parisian populace on the 4th of July, with the accompaniments of mystery, crackers, and official discourses. The

work is by M. Jean Gautherin, and will be placed on the Place St. Germain des Prés, at its intersection with the Boulevard St. Germain.

The museum of the Luxembourg, to which reference has more than once been made, will be opened to the public about the time these lines appear. We have already described the building; but we may add here that the first gallery is reserved for works in sculpture, while the paintings, drawings, and water-colours occupy the second gallery. There is here a collection of about 400 works of the best known modern artists, very well arranged by M. Etienne Arago, the venerable curator of the museum.

The last bit of artistic news is that the "Manufacture des Gobelins" has completed the sumptuous tapestries intended for the Palais du Luxembourg, as well as the large decorative panels intended for the Bibliothèque Nationale and the Palais d'Élysée. The latter, which symbolise Painting, Art, Science, and Poetry (Lyric, Pastoral, and Satiric), are executed after cartoons by M. Galland.

We have to mention the decease of two landscape painters, MM. Victor Navlet and Joseph Lecomte. The first was best known by his views of Paris and Rome. The latter, who obtained the "premier grand prix" for historic landscape in 1849, was a pupil of Picot and d'Alligny; he has died at the age of sixty-three, leaving a considerable amount of very important work behind him.

FREE LECTURES TO ARTISANS AT CARPENTERS' HALL.

THE FINE ART ASPECT OF WOODWORK.

The sixth lecture of the present course was delivered on Wednesday, March 24th, by Mr. H. H. Statham, who took for his subject, "The Fine Art Aspect of Woodwork," or woodwork regarded from an artistic point of view. The word "art," he pointed out, was now very often used in a very conventional manner. People talked about "art colours," by which they meant certain dull tertiaries which had become the fashion to use; and about "art furniture," by which they meant furniture made after a certain style, which happened to be much admired for the time. As a matter of fact, all furniture ought to be art furniture, and anything which professed to be so specially was probably rather the opposite. Now, in speaking of art as applied to woodwork, he was not going to say anything about the higher work of sculpture in wood, but should confine himself to decorative work and work made for use, without excluding ornament. Now, he had never seen any definition of what "art" meant in connexion with such matters which was so comprehensive and suggestive as one which was given by John Stuart Mill, in an address to the University of St. Andrew's, many years ago, which was as follows:—

"If I were to define art, I should be inclined to call it the endeavour after perfection of execution. If we meet with any piece of mechanical work which bears the marks of being done in this spirit, which is done as if the workman loved his work and tried to make it as good as possible, even though something less good would have answered the purpose for which it was ostensibly required, we should say that the workman had worked like an artist."

That was a broad and accurate summing-up of the truth of the matter, and the remarks he (the lecturer) had to make would have special reference to its application to woodwork. Beginning at the beginning with the mere way of constructing woodwork, it had been very well pointed out by the late M. Viollet le Duc, the eminent French architect, in the article "Menuiserie" in his "Dictionnaire," that in treating woodwork ornamentally it should, as a rule, be so treated that the ornament should not interfere with the portions which had to be joined,—the portions, in fact, where the points of construction came in. As an instance of this, trellis-work with square openings constructionally could be ornamented very effectively by chamfering-out the inner edges of the openings so as to impart a circular or other outline to them. Another instance of the way in which the simplest lattice work in wood could be ornamented was seen in the screens of Arabic work so much used for windows in Egypt and the East, these screens, effective as they were, consisting merely of small squares of wood connected together by other small pieces of wood turned in the form of dwarf columns or balusters. Reverting to Viollet le Duc, his

practice was not always equal to his preaching; indeed, some of the examples he gave were very much opposed to the principles laid down by him. For instance, he gave, as an example for imitation, a mimic column with capital and base rising up to support the underside of an arch. Now not only was the arch not a form of wooden construction, but it was opposed to all constructional laws to put a column under what, in a stone arch, would be the keystone. It was true that the example referred to had been executed in Medieval times, but it was not necessarily right on that account. The arch was essentially a stone form, and should not be executed in wood at all, and where an opening in a wooden construction needed dividing into two or more divisions it should be done not by regular architectural columns with capitals and bases, but by something more in the nature of balusters designed for the situation. Another mistake in woodwork was seen in the carving of panels so as to imitate something other than wood, as, for instance, in the "linen-pattern" panels so often imitated. These were things which surely did not fulfil Mill's law; in fact, they belonged to the category of mere sleight of hand. If, instead of having flat panels, it was desired to carve or otherwise vary their surface, there were plenty of ways of doing it in a more fit and sensible manner. One fault very common in modern woodwork, though it was found in some old examples, consisted in making the upright divisions of the framing take the form of mimic stone miter-joints, with set-offs, &c. These features, when executed in wood, were not only meaningless, but ridiculous. But, unfortunately, much worse things were done every day, in the way of imitating stone construction in wood. For instance, cornices from Greek temples, of a contour specially designed for marble or stone, were imitated in wood, and recommended for imitation in almost identical section, in some so-called text-books for the instruction of workers in wood. These things were done almost universally in the early part of the present century, although they were absolute shams. The construction of such wooden cornices for cabinets, &c., involved an amount of hollow "cradling" admirably adapted for the collection and retention of dust. Another sham of the same era, and not yet defunct, was the hollow "Doric" column, put together with 1½ in. strips of wood. Next referring to some sketches of specimens in the Jones Collection of Furniture in the South Kensington Museum, the lecturer pointed out the necessity of articulating the legs of furniture well with the superstructure, as well as designing them so as to get a firm and slightly-spread base. Other points touched upon in connexion with specimens in this collection were the need of an apparently strong junction, as well as a really strong one, between the top and legs of a table, and the necessity of all ornamentation being suitable to the material and confined almost entirely to the parts which would not be weakened in appearance by it. The lecturer condemned as "an old humbug" a bulbous-shaped and apparently very massive table-leg, which purported to be turned and carved out of one piece of wood, the fact being that the real leg was no more substantial than its smallest dimensions, the bulbous carved work being applied, and glued on in sections. After referring to an example of Sheraton's work in the form of the foot of a work-table, and to an ancient Egyptian chair now in the British Museum, the lecturer contrasted two arm-chairs,—the one plain, but artistic, because well designed and appropriately constructed; and the other, "would-be-artistic," having for its arms carved dolphins sloping at a very inconvenient angle, these arms being apparently utterly devoid of any constructive articulation with the other parts of the chair, and obviously without any continuity of design. In this latter specimen, the ornamentation was utterly misplaced. By way of emphasising his point that the ornament should never be allowed to interfere with the practical use of the object to which it was applied, the lecturer exhibited (by the kindness of Messrs. Searle, the well-known boat-builders) a rowing scull, which, as he pointed out, was a thing very fine in its lines, and necessarily so, because it had to be very carefully made to fit it in the best way for its purpose. It had to be strong enough to take a good pull, while, at the same time, it had to be made as light as pos-

sible, as every ounce of unnecessary weight would tell upon the man who used it, and the strength of the stem had to be fined off gradually into the broad thin blade. Now, although there was not the least bit of ornament about it, it was an elegantly and fitly-shaped object; and it would not be rendered more "artistic" if it were covered with the surface ornament and carving with which certain barbaric peoples decorated such implements, because its utility would be very much impaired. The lecturer next referred to some eccentricities of woodwork, which he called "German gimcrack," such as the centre-bit style; the "spiky-style," as sometimes exemplified in the large-boards of houses built by speculating builders; and the "hottle-stopper style," a familiar illustration of which was afforded by the ends of common wooden "cornice-poles" or curtain-rods. Most of these vulgarities were to be found in some of the text-books intended for the instruction of youth in "artistic woodwork." But there was English "gimcrack" as well as German "gimcrack," and he was sorry to say that some of it was by so excellent a workman as Chippendale, whose works were, unfortunately, indiscriminately worshipped and sought after by people, many of whom were purchasers of Chippendale's work, or of imitations of it, without knowing why or wherefore, except that it was "the fashion." Chippendale was undoubtedly one of the most conscientious workmen who ever lived, but much of his work was very inappropriate in design. For instance, his tables with open or perforated legs, with gimcrack pediments and crockets stuck on and in them, were very unsatisfactory, and the same must be said of his ribbon-backed chair, which he had himself described as "the best chair ever made!" No doubt it was one of the best put together, but in point of design, where was the sense in a man carving elaborate knots of ribbons for the user of the chair to lean against? Many much better chairs had been made than that, — by Sheraton, for instance, who was a far better artist than Chippendale. Having referred to a mantelpiece cabinet made up from old oak work by Mr. Harry Heins, as a good example of solid work, the lecturer said a few words as to individuality in the treatment of street-doors. As Sir Gilbert Scott had said, a man ought to know his own door by some other token than that it is No. 37 or 43. As an instance of admirable work throughout, the lecturer instanced a German cabinet now in the South Kensington Museum. It was decorated with ornament carved on the surface of the cabinet itself, nothing being stuck on. In the larger forms of wooden construction, such as roofs, much had been done decoratively by the great Mediaeval artists, as was to be seen in the roof of Westminster Hall and that of the Middle Temple Hall, the former being the most satisfactory in treatment.

Late Gothic Oak Carving: Conventional Treatment of Thistle.

Having offered a suggestion for the ornamentation of a common queen-post roof, incidentally remarking that in a hook intended to give popular instruction in woodwork, and favourably reviewed by the *Times*, a queen-post roof was described as that form of roof in which the post stood on the middle of the tie-beam, and supported the apex (!), the lecturer referred to some sketches of Renaissance and Scandinavian ornament, pointing out that naturalistic and conventional ornamentation should rarely or never be associated in the same work. A sketch was exhibited of an Italian Renaissance mirror frame now in the South Kensington Museum, which was spoken of in terms of high commendation, especial stress being laid upon the enthusiastic and loving spirit of the artist who made it, as evidenced by the fact that in lieu of providing a mere cover for the steel mirror, to serve the

utilitarian purpose of keeping it from the dust, he had delicately carved the surface of the panel in low relief, the centre containing a most beautiful head. Amongst other specimens of old work referred to was the choir-screen in Lancaster Church, believed to have been looted from one of the old abbays. The treatment of the finials and mouldings in that work was very fine. In conclusion, the lecturer referred to some inlaid and other chairs exhibited by Messrs. Collinson & Lock; to some casts and specimens lent by Messrs. Farmer & Brindley; and to some exhibits lent by Mr. G. A. Rogers from his well-known collection, including a very good specimen of Grinling Gibbons's work, concerning which he said it was very much to be regretted that so much technical skill in execution should have been wasted upon work which was so utterly lacking in all the qualities of real design, and which consisted merely of festoons of flowers and fruit, fish, musical instruments, &c., all strung together. It was noteworthy how even the most ordinary and commonplace articles of domestic use might be made more or less artistic where there was a real desire for art. As an instance of this, the lecturer pointed to an Icelandic fish-pot (from the collection of Mr. Rogers), a mere common kitchen utensil, made of wood and very elegantly carved on the exterior, of which a sketch is subjoined.

Icelandic Wooden Fish-pot.

On the motion of Mr. Clifford Smith, seconded by Mr. Preston, the Clerk of the Company, a vote of thanks was given to the lecturer and to the gentlemen who had lent specimens, &c. for exhibition. Besides those already mentioned we may state that Professor Roger Smith lent

some drawings of timber roofs, and Mr. J. D. Sedding some rubbings of bench-ends in Cornish churches. Among other objects exhibited was a very fine piece of late Gothic carving, a conventionalised treatment of the thistle, lent by Miss Rowe, the superintendent of the School of Art Wood-carving at South Kensington, and of which also a sketch is subjoined. The lecture was also illustrated by a series of upwards of fifty sketches, prepared by the lecturer and lithographed and presented to each person present.

The seventh lecture of the present course was given on Wednesday evening last by Mr. James Doulton, who chose as his subject "Terra Cotta." Mr. Alfred Preston presided, and the lecture was illustrated by the "throwing" of terra-cotta ware and the incising of the ware by the loop tool. A report of the lecture will appear in our next.

STREET RAILWAY TO ABERDEEN CORPORATION GASWORKS.

THE use of locomotives for the haulage of goods is extending to a considerable degree, so far as regards the quays and wharfs of many of the principal shipping ports. A railway along the ordinary streets of a town being of rare occurrence in this country, the following notes descriptive of that now in course of construction at Aberdeen, from the Docks to the Corporation Gasworks, may prove of interest to our readers.

The gasworks, which lie at the extreme east end of the city, were, with the remainder of the gas undertaking belonging to the Aberdeen Gas Light Company, transferred by statute to the Aberdeen Town Council as at 1st August, 1871. Since that date the continued increase of the population within the gas limits, and a corresponding growth in the demand for gas, has necessitated various additions to and extensions of the works, the chief feature being the erection of three large new gasholders. Several different qualities of coal are employed in the manufacture of the Aberdeen gas. These coals are brought to the city partly by rail and partly by sea. The gasworks are distant about half a mile from the docks and three-quarters of a mile from the South Railway station, and hitherto the gas coal required has been carted to the works by horse haulage in the ordinary way. It was frequently represented that the cartage system was becoming unmanageable, the gas superfluous pointing, as strong disadvantages, to the difficulty of thus conveying in a sufficiently limited time cargoes from the ship's side, and to the fact that it did not give due facility for storage and checking of weights of the various qualities of coals used.

So far back as 1850 various schemes for the construction of a railway to the gasworks were brought under the consideration of the Town Council, but it was not until the introduction of a City Improvements Bill in 1852 that the railway or tramway under notice was definitely proposed. The statutory plans of the railway were lodged in Parliament along with those of the City Improvements Scheme. Considerable opposition was at first offered to this as well as to the other projected works. Eventually such opposition was withdrawn, and, although the railway was not favourably reported on by the Board of Trade Inspector, the Bill (including it) was passed in 1853, with certain regulations as to the speed at which the coal trains should pass along the streets and as to the hours at which such traffic should be conducted. Great hostility was afterwards shown by the East-end inhabitants, the School Board, and a large minority of the Town Council in carrying this portion of the Bill into execution. The objections put were danger to the babes, especially children; smoke nuisance, noise, and failure to secure economy. These objections were, however, overruled, and the minority outvoted by a majority of the Town Council, who resolved to go on with the work.

The Parliamentary and also the working plans have been prepared by Messrs. Jenkins & Marr, civil engineers and architects, Aberdeen. The contract for supplying the rails, — which have all been delivered, — was secured by Messrs. Nicoll & Sons and Messrs. Brown & Tawse, both of Dundee. The contract for the construction of the line was let a few months ago to Mr. Robert Gair, contractor, Aberdeen; and the points, crossings, holts, &c., were contracted for by Messrs. James Abernethy & Co., Ferryhill Foundry, Aberdeen. The works are now in active progress, and will be completely finished before many weeks have elapsed.

The length of the railway is 3 furlongs, 48 yards, with numerous sidings and loop line or lyes within the yards, coal-sheds, and other buildings at the gasworks. The whole length, including these sidings, is about a mile. The railway commences by a junction with the existing lines of harbour rails on Waterloo Quay, near the south end of Church street. The line will be single, and will traverse and pass along the centre of the following public streets, viz., Church-street, St. Clement-street, and Summer-lane; the length of line along these streets being about 411 lineal yards. A present both Summer-lane and St. Clement-street are obstructed by two very awkward points of projections at Baltic-street and Garvock Wynd. In order to make the line of railway as straight as possible, these projecting buildings are to be

removed, and these streets widened considerably, and apart altogether from the question of the railway, this will be a decided street improvement. Chancery-street is also to be widened (where necessary) from 23 ft. 6 in. to about 47 ft., which will be the uniform width along its whole length, and the width of none of the streets traversed will be much less than the latter figure. This, it is expected, will allow ample room for the ordinary wheel and foot traffic, even when coal trains are passing.

The track of the railway will be of the ordinary 4 ft. 8½ in. gauge. The rails throughout are of steel. Those in the public streets are 8 in. broad, and weigh 67 lb. per yard. There is a small groove along the middle of the upper surface of the rails in which the flanges of the wheels of the engines and trucks will run. It may be noted that no special waggons are required in the working of the railway, which has been devised so as to allow usual railway coal-waggons being shunted direct on to it from the lines of the ordinary railway system. No transverse sleepers are required for the track so far as it is on the public streets. The rails in those streets are fish-plated, with counter-tank bolts, and spiked, at 3 ft. apart, on to longitudinal run beams of 8 in. by 7 in. creosoted wood. These beams, or sleepers, are embedded in 6 in. thick of cement concrete in the proportion of six to one, the breadth of the concrete track being 7 ft. The surface of the track is paved with square-dressed granite amseway stones in the usual way, and the top of the rails will be flush with the surface of the streets. It has not been thought necessary to "diamond" the surface of the rails the same as those on which the passenger tramcars run in their parts of the city, or to take any other means to prevent them getting smooth. There are numerous curves on the line, the sharpest in the streets being 135 ft. radius, and the beams have been bent to the radius by saw-cuts on the outer edge, with edges driven in. The steepest incline is in Church-street, where the gradient is one in thirty-eight.

The rails within the gasworks are the ordinary flat-bottomed rail, weighing 56 lb. per lineal yard. Where the line is straight these rails which are fish-plated throughout) are spiked upon to transverse sleepers, 9 ft. long by 1½ in. by 5 in., placed at about 3 ft. from centre to centre. In the curved portions the rails are laid and spiked upon longitudinal sleepers, 8 in. by 7 in., checked into transverse sleepers of the same dimensions as those above described, but placed at 5 ft. apart from centre to centre. The hole of the sleepers within the gasworks are Scotch fir, creosoted, and all the permanent way within the works is ballasted with the linker refuse from the furnaces, the box being 1 ft. wide, and the depth of ballast varying from 1 ft. 3 in. to 1 ft. 9 in., all thoroughly checked round the sleepers and longitudinal beams. Within the coal-sheds and buildings the surface is finished with square-dressed granite causeway.

The curves on which the locomotive engine will work vary from 220 ft. to 120 ft. radius, while some of the minor branches, or sidings, within the coal-sheds are only 50 ft. radius. In laying these curves the outer leg of the rail has been kept up in some cases as much as 4 in., and in order to afford some play to the wheels, and facilitate the passage of trucks round these sharp curves, the gauge has been kept ½ in. full. There are in all seventeen points and crossings, worked in the usual way, by levers and boxes. There will be a Pooley's steelyard at the point where the line enters the gasworks, for weighing the trucks and coals when entering and outgoing waggons when going out. The cost of the works as contracted for is only about 2,500,000, while the expense of the buildings (eight number) which the corporation had to purchase and which are already all taken up has been about 4,500,000. The railway to be worked under contract by the Great North of Scotland Railway Company for seven years from the opening of the line, after which the corporation may make any other arrangement found advisable. A small steam locomotive, specially constructed to suit the traffic, will be employed on the line. Apart from the cartage of refuse from the furnaces, the quantity of coal and other material required to be conveyed to the gasworks amounts to the respectable figure of 35,000 tons annually, and the promoters expect that by the

use of the line a saving of 2000l. or thereby per annum will be effected as compared with the present mode of conveying the coals and stores by horses and carts,—an anticipation the accuracy or inaccuracy of which only the crucial test of actual results will determine.

THE DISPOSAL OF THE METROPOLITAN SEWAGE.

At the meeting of the Metropolitan Board of Works on the 26th inst., the Works and General Purposes Committee presented the following important report on the Metropolitan sewage question:—

"Your committee, on the 8th inst., made a report* on the subject of the treatment of the sewage of the metropolis, with a view to preventing its being a source of nuisance or a cause of complaint in future. They now think it desirable to make a further report, setting out the various modes of dealing with the question which have been submitted for their consideration, and the course which, after long and careful examination, they have decided to recommend the Board to adopt.

The two reports of the Royal Commission on Sewage Discharge were laid before the Board on February 8 and December 12, 1884, respectively, and were referred to your committee for consideration and report. The principal conclusions and recommendations of the Commissioners to which it was necessary to direct attention were the following:—

(2) That in the opinion of the Commissioners it is neither necessary nor justifiable to discharge the sewage of the metropolis, in its crude state, into any part of the Thames.

(3) That some process of deposition or precipitation should be used to separate the solid from the liquid portions of the sewage.

(4) That such process may be conveniently and speedily applied to the two present main outfalls.

(5) These conclusions were qualified by the opinion that the liquid so separated would not be sufficiently free from noxious matters to allow of its being discharged at the present outfalls as a permanent measure. It would require further purification; and this according to the present state of knowledge can only be done effectually by its application to land.

(6) That the solid matter deposited as sludge can be applied to the raising of low-lying lands, or burned, or dug into land, or carried away to sea.

(7) The entire process of precipitation and dealing with the sludge can be and must be effected without substantial nuisance to the neighbourhoods where they are carried on.

The Board's Engineer, Sir Joseph Bazalgette, had, it will be remembered, during the sittings of the Royal Commissioners, laid before them a plan by which the sewage from the Barking and Crossness reservoirs might be conveyed through a culvert to Thames Haven, thirty-four miles below London Bridge, and there discharged in its crude state into the Thames at ebb-tide. The attention of your committee was necessarily directed to this proposal as indicating one of the possible solutions of the problem under examination. It was, however, by no means clear to your committee, especially when they came to consider the estimates of cost, that the carrying of the sewage to Thames Haven would be either the most effective or the most economical way of dealing with it. Moreover, the proposal was open to the objection that, although places near the metropolis, such as Erith, would be relieved of the presence of the sewage, other places nearer the mouth of the river would consider themselves injured by its conveyance to their neighbourhood. This was sufficiently indicated by a communication which the Southend Local Board, immediately on hearing of the project, addressed to the Board, protesting strongly on behalf of the inhabitants of Southend against any attempts to carry out the proposal.

In connexion with this suggestion for carrying the sewage lower down the Thames, it may be mentioned that the Board received from the Home Department communications which had been addressed to the Secretary of State by Colonel A. S. Jones and Mr. Bailey Denton, bringing before him a scheme for conveying the sewage to Canvey Island, and dealing with it there. The authors of the scheme seem to have propounded it on the assumption that the Board would decide to carry the sewage to Thames Haven, a course which your committee were not prepared to recommend. It was a further element of this scheme that the Board should deliver the whole of the London sewage over to Messrs. Jones & Denton, and should make them an annual payment of 110,000l.

* Printed in the *Builder* for the 20th ult., p. 457 ante.

The view taken by your committee, and also by the Board itself, upon this part of the scheme was that it would not be consistent with the Board's duty to hand over the sewage to be dealt with by other persons in consideration of a very large annual payment, and that the Board could not rid itself of its responsibility in that manner. The Home Department and the promoters of the scheme were informed to that effect.

Your committee may here mention that they have had before them numerous suggestions from persons whose attention seems to have been given to the sewage difficulty, but that none of them have seemed to your committee to contain the promise of a satisfactory solution of it.

It appeared to your committee that the Board ought, in the first instance, to apply itself to the determination of the question whether by chemical and mechanical treatment of the sewage the liquid might not be separated from the solid matter, and further he freed of its noxious and offensive character to such an extent as to enable the effluent water to be discharged into the river without giving rise to any nuisance. The precipitation of the solid matter, and the consequent clarification of the sewage waters, could, it was found after careful experiment, be satisfactorily effected by mixing with the sewage proper proportions of lime and proto-sulphate of iron, and then allowing it to subside in settling-tanks. This, however, would not be sufficient to insure complete immunity from smell arising from secondary fermentation and a fresh development of offensive gases in hot weather. Such immunity, however, it was deemed absolutely necessary to attain.

The Royal Commissioners seem to have been of opinion that the only effectual way of attaining it was, after precipitation of the solid matter, to further purify the liquid by a process of filtration through earth, and they advised that such a process of filtration should be adopted if it were decided to discharge the sewage effluent into the Thames in the neighbourhood of the present outfalls.

The acquisition of sufficient land, however, in the neighbourhood of Barking and Crossness, to enable the vast quantity of London sewage to be effectually filtered through the soil was found, upon examination, to be attended with such great difficulty, to say nothing of cost, that the Board conceived it to be its duty to endeavour, under competent advice, to find some other method sufficiently effective to obviate the necessity of earth filtration. What was required seemed to be an oxidising agent which would not only effect the immediate destruction of any offensive odour still remaining after chemical precipitation, but which would at the same time prevent the development of offensive gases. It was found that permanganic acid was effectual in accomplishing both these objects.

Your committee were extremely anxious that there should be no mistake in the conclusion arrived at upon this important point, as upon it would mainly depend the determination of the course which the Board should be advised to take. The opinion of four of the most eminent chemists in England (one of them a member of the Royal Commission here referred to) was accordingly obtained by the Board. They all, after careful observation of the experiments produced as above mentioned, and of the effluent with lime and proto-sulphate of iron were subsequently treated with manganese of soda and sulphuric acid, it would be decolorised and purified to such an extent as to render its discharge into the river unobjectionable at all states of the tide.

With this authoritative opinion before them, your committee felt that the filtration difficulty might be regarded as overcome, and that the Board might safely conclude that the adoption of the process of precipitation, with the further resort to permanganic acid in hot weather, as proposed, would effectually render the discharge of the sewage into the river innoxious and inoffensive all through the year.

This valuable conclusion arrived at, the next question your committee had to consider was how the solid matter of sludge resulting from precipitation should be disposed of. This question, which forms the subject of the fifth recommendation in the report of the Royal Commissioners, has received long and careful attention on the part of your committee. It was thought

that, whatever might be ultimately resolved upon as the best method of disposing of the sludge, it would be necessary, in the first instance, to press it into cakes. Suitable machinery for this purpose was accordingly set up at Crossness, and was found to work with such success that the Board soon deemed it expedient to supplement the first press by a much larger one. Both of these are now in operation, in connexion with the daily treatment of nine million gallons of sewage, and there seems reason to hope that the sludge, or the cake into which it is pressed, may be found useful for agricultural purposes, and that a demand for it may thus be created. Should that hope, however, not be realised, it will be for the Board to try the alternative suggested by the Commissioners, of carrying the sludge away to sea. It may be mentioned that the Board, acting upon one of the suggestions made by the Royal Commissioners, tried for some time the process of burning the pressed cake, but this process was found to be open to objection, owing to the fumes resulting from the combustion. In anticipation of an ultimate resort to conveyance of the sludge to sea, estimates for a suitable vessel were, some time ago, invited by public advertisement, and a number of persons having complied with the invitation, the plans and estimates sent in are now being examined by the Board's Engineer and the President of the Institute of Civil Engineers, preparatory to a report to the committee.

In considering this question, it is necessary to bear in mind the enormous quantities of material that have to be dealt with. It is estimated that about 150 million gallons of sewage are daily carried down to the outfalls. Supposing this quantity to be treated according to the methods mentioned in this report, there would be a residue of 3,000 tons of sludge, which, when pressed, would leave 850 tons of cake to be disposed of daily.

It remains for your committee to refer to the cost of the operations recommended in this report, and in doing so it may be well to compare the cost with that of the only other proposal which it seemed open to the Board to adopt,—that is to say, the proposal to convey the sewage into the river at Thames Haven or Hole Haven. From information given by the Board's Engineer, it appears that the capital cost of conveying the sewage to Thames Haven, and of the works that would have to be constructed there, would be 3½ millions sterling, whereas the capital expenditure required for dealing with the sewage at the present outfalls at Barking and Crossness would be only about three-quarters of a million. Comparing now the annual cost of the two proposals, it appears that the annual cost of treating the sewage at the present outfalls, including interest on capital, depreciation of plant, wear and tear, and all other expenses, is estimated at 118,000*l.* a year, whilst the estimated annual expenditure involved in the conveyance of the sewage to Hole Haven and its treatment there by precipitation is estimated at 215,000*l.*, or nearly 100,000*l.* a year more.

Your committee conclude this report by expressing their hope that the result of their long deliberations upon this important question will meet with the Board's approval, and that the course which they have recommended for adoption will, when fully carried out, be found to effect the object which the Board has so long had in view, viz., the disposal of the sewage of the metropolis in such a manner that no nuisance shall hereafter arise from it."

On the motion of Mr. F. H. Fowler, seconded by Mr. Selway, the report was unanimously adopted.

ARCHITECTURAL SOCIETIES.

Manchester Architectural Association.—The last general meeting was held on the 30th ult., at the Diocesan Buildings. Mr. L. Booth (president) in the chair. The following gentlemen were elected as officers for the ensuing session:—President, Mr. Lawrence Booth, F.R.I.B.A.; vice-presidents, Messrs. J. H. Woodhouse and F. W. Mee; committee, Messrs. P. E. Barker, J. Brooke, T. Chadwick, F. R. L. Edwards, E. Hewitt, O. C. Hill, H. Talbot, F. W. Ward, and G. H. Willoughby; treasurer, Mr. A. H. Davies-Colley; librarian, Mr. J. S. Hodgson; registrar, Mr. F. W. Mee; secretary, Mr. J. D. Mould. A discussion on the proposed new charter was opened by the President, in which Messrs. Woodhouse, Colley, Hodgson,

Talbot, and Mee took part, which resulted in the following resolution being carried unanimously:—

"That this meeting of the Manchester Architectural Association, composed, for the most part, of architectural students and junior members of the profession, called together for the special consideration of the question of 'Federation,' desires to record its cordial approval of the project generally, and its best thanks to those who, though not agreeing in all matters of detail, are actively engaged in its promotion."

"That in the opinion of this meeting no scheme of 'Federation' is either practicable or desirable that does not include the Royal Institute of British Architects as the central and controlling power; and that such powers as the Institute already possesses under its charter could be enlarged on liberal and comprehensive principles so as to enhance the usefulness of the Institute and confer greater benefits on the community."

"That, having regard to the increased and increasing importance of the duties of an architect, powers should be obtained to prevent practising of the profession by other than qualified members."

Northern Architectural Association.—A conference was held on Tuesday afternoon, March 30th, in the Old Castle, Newcastle-on-Tyne, under the auspices of the Northern Architectural Association, to consider the question of federating existing Societies of Architects practising in the United Kingdom into one common society. The chair was occupied by Mr. E. Shewbrooks, F.R.I.B.A., when the following resolution was carried:—

"That this meeting approves of the principle of federation, and will support the scheme to be held in London under the auspices of the Society of Architects, and that a scheme for federation, if possible, be drawn up by a committee representing existing architectural societies and district meetings."

THE ARCHITECTURAL ASSOCIATION SOIREE.

THE members' soiree of the Architectural Association took place on Friday, the 26th ult., in the Westminster Town-hall, and was very well attended. The play of the evening was entitled "Forced, or, The Compulsory Examination," with the following cast:—*Faust*, Mr. J. Herbert D. Appleton; *Valentine*, Mr. J. Alfred Gotch; *Mephistopheles*, Mr. Arthur Young; *First Student*, Mr. A. C. Bulmer Booth; *Second Student*, Mr. F. Stephen Granger; *Third Student*, Mr. Thomas Edward Pryce. Symbolical characters: *Marguerite* (Architecture), Mr. C. Gordon Killmister; *Mother* ("The Institute the Mother of Architecture"), Mr. W. Cranstone. The scenes were indicated by labels to be as follows:—I., "Dr. Faust's Study." II., "The Home of Architecture, 9, Conduit-street." III., "West Front of St. Alban's Abbey." IV., "The Westminster Town-hall." Without attempting to indicate the "plot" of the piece, we may mention that the dialogue bristled with good-humoured allusions to the Obligatory Examination, to the Charter question, and to other departments of what may be called professional politics. There were some atrocious puns and some very much contorted words, but, of course, these only served to heighten the fun; and there were some amusing songs interspersed. *Faust* and *Valentine* were "made up" with just sufficient fidelity to real life to suggest rather than to indicate with precision the corporeal presence of two well-known members of the Institute. The whole piece passed off very well, and all who took part in it acquitted themselves with credit. We quote the following lines from the opening of Act II., scene 3 ("The West Front of St. Alban's Abbey"):—

[Enter Faust and Mephistopheles.]

Faust. Where are we now? What's this that looms on space.

Like a foul rash upon an old friend's face?

What ill-assorted masses here abound,

Perch'd like a nightmare on th' affrighted ground!

'Tis Gothic out of tune! I bid it stand!

To think what Fate would say of this Scandale.

Meph. Peace! 'Tis St. Alban's Abbey. Are you blind?

Faust. The effect is most un-able, to my mind.

Who comes to worship here must surely feel

It would be better if he'd gone to Neale.

From what mad brain did this abortion grow?

Who was the architect? You only know.

Meph. To Canterbury? I've no doubt you've been,

And where a Beckett met his death you've seen.

Beckett was murder'd by design, it's clear;

Design was murder'd by a Beckett here.

The choruses were well rendered by the Sutton Orphans Glee Club, while the instrumental music was provided by Mr. Stewart's Orchestral Society.

Colonial and Indian Exhibition.—Her Majesty the Queen has been graciously pleased to intimate her intention of opening the Colonial and Indian Exhibition on Tuesday, May 4th.

Illustrations.

TRANSEPT WINDOW IN DENVER CATHEDRAL.

THIS window is the companion one to the Resurrection window in the south transept, previously designed and executed on the same colossal scale. The figure of Our Lord is draped entirely in white, the only bit of colour being a rich girdle. The field of colour behind, consisting of rays of glory, is painted of amber glass, varied in tint, which extends to the side lights where the angels occur, also robed in white. The group of apostles below is richly coloured, the background consisting of graduated blue glass. The figure of Our Lord in the cartoon is over 10 ft high, the centre light being 30 ft long.

In the entire treatment of the subjects the aim has been to produce work of what may be termed "Raffaellesque" character.

NEW BOARD SCHOOLS, TREWIRGIE, REDRUTH.

THESE schools now in course of erection are situate at the south-west part of the town, and comprise accommodation for 350 boys, 175 girls, and 175 infants, each having separate entrances in connexion with cloak-rooms and lavatories.

The boys' school-room is 76 ft. by 20 ft., with five class-rooms and teachers' room. The girls' school-room is 54 ft. by 20 ft., with two class-rooms and teacher's room. The infants' school-room is 50 ft. by 22 ft., with one class-room and teacher's room.

The materials used are local stone, with granite dressings. The roofs, covered with slates, are partly open, and the ceilings boarded, stained, and varnished. The dados of the schools and class-rooms are of wood, stained and varnished, and the floors are laid with wood blocks. The porches and passages have a deal of white glazed bricks, and the floors are paved with Staffordshire quarries.

The lavatory fittings are of Macfarlane's manufacture, and the latrines are fitted up with Wilcock & Co.'s and Doulton & Co.'s apparatus. The schools are heated by open fireplaces, the flues being constructed with Doulton & Co. blue-pipes.

The architect is Mr. John Robert Nichol of the firm of G. B. Nichols & Sons, of Birmingham, whose design was selected in competition. Mr. Arthur Carkeek, of Redruth, the contractor, Mr. W. Whetter being clerk of the works.

NOS. 1 AND 2, ST. MARTIN'S-COURT LUDGATE-HILL.

THIS building is in course of erection on a site at the junction of Little Bridge-street and St. Martin's-court, City.

The external fronts facing the streets had been executed in Portland stone, the interior work is of a very plain and simple character.

In excavating the site for the foundations along the Little Bridge-street frontage a portion of the old London Wall was encountered, and, owing to its great hardness, some difficulty was experienced in its removal.

The building was designed by Mr. A. Arden, architect, for Messrs. Farebrother, Ellis, Clark & Co.; the builders being Messrs. Perry & Co. of Tredgar Works, Bow.

The Institute Charter and the Associates.—Mr. Mark H. Judge writes to us expressing his dissatisfaction with the action (inaction) of the Associates' Committee in regard to the subject of the new Charter and the position in the Institute, and asks us to state as there is no time to send a circular, that the Committee having neglected to call a meeting of Associates to give expression to their views on the new Charter, some one else must take the initiative if the Associates as a body are to make their views known to the Institute before the new Charter is passed, and he, therefore, invites the Associates to a meeting to be held at the Langham Hotel on Monday next, at 10 o'clock, for the purpose of considering the report of the Charter Committee, and to pass any resolutions as may be thought desirable for submission to the Special General Meeting of the Institute.

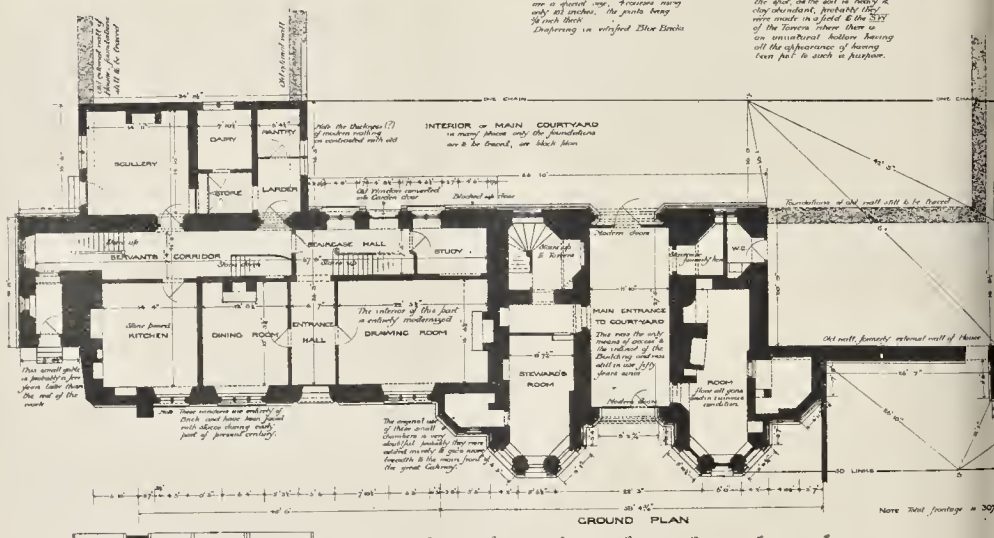

Janet's method on floor

THE ROCKY MOUNTAIN RAILWAY.

At the ordinary meeting of members at the institution of Civil Engineers, Great George-street, on Tuesday, the 16th ult., Mr. Edward Woods, vice-president, in the chair, the reading of a paper by Mr. Granville Caryle Cunningham, M.Inst.C.E., on "The Construction of the Rocky Mountain Division of the Canadian Pacific Railway during 1884," was postponed to the meeting held last week (23rd ult.). Mr. Cunningham stated that when the works were suspended for the winter of 1883 the rails had been laid to a point four miles short of the summit of the Rocky Mountains, 960 miles east of Winnipeg. Early in 1884 the summit of the Rocky Mountains, at the commencement of the Kicking Horse Pass, and at an altitude above the sea of 5,296 ft., was reached, the gradients, except in one or two cases, not exceeding 1 in 52. Passing through the Columbia Valley, the mouth of the Beaver river was reached, then the railway ascended to the summit of the Selkirks, at a point 4,300 ft. above the sea, and then on to Kamloops. The district traversed between the Rocky Mountains and the Beaver produced nothing capable of use in railway construction, except timber, chiefly spruce, for ties, sleepers, temporary bridges, trestles and culverts, a fact which necessitated the transport of material for long distances on the East. When curves occurred in connection with the maximum gradient, the grade was adjusted so that the resistance to traction could not be greater on the curved than on the straight line. The width of the cuttings in the bottom was 22 ft., with a side slope varying from 1 to 1 and 1/2 to 1. Dynamite of 7 1/2 per cent strength was used for blasting in the case of limestone, while better results were obtained from the use of black powder in the case of shale, which was very prevalent, all the drilling being done by hand labour. In the 73 1/2 miles of line constructed, there were seven tunnels, each 22 ft. in height, 16 ft. wide. The author pointed out that the increased height, as compared with European tunnels, was necessary to meet the requirements of the Canadian Railway Act, which provides that every permanent structure spanning a railway line shall give a clear space of 16 ft. above the top of a box freight-car, in order that the brakemen may not be endangered when on the roof of a car in the execution of their duty. The rails used were of the Sandberg pattern, with angle-plate joints, and secured by spikes to the sleepers. The average weight of rail used was 60 lb. to the yard; but where the gradient and curves were severe, a rail of 70 lb. to the yard was adopted. The angle-plate connexion, which has recently been introduced, and now used in Canada and the United States, in preference to the old fish-plate joint, made a very rigid and perfect track. The ties used were chiefly of spruce and jack-pine, growing on the mountains, and were laid at the rate of 3,000 to the mile, and were 6 in. thick, and not less than 6 in. on face. The wages paid for common labour were at the uniform rate of 8s. per day, and the men were charged 20s. a week for board, which was provided in a train of cars specially fitted and always located in the neighbourhood of the place where active operations were being carried on.

VISIT OF THE ARCHITECTURAL SOCIETY TO THE NEW LAW COURTS.

The fifth Saturday afternoon visit of the Architectural Association was made to the Law Courts of Justice on Saturday, the 27th March. The members assembled in the Great Hall, and were conducted through the various courts and corridors, and were shown the rooms used by the judges, and the dining-room for the bar, which is the only room decorated by Mr. Street. The members were then taken into the basement under the Great Hall, and the various engines and machinery for heating, lighting, and ventilating building. These consist of two 120-h.p. engines and a 25-h.p. engine, and eight dynamos, small engine being for working the lamps during the day time for lighting the corridors, &c. The fresh air is drawn in by means of fans, and is delivered into the courts at temperatures varying from 61° to 68°. In summer air is cooled by means of ether. The foul air is extracted by means of shafts with steam engines at the top. The machinery and boilers occupy almost all the space under the Great Hall.

SURREY ARCHÆOLOGICAL SOCIETY.

The annual meeting of this Society was held at the Whitgift Grammar School, Croydon, on Wednesday, March 24th. Dr. Alfred Carpenter presided, and was supported by the Mayor of Croydon and a very numerous audience. Dr. Carpenter moved the adoption of the report of the Council and balance-sheet for the past year, which was unanimously agreed to. The retiring members of the Council were re-elected, Mr. Watney being elected to supply a vacancy. The auditors (Messrs. J. T. Lacey and W. F. Potter), and the hon. secretary, Mr. Thos. Milbourn, were also re-elected, after which several papers were read descriptive of the old Whitgift Hospital, which had been previously visited by the company. We may here mention that this hospital has not been visited by the Society since June 12th, 1856, when a very able paper was read thereon by the late Mr. W. Pettit Griffith, and which will be found printed in *extenso* in the *Builder* of June 21st of that year.

After the routine business, Dr. Carpenter commenced by referring to the attempt at one time made to remove the Whitgift Hospital to make room for a new Town Hall, which raised such a storm of opposition that it was abandoned. Archbishop Whitgift, he said, was the greatest benefactor of the parish of Croydon ever had. To him they owed that grand foundation, — the home which sheltered forty old men and women. He then sketched out the life of Whitgift, who was the son of a merchant at Great Grimsby, down to 1577, when he became Bishop of Worcester. From that time his history became part of the history of Great Britain. He succeeded Grindal as Archbishop of Canterbury in July, 1553, and died February 29th, 1604, and was interred in Croydon Parish Church, March 27th following. The hospital was finished in 1539. The town ought to show its appreciation of Whitgift's memory. At this moment in the Parish Church of Croydon, and for the last sixteen years, there had been the embers of portions of that which was once Whitgift's monument, which had never yet been restored. It seemed to him to be a disgrace to them as a borough that that monument should remain in its present condition. It would take 500l. or 600l. to restore it. He hoped it would not be long before the inhabitants would find funds for that purpose. Having referred to the schools, Dr. Carpenter concluded by calling on Mr. J. R. Frewer to read a paper on the "History and Nature of the foundation of the Hospital."

Mr. Frewer commenced by remarking that the institution, formerly known as the Hospital of the Holy Trinity, was founded in the reign of Queen Elizabeth, in 1536. The number of the brethren and sisters fixed by the Archbishop was to be not more than forty, nor less than thirty, with a limitation of the number of sisters. These were the objects the founder had in view, and these were to a great extent embodied in the scheme approved by Her Majesty's Council, July 15th, 1581, and under which the foundation is now managed. The educational benefits originally provided by Whitgift were greatly enlarged in 1871 by the erection of the Grammar School, where now 300 boys were educated. The Middle School had also been greatly enlarged, and now accommodated 200 pupils. The letters written at the time by Samuel Finch, vicar of Croydon, gave a graphic account of the progress of the buildings, and the difficulties which arose from time to time. Some very interesting legal and other documents belonging to the hospital, which were discovered about two years ago, were shown to the meeting; these had for many years found an undisturbed resting-place in some old chests in one of the rooms of the hospital. These chests being searched, about 200 valuable parchments and papers came to light, some bearing the seals and signatures of the founder, and some going back to the reign of Edward III. Many of them were in a remarkable state of preservation, and gave instructive insight into the social and political life of the times in which they were written. The oldest deeds they had yet discovered bore date the 30th of Edward III., about 1357, and of Henry V., about 1415, and referred to properties still in possession of the foundation. Mr. Frewer said he had only briefly glanced at some of the antiquarian treasures the hospital possessed, and which had afforded him some months' pleasant occupation.

Mr. S. W. Kershaw, F.S.A., next read a paper entitled "Notes and Annals of the Whitgift's

Hospital." He said it was remarkable that Surrey possessed two such interesting buildings as the one founded by Archbishop Whitgift in Croydon, and the other by Archbishop Althott at Guildford. Both were established for the benefit of the poor belonging to, or once in the service of, the Archbishop, these charities still retain their useful objects. Their origin was to be traced to those earlier buildings which once abounded in the land, and were the asylums and refuges for the travellers, pilgrims, and the infirm in the fourteenth and fifteenth centuries. In Henry VIII's reign a commission was granted by which the hospitals and lands were to be seized for the king's use, but fortunately some escaped, and thus in various parts of the country were still found several most interesting examples of the architecture and history of the past. Whitgift Hospital was begun in 1596, and took three years in building; during that time the accounts were carefully kept and supervised by the Rev. S. Finch, and are still preserved in the Archiepiscopal Library at Lambeth Palace. The old park which belonged to the manor and see of Canterbury, was of vast extent, now locally known as Park Hill, and formed a large appendage to Croydon Palace, concerning which he hoped that modern vandalism would never be allowed to sweep away such a relic of antiquity. The interest which centred round the hospital became greater when it was known that many of the materials were obtained from the immediate neighbourhood. Its total cost was 2,716l. 11s. 11d. On Monday, July 9th, 1599, Whitgift's Hospital was dedicated to the use of the poor by Richard Bancroft, Bishop of London, and Antony Watson, Bishop of Chichester, and among those present was one George Whitgift. There was a visitation of the hospital, by Archbishop Laud, in August, 1634. As to the documents recently discovered, they were about 400 in number, and consist of court rolls, deeds, and indentures dating from the early fifteenth to the end of seventeenth century. Mr. Kershaw concluded by describing some of the most important deeds, some of which bear the signature and seals of Whitgift and members of his family and are of great interest.

Mr. H. Berney, A.R.I.B.A., then gave a short account of the pictures and paintings in the chapel of the hospital. Mr. Berney described each picture in detail, and concluded by thanking the Warden, Mr. G. Lipscombe, for cleaning and thus rendering them intelligible.

Mr. G. Lipscombe, the Warden, was then called upon by the chairman, and said from the title-deeds discovered it appeared that on the site of the Hospital formerly stood an old inn, "The Chequers," for which the founder paid 200l.; for the teneement 30l. was paid, and for some land adjoining, 50l. In building the chapel he said the most stringent economy seemed to have been observed, as the seats were made of the roughest knotted timber, which could not be used for anything else. Among the relics found were some drinking-bowls for those "above the salt" and those "below the salt," and there was also a fine old bible, known as the "treacle bible," from the fact that in the verso "Is there balm in Gilead," the word "treacle" was substituted.

Several new members were then elected, and votes of thanks to the readers of the papers and to the chairman and Court of Governors of the Hospital, being accorded, to which Dr. Carpenter, as chairman of the Court of Governors, responded, the meeting terminated.

THE NEW HOUSE OF COMMONS.

Sir,—I have naturally taken a large interest in the question originally mooted some months ago by Mr. Mitchell Henry, M.P., as to the necessary enlargement or rebuilding of the House of Commons in order that sufficient accommodation therein may be provided for the 670 members of the House, and after careful consideration of all the suggestions that have been made to the Committee of the House in 1867, 1868, and since, and after attentive study of the present building, I have come to the conclusion that it is not desirable to build over and block up the Commons Court, as was proposed by my late brother in 1867, or to do the like to the Star Chamber Court, as has also been lately suggested.

I should, on the contrary, be most anxious not to interfere with the main arrangements of the building as designed by my father by any

alteration in the position of the House, and I think that the least possible derangement in this respect affecting also the several approaches to the House will be most agreeable to the members.

I see no difficulty in effecting all that is desired by adding laterally to the House on each side to such extent as is required, and so as to provide seats for all 670 members without galleries. To do this new side division lobbies would be built in the Commons Court and Star Chamber Court respectively, diminishing their area, but still retaining a large part of the space in them, which is valuable for light and ventilation to the other parts of the building adjacent to them.

The position of the Speaker's chair and the table of the house would remain unaltered, and the bench fittings would also remain as at present, except that they should be re-spaced so as to provide additional gangway and to give more room from back to back of the seats. The arrangements at the Bar end of the House, and the Peers', Speaker's, and Strangers' galleries over the Bar would not be interfered with.

The Reporters' Gallery would remain placed as at present, but its accommodation would be considerably increased.

The present roof of the House would remain as it is, and the ceiling would be in the same form, but extended over the lateral spaces thrown into the House, thus preserving its acoustical advantages.

The warming and ventilating arrangements would need no radical changes, and only extension to the larger cubical area of the New House.

It will, I think, be evident that the scheme I propose, and which I have carefully worked out in plan and section, would be the least costly that can be suggested to meet all the known requirements. By sufficient time being given for the preparation of the work elsewhere, ready to go into its place with great expedition, I feel sure that an energetic contractor could carry out the work I propose during a single recess of Parliament, so that no temporary House would be necessary.

Another very desirable alteration could be made at the same time. The present tea-room and adjoining reading-room are very small and insufficient for their purposes. I think a better arrangement would be to place these in the river front on the principal floor where the present dining-rooms are, and to place a new suite of dining-rooms on the floor below level with the terrace and members' smoking-room. There would be no structural difficulty in doing this. A new staircase only would be needed from the library corridor to the lower floor.

If this were done the space occupied by the present tea-room and reading-room could be divided into six or seven private rooms for Ministers in close and convenient proximity to the new House in place of those now appropriated to this purpose, which are dispersed in the most inconvenient positions in different parts of the building.

It is understood that a committee is soon to be appointed to consider this important question, before whom I shall hope to be permitted to explain my views more in detail.

CHARLES BARRY.

No. 1, Westminster-chambers,
March 27th, 1886.

R.I.B.A. CHARTER.

SIR,—Although the danger of the Institute's being placed at the mercy of its own Council or being subjected to the ordinary jurisdiction of the Privy Council has probably passed away, there still remains a great chance of its suffering in future from that which has caused great inconvenience in the past, namely, finding its action limited by chance expressions in its Charter.

All the Institute requires from the Crown is an enabling charter, but it seems good to the Council to insist on the matter being considered only on the lines of a document originally drawn with the view of defining and so limiting all future action.

Having regard to the weight of the solid Council vote on divisions, I venture, with your permission, through the medium of your paper, to ask all Fellows of the Institute to be in their places on Monday and to exercise their independent judgment on the important points which will be submitted to their consideration.

LACY W. RIDGE.

CONCRETE FLOORS.

SIR,—Referring to the admirable lecture on "Concrete" reported in your this week's issue, I offer the following facts and formulae for the guidance of fellow architects and others seeking definite information on this important subject.

The "Phoenix Warehouse" (Messrs. Pearman & Corder's), of this town, erected from my designs about six years ago, is a fireproof structure, with concrete floors throughout. There are 1,800 tons of cement concrete in the floors of this building. It was only after long and patient study and research I satisfied myself that my clients' interests would not be jeopardised, but that, on the contrary, a very considerable saving of cost would be effected by the daring expedient of trusting concrete slabs (the largest of which are no less than 21 ft. by 12 ft. 6 in.) of average 13 in. thickness, to sustain the great loads and rarely impactive forces of the wholesale provision trade.

Of course, I was very careful as to the quality of cement (all of which was manufactured by Messrs. Grimshaw at North Hylton, near Sunderland), and which ranged in tensile strength from 700 lb. up to 1,000 lb. per square inch. I also endeavoured to secure that all the cement should be not less than one month old, because the cement which is hot from the heap cannot be relied on to retain its first strength.

I had the cement mixed one to four with good hard broken brick aggregate.

The result is that after six years' practical test these floors stand quite unshaken, and even those few of the slabs which before they were used cracked right across from contraction in drying, stand the heavy work, and show no indication of weakness.

There is a 12-h.p. Otto gas-engine working on the top floor, about 35 ft. above the ground, and the vibration is barely perceptible.

Two or three serious fires have occurred in this warehouse since it was opened, but beyond damage to stock and fixtures, no harm was, or very well could be, done.

Those iron girders which are used to sustain the outer edges of the large slabs above referred to are thoroughly embedded on all sides, except the soffit of the bottom flange, which is flush with the concrete ceiling.

It is important to observe that by embedding the girders thus, not only are they protected from fire, but also the concrete slabs have their edges encased, which condition adds enormously to their stiffness and strength.

The greatest stress on an *encastré* slab of any material may be found as follows:—

- L = Length of slab, in inches.
- B = Breadth " "
- D = Depth " "
- w = lb. weight per inch of slab surface-area, uniformly distributed.

$f =$ The greatest tension per inch of sectional area of slab.

$$f = 0.5 \times \frac{L^4}{L^4 + B^4} \times \frac{B^2}{D^2} \times w$$

What is required for cement concrete slabs is not a formula to represent the maximum stress, but a constant to render such formula applicable to practice.

In the case of the "Phoenix Warehouse" the maximum load per square foot of floor is about 2 cwt. imposed and 1 cwt. of concrete itself = 3 cwt. per foot, or 2.3 lb. per inch of surface area. And all the items of the formula stand as follows:—

- L = 252 inches.
- B = 150 " "
- D = 13 " "
- w = 2.3 lb.

Therefore,

$$f = 0.5 \times \frac{252^4}{252^4 + 150^4} \times \frac{150^2}{13^2} \times 2.3$$

$$f = 136 \text{ lb.}$$

Hence, it is proved that 136 lb. per inch is a safe maximum stress for cement concrete mixed 4 to 1 as before described.

I may say that some of the slabs were loaded when they were about one month old.

I believe that much larger maximum stress would be safe than that of the Phoenix Warehouse, but I would not venture on much larger slabs of that thickness and quality without wider experience to justify me.

I would, therefore, myself use the before-named formula in further practice, and take

136 lb. per inch as the safe stress for all slabs formed 4 to 1 of cement of not less than 700 lb. strength.

If one could be sure that cement concrete slabs would not be greatly loaded for the first three months after setting an allowance could be made for the enormous gain of strength which occurs during that period.

During the first twelve months after setting cement concrete is known to gain five or six times the strength it possessed at the end of the first month after setting, and the bulk of this gain occurs in the first few months of the twelve.

But, as the urgency of trade can seldom allow a clear three months for setting of concrete floors, it is safe only to calculate on tensile strength which has proved itself satisfactory under such practical conditions as the "Phoenix Buildings" present.

As regards the great density of concrete floors tending to overload the foundations of building, I do not think that it is to be feared where the concrete is not stupidly thick, and where the foundations are reasonably good for the equal distribution of load can be fairly maintained; and that is practically of no consequence than the mean intensity of the load. But where parts of the flooring are sustained by metal columns or detached pier special care should be exercised to give great spread to the footings of such detached supports.

In cases, however, where, either from insecurity of foundation, or instability of wall or from other and special reasons, an exceptionally light, and yet strong, fireproof floor is needed. Hollow terra-cotta blocks, filled with "lime riddlings" or other light suitable material, and fitted together as shown by Messrs. Doulton at the Inventions Exhibition last summer, are worthy of consideration.

But for ordinary cases, cement concrete applied to the "Phoenix Warehouse" is, I am satisfied, the cheapest and best form of fireproof flooring.

FRANK CAWSE.

Sunderland, 27th March, 1886.

ROYAL ACADEMY.

SIR,—I hope this year's architectural exhibition will be better than last, and that that may be less cause of complaint. I am sending anything myself, so am not pleading my own case, but last year there were 2 architectural drawings hung, twenty-one of which were of inferior merit, forty-eight were designs which probably may never be executed (being a design for a Christmas card), while from seven men thirty-five drawings were accepted, and many meritorious works reject

T. E. KNIGHTLEY

STAINED GLASS.

Exeter.—A large and important window seven-lights has just been filled with stained glass in the north transept of Exeter Cathedral and called the "Women's Window" from the fact of its cost having been defrayed by Devonshire women of all classes. The idea of such a window was originated by the Archdeacon of Exeter, but the selection of the subjects upon which the work of Miss E. Marriot, of the Church of Exeter; the design has been made by Harding & Co., of Birmingham, and the execution of the work has been carried out conjointly by the artists and Mr. F. Drake, of Exeter. The ceiling is somewhat larger than the others, and contains the figure of the Blessed Virgin robed in white, with three lamps, emblematic of Faith, Hope, and Charity, in the upper part; above this, in a small trefoil opening, forms part of the same light, is the half-length figure of Eve. The other six lights are filled with full-length figures:—First, Miriam, with her timbrel in her hand, representative of Poetry, Art, and Accomplishments; second, the Queen of Sheba, types high rank and intellect; third, the little girl of Israel, expressive of domestic service; fourth, Lydia, the seller of purple, representative trade and commerce; fifth, Eunice, representative of Piety; sixth, Timothy, setting forth the special work of women, the training of the young; and sixth, Dorcas, expressing personal service to Christ in His poor. The openings in the tracery chiefly of grisaille work, but in the eight feet of the large circle are half-length figures

arah and Ruth, intended to set forth Christ as the light of the Gentiles and the glory of Israel; Martha and Mary to show His consecration in human friendship; of Rahab and the woman with the alabaster box, to represent Him as the saviour of sinners; and of the widow of Naim, to point to Christ as the Resurrection and the Life. The work is described as being of great beauty both in colour and design. The figures are by Messrs. Hardman. The window was opened with a short dedicatory service on the appropriate festival of Lady Day. It may be mentioned that this window, irrespective of the glass, is one of almost unequalled beauty in design, and it is said that the late Sir Gilbert Scott loved to dwell upon its charms whenever he visited the cathedral during the work of restoration.

London.—A large single-light stained glass window has just been erected in Stationers' Hall, London. The subject represented is a figure of St. Cecilia holding in her hands the symphonical organ, with a background of sky relieved by trees and foliage, while the foreground is also of foliage interspersed with bright flowers. The figure, which is nearly 8 ft. high, surmounted by a Classic canopy, in the centre of which are the arms of the present Master of the Stationers' Company, through whose generosity the window has been placed, while at the sides of the canopy are Cherubs holding cords, which is suspended a tablet bearing the name St. Cecilia, the whole being supported on alabaster pillars and surrounded by a border. The work has been designed and executed by Messrs. Mayer & Co.

Nettlecombe.—A Munich stained glass window, consisting of two lights with tracery, has just been erected at the south end of the Raleigh School of Nettlecombe Church, near Taunton. The subjects represented are, in the one light, "Giving Bread," and, in the other, "Teaching Ignorant." The work has been designed and carried out by Messrs. Mayer & Co., of Norwich and London.

The Student's Column.

OUR BUILDING STONES.—IV.
VARIATION IN TEMPERATURE.

ANOTHER cause of the disintegration of rocks is by considerable variations in temperature. Its effects on building stones used in Great Britain are no doubt very slight, but in countries where there is a great annual range of temperature, much injury is experienced in selecting building materials from this cause. Even in this country it is as well to know something about it, for stones are frequently required to stand fierce heat; whilst if the services of a student are required in other lands, where general effects are more appreciable, it will be useful to him. Rocks are expanded by heat and contracted by cooling. Variation in temperature thus causes some building stones to alternately expand and contract, and this prevents the joints of masonry from remaining close and tight. In the United States, with an annual thermometer range of more than 90° Fahr., a difficulty led to some experiments on the amount of expansion and contraction in different kinds of building stones. It was found that in a-grained granite the rate of expansion was 0.004825 for every degree Fahr. of increment of heat; in white crystalline marble it was 0.005663; and in red sandstone 0.0009552, about twice as much as in granite.* In Western America, where the climate is markedly dry and clear, the thermometer can give a range of more than 80° in twenty-four hours. This great difference of temperature produces a strain so great that it causes rocks to crack or peel off in skins or irregular pieces, or, in some cases, it disintegrates them to sand.

Dr. Livingstone found in Africa (12° S. lat., E. long.) that surfaces of rock which during day were heated up to 137° Fahr. cooled so rapidly by radiation at night that, unable to sustain the strain of contraction, they split and flew off sharp angular fragments from a few feet to 100 lb. or 200 lb. in weight,† according to data obtained from Adie

"Trans. Roy. Soc. Edin.," xiii., p. 366, and Totten (before quoted) we are able to estimate that the expansion of ordinary rocks ranges from about 2.47 to 9.63 millionths for 1° Fahr.* "Any stone exposed to very different degrees of heat on its different faces is liable to crack from unequal expansion and contraction" (Wray, "On Stone").

The effect of a conflagration on some exceedingly durable building stones is very disastrous, and especially on those which were formed by heat.

THE EFFECTS OF WIND ON STONE.

Wind is both a destroying and a preserving agent. Its action as a destroyer of building stone consists in blowing sand and dust against the building, which wears away the stone by chipping particles of it off.

Wind also blows dust and dirt into cuttings, holes, and lines in exposed mouldings, and fills them up, adding much to the disfigurement of ornamental buildings.

A strong wind accompanied by rain, by blowing the rain hard against a building, causes it to penetrate into the stone farther than it would otherwise do, and thus the chemical action of rain and the effects of frost on the stone are increased.

The principal preservative action of wind is in its drying out moisture from stone, and the acids, &c., contained in the moisture have, therefore, less time to act on it.

This, together with the action of the sun in preserving stone, will be further referred to when treating of the best modes of placing stones in building, in order to make them last as long as possible.

BORING MOLLUSCS, AND HOW THEY DESTROY STONE.

The action of molluscs, which are capable of boring into stones used in the construction of piers, breakwaters, and embankments, is so very important that engineers have devised various methods of trying to get rid of the evil. Myriads of these marine animals congregate on the stone, and make their holes so close together that they eventually weaken it by removing its substance, thus leaving open cavities for rain and sea water to fill and promote decay. Portland Breakwater, amongst other large works, has been seriously damaged by these molluscs.

The principal actors are known by the names of *pholas*, *lithodomus*, *gastrochœna*, and *saxicava*. The first of these (*pholas*) bores into a variety of substances,—limestone amongst them. The *pholas*-shell is rough, like a file, and sufficiently hard to abrade limestone, and the animal is able to turn from side to side, or even quite round, in the hole it has made. The action is probably a "mechanical" one, aided by the foot of the animal.

With respect to the other three genera of molluscs mentioned, it is difficult to understand how they can possibly wear away the stone by a mechanical means. They bore only into calcareous rocks and attack the hardest marble. The valves of the animals cannot assist them in making their holes, for, unlike *pholas* they are smooth, and, in addition, are covered with epidermis,—a thin membrane,—neither does the foot help. Their power of moving is also extremely limited, the cells not being cylindrical, whilst *saxicava* is fixed in its crypt by a thread called a *byssus*. They have been supposed to dissolve rock by chemical means, although all attempts to detect the presence of an acid secretion have hitherto failed, as might be expected; for the hypothesis of an acid solvent supposes only a very feeble but continuous action, such as in nature always works out the greatest results in the end.†

The best way, no doubt, of overcoming the destructive action of these creatures is to build the breakwater or pier of such stone, as is too hard for them to bore into. Methods have been adopted by casing the stone with copper or other similar metal.

We might remark that the molluscs mentioned live only in the sea, or between high and low water mark, so that in selecting stone for riverside wharfs, embankments, or piers of bridges over rivers, these destroying agents need not be taken into account.

ON SELECTING PIECES OF STONE FOR EXAMINATION.

The precautions it is necessary to take before beginning to experiment on turning stress, specific gravity, and microscopic examination of stone, are as numerous as they are important.

One of the first things to do is to select piece of stone for examination. When convenient, they should be obtained *in situ*, or at least in the quarry.

Very often one quarry produces three or four kinds of stone for sale. There are generally differences in the grain, compactness, or chemical composition, of each of these kinds, which render them useful for specific purposes. One may be a better freestone than the others, and so is used for exterior mouldings and carved work; a second, perhaps, through being softer and not of a very durable nature, is fit for interior work only; a third, though it is durable under ordinary circumstances, may not be capable of being raised in blocks large enough for building purposes, and is therefore used as road metal, &c.

It sometimes happens, even after great care has been exercised in selecting a stone for a public building, that when the stratum has been singled out to serve the purpose, the selection has proved a failure for want of uniformity in grain and quality as the bed is worked into,—an unforeseen accident.

The chemical composition and physical features of stones found on the same horizon, and in the same quarry, are frequently found to vary within certain limits; whilst occasionally, although these characters are persistent for some distance, the natural joints of the rock eventually become so close together, that the stone is only fit for rubble-work. Thus, we see the great importance of not only specifying that the stone shall come from a particular stratum, but that the quarrying of the stone should be watched, and blocks examined as the work progresses.

Now and then the particular stratum, when worked into, contrary to all expectation, thins out, and the remainder of a large building must then be finished with other stones. With respect to the quantity of stone thus becoming reduced,—there can be no doubt that, in a great majority of cases, a careful geological examination of the district wherein the quarry is situated, would soon put that matter at rest. Assuming that this point is settled, let us now see how to collect pieces of stone for indoor examination.

Students are strongly advised to go as often as convenient to some of the large quarries, and select their own specimens. They will see there how the stones weather, better than in any other place, and get an idea of the different methods by which the stones are quarried, seasoned, and shaped. If it is intended to use the stone for building in a city, the additional destructive effects of the smoky atmosphere in rotting stone must be taken into account, as previously explained.

Having arrived at the quarry, it is easy to find the best bed used for building purposes, and (1) going into the heart of the working, a piece of stone should be knocked off. This piece should be retained to show the presence and amount of "quarry water." (2) Then proceed to the place where the stone is being seasoned, and obtain a specimen of the seasoned stone, but be careful to make quite sure that it originally came from the same bed as the previous specimen. (3) If the quarry-working is in the open air, go to the face of the rock, and follow the same bed away from the present workings, and (if the quarry has been opened long enough) get a piece of old weathered stone. (4) If the quarry-working is underground, and the particular bed does not come to the surface of the ground, it is of very little use to obtain a piece of stone from the workings. A block which has been brought into the open air for some years should be sought for. This will be weathered, and will answer our purpose quite well. When chipping a piece from it, inquire how long it has been quarried.

In securing these pieces, average-looking samples should always be obtained. The tendency is to bring away pieces which present some peculiarity, and which, of course, would not be fair specimens. Odd pieces lying about the quarry should never be taken away, but, in all cases, the stone should be obtained from the workings, or from a large block, the horizon of which when *in situ* is certain.

* See also experiments by Pfaff, "Z. Deutsch. Geol. Ges.," xiv., p. 493, &c.
† Woodward's "Manual of the Mollusca" (1850), p. 385; also Hancock, "Ann. Nat. Hist.," October, 1849.

* Totten, "Amer. Jour. Sci.," xxii., p. 136.
Livingstone's "Zambesi," pp. 492-516.

It cannot be too strongly urged that each specimen intended to be carried away should have a label affixed to it, on the spot where it was obtained, giving the name of the quarry, bed, and stating whether it is weathered, unweathered, or seasoned.

The numerous grave errors arising from inattention to little points like these are sufficient to warrant their strict observance. If the information obtained respecting the stones is not put down at the time, it is remarkable how soon things become mixed up or forgotten. A very good plan is to give each stone a number, and especially if a tour of different quarries is being undertaken. This number should be entered in the note-book, and everything relating to the stone it refers to should follow after. Besides general information, the note-book should also contain—

1. A rough vertical section of the quarry, giving the thicknesses of the various beds.
2. The size of the average, and the largest blocks which can be raised for building purposes.
3. The quantity of stone estimated as capable of being raised from the best beds.
4. The methods of quarrying.
5. The appearance of the stone in the quarry, weathered and unweathered.
6. The period which is usually allowed to elapse between the time when the stone is quarried and before it is thoroughly seasoned and ready for use.
7. The method of seasoning.

It is advisable to have samples of stone for examination sent direct from the quarry, when not convenient to go thither to obtain them personally.

Books.

Interior Decoration: A Practical Treatise on Surface Decoration, with Notes on Colour, Stencilling, and Panel Painting. By FRED. MILLER. London: Wynan & Sons.

This is a very useful treatise by a practical artist who may be trusted as a teacher of whatever is teachable in the art of the decorator. With patience every one drawing from draughtsman, and much judicious practice from nature and from the best examples of decorative work will give some facility in design. But colour is a gift and the fact is admitted by the author, who avows explicitly that no rules can be given for harmonious colouring. The student may be told, indeed, that such and such colours so mixed and broken produce such and such results. But the proportions to be used cannot be expressed by formulae, but depend on feeling; and this quality, though it may be cultivated and improved, cannot be imparted to those who are destitute of it. "Where a room is decorated in tones of one colour it is not a very difficult matter to produce a pleasing effect." But the decorator should be something more than a worker in monochrome, though how he shall work and by what means he is to produce his effects must be left to his own instinctive feeling of the beautiful. The writer discards the employment of positive colour,—holding that the nearer a tint approaches to a primary colour the less suitable it is to decorative requirements. He would work almost entirely in secondary and tertiary tones, although the latter of which, in the oft-expressed opinion of such colourists as the late William Burges, are not colours at all, but "nud." The author is, perhaps, a little too severe in this regard, and scarcely gives enough weight to the use of positive colour in Oriental schemes of decoration. It is to the careful adjustment of the quantities of pure colour employed that the decorator should address himself. That the colour schemes of the Medieval artists would be found too crude for modern practice may be at once conceded, but colour as positive and bright was successfully used by the Moors, and may be used again by those who have the Moorish feeling. "Pure vermilion" and "black" ceilings (pp. 93 and 129) are daring experiments, and are not likely to be attempted by the tyro.

The book is copiously illustrated, and the suggestions for stencilled ornament are all good, and every page supplies matter for profitable thought.

Dictionnaire des Marques et Monogrammes des Graveurs. Par GEO. DUPLESSIS et HENRI BOUTCHOT. Paris: Jules Rouam, 1885.

This beautifully-printed little book gives fac-similes of the customary monograms

and other methods of signing their names on their works, adopted by the principal engravers whose works have obtained name and fame in the history of the art. It does not profess to exhaust the subject, by going after rare or out-of-the-way initials or monograms; it is intended as a guide to the amateur in recognising the work of the known masters of the art. Each monogram is accompanied by a record of the date of birth and death of the engraver concerned, and the localities where both are known. The book is arranged as a dictionary, alphabetically. Of the authors, M. Duplessis is curator of the Engraving Department in the National Library of France, and M. Bouchot the "archiviste" and sub-librarian in the same department.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

- 10,940, Door-knobs. R. R. Parker.
The knob is secured to the spindle by a pin passing through it. A fine adjustment is obtained by making two series of holes at right angles through the spindle, and two holes at right angles in the neck of the knob, one slightly in advance of the other. The pin is secured by a collar screwing on the neck of the knob or fitting loosely thereon.
- 13,918, Street Gas Lamp. T. Pickett.
This invention consists in making the lantern triangular, and in fixing the sheets of glass by sliding them in grooves. Strips of glass are placed on each side to receive the names of streets or other announcements.
- 16,480, Window-sash Fastener. W. Reynolds.
The stem of the fastener, which is fixed on the stile of the bottom sash, has ratchet teeth, which enter a box on the opposite sash. This contains a lever, which engages with a rack securing the window in a closed position, or preventing any further opening if the window be partially open for ventilation. The back plate of the box presses on the curved portion of the stem, and draws the sashes together when closed. A projection which is cast on the fastener near the box prevents the insertion of a knife or other instrument so as to tamper with the fastening.
- 16,574, Indicating Door-bolt. A. A. King.
The bolt moves an arm carrying a disc. A spring prevents the bolt from being partially shot, the knob is mounted on a collar turning freely on the bolt to allow the knob to be turned down in the slot in the bolt case. The word "engaged," or other indicating word, is marked on the disc, and is exposed when the bolt is shot, or the discis plain and covers or uncovers a word on the door according as the bolt is fastened or fastened.
- 16,817, Fanlights and Skylights. R. Adams.
Relates to a method of opening fanlights by means of a notched link or lever at the side of the window or fanlight frame. Several alternative methods are incorporated in the specification, and to prevent slamming a door, check may be used in combination with any form of the apparatus.
- 16,893, Furnace Bricks and Linings, and Concrete Walls. J. Gillespie.
These bricks, or their outer faces only, are of fire-clay, and for the purpose of affording a hold for a gannet or other silicious lining, they are formed with projecting pins or ridges, which may be either in the solid with the brick, or made separately, and afterwards inserted, or holes may be employed with a similar object. They are specially applicable to the building of concrete walls.
- 16,894, Garden Training Walls. J. Gillespie.
Special bricks are employed for building these walls. The body of the bricks is made of common red or dark clay. To the exposed side or end of the brick is dovetailed, or cemented a block or tile of a superior clay. This block may be so glazed and coloured as to reflect the light most beneficial to vegetation. Recesses are moulded (with or without projecting pieces) in the brick to facilitate the training of trees, flowers, and wall plants by tying up.
- 16,630, Stone-working Machines. F. Trier.
This machine for dressing stone acts in a manner analogous to that of a planer, by dressing the stone with cutters which travel backwards and forwards, over the surface. The cutters are disc-shaped, and act alternately on the stone.

NEW APPLICATIONS FOR PATENTS.

- March 19.—3,874, T. Ford, Hydraulic differential power Lift.—3,881, W. Hill, Alarm for Windows, Doors, and Shutters.—3,903, G. Knight, Step Ladders.—3,909, H. Peters, Portland Cement.
- March 20.—3,928, A. Huxley and Others, Syphon Flushing Cisterns.—3,941, W. Macvittie, Attaching Door Knobs and Handles to Spindles.—3,944, T. Humpage and E. Shaw, Improved Sew.—3,945, H. Abrecker and N. Grew, Water-meters.—3,949, F. Humperson, Forming Sockets on Lead Pipes.—3,953, C. Jones and F. Haseldine, Portable Book-

case.—3,961, S. Frankenberg, Cement for Laying Mosaic Work, &c.

March 21.—4,000, Joints and Connections Pipes.—4,001, R. Hall, Urinals.—4,005, C. M. Ford, Guards for Circular Saws.

March 22.—4,031, T. Shipman, Heating Buings, &c., by Hot Water.—4,035, E. Wharling, Sanitary Pan.—4,039, T. Pessel and I. M. Chimney-cowl.—4,050, A. Henderson, Automatic Flushing Closet-pans.—4,065, S. Gerish, Spring Hinges.

March 24.—4,091, C. Greenfield, Trap for Drains.—4,101, S. Bamford, Chimney-tops.—4,110, Abbott, Opening and Closing Main Valves in Water-closets.—4,123, W. Sissons, Fastenings for Fall-pipe Rain-water Pipes, &c.—4,128, T. Gardener, Fastener for Window-sashes, &c.—4,153, T. and J. H. Flushing Apparatus for Water-closets, Urinals, &c.—4,160, J. Osmond, Holding Doors or Casements Windows partly open.

March 25.—4,164, D. Brecknill and T. Mall, Soldering Iron.—4,192, R. Hope, Folding Portable Table.—4,218, H. Minns, Ornamental Boards, &c.—4,224, A. Ryles, Ornamenting Panels, Tiles, &c.—4,229, M. Ismay, Double Swing Doors.

PROVISIONAL SPECIFICATIONS ACCEPTED.

- 15,436, R. Oates and J. Green, Gallies and Traps.—2,240, F. Winsor, Water-waste Preventer.—2,241, C. Groombridge and J. Rickman, Door Chain.—2,419, J. Hicken, Fixing Door Handles to Spindles.—2,421, W. Sanderson, Door Lock and Latch Furniture.—2,497, S. Fisher, Wall or Ceiling Covering.—2,558, G. Priestley, Window Fasteners.—2,567, S. Pardoe and J. Biggs, Sash Fastener.—2,687, W. Sanderson, Cupboard and Door Catches.—2,711, T. Panario, Overflow Pipe for Syphonic Cisterns.—2,841, A. Pilling, Self-closing Doors.—2,846, H. Birch, Window Sashes and Sashes.—2,850, J. Panio, Water-waste Preventer.—2,872, R. Thorpe and P. Castle-Smith, Window Fastenings.—2,873, W. Ross, Water-waste Preventer.—2,235, W. Farley, Flushing Cisterns.—2,326, R. Rae, Water-closets.—2,531, W. Egglestone, Water-closet.—2,730, S. Kershaw, Coupling for Pipe Joints.—2,742, H. Colclough, Frost-resisting Tap.—2,747, W. Martin, Window Sash Fastener, &c.—2,943, S. Sowden and W. Cowan, Hinges.—2,967, H. Hicks and C. Tight, Levels.—3,003, J. Flete, Ventilating Covers for Sewers.—3,012, W. I. Balancing Window Sashes.—3,139, F. Hannam, Hinge.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to opposition for two months.

- 6,441, C. Foster, Paving of Streets, &c.—7, A. Patrick, Glazed Bricks, Sewage pipes, &c.—7,131, J. and A. Clarke, Box Flues and Flues for Fire Grates.—7,239, H. Allan, Securing and other Pipes.—7,311, G. Garrard, Pressing Iron.—7,330, R. Hunter and J. Turnhill, Kit Ranges.—1,787, W. Lake, Screw-threaded Nuts.—2,257, L. Nash, Water Meters.—2,439, Openshaw, Fastening Rain-water and other Pipes.—2,491, J. Strang, Cement.—2,559, C. Spack, Manufacture of Portland Cement.—2,755, J. A. Duckett, Cisterns for Flushing Water-closets Urinals.

RECENT SALES OF PROPERTY.

ESTATE EXCHANGE REPORT.

MARCH 18.

By THURGOOD & MARTIN.
Croydon, Arundel-road—A Plot of Freehold Land, 8, Gloucester-road, "Hope Cottage," freehold, South Wimbledon—2 to 8 even, South-road, freehold

MARCH 22.

By J. BROWN.
Old Ford—143, Grove-road, 85 years, ground-rent 27, 10s.
Mile End—2 to 8 even, Peacock-place, freehold
Chelsea—10, Upper Manor-street, 16 years, ground-rent 10s.

By HARMAN BROS.

Canonbury—5 and 6, Alwyne-square, 10 years, ground-rent 29l.
By REVOLVES & EXON.
Shoreditch—29 and 31, Mead-street, freehold
Haggerston—29, Dove-row, freehold
Kingsland—72, Kingsbury-road, freehold

By C. & H. WARRER.

Pinhoe—An Improved Rental of 47l. a year, term 39 years
Katon-square—12, Caroline-street, 35 years, ground-rent 54l.
Pinhoe-rent—The Duke of Cambridge's beer-house, term 8 years

By WOOD & SYKES.

Hampton, Orchard-pieces—The Lease, Goodwill, and Plant of the "Albert Works," term 17 years
By A. J. BAZZLEY.
Stepney—Ground-rent of 12l. a year, reversion in 45 years
11, 12, and 14, Ben Jonson-road, 12 years, ground-rent 12s. Carr-street, freehold,

By DOWSETT & WOOD.

Whitechapel—21 to 37 odd, Chick-end-street, 23 to 33 odd, Cannon-street, 14 to 35 even, 12 to 13 even, Spelman-street, and 1 to 13, John-court, freehold, area 18,330 ft.
Peckham, Cambridge-place—Ground-rent of 18l. reversion in 67 years
Ground-rent of 6l., reversion in 63 years
Ground-rent of 11l., reversion in 63 years

By FAIRBANK, ROBERTS, & Co.
 Stoke Newington—3, Gordon-road, 74 years, ground-rent 4l. 6s. 2800

By DEBENTHAM, TEWSON, & Co.
 Hampstead—7, 9, and 11, Hall-street, freehold..... 1,640
 King's Cross-road—No. 31, freehold, 40 years, ground-rent 4l. 8s. 747
 Holloway—119, Seven Sisters-road, freehold..... 1,750
 North Kensington—129, Olonester-road, 33 years, ground-rent 3l. 12s. 430
 Chelsea—87, King's-road, "The Old Black Dog," 21 years, ground-rent 6l. 8s. 1,700
 Clarges—30, 31, and 32, Trinity-square, 9 years, ground-rent 11l. 4s. 420
 Grosvenor—45, Cow Cross-street, and 19, Beaumont-street, freehold..... 1,700
 Wood-street—A profit rental of 230l., term 13 years..... 1,900
 John's Wood—20, Marlborough-road, 61 years, ground-rent 10l. 350
 7, Finchley-place, 32 years, ground-rent 8l. 350

By OTZMANN & Co.
 Tottenham Court-road—14, Stephan-street, 11 years, ground-rent 10l. 210
 Leclonion-road—89, Harrington-street, 40 years, ground-rent 4l. 8s. 650
 13, Edward-street, 39 years, ground-rent 6l. 650
 26, Harrington-street, 38 years, ground-rent 650
 146, Hampstead-road, 66 years, ground-rent 6l. 1,400

MARCH 24

By HOOKER & WEBB.
 North Crodon, Barham-road—"Ingoldby Villa," freehold..... 520
 Clapton—6, Rigdon-street, freehold..... 235
 Leclonion-road—31A, Stock Orchard-crescent, 56 years, ground-rent 7l. 450
 Holloway—49 at 30, Tottenham-road, 62 years, ground-rent 12l. 12s. 830
 38, Grove-road, 77 years, ground-rent 7l. 450
 4, Bryant-road, 62 years, ground-rent 24l. 1,175

By GIBSON & SONS.
 George's East—8, William-street, 30 years, ground-rent 12l. 185
 Commercial-road—15 and 48, Jane-street, 15 years, ground-rent 4l. 15s. 200
 40 and 42, Jane-street, 15 years, ground-rent 4l. 15s. 185
 41, 15s. 1,800
 Bedford—10 to 6, Great Eastern-road, freehold..... 1,800

By J. L. DAVEY.
 Commercial-road—55, Tottenham-road, 46 years, ground-rent 3l. 280
 Aldstone, near Harrow—Two Plots of Freehold Land..... 99

MARCH 25

By GLASIER & SONS.
 Wimbledon—Enclosures of Freehold Land, 58s. 1r. 16p. 19,600

MEETINGS.

SATURDAY, APRIL 3.

Association of Public Sanitary Inspectors.—Dr. Alfred Ingham on "Sanitary Legislation." 6 p.m.
 Society of Arts (Special Lectures).—Professor George S. S. on "Electricity." 3 p.m.
 Edinburgh Architectural Association.—Visit to the Edinburgh Museum of Science and Art. 2.30 p.m.

MONDAY, APRIL 5.

Royal Institute of British Architects.—Special General Meeting of Members, considering Amended Draft of Charter. 7 (seven) p.m.
 Society of Arts (Cantor Lectures).—Mr. Alan S. Cole on Arts of Tapestry-making and Embroidery." I. 7 p.m.
 Society of Engineers.—Mr. Arthur Riaz on "Obscure as a Reciprocation in High Speed Steam Engines." 7 p.m.
 Builders' Works' Association.—Third Annual Dinner, at Restaurant. 7 p.m.

Society of Chemical Industry.—Professor Unwin on "The Principles and Methods of Testing Cementing Materials." 8 p.m. (Special meeting, in Technical Institute, Exhibition-road, Kensington.)
 Victoria Institute.—8 p.m.
 Inventors' Institute.—8 p.m.
 Leeds and Yorkshire Architectural Society.—Presentation of Annual Report, and Election of Officers.

TUESDAY, APRIL 6.

Institution of Civil Engineers.—Dr. Percy F. Frankland on "Water Purification: its Biological and Chemical Basis." 8 p.m.
 Society of Biblical Archaeology.—Papers by Mr. Le Page Renouf and Dr. Louis Amanat. 8 p.m.

WEDNESDAY, APRIL 7.

Carpenters' Hall, London Wall.—Mr. Banister Fletcher, M.P., on "The Influence of Architecture upon Carpentry." 8 p.m.
 Society of Arts.—Mr. J. S. Hudson on "The Preparation of Drawings for Photographic Reproduction." 8 p.m.
 British Archaeological Association.—(1) The Rev. J. J. Daxell on "A Pictorial Enclosure on Langley Barrell Common." (2) Mr. Thomas Morgan on "The Roman Monument at Piet's Bridge, Durham." 8 p.m.
 Civil and Mechanical Engineers' Society.—Mr. A. Ivor Smith on "The Working and Interlocking of Railway Signals, &c., by Electricity." 7 p.m.
 Builders' Foremen and Clerks of Works' Institution.—Ordinary Meeting. 8.30 p.m.

THURSDAY, APRIL 8.

Society of Telegraph-Engineers and Electricians.—Continued discussion on Mr. Alexander Bernstein's paper on "Electric Lighting by means of Low Resistance Glow Lamps." 8 p.m.
 Society of Arts.—Mr. James Boyd on "Asbestos and its Applications." 8 p.m.
 Society of Antiquaries.—8.30 p.m.
 St. Paul's Ecclesiastical Society.—7.30 p.m.

FRIDAY, APRIL 9.

Architectural Association.—Mr. G. R. Redgrave on "Ind. or Architecture." 7.30 p.m.
 Institution of Civil Engineers.—Mr. Ollibert M. Hunter on "Locomotive Engine and Carriage Sheds as used on the Caledonian Railway." 7.30 p.m.

SATURDAY, APRIL 10.

Architectural Association.—Visit to the Constitutional Club, Northumberland-avenue. Members to assemble at 3 p.m.
 Royal Institution.—Professor Oliver Lodge on "Fuel and Smoke." 3 p.m.
 Edinburgh Architectural Association.—Visit to Hatton House.
 Society of Arts.—Professor George Forbes, M.A., on "Electricity." II. 3 p.m.

Miscellaneous.

The Parkes Museum.—The following lectures and demonstrations for the instruction of sanitary inspectors, have been arranged for, on Wednesdays and Saturdays at eight p.m.:—April 3rd (1), introductory lecture,—"General History, Principles, and Methods of Hygiene," by Mr. George Wilson, M.A., M.D., F.R.S.E.; April 7th (2), "Ventilation, Measurement of Cubic Space, &c.," by Prof. F. de Chamont, M.D., F.R.S.; April 10th (3), "Water Supply, Drinking Water, Pollution of Water," by Prof. W. H. Corfield, M.A., M.D.; April 14th (4), "Drainage, Construction," by Prof. H. Robinson, M.Inst.C.E.; April 17th (5), "Sanitary Appliances," by Mr. W. Baasie, C.E., F.L.S., F.G.S.; May 1st (6), "Scavenging and Disposal of Refuse," by Mr. H. Percy Boudoin, M.Inst.C.E.; May 5th (7), "Food (good and bad), Milk, Sale of Food and Drugs Act," by Mr. C. E. Cassal, F.O.S., F.I.C.; May 8th (8), "Infectious Diseases and Methods of Disinfection," by Mr. Shirley F. Murphy, M.R.C.S.; May 12th (9), "General Powers and Duties of Inspectors of Nuisances,—Method of Inspection," by Mr. J. F. J. Sykes, B.Sc., M.R.C.S.; May 15th (10), "Nature of Nuisances, including Nuisances the Abatement of which is difficult," Mr. J. F. J. Sykes, B.Sc., M.R.C.S.; May 19th (11), Sanitary Law,—General Enactments, Public Health Act, 1875, Model By-laws," by Mr. A. Wynter Blyth, M.R.C.S., L.S.A.; May 23rd (12), "Metropolitan Acts, By-laws of Metropolitan Board of Works," by Mr. A. Wynter Blyth, M.R.C.S., L.S.A. A nominal fee only of 5s. for the course will be charged to cover expenses.

The Banner Sanitation Company.—Messrs. Banner, Bros., & Co., sanitary engineers, have removed from Billiter-street to Wessex House, Northumberland-avenue, opposite the entrance to the Hotel Métropole, where they will carry on business in future under the title of the "Banner Sanitation Company," and where they have arranged a permanent exhibition of models, illustrative of their system of domestic appliances, more especially applicable to drainage, ventilation, heating, lighting, water-supply, and electric fittings.

Building Trades' Exhibition.—The annual Building Trades' Exhibition in the Agricultural Hall, Islington, will open on Monday next, April 5, and will close on the 17th inst.

Provident Institution of Builders' Foremen and Clerks of Works.—On Saturday last the members of this Institution paid a visit, on the kind invitation of Mr. Rashleigh, clerk of works, to the new museum and classroom now in course of building from the drawings of Mr. Basil Champneys at Harrow Schools. The members assembled at Baker-street Station, and took the train to Harrow, and on the road to the schools paid a visit to Harrow Church. At the new museum, Mr. Rashleigh, and Mr. Winn, foreman for the contractor (Mr. Foster, builder, of Bedford), acted as guides, explaining the details of construction. The members, who were greatly gratified by seeing such good work, next paid a visit to the Speech-room, and afterwards to the chapel, erected by Sir Gilbert Scott. They then returned to the new museum, where Mr. Rashleigh had kindly provided a cold collation. Subsequently Mr. Duffy, the patentee of the solid lead flooring which is being used at the new buildings, explained his system of flooring, which has already been described in the Builder, claiming for it great advantages resulting from the dwelling of the blocks, thereby making a most rigid floor. Several of the members spoke of the practical value of such visits as this, and expressed the hope that other of their members who might be in charge of important works would copy the example set by Mr. Rashleigh, and that the Institution would have many excursions of a similar nature.

The Proposed Simplon Tunnel.—The principal project for a railway tunnel through the Simplon by which it is intended to provide a shorter and quicker route for the Eastern and Northern parts of France, and Western Switzerland, to Italy, has been for some time past under consideration of the Swiss Federal Council. Its leading feature is a tunnel through the base of Mount Simplon. The cutting would be of the length of 19,000 metres, or about twelve and a half English miles, thus making it the longest tunnel in the world. The expense of such an undertaking would, of course, be prodigious, and this fact has suggested a rival scheme, which was recently submitted to the Swiss Council. According to the latter project a tunnel is to be carried through the mountain at a height of more than 5,000 ft. above the sea level, and its length would only be 4,800 metres, or about three English miles. The approaches both on the northern and southern side of the tunnel would be by a line having a gradient of one in ten, which it is proposed to work by a toothed wheel locomotive, capable of performing a traffic of 1,200 tons a day, whereas, according to the best estimates, the average would not be more than 740 tons. The rate of speed upon the approaches and through the tunnel is calculated at fourteen kilometres an hour for passenger trains, and ten kilometres for goods trains, so that the length of the journey for this part of the line would be one and a quarter and two hours respectively. The number of trains passing daily in both directions would be sixteen, and the total cost of carrying out the latter and less ambitious scheme is estimated at not more than 14,000,000 francs, or 1,600,000 sterling.

The Preservation of Iron Structures.—Mr. B. Baker, writing to *Engineering*, says:—"Any facts connected with the preservation of iron structures are of the highest interest to engineers. I may mention, therefore, that in recently testing the old links of the Hammersmith Bridge, which will be utilised in erecting the Forth Bridge, I was much struck with the perfect state of the iron. Under direct tensile or cold bending stresses the paint scaled off in large elastic flakes, and the surfaces of the bars were as clean and as blue as in fresh rolled iron. In none of the links tested by me was there any trace of oxidation under the paint, although the chains of a suspension-bridge, with the deep narrow spaces between the links, are by no means the easiest to cover. I was the more impressed with this result as in several of the more recent bridges across the Thames it is no exaggeration to say nearly an inch of rust has accumulated between the links. To what is this difference due? The Hammersmith Bridge was built sixty years ago. Can any specialist say what was the probable mode of preparing the paint then used? According to my experience, the revival of its manufacture is much to be desired."

The Value of Building Land at Wimbledon.—Last week a large portion of the Wimbledon Park Estate, through which the Wimbledon and West Metropolitan Railway, which is about to be constructed, will pass, was brought into the auction market at the instance of the mortgagees, on behalf of whom Messrs. Glaisher & Sons offered for sale 73 acres. The particulars stated that the property already possessed upwards of 7,000 ft. of frontages, in addition to which new roads could be formed to the extent of 9,000 ft., giving building frontages of about 16,000 ft. The property was submitted in two lots, the first lot offered consisting of 58 acres, which was sold for 19,000*l.*, being at the rate of about 340*l.* per acre. It transpired that the purchase had been effected by a syndicate, with the view of immediately developing the estate for building purposes simultaneously with the construction of the railway now about to be commenced, and which includes the erection of a bridge across the Thames from the Fulham Station of the Metropolitan District Railway to Putney. The second lot submitted, immediately to the west, and containing 15 acres, was put up at 9,000*l.*, and no advance having been made upon that since it was withdrawn, the auctioneer observing that its peculiar situation rendered it still more valuable for building purposes than the lot just sold. Subsequently, however, the vendors agreed to sell it for 9,000*l.*, and it was disposed of for that sum by private contract, the purchasers of the first lot being also the buyers, at the rate of 600*l.* an acre.

Good Flat Roofs.—For town buildings, flat roofs have many advantages, but when used they should be thoroughly well constructed. Two of the best roofs of this kind which we have seen for some time are the one at the new City police station in Cloak-lane, Cannon-street, and that of the new stores of the Army and Navy Auxiliary Supply Association in Francis-street, Westminster. The roof of the former building will afford a pleasant promenade for the many men who will be quartered in the building. It has a superficial area of about 2,600 feet, and consists of a layer, one inch in thickness, of the finest Pyramont Seyssel asphalt, laid on concrete carried by iron joists, there being skirtings of the same material all round the parapets, chimneys, &c. The work has been excellently done, and to impart a pleasing appearance to the surface as well as to afford a good foothold, a thin layer of very fine and clean pebbles from the seashore is applied while the asphalt is hot. The roof at Westminster is of the same character, and has a superficies of about 12,000 square feet. The roofs at both these buildings have been laid by Claridge's Patent Asphalt Company, who have long been favourably known for the excellence of their work and material.

Lloyds' Rooms.—Messrs. A. Smith & Stevens have recently connected their hydraulic balance lift at Lloyd's Rooms, Royal Exchange, with the Hydraulic Power Company's mains. This lift is now making about forty journeys per hour, and is probably carrying more passengers than any other lift in London, the estimated number being over 1,000 per day.

A Correction.—The Campbell Tile Co., of Stoke-npon-Trent, write to say that the floor tiles in Caudon Church, mentioned on page 490, under the head of "Church Building News," were supplied by them and not by Messrs. Minton.

Technical Education in New South Wales.—For the benefit of artisans engaged in the building trades, classes have been established in decoration, plumbing, bricklaying, wood-carving, carpentry, and joinery; and many of those classes the syllabus of instruction is identical with that in use at the Finsbury Technical College. Recently, the Council of the City Guilds Institute have received an application to extend their technological examinations to the Colony, and to award certificates and prizes on the results. This application is at present under the consideration of a Committee of the Institute.—*Nature.*

The late Mr. Alfred Burges.—In the obituary notice of this gentleman in our last, for "A. Deane" read T. Drane.

Obituary.—Mr. J. H. Read, managing partner in the firm of Messrs. John & Henry Coaks, builders, decorators, &c., of Grove-road, Mile-end, died a few days ago, aged 34. During the recent severe weather he was attacked with acute bronchitis, about a week prior to his death.

The Department of Public Works in Japan having recently been abolished as a separate office of State, much interest is felt, especially by scientific Europeans in the Japanese service, as to the future fate of the Imperial College of Engineering, which, since its establishment, has been under the control of the Minister of Public Works. It has been attached now to the Education Department, but it is uncertain whether it will remain a separate college, or will be incorporated with the University of Tokio. In the latter case a considerable re-adjustment of the staff would take place, as the University has already professors of most of the subjects taught at the Engineering College, and a number of holders of Chairs of scientific subjects would be redundant. Commenting on this subject, the *Japan Mail* says that graduates of the College are found doing useful work in every part of the empire, and so high is the esteem in which they are held that to have been educated there is a certain passport to employment. It possesses the handsomest buildings and the most perfectly equipped laboratories and museums of any educational institution in Japan,—the University not excepted,—and hence it would be a pity to destroy the individuality of an institution which has been so markedly successful. Accordingly it is suggested that the wisest plan would be to affiliate it to the University, and to transfer the engineering classes of the latter to its care. If any Japanese institution may be said to be British, the Engineering College may be said to be so from its foundation until the present moment. Its Chairs have all been held by English men of science, and are still held by them.—*Nature.*

The Hiramant Tunnel.—At the students' meeting of the Institution of Civil Engineers, held on Friday, the 26th ult., Mr. James Mansergh, M.I.C.E., in the chair, Mr. W. A. Legg submitted a paper on "The Construction of the Hiramant Tunnel on the line of Aqueduct of the Yrnwy Waterworks for the supply of Liverpool." The author explained that this tunnel formed the first portion of the aqueduct of the Yrnwy Waterworks, now being constructed for the supply of water to Liverpool. Its section is a circle of 7 ft. in diameter, and its length 3,903 yards, having a gradient of 1 in 2,540. The Corporation had undertaken to drive to the rock at each end. The first 128 yards of tunnelling at the inlet end and 267 yards at the outlet end, both passing through clay, were formed 12 ft. square, and lined with brickwork consisting of four rings, set in cement and backed with concrete. This brickwork extended to 1,061 cubic yards at a cost of 3*l.* 10*s.* 4*d.* per yard. For mortar, pulverised quartz obtained from a disused lead mine in the neighbourhood, was used, as no sand could be got near. The proportions for the mortar were 2 to 1, and for the concrete 8 to 1, the latter costing 1*l.* 3*s.* 10*d.* per cubic yard. Blasting and machine drilling by compressed air, were the means adopted for driving through the rock portion of the tunnel. Two drills, working at about 500 strokes per minute, were employed simultaneously at each heading; the air-compressor, when working at 120 revolutions per minute, being capable of delivering 33 cubic feet of air at 60 lb. pressure along 3 in. cast-iron flanged pipes. For each round of blasting about twenty-three holes were drilled, dynamite being almost exclusively used. While the tunnel was ventilated by exhaust air from the drills during the operation of drilling, air for ventilation was supplied from a Blake's blower during the removal of the spoil, the compressed air pipes serving both the purpose of feeding the drills and ventilation, being regulated by a system of valves. The two headings met on the 30th of September, 1885, when it was discovered that a difference of only 2*1/2* in. existed in the centre lines, and only 0*22* ft. in. in the levels, over a distance of 3,506 yards, being the length of the tunnel. The average progress during the last fourteen months of the work had been 4*1/4* yards per day.

The Excavations at Winchester Cathedral.

IN our issue of the 13th of February, page 259, reference was made to the excavation of the foundations of a portion of what was supposed to be the New Minster, founded by King Edward the Elder close to the cathedral, or old Minster, of Winchester. The workmen have laid bare the foundations of what appears to be a nave measuring about 85 ft. from east to west, and about 49 ft. wide internal measurement, with a chancel continuous with the nave or nearly so, 63 ft. long, with apparently the same width, the proportion thus being almost exactly three squares, one for the width to three for the length. The walls have been traced entirely round the south side, the west end, and portions only of the north wall of the nave and the east end of the chancel, the work of excavating being discontinued only from very slender evidences of the existence of the walls being met with, traces of rough foundations alone remaining at a depth of about 8 ft. from the present level of the ground. The south wall is, for the most part, solid from its foundations up to about a foot of the present surface. The excavations show that the whole of the site consists of made ground, which rendered it necessary for the foundations to be carried down to a firmer basis, the earth being full of fragments of Roman brick, rough pottery, tiles, and such like. The walls are roughly constructed of small-sized rubble and flints, laid herringbone-wise in some places, with broken Roman brick at intervals, put together with brown gravelly mortar. The ground level is about 1 ft. 10 in. below the present surface, and here there is a set-off of about 2 in. on each side, on which the fair wall, which is 3 ft. 6 in. thick, commences, but it remains only 1 ft. high, the whole of the upper portion having been removed. It is formed of small-sized stones and flints, laid more closely than the foundation, and solidly bedded in a very good mortar of whiter colour than below. At the south-west angle the foundations remain of a very small square enclosure, ft. 5 in. by 5 ft. 6 in. Its walls measure ft. 2 in. in thickness on the east side, and ft. 3 in. on the north side. There is no sign of an entrance-door: the level remaining, but the form of the chamber suggests the base of a small tower or turret. No trace remains of floor, and there is nothing to guide conjecture

as to how this building, whatever was its nature, was floored, nor are there any indications of the walls having been plastered. There are traces, and no more than traces, of what appear to have been two internal buttresses or piers, within the nave, on the south side, and of a larger one at the junction with what we have called the chancel; but there is no projection either of pilaster, pier, or buttress along the whole 157 ft. of the outer face of this south wall, a circumstance not a little remarkable. There is no special evidence of style or age, but the appearance of the masonry is sufficient to show that it is very early work, very different from the earliest Norman work in the adjacent cathedral. Such, in fact, are the feeble traces which very painstaking search has revealed. No more have been met with. The result is not so satisfactory as might have been expected, and it must be a matter of regret that the building had been so completely demolished as to leave such slender signs of its former existence to reward the explorers. While there is so little in the remains thus found to show anything of the stateliness we should expect from a royal foundation of such an important class as New Minster appears to have been, there is a doubt in some minds as to whether or not the remains met with are not those of one or another of the Saxon cathedrals of Winchester rather than those of New Minster. In our issue of February 20th (p. 295), the Dean, under whose direction all the works of clearance are being carried out, "thinks it unlikely that the New Minster would have been built on the southernmost line of their territory," and favours the opinion that the remains are those of some former cathedral. The consideration of local matters of detail merely from references to monastic chroniclers is, doubtless, a work of difficulty and uncertainty, likely to be set aside by some fortunate discovery or by some more direct evidence. Still, the subject of the relative positions of New Minster and the cathedral is sufficiently curious as to warrant a short space being devoted to its consideration. We have already, p. 259, referred to the statement that the New Minster was close to the old one at its foundation, it being partly in the cemetery of the latter, on a contracted and costly site. The excavations show that the burials come close up to the south wall, while the wall itself, without projection or transept, seems to show that it was so designed to form a boundary line. At any rate, had this been the intention the building, whatever it was, could not have been planned better to suit the ground, supposing that the intention was to come close up to the boundary. Then there is the reference

to the removal of New Minster on account of the troubles consequent upon the ringing of the bells, &c., owing to its proximity to the cathedral. The actual nearest distance from the Norman transept of the latter is but 27 ft., a sufficiently small distance to occasion trouble; but if the foundations are not those of New Minster it must follow that the latter was on some other site which would have been further away, which would have lessened the trouble referred to, if not have prevented it altogether. The small distance, therefore, supports the statement of the old chroniclers, and is in favour of the site being that of New Minster. A good deal of weight must be attached to the references of the Norman rebuilding of Winchester Cathedral by Bishop Walkelin, for if it can be shown that a new site was then chosen for the building, then it follows that some little uncertainty may attach to the identification of New Minster. While we know that the Saxon cathedral was close to New Minster, it is the Norman cathedral which is referred to as experiencing the evils from the proximity, thus supporting the belief that the Normans rebuilt upon the old site, as was the almost universal custom. We may conclude that they commenced the rebuilding at the east, and probably extended the building westward. The records of that event show that Walkelin left standing the domestic buildings while he was erecting the new ones, and that for some time after the cathedral had been rebuilt and the new domestic buildings occupied, a portion (one altar) of the old Saxon church was left standing. Now this is more consistent with the supposition that Walkelin rebuilt his church on the same axis, but more to the west, than that he went to a new site altogether; for if the foundations now laid open are those of the old cathedral, then the old domestic buildings, if in their usual place on the south side, would have been in the way of his work. But we find there is an ancient cemetery in this place, which prevents the supposition that there were buildings there. Is not this more likely to have been the cemetery of the cathedral, in its proper position on the north side, in relation to the present church, rather than the cemetery of a cathedral more to the north, on its south, or unusual, side? But Rudbourne tells us that Walkelin took down the western portion of the old domestic buildings to enable him to rebuild them, which also points to the fact that he was working on the same lines, but more to the west, of the old Saxon work. A curious little structural point has been brought more prominently forward by the removal of earth from the crypt of the cathedral, which appears to

support the same line of reasoning. The whole of Walkelyn's work is faced with squared stone with wide joints, alike on the inner and outer faces of the crypt. At the junction of the charming Norman crypt of Walkelyn's Lady-chapel, where its eastern apse ends at the western commencement of Bishop Lucy's extension, there is to be seen on the north side and also on the south side alike,

known to us of such a building of such dimensions. The largest churches of Saxon date in existence are cruciform; that in Dover Castle and some others having its tower over the crossing; that at Worth, cruciform and having no original tower at all. The plan of the old cathedral of Sidnacester (Stow) appears also to have been cruciform from the portion of the north transept remaining. The plan of a nave

from the earth only a little below them, the shafts being about one half buried, their bases being completely out of sight, and the walls appearing very low. The enormous mass of accumulated earth is being gradually carried away in baskets, and as it thus appears a finely altered appearance is the result.

The piers are being opened out to view to their entire height, and their bases revealed,

Plan of Remains Discovered.

a mass of rubble walling formed of small stones, remarkably like the early work of the foundations we have been describing. While the contrast of these fragments is at once apparent as being unlike the Norman work, it is still different to the thirteenth-century work of Lucy's. That it existed before the work of the latter bishop is at once apparent, for the first, the most westernmost, of his wall shafts, north and south, is made of less height than the others in consequence of the existence of these masses of masonry. His work is accommodated to them. It is within the bounds of fair reasoning to say that these fragments of walling mark the east end of the Saxon cathedral. If so, they are conclusive that the latter stood on the same site as the present one, and we may suppose that Walkelyn, while completing his choir, left the Saxon choir standing for a time, so as not to interfere with the services, and on its site he afterwards erected his curious long Lady-chapel, bringing its east end up to the extreme end of the old Saxon work. No settlement has occurred on any of this portion of the work, but it may be noticed that Lucy's eastern extension has sunk materially to the east. This is not evidence of very much value, but we may assume, on the hypothesis stated, that a site occupied by buildings for a long series of years would be firmer than the extended portion on new ground.

Be these foundations what they may, and slender as they are, they are worthy of all the attention we can bestow upon them, since they illustrate a subject of which we know so little, namely, what was the plan of a large Saxon church?

These remains appear to indicate to us that there was a church consisting of a long nave without aisles (unless the great width between the walls was divided by wooden columns, which is not unlikely) joined to a similar aisleless chancel, a plan unlike anything at present

and chancel only is familiar enough to us, since it occurs in a great number of Saxon churches, but only in buildings of small or moderate size, nothing at all equaling the length of the foundations now laid open, and which we must consider as being unique in respect to their size. In the cases referred to the chancels are of less width than their naves, a distinction not observed here.

A comparison with some of the largest of our pre-Norman churches may not be without interest. These are mostly of small dimensions, and the following buildings, fairly moderate as are their sizes, have to be referred to as the largest. The cathedral of Sidnacester, as it may fairly claim to be, is, perhaps, the first as regards dimensions, the Saxon transepts having a length of about 90 ft., the present nave and chancel being about 150 ft., and the original was probably longer. Brixworth is about 136 ft. long; church in Dover Castle, 117 ft.; Worth, 98 ft.; Stanton Lacy, another transeptal church, 64 ft., without its later chancel. The chancel of Jarrow Church is 42 ft. long, which shows that it was part of a building of some size.

So far as regards width, there is little in anything actually existing to compare with the width of 49 ft.; Brixworth nave is about 32 ft. wide; Reculvers nave, 23 ft. 6 in., nave and aisles, 43 ft. 6 in.; Worth, 23 ft.; Dover Castle, 27 ft.; Stanton Lacy, 20 ft.; Jarrow chancel, 16 ft. 6 in. These figures are given approximately only from various published plans.

Let us turn to the works in progress in the crypt of the cathedral. Any one who is familiar with this fine old work will be most agreeably pleased with the altered appearance which is taking place day by day. The old proportions were so seriously destroyed by the level of the earth being several feet above the original floor line, that the work could only be studied under great disadvantage, the curious caps of the heavy central columns emerging

the excavations being carried down to the original level. Strange to say, except in the eastern extension, no traces of paving have been met with. The columns and walls appear more than double their recent height, and the fine effect of the work can be considered. Several masses of modern masonry have been removed to lay open the old work, and some tamperings with the vaulting have been seen, but the blocks of stonework which

COLUMN IN CRYPT

support the Waynflete and Beaufort chantries in the choir above are bound to remain mute as they obstruct the view. Their construction shows that the filling up of the crypt is a recent work.

As is well known, the crypt of Walkelyn's Lady-chapel remains in all but perfect condition, notwithstanding that the chapel itself soon gave place to Bishop Lucy's extended work. It indicates precisely the size an

place of what Walkelyn erected. It has a range of central shafts, consisting of single columns, but their effect has been marred for centuries by a mass of walling built between them. This is being removed in order to detach the columns, and when completed a charming effect will result when seen from their junction with the crypt of the cathedral, the pointed-arch work of Lucy's square east-ended extension being in full view beyond it.

The walls of Walkelyn's work were pointed with a broad square band of excellent mortar, fully 1 in. wide, the joints being neatly squared.

Some of this pointing has always been visible in various parts of the cathedral, but the recent works have demonstrated that it is original, and not done at some later period, for it is found in perfect condition on some of the portions of walling which have now been opened to view after having been hurried for many centuries. The internal walls have never been plastered, only the vaulting; and there is no evidence that colour has been used to any portion.

THE INSTITUTE AND ITS CHARTER.

AFTER two meetings, one continued to a late hour on Monday evening, and the second occupying the greater part of Tuesday, the general meeting of the Institute of Architects has adopted, in the main, the form of charter as recommended by the Charter Committee, only one or two of the numerous alterations made in the wording affecting it in any important principle.

It is not our intention to report in any detailed manner the proceedings of what was essentially a private meeting; the official reports already in the hands of those whom it specially concerns. Some portion of the proceedings on Monday, indeed, are much better fitted unrecorded; and the member who made the principal attack on the proposals of the committee, in one of the most discourteous and unseemly speeches that we ever had the misfortune to listen to, ought to feel that he owes some gratitude to the persons whom he attacked in this manner for their expressions of willingness, at the close of the second meeting, to condone and forgive an exhibition of superlative oratory which, however, is not likely to be altogether forgotten. Apart from this, the proceedings at the two meetings may be regarded as satisfactory in their results.

A great many points were considered in a very full and mostly business-like spirit, and (what more) a conclusion was arrived at, and by a process of taking the meetings consecutively till the matter was gone through, by country members who had attended for the purpose of taking part in the debate were enabled to see it through without the inconvenience of a long stay or a second visit to London for the purpose; an inconvenience of which they have complained, with good reason, on former occasions, when important debates have been cut short and adjourned to a distant date. To two of the provincial members, it may be observed, Mr. Cannon (Leeds), and Mr. Aldridge (Liverpool), the meeting owed a very excellent and useful suggestion; among the London members who have shown an interest in the subject, the Institute ought to feel much indebted to one of its younger members, Mr. E. T. Hall, who has been the originator of a great number of modifications in the form and wording of the Charter, a large portion of which have been adopted, and which it is to establish their author in a reputation of merit for practical business qualities. The new Charter as now proposed perhaps on the side of being over full in its provisions, though on going through them *seriatim* it does not appear that there was much in them which could very well be omitted. The most important modifications made were, indeed, in the form of addition rather than subtraction. With regard to the clause providing that Associates should have future voting powers, subjoined definition or restriction by by-laws, the Charter rather rashly went into definitions on this point, partly from a wish to have done with this wholesome subject, partly on the ground

suggested by one or two speakers, that matters of privilege were much better incorporated in the Charter for good and all, and that there was less chance then of their being overturned or meddled with at any future time. The result was the modification of clause 19, to the effect that in future Associates should be entitled to vote on all questions except the making of by-laws: a result which seemed to give satisfaction to the Associate members present, as indeed it ought. We question the wisdom of conceding as much as that at present; but if it puts to rest a cause of contention it may be as well that a definite conclusion was arrived at without further loss of time. There are a great many members among the Associate class, no doubt, who would be perfectly competent and desirable voters on every subject that comes before the general meetings; of the feeling of some of these there is excellent evidence in the letter from Mr. Richards Julian which we print in another column. But there are unfortunately others who are not. The reasonableness of the views of some of these gentlemen may be gauged by the fact that some of those present openly intimated that they considered they ought to have the same votes and privileges as the Fellows in every way, while paying only an Associate's subscription; and the fitness of some other gentlemen for the additional influence they seek to obtain may be estimated by the fact that three or four of them were reported to have voted clandestinely in the debate of Monday evening; nor is this all that might be said. The best of the Associates would probably prefer to forego for the present some privileges for which they are perfectly qualified, rather than share them with such coadjutors. We very much doubt whether some of the members of the Council are fully alive to the possible consequence to the status of the Institute of the provision which they lightly and good-lumouredly passed. They have bestowed the power of voting the election of Fellows on a body more numerous than the Fellows, and containing a certain proportion of men who have not, and perhaps never will have, any very high status, either socially or professionally. Considering the possible combinations in voting for Fellows elected from the class of Associates under these circumstances, the Council will do well to exercise their right of decision as to the putting up of candidates with extra care and discrimination, if they wish to preserve to the Institute the high character and tone which, amid whatever other shortcomings, has always hitherto belonged to it. Ultimately, no doubt, the effect of the compulsory examination on entrance will be to put a bar on the election of undesirable members, and to assist in maintaining a universally high standard both of character and capability.

The other main addition made to the form of the Charter was, on the motion of Mr. Hall, to retain in the preamble the words relating to the spirit and intention in which it was originally conferred, mentioning the importance and dignity of the art of architecture and the desire of the Sovereign who conferred the Charter to assist the architects in their aim of further developing and improving so noble an art, &c. This, as we have before observed, may be considered less necessary now that the importance of architecture is more generally recognised and admitted; but we are glad the meeting decided to retain the words, because they are, in the first place, exceedingly dignified and admirable in expression, and set up a very high view of the subject, and because also they are of interest historically as evidence of the feeling and spirit in which the original Charter was conferred.

We hope the Charter, as now approved by the general meeting, will before long be confirmed and conferred. With this freer scope for its action, the Institute, having got through the formal business necessary to give it the foot-hold for a new start, ought to take up with fresh vigour the higher task of promoting and raising the art of architecture in the spirit embodied in those words of the preamble of the original Charter, which it has wisely determined to keep on record.

NOTES.

THE action of the Railway directors with regard to Mr. Mundella's Bill has had precisely the effect we anticipated. The alarm created amongst shareholders has forced stock upon the market, and a feeling of great uneasiness prevails. The directors have received the support of the shareholders generally, as the latter are very much in the dark as to the real merits of the case, but the press unite in condemning the exaggerated statements which have been made, and the same may be said of the Stock Exchange. The *Economist*, while naturally sympathising with the directors to a certain extent, is of opinion that much that has been said is nonsense,—and mischievous nonsense,—and that the directors must alter their tactics if they wish to achieve any success. It is very improbable that the Bill will be rejected, as the opposition is narrowing down to three or four clauses, and the resolutions passed at the more moderate of the shareholders' meetings were in favour of amendment rather than rejection. The attitude of the traders may be judged by the remarks of the Railway Rates Committee and the Railway and Canal Traders' Association. The former body, in their report presented to the Chambers of Agriculture on the 6th inst., recommend that support be given to the second reading of the measure, though considering it necessary to propose amendments if the Bill is to be accepted as a satisfactory solution of the existing controversy, while the Traders' Association, after condemning the Bill as it at present stands, remarks:—"Nevertheless, we have so much confidence in the public spirit of the present House of Commons that we believe it would be safe to allow the Bill to pass the second reading, and that its vices may be cured in Committee." Both parties look for benefit from the measure, and both find clauses that go against the grain, and the Bill will, doubtless, undergo considerable alterations before becoming law.

WE may note that on Friday, the 2nd inst., on the motion of Mr. W. H. Smith, it was resolved that a Select Committee be appointed "to reconsider the plans and proposals for an Admiralty and a War Office," which in itself we are glad of, as there is, we hope, some chance that the site may be rearranged on the lines suggested by the Institute of Architects. The only information added in regard to the points for the consideration of the Committee, however, is rather ominous, as it is "that it be an instruction to the Committee to report whether some or all of the existing buildings of the Admiralty may with advantage be retained." This looks like a further development of the wretched spirit of parsimony which is practised in regard to Governmental architecture in this country, in place of any preconceived wish to carry out the scheme in a manner more worthy of the nation. We earnestly hope that some Members of Parliament who have a real knowledge of and interest in architecture for its own sake will find a place on the Committee.

THE case of Saunders v. Pawley, which was recently discussed before a Divisional Court, involves points which are of some importance to the public at large as well as to our readers. The trial of this action took place in June last before Mr. Justice Day and a special jury, the claim being for damages against an architect, by reason of injuries sustained through the alleged fraudulent representations of the defendant as regards the sanitary condition of a house at Norwood. It was also alleged by the plaintiff that there was a breach of contract, inasmuch as the defendant had stated that the system of drainage was good and had been approved by the Local Sanitary Authority. The case, as presented on behalf of the plaintiff, was that sewer gas escaped into the house at the time of the letting and afterwards, resulting in the serious illness of some of the servants and in the death of the plaintiff's wife from blood-poisoning. This lady had enjoyed an income of 800l. a year, and, by reason of the loss

occasioned through her death, and of various expenses necessarily incurred, the plaintiff claimed the sum of 2,400l. The jury returned a verdict for the full amount, but execution was stayed upon the defendant paying into Court the sum of 1,000l., pending an application for a new trial, or, in the alternative, that judgment should be entered for the defendant. The arguments in support of this application, and *contra*, have now been heard, and in the result the verdict is set aside, and the defendant obtains judgment, execution being stayed, however, for ten days, in the event of the plaintiff deciding to go to the Court of Appeal. Upon the question whether a civil action could be maintained for the loss sustained by a man in consequence of the death of his wife, Mr. Justice Grove pronounced an unhesitating negative. Upon the other point, as to the alleged representations of the sanitary state of the premises, the Court decided that there was nothing in the evidence to justify the verdict, inasmuch as it had not been shown that the defendant had made any representations which he did not at the time believe to be true; in other words, there was nothing fraudulent or dishonest in his conduct. The case should, however, serve to make people cautious as regards making representations in answer to the inquiries of incoming tenants.

It is to be regretted that the London daily papers do not follow the fashion of many provincial papers and publish the evidence taken before Select Committees of the House of Commons. Thus the *Freesman's Journal* has recently printed pretty nearly *in extenso* the evidence given by Mr. Robinson, a civil engineer and a member of the Kingstown Town Commissioners, before the Select Committee on the Tenure of Houses in Towns. From his evidence it would appear that leases are renewed in Kingstown on unreasonably high terms; thus a lease at a rent of 6l. 10s. a year is renewed for 26l. a year, and then another example of an enormous increase. But we fail to find in Mr. Robinson's evidence at what date the old leases began,—a very important factor in estimating the justice or injustice of the new rents. It does not follow that because a man has been paying too low a rent for ten years he is to be allowed to go on doing so. It is clear the whole question largely hinges on this. We are sorry also to find that the had system of leases for lives still continues in Kingstown. Mr. Robinson also mentioned many instances of overcrowding and of houses falling into decay, all of which evils he put down to the leasehold system. It has, doubtless, many evils to answer for, but we can scarcely put all of these matters to its door. If a woman, as Mr. Robinson stated, lives in a room 6 ft. by 9 ft. and 5 ft. high, with an open dustpit and a privy by its side, we should certainly say that this is the fault of the sanitary authorities, not of a system of leasehold tenure.

At the ordinary meeting of the Institution of Civil Engineers, held on Tuesday, the 6th inst., Sir Frederick Bramwell, F.R.S., President, in the chair, Dr. Percy Frankland read a paper on "Water Purification: its Biological and Chemical Basis." In considering the various attempts to purify water by the removal of suspended particles, he said that the passage of micro-organisms through filtering material had long been considered, and, until recently, there seemed to be little reason to doubt that the majority of filtering substances offered no barrier; but a series of carefully-conducted experiments had recently proved that certain materials are less favourable than others to their passage; and this degree of efficiency was more or less maintained by a frequent renewal of the filtering material. He had found invariably, that very porous substances, like coke, animal and vegetable charcoal, were highly efficient in removing organic matter from water when the latter came in contact with them by a process of agitation. Dr. Clark's precipitation process for softening water with lime had a most marked effect in removing micro-organisms

from water. The process consists merely in the addition of a small quantity of slaked lime. The chemical improvement resulting from this softening process is not often considerable; but it is found to reduce the presence of micro-organisms 98 per cent. He was satisfied that the only explanation of the freedom from micro-organisms of water taken direct from deep wells was to be found in the fact of its having been subjected to a long and exhaustive process of natural filtration. He thought the effect of this natural filtration upon the biological condition of water could not be better understood than by comparing water obtained from the Thames and the Lea with deep-well water taken from the chalk near London. While, in the last case, as few as eight organisms per cubic centimetre will not unfrequently be found, the number in the case of the two former may, and often does, reach as many thousands.

A REPORT on the sanitary arrangements in various parts of Italy is of considerable interest in these international days, when so many English elect, for climatic and other reasons, to make their home in foreign countries. There are 8,259 communes in Italy, and of these there are only 318 which have thought it worth while to keep up any inspection of the water-supply. Of these, 198 have good drinking-water, 85 tolerable, and 35 bad; of the remainder (a very large majority) 1,454 allow that the water is either indifferent or very bad, while 509 have returned the supply as being very scanty. There are 4,877 communes totally unprovided with sewers, and 1,503 from which no information was received, the inference therefore being that nothing good could be reported. As to dwellings, 37,296 were subterranean, giving shelter to 101,457 persons, while 2,836 deplored the dearth of salubrious habitations. In the Abruzzi, the Basilicata, Apulia, and the Roman Campagna, many families live in hollows scooped out of the rock or tufa. In 1,876 communes there are no latrines, and the sewage remains in open ditches, close to the houses. In 3,976 there are closets, but only in the houses of the well-to-do. In 158 communes the excrements are emptied out of the windows into the street, where they remain until dispersed by the combined action of wind, rain, and scavenger dogs. In 1,483 communes the houses are unprovided with chimneys to the fireplaces, so that the only exit for the smoke is the door or the window. In 259 *circondari*, 194 are more or less troubled with malaria, which spreads over at least 90,000 square kilometres, and affects about 6,000,000 people. In 1879 there were in Italy 97,855 persons suffering from pellagra (the result of malaria), and this number had increased by 1881 to 104,067. Between 1835 and 1885 Italy has been visited seventeen times by cholera. To wind up this rather unsatisfactory condition of things, 326 communes have no burial-ground.

THE building trades of Rome, where a very large number of new houses are in course of construction, are greatly exercised at the sudden collapse of many of these schemes, sometimes even before the buildings are finished. The rage for speculative undertakings of this kind is becoming as great a nuisance in some parts of Italy as it is in England; but although scamped work is no novelty with us, it has never gone to the same length as at Rome. About a fortnight ago a large building gave way at Prato di Castello while a number of masons were at work upon it, and several were killed; while, more recently, another house has fallen, though it had been in existence longer than the other. The evil has become so serious that the municipality has at last issued an order that the owner of every building in course of erection must make a return of the name of the architect employed, accompanied by a declaration of the latter that he accepts the responsibility of any accident that may occur. Until this is done, the works will not be allowed to proceed. The architects have one and all concurred in this, and have

come forward most creditably to assume the supervision of all future operations. There is clearly a great need of some such system, seeing that the number of skilled masons in Rome is comparatively small, and that the great majority of the workers are men who have never been on a roof-top in their life, but whom lack of agricultural employment has driven into the towns to gain a livelihood as best they can.

THE recently decided case of Kiddle & Son v. Lovett ought to afford a lesson to those who, having entered into a lawsuit, hurry hastily into a compromise. It was an action by a firm of builders who had taken a contract to paint the outside of a house. They engaged a separate contractor to put up bost-staging for the purposes of the work. During the progress of the work some of the staging gave way, so that one of the painters was thrown into the street and injured. He brought an action against Messrs. Kiddle & Son under the Employers' Liability Act. They, just before the case came on for trial, settled the action for a sum of 125l. Then they brought the present action to recover this sum as damages from the contractors who had put up the staging. Mr. Justice Denman held that they were entitled to recover against the contractors, because they had erected a defective staging, but he also held that Messrs. Kiddle & Son could not recover the damages paid to their workman, because he had no right of action against them, since no act of negligence had been committed by them or their servants, and, consequently, they were under no liability to pay the 125l. Therefore, they obtained judgment for nominal damages only, without costs. The unfortunate position of Messrs. Kiddle, who compromised the action in which they were right and fought out that in which they were practically wrong, certainly provokes a smile.

SOME little time since we commented on the fact that in the Birmingham Workhouse Infirmary Competition, the architect who prepared the particulars on which the instructions were based was not, as he should have been, debarred from competing, and we drew attention to the feeling expressed in correspondence in the Birmingham papers, that the state of things was calculated to give such competitor an unfair advantage over other competitors. The result seems unfortunately to have done too well justified these anticipations. In a letter to the *Birmingham Daily Post*, Mr. Victor Scruton calls attention to the fact that only six architects responded to the invitation to compete (the profession seem to have been wiser than usual in this case, that among the six was the architect who prepared the particulars, and that his plans have been accepted. Mr. Scruton pointedly contrasts this with the course pursued in the case of the Birmingham Assize Courts Competition, where Mr. Waterhouse, who had occupied an analogous position of architectural adviser of the Corporation before competition was determined on, withdrew from any claim to compete, and acted only as assessor, being, by his previous knowledge of the wishes of the Corporation, specially qualified to do so. In this latter case 134 architects competed; in the former only six. The competition was manifestly intended as a fair one from the outset; the other was suspicious. We hope promoters of competitions will recall the lesson conveyed.

IN answer to a question asked by Mr. Sturges Wortley in the House of Commons a few days ago, in regard to the antique sculptural encoined in the basement of the British Museum, Mr. H. Fowler, after describing the conditions of light under which these works were placed, and stating that in favourable weather they can be viewed and sketched by students though they cannot be visited by the general public, added that "the room formerly occupied by the department of prints and drawings can be made to accommodate the principal part of the sepulchral monuments"

an estimated cost of 1,600*l*." If so, we hope this small sum will be voted for the purpose on the first opportunity, and the soul of Mr. Newton set at rest in regard to this portion of the works of which he has so long been the careful and learned custodian.

SO Lord Carrington's house is not to be removed *en bloc*, after all! The necessary plans and calculations had all, it is said, been made, and the *modus operandi* determined, when the exigencies of the Lands Department of the Crown necessitated an abandonment of the scheme. It is very much to be regretted on some grounds that so interesting an experiment should have been nipped in the bud. But the want of a permanent Minister of Public Works, and the rapid revolutions of the political wheel, render changes of this kind inevitable, we suppose, in building matters.

THE BUILDING TRADES' EXHIBITION.

THE seventh annual Building Trades' Exhibition was opened in the Agricultural Hall, Islington, on Monday; but, as usual, was far from ready then. So dilatory, indeed, were some exhibitors that their "Stands" were not completed even so late as Wednesday evening. The present exhibition is perhaps a trifle better than last year's display, but several well-known and prominent exhibitors hitherto (Messrs. W. H. Lascelles & Co., to name only one) refrain from exhibiting this year, while some others who have in former years occupied considerable space are this year content with very small displays. There are, it is true, one or two new names of repute in the list of exhibitors (such as Messrs. Sandell, Saunders, & Co., and Messrs. Heaton, Butler, & Bayne); but, on the other hand, the pace in the hall is not fully occupied, though falls for the sale of head necklaces, pinchions, and other miscellaneous trifles whose connexion with the building trades it would be hard to discover, have been allowed standing-room. On the whole, the present show only confirms us in our oft-repeated opinion that these exhibitions occur at too frequent intervals to be of such real value as an index of progress in the building trades. We know that they are regarded by many of the exhibitors as something akin to nuisances, and one of the largest exhibitors in the present exhibition has, within the last two or three days, given forcible expression to this sentiment, coupled with a wish that something could be done to put down these recurring displays, the iteration of which is, even in this exhibition-ridden age, a great bore. Possibly some of the exhibitors were led to take leave because this year the exhibition is styled "Architectural and Building Trades' Exhibition," the only apparent ground for this additional nomenclature being that, by some arrangement into which it does not concern us to inquire, the show is announced as being held "under the auspices" of a society whose pretensions, as indicated in the preface to the catalogue, are about on a par with those of the monks of Three Tailors of Tooley-street.

Messrs. Shanks & Co. (Bay 1) exhibit a varied assortment of baths, lavatories, water-closets, sinks, and other sanitary appliances and fittings. An enamelled stoneware pedestal water-bath, shown by these exhibitors, has the merit of compactness.

One half of Bay 3 is occupied by Messrs. E. Gons & Sons, who exhibit their hot and cold water extractor for ventilating houses and ships. Its appliance has been described by us on a previous occasion of former exhibitions. The same exhibitors' "Inlet and Exhaust Double-Action Ventilator" is claimed to be "automatic and perfect in action," and, no doubt, is claim is a good one if, in all states of wind and weather, the respective channels for warm and cold air are found to keep to their allotted work. One merit which this ventilator possesses consists in the absence of moving parts. A valve-trapped earthenware closet for fixing over the floor-line, and somewhat cumbersome in form, is shown at this Stand; also a ventilating stove for heating purposes.

Bays 4 and 5 are occupied by Messrs. H. & Edwards with a good display of school-bags, furniture, fittings, and teaching appliances.

The Patent Victoria Stone Company (Bay 6) exhibit the practical applications of their excellent material in the shape of steps, paving-

flags, sinks, &c. A specimen of this stone, after five years' wear under the heavy and almost continuous pedestrian traffic at the corner of Commercial-street, Whitechapel, presents a good and even surface, such as would hardly be possible, we should say, with the best York flagging after such a trial. The same material is shown in its "ornamental" applications, but these constitute the least satisfactory part of the display.

In Bay No. 7 are shown Kaye's Patent Automatic Locks and Door Openers, two exceedingly good and simple applications of which are adapted to railway-carriage doors. One of these forms of lock, we are informed, has been adopted for use by the Great Northern Railway Company, after careful trial. Excellent locks and handles for shop and office doors, calculated to work for years without the many vexations incident to older forms of door furniture where the wear is heavy and incessant, are shown by the same exhibitors.

Bay No. 8 is apparently in the joint tenure of the Pulsometer Engineering Co., the Remedy Ventilator Co., and other exhibitors. Of the well-known pumps of the first-named Company we need say nothing. Of the "Remedy" ventilator, also adaptable for use as a chimney-cowl, we will only call attention to it without expressing an opinion as to its efficiency.

The Broomhall Brick and Tile Company have at this Stand a good selection of their well-known moulded and perforated bricks, which, for truthness of shape and excellence of quality, are not surpassed by any others. They also exhibit their patent roofing tiles. The 3½-in. lap-tiles are especially worthy of notice. They are light and cheap. Hard by, Messrs. T. J. Mayfield & Co. have a small display of electric-hell apparatus, burglar-alarms, &c.

The Thames Bank Iron Company (Bays 9 and 10) have a large display of tubular, saddle, and other boilers for heating purposes. They have also a good show of hot-water fittings, such as pipes, coils, valves, &c. The back-water way saddle-boilers are now made by this Company up to 5 ft. 6 in. long. At this Stand are also exhibited some cast-iron traps, soil-pipes, bends, and junctions. The patent "Expander" for facilitating the jointing of hot-water pipes is also shown.

Bay 11 is occupied by Mr. R. Howard, with a horticultural building and gearing, calling for no special remark except that the levers and cranks of the gearing seem to be likely to be somewhat in the way of the plants which the building is to contain.

Messrs. Ewart & Son (Bay 17) exhibit their "Dido" gas bath, enamelled with Price's "cheerful" a hard drying enamel. The "Dido" bath seems to be very compact, and is fitted with the "shower" geyser or water-heater, which is rapid in action, and possesses other merits. The "Empress" Ventilator, in various forms, is shown by the same exhibitors.

Messrs. J. Pickles & Son, of Hebdon Bridge, Yorkshire (Bay 18), exhibit a small collection of very well made wood-working machinery, including a saw-hench and an improved moulding machine, as well as spiral-cutter planing-machines.

Bays 19, 20, and 21 are occupied by Messrs. Wrinch & Sons, of Ipswich, with two horticultural buildings and a summer-house, which call for no special remark.

Bay 22 is occupied by Mr. W. Harris with an improved cast-iron horizontal pug-mill, for shafting, and a vertical standard pug-mill with chain wheel.

Bay 23 is sparsely occupied by a few brick-making appliances, including Whitehead's brick press.

Mr. J. Matthews, of Weston-super-Mare (Bay 24), exhibits Poole's patent bonding-roll square-cornered roofing tiles and a variety of rustic and other vases, hanging flower-pots, &c., for horticultural use.

In Bay 25 Messrs. J. E. H. Andrew & Co., Limited (Stockport), exhibit the "Stockport Silent Gas Engine," which works very smoothly and is fairly well entitled to its name. This and two "Bischoff" gas engines at the same stand serve to drive two or three of Messrs. F. W. Reynolds & Co.'s excellent wood-working machines.

Messrs. Carter & Co., of Poole, Dorset (Bay 26), exhibit some very good encaustic and glazed majolica tiles. These are excellent in quality and colour. There are a variety of hand-painted tiles and panels, of which some of the figure-subjects are good. Other panels, on the con-

trary, all stated to be hand-painted, are too realistic and naturalistic in style, some of them being more suggestive of varnished oleographs than of anything else. In the rear of their Stand this firm have an exhibit more worthy to come to the front than some of the pictorial panels just mentioned, viz., a new kind of wall-decoration which is called "tile fresco in outline." It consists of a number of buff tiles, 6 in. by 6 in., put together so as to form a panel about 6 ft. by 5 ft., on which is drawn a seated figure symbolical of "Education" teaching a group of young children. These figures are all in outline merely, and the dark lines, burnt in on the lighter ground of the tiles, are very effective. The surface is unglazed. This method of wall-decoration, which is stated to be comparatively cheap, seems likely to have a future.

Stand 1 (Avenue A) is tenanted by Mr. R. Adams, who exhibits his "Anti-accident Window," patent doorsprings, &c.

At Stand 3 Messrs. Burney & Co., of Millwall, exhibit galvanised iron tanks and cisterns.

Messrs. C. Kite & Co. (Stand 5) exhibit their excellent exhaust and other ventilators, of the merits of which we have often spoken. Besides these they exhibit a quite newly-patented invention, the "Counterpoise" silent automatic valve for smoke-flues and extraction shafts, which appears to embody a valuable improvement. Their mirror-ventilators are ornamental as well as useful, and likely to disarm the preternatural susceptibilities of people who always fancy they "feel a draught" when they know they are in the proximity of a ventilator.

At Stand 8 Mr. J. Robson exhibits his patent drip-tiles for weathering cornices, chimney-stacks, parapets, &c. We spoke of their merits in one of our notices of the Inventions Exhibition last year.

Mr. P. Maignen (Stand 10) exhibits his "Filtre Rapide" and his patent process for softening water.

At Stand 13 Messrs. Muldoon Bros. show their system of wood-block flooring and asphalted wood pavements for roadways. They also have a good display of enamelled slate chimney-pieces, tile-heartis, stoves, &c.

The Adamantine Clinker Pavement, so well adapted for stables and yards, is exhibited at Stand 14 by Messrs. Towers & Williamson in conjunction with Musgrave's patent stable gulley.

At Stand 17 Messrs. T. J. Marshall & Co. exhibit some good stained-glass work suitable for domestic purposes.

Tighe's patent door-knobs and handle are shown in a case at Stand 20. The door-handles have no tap screws.

At Stand 24 is shown a new form of protected sash-fastener (Garrood's patent), which at first sight appears to be somewhat cumbersome and complicated, but its patentee claims that it is absolutely thief-proof, and incapable of yielding to the persuasions of the "drop-key" and other tools of the expert burglar.

The Luton Brick and Lime Company (Stand 24) exhibit an archway showing the use of their grey and red Luton bricks, which are most effective in appearance when not used with that sham known as "tack-pointing."

Messrs. A. Attwood & Co., late Salmon, Barnes, & Co. (Stand 27), show some good self-sustaining lifts and hoists, and a model of their patent revolving shutters.

At Stand 29 Messrs. Smith & Turner show their admirable adjustable silent door spring, which is likely to meet with increased favour as it becomes better known. They also show Ben Turner's regulating door springs, and other excellent door and window furniture.

A simple form of sash-fastener is shown by Messrs. A. Lewis & Co. (Stand 33). This fastener will be found proof against being forced back by the insertion of a knife or other instrument between the meeting-rails of the sashes, provided that the slit in the arm be exactly adjusted in fixing.

At Stand 59 Messrs. Poulton & Son, of Reading, exhibit a doorway built up to show the use of their red and grey moulded and enriched bricks.

Messrs. A. Cappello & Co. (Stand 61) have a small but good display of mosaic work for floors and for wall-decoration.

Mr. W. F. Stanley (Stand 63) has a small display of surveying and drawing instruments. There is also exhibited at this Stand one of

Mann's cement-testers, for testing cement by adhesion.

Messrs. Wenham & Waters (Stand 65) exhibit plumbers' work and sanitary fittings, including a regulating-supply lavatory.

Stand 69 is occupied by the Coalbrookdale Company, who have a very good show of cast-iron mantels and overmantels, besides stoves, grates, fenders, and railings.

Messrs. Ewart & Son (Stand 71) are exhibitors of baths and other sanitary appliances.

Messrs. T. Lawrence & Son, Bracknell, have a small structure (Stand 72) exhibiting the use of their red rubber and facing bricks. The red facing work is executed with the exhibitors' improved hand-made and hand-pressed facing bricks, which are free from sand-flaws, and leave nothing to be desired in colour and texture. The adaptability to plain and fancy wall tiling of the "T. L. B." tiles is shown at the rear of the Stand.

At Stand 73 Messrs. Robert Boyle & Son (Limited) have a very good display of their well-known specialties, including their most recent developments. The reputation of this firm for such appliances is of long standing.

Messrs. E. & J. M. Verity (Stand 74) exhibit some of their well-known and convenient appliances for opening, closing, and fastening fan-lights and sashes.

Messrs. Johnson, Clapham, & Morris exhibit specimens of their patent wire lathing, which affords an admirable key for the plaster.

Mr. J. J. Carpenter (Stand 79) exhibits what he calls "the patent combined fast and slow combustion stove," which embodies an idea which we do not remember to have seen worked out before. This stove has really two bottom gratings, one sliding over the other on the "hit-and-miss" principle, thereby affording means for regulating the rate of combustion.

At Stand 80 Mr. M. F. C. Turpin has a very good display of parquetry and dado work, excellent in execution and material.

The Willensden Paper and Canvas Company demonstrate, at Stand 81, the waterproof qualities and other advantages of their excellent light roofing material.

The House Sanitation Company (Stand 87) exhibit some of the sanitary appliances patented by Mr. Thomas Durran, A.R.I.B.A., including cast-iron drain-pipes with screw joints to facilitate inspection or removal. The "Airi" filter, which consists essentially of a porous porcelain tube, is also shown at this Stand. A new form of trap for sinks, called the "scour" trap, is ingenious, though simple, the water passing through it receiving a spiral motion so as to prevent the unsealing of the trap by the too sudden passage of the water. The central portion of the trap is removable for the purpose of cleaning out the sink-pipe when necessary.

Messrs. H. and C. Davis & Co. (Stand 88) exhibit their "Metropolitan" and other gas-kitcheners and stoves, to the great merits of which we have referred on previous occasions.

Mr. Joseph Westwood, jun. (Stand 96), exhibits Hawkey's patent treads for stairs, which are coming largely into use, not only for railway stations, but for warehouses and other buildings where there is much wear and tear on the staircase. An adaptation of the invention to the purpose of hydrant-covers has been largely used in the City.

Messrs. Brazier & Son (Stand 97) exhibit their "aromatic" and deodorising water-closets and other sanitary fittings, which have been noticed by us on former occasions.

At Stand 104, Messrs. Jeffrey & Co. have a good representative collection of their non-poisonous wall-papers, which are all admirable in design and colour.

Mr. J. M. Boekbinder (Stand 106 and 112) exhibits some of his carton-pierre and fibrous plasterwork, for interior decoration, as well as a number of specimens of painted tapestry.

At Stand 110, Messrs. Hayward Bros. & Eckstein have a good show of their specialties, foremost amongst which we must place their well-known "semi-prism pavement lights" and their self-locking coal-plates.

Mr. Julius Sax (Stand 111) exhibits electric bells and apparatus.

Roberts's rain-water separator, described at length in another column, is shown at Stand 115. An illustration and description of this will be found on another page.

The "Lincrusta" and General Decorating Company (Stand 118) exhibit, in conjunction

with their decorative specialties, a mantel-piece and overmantel provided with a folding screen for use when the fire is not required.

Messrs. George Wright & Co. (Stand 123) have a good display of slow combustion and other stoves, with marble and wood chimney-pieces, tiled hearths, &c. A specialty to be noticed is their patent bivalve grate. Some very good close and open fire kitcheners are shown by this firm.

Messrs. F. W. Reynolds & Co. (Stand 124) exhibit their double-handed locks and one of their mortising machines.

Messrs. A. Moore & Co. (Stand 128) have a display of stained-glass work, including a good window for the New Pump Room at Bath.

Mr. John Smeaton (Stand 129) exhibits a collection of very good sanitary appliances and fittings, including one or two novelties. Among these we may mention a swing-urinal for affixing to doors and in other positions where space is restricted. A dust-shoot, shown at this Stand, for use in artisans' dwellings, is so arranged as to prevent the passage of foul odours into the dwellings should the hopper be left open. Smeaton's new patent water-waste preventing valve for water-closets (manufactured by John Warner & Sons) is also shown at this Stand.

Messrs. Heaton, Butler, & Bayne (Stand 131) exhibit some good stained and painted glass; a part of a painted reredos for Croswater Church, Kendal; and part of a reredos for Mr. C. Lucas, Warham Court,—the latter designed by Mr. A. W. Blomfield, and both painted and decorated after the style of the screens in the churches of Norfolk and Suffolk.

Mr. George Jennings (Stand 138) has a good display of sanitary appliances and fittings, including a new form of his pedestal vase-closet. Baths, lavatories, urinals, housemaids' closets, water-waste preventers, stoneware and other traps, plumbers' and other brasswork, go to form what may be taken as a fair representative show of the work of this well-known exhibitor.

Messrs. Woollams & Co. (Stand 135) exhibit a good variety of their excellent non-poisonous wall-papers, including a number of new designs, which are well worth the attention of visitors.

The New Patents Development Association (Stand 136) exhibit specimens of "wood-carving" by machinery. We believe that the process consists in the main of harring or charring off the superfluous wood, so that the term "wood-carving" is rather a misnomer. The work produced is, no doubt, cheap, but it is flat and spiritless.

Mr. Henry Bassant (Stand 139) makes a very good display of parquetry work for floors. Teak seems to be coming into increased use for this purpose, and with very good effect.

In the centre of the hall the *Æolus* Water-spray and General Ventilating Company have a very good show of their well-known appliances for ventilating and warming, and at Stand 119 they exhibit a number of drawings showing the application of the appliances to churches and other buildings. Of the effectiveness of these inventions we have often spoken.

At Stand 141 Messrs. Mosaic & Co. have a good display of marble mosaic pavements and of glass and marble mosaic wall decorations.

Messrs. Frederick Jones & Co. (Stand 145) exhibit their silicate cotton or slag-wool, with especial reference to its use in protecting exposed iron-work in buildings from the action of fire.

Messrs. Starkie, Gardiner, & Co. (Stand 147) have an excellent show of wrought-iron work as applied to lamps, gaseliers, fenders, grilles, &c.

Mr. Jos. F. Ebner (Stand 150) exhibits some very good marble mosaic flooring and glass mosaic wall decorations, all good in colour and design. Mr. Ebner's parquetry work is not excelled by any that we have seen, and he exhibits a new method of attaching it firmly to basement floors without the necessity for any under-flooring. The same method is equally applicable for use in connexion with fireproof construction. Some good woodwork in the shape of doors, dados, and mantelpieces is shown by the same exhibitor.

Messrs. Nettlefold & Sons (Stand 152) exhibit locks and door furniture of all kinds, and in conjunction with them Messrs. Richardson, Ellison, & Co. have a small display of wrought-iron work.

Messrs. George Jackson & Sons (Stand 155) exhibit some new and good designs for ceilings and mantels in fibrous plaster. These will well

repay inspection. They represent sections of ceilings which have been put in at the Badminton and Constitutional Clubs, under the direction of Mr. R. W. Edis, and at the new addition to the Junior Carlton Club-house under the direction of Mr. J. Macvicar Anderson.

Mr. Thaddeus Hyatt (Stand 157) exhibits his well-known pavement-lights and other cognate appliances for transmitting daylight to basements of buildings. The tile-illuminate-gratings have a decorative appearance, whilst they afford a better foothold than the glass lights alone.

Wilkes's Patent Metallic Flooring and Eureka Concrete Company (Stand 158) exhibit some of their specialties in paving work and fireproof construction. These, as well as the architectural enrichments shown, are well worth notice.

Messrs. Randell, Saunders, & Co. (Limited) exhibit the application of their well-known Bath stone for external purposes, as exemplified in the porch of the Church of St. Lawrence, Catford Bridge, Lewisham, the greater part of which is actually built upon the floor of the exhibition-hall. The architect of the church is Mr. Hugh Ronnie Gough. The plinths and bases are of Westwood Ground stone, the shafts and arch moulds of Cornham Down stone, while the interior lining is of Farleigh Down. The stone has been admirably selected and worked and goes very well with the red brickwork and diapers of the walls. The bricks have been supplied by Mr. James Brown, of Cannon-street, and are excellent in texture and colour.

Mr. J. E. Ellison (Stand 162), exhibits his "radiator" and other ventilators.

At Stand 164, Messrs. Lindsay & Co. exhibit their well-known systems of fireproof flooring—the "steel-decking," and their patent truss-concrete flooring, which were referred to by Mr. John Slater in his lecture at Carpenter's Hall the other evening. The built-up steel columns, for use in combination with concrete, should also be seen by visitors to the exhibition.

Messrs. Jones & Willis (Stand 165) have a large show of their excellent and varied productions in the shape of church furniture, fittings, and decorations.

Messrs. Humpherson & Co. (Stand 169) had a good display of sanitary appliances and some good plumbing work. One piece of the latter called a *tour de force*, and in our hearing some of the visitors did not hesitate to express their scepticism as to its having been executed out of one piece of lead. The exhibitors, however, state that they are prepared to demonstrate this any time by performing another piece of work like it.

Webb's Worcester Tiles Company (Stand 167) have a good show of encaustic and other tiles.

Mr. Roger L. Lowe (Stand 172) exhibits his patent wood block flooring, which has many advantages, and is capable of being used with very good effect by variation in the colour and disposition of the blocks.

Messrs. Steven Bros. & Co. (Stand 187) have a very good show of marble, wood, and iron cabinet-pieces, with grates, fenders, tile hearts, &c., *en suite*. There are also a number of kitcheners and ranges, slow-combustion stoves, bath, manhole covers, &c., to name only a few of the innumerable articles exhibited at this Stand in the way of builders' ironmongery and hardware.

The Madeley Wood Company (Stand 193) exhibit a number of pressed Broseley roofing tiles a wall fitting.

Mr. J. Stannal (Stand 194) exhibits lifts and models of lifts, besides pumps and other articles of builders' plant.

Messrs. Esdaile & Co. (Stand 195) exhibit mouldings, doors, and joinery of English, American, and Swedish manufacture, which may be usefully compared by visitors.

Messrs. M. C. Duffy & Son (Stand 196 & 201) exhibit a large show of builders' turnings. They also exhibit their "Acme" system of solid wood-block flooring, which was not long ago described and illustrated in our columns.

Messrs. Carter, Johnson & Co. (Stand 202) have a good space laid with their glass church purposes, which are very good in appearance.

The Decorative Wood Company (Stand 203) exhibit what appear to be carved panels, doors, &c., but we believe that they are carved, but consist of a thin veneer of wood, a layer of pulp, the whole being pressed into moulds. The effect is much sharper and better

than that obtained by the process previously referred to.

Mr. J. P. Lilly (Stand 233) exhibits specimens of the Chilmark & Wardour stones as selected and used for Westminster Abbey.

At Stand 234, Messrs. S. & G. Staple exhibit specimens of Donlting and Ham Hill stone.

Stand 240 is in the occupation of Messrs. Musgrave & Co., who exhibit a large model showing their patent stable fittings. Messrs. Musgrave also exhibit their patent slow combustion ventilating stoves.

Messrs. Geary & Walker (Stand 243) exhibit their wood-block flooring, which is described in another page of this week's *Builder*.

The St. Pancras Ironwork Company (Stand 16) exhibit some stable fittings and a few good specimens of good decorative wrought iron.

Hitchins's Fireproof Plastering Company (Stand 319) have erected a cottage, in the interior of which they exhibit specimens of crices executed in their material recently for Fr. Chaffield Clarke and other architects.

There is very little machinery in motion, but among the few exhibitors in this line we may mention Messrs. E. Jacobs & Co. (Stand 329), who exhibit woodworking machinery.

Messrs. Edgington & Stevenson (Stand 343) exhibit mortar-mills and other items of builders' plant.

Mr. E. S. Hindley (Stand 348) exhibits steam engines, &c., specially adapted to the requirements of builders and contractors.

There are very few exhibitors in the Arcade connecting the hall with the Islington-green entrance, but among them are Messrs. Chambers, Monney, & Co., who exhibit a varied assortment of builders' ironmongery, including air well-known iron wall-ties and some very good cottage kitcheners.

The exhibition will remain open until the evening of the 17th inst.

THE EXAMINATION IN ARCHITECTURE.

The following gentlemen passed the examination recently held in Leeds by the Royal Institute of British Architects, and are qualified to become candidates for the Associateship, *viz.*—

Cones, Lister, Halifax.
Fairley, James McLellan, Edinburgh.
Gelder, William Alfred, Hull.
Hesketh, Peter, Manchester.
Ridgway, Frederick William, Dewsbury.
Smithson, William George, Derby.

The following gentlemen passed the examination recently held in London, and are qualified to become candidates for the Associateship, *viz.*—

Birkett, Isiah Robert Edmondson, Manchester.
Box, Stephen, Eastbourne.
Collins, Henry Albert, Reading.
Coxhead, Ernest Albert, Eastbourne.
Cresswell, Herbert Osborn, Putney.
Dunn, William, Crouch-hill.
Fanger, Frank Stephen, Nottingham.
Fraser, Henry, South Shields.
Gummow, Michael John, Pall Mall.
Swyther, William Banks, Calcutta.
Hamilton Gordon, George William, Finsbury-pavement.

Heyes, Austin, Clyde-street, S.W.
Hirst, Henry Cecil Montague, Bristol.
Hooker, Walter, Andover.
La Trobe, James Henry, Bristol.
Law, William Ralph, Basinghall-street.
Milburn, Thomas Ridley, Sunderland.
Mitchell, Arnold Bidlake, Clapton.
Muller, John Joseph, Hampstead.
Jakley, Frank Page, Manchester.
Parke, Thomas William, Bromley, Kent.
Parks, Sydney, Wandsworth Common.
Pethick, Benjamin Herbert, Paddington.
Scruton, Victor, Birmingham.
Tugwell, Frank Alfred, Scarborough.

Utilising the Coast Guard as a means of National Defence.—The Admiralty are at present erecting a battery and drill-hall at each of the principal Coast Guard stations, constructed on a new plan designed by H. R. H. the Duke of Edinburgh. There will be one large battery in each battery, which will be worked by Coast Guard men on the station. The first of these batteries and drill-halls have just been completed at Sunderland, and are fitted with the latest improvements, the ventilation being specially attended to.—Boyle's latest proved self-acting air-pump ventilators being adopted.

FREE LECTURES TO ARTISANS AT CARPENTERS' HALL.

TERRA-COTTA.

The seventh of the present course of lectures at Carpenters' Hall was given on Wednesday, the 31st ult., by Mr. James Doulton.

Mr. Doulton said,—The term "terra-cotta" is of significance, and in its literal meaning embraces in its history and manufacture a period from prehistoric time, and a range of work from the roofing of the humblest cottage to ornaments suitable for the grandest palace.

The earliest mention of burned earth is in Genesis (ii. 3), where the people said, "Go to, let us make brick and burn them thoroughly. Go to, let us build us a city and a tower whose top may reach unto heaven, and let us make us a name lest we be scattered abroad upon the face of the whole earth"; the result being the confusion of tongues at Babel. Many allusions are made in sacred history to clay and the potters' work, the power of God himself being set forth in the similitude of the potter. If we turn to secular history we obtain the same testimony of its ancient character; there is not a country or a people in the world who have not in one form or another some knowledge of pottery, and from the imperishable nature of well-burned clay we have an unwritten history of many countries otherwise unknown. Pottery is constantly being found which gives us another link in the chain mingling us to the far-off ages. The history of pottery really is to a great extent the history of the world. There is a pretty little theory suggested as to the discovery of the properties of clay, which, like many such, is attributed to accident.—Man in his savage state, after forming a hollow in which to hold the embers of his fire, noticed that the earth had become capable of retaining water. This hardening process by the action of heat was turned to practical uses; vessels were made not only for holding, but for carrying, water; bricks for the purposes of building, until little by little that perfection was attained which culminated in the works of Greece and Rome. Doubtless amongst the most popular forms of pottery were the drinking-horns of the Greeks; the term "ceramics" being taken from *keros*, a horn or drinking-vessel. We can but imagine the course that pottery took: first it was merely sun-burned; then artificial heat was applied, producing greater density, followed by yet another step, the introduction of the art of glazing. The kiln was evidently known at a very early period, as is shown by the sculptures of ancient Egypt. The same may be said of the wheel, and to whom we are indebted for this invention it is impossible to say; it appears to have been known at least 2,500 years B.C. One singular fact remains, that notwithstanding the wonderful discoveries and improvements in all else, the potter's wheel remains practically the same as at the commencement of our knowledge of it, the only difference being in the methods of turning it and the motive power used. The earliest type of wheel that we know is that still in vogue amongst many people of the East, in which a heavy wheel, attached to the table on which the clay is thrown, is rapidly turned by the potter, with such force that the momentum attained is sufficient to enable him to throw the form required, the great disadvantage being the necessity for the potter to stay his work and give to his wheel fresh impetus as often as needed. After this the same form of wheel was made, but in such a way as to enable the potter to propel it with his feet, and thus keep a steady, constant motion. There are still men living to whom this was the only method of gaining the necessary rotary motion, and I am given to understand, at the present time there is a Japanese at Knightsbridge showing his skill in throwing, having only this means of obtaining his motive power.

But as large vessels were required this method became totally inadequate and was superseded by a further advance in which the disc was attached to a large fly-wheel worked at right angles and turned by a crank handle. This gave the potter better control over his clay, enabling him to devote all his energy to the throwing, and giving him the power of regulating the speed by word of mouth to his assistant whose duty it was to turn this wheel. And lastly came the addition of steam and the invention of the conical drum, enabling the potter himself to regulate the speed of his wheel by the mere pressure of his own foot. Thus, while the modes

of turning the wheel have changed, the wheel itself remains the same as in the days of the prophet Jeremiah, whose description of the potter and his work is so graphically given in his denunciation of the children of Israel. I have mentioned the wheel thus fully as it is and always will be the means by which the potter does his principal work. The dexterity and skill with which a good potter can throw his work constitutes his art, and I trust the day will never arrive when the wheel is superseded by the mould in the formation of circular work. The mould reduces everything to the one dead mechanical level, while the wheel brings out the powers and the individuality of the workman.

Clay, of all substances, is that which lies most readily to hand, and could not but be found most available for an infinite number of objects of first necessity; its use, however, was progressive, and the bound from the rude vessel of the savage to the exquisite Etruscan vase,—from the bricks of Babel to the beautiful terra-cottas of Germany and Northern Italy,—is as great as is the period of time that divides them. The uses to which pottery is put have extended much of late years, and will no doubt continue to extend; at the present moment there is scarcely a trade which does not, more or less, call upon the potter for help. People always build with the material most readily to hand, and thus it came to pass that in the early history of man, with forests almost untouched, and a necessity to clear the same for the cultivation of the ground, wood was universally used, as in many parts of Russia, Norway, Sweden, &c.; but as these became exhausted, or more permanent dwellings were required, wood gave place to clay, to stone, and even to iron, affording in their preparation alone, employment to a vast multitude of workers, making the building trade the most important in all countries. As civilisation increased dwellings became more luxuriant, until, at the present time, the providing of this necessity finds one of the chief occupations of man. It would be very interesting, did time permit, to trace the steady growth of the builder's art; how, from the mud hut or from the mere protection formed by boughs, we have come to the magnificent structures of the present day, replete with every comfort and demanding the utmost amount of care, thought, energy, and skill in erecting, the hall in which we now are being an example of this.

Of all trades that of the builder has, perhaps, benefited the most by the extended use of clay. It seems but a few years since the introduction of stoneware drain-pipes, and, though at first looked upon as a great innovation, meeting with much opposition, their use has become so general that our firm alone makes about 1,200 to 1,500 miles annually; and now, step by step, terra-cotta appears to be advancing into public favour, buildings in which it is used springing up in all parts of the country. While, in its literal meaning, terra-cotta, as I have already remarked, embraces every kind of pottery, it has now come to be applied exclusively to that class of ware used in the construction of buildings which is more or less ornamental and of a higher class than ordinary bricks, demanding more care in the choice and manipulation of the clay and much harder firing, and being, consequently, more durable and better fitted for moulded and modelled work.

It is always necessary that those desirous of using any particular material should be thoroughly acquainted with its characteristics. Were this always the case it would save a great amount of disappointment, and potters would never be expected to do impossibilities. An eminent architect has described terra-cotta as the highest development of bricks; its place certainly seems most appropriate in conjunction with brick, and in this form it has been most successfully applied. I have known buildings of stone in which terra-cotta has been introduced, but only in the ornamental parts, and principally on the score of economy. To understand a material thoroughly, its characteristics and nature should be studied and all its peculiarities known. I would, therefore, draw your attention to the mode of manufacturing terra-cotta.

All clays require careful preparation before use, and their after characteristics are often as much determined by this as by anything; the same clay being different under different treatment. The first necessity is that of kneading,

or, as it is termed, pugging. This consists of well mixing the clay and reducing it to a perfect consistency throughout; originally this was done by men treading it out with their feet (much in the same way as we read that the juice was pressed from the grapes in primitive times), but now pugging-millars are used, through which the clay is passed and thoroughly mixed. Most clays, like gold itself, require an alloy to make them more workable. In a pure state they are often what is termed too fat; their shrinkage is too great, and they are liable to twist and warp in drying and burning; rough stuff or burned clay ground fine is, therefore, added in proper quantities to prevent this, and to give the potter a more certain command over the clay: thus mixed, it is raised in a dry state into the mixers, and with the necessary addition of water it is passed in through the pug-mills ready for use. In some particular instances the clay is wedged or barred; that is, made more homogeneous by being continually struck with an iron bar, or by being cut with a wire, and the two separated pieces violently struck together: this tends the more thoroughly to assimilate the parts and to expel any imprisoned air. The clay being thus prepared, is pressed into a mould with considerable care, to prevent, as in the case of pugging and wedging, any accumulation of air in the clay; for should this occur, the heat of the kiln expanding the air will completely shatter the work. The moulds are of plaster, being taken from the models in the usual way; care is also necessary that in pressing into the mould an equal thickness should be kept throughout, as without this there would be uneven shrinkage, the result of which would be distortion. It is not safe to make any blocks of solid clay much more than 1 in. thick; to meet this difficulty, when work is required of a greater thickness the blocks are formed hollow with cross webs to strengthen them; when necessary these cavities are filled with concrete: this filling also prevents the accumulation of moisture to which the blocks would be liable were they left open. The use of moulds, of course, applies more especially to all repetitive work, such as string-courses, mullions, plinths, cappings, cornices, balusters, &c., but it often happens that only one or two pieces of a particular kind are needed. These are then formed by hand, without the help of a mould, and at once passed through the kiln. This is particularly the case with sculpture, to which I shall allude presently. The last process is that of drying and burning, both of which form a very critical stage. Drying is the exhaustion of the water by evaporation, which must be done very gradually and very evenly, otherwise there would be a liability to crack and twist. The burning is the mysterious process and is of the utmost importance, as on it depends the lasting qualities of the material, for if the terra-cotta is well burned it will last for all time. An eminent American geologist, whom I knew personally, being asked what the burning was, replied simply expelling moisture from clay; but it is more than this, otherwise sun-burned pottery would be as good as any other. The fact is, chemical action goes on in the firing which changes the whole nature of the clay. It is no longer plastic, but rigid, and when once burned never admits of being worked up again, as in its original state. To accomplish the burning successfully requires much experience, much skill, and much patience. Kilns themselves often differ materially, and require to be known to avoid failure. In this as in everything, knowledge may be gained in three ways,—by reading, by hearsay, by experience, but the last-named is of the greatest importance. The burner, to be successful, must know his kilns thoroughly, but besides the kilns the clays have to be studied, and when we remember that the same bed of clay will sometimes change in character, and be differently affected by the application of heat, you will readily understand some of the difficulties with which the potter has to contend. A practical potter, speaking of this subject of burning, once said:—"I can only add, after twenty years' experience,—not that I know less than I did fifteen or twenty years ago, but rather how little I know compared with what still remains to be learned about burning." I am aware that some people have thought the potter's an easy trade to learn; but many have lived long enough to alter their opinion, having found by bitter experience that, even in the manufacture of pottery, there is no royal road to success. I once heard it said of a person who, without any

previous knowledge of pottery, had gone into the business, that he had affirmed that after a twelvemonth at the work he had mastered it in all its details: this is not the experience of those who have spent a lifetime at it, as my previous quotation from the speech of a practical potter testifies. Need I add that the place of this gentleman knows him now no more? He has accomplished a forced retirement. There is no doubt, however, that the potter's is a very seductive business, and one may be led on and on in the endeavour to attain an end at a very heavy cost; but, on the other hand, it is the only way of ultimate success. Amongst Wedgwood's papers were found trials numbering many thousands to obtain one result; and who has not heard of Bernard Palissy being so engrossed in attaining his end, that in default of anything better, he burned up his furniture, to his wife's dismay, that he might obtain fuel necessary for the firing of his kilns.

Having thus described some of the difficulties of the manufacture, I now turn to some of the advantages in the use of terra-cotta as a building material; and, first, I would mention its durability. It is, in fact, the only substance that may be said to be imperishable. Stone of every kind disintegrates by time, but well-burned clay resists all that has defied the work of time for thousands of years. From Egypt, Persia, Syria, Mesopotamia, Nineveh, Babylon, and the far East, have come to us pottery the age of which is past computing. Dr. Schliemann's not long since brought to light some wonderful specimens; but a visit to the British Museum will surely convince the most sceptical: here may be seen slabs of hurred clay which date not tens, nor hundreds, but thousands of years ago, covered with delicate writings, showing as clearly as the first day they left the operator's hands. To these slabs we are indebted for almost all we know of prehistoric time. In Greece and Italy pottery is continually being found of ancient date, and it was only since 1873 that those beautiful Tanagra figures were first brought to light, which have resisted the work of time for upwards of 2,000 years, having been made about 350 years before Christ; while some of the finest examples of Greek terra-cottas date back 100 years previously to this.

Turning to more recent times, we have the terra-cottas of Northern Italy and Germany, the former of which have been so well described and beautifully illustrated by Louis Grüner in his work entitled "Terra-Cotta Architecture of North Italy." Most of these structures date back to the twelfth century, and in one instance, at all events, that of the Church of San Pietro in Ciel d'Oro as far as the seventh century; the study of this work, which shows also many examples of colour, would well repay any one desirous of knowing more of this beautiful material. Throughout the plains of Lombardy, and in many parts of Germany, stone is rare, and here, buildings of considerable importance have been erected in which clay has been moulded into such exquisite forms as to raise it into a material of both value and dignity.

Many examples of brick buildings with terra-cotta mouldings and ornaments exist in England, having been erected mostly between the thirteenth and fourteenth centuries. Generally the use of terra-cotta died out in this country with the Tudors, and, except a slight revival of moulded brickwork about the seventeenth and the beginning of the eighteenth century, architectural terra-cotta was not practised until the time of George III. Wedgwood attempted a revival, but was not successful. Examples of this earlier period are found at Sutton-place, in Shrew, and at East Ham, and, later still, some medallions at the Hampton Court Palace, all of which are in excellent states of preservation. Among other specimens of terra-cotta building may be mentioned Eastbury Manor House, between Barking and Ilford, and Layer Marney Towers, near Colchester, Essex (the latter being illustrated in the last and present number of the *Builder*).

[At this stage of the lecture a pause was made for the purpose of exhibiting the mode of working the potter's wheel, which was illustrated by Mr. Butler showing the method of ornamenting the work.]

Towards the close of the last century there was a partial revival in the use of terra-cotta resulting in the establishment of a manufactory in Pedlar's Acre, Lambeth, under the management

of a lady named Coade. From this factory was turned out much good work, which found its way into all parts of the country as well as in London. The frieze at the Italian Opera House in the Haymarket, the caryatides and other ornamental work in St. Pancras Church, are from this factory. On the top of the Exchange at Liverpool is a colossal figure of Britannia, also made by Coade nearly a century since, which, notwithstanding its exposed position, retains its original sharpness; some time ago it was proposed to paint it, but this was abandoned as being unnecessary. While staying myself with a friend in the Vale of Clwyd, I came across some excellent specimens of terra-cotta, which, by much research, I found had been exposed for nearly 100 years in the least; they had formed part of Llewenni Hall, a mansion built by the Salisburys, a print of which I have seen showing the terra-cotta ornaments, many of which are about the grounds and some bearing the name very distinctly of "Coade, Lambeth." In the early part of the present century the mansion was destroyed, by fire and never restored; portions, however, which were left, were converted into farm-houses, and it was in them that there would be seen many relics of the terra-cotta, one of which—a medallion of one of the seasons,—was able, through the kindness of the agent, to bring away with me. It was as sharp as the day it was first made. I am sorry I could not find the piece itself to show you (I exhibit a facsimile of it). The print to which I have alluded was published by Boydell, of Cheap-side, and was dated 1792. In it was shown a fountain surmounted by the figure of Neptune; it was this figure that I found in the garden of one of the farms, and on which was the name "Coade, Lambeth." In Bishopsgate-street, in a niche outside Crosby Hall, is a terra-cotta figure of Sir Richard Crosby made by us more than fifty years ago, and which shows not the slightest signs of decay. It has been painted of late years,—not, however, for the purposes of preservation, but only for decoration. I think you will agree with me that fifty years in the atmosphere of London is far more trying than 100 years in the Welsh valley. The atmosphere of our large towns and populous districts is very destructive to stone and iron, from the smoke given out by the increasing consumption of coal, or from the fumes of chemical and other manufactories; but the close texture of well-burned terra-cotta makes it a very reliable material under these circumstances. I would mention one instance which came under my own notice some time since, and which, no doubt, may be seen at the present time. At Buckingham Palace, about thirty years ago, to that part adjoining the stable yards were placed several large vases, made by the late Mr. Blashfield. These are in perfect preservation, while the York stone coping on which they stand is in a state of decay. Bath stone is even less reliable; for, notwithstanding the care bestowed upon the choice of the stone, the Houses of Parliament in Westminster are constantly needing extensive restorations. I once was called to see a balustrade on some terraces of a mansion, near Luton, where the balusters had worn down to a thread, by the mere silent action of the atmosphere, and the air removed from any town; while at the chancel the top of Langham-place, London, the balustrading and cornice became so decomposed and shattered by the weather that a large portion fell, narrowly escaping some people below. But metal itself is not proof against the atmosphere of London; for the panels and lions at the Nelson Monument, Trafalgar-square, have long since shown signs of decay. It is only fair, however, to mention that some terra-cotta has been made which, from defective burning, is of a very inferior character, disintegrating shortly after exposure. In such the heat applied has not been sufficient to effect the necessary chemical change which gives to terra-cotta its indestructible character.

Good terra-cotta is easily tested, when struck with steel it should emit sparks and merely show a black line, and ring like a bell. Sir Charles Lyell, in his "Antiquity of Man" (chap. iii.) bears remarkable testimony to the wonderful durability of clay, which I cannot do better than quote in concluding this part of my subject. He says:—

"In the vast changes this planet has undergone, few things remain to mark the acts of its earliest inhabitants. Flint, spearheads, arrowheads, fragments of iron, bronze, of pottery, are almost all that remain. Of the latter burned bricks, jars, vases, the human figure,

burned clay, are found in the remains of submerged towns, in the channels of the Nile and in Upper Egypt; in the Mexican buried ruins of America, and elsewhere, as the enduring types of civilisation of peoples and races whose names even are not known in the pages of history. Granite disintegrates and crumbles into particles of sand, quartz, and felspar, marble soon moulders into dust of carbonate of lime, but hard-burned clay endures for ever in the ancient landmarks of mankind."

My next point is that of strength, and, as in the matter of durability, I was able to give you actual examples of the power of terra-cotta, so I can also do with regard to its strength. As already mentioned, terra-cotta for building purposes is generally made of hollow blocks formed with webs inside, so as give extra strength, and keep the work true while drying. This is necessitated because good well-burned terra-cotta cannot safely be made of more than about 1 in. in thickness, whereas, when required to bond with brickwork, it must be at least 4 in. thick. When extra strength is needed, these hollow spaces are filled with concrete, mixed rather weak, as otherwise the cement is liable to swell and burst the terra-cotta. Terra-cotta alone is able to bear a very heavy crushing weight, but thus strengthened its powers are much increased. Some years ago I had occasion to test a block of terra-cotta about 1 ft. cube, but without any cross webs or concrete filling to strengthen it. At 40 tons it splintered at the edges, and at 100 tons it became generally broken but not crushed, for I was able by tying it up with string, before releasing it from the jaws of the hydraulic press, to preserve it in its original shape. This very block I am able to show, though the experiment was made about ten years ago.

The late Mr. Blasfield, at the request of Mr. Charles Barry, and to illustrate a paper on the subject of terra-cotta, read before the Royal Institute of British Architects, prepared an exhaustive series of experiments giving the strength of terra-cotta, the result of which showed that as a building material it greatly exceeded all others in ordinary use, comparing most favourably with Portland, Bath, and ordinary stock bricks. Each specimen was placed between two pieces of 4-in. pine slabs, and the pressure then applied.

The result of these trials was published in tabulated form in the Proceedings of the Institute of British Architects at the time they were made, and a few comparative tests will be sufficient for the present occasion.

A block of Portland about 6 in. by 6 in. by 6 in. bore crushing weight equal per foot super, of 223 tons.	104
A block of Bath of similar dimensions	82
A stock brick	53
A similar solid block of terra-cotta	80
A hollow block, slightly made, and unfilled	163
The same, but filled with concrete	183
A hollow block unfilled, but made with thicker walls	183

These figures are ample to show the correctness of my statement.

Terra-cotta possesses another element of strength, which is not shared either by stone or iron, but which is most important, that of resisting the action of fire. Heat, which would destroy stone, has merely the effect of burning off the dirt from the terra-cotta, giving it the appearance of having just left the kiln. This, as exemplified at our own building a short time since. After the late fire there, which, though of short duration was terrifically fierce, an examination of the sills of windows and copings of walls which were of stone were destroyed, and the dressings to windows which were of terra-cotta were perfectly sound, the great benefit being brightening them up and making them look like new.

This power of resisting heat has been turned to advantage by the introduction of a patent re-proof flooring, called the "Doulton-Peto," samples of which I have near me. The principle consists of a series of hollow blocks of fire-proof material, which, placed between the rolled iron sills, make a flat ceiling, and which may be plastered or not. The blocks next to the iron sills have flanges, which protect the joints from the fire and which form a perfect key for the plaster. We have subjected this flooring to very severe tests with great success. With a weight equal to about 7 cwt. to the foot sup. on a floor of 50 ft. sup. we have lighted a fire underneath, making it red-hot in parts, and, while in this state, have turned on a hose with a considerable pressure of water, but without the least effect. It has also been tested with unevenly distributed weights and with vibration and concussion, all of which it has successfully withstood. This flooring is used throughout at the London Pavilion, where it was found very advantageous from its lightness, the speed with

which it was constructed, and its cleanliness. One of our own factories is also floored with it, where it may be seen by any one interested in the use of fireproof construction.*

The third advantage I would bring under your notice is that of economy, and this is of the utmost importance in the present times, and, perhaps, more than anything else tends to popularise terra-cotta.

In comparison with good stone, while being much more durable and possessing more strength, it is also much cheaper, and I have known the use of terra-cotta to be most helpful to architects, enabling them to carry out their designs in their entirety. You can readily understand how this is in repetitive work; the model once made, the pressing into the mould is a labour which may be repeated as often as required, and at comparatively small cost.

The actual cost of terra-cotta as compared with stone varies according to the class of work and the quantity of repetition. The more elaborate the design the greater advantage will there be in the use of terra-cotta; in some instances as much as one-third less is saved. But even in cases where there is repetition, it may be by good management cheaper than stone. We once carried out a work in which were a number of capitals to columns, all of which were to be different. To accomplish this economically we cast the bell, dressing each one with a different ornament; you will readily understand the economy effected when you remember how much easier it would be to form all such ornaments in the soft plastic clay than to carve them in the hard stone.

This is especially so in the case of sculpture, and I cannot help thinking the day will soon arrive when terra-cotta will be much more used for monumental purposes than it is. Mr. John Bell, the eminent sculptor, has expressed himself very favourably on this score. I will remember his describing to me the immense labour attendant on his executing the colossal group of America at the Albert Memorial, and the method pursued was what is always done in all sculpture. The work is modelled first in clay, and, when finished, a waste mould is taken of it and the stone is carved from this, the finishing touch being done by the sculptor himself, and should it be necessary to carry the work out in bronze, or any repetition needed, a further piece mould would have to be taken, whereas should the work be done in terra-cotta, the first model made in the clay would be burned, and all after labour would be saved. I am aware that this process is attended with some risk, for should any accident happen to it in the burning the work would have to be remodelled, neither could such a method be carried out by the sculptor alone. It must be done in conjunction with the potter, who knowing the difficulties of burning, would carefully select the clay and see that the thicknesses throughout were as even as possible. Beautiful pieces of sculpture have often been ruined in the burning by neglecting this principle.

The largest piece of sculpture that has ever been executed in terra-cotta was Mr. John Bell's group of America at the Albert Memorial, which was manufactured in 1876; and some idea may be formed of the difficulty of the work when I tell you that it consists of five figures each about 10 ft. high, with a buffalo of like proportion in the centre, each figure being in a single piece. This group was sent to the Philadelphia Exhibition, where it was accorded the post of honour, and is now at the Smithsonian Institute, Washington.

Mr. Tinworth, whose studies from Scripture are so well known, rarely moulds his work; but by finishing up the subjects at once in clay, they are then burned, such never being repeated. His work is mostly in very high relief, his method being to make small sketches like those I have here, and from such to model to the size required. Some photographs here represent many of Mr. Tinworth's panels.

Another source of economy is its lightness in comparison with stone, by which means a saving is effected in carriage and handling; and as the filling of the blocks may be done with the broken bricks lying about, the expense of carting away this rubbish is avoided.

The absolute cost of terra-cotta in comparison with stone varies not only with the class of work but with the locality; if in a district where stone abounds it would not be so advantageous. In London it would be on an average, say 20 per

cent. less than Bath, and 40 per cent. less than Portland.

Another advantage it possesses is that of colour. In stone of all kinds except marbles, there is always one uniform tone, whereas in terra-cotta the colour varies, giving an appearance of depth to the work, and producing very pleasing effects.

This variety of colouring is generally produced by the flash of the fire; and its beauty of appearance can best be obtained in this way.

The natural colours of terra-cotta are the buff, the red, and the blue, these colours being more or less intensified by the amount of heat to which they are subjected. Other colours are obtained only by the admixture of foreign matter.

While thus speaking of the advantages of terra-cotta, I would not have you imagine there are no attendant disadvantages or difficulties; the difficulties I have already mentioned being occasioned chiefly by the nature of clay, in the varying effects produced by the action of fire, and the care under these circumstances required to keep the ware from cracks, warps, and twists. The disadvantages in the use of terra-cotta are neither numerous nor insuperable.

As I have already observed, there is the difficulty of getting the blocks true, but this is a matter mainly for the manufacturer; at the same time, much rests with the architect in designing his work so as to be suitable to the material. But the great difficulty is on the score of the extra time required to prepare the necessary drawings, one set for the builder, and another to the shrinkage scale for the manufacturer. But makers now are generally willing to undertake the latter work themselves, the full-sized drawings being all that are necessary.

There are also risks to be run. After all the labour has been spent upon the work, the fire, which is said to try all men's work, may find out some defect in the making and render it useless; to guard against this much care is necessary throughout all the various stages, and generally a few pieces more made than are absolutely required.

This brings me to that greatest of all troubles, the time needed in manufacture, and to combat this, I cannot do better than quote the words of Mr. Charles Barry, in the paper to which I have already alluded, and which would point to really an advantage rather than a disadvantage. He says:—

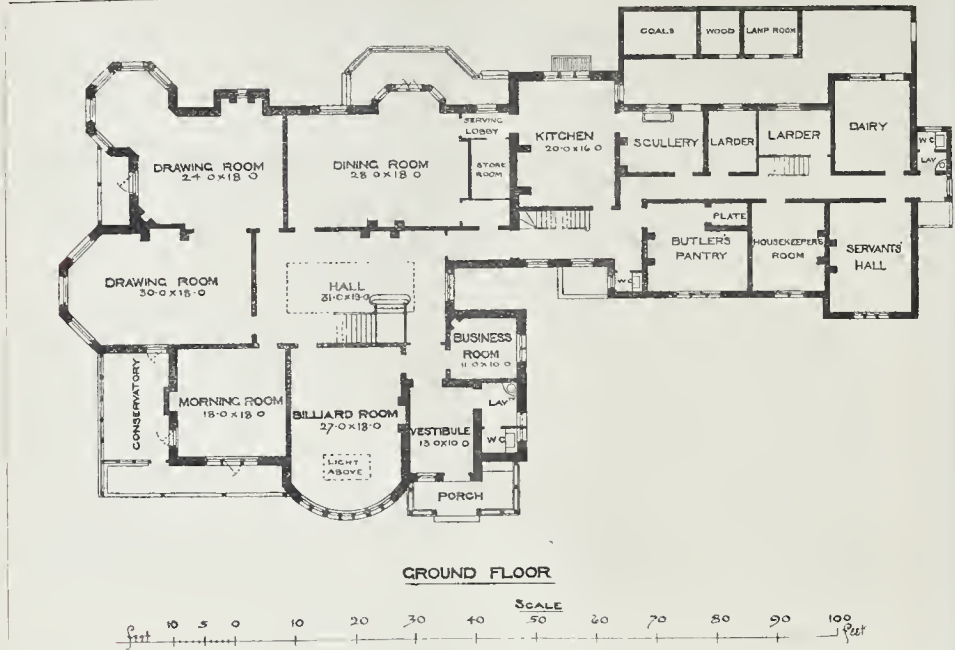

"Of these [that is, the disadvantages] perhaps the most embarrassing is the arrangement necessary to have the terra-cotta blocks made and ready on the ground, before the rest of the work is begun, in order to work in with the bricklayers' progress. At times this is found impossible, and annoying delays in the general work take place, for which clients will be apt to blame the architect. The lesson, of course, to be learned from this is to carefully mature the design at the outset, instead of consulting ourselves, as we now often do, with a mere sketch of what is intended, with the hope and intention of working in parts as time goes on and the work proceeds. I am not sure that architects ought to object to this, since it must produce decision of thought and precision of detail, which may be an advantage in an educational point of view, and is a serious corrective to indolence of thought in design."

Terra-cotta has been objected to on account of its retaining its original colour, and not being toned down as much as other materials by age. Again let me quote from the words given by one of the profession:—"If a design requires age before its beauty becomes apparent, it surely needs re-consideration." But this objection no doubt arose from the fact that at one time it was considered that terra-cotta should be like stone, very even in its colour, whereas one of its greatest beauties, and certainly a distinctive feature, are those slight variations of colour which form its most charming characteristics.

To obviate the risk of warping, every block should be kept within reasonable limits, and large pieces only used where absolutely necessary. Large blocks may indeed be made, but it is very difficult, and the cost of manufacture is thereby considerably increased. In those beautiful examples which I have already mentioned which occur in Northern Italy, and which were erected from the seventh to the thirteenth centuries, brick dimensions are as much as possible adhered to. It is often absolutely necessary to make blocks of large dimensions, but when this is so, a corresponding time should be allowed in their manufacture, — indeed, we have made cornices, &c., of great size, and at the present moment are engaged upon some columns about 10 ft. high, of which one portion of the shaft alone is 5 ft. long.

Some time ago the use of terra-cotta steps

* For section of this system of flooring see *Builder* for December 19 last, p. 877.

Plan of "Ridgemoor," Englefield Green.

was much advocated, especially in buildings erected by the London School Board. Knowing the unreliable nature of the material for such a purpose, we always refused to make them, but to meet the case have lately patented a tread of pottery, of great density, which may be used also as a nosing to stone or concrete steps. The Sicilian tread, as it is called, is absolutely indestructible, and does not become slippery by any amount of use. A flight of steps in one of the main galleries at the Exhibition at South Kensington, which has been in use for the last two years, is still as perfect as when first fixed.

A late development of terra-cotta has been in the form of glazed work. Glazed pottery has long been known, but only as applied to vessels, such as plates, vases, &c., or to tile work for the lining of walls, such as the works of Lucca Della Robbia, &c., and the Saracenic mural decorations; but in the present day there have been some few examples of structural glazed pottery. This glazing may be effected in two ways,—by the application of a glaze washed over the ware, or by the action of salt thrown into the fire. Of these by far the most durable is salt-glazed pottery. It is thought by some that the slight smear on many of the Etruscan vases is due to salt glaze. Certain it is that in excavations made in England several articles of Roman origin have been discovered in this ware. It was not known in England till comparatively late years; but, though Germany in her Grès de Flandres and Rhine ware may be considered as the first in the revival of the salt-glazed stoneware, it was reserved for England to carry this art to its present state of perfection, and it is only a laudable pride to say that at the Lambeth pottery Donlon ware, in its successful manufacture, its range of colouring, and variety of design, has far outstripped the Grès de Flandres which suggested it. The latter was limited in colour, design, and application; but the samples here shown testify to the great strides made by the manufacture of what is now known as Donlon ware. Its application to architectural work has only been attempted within the last few years.

The intense heat to which it is subjected, and the consequent difficulty of keeping its true shape, make its use in this form very difficult. It is comparatively easy in all thrown ware, which, from its circular form, shrinks evenly in all its parts, as may be seen in these vases and pedestals. But in all moulded work the difficulties are immensely increased, the liability to

warp and twist requiring increasing care in all its stages.

That this is not impossible, however, is proved by a work we carried out some short time since, where every portion was salt-glazed stoneware. The vestibule of the Palsgrave, a public building in the Strand opposite to the New Courts of Justice,—is a triumph of patience and skill, and shows how successfully this salt-glazed ornamental stoneware may be used. Mr. Sparke, the principal of the Art School at South Kensington, speaking of this material, says:—

"It comes as an absolutely new application, which it is for the architects of to-day to develop. Such a material if used to touch up a building must be a valuable addition to an architect's resources. With such colours of a soft and rich brilliancy of tone, applicable as they are to every variety of plastic forms: sober, quiet, harmonious, and deep, full of quality, and without any possibility of their ever becoming (even in the hands of inexperienced designers) garish or common; almost any conceivable effect may be produced. The very virtues of this stoneware, which are the results of its greater trials, make it of different application to terra-cotta, as by the greater closeness of texture and the greater heat that must be employed to verify it, a greater risk of warping and cracking is inevitable. This at once indicates its use in small pieces, and in such places where absolute flatness of surface is not indispensable, but under these conditions it may be applied with admirable effect to heighten mouldings, or to panel terra-cotta pilasters; as bases and capitals, especially as shafts to ornamental columns, and as bosses. It is also clear that the disadvantage attached to the use of polished marble for shafts or decorative bosses are completely overcome by the unalterable nature of the new material and the certainty that it will retain its brilliant surface for centuries, without any exfoliation or weathering which too often leaves the most delicate composition without a point of interest, except a regret at its premature decay."

I have thus endeavoured briefly to lay before you some of the advantages accruing from the use of pottery as a building material, both in terra-cotta and stoneware. The necessary cost from the difficulty of manufacture will doubtless limit the latter in its application, but the increasing use of terra-cotta shows its value and popularity, whereas a few years ago one had to search for examples; now they may be found in every part of England and in every style of architecture, from the severe type of work carried out by the Brothers Adam to the picturesque Elizabethan in Early English, not omitting even the Classical.

The durability of terra-cotta, its strength, its economy, its picturesque appearance, will all tend to its extended use. As I have already said, there are difficulties in the way of its universal application, but these are being continually met, and doubtless when the material is more fully understood it will be even more extensively used.

[At the close of the lecture the wheels again shown, and Mr. Butler, who is one of the principal artists at the Lambeth Pottery, showed his skill in carving shafts of columns, bosses, &c.]

The last of this series of lectures was given on Wednesday last by Mr. Banister Flett, M.P., F.R.I.B.A., on "The Influence of Architecture upon Carpentry." The lecture was frequently applauded, was illustrated by many drawings and models. A report will appear in our next issue.

Illustrations.

RIDGEMOOR, ENGLEFIELD GREEN.

THIS house has been lately built for A. de M. Mocatta, on the high ground near Cooper's Hill College. It commands very extensive and beautiful views to the north, and has been so planned that windows of the principal rooms may have advantages of outlook, and, at the same time, be not without sun.

The materials are Bracknell red bricks, stone, and Fareham tiles.

The works have been executed by Watson, builder, of Ascot, from the design and under the superintendence of Mr. E. Cowell Boyes.

FONTAINE D'AMOUR: DESIGN FOR STAINED GLASS.

THIS, a reproduction of the style of the French Renaissance glass, is one of the windows designed by M. Champigneulle and exhibited him in the "Exhibition du Travail," held at Palais d'Industrie at Paris in the autumn last year, and referred to in our "Letters from Paris" of November 7, 1885. We have previously given another of the windows, "Return of Alsace and Lorraine," exhibiting the same time and by the same artist.

LAYER MARNEY TOWERS.

We give this week the further measurements, drawings, made by Mr. A. B. Mitchell, of an interesting building. For a descriptive historical sketch, see the first article in this week's number.

IRON LIGHTHOUSE, SANIBEL ISLAND, U.S.

**"BAINBRIDGE MEMORIAL" CHAPEL,
HEATON-ROAD, NEWCASTLE-ON-TYNE.**

This building, erected for the Wesleyan Methodist body, was opened in November, 1885. The chapel has sittings for 900 adults, capable of increase upon occasions to upwards of 1,000. The lecture-hall adjoining will accommodate 300 to 350 persons, and there are five vestries or class-rooms on the ground and first floors.

In plan the chapel consists of a nave with side aisles and shallow transepts, the extreme internal dimensions being 98 ft. by 55 ft. 6 in. by 40 ft. high to ceiling. There are galleries all round the interior, that for the choir and organ being behind the platform in an apsidal recess. The edifice is substantially built of stone, with internal fittings of pitch-pine. The general contractors were Messrs. Greason & Stockdale, of Gateshead, who executed the carpenter and joiner's work, and entrusted the mason work to Mr. T. H. Hutchison, and the ironwork to Messrs. Bainbridge & Crimson, also of Gateshead; the lead glazier's work to the Gateshead Stained Glass Company; the slating to Mr. John Hewitson, and the plastering to Mr. Thomas Wallace, the plumbing to Mr. R. Herron, and the ordinary glazing, painting, and varnishing to Messrs. A. Robertson & Son, all of Newcastle. The gas-fittings have been supplied by Messrs. T. Thomason & Co., of Manchester; the lightning conductor by Messrs. Henry Walker & Son, of Newcastle; and the warming and ventilating apparatus by Messrs. Dinning & Cooke, Newcastle.

The clerk of works was Mr. James Grant. The buildings are warmed by hot water on the low-pressure system, arrangements being made for the admission of fresh air warmed by passing through coils of pipes, while the tower (90 ft. high) is utilised for ventilation and forms a powerful extracting-shaft for the vitiated air; tests by an anemometer showing that the air of the interior of the chapel can be changed every twenty minutes.

The architects are Messrs. S. Oswald & Son, of Newcastle, whose designs were selected in limited competition, and the whole of the works have been carried out under their supervision at a cost within the contract amount of 4,956*l.* The total cost, including site, &c., was about 6,500*l.*

LIGHTHOUSE, SANIBEL ISLAND.

In many places round the coast of the United States, in the large inland lakes, and in important rivers, the Government have built and are now erecting many Lighthouses which are designed in the Government Offices at Washington, D.C. Iron is extensively used in their construction, some of them being built wholly of this material, and of bold and original design. The drawings are very carefully elaborated, every detail being worked out, and are especially valuable as showing what is, perhaps, one of the most successful of the systems of iron construction for buildings.

I am indebted to Mr. P. J. Peltz for the fine series of lighthouse drawings, some of which were exhibited at the Institute recently. The one here given, on Sanibel Island, may be taken as a type of the class. JOHN B. GASS.

COMPETITIONS.

Congregational Church, Sidcup.—In a competition between five architects for a Congregational Church at Sidcup, Kent, the plans submitted by Mr. George Baines, of Great Winchester-street, London, have been unanimously selected by the committee. The church will ultimately seat 840 persons, and will be in the Geometric Gothic style, with a tower and spire.

Whitehaven Colliery Recreation Ground and Buildings.—The designs of Mr. George Dale Oliver, architect, of Carlisle and Workington, submitted in competition, for laying out the recreation-grounds and for the new club buildings, pavilion, &c., have been selected by the professional adjudicator, and awarded the premium. The committee has confirmed the award.

New School, Coathridge, Scotland.—The School Board of Old Monkland have selected designs submitted by Mr. James Higgins, architect, 95, Bath-street, Glasgow, out of thirty-two sets submitted in open competition for new school, Whifflet, Coathridge. The selected plan is designed to accommodate 1,000 children at a cost of about 8*l.* per scholar.

**CLERKS OF WORKS' ASSOCIATION OF
GREAT BRITAIN.**

THE third annual dinner of this excellent Association was held on Monday evening last, in the Venetian Saloon of the Holborn Restaurant, Mr. T. Chatfeild Clarke, F.R.I.B.A., in the chair. About 220 members and visitors sat down to table. The usual loyal and patriotic toasts were heartily received, Mr. Aitchison replying on behalf of "The Reserve Forces."

Mr. J. Wilkinson proposed "The Architects," coupled with the name of Mr. Francis Chambers, F.R.I.B.A.

Mr. Chambers, in an able and entertaining speech, said that in his younger days those who were entitled to be ranked as architects might almost be counted on the fingers of one's hands, but owing to the extensive rebuilding operations which had been going on during the last half century in London and other large cities of the country, architects had greatly increased in numbers, although many an incompetent person had dubbed himself "architect" without any right to that honourable designation. Not only land-agents and undertakers, but even linen-drillers had been known to call themselves architects. With a view to prevent this sort of thing, and for the protection of the public, the Institute of Architects had a few years ago set on foot a system of examination in order to test the fitness of the candidates for architectural practice. Mr. Chambers went on to speak of the indolence of architects to clerks of works, remarking that, just as it had been said that no man was a hero to his valet de chambre, so might it be said that very few architects were perfect in the eyes of their clerks of works. It was the clerk of works who generally found out the weak points in specification or drawing, and who very quietly and respectfully pointed them out without making any fuss.

Mr. Brady proposed "The Surveyors," on whose behalf Mr. H. H. Leonard responded.

In proposing the toast of the evening, "The Clerks of Works' Association," the Chairman expressed his great gratification at the success of the Association, and said that the clerk of the works was still a very important personage, although he was no longer in holy orders, as was the fact in mediæval times. In 1365, it was recorded that the pay of the clerk of the King's works was £18.4*s.* per annum—a very different sum to that which was now represented by those figures. He quite endorsed what had been said by Mr. Chambers as to the immeasurable advantage which it was to any practising architect, struggling with a number of diverse engagements, to have a responsible man upon whose perfect integrity and ability he could rely to see that the specified requirements of construction were met. The clerk of works of the present day had to supervise the details of a number of special things, such as fireproof construction, electric lighting, and heating and ventilating arrangements, all of which called for some amount of study of scientific matters. With the toast he coupled the name of Mr. F. Dashwood.

Mr. Dashwood, in reply, stated that the Association now numbered 98 members, all of whom were men of proved experience.

The other toasts were, "The Honorary Treasurer, Mr. John Oldrid Scott" (proposed by Mr. Woodley), on whose behalf Mr. Redden responded; "The President, Vice-Presidents, and Committee," proposed by Mr. Calvert, and replied to by Mr. Hocking (who stated that the hope that the time would come, and that before very many years, when the Association would have its own library, lecture-hall, and building museum); "The Past Officers" (proposed by Mr. King, and responded to by Mr. Moore); "The Press" (proposed by Mr. Dillon, and responded to by Mr. Brady, the editor of the *Journal of the Association*); "The Visitors" (proposed by Mr. Griffiths, and replied to by Mr. Burch); and "The Chairman," proposed by Mr. Birtchell.

Tunbridge Wells.—Salvation Army Barracks are to be erected at Tunbridge Wells, on the site of the Old Gasworks in Varney-street. The style adopted is the Jacobean, and the front elevation is of brick, with stone dressings. The building will seat about 1,000 persons. For week-night services revolving-shutters will be so fixed as to shut off the gallery and part of the main hall. Mr. E. J. Sherwood, of Queen Victoria-street, is the architect.

**SALE OF THE MATERIALS OF LORD
CARRINGTON'S HOUSE.**

A FEW weeks will see the last of Lord Carrington's house, Whitehall, which is about to be taken down to clear the site for the Whitehall improvement and the new approach to the Thames Embankment, which is to be called Horseguards Avenue. The first portion of the materials of the mansion was sold on Tuesday last by Messrs. Horne, Son, & Eversfield, in direction of the Commissioners of Woods and Forests. They comprised the fixtures and fittings of the ball-room, the how-room, the painted-ceiling room, the music-room, the north and south drawing-rooms, the centre-room, the dining-room, and the landing at the top of the principal staircase. The sale attracted a numerous attendance, which was not confined to the ordinary dealers in building materials, but included several gentlemen who were large purchasers of the most valuable lots. It was considered that unusually high prices were realised for the whole of the lots submitted, the competition throughout being very active. The chimney-pieces in the different apartments fetched the longest prices, 85*l.* being given for that in the dining-room, consisting of white statuary marble, inlaid with Brocatella. That in the painted-ceiling room, consisting of statuary marble, inlaid with Sienna marble, realised 75*l.*; whilst the wood chimney-piece in the steward's room, having carved caryatides, centre, mouldings and frieze, and marble jambs, was sold for 60*l.* That in the music-room, consisting of statuary marble, inlaid with Brocatella, and having carved trusses and ornaments, fetched 55*l.* Those in the north and south drawing-rooms, consisting of statuary marble, with Genoa green marble friezes and jambs, were sold for 30*l.* and 32*l.* respectively. The carved wood chimney-piece in the bow-room, with Sienna marble frieze and jambs, realised 20*l.*, whilst the statuary marble chimney-piece in a bed ante-room, inlaid with Sienna marble, was sold for 16*l.* 10*s.* With one or two exceptions the whole of these chimney-pieces were purchased by a gentleman who was understood to be the representative of a nobleman who is erecting a new mansion, in which the chimney-pieces are to be introduced. The several carved and panelled doors realised prices ranging from 5*l.* to 8*l.* each. All the floors of the various rooms are in oak, and it was notified that the flooring of the ball-room,—60 ft. l. length and 30 ft. in width, was not to be sold. The stone steps of the principal staircase, 6 ft. in width, together with the balusters and hand-rail, were similarly reserved. During the sale specimens of photographic views of the different apartments in the interior of the mansion were exhibited by Messrs. Bedford Lemere & Co. architectural photographers. The remainder of the materials of the mansion will be sold on Tuesday, the 20th inst. Views of the dining-room and of the staircase appeared in the *Builder* for Aug. 9, 1884. These interiors are attributed to Sir William Chambers.

The Parliamentary Committee of the Metropolitan Board of Works have resolved to recommend that the Board's petition against the Horse Guards Avenue Bill be withdrawn until the promoters undertaking to strike out the words providing that the Board may contribute towards the cost of the work, and to convey to the Board another piece of ground in exchange for any portion of the Embankment Garden which may be taken for the purpose of the undertaking.

Exhibits for Edinburgh and Liverpool. Messrs. Strodé & Co., the well-known engineers, have made a large number of articles for the forthcoming exhibitions at Liverpool and Edinburgh, including gasoliers, brackets, &c., for gas, in wrought iron and brass; number of lamps for burning oil; some wrought iron dog-grates and fenders; handy and elegant "five o'clock tea tables"; and a variety of miscellaneous articles, all characteristic of good in workmanship and design. We had the opportunity of seeing the goods on Saturday last, at the factory in Osnaburgh-street, prior to their being sent off. While speaking, Messrs. Strodé's work, we take occasion to call attention to their special pliable wrought-iron gas-pipe, which is manufactured with special regard to bending without fracture, and especially to come into general use wherever the work is desiderated.

ROBERTS'S RAIN-WATER SEPARATOR.

This useful invention, which was noticed in *The Builder* some two or three years ago, has lately been considerably improved, and the improvements form the subject of a new patent No. 10,994 of 1885. The new separators are divided into two classes, the simple and the compound; the latter being specially contrived to remain canted for five hours after the cessation of rain, so that any subsequent rain, falling within that period, shall be at once conveyed to the storage-tank. This form is not fitted for use in towns, but is intended for country houses where it is necessary to economise rain-water to the utmost. The simple separator, illustrated by the accompanying figure, is preferable wherever the occasional loss of a few gallons in showery weather is not of importance; it is free from all complication and needs no attention under ordinary circumstances. Both the simple and the compound separators possess the following advantages over the earlier forms of apparatus:—1st, they do not require such a heavy rainfall to start them; 2nd, the time of starting varies inversely with the heaviness of the rainfall; 3rd, the exact amount of washing allowed for the roof is very easily regulated by the insertion of different time gauges at B to

into the position shown in the section. When there is more rain than can pass through B it flows through an adjustable sluice-passage C, which can be made wider or narrower by the aid of a graduated scale marked upon it, to correspond to the area of the roof. With each increase of rainfall, the depth of the stream flowing out at the sluice C increases, causing a slight increase of pressure, and consequently a greater flow of water through B. A is the strainer, removable for washing; D is the outlet for surplus water; E the delivery-pipe.

The use of one of these rain-water separators, combined with a properly-constructed and adequately-protected tank, will, we should think, be found to solve the question of water supply in the case of many an isolated house, for by their means the water of copious rainfalls may be stored up against times of drought. In towns, the usefulness of the appliance in securing a good supply of clean soft water for domestic purposes is likely to be fully appreciated. Prior to the introduction of Mr. Roberts's separators it was not possible to obtain rain water in towns in any appreciable quantities without the sooty and other impurities from the roofs. By the use of the separator all these impurities are carried away by the first flush, and only the clean water is stored. The separator is to be seen at the Building Trades' Exhibition.

A NEW CISTERN-VALVE.

MANN's patent high-pressure cistern-valve, of which the accompanying diagram represents a section, has been devised with a view to the utilisation of the power given by the force with which water propels itself through mains from any elevated point. The pressure, which varies according to the head of water,—say, from 20 lb. to 100 lb. to the square inch,—is, in this invention used as a means for stopping the supply the moment the cistern becomes full.

The water enters the valve at the inlet union A, passes up the stem B, and issues, at full pressure, from outlets C until the cistern is

charged. As soon as the level of water in the cistern has reached and covered the lower half of the ball F, the ball and cylinder, D, commence rising from the base-plate E. Having risen 1 in., the force of water, by the partial closing of the outlet ports C, immediately takes possession of the interior of the cylinder D, by passing down the annular tube between the cylinder and the stem B into the pressure receiver G. The force of water from this receiver, being directed upwards, strikes the upper internal portion of the cylinder D, thereby causing the ball and cylinder to leap from the level of the water in the cistern to the rubber seating, H, at the top of the valve. This at once seals the outlets C. The full pressure then acts instantaneously

between the internal head portion of the cylinder D, and the loose flange collar, I, resting on the rubber seating, J. This seating, by the pressure of water on the flange collar, expands, and effectually closes the lower portion of the cylinder D; and thus, in conjunction with the air confined in the cylinder, the supply is immediately stopped in a silent manner. The working portion of the valve has free play, and is clear of any kind of packing. The diameter of the ball is 5½ in., and the length from base E is 9 in.

We are informed that this valve has been severely tested, and that its use has been sanctioned by several of the London water companies. It is manufactured by Mr. George Day, of 31, Liverpool-road, Islington.

WOOD-BLOCK FLOORING.

AN improved system of wood-block flooring has recently been introduced by Messrs. Geary & Walker, of London and Manchester, who are well known as specialists in this class of work. The distinguishing feature of the patent, which will be known as 'Geary's improved patent 'Invincible' system of Wood Block Flooring,' is that each block forming the flooring is firmly 'keyed' to the substructure by means of metal 'keys,' which are dovetailed into the under-sides of the blocks; the other extremities of these 'keys' being embedded in a specially-prepared matrix; the latter acting not only as a damp-proof course and a preservative against dry-rot, but also as a 'floating' to the concrete foundation, thus rendering the usual cement-finished surface un-

necessary. Reference to the illustration here given will make this clear. By this system of flooring, each block is keyed, independently of its neighbour, to the substructure. An additional key is also formed by means of the grooves which traverse the sides of the blocks, as shown in the illustration: the mastic being forced into these grooves, thereby binding the blocks to each other and to the concrete foundation. The grooves also prevent the mastic working to the top of the blocks, and enable perfectly close joints to be obtained. As the mastic on which the blocks are hedged is strongly adhesive, a third agency thus assists in constituting what is a thoroughly solid and immovable flooring, admirable for use in warehouses, basements, railway station waiting-rooms, and offices, hospitals, churches, mansions, schools, and public buildings generally.

Messrs. Geary & Walker employ a new form of machine for preparing the blocks, ensuring mathematical accuracy in size, and consequently perfect joints when laid.

The Proposed Railway up Mount Pilatus.

The project for a railway to the summit of the well-known Alpine height, Mount Pilatus, is making very satisfactory progress. A considerable portion of the 2,000,000 francs required for carrying out the undertaking has already been subscribed in Switzerland. The line will start from Alpnach, and rise gradually to a height of nearly 7,000 ft., terminating at the Hotel Bellevue, which is situated at that altitude. The total length of the railway will be rather more than 2½ miles, of which distance fully one half will be occupied by the necessarily circuitous curves and windings. The majority of the curves have a radius of from 200 ft. to 300 ft. The gradient varies from one in ten to one in four. Amongst the principal features of the work will be a viaduct over the Wolfbach, as well as four tunnels. When completed, the cars, which will be drawn by a rope moved by a stationary engine, will perform the ascent in about eight minutes. The Mount Pilatus railway will, in fact, be a somewhat serious competitor to the similar line already in existence up the Rigi, and the rivalry will, it appears, be still greater when the new hotels which it is designed to build upon Mount Pilatus shall have been finished.

a wash of 1, 1½, or 2 gallons to each ft. of roof; 4th, leaves and other rubbish longer need to be removed by hand, as the passage is provided for them into the pipe. In the earlier forms of separators the whole of the water passed through the filter; now, in heavy rains, only a small portion passes through, and the surplus carries rubbish over the surface of the strainer. Leaves are thus washed away at the commencement of the shower into F and down the water-pipe. This takes place while the roof is being washed clean, and before the chamber K is filled up and caused the centre part to swing down upon the pivot J and assume the position shown in the illustration, where the pure water only passing into storage. In the earlier form of separator there was no action till the amount of water was more than could escape through two holes; now the filling commences as soon as there is more rain than can pass through the one small hole at L, hence it is a much lighter rainfall. The following method adopted for making the time of starting short in a heavy and long in a light rain. In a very light rain all the water passes through B and into K, and, if there is more than can run out at the small hole L, the chamber K fills very slowly till, the left side being heavier than the right, it is canted

ASSOCIATES OF THE ROYAL INSTITUTE OF BRITISH ARCHITECTS.

SIR,—The new Charter of the Institute was yesterday, at the close of an all-day sitting, finally passed by the Fellows without dissent. Under this Charter the right of voting on all questions, except the making of by-laws, is secured for every Associate, and nothing is enacted to prevent Associates being placed on the Council, should the by-laws so provide.

At the ordinary business meeting held on the 29th ult., another very important step, directly affecting the Associates, was taken by the Institute; and as the attendance at that meeting was not very large, I desire to draw special attention to the subject.

The scheme of "Departmental Action" originated by Professor Kerr, and brought into form by a Special Committee, of which I have the honour to be a member, was, with certain alterations, accepted by the Institute; and the members of the four standing Committees, thus created, are to be appointed at the annual meeting on the 3rd of May next.

Six seats on each of these Standing Committees are reserved for Associates, and the Council has requested Associates to volunteer to serve on them.

I wish now to impress upon my brother Associates that it is their duty to throw their energies and their enthusiasm into the work of the Institute. It will be shameful for them to complain in the future that the Institute is "sleepy" or "useless"; if such be the case it will be their own fault.

In whatever direction their particular taste and abilities lead them, there is opportunity for assisting in the work, as the four committees deal, respectively, with:—1, "Art," including Archaeology; 2, "Science"; 3, "Literature"; and 4, "Practice of the Profession." These committees appoint their own chairmen, vice-chairmen, and hon. secretaries, and have the power of initiating their work; it will be their duty to carefully watch and consider everything of interest to architects, each in its special department, leaving the Council free to exercise all the functions properly appertaining to the supreme executive authority.

I therefore hope that Associates will now come forward, and be prepared to exercise some self-denial, for the sake of our noble art, of the honourable profession to which we belong, and, may I add, of our representative Institute, which, having successfully struggled with those ills which are incidental to childhood and to youth, has now passed into the period of manhood. May it be a vigorous and a useful one!

April 7. G. RICHARDS JULIAN.

SUNDERLAND MUNICIPAL BUILDINGS COMPETITION.

SIR,—I understand it is freely rumoured in Sunderland and the district that a Sunderland architect, with friends among the authorities, had his sketch-design prepared before the advertisements were issued, and is more than likely to be the successful competitor in the Sunderland Municipal Buildings Competition. Time will show what truth there is in such rumours. But, as a competitor, I for one intend to address a letter to the Council, urging them to give a guarantee of fair play, by appointing Mr. Waterhouse or some equally eminent architect, to adjudicate on the plans, in which case the local architects will stand as good a chance as others. A COMPETITOR.

STONE-SAWING AND MOSAIC MANUFACTURE.

SIR,—As some of the readers of the report of the stone-working machinery case (Hall & Co. v. Burke & Co.), in your issue of March 27th [p. 489], may be interested in the conversion of marble, granite, and other hard stones, I send you a short description of the Belgian machines purchased by the defendant, and referred to in the trial, as they are without doubt considerably in advance of any machines for the like purpose yet made in this country.

The swing or saw-frame carrying the blades is driven by a crank attached to a countershaft in the usual manner, but in place of the connecting-rod being attached to the end of the saw-frame, a pair of side levers are arranged to take hold of the frame at about the centre on either side, thus giving a longer connecting-rod and increased steadiness in working. The blades are lowered into the stone by an improved form of downward screw-feed, which can be regulated in speed in proportion to the hardness of the stone being cut; at the same time, the blades are kept steadily to their work at an even

pressure. One of the chief difficulties in converting hard stones is in securing a regular and uniform supply of sand and water over the whole surface of the block, but this has been well overcome in the machines under notice. In the place of the ordinary contrivances a wooden sand-box extending the whole length of the stone is employed; this is perforated, and jets of water from a flexible pipe are allowed to fall in it in the usual way, but by an ingenious automatic cam-motion the sand-box is arranged to traverse slowly in a transverse direction across the face of the stone, thus all the blades are equally supplied with abrading particles, and their cutting is uniform. By simply pulling a lever the saw-frame containing the blades is automatically raised or lowered as may be required. There are other good points in these frames, but the above are the most important. The downward cutting speed in tolerably hard marbles is about $\frac{3}{4}$ in. per hour.

Author of "Stoneworking Machinery," &c.

THE MARNEY MONUMENT.

SIR,—There is a passage in the inscription quoted from the Marney monument at Little Horkesley, Essex, which preserves a mode of address or designation now repudiated as "bad form." Your engraving reads thus:—"Wife to Mr. Thomas Fyrdorne, Esquire." We do not now admit the conjunction of magister and squire, and it is of interest to know if the inscription is correctly so read.

The prefix "layer" is not topographical, but like the affix in Layer Marney, both words are patronymics. Sir Robert de Marney, kt., temp. Ed. III., married Alice, daughter and heir of Richard Layer, and their joint names are thus preserved to this day. Layer is a common name in the Eastern Counties, where it is possibly connected with oyster culture (9). A. H.

The Student's Column.

OUR BUILDING STONES.—V.

RESISTANCE TO THRUSTING STRESS.

STONES having a somewhat similar appearance to each other are often found on examination to be of different strength, so that considerable attention has been paid to the results of experiments dealing with this part of the subject.

The weight necessary to crush a stone varies with the state of cohesion and hardness of the particles composing it. It follows, therefore, as the amount of water a stone absorbs is proportionate to the state of aggregation of the particles composing it, that the crushing weight will be proportionate to the amount of absorbed water. Or, to put it in another way, suppose we know the average amount of water absorbed by certain stones, we can get an idea of their relative strength. A careful comparison of several published accounts of crushing weight and absorption of water by stone, would show that this rule is almost invariably borne out. The few exceptions that exist are due in a great measure to the insufficient manner in which the stones have been described, causing the comparison to be made between stones widely different from each other, but which, unfortunately, bear the same name.

In comparing published results of experiments with each other, care should always be taken to see whether the exact stratigraphical horizon of the stone in each quarry is stated. Many recorded "crushing weights" do not show this, and it is quite evident, therefore, that mistakes are sure to happen, unless there is only one bed worked for building purposes in each of the quarries whence the stones were respectively obtained.

Again, where stones found in quarries adjacent to each other are known collectively under one term, it is very necessary to be certain not only of the exact horizon, but of the name of the quarry of each of the specimens examined. The terms Portland stone, Cornish stone, Bath stone, for example, require something further to qualify them, for there are several kinds of stone included under each of these headings, varying greatly in structure, texture, and durability. Unless these terms are qualified, all records of their chemical or physical characters are of little or no use.

Occasionally, after going carefully into the matter, we may find that the beds from which certain kinds of stone, having good repute a few years ago, were obtained, have been worked out or abandoned, as becoming too expensive to work. In spite of this, however, to keep up the

rate of sale the same names are retained to the present day, and designate stones which may come from the same localities, but are quite different in many particulars from those to which the names originally referred. (We shall point them out as these articles progress.) The discrepant results, on comparison, which may arise from this cause are at once manifest. Sometimes no appreciable difference in quality or durability exists between the original stones and those bearing the original names, but the latter are quite as often stones of inferior quality. In all cases the crushing weight, amount of absorption of water, &c., must vary, and it is for these reasons that all recent results should be the most trustworthy. Unfortunately, however, in the absence of recent experiments, the old ones are still adhered to: hence many serious errors arise.

Stones made up of large shells are difficult to deal with in selecting pieces for crushing; it is not easy to obtain average pieces. It is simply ridiculous to find the strength of 1 in. cubes of such stones (as has often been done): large pieces should always be experimented upon, certainly not smaller than 6 in. cubes. It can be shown that in many cases no very great difference exists between the relative crushing weights of 1 in. and 6 in. cubes of stones of homogeneous character; but when rocks contain large crystals, such as the porphyries, or large shells, such as are found in many lime stones, the crushing weight must vary considerably according to the general position of the cleavage planes of the crystals, or the predominant direction of the exterior faces of the shells.

A small cube might fail to prove the existence of cracks and flaws invisible to the naked eye, in large blocks of the same stone. The comparative strength of the large blocks would thus be lower than the examination of the small cube would seem to warrant, for it must be remembered that the strength of a stone is only the strength of its weakest part.

Experiments as to the strength of stone also vary according to the machinery used, as well as the skill and care with which the experiments are made and recorded.

In a paper read at the Royal Institute of British Architects,* Captain Seddon, R.E., says:—

"If we take a stone which has been quarried, perhaps, than any other, namely Portland, we learn from Barlow that its crushing strength ranges from about 1,384 lb. to 4,000 lb. per square inch, whilst, in the experiments made by this Institute and recorded in your sessional papers for 1864, the average resistance to crushing per square inch arrived at was, for 2-inch cubes, 2,576 lb.; for 4-inch cubes, 4,099 lb.; and, for 6-inch cubes, 4,300 lb."

"According to Rennie his crushing strength may be taken as 3,729 lb. per square inch, which has been followed by Moleworth in his 'Handbook,' whilst in Hurst's 'Handbook' it is given as 2,022 lb. per square inch."

The many kinds of Portland stone, the different methods pursued in making them, experiments, amount of seasoning and direction of the natural bed of the stone when crushed, no doubt cause the discrepancies between these results.

In testing the crushing weight of stones it is desirable, for comparison's sake, that the should be of the same size and shape. Cubes are generally used, but occasionally quadrants and octants of columns of different diameters and heights are tested for special purpose. The results obtained from the latter should be kept by themselves as much as possible.

When cubes are used they should all be carefully dressed by rubbing down in the ordinary manner, and the faces which have to receive the compressing force should be made parallel. Some experimentalists, knowing how important it is to have these faces exactly parallel with each other, and to have all the specimens of the same height, as nearly as possible, finish them with a steel frame, which encloses and holds all the stones at the same time. After dressing or setting of faces in this manner they are all turned over, and the opposite set is similarly treated. Before being crushed, some stones have been gauged to the thousandth part of an inch.

It is particularly necessary to notice whether the stones to be crushed are placed on or against their natural bed.

* See the Builder, vol. xxx. (1872), p. 418.

The machine used to ascertain the amount of stress to thrusting stress is generally the hydraulic press. The principle of the press is simple to any one who understands the equal transmission of fluid pressure. Conceive that a vessel with its upper surface level is completely filled with water, and that two openings are made in it, which are replaced by pistons of 1 and 10 square inches. If a weight of 1 lb. be placed on the smaller piston, a pressure of 1 lb. will be felt everywhere in the interior of the fluid, and the pressure on the larger piston will be 10 lb. Thus a force of 1 lb., acting on the area 1 square inch, produces a pressure of 10 lb. on the area 10 square inches.*

The principle of the press admits of extension as far as the strength of the containing sides of the pressing-chamber will permit. Very good presses have a hemispherical base.

The circular of Messrs. Poole & Son relating to the press between parallel iron plates, and the pressure is communicated to the cubes interposing above and below each cube, two parallel plates of sheet lead, and the upper or lower plate communicates its force upon the plates of lead by a conical heap of sanders' sand carefully pressed by the upper into a parallel mass, so as to press equally over the upper bed of the cube. It is stated that this method was adopted to insure an equal pressure on every particle of the upper and lower beds of the stone.

The pieces of stone are also frequently loaded with pieces of pine varying from 2 in. in thickness; and leather has likewise been used.

Mr. David Kirkaldy, who has had great experience in testing the crushing weight of rocks, we may judge from the number of results obtained, appears to prefer to experiment on cubes 6-in. cubes. It is not an easy matter, never, to get all the cubes exactly 6 in.: so, to be precise, he shows the dimensions of the cubes to two places of decimals. He works on the base area of each sample, shows the weight, pounds per square inch, and tons per square foot when the stones cracked slightly; and similarly when they were crushed and the fragments dropped. The mean strength of the pieces is then struck.

Some authorities seem to think that experiments should be made on prisms, whose heights are about one and a half times their breadth. It is not necessary to state that the stone varies considerably in different samples, and even in different cubes from the same sample. Although it is usual to strike an average in all cases, in practice it will never be possible to get all the stones equal to the average, and therefore very great allowance must be made for weak, bad, and cracked cubes. Thus, we see that experiments indicate a strength than the real strength of the material.

Professor Rankine shows that this remark applies for another reason, for the fracture of stones under compression generally takes place either shearing on a plane inclined at a slope of 1 1/2 rise to 1 of base.

There is practically no cause of danger in masonry buildings by the crushing of the stone, which they are built.

The greatest stress that comes upon part of the masonry of St. Paul's Cathedral under 14 tons per square foot. In St. Peter's, Rome, it is about 15 1/2 tons per square foot. The weakest sandstones (used in buildings that exist will bear a compression of 120 per foot, while the resistance of ordinary building stones ranges from 140 to 500 tons per foot, and in the case of granites and gneisses 700 or 800 tons per square foot.*

There are in some forms of arches, retaining walls, &c., are liable to be crushed by reason of pressure being concentrated upon certain parts. The walls of buildings made of stone of different qualities are sometimes subjected to severe strains by reason of the inferior quality of the masonry, leaving the pressure which was intended to be distributed on the others concentrated upon them.

A few experiments testing the transverse strength of stone have been carried out. We find that some stones are more capable of resisting a bending stress than others, and seeing so many tests in practice are subjected

to a bending stress it is remarkable that so little attention has been paid to it. Most of the samples which have been tested are used for paving, but we want to know more about the transverse strength of stones used for stairs, &c.

RECENT PATENTS.
ABSTRACTS OF SPECIFICATIONS.

16,465, Quays, &c., Retaining Walls, and Similar Structures. H. J. Fourmond (Rouen).

The walls are of plated ironwork in place of the ordinary stone or concrete now in use. Beams and uprights are so placed that earthwork may be thrown up behind and around them, the front of the uprights being plated with iron, mud or earth in a liquid or plastic state is poured in so as to fill all the interstices, and, if desired, may be built on shore and sunk into place by means of air-tight caissons, which are then removed. Piers are constructed in a similar manner, two walls tied together being employed and sunk into position, and then filled in the same way as described. Docks, locks, &c., are built on slipways, launched, floated, and then sunk into place by being filled with water. Retaining walls can be founded on concrete or masonry in place of tiles, as their foundations are not commonly under water, and are anchored to piles or masonry in a precisely similar manner to that described above.

17,039, Core Stoves. R. Buchanan.

Stoves for drying moulds and cores are heated by gas from a gas producer in connexion with the stoves. The gas is admitted to the stove with air, and burns near the roof the products passing away through holes in the floor.

17,076, Chimney Top. E. and J. M. Verity.

A cylindrical shaft which may have a conical top is constructed externally with a number of spiral, trough-like fins or hollow grooves having open spaces or slots between them. The whole is made in sections which can be easily fitted together.

17,070, Fixing Rounds of Ladders. T. Ray.

The hollow metal bar or tube which forms the round of the ladder has taper ends, and when inserted in a countersunk hole in the side-piece to which it is attached, this taper portion is pressed outwards by pins to fill the hole and fix the tube in position.

MEETINGS.

SATURDAY, APRIL 10.
Architectural Association.—Visit to the Constitutional Club, Northumberland-avenue. Members to assemble at 3 p.m.
St. Paul's Ecological Society.—Visit to the Church of St. Bartholomew the Great, Smithfield. 3.15 p.m.
Royal Institution.—Professor Oliver Lodge on "Fuel and Smoke." I. 3 p.m.
Edinburgh Architectural Association.—Visit to Hatton House.

MONDAY, APRIL 12.
Surveyors' Institution.—Adjourned discussion on Mr. Wm. Mathew's paper on "The Taxation of Real Property." 8 p.m.
Society of Arts (Cantor Lectures).—Mr. Alan S. Cole on "The Arts of Tapestry-making and Embroidery." II. 8 p.m.
Society of Antiquaries of Scotland (Edinburgh).—8 p.m.

TUESDAY, APRIL 13.
Institution of Civil Engineers.—(I) Discussion on Dr. Percy Frankland's paper, "Water Purification." (2) Time permitting, Paper by Mr. Henry Ward on "Brick-making." 8 p.m.
Society of Arts, April 14.
Society of Arts.—Dr. C. Heymott Tidy on "The Treatment of Sewage." 8 p.m.

WEDNESDAY, APRIL 14.
Society of Arts.—Dr. C. Heymott Tidy on "The Treatment of Sewage." 8 p.m.

THURSDAY, APRIL 15.
Society for the Encouragement of the Fine Arts.—Mr. E. P. Loftus Brock on "Old Engravings of the Italian Schools." 8 p.m.
Parkes Museum of Hygiene.—The Rev. F. Lawrence on "Eremacausis: Sanitary Burials." 8 p.m.
Edinburgh Architectural Association.—Address by Mr. James Sellar, of Glasgow. 8.30 p.m.
York Architectural Association.—Mr. William Hepper on "The Development of Window Tracery in England." 7.30 p.m.
Dundee Institute of Architecture.—Social Meeting. 7 p.m.

FRIDAY, APRIL 16.
Parkes Museum of Hygiene.—Extraordinary General Meeting for the purpose of considering the desirability of amalgamating with the Sanitary Institute, and applying for a Royal Charter. 5 p.m.

SATURDAY, APRIL 17.
Royal Institution.—Professor Oliver Lodge on "Fuel and Smoke." II. 3 p.m.

The Working Lads' Institute.

The Committee of the new Working Lads' Institute, Whitechapel, have instructed their architect, Mr. George Baines, to prepare plans for the second section, consisting of a large swimming-bath and gymnasium and lecture-hall for 550 persons. A boat fifty unemployed workmen have recently been engaged on the excavations for the swimming-bath, 4000, having been voted from the Mansion House Relief Fund for this purpose.

Prof. Goodvee, "Prime of Mechanics," 1883, p. 232. Notes on Building Construction," Bivingtons, 1879, III., "Materials," p. 6.

Miscellanea.

Brickmaking in New York.—The largest brickmaking district of the United States is that of Haverstraw, New York State, on the Hudson River, thirty-two miles above New York. The forty-five brickyards of the district, with a capacity for making 340,000,000 bricks annually, turned out 300,000,000 in 1885, and a similar number in 1884. Employment is found for about 2,000 men, besides 300 in the river carrying trade, which keeps forty-four barges and fifty small vessels going. Haverstraw bricks are preferred on account of the excellent sand and clay used, and fetch between 25 and 50 cents more per 1,000. Their average price last season was 6 dols. per 1,000 in New York, after paying 1 dol. river freight and 1 dol. to 1.25 dol. per 1,000 royalty to the owners of the land where the yards are situate. The works use during a season 42,000 cords of wood for heating the kilns, at 5 dols. per cord; 12,000 tons of coal dust, at 2 dols. a ton; and 4,000 tons of coal, at 4.25 dols. a ton; total cost for fuel, 251,000 dols. The total amount of royalties paid was about 337,000 dols.; and wages (averaging 2.25 dols. a day), 770,000 dols., during a season lasting about six months. Two hundred patent brick presses are employed in the manufacture. The total gross receipts last year are given at 1,800,000 dols. The industry was established at Haverstraw about fifty years ago. At that time 3 dols. per 1,000 was a fair price. Quotations have been as high as 9 dols. ago.

New York Underground Electric Railway.—The New York District Railway Company recently published an illustrated circular descriptive of its projected system of underground railways for the great American port. In addition to the routes extending from the Battery to Harlem, there are several others running to the Second and Ninth Avenues at Union-square, as well as a western division along the Upper Broadway. The Broadway is, according to the plans, excavated from curb to curb, to a depth of not less than 16 ft., and occupied by four railroad tunnels. There are likewise a series of smaller tunnels for the purpose of conveying water, steam, gas, &c., besides other electrical conductors of various descriptions. The roof structure is supported by iron columns, which separate the tunnels, whilst the panels in between consist of a new non-resonant material, called ferlax. It is proposed to construct the roof of iron beams and steel plates, upon which there will be laid a concrete foundation for the pavement surface. The cars will, when completed, be run by electricity, thus entirely preventing the smoke nuisance, and, moreover, rendering travelling far more healthy. The cars and lightings will also be lighted up with the electric light. The Company omits to state the estimated cost of the enterprise.

A New Sewage Process.—In the *Chemical News* of the 3rd of April we have an account of a new sewage process, the invention of Mr. A. McDonald Graham. It is well known that the sewage of many manufacturing towns in the North of England consists for the most part of surface-water and refuse from mills and factories, and contains but little plant food. It would be a very costly operation to irrigate land with such a large volume of water, and when treated by precipitation, the sewage of these towns deposits mud which the farmers cannot be induced to cart away. Mr. Graham proposes to regenerate this mud at a comparatively small cost, and make it again available as a precipitating agent; and by the same process of slow oxidation, to burn off the organic matter without the escape of any noxious or unpleasant odours. The first crude conception of the process appears to be due to a Japanese gentleman who was a student at the Imperial College of Engineering, Tokio, Japan, in 1879, and being Asiatic in its origin, it differs somewhat from our preconceived European ideas. One thing worthy of notice is the fact that the burning or oxidation process commences at a point furthest from the source of heat, travelling from the top of the mixture to the bottom.

St. Thomas Charterhouse School of Art.—The Lord Mayor will, on Saturday afternoon at 3 o'clock, distribute the prizes awarded to students of this school. The chair will be taken by the Rev. J. R. Diggle, M.A., chairman of the London School Board. On Friday evening there will be a free exhibition of students' works.

Birmingham Architectural Association.

The eighth ordinary meeting of the current session was held in the library at Queen's College on Tuesday evening last. The President, Mr. F. B. Osborn, was in the chair, and there was a good attendance. The Vice-President, Mr. John Cotton, gave his annual address, in the course of which a contrast was drawn between the ancient guilds of masons, wrights, &c., and the modern system of professional practice. Mr. Cotton very ably pointed out the immense advantages to be gained by architects associating together for purposes of study, and for the advancement of their art; and in referring to the junior members of the Association, showed very clearly the great profit which might be derived if the attendance at the various classes held during the session was regular and enthusiastic. A vote of thanks, proposed by Mr. W. Donbleday, and seconded by Mr. V. Scruton (hon. sec.), was unanimously accorded to the Vice-President for his very instructive address. After a response from Mr. Cotton, the meeting terminated.

The Relation of Geology to Engineering.—On the 2nd inst. Mr. George F. Harris, F.G.S., lectured before the Junior Engineering and Scientific Society on "The Relation of Geology to Engineering" at the Hawkstone Lower Hall, Westminster-road, S.E. The lecturer prefaced his remarks by explaining the mode of formation of sandstone, limestone, granite, and slate, and showed by the variations in thickness of strata, together with their natural sequences, that the civil engineer should lay the foundation of his profession by acquiring a knowledge of geology. Reference was made to the great value of stratigraphy in estimating contracts for the construction of tunnels and railway-cuttings, and the conditions necessary to ensure the success of artesian wells and well-boring generally. Subsequently attention was directed to some of the principal difficulties met with in coal-mining, and the scientific methods of laying foundations of large structures, such as embankments, piers, and breakwaters, were explained. A brief account of road-metal and the kind of stones necessary to bear heavy traffic brought an interesting lecture to a close.

Crystal Palace Company's School of Art.

A division of this School for promoting the study of the artistic and economic improvement of estates and landscape gardening, has just been made. The principal is Mr. H. E. Milner, A.-M. Inst. C.E. We learn from the prospectus that the student is under articles which secure both theoretical instruction and the advantage of practical outdoor work. During the employment of the student in practical work, a certain salary may be allowed. The term of studentship is three years, one year at least of which is devoted to outdoor work. A premium is payable to the Company. The lecturers in connexion with the classes are:—For Architecture, Mr. G. Richards Julian, A.R.B.A.; for Physiological Botany, Soils, &c., Mr. R. Honston, F.L.S.

Turpin's Parquet Floor, Joinery, and Wood Carving Company, Limited.

This Company, of which the prospectus is printed in our advertisement columns, has been formed for the purpose of taking over as a going concern, and further developing, the well-known business of parquet flooring, joinery, wood carving, and modelling, which has been carried on in London by Mr. M. F. C. Turpin for the past thirteen years and upwards. It is stated that the accounts of the business during the four years ending the 31st of January last show the profits to exceed 25 per cent. upon the capital employed. The services of Mr. Turpin will be retained by the Company as Managing Director. We may mention that some of Mr. Turpin's productions are on exhibition in the Building Trades' Exhibition at Islington.

Royal Academy.—The Class for Modelling in the Architectural School has terminated for the session; and a series of demonstrations will be given by Mr. Stannus, on Monday evenings from six to eight p.m., on "Accessory Features in Architectural Ornament," as follows:—April 12 and 19, "Tablets and Shields"; May 3 and 10, "Festoons," &c.; May 17 and 24, "Masks," &c.; June 1 and 8, Miscellaneous.

Faversham.—Mr. William Eve, Union-court, Old Broad-street, has been selected by the Guardians of Faversham to re-value, for rating purposes, the whole of the rateable hereditaments in their Union, extending over an area of 44,000 acres.

Monument to Liebig.

For some time past subscriptions have been collected for the purpose of erecting a monument to the late Baron von Liebig, whose fame as a chemist was as great in England as in his native country Germany. Up to the present the sum of 5,000l. has been subscribed, and the committee one of whom is Liebig's celebrated pupil, Professor Hermann, formerly of the London Boyal College of Chemistry, have unanimously decided that the monument shall be erected at Giessen, at whose University the deceased chemist first attained distinction. It is intended that the monument shall consist of a statue of Liebig surrounded by several figures, symbolical of the sciences and agriculture, all cast in bronze. The pedestal is to be of polished red granite placed upon a foundation, bordered by a series of steps in black granite. The committee have not yet arrived at a final decision as to the precise spot where the statue shall be erected, but it will, in any case, be placed in a commanding position facing the University, and in all probability, close to the new chemical laboratory.

Luton.—New "Salvation Army Barracks" are about to be erected in Lea-road and Vicarage-road, Luton, Bedfordshire. The lowest estimate received for the work is 2,190l., and the hall will accommodate 2,000 persons. The plans and quantities have been prepared by Mr. E. J. Shewwood, Queen Victoria-street, London, and the work will be carried out under his superintendance.

Lifts.—Messrs. A. Smith & Stevens have received an order for a large 1-ton lift travelling 70 ft., for Messrs. W. Briscoe & Son's new warehouse at Sydney. This will be driven by a gas-engine, and is to be a duplicate of lift supplied last year for the Hon. B. Rundle's new building in the same town.

Leyton.—Mr. George Baines, architect, Great Winchester-street, London, has been instructed to prepare plans for a Baptist church at Can't Hall-road, Leyton. The designs provide accommodation for 660 persons, and are in the Romanesque style.

Table with columns: Item, £. s. d., and other units. Includes items like LONDON, LONDON, LONDON, LONDON, LONDON, etc.

NORTH FULHAM.—For the erection of new Police Station, from the plans and under the superintendence of Mr. John Butler, Architect and Surveyor to the Metropolitan Police:—

Table listing names and amounts for North Fulham project, including F. & F. J. Wood, J. M. Goodwin, G. Jenvey, Leeks & Hooker, F. R. Tozer, W. H. Smith, Pierce & Lansdowne, H. Smith & Son, J. T. Chappell, W. D. Tink, J. Grover & Sons, G. Leyford, Olesander, W. Scrivenor & Co., T. L. Green, Gibbs & Flew, J. Ball & Sons, Staines, C. Ansell, F. Higgs, A. & E. Brad, Lathey Bros., J. Bryant, H. C. Howell & Sons, Higgs & Hill, Bilsam Bros., W. Johnson, C. Barnes, E. Toms, Kirk Bros., Tack Bros., G. Stephenson, Stimson & Co., P. H. Dawes.

RAMSGATE.—For certain alterations to shop-front of No. 6, Harbour street, Ramsgate, for Mr. F. Green. Mr. R. E. L. Elgar, architect:—

Table listing names and amounts for Ramsgate alterations, including C. Collins, W. W. Martin, H. Miller, T. Elgar.

RAMSGATE.—For the erection of three cottages in Rodney street, for Mr. G. J. Norris. Mr. R. E. L. Elgar, architect:—

Table listing names and amounts for Ramsgate cottages, including H. Miller, R. Stock, White Bros., Grunman, J. Myles, H. Port, H. Bowman, T. Elgar, Bugden, W. W. Martin.

RAMSGATE.—For the erection of a dwelling-house and shop on Abbot's Hill, Ramsgate, for Mr. L. Hart. Mr. R. E. L. Elgar, architect:—

Table listing names and amounts for Ramsgate dwelling-house, including J. Newby, T. Elgar, J. Myles, H. Bowman, White Bros., W. W. Martin, Newby Bros., H. Miller.

RICHMOND (Surrey).—For the erection of a cottage and shooting range for Mr. W. Wiso. Mr. E. Maynard, architect, College Chambers, Richmond. Quantities supplied:—

Table listing names and amounts for Richmond cottage, including Pierce & Lansdowne, Lillywhite, Blashy, Mafon, Sweet & Loder.

TOXTETH PARK (Liverpool).—For the re-construction of the carriage-way in Smithdown road, between Lodge Lane and Salisbury road. Quantities supplied by the engineer, Mr. John Price, Assoc. M. Inst. C.E.:—

Table listing names and amounts for Toxteth Park carriage-way, including Sayce & Randle, Worthington & Founall, C. Burt, J. Randall, W. Vaughan, Ireland & Huxley, Catterall & Co., R. Lomas, W. F. Chadwick, L. Mar, Walkden & Co.

TOXTETH PARK (Liverpool).—For the construction of sewers in Smithdown road, between Clarence and Greenbank roads, for the Toxteth Park Local Board. Quantities by the engineer, Mr. John Price, Assoc. M. Inst. C.E.:—

Table listing names and amounts for Toxteth Park sewers, including Ansell, Wainwright & Dyson, Macnahe & Co., Sayce & Randle, J. Randall, Worthington & Founall, W. Vaughan, J. White, Walkden & Co., R. Lomas, W. F. Inglis.

SHERRNESS.—For the erection of sixty-six houses at Sheerness:—

Table listing names and amounts for Sheerness houses, including H. J. Carter, Orays.

Re Additions at "Holmleigh," Putney.—The name of the firm whose tender was accepted should have been printed in our last (p. 629) as "Loren & Son," not Corden.

SPECIAL NOTICE.—Lists of Tenders frequently reach us too late for insertion. They should be delivered at our office, 49, Abchurch-lane, W.C., not later than Four p.m. on THURSDAYS.

TO CORRESPONDENTS.

Registered Telegraphic Address, "THE BUILDER, LONDON."

H. W. G.—H. A. (Madison).—M. P. B.—P. G. S.—A. J. D.—T. F. B.—W. C. R.—M. P. (we have seen the plan you refer to, and are satisfied that it is perfectly feasible and by far the best suggestion that has been made. If you will find there is an overcost in your multiplication by 24 for the hours, leaving your quantity only about one-third of the true result, in some cases, the whole pass per second, giving 801,000 in 24 hours; which would allow for a population of 100,000 in 24 hours; which would allow for a calculation based on the pipe running "full bore" for the whole 24 hours must be completely misleading; the volume of sewage necessarily varies at different times of day, and a nice calculation for taking the amount on that basis would be half empty during part of the day and night, and choked at night. If you will refer to every information on writing to the Secretary R.E.S.A. P. Conduit-street, W.)—H. B. & C. A. G.—E. S. E.—J. & W.—W. & Co. (last week).

All statements of facts, lists of tenders, &c., must be accompanied by the name and address of the sender, not necessarily for publication. We are compelled to decline pointing out books and giving addresses. Note.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors. We cannot undertake to return rejected communications. Letters or communications (beyond mere news items) which have been duplicated for other journals, are NOT DESIRED. All communications regarding literary and artistic matters should be addressed to THE PUBLISHER, and not to the Editor.

PUBLISHER'S NOTICES.

Registered Telegraphic Address, "THE BUILDER, LONDON."

CHARGES FOR ADVERTISEMENTS. SITUATIONS VACANT, PARTNERSHIPS, APPRENTICESHIPS, TRADE, AND GENERAL ADVERTISEMENTS. Six lines (about fifty words) or under 6d. Each additional line (about ten words) 6d. Term for insertion, 14 days, for special advertisements on front page, Competitions, Contracts, Sales by auction, &c. may be obtained on application to the Publisher.

FOUR Lines (about THIRTY words) or under 2s. 6d. Each additional line (about ten words) 6s. 6d. PAYMENT IS ABSOLUTELY NECESSARY. *Stamps must not be sent, but all small sums should be remitted by Cash to Registered Letter or by Money Order, payable to the Post-office, Covent-garden, W.C. to DOUGLAS FOURDRINER, Publisher, Addressed to No. 46, Catherine-street, W.C.

Advertisements for the current week's issue must be delivered before THREE o'clock p.m. on THURSDAY. The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to Advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

SPECIAL.—ALTERATIONS IN STANDING ADVERTISEMENTS OR ORDERS TO DISCONTINUE same, must reach the Office before TEN o'clock on WEDNESDAY mornings.

PERSONS Advertising in "The Builder," may have Replies addressed to the Office, 49, Catherine-street, Covent-garden, W.C., free of charge. Letters will be forwarded if addressed to our office, together with sufficient stamps to cover the postage.

TERMS OF SUBSCRIPTION. "THE BUILDER" is supplied gratis from the Office to readers in any part of the United Kingdom at the rate of 10s. per annum. To all parts of Europe, America, Australia, and New Zealand, 20s. per annum. To India, China, Ceylon, &c. 30s. per annum. Remittances payable to DOUGLAS FOURDRINER, Publisher, No. 45, Catherine-street, W.C.

Best Bath Stone for Winter use. WESTWOOD GROUND, Box Ground, Corsham Down, Corsham Down, (Smaller Farleigh Down, Dried). RANDELL, SAUNDERS, & CO., Limited, Corsham, Wilts. [Adv]

Box Ground Stone is the best for use in all exposed positions, being a well-known and tried Weather Stone, 50,000 ft. cube in stock. PICTOR & SONS, BOX, S.O., WILTS. [Adv]

Doubling Freestone. The stone from these quarries is known as the "Weather Bed," and is of a crystalline nature, and is doubtfully one of the most durable stones in England. THE BRAMBLE DITCH STONE. nature as the Chelvyng Stone, but finer in texture, and more suitable for flint-moulded work. HAM HILL STONE.

Greater facilities have been provided for working these quarries, and the stone can be supplied in large quantities at short notice. Prices, and every information given on application to CHARLES TRASK & SON, Norton-sub-Hamdon, near Ilminster, Somerset. London Agent—Mr. E. WILLIAMS, 16, Craven-street, Strand, W.C. [Adv]

Doubling Free Stone For prices, &c., address S. J. STAPLE, HAM HILL STONE, Quarry Owners, Stone, and Blue LIAS LIME, Stoke-under-Ham, Ilminster. [Adv]

Ham Hill Stone! Ham Hill Stone! For Ham Hill Stone of best quality and workmanship, apply to JOHN HANN & SON, Quarry Owners, Montacute, Ilminster. Established 1837. Agents, MATTHEWS & GEARD, Albion Wharf, Regent's Park Basin, N.W. [Adv]

Asphalts.—The Seyssel and Metallic Lias Asphaltic Company (Mr. H. Glenn), Office, 49, Abchurch-lane, E.C.—The best and cheapest material for damp courses, railway arches, warehouse floors, flat roofs, stables, cow-sheds, and mill rooms, granaries, tun-rooms, and terraces. [Adv]

Asphalts. Seyssel, Patent Metallic Lava, and White Asphalts. M. STODART & CO. Office: No. 90, Cannon-street, E.C. [Adv]

EVERY DESCRIPTION OF SEASONED WOODS AND VENEERS IN EXTENSIVE QUANTITIES.

B. J. HUDSON & SONS, Millbank Sawmills, Grosvenor-road, S.W.P. Whitfield-street, W.; And Store-street, London, W.C. Telephone No. 3,152, and Private Wire connecting Business Premises.

BANNER VENTILATORS.

The Strongest Exhaust Ventilators for all Buildings, Public Halls, Churches, Billiard-Rooms, &c.

HIGHEST PRIZES at all the most important Exhibitions.

BANNER SYSTEM OF SANITATION AND SANITARY APPLIANCES

WERE AWARDED AT THE International Health Exhibition, 1884, One Gold Medal, Three Silver Medals, and One Bronze.

For further Particulars and Prices apply to BANNER BROS. & CO. Sanitary and Ventilating Engineers. 11, BILLITER SQUARE, LONDON, E.C.

Gray's Inn.*

who, at this distance of time, would discourse upon London of the past, should consider whether he shall write for the diversion, or for the instruction, of his readers. If he do not aspire higher than their easy entertainment, ample materials lie ready to his hand; and we shall scarcely be richer by yet another compilation like to those which Hare, or Thornbury and Walford, apply. So infinitely vast and varied a field tends before the genuine historian that we have long been of opinion that to produce a really valuable book an author must perforce confine his labours within some closely-drawn limits of research. Of such a book, and on such a subject, the latest example is open before us,—being a distinct and conspicuous advance in every respect upon the cognate efforts of W. Herbert's "Antiquities of the Inns of Court and Chancery."

In the choir of St. Paul's Cathedral the north right-hand stall appertains to the ancient prebend of Portpole. That, with other prebendal manors, lay within Osulstone hundred. In his "History of St. Paul's" Dugdale names one Theobald as its first prebendary. The date of his collation, says Mr. Douthwaite, is not given, but he is supposed to be the same person who is mentioned as a chieftain of Essex in 1218 and again in 1228. The "streets of Holeburne and Portpole" are mentioned in the Fine Roll, 42nd Henry III. (1257);† and in Parton, in his "Account, &c., of St. Paul's-in-the-Fields," tells us that the manor mentioned in a deed of 46th Henry III., whereby one Rohert de Portpole,—possibly the then owner,—charges his house in St. Andrew Holborn parish, with 10s. yearly, to a chaplain to celebrate his anniversary in St. Giles's Hospital church. We next find of Portpole Manor as being vested in the Greys of Wilton. Reginald, grandson to Henry de Grey, of Codnor, co. Derby, lived and died here. According to an inquisition taken after his death (1st Edward II.) at Portpole, he died seised of a certain messuage, with gardens, and with one dove-house, which was worth by the year beyond reprise 10s. 6d., together with certain named thirty acres of arable land, valued at 20s. yearly, and a windmill,—whence Windmill-hill,—also

* Gray's Inn, its History and Associations; compiled from original and unpublished documents by William H. Douthwaite, Librarian. London: Reeves & Turner, 1897.

assessed at 20s. yearly, he is stated to have held of the Dean and Chapter of St. Paul's, in chief, by a service of 42s. 2d., payable at two terms of the year.* John de Grey, his son and heir, was granted a licence in mortmain, under letters patent May 27th, 1315, to assign thirty acres of land, two acres of meadow, and 10s. rent with the appurtenances in Kentish-town and in St. Andrew Parish, without the Bar of the old Temple, to St. Bartholomew's-the-Great for a chaplain to celebrate daily service in perpetuity in the chapel of his manor of Portpole. The existing Gray's Inn Chapel is credibly believed to mark the site of John de Grey's chantry. Subsequent inquiries go to show that the *Hospitium* in Portpole remained in possession of the family. By an inquisition of 19th Richard II. taken after the death of Sir Henry de Grey de Wilton, knight, we learn that he had enfeoffed Roger Harecourt and others in fee "of his manor of Portpole, in Holburne, called Greysyn . . . holden of the Dean and Chapter of the Church of St. Paul, London." And so, until the year 1505, when Edmund, Lord Grey de Wilton, conveys his manor, with the chantry, adwoson, and all his possessions in the parish to Hugh Denny and Mary his wife, and other feoffees, some of whom were members of Gray's Inn, and eminent lawyers. Eleven years later, in the 7th Henry VIII., the survivors of these feoffees obtain a royal licence to alienate to Shene Priory "the manor of Portpole, with the appurtenances . . . and four messuages, four gardens, one toft, eight acres of land, and 10s. rent . . . holden as an escheat for that Robert Chigwell, of whom the manor aforesaid and other the premises were holden, died without heir, by service, fealty, and the rent of one red rose." Mr. Douthwaite's inquiries into the connexion of the Chigwells with this property are of great interest, and will repay careful perusal. As touching the monastery at Shene, it appears that for some years the society continued to pay to the prior an annual rent of 6l. 13s. 4d. That rent afterwards passed to the Crown, and was eventually sold to Sir Philip Matthews, to whose co-heirs it descended. Having enjoyed for 200 years previously continuous and undisturbed possession, the Society purchased back again the fee-farm rent in the year 1733. Since that date our author triumphantly affirms that they have held and now hold the property unencumbered by any rent or other payment.

We have spoken of the old Temple. The Knights Templar on first coming to London were settled in Holborn, almost directly opposite to the now Gray's Inn gateway, for nearly seventy years. A reference to their sojourn in this quarter, succeeded by a migration to what

since became one of the four "great" Inns of Court, would complete the pretty picture given in the introduction to this book. Again, to his list of the Chancery Inns which clustered around Holborn, Mr. Douthwaite might have added Scroope's Inn, thus styled as being the original town-house of the Lords Scroope of Bolton, next eastwards to Ely-place. Under the name of Serjeants' Inn it passed, by an indenture dated the 8th of February, 1494, from Sir Guy Fairfax, of the King's Bench, to Sir John Scroope, knight, Lord Scroope of Bolton. Its memory,—as with that of the Old Temple,—was long preserved in Scroope's, latterly Union Court, over against St. Andrew's Holborn church.

The old-world chronicles of Gray's Inn as an Inn of Court, of the Readings, its famous Masques and Revels, of the Boltings and Moots,—these last have been recently revived, and with great success,—are all faithfully recorded. quaint presentments of obsolete manners are afforded by the orders for regulating the conduct and apparel of the fellows and other members; to which may be added the practice of "chumming" in chambers. At a pension, held on July 9th, 1530, Sir Thomas Neville agreed to take Mr. Attorney-General, Sir Christopher Hales, for bedfellow. In the 21st Elizabeth it was ordered that "henceforth no Fellow of this House shall make choice of his bedfellow, but only the Readers." The personal associations of the Inn centre around the names of Chief Justice Gascoigne; the author of "De Naturâ Brevium" and of the "Grand Abridgement"; Sir Anthony Fitzherbert; David Jenkins, the patriotic and loyalist Welsh judge; and the regicide Bradshaw; Riston, Camden, and Dugdale; Gardiner and Laud; Johnson and Goldsmith; the Cromwells and the Claypoles; Butler, Chapman, Cleveland, and Southey; and William, Lord Burghley (here best known, by the bye, as a genealogist). To these should be added Whitgift; Dr. Richard Sibbes, author of the "Soul's Conflict" and the "Bruised Reed"; Archbishop Usher, who, being then bishop of Meath, was admitted 26th Jan., 1623-4; Sir Nicholas Bacon, Lord Keeper, and his son, Viscount St. Alban. We cannot dwell herein upon the public life of one who united the loftiest intellect with so despicable a soul. Yet there is a fascination in tracing Sir Francis Bacon's intimate relations with Gray's Inn. Here together with his four brothers, he entered as student in November, 1576. Here he laid out what he himself terms "the purest of human pleasures, . . . the greatest refreshment to the spirits of man"; the same gardens, having at that time a clear prospect towards Hampstead, in whose good air Sir Roger de

* Chanc. Inq. P.M. 1st Edward II., No. 64.

Coverley did love to clear his pipes, and whither Mrs. Pepys would repair to observe fashions of the ladies. Hence set forth the goodly procession which accompanied Bacon to Westminster when he became Lord Keeper; and hither he returned, broken in credit and fortunes, after his condemnation. In retreat at Gray's Inn he passed, mainly, the remainder of his life. As from his "chambers at Graie's Inn this 30th of January, 1597," he dedicates the first ten of his Essays; so hence, in later days, he gives to the world his "History of King Henry VII.'s Reign"; his "De Argumentis," an expansion of the earlier "Two Bookes of Proficience and Advancement of Learning";* and his "Apophthegms: New and Old"; besides completing the "Instauratio Magna," whereof the "Novum Organum" formed part.

The naturalist will welcome Mr. Douthwaite's notices of the rooks that yet revert to their pristine, though sadly denuded, haunts; as well as of the carrion crows who can boast of a pedigree which dates back, in all likelihood, to well nigh three hundred years since. Cuckoos, jackdaws, robins, and wrens, rank as smaller, though by no means lesser, favourites, whilst their more tuneful brethren share refuge amongst the planes and sycamores that are often rendered vocal with the notes of the chaffinch, the linnet, the goldfinch, and the thrush. A detailed category of the several emblazoned charges which adorn the Hall windows appeals forcibly to students of genealogy and heraldry. Some coats are known, *testibus* certain cited MSS., to carry us back to Queen Elizabeth's reign. Her portrait hangs over the high table whereat her pious memory is solemnly invoked beneath their parti-coloured light. A comparison made with a list of the armorial bearings engraved for the *Origines Juridicales* shows what particular escutcheons, as prefigured in Dugdale's work, have altogether disappeared. Moreover, "from an heraldic point of view many of these coats have a special value, in being assigned to individuals who bore arms somewhat different from the blazons given in heraldical dictionaries." Such discrepancies may be partly owing to an incorrect re-fixing of much of the ancient glass which, and notably at the eastern window, has suffered grievously from time to time through tempest or other disaster.

Mr. Douthwaite says that Bacon's chambers were in the building now "known as No. 1, Gray's Inn-square." Thus also Basil Montagu. There is, however, a tradition that Bacon occupied a large house opposite to the great gates in Field-court, whither Fulke Greville would frequently send him some home-brewed beer from Brooke House in Holborn.† Lord Campbell's statement, in his "Lives of the Chancellors," that Bacon's rooms remain as they were during his tenancy, and are still visited by those who worship his memory, should be read with a passage in the "Historian's Guide," third edition, 1688, to the effect that the house (site of No. 1, Gray's Inn-square) and sixty other chambers were burned down on February 17th, 1679. Mr. Douthwaite does not mention this particular fire, though he tells us that the greater part of Coney-court was destroyed by fire in 1683-4 and rebuilt in 1687. This is the Coney-court of the Survey of 1688, which, with the Middle, or Chapel-court, occupied the area known since 1793 as Gray's Inn-square. From Strype's "Stow," edit. 1720, quoted by Mr. Douthwaite, it is clear that Coney-court was the more northern of the two. A plan of 1720 shows no division (east and west) between these two courts, north of the Chapel and Hall. So, looking to the present site of No. 1, Gray's Inn-square, we conclude that Bacon lived in Chapel, but known in his time as Middle, court. South-square was formerly Holborn-court; a reference to the "Pickwick Papers" will show it was known as Holborn-court less

than sixty years ago. Plans of the former buildings, if, indeed, they are to be found,—that is to say, to a much larger scale than the view in the map by Ryther, of Amsterdam, 1604,—would make a useful complement to the pleasing modern-day illustrations contained in this volume. The Hall was built in 1556-9, and deservedly ranks next, in London, to those at Charterhouse and Middle Temple for the beauties of its screen and open roof. Like to that of Lincoln's Inn, the red brickwork and stone dressings of its exterior are defaced and hidden by compo and tasteless appendages. It contains, we have observed, a picture representing its former state, with the original and characteristic lantern. In congratulating Mr. Douthwaite upon his able treatment of a worthy theme, we think the Society are equally fortunate to possess a librarian who can put to such good account the copious materials at his command.

A FINE OLD ENGLISH ARCHITECT.

IN these days, when the happy student is solicited by so many aids to study and advancement that he may almost be said to glide by easy gradients to the Temple of Fame, rather than ascend the sacred hill by toilsome effort, it may not be impertinent if we outline for him the history of an architect of the olden time, when encouragements to art were scanty and discouragements rife, and when self-reliance was the only road to success.*

Born in 1787, John Dobson was apprenticed at fifteen years of age to a builder, where he learned to make a plan, and acquired some practical acquaintance with builder's work, filling up spare time by studying land surveying, and receiving from a versatile Italian refugee instruction in the curiously various arts of fencing, enamel-painting, and perspective. Betaking himself to London, he sought instruction in art from an eccentric painter, who would only engage to give lessons at five o'clock in the morning, at which early hour our ardent young student never failed to present himself. Returning to his Northern home, he boldly started as an "architect," finding, as might have been expected, little or nothing architectural to engage him, and occupying himself in "painting scenery for the local theatre,—the school of so many English artists. Meanwhile, he sketched and measured old buildings assiduously, and in an age when Gothic architecture was considered merely barbarous, gave his heart to the study of all the Mediæval remains in his neighbourhood, "rising constantly at four or five o'clock," and working frequently till midnight. A strange, lonely, courageous life, this earnest student led, without immediate aid or helpful appreciation, but destined to be rewarded thereafter by deserved success.

Architects were not wanted there and then because their functions were not understood and their proper duties were usurped by builders. It is not without an involuntary moistening of the lips that one can in these days of fierce competition read that in our young hero's time there was but one architect between York and Edinburgh. A certain Mr. Payne, of whom history has hitherto been strangely silent, was, it appears, after Sir John Vanbrugh, the architect of the North of England. He seems to have been employed by the nobility and gentry, and to have run off his designs in an easy-going manner, fluently, and upon a uniform plan. Entrance in centre of south front. Hall in centre, staircase opposite, drawing-room on one side, dining-room on the other, library behind. This artful arrangement was thought to be so suitable and perfect that the honest English squire would, in their simple way, order a house of their builder "on Payne's plan," with rooms of such and such a size. But the houses built by the ingenious Mr. Payne had one drawback, they were draughty and cold,—too trying even for our hardy fore-

fathers. The rough winds entered them unopposed; coursing round their vacant halls they blustered up the stony corridors, and swirled around the domestic hearth, in wintry gusts.

Our friend saw the weak point and it remedied. He turned the entrance away from the principal view and screened it by shrubs and trees, defended his halls by porches, anby lobbies and "air-traps" he restored tranquillity to the fireside and the domestic temper,—abating and allaying breezes of more than one description. He was so called upon to remodel Mr. Payne's work and as his fame spread abroad, was entrusted with new buildings of importance in the erection of which he was so happy to give unvarying satisfaction to his client. By dry areas and hollow walls, of which he may be said to have been the local inventor, he still further improved the sanitary quality of his houses, and his instinctive love of a and patient study of ancient examples enabled him to improve in picturesqueness the somewhat frigid and formal structures of his predecessor. The castles, mansions, and private houses which were either built or enlarged by him form a goodly list. But he was equally active in other directions, actually building Gothic churches before later lights had begun to study them. With the growth and consolidation of his fame he was beset by commissions of all sorts,—railway station prisons; characteristically qualifying for attaining the former problem, then a new one,—spending three days in mastering the details of the routine of railway life, and for the latter by friendly conferences "with more than a noted burglar." The remodelling of his native town, and the erection of its principal streets and public buildings, fell naturally to him, a his sound knowledge of the values of property and his known integrity, combined to bri him a vast amount of arbitration and such lucrative employment. His first great work was the rebuilding of Seaton Delaval after a destructive fire; and it is curious that a second fire caused a second reconstruction which proved his last professional work. His long, honorable, and useful life has been well written by a daughter's hand, who is unwilling that the history of her father and his work should be unrecorded. She has performed her task with remarkable skill, tact, and judgment, and has shown an acquaintance with technical and professional details which could scarcely have been expected even from an architect's daughter. Her hook will not, without its usefulness, and we can only regret that it has not been found possible to illustrate her father's numerous works. His portrait conveys the idea that he was a shrewd, genial gentleman, and of his great ability there is no question. He died in the seventy-seventh year of his age, and the daughter, who admired and loved him so much, has unconsciously written the epitaph an architect would perhaps most desire to merit. "He never exceeded estimate, and never had a legal dispute with a builder."

NOTES.

FURTHER particulars are now in hand in regard to the competition for a new façade to Milan Cathedral, which has been ordered possible by a legacy left with the object by a citizen of Milan, the late Sig. Aristide de Togni. The competition is open to the world, and the Directors of the Cathedral have, in a spirit too rare now-a-days, placed no limit on the cost, the object being to secure a great work regardless of pecuniary considerations. Architects are free to adopt "whatever, in their judgment, is best adapted to suit the historical and artistic renovation of the Cathedral," change the number, form, or size of the openings, or advance the façade beyond its present line,—so far, at least,—may not interfere with the traffic of the piazza,—but they must conform to the style and material of the building, and the width of the nave and aisles. The jury will consist of the Director of the Cathedral, who will preside

* First published, in one vol., 4to., price 10s. 6d., at the Holborn Gate by Henry Tomes, 1695. This gate was opened in 1592.

† The tenement at what is now the north-western corner of Falmouth's Rents is possibly old enough to have originated this belief. Its aspect is certainly more ancient than those of its neighbours.

* Memoir of the late John Dobson, M.R.I.B.A., of Newcastle-upon-Tyne. By Margaret Jane Dobson. London: Hamilton, Adams, & Co. Newcastle-upon-Tyne: Lambert & Co.

member of the clergy; four architects, French, German, Italian, and English, chosen by the "Accademia di Belle Arti" of Milan; a painter or sculptor and an architect, chosen by the Municipality of Milan; a Fellow of the Royal Lombardy Institution of Science and Literature; an architect chosen by the Commission for the Conservation of Monuments in the Province of Milan; an engineer and an architect chosen by the Royal College of Engineers and Architects in Milan; and four artists, two architects, one painter, and one sculptor, to be elected by the votes of the competitors of their agents in Milan, under regulations learned from the official paper of instructions, published by U. Hoeppli, bookseller, Milan. Designs will be received between the 1st and 15th of April, 1887 (under motto), and after a public exhibition of them, the jury will select from ten to fifteen for a second competition. In this second competition 40,000 francs will be given to the author of the design considered worthy of execution, half down, and if after he has worked out the detail and made a model in relief. Other prizes, three of 100 francs, three of 3,000 francs, and three of 2,000 francs, will be given according to merit. There is a great opportunity; but a word of warning to ambitious young English architects: you will find the commission will certainly go to an Italian architect.

HERE is still a great deal to be done in the Indian and Colonial Exhibition, the majority of the colonial portion being still in very backward state, and presenting in many quarters only the outward and visible sign of confusion of packing-cases. But the Indian department is in a sufficiently forward state to render it evident that this portion at least will be one of the most charming and interesting exhibitions that has been seen in London. The great avenue of the Exhibition is lined with examples of elaborately-carved woodwork in the shape of house and shop fronts and balconies and windows, showing a variety of useful workmanship such as ought to open the eyes of English artisans, who are not accustomed to have anything like this demanded of them even in the work on what are intended to be first-class houses. Opposite the entrance-way of the Old London Street, which remains as an example of the style of our own country, is erected the marble gateway from the Gwalior, which was formerly in the Calcutta Exhibition, and was sent over here as a present from the Government from the Maharajah of Gwalior, and, as we have previously remarked, was suffered to lie in matting in a corner of the ground outside the South Kensington Museum for a couple of years. It is a fine piece of work, and makes a curious and pleasant contrast to the plain and comparatively clumsy architecture of the Old London Street Gateway. The Gwalior Gateway gives access to a reproduction of the courtyard of an Indian palace, which deserves a good deal of finishing yet. The plan section is in a tolerably advanced state, and the walls have been decorated in a characteristic and effective manner, with vertical stripes of black and yellow alternately, decorated by stencilling. It is curious to notice how things repeat themselves. Among the Indian fronts are many details having affinity with Greek or Renaissance architecture, in one place we noticed the Greek key ornament in its purity; while the African Court is a barbaric wooden stool the surface of the seat covered with an ornament of hatched lines in squares and bands, so exactly like the decoration of the archaic vases in the British Museum Vase-room that it might have been taken from them. At the top of the central air avenue a great canvas is stretched over two circles on it prepared for a map of the world's hemispheres to show the extent of the British colonies and dependencies, and over five clock-faces marked respectively "Ottawa," "Cape Town," "Sydney," and "London," and intended, we presume, to show, when completed, the time of day at the same instant in these five places; a logical argument, whether intentional or

not, in favour of that adoption of a single "world-time" of which a good deal has been said recently, and which will assuredly be adopted sooner or later. As far as any of the Colonial work is up, it is melancholy to see how on coming to it from the Indian galleries all beauty and art and taste seems to disappear. We enter the New South Wales section through a temporary arched erection of the weakest and most commonplace Renaissance detail; and in the court allotted to Victoria the principal central object so far is a great trophy of biscuits behind glass cases, forming a kind of obelisk in lessening stages up to the roof. Thus the English origin of these colonies aesthetically asserts itself.

THE great iron roof of the National Agricultural Hall, designed by Mr. Am Ende and Mr. Walmisley, which is now in process of erection, will be one of the most remarkable constructions of the kind. The whole width of the hall is 250 ft., of which 40 ft. on each side are occupied by the aisles with low roofs, and the semicircular roof over the centre space has a span of 170 ft. The principals are semicircular lattice ribs of 7 ft. depth, springing from cast-iron columns, which are treated on a new method, the connexion with the principal at the head, and with the base plate, being made by a ball and socket bearing, so that the column will have free play in regard to any expansion and contraction of the roof. The abutment for the principals, which are in reality iron arches rather than girders, is formed by the framing of the iron trussing forming the constructive portion of the side aisles, which is again based on a subterranean truss bolted to the baseplate of the column and carried down into a deep trench across the width of the side aisle, which will be filled up with concrete in a solid mass surrounding the iron truss or subterranean cantilever, as it may be termed. Any thrust from the haunches of the arched girders is further provided against by a Λ member between the horizontal and raking members of the aisle roof, the raking member taking a bearing on the top of the Λ , the inner leg of which is in tension (in the case of any thrust) and is bolted down to the horizontal girder of the aisle. The roof is thus entirely independent of the brick walls, which are mere enclosures. The first of the arched principals is nearly complete now. An immense travelling-stage, comprising 1,000 cubic feet of timber, has been erected, wide enough to take two principals (34 ft. apart), and high enough to admit of the manipulation of the upper sections of the principals by a travelling-crane on the top of the staging. Considering the great span, the roof is wonderfully light in appearance; the strain on every member has been carefully calculated so as to avoid any unnecessary "margin," and the result is a roof which will be exceedingly strong and stable without any appearance of massiveness, which, in the case of ironwork on a great scale, is a consummation to be wished, though architects would not wish to apply the same principle, perhaps, to masonry or brickwork. We only regret that a concession to a mistaken idea as to the employment of ordinary architectural forms will lead to spoiling and falsifying the effect of the best and most original point of the work, the treatment of the columns. The appearance of these, with their ends tapering to the hall and socket bearings, is, in fact, both elegant and scientific, but this genuine piece of scientific engineering is to be masked by the application of foliated capitals, which are quite unsuitable in form for treatment in iron, and which will conceal the real nature of a very clever piece of construction, and render it commonplace as well as deceptive in appearance. We very much wish that the architect and the engineers concerned would, even at the last moment, reconsider this point, and have the holdness to treat the construction as what it really is, and not what it is not and could not be.

THE report on the Boiler Explosions Act, 1882, for the year ending June last, has lately been laid on the table of the House of Commons. It appears that inquiries were held

into forty-three explosions, in which explosions forty persons were killed and sixty two were injured. Of these accidents, twenty were caused by deterioration or corrosion of boilers and safety-pipes, and eleven by defective design or construction; four were from shortness of water, four from ignorance or negligence of attendants, and four arose from miscellaneous causes. It is clear from this that thirty-one explosions out of the whole forty-three, arose from the proper repairs not being executed by the owners of boilers, either from motives of economy or from mere carelessness. No censure can be too strong for owners who risk the lives of workmen as if they were not worthy of thought. Thus in regard to an explosion of a boiler at a certain Mr. Jones's brick-works, at Broad Green, near Liverpool, the inspector remarks, "Although no one happened, fortunately, to be killed, I look on this explosion as one of a very serious nature, and for which, with its attendant risks, the owner was solely responsible. He must have been aware of the responsibility he incurred in working an old boiler without proper supervision, and he persistently ignored the insurance company's repeated warnings." In another case, "the boiler was worn out, and unfit for any pressure whatever." It is, therefore, not surprising that the boiler blew up, killing one person, and wounding a boy and a woman, who seem to have recovered from their injuries. Fortunately or unfortunately, the person killed was the owner of the boiler, who must have, probably for the sake of saving the cost of a new boiler, preferred to risk his life every day on which the boiler was used. It is to be regretted that, in spite of the publicity given to these inquiries, there were two explosions more which had to be inquired into in 1884-5 than in 1883-4. But we fear that the cupidity or the rashness of men will always cause a certain number of these and similar misfortunes.

THE case of Harris v. De Pinna, on which we commented in a recent article in regard to the meaning of the word "building" in respect to the law of light, came before the Court of Appeal last week. This court, however, did not think it necessary to consider the word "building," it being sufficient for their decision that the light had not been continuously enjoyed in a definite mode through the same apertures. It may be remembered that the structure in respect of which the light was claimed was practically no more than a roof with floors beneath and open sides, which was used for the purpose of storing timber. It is stated in Roscoe's "Digest of the Law of Light" that "the right to light means such an amount of light over the servient tenement through an aperture or apertures in the dominant tenement as is sufficient," &c.; this proposition will therefore now be further supported by this recent decision of the Court of Appeal, which, taken together with that of Mr. Justice Chitty, will put an end to claims in respect of structures which are not actually houses, shops, and similar substantial and walled-in buildings.

THE system of propelling sewage through pipes by means of compressed air, in substitution of the ordinary method of pumping, seems to be extending. The Local Government Board has just given its sanction to the construction of a separate scheme for the disposal of the sewage of Heston, Isleworth, and Hounslow, at a cost of 77,000*l.*; and one of the principal features of it is the adoption of this system of sewage propulsion in the low level areas of these districts. At the recent Hounslow Inquiry of the Local Government Board some strong evidence by experts was given in favour of this compressed-air system. It was stated that this mode of sewage propulsion obviates the necessity, the risks, and costs of deep gravitating pipes; while the system operates as an automatic flusher. It is asserted that the ejectors, by the velocity with which the sewage is propelled through the pipes, prevent those accumulations of decomposing matter which are at the root of all the difficulties and evils in connexion with the problem of sewer ventilation. The system which has

just been adopted in Hounslow, and which has been in operation at Eastbourne and Warrington for some time, is that in which Shone's Pneumatic Ejector is used.

WE learn from the *Gazette Archéologique* that M. Ravaisson has presented to the Académie des Inscriptions et Belles Lettres a cast reproducing a mould (made in Roman cement) of half of the beautiful slab from the Parthenon frieze, the original of which is in the Louvre. The great value of the mould consists in the fact that it was taken at the time when M. Choiseul was ambassador, *i.e.* in or about 1785. At that time the original slab was in far more perfect condition than it is at present. The mould restores to us two of the heads of the maidens and some details of drapery. It is much to be wished that a cast from this mould should be exhibited near the original, in Paris, and, we may add, near the cast which replaces the original in the British Museum. The mould was found in England.

THE Marlborough Art Club "consists of some fifty members, who are all, more or less, united in their art sympathies," and have associated themselves together with the view of holding an annual exhibition, for which purpose they have engaged the old room of the Institute of Painters in Water-colours, in Pall-mall, now called "The Marlborough Gallery." The first exhibition, now open, conveys the idea that the general tendency of the Club is towards "impressionism," so far as that indicates a view of art which attaches more importance to general composition and colour than to finish or detail. We should imagine a considerable French influence pervaded its members. But the exhibition is no common-place one, at all events; the average standard is high, though some of the pictures are much too large for their subject, and Mr. La Thangue's "In the Dauphiné," besides this defect, appears to us to be only a bare repetition of Manet. Mr. H. S. Tuke's "The Bathers," some boys partly in shadow and partly caught by sun-light over a rock by the sea, is a capital study of its kind. There is a great deal of point and feeling in Mr. Gogin's "Soothsayer," a wizard "spae-ing fortunes" in a crystal globe, watched with intense earnestness and apprehension by the object of the inquiry. Mr. Tuke's "Basking," a lad lying on the seashore in bright sunlight, is very successful in giving the effect of bright light, though not otherwise interesting. Mr. Bartlett's "Venturesome," a young girl seated on a rock, preparing to slip into the water, is a very pleasing study in the same category as Mr. Tuke's "Bathers," realistic in a sense, but not in a mere mechanical sense, and very graceful. Mr. Goodall's "Last Load" is a reminiscence of Millet, to some extent. There are a good many reminiscences in the gallery, but some of them are not the worse for that. Mr. Sargent's "Portrait of Mrs. Barnard" is an example of the smears school,—not without character, but simply suggesting the notion that it is a first sketch for a portrait never completed. What purpose in art is gained by painting a dress, or, rather, indicating it, so that it looks palpably like a mass of paint and not like a dress? "The picture would have been better painted if the painter had taken more pains," is the criticism one naturally thinks of here. Where did Mr. Steer, who paints a musical group called "Andante," see a girl with so small a head as she who plays the violin? "Hard Times" and "Waiting" by Mr. Fred. Brown, should be looked at, and there are other small character-paintings of interest. Mr. Gotch's very ambitious allegory, "Destiny," is a mistake; the poetic nature of the subject only calls attention to the prosaic character of the figures. But the exhibition is a distinctly interesting one, and represents some tendencies in the painting of the day which can hardly be said to have a recognised place in the other contemporary exhibitions in London.

WE have before referred to Mr. Muir's remarkable series of fac-simile reproductions of Blake's engraved poems which are in

course of publication by Mr. Quaritch. The copy of the "Milton," the last published of the series, is before us,—one of the longest of Blake's illustrated poems, and containing some of his most powerful, and also some of his wildest, work in the illustrative plates. The illustrations here differ very much from those of the "Songs of Innocence and Experience" and the "Book of Thel" (which, we hold, will always remain Blake's central and most typical works of this class); they are much less pictorially beautiful, and are in a very different manner; some of them are in a curious combination of line shading with colour over it; but the principal ones are of great power and even sublimity, in despite of the peculiar defects of drawing characteristic of their author. There is one showing two figures asleep on the rocks by the margin of the sea, with an immense eagle hovering over them, and a weird unreal light pervading the whole scene, which is one of the most extraordinary designs Blake ever made. What it means who can tell?—but, then, the meaning in the literal sense is of no consequence; it is a sublime conception, and may suggest its own allegory to each observer. Another very powerful design is the one on page 15, of which the general allegorical meaning is obvious enough: a nude figure goes up to grapple with an aged figure, who rests his failing hands on two stones inscribed with mystical characters; this obviously represents the emancipated man putting down the reign of old law and custom; above is a kind of procession of the emancipated ones amid rays of light, playing on various instruments and dancing. The design illustrates the idea which runs through all Blake's strangely-expressed philosophy of life and art, that nature is holy; it is the tyranny of laws and customs that fetters and debases mankind. Few purchasers will read through the "poem," which is in the picturesque but crabbed writing which Blake employed for these engraved poems, and is rendered more decorative, but more difficult of perusal, by the shading and colouring behind the writing and the numberless little sketches and ornaments with which it is interwoven. It contains, however, very grand passages amid much of "wild and whirling words," and the preface, with the beautiful little poem attached to it, is worth every one's reading. The first portion, in prose, is a protest against unimaginative worship of precedent in art, and the running after commercial success, "O young men of the new age, set your faces against the ignorant hirelings. . . . Painters, on you I call! Sculptors! Architects! Suffer not the fashionable fools to depress your powers by the prices they pretend to give for contemptible work, or the expensive advertising boasts they make of such work. . . . We do not want either Greek or Roman models if we are but just and true to our own imaginations, those worlds of eternity in which we shall live for ever."

MR. TRISTRAM ELLIS'S exhibition of water-colour drawings illustrating the watering-places of the Channel, which is now to be seen at the Goupil Gallery in New Bond street, has a popular as well as an artistic interest. Mr. Ellis is well known for his drawings of Cyprus and other parts of the world, but we think that the present exhibition will considerably add to his reputation. The versatility which these drawings display is very remarkable and very gratifying, when so many capable artists seem satisfied to work altogether in one groove. To take two instances at random: No. 36 represents the Butterwalk, Dartmouth, a drawing of some old houses built about 1620 on granite pillars. But this is not a mere architectural drawing; Mr. Ellis depicts the Butterwalk on a soaking wet day,—it might well be entitled "A Wet Day," so much is it a study of rain and atmospheric effects. The next drawing to it, No. 39, is "A Rising Sea, Dawlish,"—a study of waves and foam warning us of the coming storm. Here, then, are two drawings quite in contrast, and the entire exhibition is illustrative of this versatility.

THE galleries in the British Museum, the former hired galleries, which were re-opened the other day, are now filled with a very interesting collection of work, including some fine cases of Chinese porcelain, a large collection of arms and armour, and a number of examples of barbaric art-work from various parts of the world. The general arrangement and style of the collection suggests South Kensington rather than the British Museum. It is a relief to have got rid of all recollection of the stuffed animal department, and to see the great central museum occupying its proper function as a repository of art and archaeology.

WE desire to draw attention to the correspondence, printed in another column, in regard to the Fulham Vestry-hall competition, on which we will leave those interested in the subject of architectural competitions to make their own comment.

FREE LECTURES TO ARTISANS AT CARPENTERS' HALL.

THE INFLUENCE OF ARCHITECTURE ON CARPENTRY.

THE last of the present course of free lectures, which have been inaugurated by the Carpenters' Company, was given on Wednesday, the 7th inst., in Carpenters' Hall, by Mr. Banister Fletcher, M.P., F.R.I.B.A. He said:—My subject is the actual work of carpentry in all ages, and its action and reaction upon architecture. The faculty which both architect and carpenter must each possess in order to attain excellence must be the power of earnest thought on his work. The architect's is the inventive quality of art, the carpenter's is the actual work. The artist's pencil and the carpenter's tools, though wielded with the utmost skill, would, in the absence of earnest thought, produce but poor and imperfect results. Technical education has its limits; like the notes of an organ, its tones are fixed, and these can be learned to a degree of excellence by all; but to produce a new design or original thought could never be arrived at by simple study, however closely applied. Turning a moment to consider the birthplace of architecture, it would be seen that a primeval civilisation, like the faculties of childhood, could necessarily only conceive simple ideas, and these were converted into the first tangible forms of construction. The rapid architectural development of the earlier nations must be ascribed to the constructive faculty of mankind; but the epoch of simplicity of construction gradually yielded under the dominion of forced requirements, stimulating the forerunners of the art to increased efforts. The first efforts of plain post-and-rail construction gave place to a more homogeneous mode of building, and, hit by hit, construction more or less rude, was, from time to time, added, the material essence of nature being lost by material coverings and symbols. The instinct of construction is as common to men as to animals, and is undoubtedly the origin of architecture. It is, to my mind, extraordinary how, in all disquisitions on this subject, both in the present and the past, how much this has been overlooked. See how the heaver builds a house, whose construction, when analysed, is even from a carpenter's point of view, simply wonderful in its applied use of material. With this instinct, man himself can claim kinship, and from this desire to shelter himself and his offspring proceed the first germs of construction. Man, having satisfied the natural craving for a mere shelter, commenced his first efforts at architectural embellishment, which, of course, though naturally primitive, were purely the outcome of nature and her surroundings, and these, to a great extent, dominated its votaries in these early times, and even in a later period when rapid strides had been made towards perfection; and I think, even in these late days, advantage might be derived from a little more attention being paid to the sources from whence sprang the germs of architecture. In early buildings, the carpenter held an important place and he was, in fact, the architect, with this advantage over modern ones, that he himself put his ideas into execution, so that you have the actual impress of the man's thoughts shining out through his works to all ages, speaking in a way that no other form could tell; for why can give such loving care to a mould or framing as he whose mind first thought it out? It is

like the difference between a picture by a great artist and a mere copy of the same, for the latter, however clever, can never give it that nameless something which stamped it with the impress of a master-mind. After the final decay of architecture in its Southern birth-place, a new creation arose in its Northern borders, and it was to the new creation we owed the roofs of modern Europe. During this period the art of carpentry advanced by leaps and bounds till we stood gazing with wonder on the marvellous beauties of construction left us in many a wide-spaced roof of church and hall. These were no formal copies of the work of preceding ages, but the pure outcome of earnest thought brought to bear on its new conditions. What the debt of gratitude is that we owe to these earnest workers and thinkers of the past (synonymous terms these in many cases), we cannot tell until we have searched through the various musty documents of the past treasured up as heirlooms in many a lonely monastery, showing the loving labours that were expended on those works by those long-forgotten monks. During the Norman period the roof, though plain, was often open to the actual frame timbers. It was evident, from the weather-mouldings, which frequently remained to this day on Norman towers, that the outer roofs of this style were often of a high pitch, but sometimes they were very low. They appeared to have had generally, if not always, the beams placed very near together, on the under-side of which a flat boarded ceiling was perhaps made. It might be doubted whether any example of this period now remained, though we had sufficient evidence to show that they were in several instances. Portions of some very remarkable wooden roofs of this style remained at Oakham and at the Bishop's Palace, Hereford. Of the Early English style few roofs still remained in country districts, especially in Sussex. They were of steep pitch, and either canted or of a circular form like a barrel-vault, and had generally tie-beams. Alesowen Church, and one of the aisles of Rochester Cathedral, had roofs with moulded eaves clearly of Early English character; and Old Shoreham was a tie-beam with the tie-beam ornament on the original circular braces, coming to the Perpendicular period, we find Westminster Hall one of the finest specimens of a large span roof. The principals were here made into a sort of trefoil arch, and the interstices of the framing were filled with panellings; there were also arches from the principal to another. Of the same class are the roofs to Crosby Hall, and Christ Church, Oxford; but this style of roof was not common in churches, where the flat, or nearly flat ceiling, roof was more usual. Half-timbered ones were frequently erected in the Perpendicular period, both in this country and in Germany and France. The houses of the richer burghers were often constructed in this manner, and were enriched with ornamental carving, in woodwork, while not belonging to art of very high order, being generally entirely executed by the carpenter, was pervaded, as a whole, by a peculiar charm. In our own country, especially in Warwickshire and Cheshire, many picturesque specimens could be seen, and a holiday would be well and pleasantly spent in studying the examples remaining in Warwick, Coventry, or Chester, and Lancashire. In most cases, if the works were minutely examined, by would be found to bear the impress of careful artistic work, rightly applied, although many instances these were purely the outcome of the individual workman's ideas. However much work had been lavished on a building, seldom was the same moulding, stop, or ornament employed throughout, and this constituted the real charm of the treatment. In order to show the advantage of living among and studying these works, I call attention to some moulded ends to beams, both the outcome of the workman, independent of architectural control, both taken from buildings erected in Warwickshire. The one, which is refined in its details, was taken from the neighbourhood of a rustic old work; the other, debased and clumsy character, was surrounded by stucco and sham.

Much in the same way architecture always elected carpentry, and I consider that it is only architects working up to a high standard of art that the workman could improve himself. Discussing these wooden house-fronts, roofs, and other huge pieces of mechanism, which depended in boldness and variety, it should not be

overlooked that the abundance of oak timber in the North of Europe both suggested much of this art, and admitted of bold features of construction from the size of the logs and the tenacity of the material. Timber was in the fifteenth century to be had at low prices and in any quantity, whole cities being mainly constructed of timber. The houses were framed together with posts about 1 ft. 4 in. square in section, arching outwards and meeting the projecting floor timbers, and so with the upper stories. In the Rows of Chester an open gallery or passage was left in the first floor within the timbers of the house-fronts. Projecting oriels often jutted out from these overhanging stories, and the spaces between these framing-pieces were filled in with laths and mortar, or in later years with glass. In London, Rouen, Blois, and Coventry the angle-posts were occupied by niches having statues in them, or fifteenth-century window tracery was sunk in the surfaces. Most of the ornamental work to the early half-timbered houses was, however, confined to the ends of joists, beams, and posts, and it was not till a later date,—about the sixteenth century,—that the panel spaces were filled in with ornament, having nothing to do with the construction, and in some cases not improving the beauty of the work. Architecture, having now reached its zenith, seems to have entered into a period of torpor, when everything that was good seems to have slept, even if it had not entered upon a downward course, which once entered upon is so difficult to stop. "*Facilis descensus averni*" is a well-worn quotation, but still, nevertheless, very true. From this fatal decay of power it had at last awoke, and if not able in its new development to produce anything new or original, it had, at least, the merit of seeing and utilising all that was worth preserving in the past, and its very eclecticism has a beauty of its own, the outcome of which perchance may be a new style and a new power. I will, in the next place, consider carpenters' work in furniture, both ancient and modern, with a view of inquiring if even in this branch of work the carpenter had not had some share in aiding the cause of architecture. In the British Museum are preserved some Egyptian chairs which, from the simplicity of their construction, are well worthy of a visit, pointing aside their wonderful preservation after the lapse of centuries. Another old piece of furniture is St. Peter's Chair, at Rome, and this old piece of work, though at times repaired, still retained much of its ancient character. During the sixteenth century especially, furniture possessed an architectural character in its outlines. In the fifteenth century, chests, screens, stall-fronts, doors, and panelling followed or fell in with the prevailing arrangements of architectural design in stone-work, such as window-tracery or wall tracery. But in the sixteenth century furniture of architectural character, not proper to woodwork for any constructive reason, was imparted to cabinets, chests, &c.; but I will not dwell on this, as you have recently had the advantage of seeing the charming drawings at the lecture given here by Mr. Statham. They were artificially provided with parts that imitated the lines, brackets, and all the details of Classic entablatures when these had constructive reasons, but which, reduced to the proportions of furniture, had not the same property. These sub-divisions brought into use the art of "joinery." As the vigour of the great sixteenth-century movement died out, the mania for making furniture in the form of architectural models died out also, nor did it again become the fashion until quite modern times, under the Gothic and other revivals, at the end of the last and the beginning of the present century. The architectural idea was in itself full of grandeur, and productive of very beautiful examples in the shape of sarcophagus-shaped chests or cabinets, but the façades of temples, the vaults, columns, and triumphant arches of Rome would not bear reduction to such small proportions. With the introduction of marquetry into more general use, there was apparent not only a new or renewed method of decoration, but a changed ideal of construction. Pieces of furniture were no longer subdivided by architectural mouldings and columns; all such meant extra work added to the sides and fronts. I ask why modern carpenters have not taken in hand some of the work required in designing and executing furniture. At no period had there been such a demand for good,

sound, solid, and substantial work in this direction, work, in fact, well within the carpenter's domain, and a large field was open to the craft in the future. Why should not the hall furniture of a modern house fall entirely to the share of the carpenter? I exhibit some hall furniture designed for my own residence, and which I had executed solely by carpenters some seventeen years ago. They had thus seen in their survey of art, as far as traced, a continual progress of human ideas and conceptions, beginning with evolution, followed by imagination, and completed by adaptation. When we look from our present standpoint of critical examination as to the real manner and use of the various means of construction, it must be counted an anachronism that our predecessors of the last century, incapable of comprehending the true spirit of preceding ages and the principles on which their work was based, should have been so fond of reproducing archaic forms of construction, false alike in art and principle, and unsuited to a material in which they wrought. The error into which they fell was that they attempted only to reproduce the forms of older work without regard to its spirit. What we wanted was the love of truth that animated the workers in olden times, and when we had mastered the first principles of such a revival we should be on the high road to success. The designer should so use every material dealt with as to bring out its distinctive properties. One great and too common error was that of not letting well alone. How often did we find a well-moulded beam spoiled by the addition of meretricious ornament, having nothing in common with the member itself, and injuring by its presence what it was intended to enhance. As a result of the spread of technical schools, art is, I am pleased to notice, making its influence felt in our workshops, and I am hopeful that in the not far distant future our workmen would take their right place in the hierarchy of art, and a better understood connexion between the arts of construction and design would assuredly be the outcome. More than anybody, the carpenter had greater opportunities in the present day of improving his knowledge. Nearly every modern roof proclaimed the fact from the honesties. The roofs of our Georgian forefathers were perhaps nearly without exception the most inartistic fragments of a sham age. Concealed between lofty parapets from without, and by lath and plaster work went on hand in hand unchecked; but a change for the better had now opened, and instead of seeking to hide his work, each architect vied with another to show more and more both of the roof and its construction. No one could deny that the change was for the better. The man of all others to whom our thanks were due for this alteration in public taste was the late Mr. Pugin. He it was who first played havoc with the old tie-beam school of construction, without which the whole superstructure of collars and braces would have fallen to the ground. In our enthusiastic effort after the ideal we were sometimes apt to adopt archaic forms, which in our sober moments we were sorry for. I refer more particularly to the debased form of French and Flemish roofs just at present in vogue of the bedpost order, wherein the canons of the constructive position of materials are sometimes set at naught. The old carpenters evolved from their experience the constructive excellence that we found in most of their work. We must not, in our efforts to be eclectic, sin on the other side, and lose all trace of real worth. One point that was sometimes overlooked in adopting old examples by rule of thumb without taking into account the age in which they were executed is, that the extra strength of timbers in old roofs has been in many cases the main cause of their stability. Parts evidently designed under the direct laws of stress, intended originally to act as a strut, had, under changed conditions, come to serve the purpose of a tie, and if, on examination, the pins had given way, we might be certain that some power other than originally intended had been exerted, as pins could never have been properly utilised where tension of the part had been pre-supposed. The peculiarity of the present position of architecture was the reversal of the conditions under which it progressed. In the past the secular element was subordinated to the religious conception; now the utilitarian preceded all others, and it was the multiplicity of the requirements of our latter-day architecture that made the fulfilment so difficult a task. To

the young man starting in life my advice is, study anywhere and everywhere, but learn to sift the tares from the wheat, striving to remember that old work was not necessarily good because it was old. If the young student could sink self and learn to follow the spirit that animated the constructors of the thirteenth century,—the period when construction had attained its full development,—without copying all its forms and conditions, he would eventually retain something worth knowing. The unfortunate part of it was that the workman, like too many members of the architectural profession, only made bad copies of the old forms, taking little heed of the different conditions and requirements of the work. I would remind my hearers of Mr. G. E. Street's last address at the Institute of Architects, in which solid construction was insisted upon, and from a recent Royal Academy lecture by Mr. Aitchison pointing out that,—

"We modern architects are too much divorced from our materials, so that our mouldings are too apt to represent artistic rather than real needs. The early Medieval architects were mostly masons, even so late as the building of the Ducal Palace at Venice. The architect, then, was called a stone-cutter (*lapideus pictor*). Carpentry, too, is extinct in England, and so are carpenters: excepting the hedge-carpenter, we have none,—they are all joiners,—and their maxim is never to work timber, but to case it. The Saracen architects did the same. Their beams are often round balks, with the square ends, and fretwork in thin casing. In consequence of this the architect loses all sense of constructive propriety in his mouldings,—their only propriety is æsthetic."

I think that jerry building will soon have had its day; the work of the future will be solid, substantial work; that solid woods will be used, and veneer discarded. I find houses built from my designs and in a solid manner by so-called speculative builders let and sell far more quickly, though a larger price is asked for them than for the usual flimsy class of house, whereas these stronger, more solid, and more expensive houses would not have let or sold a few years ago. In my judgment, therefore, the time has arrived when to build solidly and well will pay best even the speculative builder, and this will make the carpenter more than ever in request if he will give his attention to technical knowledge. The scope of his trade will be increased, for the demand for solid and substantial houses will induce the furniture therein, and the carpenter and joiner may certainly make the hall and dining-room furniture, the panelling of ceiling, in conjunction with enamelled iron, the dadoing of halls and rooms, the solid parquetry of floors. The great thing that the carpenter must remember is that he must cultivate taste, for this now pays, and its cultivation is one of the weapons we have against foreign competition. In dealing with this subject I have almost refrained from speaking of the carpenter himself, yet permit me before concluding to say one word. I have often thought it should elevate the thoughts of the carpenter when he reflects who it was who condescended to work at his trade,—that it should be his aim not to have one article of furniture in his cottage, house, or room that is not made by himself (excepting, perhaps, the bedstead). Everything the carpenter does should bear impress of his trade; all being solid, simple, yet tasteful. Where he can, he should build his cottage with some portion of half-timbered work, with barge-boards, &c., if not prevented by local regulations; he should be content with bare walls at first, and gradually panel and fit up each room. Nothing would more help to elevate his own taste and the taste of his neighbours, and it should be borne in mind that he would be educating himself as an art workman, and thus the carpenter would be helping to influence the architecture of the future.

New Tramway Depots in South London.

The London Tramways Company, which have recently erected large new offices and other buildings in Camberwell New-road for the engineering and general staff, and also a new depot in Rye-lane, Peckham, several acres in extent, have just purchased a site in High-street, Clapham, near the company's present terminus, on which they are about to erect ranges of stabling, carriage sheds, offices, and other buildings. The site is between three and four acres in extent, and during the present week the materials of the mansion and outbuildings upon it have been sold. Stabling will be provided for 400 horses, whilst the sheds will afford standing-room for forty of the company's cars. The several buildings have been designed by Mr. Willing, the company's architect, and will be carried out by their own workmen.

THE UNIVERSITY AND CATHEDRAL CITY OF ST. ANDREWS.*

THE ancient city of St. Andrews is situated at the head of a bay of the same name on the east coast of Fife. As the crow flies, it is about thirty-five miles to the N.N.E. of Edinburgh. A single line of rails connects it with the North British Railway system at Leuchars Junction, just six miles south of the ill-fated Tay Bridge.

St. Andrews is fast becoming a fashionable watering-place, and on this account the gradual disappearance of its ancient buildings is to be expected.

In name alone is St. Andrews a city; in point of size it is very insignificant, its importance being chiefly due to the presence of the university. Independently of the monastic foundations, the city is very ancient, having been erected into a free and royal burgh by David, first king of Scotland, in 1153. Its leading features are three wide streets, North-street, Market-street, and South-street, all

overlooks the harbour; the second is in the south side, but is not used; the third abuts on South-street; and the fourth is on the north side of the cathedral. The one abutting on South-street is the most important, and was vaulted over; it is called the Pends. Why it is so called, or whence the word is derived, I have not been able to ascertain.

In the early days of Christianity there was a religious order in Scotland called the Culdees (the word is derived from Cille-de, the Gaelic for God's servants), a branch of which existed at St. Andrews two or three hundred years before it became an episcopal see. Foundations of an ancient church have been discovered on the hill overlooking the harbour, and there can be little doubt that this was the ancient Culdeean church. When the Priory was founded, about the year 1130, the Culdees were excluded, because they were a secular clergy,—married and possessed of property. It is supposed that they refused to acknowledge the Pope, and were gradually deprived of their rights, until they either migrated or died out.

East End of Cathedral, St. Andrews.

converging towards the east, where stand the ruins of the cathedral. This arrangement is in itself almost sufficient to convey the impression that the religious institutions were always of the first importance, and, in point of fact, they were so, until John Knox came and altered the state of affairs. St. Andrews never was a walled city, although there were gates at the ends of the three main streets; the one at the end of South-street, called the Argyle Gate, or West Port, still remains.

The Priory was enclosed with a wall said to have been built by Prior Hepburn, in 1510, part of which is still standing. It was about 20 ft. high, and had large towers at intervals, some of them were square, others round or octagonal, and were ornamented with canopied and crocketed niches.

The walls have four large gateways, the first

St. Andrews was created a bishopric in 575, and some few years afterwards most probably the Church of St. Regulus was built, of which the tower still remains.

The date of this tower is a much-disputed point, but, judging from its architecture, it could hardly have been built before the tenth century, if it were not even later than that. The nave is clearly of a later date, about 1080.*

The tower, which might be considered a specimen of Byzantine architecture (and it certainly reminds one of some of the Italian campaniles), is 108 ft. high and 24 ft. square at the base. It is built of ashlar from top to bottom, and the stone, which is entirely of a different description from any in the other buildings, must have been brought from a distance. It is in a capital state of preservation, and, beyond having been repointed at the

* Part of a paper recently read before the Liverpool Architectural Society by Mr. R. B. Preston. The illustrations are reproduced or copied from Mr. Preston's sketches.

* It is now roofless, but the grooves in the tower clearly show that there have been three roofs upon it at different periods.

end of the last century and a new staircase built inside it, stands as perfect as it did 800 years ago; and this is still more surprising when we consider its exposed situation, viz., at the top of a cliff overlooking the sea.

For nothing is St. Andrews more distinguished than by its long line of bishops and archbishops, extending from the year 870 to the year 1688, a period of 818 years. After that time Presbyterianism succeeded

wall of the south transept and the south aisle wall are also still standing.

The foundations of the entire building have been laid bare so that the plan can be easily traced. It was a cruciform building, the plan resembling a Latin cross almost exactly. It consisted of nave and aisles, choir and aisles, north and south transepts, north porch, and central tower. At the east end there was also a Lady-chapel. Of our own cathedrals it most

guest-house, and offices; in addition to these buildings, extending southwards towards the harbour, there were corn-mills, granaries, barns, and stables.

All these buildings have entirely disappeared, for, after the Dissolution, they were left roofless and tenantless, and formed a convenient stone quarry for the townspeople; and fully one half of the older houses in St. Andrews have been built with the stones taken from these buildings.

Argyle Gate, St. Andrews.

Episcopacy, because the Scottish bishops could not take the Oath of Supremacy to William III.

The cathedral was founded by Bishop Arnold about the year 1160, and was finished by Bishop Amberton in 1328; its erection thus occupied 68 years. As was the case with many other churches, they began at the east end and worked westwards, and the gradual change from Norman to Transitional, from Transitional to Early

nearly resembles Peterborough, and in point of size it is not much different. The total length inside the walls is 370 ft.; width across transepts, 180 ft.; across nave and aisles, 65 ft. It was the largest cathedral in Scotland, and is described by Fordun, an ancient writer, in these words:—"To have been built of hevn stone, the pillars and their cornices, with the doors and windows, to have been neatly carved and embossed in the light Gothic manner."

It is generally supposed that although the destruction of the monastery was gradual, that of the cathedral was completed within a few days of Knox's sermon in the town church, wherein he incited the people to this work of wanton destruction. He was so successful that in St. Andrews alone, besides the cathedral and monastery before mentioned, they demolished two churches, the monasteries of the black and grey friars, and three colleges.

The grey friars' monastery has entirely disappeared; but there is a small ruin, said to be part of the chapter-house belonging to the grey friars' monastery, still standing in front of the Madras Colloge in South-street.

Not satisfied with their work of demolition at St. Andrews, the Reformers actually passed an Act in the following year for the destruction of all the remaining abbeys and churches.

It is difficult in Scotland to ascertain the dedications of the various churches one sees; that of the cathedral at St. Andrews I did not succeed in obtaining. The churches are never spoken of by their dedications, but are alluded to as the Parish Church, the Colloge Church, the Town Church, and so on.

The Town Church of St. Andrews, or Trinity, is on the north side of South-street, about halfway between the Pends and the Argyle Gate.

It was founded by Bishop Turgot in 1112; it suffered at the hands of the Reformers, and was rebuilt in 1797, and, therefore, with the exception of the tower and spire, which escaped it, calls for no further remark. This is, fortunately, still untouched, very simple in character, but unusually effective, owing in a great measure, no doubt, to the quaint little square stair-turret at the corner.

The Parish Church of St. Leonard served as a chapel to a college of the same name; a portion of this college was originally a hospital or house for the accommodation of the pilgrims who at that time visited St. Andrews in such large numbers; but in the year 1512 Prior John Hepburn appropriated the funds belonging to the hospital for the building and endowing of the College of St. Leonard.

The Colloge Buildings have vanished entirely, but the nave of the chapel is still in existence, though so much mutilated as to be of little interest except historically.

Plan of part of St. Andrews.

English, from Early English to Early Decorated, can be clearly traced even from the comparatively small portion which remains. The east wall and gable flanked by a pinnacle on each side is of very massive character, and is probably due to this that it has escaped the fury of the fanatic under John Knox. The best front being less massive has not been so ruinous, but sufficient remains for us to judge what the whole must have been. The west

About the year 1420 the upper triplet in the east gable was replaced by a large three-light window, but the west windows seem to be of the same date as the surrounding work. It is recorded that the cathedral had carved stalls, stained-glass windows, and a tiled pavement. There was a cloister on the south side separating it from the monastery, which belonged to the order of St. Augustine. There were the usual dining-hall, dormitory,

St. Mary's College, also in South-street, has been almost entirely rebuilt, and therefore requires no further comment.

The Madras College, which is really a large public school, and also in South-street, is comparatively of recent foundation, having been endowed in 1832.

St. Salvator's College, in North-street, founded by Bishop Kennedy, in 1456, is now known as the United College, because it was united to St. Leonard's, of which I have already spoken, in 1747, but the chief part of the revenues belong to St. Leonard's.

The buildings of the United College are disposed on three sides of a large quadrangle, the chapel, or, as it is popularly called, the College Church, occupying the south or street front. This has in the main escaped destruction by the Reformers, but the remaining buildings have either been rebuilt or so modified that they are of little or no interest. The quadrangle is entered from the street through an archway under the tower and spire, which rises to a height of 160 ft. The proportion between the two is rather unusual, the spire being so much smaller than the tower.

Above the archway before mentioned is a carved square panel, containing the arms of the college, and on each side a canopied niche, which, it is needless to add, have lost their occupants.

The upper portion of the buttresses, the pinnacles, and parapets are restorations not altogether meritorious, but the tracery of the windows has all the appearance of a careful restoration. Two curious angle niches may be noticed to the buttresses of the bay adjoining the apse. Possibly if the figures had not vanished we might have had some clue to the reason for thus placing them. There is also some corbelling to the tower at the south-east corner for which there seems to be no apparent reason. A quaint little turret at the corner of the building, at the east end of the chapel, is a relic of the old college buildings, and I think from this alone we may imagine what a picturesque group they must have formed before the ruthless hands of John Knox and his herd of fanatics were raised against them.

In the spires to the College Church, the Town Church and its corner pinnacle, and the pinnacle at the west end of the cathedral, we may notice that the entasis in every case is considerably exaggerated, so that the outline is something like a how, and the effect, though unusual, is certainly good.

Inside the College Church the only thing of any interest to us is a monument of the founder, Bishop Kennedy; but this is so elaborate, and at the same time so mutilated, that I did not attempt a sketch of it, and, unfortunately, it has not been photographed. It suffered irreparable injury when, some 100 years ago, the wisacres who had care of the College thought that, because there were no visible supports to the roof (possibly it was a double roof with a flat panelled ceiling below), therefore it must be dangerous. Very likely their ideas went no further than an ordinary king-post roof, so they set to work to pull it down; but they found that it was so firmly framed together that they could not take it to pieces, and were forced to detach it from the walls and let it fall *en masse*. The effect upon the monuments and other valuable furniture below can be more easily imagined than described.

The Castle is placed in a most commanding position at the top of a cliff 80 ft. high, the sides of which rise nearly perpendicularly from the water's edge. Its site has been well selected, for it has the sea on two sides of it; the other two are protected by a wide moat. It was entered by a drawbridge on the south side, through a lofty archway leading into a central courtyard. The keep was at the N.W. corner. It would be difficult now to imagine what it was like originally, as it has been rebuilt three times. It was founded by Bishop Rodger in the year 1200, and served as a palace, State prison, and fortress. It fell into the hands of the English several times, and was once entirely demolished to prevent it being recaptured. It was the scene of the murder of the celebrated Cardinal Beaton, the proudest and most ambitious prelate that Scotland ever possessed. His murderers held the castle for about a year. They were besieged for three months by both Scotch and French troops, and the French king sent a fleet of twenty-one galleys to assist. Cannon were mounted on the abbey wall, the

Portion of West Front of Cathedral, St. Andrews.

towers of St. Regulus, and the College Church. The besieged eventually yielded to the French king, and the castle was demolished for the third time. This happened in 1547. What now remains of the castle was erected by Bishop Hamilton, Cardinal Beaton's successor, whose arms and initials are under one of the south windows, and his device a seven-rayed star, above the entrance archway.

In the keep at the north-west corner is a bottle-shaped dungeon, entirely hewn out of the solid rock; it is 18 ft. deep, 16 ft. diameter at the bottom, and about 4 ft. at the top. The wretched occupants were raised and lowered by means of a windlass. A more horrible spot could scarcely be imagined, or a more perfectly secure place devised for keeping a prisoner. There is a well in the centre of the courtyard, 50 ft. deep, containing 14 ft. of good fresh water. When we consider that it is within a few yards of the sea, it is surprising that the water is not salt.

In 1879, when the foundations of a new house, opposite the castle, were being laid, the workmen came upon a subterranean passage, which, on being explored, was found to lead to the castle in one direction and to the cathedral in the other. It is supposed that, at the time when St. Andrews was constantly occupied by the

English, and the castle therefore continually in a state of siege, the occupiers would, on finding that they could no longer hold it, retreat to the safety of the cathedral precincts by means of this passage.

St. Thomas, Charterhouse, School of Art.—The Lord Mayor was present on Saturday last at the annual distribution of prizes in connexion with the St. Thomas Charterhouse School of Art in Goswell-road. The Rev. Joseph Diggle, Chairman of the School Board for London, presided. Mr. Francis Black, the head-master, read the annual report, in which it was stated that 240 students attended during the year, executing 3,894 works, which were forwarded to the Science and Art Department for inspection. He points out that this school of art is in need of local scholarships similar to those enjoyed by other metropolitan schools of art, making it possible for energetic, able, and industrious students to lay a thorough foundation in practical art before passing to the head central schools at South Kensington, or to continental schools, for high perfection in knowledge and technical skill. The national scholarship, value 150*l.*, the national bronze medal, and the national Queen's prize for stained glass designs were awarded to Miss Augusta Mair.

SANITARY ORGANISATION AND LEGISLATION.

THE METROPOLITAN SEWAGE QUESTION.

At the April meeting of the Association of Public Sanitary Inspectors, held at Adam-street, (Delphi, on the 3rd inst., Dr. Alfred Carpenter read a paper on Sanitary Legislation, which was mainly devoted to an outline of a proposed national scheme of sanitary organisation. Dr. Carpenter claimed to have pointed out at various congresses, from that of the Sanitation Association at Norwich in 1873 to others of more recent date, that to force upon the public, before it had been educated up to the required point, legislation on sanitary matters would be to incur certain failure through the indifference on the one hand of legislators and administrative authorities, and on the other the opposition of ratepayers and persons interested in letting matters alone. These views were put forward a great tactical advance had been made both on the part of the magistrates and the people, and the road was now better prepared for an extension of sanitary legislation and sanitary work. This was attributed mainly to the influence of the press, daily and weekly, by which daylight had been let into the subject all over the country. Discussions in Parliament, to be useful, must flow, not lead, the discussions among the local authorities, and he regarded it as one of the best results of the works of Edwin Chadwick, Robert Rawlinson, the late Dr. Parkes, and a host of others, that a body of men had been set on foot, such as composed that Association, possessing a knowledge of the real operations of a city of health. He had been assailed as a vile-monger, and had been called many other names, for having ventured to point out the dangers attending sanitary neglect, but he had to step in and carry off his holocaust victims before the measures he had proposed were agreed to, and before that society of scientific plumbers could be established which he had done and would do more good to society than a dozen Acts of Parliament. He was no rooster of centralisation where local action could be completely relied upon, but he thought ought now to organise a sanitary army, with a power and a real authority in sanitary matters. A commander-in-chief was required, should be in touch with medical officers of all ranks all over the kingdom, as well as with the staff and file of the sanitary army, and who should promote to higher duties any unit of the army who had shown superior qualities in the performance of district work. Such men there are, as worthy to be called out and decorated the commander-in-chief as any soldier who has earned the Victoria Cross in the Sudanese other campaigns. Such a superior would be possible to Parliament, but he would have to bring him generals of division, who should not be affected by changes of Government, and who should be responsible to him for the health of the counties and great cities of the empire. The general of division would be a district medical officer of health who had proved himself an efficient administrator, who should sit with the owner as medical assessor at all inquests, and should be an expert in the performance of post-mortems, but who should never be permitted to practise midwifery. The nuisance inspectors, the foremen and inspectors of markets, the sergeants of such an army, working under necessary medical officers, who would represent the lieutenants and captains. The reduction of the typhoid death-rate, even in the face of an increase in the density of population, could be such as to ensure a liberal and willing attitude to both the officers and privates of the force, the position of the inspector,—held as he is, too often was in the grip of a chief-stick,—could be greatly improved. Fixity of tenure, an increased pay and chances of promotion, would secure a superior class of men, the owners of defective houses or sanitary property would no longer be able to shelter themselves behind a dodging inspector. The housing of the poor should be really to the front, and landlords would be brought to book. No cottage would long remain without that pure water supply which they could afford. With regard to the great question for the cities of the disposal of their refuse, it seemed to him that legislators were giving a deaf ear to a terrible certainty. The sanitary interests were being destroyed, and at the same time, the valuable fertilising

elements contained in the refuse and sewage were being irrevocably thrown away. The Thames and other rivers were being silted up with dangerous mud-banks, which, under the influence of heat, would some day rise up like the toys known as "Pharaoh's Serpents," and destroy the trade of our ports. It ought to be an offence against imperial authority to destroy that material which could and should be utilised for the production of food. China afforded an example of what could be done to produce food for the densest populations without having recourse to outside assistance. The sewage and refuse of every hundred persons would grow two bullocks, and produce milk enough for the hundred people or vegetable food in corresponding quantity. If the Metropolitan Board of Works persisted in its ruinous course of putting into the Thames what ought to go to the surrounding fields and pastures of London, and if the evil were not otherwise counteracted, a terrible retribution would be brought about at an early date. With an increase of population we must have increase of fertility or we should cease to be a nation, and if all sewage products were to be destroyed by fire, or sent into the sea, the end sooner or later must certainly be the national defeat and disaster. The lecturer said, in conclusion, that he would much sooner trust Bailey Denton and his school to meet these difficulties than Sir Joseph Bazalgette and his followers. Any attempt to delay the return of the sewage to the soil was manifestly wrong and contrary to the teaching of nature.

An interesting discussion followed, in which the Chairman (Mr. Jerram), Dr. Drysdale, Mr. Bailey Denton, jun., and various members of the Association took part.

The Chairman, in illustration of the necessity for consulting sanitary officials before making laws and by-laws, pointed out a defect in the new legislation proposed. A man might, he said, be compelled before building to make a street, but there was nothing to compel him to put in a drain. He bore testimony to the soundness of the views of Dr. Carpenter as to the utilisation of sewage, and he hoped shortly to be able to point to a large sewage farm of which he had charge as a model to London.

Mr. Bailey Denton said there were twenty towns in England in which sewage had been satisfactorily disposed of by being put upon the land, and in every case the effluent water was pure enough for cattle to drink and for the increase of fish. In the country no difficulty was found, but in London they had not been able to induce the Board of Works to look at plans for the utilisation of sewage. He contrasted the wasteful scheme of Sir Joseph Bazalgette, favoured by the Board of Works, by which it was proposed to continue to get rid of the London sewage by discharging it into the river, with the scheme proposed to be carried out on Canvey Island by his (Mr. Bailey Denton's) father and Col. Jones, in which, after saving the fertilising elements from the sewage of London, and depositing them to enrich the soil of the island, they would be able to return the effluent water, purified, to the stream. Canvey Island was an area of 5,000 acres of low-lying land surrounded by a wall 8 ft. high. By mixing the solid residuum from the sewage with the brick-earth of the island, they would under the scheme provide for the relief of the metropolis for 100 years, and land which was now below the level at high tide would be enhanced in value productively and commercially by being raised above high tide with enriching solidified materials. By means of the brown earth and the shells and sand washed up at every tide the soil could be made as porous as they liked. They could treat sewage at Canvey Island at a cost to the ratepayers of 1½d. in the pound, while the scheme favoured by the Board of Works would only be half done at a cost of 2½d. in the pound.

Noble's Isle of Man Hospital.—The following official report was presented at the conclusion of the meeting last week:—"A meeting of the new Hospital Committee was held in the council-chamber for the purpose of considering the revised plans of the new hospital, as submitted by the architects, Messrs. Bleakley & Cubbon, of Birkenhead, which were unanimously approved. Tenders will be invited from contractors for the work forthwith."

THE CONGRESS OF FRENCH ARCHITECTS FOR 1886.

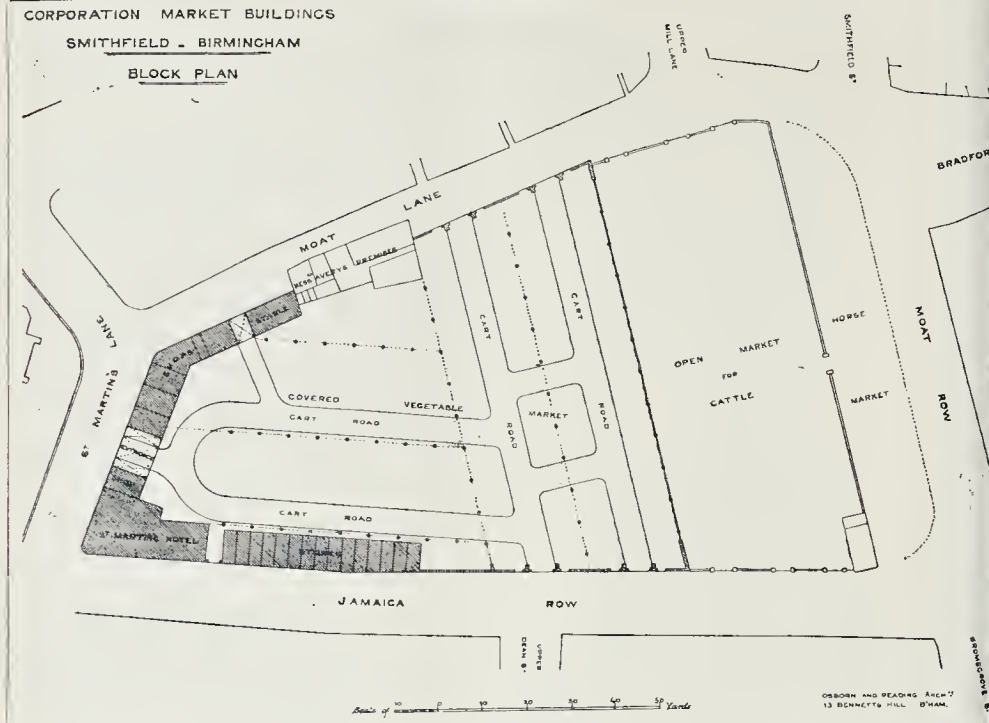

The following is the programme of the Congress for this year, which will be held in the Ecole des Beaux-Arts from the 7th to the 12th of June, inclusive.

"PROGRAMME DES SEANCES ET VISITES.

- Lundi, 7 juin.*
- à 2 h.—Constitution du Bureau et ordre des travaux du Congrès.—Nomination des Commissions sur les questions suivantes: Concours publics, Honneurs, Hygiène, Industrie du Bâtiment, Propriété artistique, Responsabilité, Voirie, &c.—L'architecte au Salon, par M. C. Moxeux, architecte du Gouvernement, membre de la Société.—Visite de la Synagogue de la rue de la Victoire, M. Aldrophe, architecte, membre de la Société.
- Mardi, 8 juin.*
- à 9 h.—Visite des ateliers de M. Guilbert Martin, chimiste mouiste, lauréat de la Société en 1885, avenue de Paris, 275, Saint-Denis.—Visite de l'Abbaye, de l'Hôtel de Ville de Saint-Denis.
- à 2 h.—Conférence par M. Eug. Guillaume, statuaire, membre de l'Institut, professeur au Collège de France.—Compte rendu du Congrès des Sociétés savantes.
- Mercredi, 9 juin.*
- à 8 h.—Palais du Louvre, les mosaïques du grand escalier, exécutées par M. G. Martini, sur les cartons de M. Lenoxy, membre de l'Institut, sous la direction de M. Edm. Guillaume, architecte du Palais du Louvre.
- à 10 h.—Visite du chœur de la Sorbonne, M. H. Néau, architecte.
- à 11 h.—Visite du Panthéon: mosaïques, peintures, caveaux.
- à 2 h.—Conférence par M. Heuzey, membre de l'Académie des Inscriptions et Belles-Lettres, membre libre de l'Académie des Beaux-Arts.—Communications et rapports des Commissions nommées le 7 juin.
- Judi, 10 juin.*
- Excursion à Troyes, en Champagne, départ à 8 h. 25 du matin, gare de Strasbourg, retour à Paris, à 9 h. 25 du soir.
- Vendredi, 11 juin.*
- Matinée réservée à la Caisse de Défense Mutuelle.
- à 2 h.—Suite des communications et rapports des Commissions nommées le 7 juin.
- Samedi, 12 juin.*
- à 9 h.—Visite des Catacombes.
- à 1 h.—Distribution des médailles décernées par la Société Centrale des Architectes, à l'Architecte privé, à l'Ecole des Beaux-Arts, aux Ecoles d'Albion et de Rome, aux Ecoles privées, au Cercle des Alcaons, au Cercle de l'Édification, aux Industries d'Art, MM. Paul Scéille et Paul Wallon, rapporteurs.—Notice sur la vie et les œuvres de M. Th. Bella, membre de l'Institut, par M. Paul Scéille, architecte, vice-président de la Société.—Notice sur la vie et les œuvres de M. Th. Laiton, vice-président de la Société, par M. Simon Girard, architecte, membre de la Société.
- à 7 h. très précises.—Dîner confraternel, à l'Hôtel Continental.
- NOTA.—Tout membre du Congrès devra prévenir à l'avance le Bureau pour être autorisé à traiter une question relative à l'Architecture ou à l'Archéologie, au dehors de celles indiquées ci-dessus. Pour toute demande d'invitation ou tout autre renseignement, écrire au Secrétaire du Congrès, au siège de la Société Centrale des Architectes, boulevard Saint-Germain, 165."

TAPESTRY-MAKING.

The second of the series of Cantor lectures on "Tapestry and Embroidery," was given by Mr. Alan Cole on Monday evening last, in the Hall of the Society of Arts. The subject of the lecture was tapestry-making. Explaining how the term "tapestry" had been used in two senses, the one having reference to decorated hangings generally, the other to a special process; the lecturer described the process in detail. He then showed diagrams of early specimens made, during Græco-Egyptian times, by that process. These were for ornamenting costumes. The method was known to the modern Japanese, who claimed to have "invented" it quite recently, as well as to the natives of Peru and the Peruvians. This method was identical with that worked in high-warp and low-warp frames, from the thirteenth century onwards, by *tapiciers* and *tapissiers*. A considerable series of diagrams was devoted to illustrate the predominance, during the fourth to the thirteenth centuries, in woven and embroidered textiles, of a scheme of pattern composed of circular bands enclosing birds and beasts. The earliest known tapestry-made hanging was wrought with such a pattern. It came from the Church of Saint Gercon, at Cologne, and parts of it were now preserved in various museums. The fashion of long and narrow bands with patterns of figure designs illustrative of religions, chivalric, and domestic episodes, survived into the fifteenth century. But towards the middle of the fourteenth, a change in size and shape of hangings (tapestry-made) had taken place. The Dukes of Burgundy, at that time, greatly patronised the particular art, and to the patronage of such nobles, of kings, and pontiffs is due the production of very large hangings of complex pattern, in which hundreds of figures, in elaborated costumes, illustrative of mythological, historical, and allegorical events, are used.

Illustrations.

NEW YORK STATE CAPITOL, ALBANY: GRAND STAIRCASE.

THE New York State Capitol at Albany is approaching completion, portions of it being now occupied. In competition, the designs of Mr. Fuller, now Government architect at Ottawa, Canada, were accepted, and a considerable portion of the structure was built under his superintendence. Owing to some political action, he resigned his position, and Mr. H. H. Richardson, of Brookline, Massachusetts, and Mr. Eidlitz, of New York, were entrusted with designs for completion, having certain parts allotted to each of them, the work being executed under the supervision of a resident architect. The original design was Italian Renaissance in style, but this has not by any means been adhered to, and considerable changes have been made, both externally and internally, parts of the building having been pulled down. The portions designed by Mr. Eidlitz, including a large staircase, and one of the meeting-chambers, are in style a free treatment of ornamented Gothic, which ill accords with the surroundings. Mr. Richardson's work comprises the large meeting-chamber, many important rooms, and the grand staircase, as shown in the illustration. The original from which our illustration is taken formed one of the very fine series of drawings which were exhibited at the Institute among the Godwin Bursary (1885) collection of works illustrating modern American architecture. The design has been somewhat altered in execution. The stone of which it is being built is imported from Dumfriesshire, Scotland. I am informed that the whole of the work throughout the building is being executed by day-work, the men employed being nominated by members of the Houses of Representatives. No expense is being spared in any portion of the building, materials of the most costly description being used in many places.

JOHN B. GASS.

DESIGN FOR A TOWN MANSION.

This picturesque design was submitted by Mr. E. Guy Dawber, in the Royal Academy Students' Competition of this year. The plan

was worked out for a domestic town house, and the general design founded on North German types. It was designed with the idea of execution in red brick with stone dressings, and a tile roof.

CORPORATION MARKET BUILDINGS, SMITHFIELD, BIRMINGHAM.

IN connexion with the covering over of the Birmingham Corporation Smithfield Market and the widening of St. Martin's-lane, a large block of buildings has been erected in the latter thoroughfare, extending from Jamaica-row to Moat-lane, so as to form a suitable front to the vegetable market. The buildings, which are from the designs of Messrs. Osborn & Reading, architects, are designed in the style of the English Renaissance of the Stuart period, and are constructed of red brick, with red terracotta dressings.

The main entrance to the markets is in the centre of St. Martin's-lane front, and consists of a central roadway for carts and wagons, 15 ft. wide and 24 ft. high, together with a wide entrance on each side for foot-passengers. The piers supporting the large archway are of stone, but the arch itself is constructed of terracotta, richly moulded and carved. Over the archway are two sculptured figures in red terracotta, representing Flora and Pomona. The whole of the carving and sculptured work has been executed by Mr. John Roddis, of Aston. The archways are fitted with massive wrought-iron gates, manufactured by Messrs. Hart, Son, Peard, & Co., of Grosvenor-street, Birmingham. The Jamaica-row front and about one-third of the St. Martin's-lane front are occupied by the new St. Martin's Hotel, which stands as nearly as possible upon the same site as the old hotel, and contains large hall, smoking-room, bar, luncheon and dining-rooms, &c. In the centre of the building on the ground floor, a manager's office is placed, with windows and doors overlooking the liquor vaults, bars, hotel entrances, and staircases. On the basement, also, there is a large luncheon-bar and a grill-room, entered by a staircase leading down from the doorway at the extreme end of the Jamaica-row front. This row extends under the footpath in Jamaica-row and under a portion of the markets, and is amply lighted by means of prismatic glass.

On the left of the large entrance to the markets has been placed the market superintendent's office, which has a staircase communicating with his house, on a portion of the first and second floors. The remaining portion of the St. Martin's-lane front is occupied by large shops, with show-rooms on the first floor and well-lighted basements extending under the footpath. That portion of the building which faces Moat-lane has been planned to use as a coffee-house, and has a good entrance hall and a staircase leading to all the upper floors.

Extending down Moat-lane, there is an entrance to the main building, forming a secondary gateway entrance to the markets, a stable and carriage-house for the superintendent, and lavatories for women. The gateway is 15 ft. wide and has ornamented wrought-iron gates, similar to those of the main entrance. The upper floor of the extension is occupied by public lavatories.

The various lettings in the building are divided by fireproof floors and walls, and the floors of the kitchens are constructed of fireproof materials.

The contractor was Mr. Frederick J. Brien of Coventry-road, Small Heath.

The cost of the building has been 15,000*l.*

THE ROSSETTI MEMORIAL.

It is proposed to erect a monument to the memory of the late Dante Gabriel Rossetti in the public garden of the Embankment, in front of the residence of the painter-poet, No. 31 Cheyne-walk, Chelsea, or some other suitable site.

It is to be executed by two intimate friends of Rossetti's from his early youth, taking the form of a bronze alto-relievo portrait, modelled by Mr. Ford Madox Brown, as the central feature of a granite fountain designed by Mr. John P. Seddon.

The plaster-cast, which has been taken from the full-sized clay model made by Mr. Ford Madox Brown, and a small model of the Gothic monument are now on exhibition in the South Kensington Museum, having been placed exactly opposite the entrance to the refreshment-room in the corridor adjoining thereto.

The list of the supporters of the proposal is already a long one, and includes numerous

dential and representative names of artists, poets, and art amateurs, among whom we find those of Sir Frederick Leighton, P.R.A., Sir Charles Burton, Sir John Millais, W. Holman Hunt, Alma Tadema, F. J. Shields, William B. E. East, Sir John Gilbert, Sir Noel Paton, V. Prinsep, Arthur Hughes, the late Sir Henry Taylor, Robert Browning, Algernon Swinburne, George D. Conway, Lord Aberdare, J. Comyns, J. Sidney Colvin, Vernon Lushington, Professor J. Marshall, William Linnell, W. G. Thomas, Theodore Watts, J. H. Pollen, the Dean of Manchester, and Lord Mount-Edwards.

The Honorary Secretary to the Committee is Mr. F. G. Stephens, of 10, Hammersmith-terrace, W. The Honorary Treasurer is Mr. W. H. Buxton Forman, of 46, Marlborough-hill, W. John's Wood, who will gladly receive the names of those who may be desirous of supporting the undertaking; art students in particular being invited.

In the accompanying illustrations we give the full-length portrait, taken from a photograph in the model by Mr. Ford Madox Brown, of a seated figure of a good and life-like likeness of Rossetti, together with a perspective sketch of the fountain designed by Mr. Seddon, as it will appear when executed and fixed on the proposed site.

SCULPTURE: "THE REMORSE OF CAIN."

Two groups of sculpture illustrating this subject were submitted in the Royal Academy Students' Competition of this year; that by Mr. W. Pomeroy being the successful one. The composition of this group is exceedingly good, the three figures combining into one motive in a very expressive manner, and we think it rightly deserved the prize. The figure of Cain in Mr. Frampton's group is more powerful in effect, but those of the mother and child seem much thrust apart in the composition, which does not unify the other group. It is not well, however, for the future of English sculpture that even an unsuccessful design in a student's competition shows such fine qualities.

Mr. Frampton's group, we are asked to mention, is the property of Mr. H. D. Olivier.

RAINAGE AND SEWERAGE WORKS.

On Friday, the 2nd inst., Mr. Harrison, M. Inst. C.E., one of the Inspectors of the Local Government Board, held an inquiry respecting an application made by the London and Church Joint Sewerage Board to borrow 30,000l. for outfalls and works of sewage disposal. Mr. E. C. Poles, C.E., Engineer to the Board, explained the plans. The Board propose to construct 122 yards of 3 ft. barrel sewer; 559 yards of 2 ft. 8 in.; and 630 yards of 6 ft. 8 in., the latter being in tunnel through the street.

The sewage is intended to be precipitated by lime on the quiescent principle. After passing through a screening chamber, it is to be filtered through a building in which the lime will be mixed and the sewage, thence passing alternately through one of two large tanks, 100 ft. by 60 ft., and 8 ft. deep. In these the greater portion of the sewage will be intercepted, and the partially treated sewage will then be drawn into one of the other tanks, each 120 ft. by 100 ft., and 8 ft. deep. Each of these tanks is capable of holding one day's dry-weather flow, namely, 60 gallons, from a present population of 100,000. The latter tanks are used for final settlement, and the sewage will in one be percolated, while the other two are being actively filled and run off. The effluent from the tanks will be run upon some portion of the filtration-ground, which, being freed from the debris of the old quarry will be the nature of a water filter. The river runs directly through the site, and all within the site capable of allowing to be utilised for power which is intended to be done by putting on a turbine. This will be sufficient for all purposes. The works laid out that by an addition of two other tanks of the same size as the last-named (for which room is provided), will be sufficient for a population of 1,000,000.

The drainage of this port on the coast has long been in a very bad condition, and the present unventilated and badly-constructed sewers have poured their sewage by numerous outfalls into the river Ouse. The Local Board, being determined to remove all cause of complaint and to place the town in a thoroughly satisfactory sanitary condition, advertised a competition open to all the sanitary engineers of the country, offering 50l. premium for the best scheme for the drainage and sewage disposal of the town, and agreeing to engage the successful engineer to carry out the works. Eighteen schemes were sent in, accompanied by plans and reports, and the Local Board has accepted the scheme bearing the motto "Gravitation" as being, in their opinion, the best. The author of the successful scheme is Mr. W. H. Radford, Assoc. M. Inst. C.E., sanitary engineer, Nottingham. Mr. Radford's scheme is, briefly, to retain those present sewers which are in good condition, and utilize the remainder of the present sewers for surface-water only. New, well ventilated and flushed sewers, of suitable sizes, will be placed in those streets where they are required. Hassall's patent pipes are proposed to be used. The sewage from the town on the west of the river will be conveyed by a main outfall to a point away from the town, and near the mouth of the river, where it will impound in a specially-constructed concrete storage-tank during high tide. The sewage will then be run into the mouth of the tidal river at half ebb, so as to take advantage of the powerful seaward current; the last remnant of thesewage will have entered the river while there is still one hour and a half of the ebb tide left to wash it far out of sea. On the east of the river, the present sewers and outfall at the mouth of the river will be utilised, but the sewage will be prevented from backing up the sewers by the provision of a suitable storage-tank, and the sewers will be well ventilated and flushed. Provision is made to connect this outfall at some future time with the main outfall, on the west, by means of a siphon under the river.

At the meeting of the York City Council, on the 5th inst., the Urban Sanitary Committee reported that the resolution of the Council, passed on October 5th last, in reference to the selection of a sanitary engineer for the purpose of advising on the system of drainage of the city, under the provisions of the York Extension and Improvement Act, 1884, having been further considered by the committee, it was resolved that Mr. Mansergh, C.E., be selected as the engineer to be consulted, and that the Town Clerk be directed to communicate with Mr. Mansergh, in order to ascertain the probable amount of his fee for preparing and making his report. A letter from Mr. Mansergh was read, containing the following passages:— "The question of terms is always a somewhat difficult one, because the cost of preparation of a report depends so much upon the existence or otherwise of reliable plans of the place and neighbourhood, and of sections or other particulars of existing sewers and works. If your committee would be good enough to allow me to come down and make inquiry on the points, and then to talk the matter over with them, I think it would be the most satisfactory way of coming to an arrangement."

This course was agreed to. York Rural Sanitary Authority.—At a meeting of this Authority, held on the 8th inst., a letter was read from the Local Government Board, asking for further information on the Fulford drainage scheme. The Board pointed out that as regards the proposal of the Sanitary Authority to construct an additional sewer into the River Ouse, this would apparently involve a contravention of the provisions of section 3 of the Rivers Pollution Prevention Act, 1876, and that some other means should be devised for disposing of the sewage. It was decided to remit this communication to the sub-committee having the matter of the Fulford drainage in hand.

Railway Time Tables.—The "Twopenny Alphabetical Monthly Time Table" of the Railways of the United Kingdom* is very clearly made out, and will prove very useful for those who want the times of through routes at a glance, without hunting through the fuller but more complicated tables of Bradshaw. Small maps of the railway systems of the kingdom are added, and enlargements of the districts round London and Manchester, and one or two other portions of the system. There is a separate detailed guide for the places within a radius of thirty miles round London.

ARCHITECTURAL ASSOCIATION. INDOOR ARCHITECTURE. The twelfth ordinary meeting of this Association for the present session was held on the 9th inst., at 9, Conduit-street, Mr. C. R. Pirk (President) in the chair. Votes of thanks were passed to Mr. J. J. Stevenson for permitting the members to visit the houses now being erected from his designs at Kensington Court, and to the Superintendent of the Law Courts for allowing some of his officers to accompany the members in their visit to that building on the 3rd inst. A special vote of thanks was accorded to Mr. H. D. Appleton (hon. sec.) and others for their services in connection with the members' soiree. Mr. G. R. Redgrave then read a paper on "Indoor Architecture." He commenced by saying that, strictly speaking, the title he had selected for the paper was a misnomer, for he had really no right to separate external from internal architecture, but as he wished to present a few ideas relating to the arrangement and design of domestic interiors, he had endeavoured by the title he had chosen to show that his remarks would be thus limited in their application. He proposed to deal only with the evolution of domestic interior architecture, and to retrace some of the chief features of interest in the days of the French chateau and the late Tudor dwellings. The excellent paper the Association had recently heard from Mr. Gotch* went over much of the ground he had proposed to occupy. The art of house-planning, which was inseparably connected with his present observations, had, at any rate in all our large towns, become a question of making the best use of the smallest possible amount of space, and the skill of the architect was largely exerted in contriving to make a very limited area contain the nimost accommodation practicable. In the usual frontage to the street his task was confined to so arranging his plan as to give access to his interior, and to light his front rooms, and we were thus tied down to the narrow passage leading to the front door, with the dwelling-room on one side of it. Where we were less limited in width, it might be possible to introduce a central passage with rooms on each side. It was not possible to say much about the entrance passage; it was, and must always remain, in town houses (to which his remarks were chiefly applicable), a narrow, and generally a rather dark approach to the staircase-well. It was a matter of necessity also that the position of the staircase should be central, or nearly so, in the block, and the proportions of riser and tread, and the length of each flight, were, to a certain extent, dictated to us by their intended use, and left little chance of variation, or of altered modes of construction. Still, he had a great quarrel against the modern staircase, and he regarded most staircases as opportunities missed. He was not prepared to do as they had done in America, namely, abandon the staircase altogether in favour of the lift; though he thought the well-managed lift had everything in its favour. It was most economical of space. It saved a vast amount of muscular wear and tear, and if its mechanical arrangements and details had received as much care and thought from architects and engineers as they deserved, it would long ago have come into far more general use. As to the height of the story from floor to floor, it was a matter of faith with the builders of Medieval times to keep their dwelling-rooms low, and apart from their age or from any antiquarian consideration, there was an inexpressible charm, and a certain indefinable sense of ease and comfort in a low room, which he never experienced in a lofty one. Many of the rooms in modern houses were really too lofty. A low room could be warmed, ventilated, furnished, and decorated much more easily than a high one, and he had yet to be convinced that we had done rightly in doubling the height of our rooms since the days of the Stuarts. It might be said that with gas burning in a room it must be made at least 10 ft. or 12 ft. high; but then gas, in the way in which we generally burned it, was one of the most ghastly evils of the nineteenth century. By common consent the square, or the parallelogram, has been for all time the form usually chosen for the plan of a room. Authorities, from Vitruvius downwards,—the downward authorities mostly quoting, by the bye, from Vitruvius,—had propounded laws and proportions which should regulate the sizes of the

* 13, York-street, Covent Garden.

* See Builder, vol. xlix, p. 891.

rooms, but all founded on the square and its extension. Now, without denying in any way the excellence of these figures, he was quite sure the architect who could contrive to avoid them would get undreamed-of advantages in all rooms, except, perhaps, dining-rooms, and even in them, if he would only keep a free space large enough for the table and the servers. The best shaped room is the L, but all rooms were greatly improved, both for comfort and effect, by frequent departures from the normal type.

With regard to the subject of projection into rooms,—i.e., fire-breasts,—we had become the slaves of fashion, and the provision for the 14 in. by 9 in. flue had made a sad mark upon our indoor architecture. Many of our internal arrangements were, of course, guided, or to a certain extent controlled, by the exigencies of the elevation. He could not say that architects had, so far, been bound to place their fireplaces in unsuitable positions because they had felt that a stack of chimneys would look well in that or the other part of the building in the elevation. The position of the fireplace with respect to doors and windows was a very important matter, and one too frequently disregarded. He was inclined to think that, except in the case of large rooms, an angle fireplace was the best for heating of the room, and for the certainty of a good draught. If we could accept this as one of the best positions, we should largely do away with projecting jambs and fire-breasts, and we should emancipate ourselves from some of the tyrannies of planning; but where the projection had to be faced, it should be grappled with boldly, and considered as an architectural feature, just as much as a door or a window. In the olden days, when fireplaces and chimneys were just becoming a part and parcel of our civilisation, the chimney-breast was a very dignified and important feature; it was made much of by the architect; it was the part of the interior on which he bestowed almost the chief share of his attention, and the chimney-corner was a reality and not a sham. Of course, the fireplace was a doomed feature, because we were on the eve of better times in heating and ventilation, and nothing so entirely unscientific and unsatisfactory as the ordinary open fireplace would ever be seen (except as a curiosity in our museums) 100 years hence. Bad as it was, however, in every way, from the sanitarian's point of view, English people would not relinquish the domestic hearth without a struggle. It should be remembered, too, that the heating of the room was not the only mission of the fireplace; it had also, generally speaking, to ventilate the apartment. All these points should be duly studied by the architect, and not be left entirely to tender mercies of the hardware merchant who supplied the grate. Practically, the only feature common both to the exterior and the interior, leaving the door out of account, was the window; and in the matter of windows, speaking on behalf of the internal arrangements, householders were great sufferers. They were virtually slaves to the elevation, for nobody dreamed of placing the windows where they would look best or where they would suit best when seen inside the rooms. Windows carried right up to the cornice of the room, with no place for the curtain-poles, bedroom windows only 2 ft. above the floor, long, thin, narrow windows, windows high up, and windows low down, and a host of lop-sided windows of all kinds, should, if possible, be avoided. As he inclined, on the score of comfort, to low rooms, so did he also most strongly prefer windows wider than they were high, also bay-windows and projecting windows of all kinds. He was speaking now only with respect to internal effect. Of all contrivances we now suffered from at the hands of builder, the most abominable and the most utterly unprincipled was the gullotine sash. No thinking man, sitting down to work out a design for a window on true principles, would ever evolve such an abortion, and that vile contrivance plainly showed how entirely the architect was a slave to precedent. That form of sash had of course some small advantages to counterbalance its defects; for one thing, it invariably fitted so badly into the frame that it supplied sufficient draughts of external air to enable the fire to burn; but then it must be remembered that the sashes rattled all night if there were any wind. It was not within his province to attempt to calculate the amount of sash-line the windows of an ordinary household would require in the

course of a year; to set down the number of lives annually sacrificed in attempting to clean such windows, or to estimate the amount of property they enabled the burglar to secure by shifting the fastening with a putty-knife. Of course, he knew that there were patent plans for removing the upper sash from within, and for turning it inside out, for the purpose of cleaning; that there were spring sash-fasteners, and screw-down sash-fasteners, and a host of contrivances, which we generally applied after our houses had been robbed for the first time. A window patiently thought out, with tightly-fitting small casements to open,—we did not want the entire sash to open at once,—with pleasant seats in it, and with room for the blinds and curtains, might become a domestic luxury instead of being a curse, with its weights, and pulleys, and boxings. It only existed as a kind of drawing torture for the architectural pupil. Great care should be exercised in selecting the place for the door when choice was left to the architect in that matter. When it was a question of reaching a bedroom from a small landing, or avoiding a staircase, of course he was often tied down to one place in the room and no other. In the dining-room the door was often so placed as, every time it was opened, to prevent the servant from passing round the guests seated at table, or to render the passage to the sideboard an enterprise of circumnavigation, requiring great courage and ingenuity. It was as well to mark on the plan the position of a dining-table, say 10 ft. by 4 ft. 6 in., and also the plan of the sideboard. With these facts before him the architect was less liable to go astray in placing the door. In an L-shaped room the position of the door could be arranged so as to avoid these difficulties, and there was far less danger of draughts if the door were placed in the recess. There were few subjects of more importance in the in-door architecture of the present day than sanitary arrangements, and these architects had by common consent, until within quite recent times, felt to be wholly unworthy of their attention. In fact, it was not until the "sanitary engineer" came upon the scene and loudly announced that the architect was an ignoramus, and not to be trusted, that the profession awoke to a due sense of its responsibilities. It would, in all cases, be advisable, if possible, to partition off a space in the attic, well lighted, and under lock and key, in which the water-cistern could be placed and frequently examined and cleaned out. The cistern should have a close-fitting cover, and the cistern-room would be kept warm by fixing just below the cold-water cistern the hot-water reservoir tank. For use in the closets the supply should, of course, be wholly distinct from the water used for drinking and cooking. It was quite impossible to estimate or form any opinion as to the amount of injury inflicted upon ourselves and our dwellings owing to the faulty arrangements made for the burning of gas. It was only by the rarest possible chance that we ever found proper provision made for carrying away the waste products arising from its consumption, and, in the absence of suitable exhausts and outlets for the vitiated air, gas was an unmitigated evil.

The Chairman, in inviting discussion, said, the development of home comforts had been very rapid, as had also been the development of house decoration and the supply of materials. The staircase was doubtless a *crux* to the architectural pupil, and even to those who were much more advanced. The staircase, communicating as it did with the hall, should be always warmed, as the doors of the principal rooms opened upon it. In speaking of the tread and riser, and the various complications of staircase construction, he always rendered a good rule which should be kept in mind, viz., that twice the rise and once the tread should equal 24 in. The stereotyped rectangular room, he agreed, might be modified in many instances. In such palatial structures at Hampton Court, and even in such old houses as could be found in Chelyne-row, there were some charming L-shaped rooms, and others with angle fireplaces. He was also of opinion that, as a rule, the rooms of the present day were excessive in height. This often rendered the rooms less comfortable, and less easy of proper ventilation, and warming. The open fireplace was a very unscientific arrangement, but it would take a long time to kill. The members would do well to study a paper written a short time ago by Dr.

Fridgin Teale, which was printed in the *Builder*,* referring to his use of the "Economiser," and the various improvements on the fire-basket. Many of these improvements worked very well in practice. There were doubtless great objections to sash windows, but they also had many advantages, and in some positions he would sooner see them than any other form of window. The position of the door of a room, in relation to the fire-place and windows, was the most important thing in the planning. As to fastenings, the Kaye lock was a great improvement on the old forms. Turning to sanitary matters, there was no lack of careful study of the subject on the part of the students of the Association. He only hoped that the action of the Plumbers' Company, and other bodies, would insure a supply of better plumbers than had carried out some of their works in the past.

Mr. Henry Lovegrove proposed a vote of thanks to Mr. Redgrave for his paper. He believed the staircase would continue. Lifts were all very well in public buildings and offices, but a lift in a private house would be extremely dangerous, especially where there were children.† The staircase might also be made a feature, although it was difficult to do so when it rose from a narrow passage. It might be like some of those in Gower-street, very ordinary indeed, or, as in the old houses in the Adelphi and at Chelsea, an attempt to make an artistic staircase. On an ordinary site, the architect should, if possible, make his staircase round a corner, and out of the way of the front door. Somewhere on the first landing, again, a tall window might be introduced, such as Mr. Norman Shaw used in some of his buildings. Then, common-place details might also be done away with.

Mr. J. A. Gotch, in seconding the vote of thanks, said he believed that lifts were a long way yet from general adoption, as architects had always to reckon with the British householder, and more especially with the wife, who was a conservative of the most pronounced type. The reason why an angle fireplace did not find favour in living-rooms was that only a quarter of a circle could sit round it.

Mr. Leonard Stokes thought Mr. Redgrave had been rather hard upon modern staircases. Many of them, no doubt, were atrocious, but that was because they had not been designed, for a well-planned staircase added a deal of artistic value to a house, and made it enjoyable.

Mr. H. D. Appleton held that lifts could be seen working at Kensington Court by hydraulic power, and with special safety locks. Each lift registered the number of times it was used, and the rent charged per lift was something like 20s. a year.

The vote of thanks was then put, and Mr. Redgrave replied to some of the points raised in the discussion.

THE BUILDING TRADES' EXHIBITION.

This exhibition closes this (Saturday) evening, the 17th inst., at ten o'clock. We add to the notice of its contents which we published last week a few paragraphs which were then crowded out for want of space.

Messrs. Broad & Co. (Stand 188), exhibit a good variety of sanitary specialties in white enamelled stoneware, which will repay attention.

Mr. Sannel Elliott, of Newbury (Stand 232), has an admirable display of mouldings in all kinds of woods. They are in a great variety of sections, and are very clean and sharp in execution. This is one of the best displays of the kind we have ever seen, and visitors who see it are sure to linger over it for a few moments.

Messrs. Bower & Florence (Stand 215) exhibit a Celtic monumental cross, 9 ft. high, in polished grey granite, ornamented with interlacing work produced by alternating polished and unpolished surfaces.

Messrs. Wright & Co. (Stand 246) exhibit the applications of their fireproof fixing-blocks for securing carpenters' and joiners' work to walls. Their use will be found advantageous.

The Patent Sliding Sash Casement Company (Stand 62) exhibit their patent sashes, which afford great facility for cleaning the panes inside and out, without risk to the life or limb of the cleaner. The invention combines the principle of the sliding-sash with

* See p. 235, ante.

† We entirely concur with Mr. Lovegrove.—Ed.

of the casement, each sash consisting of an outer and inner frame, the latter being hung within the former by means of hinges or pivots, and admitting of being opened or closed at will. Cleaning is effected as follows:—Beginning with the lower sash, the fastening of the inner frame is released, and it opens like a door into the room; the outside of the glass can then be as readily cleaned as the inside. When the top sash is cleaned it is lowered to the level of the bottom sash, which is pushed up to the top for the time being. This patent sash is devoid of any complicated mechanical movements, and is likely to go far in meeting a long-felt want.

Messrs. C. Drake & Co. (Stand 248) exhibit a pilastered and transomed window in their red concrete, and a hath and other articles in their well-known marble concrete.

The Blackman Air-Propeller Ventilating Company (Stand 347) exhibit one of their 48-in. fans in motion. Its effectiveness is easily appreciated by visitors whose path lies across the strong current of air induced by the motion of the fan.

Mr. John Grandy (Stand 353) exhibits some of his patent warm-air ventilating fire-grates, which possess many claims to the attention of the visitors.

Hall's patent self-locking flush-holt, for casements and doors, is exhibited at one of the stands. It is likely to be much appreciated, as it is much more secure than the ordinary flush-holt; it cannot be forced back by the insertion of a knife or other instrument.

In the Arcade, the Patent Liquid Fireproof Granite Company afford daily demonstrations of the non-inflammability of woodwork treated with their protective fluid.

CASE UNDER THE METROPOLITAN BUILDING ACT.
WHAT IS A "WITHE" ?

At the Marylebone Police Court on the 8th inst., Mr. Cooke, the magistrate, gave judgment in the case of Blashill v. Garrett, the effect of which is of interest to builders. This was a summons by Mr. Thos. Blashill, District Surveyor for the Parish of Hampstead, against Mr. Edmund Garrett, a builder, of Ravenshaw-street, Mill-lane, for Jan. 3rd erecting a building at 5, Gordon Villas, venshaw-street, and omitting to put a withe to the flues on the north side of the house against the party-wall, properly secured, &c., contrary to the Act. For the defendant it was contended that the defendant had purchased the land in Gordon Villas, West Hampstead, abutting on a piece of which he had purchased half the party-wall. The defendant erected his house, and committed the erection as it was being put up. It was noticed that two of the flues touched the party-wall at the house already built, and that, he should be bound to do so. The sixth rule of the Act was as follows:—"The breast of the chimney and the front, withe, partition, and the thickness of every flue must at the least be 4 in. in thickness." Then the seventh rule said:—"The thickness of every chimney, opening from the hearth to the height of 12 in. above the mantel, must at the least be 8 1/2 in. thick in the party-wall, and 4 1/2 in. if not in the party-wall." He contended that according to the Act the defendant should have put a withe, otherwise a 4 1/2 in. course of brickwork, against the party structure from the bottom up to a certain height, or there would be no protection against fire should there be any in the party-wall, but there was a possibility of a being the case. Many years ago this point was raised before the late Mr. Corrie at Bow-street, in the decision was against the Metropolitan Board of Works; and since then no case of the kind has been placed before the courts. It had a thought to be raised against the point. In the report of his case Mr. Blashill called Mr. Garrett, a carpenter and builder, who said that the house adjoining that of the defendant, was not prepared to swear whether or not there any timber in the party-wall. In his opinion, the defendant's builder, with a course of brick 4 1/2 in. thickness going up to a certain height, bound to the party-wall.

The Magistrate.—You mean that the wall to be thickened to the extent of 4 1/2 in.—Yes, well, suppose the wall originally was 13 in. in thickness, do you think there should then be a 4 1/2 in. Yes, sir.
It is necessary that the withe should be discontiguous?—No; it might touch. I say a withe is work between the flue and the party structure. The term "withe" is generally understood to be a one between two flues.
The defendant, on his behalf, said he had built the beds of houses. He understood that one party had half of a party-wall, and built one, that 4 1/2 in. of the 9-in. party-wall was his

to use. No complaint had been made to him of the manner in which he was building until the roof of the house was on. He believed attention was first drawn to this matter through one of his workmen lighting a fire in an unfinished fireplace, and some smoke went through a hole into his neighbour's house. That had since been rectified.
The Magistrate.—Then you say that half of the party-wall is a withe?

Defendant.—Yes. And I have consulted several experienced architects and surveyors, and they are of the same opinion, and they consider the matter should be brought before you for decision.

Mr. Charles Wisber, Chesnut Villas, Croydon, said he was an architect and surveyor. In his opinion a withe was the division between the flues or chimneys. In this case the flue was built against a flank wall, and there was no flue on the other side.

Mr. Cooke remarked that the wording of the Act made it somewhat difficult to determine the point at issue, and he should, therefore, take time to consider it.

Mr. Bartlett, solicitor for the defendant, pointed out that, according to the contention of the complainant, a withe would have to be constructed if the party structure were 3 ft. in thickness.

In giving his decision, Mr. Cooke said:—"The meaning of the word 'withe' in the 14th rule of section 20, 18 and 19 Vic., cap. 122, is somewhat ambiguous, and a correct interpretation is not arrived at in my mind without some difficulty. That rule says 'no flue shall be built against any party-structure, unless a withe is properly secured thereto at least 4 in. in thickness.' Now, had the words been 'party-wall' it would have left less doubt. But 'party-structure,' by the interpretation clause, section 3, includes 'party-walls,' and also 'partitions, arches, floors, and other structures separating buildings, houses, or rooms belonging to different owners or which are approached by distinct staircases or separate entrances from without.' In rule 6 the different parts of a flue are distinctly enumerated, and rule 7 provides for the construction of the back of every chimney, and says it shall be at least 8 1/2 in. thick from the hearth up to the height of 12 in. above the mantelpiece, if it is a party-wall, or 4 1/2 in. if not a party-wall. The contention here is on one side that the withe is new work which should be built against the old wall, and parallel thereto, thus forming the back of the flue entirely of new work. The other side contends that the word 'withe' means a division between two or more flues, or a vertical division or partition between two flues. Looking at what I have said in reference to the rules, and especially at rule 7, which provides for the back to a certain height being considerably thicker than the withe, I think the latter construction is the right one. And this seems to have been the decision of the late Mr. Corrie, in the case of the District Surveyor of St. Giles's in Cleave, heard at Bow-street Police Court in 1862. Mr. Cooke added that it should be thought of sufficient importance to have a case stated for the consideration of another Court, he should be most willing to grant a case on an application being made to him.

Mr. Blashill asked to be allowed to consult the Metropolitan Board of Works as to the taking of a case, and Mr. Cooke assented.

On the application of Mr. Bartlett, the Magistrate allowed the defendant 2s. costs.

FULHAM VESTRY-BALL COMPETITION.

SIR,—This competition, which has been of an exceedingly unsatisfactory nature from its beginning, owing to a recent decision of the Vestry, is about to be brought to a climax. Entirely disregarding their assessor's award, the Vestry have selected, from the designs first sent in, twelve for a final competition, which when modified are to be returned to the Vestry, who will adjudicate upon them without any professional aid. Members of the "Competition Memorial," who, like us, have agreed to enter no competition without a professional referee he first appointed, are thus barred from competing further.
As the course we deemed it necessary to take is portrayed in the following correspondence, which, we think, may be of some interest to the profession, may we ask if you will be good enough to spare the space for its insertion in your valuable paper.
We would wish to call the attention of the "Competition Memorial Committee" to this matter, as it appears to be a case in which an appeal from them is much needed.

NEWMAN & NEWMAN,
Authors of the Design marked "Light and Air."

[COPY.]
"Vestry Offices, Waltham Green, 9th April, 1886.

DEAR SIRS,—With reference to the plans sent in by you for a Vestry-hall for the Parish of Fulham, under the motto of "Light and Air," I am instructed by the Vestry to forward to you copy of resolutions passed at their

meeting on the 6th inst., and shall feel obliged by your making arrangements to fetch away your plans to carry out such resolutions.

If you will make an appointment, I will be here to receive you any day between 10 a.m. and 1 p.m.—I am, dear sirs, yours faithfully,
(Signed) CHAS. J. FOXES,
Messrs. Newman, Clerk to the Vestry.
10A, Tooley-street."

"Copy of Resolutions.

Resolved.—
a. That the twelve selected plans be returned to the competitors with an instruction that, as they do not comply with the requirements, they may alter, modify, or remodel the plans, for a final competition.

b. That the plans be sent in on plain white paper, without any distinctive mark, colour, or motto, and that canvassing, or writing to, the Vestrymen directly or indirectly by the competitors, shall exclude the plans from competition.

c. That the twelve competitors be informed that the Vestry will themselves adjudicate upon the plans, and that they be returned to the Vestry not later than the 22nd May, 1886."

[COPY.] "April 10th, 1886.
SIR,—With reference to your letter of the 9th inst. in regard to a final competition:

Firstly.—We may say that, having fully complied with all the requirements contained in the conditions of the competitions for the above, and having been placed first by Mr. Curry, the assessor, who further explained, in answer to the objections raised by your Vestry, that one plan could be placed upon the site, we fail to see that your Vestry has clearly shown upon what grounds exception has been taken to the approval of this decision, and why they deem it necessary to have another competition. The only point clearly is that they have failed in every respect to be guided by their own conditions, more especially with regard to the statement that the sealed envelopes should not be opened until after the premiums had been awarded.

Secondly.—You state in the copy of the 'Resolutions' that the Vestry will themselves adjudicate upon the plans. This appears to us to be a very ingenious method of forcing us, and possibly others, to abandon the position we now hold owing to our being members of the Royal Institute of British Architects and having agreed to enter no competition unless a professional assessor be first appointed.

In conclusion, we need hardly say that we shall refuse to tender any further plans, and as adequate reasons why they have not been given for the overthrow of Mr. Curry's award, and having, we consider, a legal claim to the first premium, we desire to offer this point for the unbiased consideration of the Vestry before proceeding further in the matter.

We consider the note respecting the fetching away our designs is equally worthy of the treatment which competitors have received hitherto, but slight, nevertheless, send for our drawings on Monday next, at twelve o'clock.—We are, Sir, yours truly,
(Signed) NEWMAN & NEWMAN,
C. J. FOXES, Esq.,

STONE SAWING AND MOSAIC MANUFACTURE.

SIR,—I have read the letter of Mr. Powis Bale which appears in your issue of to-day (p. 560). His assertion that the Belgian sawing-machines to which he refers "are without doubt considerably in advance of any machines for the like purpose yet made in this country," should not be allowed to pass without question.

So long ago as 1874 a patent was granted to Mr. Richard Cox for a machine, which appears to exactly answer the description of the Belgian machines in Cox's machine the connexions are fixed to the centres of the frame, and the whole of the driving gear is fixed to the machine itself, so that there is no thrust and no vibration. The weight of the stone which is being sawn is very cleverly made use of to keep the framework steady. Several of these machines are in use in different parts of this country, and it now seems that the principle has been copied by the Belgian manufacturers. Honour to whom honour is due. The discovery that a sawing-frame could be better worked with connexions from the centre instead of from the end is that of an Englishman; and the English machines constructed on this principle have been in the active service for years before the Belgian machines were ever heard of.

The "improved form of downward screw feed, which can be regulated in speed in proportion to the hardness of the stone to be cut" has been used by my firm for the past twenty-five years. By a simple clockwork arrangement the speed at which the saw-blades are lowered into the cut can be regulated to the greatest nicety.

At a time when it is the fashion of the day to point to the enterprise of the foreigner, and to call in question the commercial superiority and inventive genius of our own countrymen, it is well that we should know what has been and is being done by Englishmen.

In the matter of stone-sawing, at any rate, we are not so far behind the foreigners as Mr. Bale would have us suppose.
ARTHUR LEE,
Canon's Marsh, Bristol, April 10, 1886.

King's College, London.—The Council have appointed Mr. Hulme, head-master of the Putney School of Art, to the Professorship of Geometrical, Engineering, and Architectural Drawing, vacated by the death of Professor Glenny, who held the appointment since 1864.

The Student's Column.

OUR BUILDING STONES.—VI.
ON SPECIFIC GRAVITY AND ITS USES.

It is often found useful to know the weight of stones, because to a certain extent it is an index to their durability. Many published results show the average weight per cubic foot, whilst others give the specific gravity. The trouble of preparing several samples of hard stones, making them of the required size and shape, in order to find their average weight, is a drawback to the former method. The latter method is, perhaps, the preferable one, for not only can the stones be of irregular shape, but when an average piece is carefully selected more accurate results are obtained.

The specific gravity of a substance is its weight compared with that of an equivalent bulk of pure water at a definite temperature and pressure. The density of a rock or mineral depends, to a great extent, on chemical composition and minute structure. The stone to be weighed must be an average-looking specimen, because two fragments of the same rock may contain different proportions of its constituent minerals.

The most convenient way of finding the specific gravity is by weighing the same specimen first in air, then immersed in water, and dividing the former weight by its excess above the latter.

The weight of the piece of stone must be made with a delicate balance. Now, suppose we have found that its weight in air is 4.32 oz. we then proceed to weigh it in water. To do this a piece of silk or fine thread should be securely fastened round the specimen, which should then be immersed in water, the other end of the thread being attached to the balance. If any air bubbles appear adhering to the stone they should be carefully removed with a brush or the result would be inaccurate.

After due care has been exercised we may find that the specimen weighs only 2.46 oz. in water. We should then find the specific gravity as follows:—

Weight in air ...	4.32 oz.
" " water 2.46 oz.	
	1.86)4.32(2.32
	3.72
	—
	.600
	558
	—
	.420
	372
	—
	.48

2.32 is therefore the specific gravity of the specimen.

In order to obtain very accurate or reliable results, it is necessary to procure a proper instrument for the purpose.*

A good machine is that called "Walker's Specific Gravity Balance," invented by Mr. W. N. Walker, F.G.S., and sold by Mr. G. Lowden, optician, Dundee. It is a steelyard in which a

fixed weight is made to act at different distances on the arms of a lever. Thus,—

AB.—A lever graduated from X in inches and tenths of an inch; hundredths must be guessed.

C.—Upright with rings to receive knife edge of lever.

D.—Upright with slit to steady lever while shifting object.

EH.—Weight which can be moved backwards and forwards, and placed according to the size of the specimen to be weighed.

* Several kinds are treated of by Professor Judd in "Proc. Geol. Assn.," vol. viii., pp. 273-287.

T.—Tumbler of water.
Z.—Object, the specific gravity of which is to be found.

Erect the balance as represented above. Suspend Z by a fine thread from the lever AB, and move out or in until the weight at EH is balanced by Z,—say at point Y.

Next immerse Z in a tumbler of water (as Z') and move out towards B until balance is again restored, say at point Y'. Then it follows from the properties of a lever that $\frac{XY}{XY'}$ is the specific gravity of the object. The result may be checked by changing the point of suspension of EH, say to a, and then re-weighing the object.

Instead of XY and XY' the points of equilibrium will now be b and b', and as before,— $\frac{Xb}{Xb'}$ specific gravity of object.

Professor J. W. Judd, F.R.S., speaking of this instrument, says,—“Any one with ordinary care may obtain for the specific gravity of a rock or mineral a result which is absolutely reliable as far as the first place of decimals and approximately true for the second.”*

A knowledge of specific gravity is perhaps more useful in selecting stone for marine works than anything else with which we have to deal. For sea-walls and pier harbours, exposed both to heavy breakers and shingles, hardness and durability, with great specific gravity combined should be sought for.

The greater the weight of a given sized sea-wall or pier, all other things being equal, the better will it stand the force of the breakers.†

Some years ago Mr. Thomas Stevenson conducted a series of experiments on the force of the breakers on the Atlantic and North Sea coasts of Britain. The average force in summer was found in the Atlantic to be 611 lb. per square foot, while in winter it was 2,086 lb. But on several occasions both in the Atlantic and North Sea the winter breakers were found to exert a pressure of 3 tons per square foot, and at Dunbar as much as 3½ tons.‡

Besides the continual bombardment of breakwaters and other marine works, caused by waves throwing huge blocks of stone against them, we have to take into consideration, even where this action is less violent, another powerful agent which also does a great deal of damage. It is the alternate expansion and compression of air in crevices made in the masonry, which dislocate large masses of the stone even above the direct reach of the waves.

Engineers know that, even from a vertical and apparently perfectly solid wall of well-built masonry exposed to heavy seas, stones will sometimes be started out of their places, and that when this happens a rapid enlargement of the cavity may be effected.

At the Eddystone Lighthouse during a storm in 1840, a door, which had been secretly fastened against the force of the surf from without, was actually driven outward by a pressure acting from within the tower, in spite of the strong bolts and hinges, which were broken. We may infer that by the sudden sinking of a mass of water hurled against the building a partial vacuum was formed, and

We quote these examples to show the influences to which stones selected for lightnesses sea-walls, &c., are in some instances subjected. There can be no doubt whatever that stones having a high specific gravity, which include some of the compact, medium-grained, heavy varieties of granite, are amongst the best materials for these purposes. Exceedingly heavy and compact limestones have been used for large marine works; but the action of molluscs before alluded to (p. 525) is a serious drawback to them in many instances.

Bearing in mind what we have said as to stones weighing less in water than in air, the student will readily understand that in dealing with submarine structures the relative weight of the stones used is greatly reduced.

The following examples, taken from Mr. T. Stevenson's "Harbours," p. 107, will further illustrate this fact:—

	Specific Gravity.	No. of cubic ft. to a ton in air.	No. of feet to a ton in sea-water of specific gravity 1.028.
Basalt.....	2.30	11.9	18.28
Red Granite	2.71	13.2	21.30
Sandstone..	2.41	14.8	28.00

Although the care in the selection of stone by specific gravity for rather deep submarine work should by no means be neglected, it is no so important, perhaps, as for that portion of the structure near and just above the surface of the water; for this reason,—waves, which are the principal source of the destruction of the works, only exist at the surface of the water. Underneath, everything is comparatively quiet, and very little or no damage is caused from the motion of the water.

Delessé says that engineering operations have shown that submarine constructions are scarcely disturbed at a greater depth than 5 metres (16.4 ft.) in the Mediterranean, and 8 metres (26.24 ft.) in the Atlantic.*

As might be expected, there is an intimate connexion between the specific gravity and crushing weight of stones. Information bearing on this point may be found in Barlow's "Treatise on the Strength of Materials" (ed. 1867), p. 110, and the *Builder*, vol. xlviii. (1885), pp. 192-3.

British Archaeological Association.—At the meeting of this Association on the 7th inst. Mr. C. H. Compton in the chair, Mr. Cecil Brent, F.S.A., exhibited a fine Merovingian buckle with clasp, having ornamental similarity to some of the objects recently found at Taplow. Mr. Loftus Brock, F.S.A. described a series of coins of Antoninus Pius found in London, with the figure of Britannia on one of these, a new type, the figure represented clearly that of a female, and there is trophy, a human head on a spear, by her side. Mr. Roope exhibited a very good double-banded Etruscan vase. The Rev. J. J. Daniell described the prehistoric monument recently discovered at Langley Burrell, and a plan was exhibited showing the extent of the paved oval space which is surrounded by a fosse. Mr. K. Ferguson, F.S.A., spoke of the radiating lines having some resemblance to the star tumuli of the north of England. Mr. T. Blashill, F.S.A., referred to the length to the proposed restoration of Waltham Cross, and exhibited an elaborate series of plans prepared by Mr. Ponting. The whole of the stone used in the restoration of 1832 is found to be in a loose and crumbling condition, except the upper shaft, and it appears to be expedient in consequence to renew the whole. The original portions of the ancient work are not to be touched.

Whitechapel.—Last Sunday Mr. Montagu presided at the dedication of the "Poor Jew Shelter," in Leman-street, Whitechapel, altered to suit all the requirements of a casual ward. Special attention has been given to sanitation throughout the building; the drainage and the adjacent fittings are of the most effective yet simple kind, and have been executed to suit the rough usage at the hands of the inmates. The constant action of water on the drains from two distinct automatic flushing-tanks, and the continual ventilation of the whole of the system are what is required in a building of this kind. The disinfecting-chamber for clothing has been carried out by Messrs. Bird. The heating and bath work have been executed by Mr. F. Brown, engineer. There are two dining lifts by Waygood going from the kitchen direct into the large dining-room. The builder was Mr. Triggs, and the architect Mr. Lewis Solomon.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

16,922, Planing and Dressing Stone. P. Orooran.

The stone to be operated upon is fixed upon a table below the cutters. This table is traversed on rollers or pulleys mounted in the bed-plate of the machine by a screw and pinion driven in the ordinary manner, so as to be easily reversed. The tools for working the stone are either steel cutters, or of amonds or other hard material mounted in steel holders, and which are fixed at a suitable angle in a case on the end of a spindle, the tools being rotated a given amount as used. When diamonds or other substances are used, several are set in the steel, so as to prevent the wear from wearing away. When required, similar slides and tool-holders may be fixed on the uprights to plane the sides of the one.

16,952, Disinfecting. J. Watts.

This is an apparatus for generating and ejecting mes, smoke, or vapours for disinfecting, deodorizing, or fumigating purposes, or for testing pipes of passages by what is known as the smoke-test, for analogous purposes. The fumes, &c., are produced from any suitable material fed into a generating-chamber provided, when a fire necessary for the production of the fumes, the adjustable inlets for air. A blower or ex-tender is also employed, by which a current is created which is not passed through the generating-chamber, but is caused to pass independently to and from the same, where the current meets the mes, and conveys them along suitable pipes to the place where they are to be utilised.

16,951, Planing Wood. S. S. Hazledorn.

The wood to be planed is fed along a table over a stationary cutter by an elastic feed-roller on a shaft, actuated by two hand-wheels provided with handles, adjustable in slotted spokes. Provision is made for turning up the table towards the roller by weights, also for preserving the knife from contact with the roller by bars on the brackets adjust-able against hoses on the uprights.

16,862, Lavatory. G. Pepper.

The service cistern is divided into three compart-ments. The middle one is supplied by a ball-cock the usual way, and communicates by valves with other compartments, which control water to the basin by pipes. The valves which control the supply to the outer compartments, and also those which regulate the basin supply, are connected to a rack extending from a weighted spindle, which is connected by wire to the free end of a foot-board to which the spindle of the outlet valve is connected. When the foot-board is depressed the outlet valve is closed, and the basin filled from one of the side compartments, when the foot-board is released the discharge-valve is opened the basin is filled from the other side compart-ment. If required, hot water can be supplied by a separate pipe.

MEETINGS.

SATURDAY, APRIL 17.

Royal Institution.—Professor Oliver Lodge on "Fuel and Smoke." 11. 3 p.m. Edinburgh Architectural Association.—Visit to Niddrie Marshalls.

MONDAY, APRIL 19.

Victoria Institute.—(1) Professor Post on "Syrian Meteorology." (2) Paper by Mr. W. St. Chad Boscawen. 8 p.m. Inventors' Institute.—8 p.m.

TUESDAY, APRIL 20.

Institution of Civil Engineers.—Mr. Henry Ward on "Brickmaking." 8 p.m. Statistical Society.—Professor Leone Levi on "The Progress of Joint-Stock Companies with Limited and Unlimited Liability in the United Kingdom during the Fifteen Years, 1869-1884." 7.45 p.m.

WEDNESDAY, APRIL 21.

British Archaeological Association.—(1) Mr. W. de Gray Birch, F.S.A., "On Two Sculptured Slabs in Chichester Cathedral." (2) Mr. J. T. Irvine on "The Saxon Tower of Bernack Church." 8 p.m. Civil and Mechanical Engineers' Society.—Mr. C. T. Wairson on "Some Details of Drainage and Water Supply." 7 p.m. Builders' Foremen and Clerks of Works' Institution.—Quarterly Meeting of Members. 8.30 p.m. Royal Meteorological Society.—Five papers to be read. 7 p.m.

SATURDAY, APRIL 24.

Edinburgh Architectural Association.—Visit to the Drum.

Miscellaneous.

Architectural Association.—The sixth Saturday afternoon visit of the Architectural Association during the present session was made on the 10th inst. to the Constitutional Club, now being built from the design of Mr. R. W. Edis, F.S.A., in Northumberland Avenue, Charing-cross. Mr. Edis kindly met the members, and gave a brief description of the building. The ground-floor contains the morning-room, 110 ft. long by 30 ft. wide; reception-room; and smoking-room. The first floor contains the coffee-room, 139 ft. by 30 ft.; library, 50 ft. by 27 ft. The second floor contains the smoking-room, 100 ft. by 30 ft.; billiard-room; and committee or house dining-room. In addition to these are the service-rooms on each floor. On the upper floors are eighty sets of chambers. The main staircase is being constructed on a plan suggested by Mr. Holloway, the clerk of the works, of coke breeze concrete with a light iron girder just at the back of the riser, the treads and risers being faced with marble. The staircase is 10 ft. wide. The ceilings of the principal rooms, which are just being fixed, are of rich and quaint design, in plaster relief. The electric lights are studded all over the ceiling at numerous points, and are worked into the general design, the ventilating extract openings being connected with these ornaments, in which lights are set. The whole of the heating is to be done by open stoves. Mr. Edis stating his experience of hot-water coils in clubs as being that they made the rooms stuffy, and he had had them taken out in several instances.

Window Blinds.—Messrs. Guyman & Son, of Carbnrton-street, supplied the blinds throughout the Cambridge Union Society's new buildings, recently mentioned in the Builder. The same firm are now fitting the vertical and horizontal windows of the new Lecture Theatre at the Liverpool University College with dark blinds, which are of a special character.

Liverpool Engineering Society.—The usual fortnightly meeting of this society was held on Wednesday, 7th inst., at the Royal Institution, Colquhoun-street, Mr. Coard S. Pain, A.R.C.E., in the chair. A paper was read by Mr. W. E. Mills, entitled, "Notes on the Damage sustained by a large Building from Subsidence and the Means taken for its Support." It was requisite that the front face of the building referred to should be supported, and as much weight as possible taken off the foundations. The authorities required that whatever "shoring" was introduced should not obstruct the footway, and the owners desired that access to the building should not be interrupted. Hence the ordinary methods of "shoring" were inadmissible, but the difficulty was overcome by means of a special arrangement of timber supports or "shores," which the author described in detail. The state of the building continued to become worse, and a portion was at length condemned by the authorities, and ordered to be taken down. It was found that the necessary requirements would be met by removing the main outer walls, but it was stipulated that the use of the building must be preserved while the work was being executed, and the inmates interfered with as little as possible. The author then described the means by which this was accomplished, a timber wall or partition being built up inside the main wall, so that when the latter was pulled down the timber partition took its place, and the work was thus completed without interrupting the ordinary course of business carried on in the building for a single day.

The Farmer New Schools and Hall, Victoria Park.—A boys' school with large hall for secondary and high-class educational purposes is now in course of erection in Approach-road, Victoria Park, for the Governors of the Farmer Charity. The building, which has a frontage of 152 ft. to Approach-road, is Domestic Gothic in character, and, including the basement, has four floors. It is faced with red brick and Portland stone. Two prominent features are a tower 100 ft. in height, and a lofty bay-window to the great hall. The general face of the building is 60 ft. in height. The interior is approached by a porch at the head of a flight of steps, leading to the entrance-hall. The ground-floor of the building contains the large hall, also the head-master's room and two class-rooms, lecture-theatre, laboratory, &c. The first floor contains three class-rooms, and masters' apartments, and also gives access to the gallery in the large hall. The second floor contains class-rooms, and also one large room for drawing purposes. The basement, in addition to a covered playground, contains a dining-room for the use of the students, with the kitchen and culinary departments, and also the caretaker's apartments. The heating of the building will be effected by hot-water pipes and radiators, this portion of the work being carried out by Mr. W. P. Phipson, engineer, of Salisbury-street, Strand. Messrs. T. Chaffield Clark & Son are the architects; and Mr. Charles Cox is the contractor, the contract having been taken at the sum of nearly 9,000l.

Sanitary Assurance Association.—At a meeting of the Council, on the 12th inst., General Sir Peter S. Lumsden, C.B., C.S.I., was elected a member of the Executive Council, on the motion of Sir Joseph Fayer, F.R.S. Mr. Mark H. Judge submitted a draft Bill for the better sanitation of dwellings. This draft was referred, for consideration and report, to a committee consisting of Professor Roger Smith, F.R.I.B.A., Dr. James Stevenson, Mr. Andrew Stirling, Mr. H. Rutherford, Barrister-at-Law, Mr. M. H. Judge, A.R.I.B.A., Members of the Council; and Dr. R. Farquharson, M.P., Member of the Honorary Council. One of the provisions of the proposed Bill is as follows:—"After January 1st, 1888, it shall not be lawful for any dwelling-house, school, hotel, or other public building, used, or intended to be used as such, to be used unless and until a certificate has been deposited with the local authority in accordance with the provisions of this Act."

Proposed New Municipal Buildings for Edinburgh.—The Edinburgh Town Council, at a meeting held on Monday last, adopted by twenty-six votes to ten a report by the Lord Provost's Committee recommending the erection of new municipal buildings on the site of the present buildings and adjoining property, and craving a remit with powers to obtain competitive plans, and offer premiums for the first and second designs.

Colonial and Indian Exhibition.—A meeting of the Reception Committee was held a few days since, at the Society of Arts; the Duke of Abercorn, C.B., in the chair. The Committee considered a report from the Sub-committee as to the arrangements which could be made for excursions for Colonial and Indian visitors. Mr. Somers Vine, the Official Agent of the Exhibition, attended, and reported to the Committee the arrangements which had been made with the railway companies with the view of affording extended facilities for railway travelling to all Colonial and Indian visitors coming to the Exhibition. The Chairman reported that, in accordance with the wishes of the Committee, and with the approval of H.R.H. the Prince of Wales, he had communicated with the mayors of some of the chief principal cities, asking if they would arrange for visits of parties of distinguished visitors.

National Smoke-abatement Institution. A meeting of the committee of this Institution was held at the Parkes Museum on the 6th inst., Mr. Ernest Hart in the chair. A letter was read from the Home Secretary saying that from correspondence with the Commissioners he is satisfied that the police have taken proceedings in all cases of smoke nuisance in which they could properly do so, and exercise due supervision over the steamers on the river, adding that the extension of the Acts to which the Smoke Nuisance Acts apply is a matter for the consideration of the legislature. A sub-committee was appointed to correspond further with the Home Secretary, and to urge upon the Government the necessity for the extension of the area embraced by the Acts. The secretary reported that the furnace of a steam-lantern on the Thames at Hampton had been tested by the engineer of the Institution, who, in his report, stated that during a run of thirteen miles no smoke was visible at the top of the chimney throughout the trip, an improvement of great importance to all owners of launches. Several descriptions of new appliances for smoke abatement were reported and discussed, and it was resolved to publish shortly a selection of the numerous tests of apparatus made by the Institution since the publication of the report on the Smoke Abatement Exhibition in 1881-82.

Archæology.—Professor Newton will deliver at University College a course of three lectures on Greek Inscriptions, followed by three on Greek Myths, illustrated by fictive vases and other monuments, on the following dates:—May 7, 14, 21, and 28; June 4, 11, 18, and 25. Dittonberger, Sylloge Inscriptionum Græcarum, Lips. 1833, and Hicks, Manual of Greek Inscriptions, will be used as text-books in the lectures on Inscriptions.

Mr. Holman Hunt's Pictures.—Mr. Wm. Reeves will issue early next week "Notes on the Pictures of the Holman Hunt Collection" (now on view at New Bond-street), with criticisms by John Ruskin, and other critical notes. The work will be issued at 1s., with a few large-paper copies, and will be uniform with the recent "Notes on the Millais Collection," with preface and criticisms to date by John Ruskin.

Table listing contractors like Stevens & Sons, Cook & Sons, H. J. Sanders, etc.

STEPNEY. — For the erection of a mission-hall, Sunday schools, &c., Dorgals-street, Stepney, for the Rev. J. F. Kitto, M.A. Mr. J. T. Newman, Fen-court, E.C., architect. No quantities:—

Table with columns for Foundations, Structure, and Total, listing contractors like F. F. & J. Wood, A. Reed, etc.

SWANLEY (Kent).—For the erection of a detached residence near Swanley Junction, Kent. Mr. St. Pierre Harris, architect, Messrs. Barter, Payne, & Lepper, surveyors:—

Table listing contractors like H. Someford & Son, F. Wood, D. Payne, W. & F. Croaker with prices.

SPECIAL NOTICE FOR NEXT WEEK.—As we publish a day earlier than usual next week, Lists of Tenders for insertion in our next issue reach us not later than 4 p.m. on WEDNESDAY, April 21.

TO CORRESPONDENTS.

Registered Telegraphic Address, "THE BUILDER, LONDON."

C. L. Paris (thanks).—T. P. M.—J. E. H.—A. L.—F. & G. H. (plan received); thanks.—F. H. T.—E. H. B.—A. Reader of "The Builder."—R. P.—J. S.—B. & C.—J. R. M.—L. & D. (below our notice).—H. B. (should have sent name)...

We are compelled to decline printing out books and giving addresses. The responsibility of signed articles and papers read at public meetings, rests, of course, with the authors. We cannot undertake to return rejected communications. Letters or communications (beyond mere news items) which have been duplicated for other journals, are NOT RETURNED. All communications regarding literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

PUBLISHER'S NOTICES.

Registered Telegraphic Address, "THE BUILDER, LONDON."

GOOD FRIDAY.—"THE BUILDER" for the week ending APRIL 24th will be issued on THURSDAY, APRIL 23rd. Advertisements for insertion in that issue must therefore reach the Office before THREE p.m. on WEDNESDAY, the 22nd. Alterations in Standing Advertisements, or ORDERS TO DISCONTINUE the same, must be sent to the Office by TEN o'clock on TUESDAY Morning.

CHARGES FOR ADVERTISEMENTS. SITUATIONS VACANT, PARTNERSHIPS, APPOINTMENTS, TRADE, AND GENERAL ADVERTISEMENTS. Six lines (about fifty words) or under 6s. 6d. Each additional line (about ten words) 6s. 6d. Terms for rates of Trade Advertisements, also for special Advertisements on front page, Competitions, Contracts, Sales by Auction, &c., may be obtained on application to the Publisher.

POUR LINES (about THIRTY words) or under 2s. 6d. Each additional line (about ten words) 6s. 6d. PREPAYMENT IS ABSOLUTELY NECESSARY. * Stamps must not be sent, but all small sums should be sent by Cash in Registered Letter or by Money Order, payable at the Post-Office, Covent-garden, W.C. to DOUGLAS FOURDRINER, Publisher. Addressed to No. 36, Catherine-street, W.C.

Advertisements for the current week's issue must reach the Office before THREE o'clock p.m. on THURSDAY. The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

SPECIAL.—ALTERATIONS IN STANDING ADVERTISEMENTS OR ORDERS TO DISCONTINUE the same, must reach the Office before TEN o'clock on WEDNESDAY morning.

PERSONS Advertising in "The Builder," may have Envelopes addressed to care of, 45, Catherine-street, Covent-garden, W.C. free of charge. Letters will be forwarded if addressed envelopes are sent, together with sufficient stamps to cover the postage.

TERMS OF SUBSCRIPTION.

"THE BUILDER" is supplied direct from the Office to residents in any part of the United Kingdom at the rate of 19s. per annum PREPAID. To all parts of Europe, America, Australia, and New Zealand, 25s. per annum. To India, China, Ceylon, &c. 30s. per annum. Remittances payable to DOUGLAS FOURDRINER, Publisher, No. 36, Catherine-street, W.C.

Best Bath Stone, for Winter use. WESTWOOD GROUND, Box Ground, Corham Down, and Farleigh Down. { Summer { Dried. RANDELL, SAUNDERS, & CO., Limited, Corham, Wilts. [ADVT.]

Box Ground Stone is the best for use in all exposed positions being a well-known and tried Weather Stone. 50,000 ft. cube in stock. PICTOR & SONS, BOX, S.O., WILTS. [ADVT.]

Doubling Freestone and Ham Hill Stone of best quality, in blocks, or prepared ready for fixing. An inspection of the Doubling Quarries is respectfully solicited; and Architects and others are CAUTIONED against inferior stone. Prices, delivered to any part of the United Kingdom, given on application to CHARLES TRASK & SONS, Norton-sub-Hamdon, Ilminster, Somerset.—Agent, Mr. E. WILLIAMS, No. 16, Craven-street, Strand, W.C. [ADVT.]

Doubling Free Stone For prices, &c., address S. & J. STAPLE, HAM HILL STONE, Quarry Owners, Stone and Lime Merchants, Stoke - under - Ham (Ground or Lump), Ilminster. [ADVT.]

Asphalte.—The Seyssel and Metallo Lava Asphalte Company (Mr. H. Glenn), Office, 38, Poultry, E.C.—The best and cheapest materials for damp courses, railway arches, warehouse floors, flat roofs, stables, cow-sheds, and milk-rooms, granaries, tun-rooms, and terraces. [ADVT.]

Asphalte. Seyssel, Patent Metallo Lava, and White Asphaltes. M. STODART & CO. Office: No. 90, Cannon-street, E.O. [ADVT.]

EVERY DESCRIPTION OF SEASONED WOODS AND VENEERS IN EXTENSIVE QUANTITIES. B. J. HUDSON & SONS, Millbank Sawmills, Grosvenor-road, S.W., Whitefield-street, W., and Store-street, London, W.C. Telephone No. 3,152, and Private Wire connecting Business Premises.

MICHELMORE & REAP. Manufacturers of CHARLES COLLINGE'S PATENT. COLLINGE'S PATENT HINGES, LEVER, SCREW, & BARREL BOLTS and IMPROVED GATE FITTINGS of every Description. 36A, BOROUGH ROAD. DISCOUNT TO BUILDERS. LONDON, S.E.

GOLD AND SILVER MEDALS AT AMSTERDAM EXHIBITION. IRON CYLINDERS. F. BRABY & CO. LONDON, LIVERPOOL, GLASGOW. VERY PROMPT SUPPLY. LARGE STOCK READY. CYLINDERS FOR HOT-WATER CIRCULATION. Particulars on application. Chief Office: 360, EUSTON ROAD, LONDON.

The Builder.

The Royal Scottish Academy.

THE first recognition of art by any public body in Scotland proceeded from what is now known as "The Board of Manufactures."

The Board of Trustees for the improvement of Fisheries and Manufactures Scotland owes its origin to the fifteenth article of the Treaty of Union in 1706, but the Board was not actually constituted until 1707, under Letters Patent of George II. Its principal functions in regard to fisheries ceased in 1809, on the establishment of a special Board constituted to attend to that matter, and the functions of the Trustees are now confined entirely to the encouragement of manufactures with a special view, however, to the industrial application of its principles. Accordingly, their chief work consists in the maintenance of a National Gallery, and the management of a School of Art and Design.*

The funds at the disposal of the Board consist of a sum of 2,000*l.* annually voted by Parliament. The Trustees, in furtherance of the purposes of their constitution, offered premiums for the best designs or drawings for textile fabrics, and in 1760 a drawing-master was appointed to teach both sexes the art of drawing, thus laying the foundation of the School of Design. In 1819 was founded the "Institution for the Encouragement of the Fine Arts," on the same principle as the British Institution. By its constitution the management of the Institution was vested exclusively in directors chosen from among the subscribers, and one of its objects was to effect that "No artist was to be able of being elected on any committee, or of voting as a governor, while he continued a professional artist." The function of the directors, therefore, was restricted to the production of works which the Institution consented to receive and exhibit along with those by the old masters.

The first exhibition by the Institution took place in 1819, and it had no rival; for, although during the five years from 1809 to 1813 a number of artists had combined their works, so as to form an annual exhibition, the combination broke up at the expiry of the exhibition of 1813. It appears that a sum of 50*l.* had accumulated from the proceeds of five exhibitions, and, as there was no rule to the contrary, the existing members resolved to divide the amount. This resolution rang the death-knell of the society.

In 1826 the Institution had 131 ordinary members, thirteen honorary members (five of whom were artists), and twelve associate members (all of whom were artists). The Board of Manufactures had accumulated a fund from the money entrusted to their management, and this accumulation was sufficient to enable them to build the Royal Institution on the Mound. In this building sufficient accommodation was afforded, not only for the Board itself, but for the Royal Society, and for exhibitions of works of art. The spacious galleries in the centre of the building, provided for the latter purpose, were let to the Institution for the Encouragement of the Fine Arts, at an annual rent of 380*l.* Ample accommodation having thus been provided for the exhibition of pictures, in well-lighted galleries, specially constructed for the purpose, rendered the annual exhibitions more attractive, and contributed materially to the prosperity of the Institution. In these circumstances the associate members made advances to the directors of the Institution with a view to their having a share in the management of the exhibitions, but these advances were repelled in a manner which so thoroughly disgusted the associates that they resolved to make arrangements for founding a Scottish Academy. Twenty-four artists affixed their signatures to the document, in which it was proposed to found the Academy, and these consisted of thirteen Academicians, nine Associates, and two Associate Engravers. Thus were laid the foundations of what ultimately appeared as the Royal Scottish Academy.

The Board of Manufactures and the Institution were composed of gentlemen of high social position, who could brook no opposition, and they set themselves deliberately to endeavour to quash the new organisation. Their influence was such as to cause nine of the twenty-four original members of the Academy to resign, leaving only fifteen to carry on the work. This they did with resolute determination to persevere, and in this course they were mainly sustained by the late Mr. Thomas Hamilton, architect, whom they had elected to be their treasurer.

Early in 1827 it was announced that the first exhibition of the Scottish Academy would be held in two large galleries which had been engaged for the purpose. A counter-announcement was published by "The Royal Institution, under the immediate patronage of His Majesty," in which it is stated that "The Directors of the Royal Institution have observed in the *Scotsman* of the 3rd of January current, a paragraph under the title of 'Associated Artists,' stating,—'It will be observed that the Associated Artists are to have an

exhibition of their own early in February distinct from that of the Royal Institution.' As this might lead to the supposition that the exhibition of the works of modern artists to be opened at the Institution Rooms on the Earthen Mound next month was not supported by the Associated Artists of the Institution, the Directors think it right to mention that at a late meeting of these gentlemen they were informed by the following eminent artists, namely, Messrs. William Allan, A. Nasmyth, J. W. Thomson, J. Watson Gordon, H. W. Williams, J. F. Williams, and W. Simson, being the whole Associated Artists present, that it was their intention to send their works to the exhibition in the rooms of the Institution and to make the utmost exertions to give it every support in their power. The directors may add to the above list the names of Mr. Playfair and Mr. Andrew Wilson, the latter of whom, when leaving the country for Italy, promised to contribute to the approaching exhibition. Messrs. George Watson, Samuel Joseph, and William Nicholson, the remaining Associated Artists, did not attend the above meeting, and, therefore, the directors had no means of learning their views on the subject."

By way of recognising their adherence to the Institution the directors gave commissions of 50*l.* and upwards to each of the Associates who attended the meeting, while the three who did not attend received no share of their patronage. The two exhibitions were opened simultaneously, and it was conceded that the Institution had the best of it as regards the excellence of the works exhibited. Still, however, it was found that the newly-formed Society had made a fair start, the gross proceeds amounting to 317*l.* 13*s.* 11*d.* The second exhibition in 1828 was more successful, and the third so much so as to supersede entirely that of the Institution.

The infant Academy, with the view of establishing its position upon a firm basis, made application to the Home Secretary, Mr. Peel, for a Charter of Incorporation, who, in reply, stated that he had referred the matter to the king's law officers, and that "the Scottish Royal Academy will have my warmest wishes for its prosperity." The application was supported by Sir Thomas Lawrence, President of the Royal Academy, and other "men of light and leading." But the old enemy was at work, and the Institution, which had for itself secured the distinction of "Royal," could ill brook any rival, and from time to time the application was set aside, and ultimately refused; upon what grounds could not be ascertained; for, though a request was made for permission to peruse the report of the Lord Advocate, such permission was not granted. Keeping an undaunted front, and

* Report of Sir J. G. S. Lefevre, of December 13, 1817.

under the able leadership of Mr. Hamilton (whose much-admired classical structure, the High School, was then in course of erection), the Academy used every exertion to secure the favour of the public, and, as already stated, their third exhibition proved eminently successful. Amongst the contributors were Sir Francis Grant, P.R.A., John Linnell, John Martin, and others who subsequently distinguished themselves.

The exhibition was not, however, confined to the works of living artists, for one of its chief attractions was the "Adoration of the Shepherds," by Rubens, lent for exhibition by Lord Hopetoun. This picture was so large that it could not be admitted to the exhibition-room by the ordinary entrance, and it was found necessary to remove the cupola, and swing it down through the roof, an operation which was successfully carried out under the superintendence of Mr. Hamilton. What ultimately secured for the Academy the high approval of the public was the purchase of Etty's great picture of "Judith and Holofernes," a step which, although considered by some to be rash, was the means of consolidating the Academy. The wisdom of the proceeding became manifest when it was found that at the close of the exhibition there was a surplus sufficient to meet the purchase-price, which, according to the arrangement entered into with Mr. Etty, was remarkably moderate. At a subsequent period the Academy secured other important works by Etty, amongst them, "The Combat: Woman pleading for the Vanquished," which was purchased from Mr. Martin for 300*l.*, and for which ten times that sum has since then been offered and refused. The artists who had adhered to the Institution, finding that they were left in the lurch, made an attempt to organise another Academy, but the folly of such a proceeding becoming apparent they came to the resolution of placing their case in the hands of Mr. Henry Cockburn, advocate (afterwards Lord Cockburn), with a view to their being admitted members of the Scottish Academy. Mr. Cockburn suggested that the Academy should appoint some one to act for them in the proposed negotiation, and in his communication to the President he says, "Some of the gentlemen for whom I act belong to the Royal Institution, others do not. But this circumstance is immaterial, because the only footing on which they wish to treat, or to be treated with, in this proposal is that of their professional character, apart from all consideration of any other establishment here or elsewhere, to which they may happen to belong. In proposing to join the Academy, they of course subject themselves to all the rules of that Institution; and the only condition on which the proposal is made is that they are all received together as Academicians." The gentlemen making this proposition were twenty-four in number, and to have admitted them would virtually have been to deliver over an institution which had cost much time, labour, and expense into other hands, "since, from the constitution of the Academy every member is entitled to an equal share in the management of its concerns." The Academy, however, considering the importance of securing unity, resolved to meet the applicants in a fair and candid manner, and appointed Mr. Hope, the Scottish Solicitor-General, to represent them. In their award the referees, after minutely detailing the circumstances of the case, came to the conclusion that "a general and complete union of the artists was an object of such vast importance that no temporary difficulties ought to be allowed to interfere with its attainment."

The result of these negotiations was that the applicants were, by the unanimous vote of the Academy, admitted to the full privileges of that body.

In their award the arbiters "earnestly, strongly, and respectfully recommend to the general body of the Academy to continue in office the intelligent, active, and public-spirited gentleman" then in office, notwithstanding which, on the first general meeting of the Academy after the admission of the twenty-four new members, a resolution was carried depriving Mr. Hamilton of his office as

treasurer, and appointing Mr. J. Watson Gordon in his place. Some of the new members, it is said, were heard to express a determination that "they would not be ruled by an architect."

Sir George Harvey in his notes on the Early History of the Academy says,—“The remarkable sort of management in relation to art existing at this period in Scotland is shown in the fact that the Royal Institution, a society of amateurs, received a Charter of Incorporation, while the Academy of Painting, Sculpture, and Architecture, consisting solely of professors of those arts, had been hitherto refused one; and then also a yearly grant of 500*l.* was given to the former, while the Academy got nothing, but, on the contrary, had for above twenty years to pay 100 guineas annually for the use of galleries for three months in the year to hold their exhibitions, forming a strange contrast with the manner in which Government dealt with the kindred Academies in London and Dublin; the former having apartments free of charge in Somerset House, and the latter an annual grant of 300*l.*”

On August 13th, 1838, a charter of incorporation was granted to the "Royal Scottish Academy of Painting, Sculpture, and Architecture," which was "to consist of artists by profession, being men of fair moral character and of high reputation, resident in Scotland."

It is bound to arrange an annual exhibition, and, so far as it can, to give instruction in art. The only assistance afforded to the Academy by Government consists in the accommodation given to it, rent free, in the National Gallery.

NOTES.

SOME disappointment has been expressed that so little is said about canals in the Railway and Canal Traffic Bill. The deputation which waited upon Mr. Mundella on the 16th inst. from the British Iron Trades Association drew attention to this, and elicited from the right hon. gentleman that the Government are preparing clauses with a view to rendering the canals more useful. He is of opinion that through rates should be adopted, and that the canals should be kept in better repair, but that it is a difficult matter to decide by whom and how this should be enforced. However natural it may have been for railways to supersede waterways for the conveyance of general merchandise, it is certainly a pity that the latter should, through neglect, be practically unavailable for the traffic for which they are still adapted. Mr. Mundella took occasion to remark that there was no desire on the part of the Government to injure the railway companies. This might tend to reassure the frightened shareholders, but their directors have worked upon their fears to such an extent that this Bill is regarded by some with as much alarm as Mr. Gladstone's Irish scheme,—to which it was seriously compared at some of the meetings. With regard to preferential rates for foreign produce, Mr. Mundella says that such rates generally should be strictly prohibited. It seems probable that he contemplates altering the clauses dealing with this subject, for they do not, as they stand, impose sufficiently severe restrictions upon the system to satisfy the home producer. The deputation was assured that the points brought forward should receive Mr. Mundella's careful attention, and that he considered it very evident that the manufacturers of this country required a cheap outlet for their products to enable them to compete successfully with others.

THE final Report of the Royal Commission on Mines, which occupies 110 pages of a large Blue Book, was issued on the 10th inst. The results of an elaborate series of scientific experiments, made with the object of establishing the best guarantees against accidents in mines, are stated with much clearness. Various methods and appliances are discussed. Particular stress, however, is placed upon the advantages offered by electrical exploding appliances for firing shots in mines, as opposed to the most im-

proved kind of fuse which has to be ignited by the application of flame to its exposed extremity. Several reasons are advanced in support of the electrical method of firing; very little instruction is necessary to ensure its efficient employment by men of average intelligence; the firing is under complete control up to the last moment, and it is accomplished out of contact with air; and finally, its cost, simplicity, and certainty of action, are all in its favour.

THE case of Raper v. Fortescue, which was before the Court of Appeal last week, so far as the actual decision went, did not decide any important question; for the Court refused an interlocutory injunction in regard to a claim of light, on the ground that no substantial injury had been shown. That some substantial injury must be proved is an elementary proposition in regard to the law of light. But Mr. Justice Pearson, from whose Court the appeal came, seems, from the report of his judgment with which we have been supplied, to doubt whether a man can claim relief in consequence of the infringement of an ancient light when the building in respect of which it is claimed is a new one. He says that the building has been so much altered "that it is no longer the same building," and further on he says, "there is really no case to refer to, as I should have desired." But Lord Justice Cotton says, though it was not necessary for the Court of Appeal to decide the point, that he could not agree with Mr. Justice Pearson that the light must be in the same building as that in regard to which the right had accrued. As a matter of fact, there is a clear decision that the light need not be to the same building. In the case of the Ecclesiastical Commissioners v. Kino (Roscoe's "Digest of the Law of Light," 2nd edition, p. 30), a church had been pulled down, the site was vacant, it was intended to erect in place of the church some secular building, and for the purpose of the action a hoarding was put up with apertures in it. It was decided by the Court of Appeal that relief could be granted. It is obvious that a warehouse is not the same building as a church. Therefore, if we may say so without disrespect, Mr. Justice Pearson discovered a legal mare's nest. In the interests of the profession it is desirable to notice Lord Justice Cotton's observation, otherwise the statement of Mr. Justice Pearson may be apt to mislead those who are not lawyers.

INDUSTRIAL undertakings at the present day are certainly under a cloud, no matter in what country they are carried on. In the history of civilisation, there has probably never been such a universal outbreak of discontent as is now prevalent throughout Europe and America. For many years past, strikes have unfortunately become the familiar attendants of English industry; but it has been reserved for 1886 to show a world-wide series of strikes, accompanied, moreover, by a lamentable amount of unreasonable violence and ferocity. The most notorious English riots have usually been marked by some supposed political grievance, such as those of the Chartists, the Lord George Gordon riots at Bristol, and the London riots of the other day, although the Luddite riots, in which so much machinery was broken in the Midland factory districts, were the result of combined ignorance and starvation. Just now, the area of disturbances is unusually extensive, capital and labour being paralysed simultaneously in the United States, many parts of France, and all Belgium. Sweden also is beginning to feel the throes of trade disputes, while an outbreak has taken place in Milan, and even quiet Switzerland is contributing to the general trouble by strikes at Basle and other places. The singular part of it all is that, although trade depression is an unusual factor throughout the world, the prices of labour generally are still remunerative; and one would have thought that the spread of education would at least have enabled workmen to understand how utterly useless it is for them to kick against the inevitable recurrence of bad times. There is,

lead, but little encouragement for those who open to have money to invest in it in new undertakings, at all events those which depend for success on the tolerance and co-operation of labour.

THE following extract from a recent number of the *Revue Scientifique* is of interest showing the very tangible improvement in sanitary matters that has resulted since the abolition in many towns of the fixed cesspool system. At Brussels it was in vogue until 170-1, when the mortality from typhoid reached 105 per 100,000 inhabitants; but on the disappearance of the fosse or cesspool, the mortality at once fell to 40, while, within the next ten years, it has not exceeded 30. At Frankfurt the number was 89 per 100,000 in 1870, when water-closets with direct outflow became pretty general, resulting in a fall of deaths to 29. At Berlin the old system was abandoned in 1875, with the effect that the mortality per 1,000 was reduced from 38 to 29, and from typhoid declining from 50 to 28 per 100,000 inhabitants. In London the suppression of cesspools was commenced about 1819 and was completed in 1848, and at the present time the mortality from typhoid is about 26, and that of diphtheria 18 per 100,000, while at Paris these are still 70 and 75 respectively. There are something like 70,000 cesspools even yet in Paris, most of them situated in the slums of the houses, and productive of the most pestiferous evils. The matter ferments in 12 months or even years, exhaling noxious vapours which fill not only the dwellings but the whole quarters, while the periods at which *viduages*, or emptying, is performing, unsavoury rites is but too evident in a large area. This is especially the case in the poorer and most populous districts in the north and north-east, where the greatest number of the cesspools are to be found. On the other hand, it must not be forgotten that improvements on a large scale are taking place in Paris. There are at present about 700 kilometres of sewers, terminating in 150 great holders on each side of the Seine, which unite their contents at Clichy, below the city, whilst a third at St. Denis sewers the quarters of Belleville, Menilmontant, La Chapelle, and Montmartre. The system which, now finished, will be 1,040 kilometres in length, carries into the Seine a daily flow of 1,000 cubic metres of liquid sewage per day, or 131 millions per annum, including rainwater.

THE publications of the German Imperial Archaeological Institute, which from time to time we have reviewed, enter, with the year 1886, on a new epoch, and are to be fundamentally reorganised to meet the enlarged demands of archaeological discovery. It will be remembered that this Institute has hitherto published: 1, for Berlin, the *Archaeologische Zeitung*; 2, for Rome, the *Annali del Monumenti*; 3, for Athens, the *Mittheilungen*. Of these periodicals, the *Archaeologische Zeitung* for Berlin, and for Rome the *Annali del Monumenti* are to cease entirely, and in each department the following additions and modifications are to be made:—At Berlin, at the end of each year, a folio volume is to appear under the title of "Antike Denkmäler"; it is to consist, as a rule, of five plates and a brief accompanying text, which will confine itself to a terse statement of the scientific facts of the monuments published. These "Denkmäler" are to be taken impartially in the whole field of classical archaeology, including, it is expressly stated, the department of architecture. The editorship of the "Denkmäler" will be in the able hands of Max Frankel, with whom the heads of the branch Institutes at Rome and Athens will cooperate. Further, in quarterly numbers, I appear the *Jahrbuch* of the Institute, also published at Berlin, and edited by Dr. Fränkel, which will appear in octavo form, with illustrations in the text and supplementary plates. A section of the periodicals will be largely devoted to the bibliography of the subject, and *résultats* of excavations. Passing to Rome, in place of the usual *Annali*, there will

appear each quarter an octavo volume, under the title of *Mittheilungen Römische Abteilung*; the text will be accompanied annually by twelve plates and woodcuts. The articles will be written in German, Italian, Latin, or French (English, it appears, is to be excluded). This is a distinct gain for foreigners, as the *Annali* were uniformly Italian; naturally, these *Mittheilungen* will have Italy and the adjacent islands for their field. At Athens (3), a quarterly volume will appear under the title of *Mittheilungen, Athenische Abteilung*, with yearly twelve plates and text illustrative interspersed. It will appear in German or modern Greek. This last alternative we regret. Its special field will be Greece proper, and all countries to the east of Greece proper. This notice is issued by the central direction at Berlin at the beginning of April, and the first instalments of the new periodicals may shortly be expected.

A CHANGE of considerable archaeological and architectural interest is impending in the city of Florence, which, like most Italian cities, is feeling in a marked manner the somewhat sweeping tendency to obliterate old landmarks, and to improve antiquities off the face of the earth. It may be said, however, of the present project, which is that of pulling down the ancient Ghetto or Jewish quarter, that it is at least utilitarian, the ultimate intention being to erect poorer-class habitations in one of the most crowded parts of the town. Florence possesses its quota of poverty, but to nothing like the extent seen in other European cities; and there are certainly quarters which, from their overcrowding, loudly call for remedial measures. The Ghetto was (for the Jews have been emptied out of it) one of these; and although its historic associations are numerous and interesting, one cannot but concur in the feeling that it has played its part and is now better away. Situated in the very heart of the city, it was, up to the fifteenth century, the site of the castellated houses of the first families of the time,—a time in which every man's hand was against his neighbour. The Jews had been allowed to reside in Florence about 1430, although, as usual in the Mediaeval days, under considerable restrictions both of place and occupation; but when Cosmo di Medici came to power he determined that the Jews should be all shut up in one enormous building, and this was carried out in 1571. This building, which can now be seen to greater advantage when empty, than when it was a human rabbit-warren, consists of a huge square of some eight stories, with walls of enormous thickness; and is a miniature town of itself, with several courts (of which one, the Piazza del Fonte, is extremely picturesque), and various streets and alleys radiating from it. A large synagogue is a striking feature in the arrangement; and although a few of the apartments are tolerably roomy, the majority are no better than cellars, in which two or three families found shelter. When we consider that for the last three centuries this gloomy hive has been constantly inhabited by at least 2,000 people, who lived with the minimum of light and air, and with no drainage whatever, it is marvellous that the Ghetto and surrounding neighbourhood has not been decimated by pestilence over and over again.

WE are glad to hear that the Corporation of Sunderland have appointed Mr. Waterhouse as assessor in the competition for the new Municipal Buildings. This will put matters on a right basis, and put an end to the rumours about favouritism.

THE Edinburgh Town Council have, as was briefly mentioned in our last, adopted a resolution to build new municipal buildings on the site of the present buildings and adjoining property, competitive plans to be received and premiums given for the first and second designs. Objection was made that a town-hall did not form an integral portion of the scheme, but it was conceded that, were such resolved upon, another site would have to be fixed upon, and considerable extra expense incurred. The retention of a portion of the

present buildings was suggested, as they are considered by many to possess characteristic features worthy of preservation; the great mass of unadorned wall (ten stories high) to the north, which forms a striking feature in the view of the old town as seen from Princess-street, being not the least remarkable. The Architectural Association have addressed the Municipal authorities with a view to urging the adoption of the suggestions for the conduct of architectural competitions sanctioned by the Royal Institute of British Architects. The new buildings, if carried out in a worthy manner, should form the centre point in a panorama which is considered one of the finest in Europe; ornamental detail should form a minor consideration, and a dignified and massive picturesqueness should be aimed at.

THE *Δελτίον της Έστιας* (No. 479) reports that at Gortyna, in Crete, a colossal female statue has been discovered, made of Pentelic marble. The head is missing, one arm is preserved entire, another remains of the other to make the position of it certain. The statue is of a draped figure of somewhat late date, two metres high. The great interest of it lies in the fact that it is inscribed with the name of the sculptor, *Εισιδωτος Αθηναίος ετοιμ.* "Eisidotos, the Athenian, made it." This sculptor, Eisidotos, is till the present moment unknown either to literary or monumental tradition.

DR. HELBIG, in the *Bullettino di Correspondenza Arch.*, No. 10, reports an interesting discovery made not far from Siena. Deep down below the ancient fortification known as La Mula, a dome-shaped chamber has been discovered, arched over with a roof, constructed on just the same principle as the Mycenaean "Treasure-house" of Atreus, *i.e.*, in the primitive fashion of horizontally-placed layers of stone projecting over each other till they meet at the top. Dr. Helbig thinks the structure is Etruscan, and dates it as anterior to the sixth century B.C. Here, too, popular tradition supposes a buried treasure: the peasants of the neighbourhood say, "Fra Quinto, Sesto e Colonnato giace una mulo d'oro dissotterrato."

A MAN who is his own lawyer is said to have a fool for his client. This adage may perhaps apply to a man who, when he builds a house, is his own builder. At least, the recent case of Deyve v. Drummond seems to point to this conclusion. Mr. Drummond, who was going to alter a country-house, finding the tenders were higher than he liked, determined to be his own builder, and contract with the various artificers and others himself. Mr. Drummond seems to have wished to keep his name out of the contracts, and so they were made in that of the clerk of the works, but afterwards in Mr. Drummond's name. This way of going to work finally resulted in lawsuits. The joiner brought an action against him, and it was referred to arbitration, as something was due on the accounts. The architect did the same; it also was referred to an arbitrator, who held thirty-six sittings; the award came before the Court on the question as to whether he was right in finding that Mr. Drummond had authorised the architect to make certain contracts, and they found that he was. So in addition to being his own builder, Mr. Drummond has had the satisfaction of having had two law-suits, and if the report in the *Times* is correct, instead of having paid 9,000*l.*, the amount of the tender, he has had to pay 20,000*l.* One may be pretty sure that the ordinary practice of society is, as a rule, the best for ordinary people to follow. This case shows, at any rate, that for a man to be his own builder is not economical; we believe also,—*pace* Lord Grimthorpe,—that it is not peculiarly advantageous for a man to be his own architect.

COMPLAINTS arise rather too frequently, in the case of acceptance of tenders, of the lowest tender being refused without apparent reason,—a procedure which is hardly fair to competent and responsible firms which have

gone to the expense of estimating on the understanding of the acceptance of the lowest tender. Our attention has been called to a case in connexion with the Great Eau Improvement Works at Saltfleet Haven, to be carried out under the Louth Court of Sewers. Here the amounts of eight tenders ranged from 4,594l. 6s. 4d. up to 5,870l.; not an abnormally wide divergence; the engineers' estimate having been 5,253l. 19s. 8d. The second lowest tender, 4,814l., from Messrs. Hibbitt & Desforges, of Louth, was accepted in preference to the lowest (as above) by Mr. Goddard, of Grimsby. Local authorities state that the latter is "a competent and experienced contractor for works of this character"; and unless there is any explanation which does not appear on the face of the published reports, it certainly seems that the lowest estimator has some cause of complaint.

WE understand that the Council of the Water Assurance Association is getting into shape a Bill to be presented to Parliament for amending the condition of sanitary legislation. The main objects of the Bill, which has been sketched out by Mr. Mark H. Judge, are to simplify and include in one measure the regulations relating to the powers and responsibilities of public authorities, and to increase the responsibility of owners and occupiers in respect of the sanitary condition of their own buildings.

AT the Art Exhibition at Folkestone, which will be opened about the middle of May, there will be one section devoted, among other things, to the exhibition of examples of Medieval decorative art, and Mr. Alfred Newman, of 19, Maddox-street, who has undertaken to arrange this department, would be glad to hear from architects and others who are in possession of old examples of wood and stone carving, metal-work, &c., which they would be willing to lend for the occasion. All objects lent will be insured, and the cost of carriage paid.

MR. CHAS. LUCAS, of Paris, has published, in a separate pamphlet, the very sympathetic notice which he read before the "Société Centrale des Architectes" last year, on the works of the late Mr. Burges and of Mr. R. P. Pullan. He speaks with great admiration of the series of illustrations of Burges's house which Mr. Pullan is bringing out.

THE Annual Report of the Council of the Institute of Architects gives a good account of the position and recent work of the Institute. To adopt a phrase frequently used in the "Queen's Speech" in Parliament, the Institute may say, "My relations with foreign powers continue to be satisfactory," especially in reference to the communications which have been received from provincial and colonial societies. In the matter of examinations, thirty-two candidates presented themselves for the last examination held in London, of whom twenty-five passed, six were recommended another year's study, and one was rejected. Six candidates passed at the Examination held in Leeds. The next examination is to be held in November, in London, for which applications to be examined may be made at once. The question of facilitating the admission of students into public edifices at home and abroad, for the purposes of study, has had the attention of a Committee of the Council, and the idea has been entertained of furnishing a form of credential to members, stating the object of their study; such credentials to bear the insignia of the Institute, and to be made out in French, German, and Italian, as well as in English. It may be noted that the Owen Jones Travelling Studentship is, for the years 1887 and 1888 at all events, to be thrown open to all comers without restriction as to age. The *Transactions* commenced a new series in October last, in a quarto volume of 172 pages of text and 93 pages of illustrations, copies of which have been accepted by the Queen and the Prince of Wales, who have, in reply to an offer by the Council, expressed a

wish to be furnished regularly with the *Transactions* as they appear. The practical interest taken by the Institute in the matter of great public works, and their method of treatment, is a good feature in the record of the past year.

ST. MAGNUS THE MARTYR, LONDON BRIDGE.

In a paper which he read twelve months ago to the St. Paul's Ecclesiastical Society,* Mr. E. P. Loftus Brock, F.S.A., appositely showed how remarkable a group of City churches occupied a small space eastwards of St. Paul's. Setting out what is practically a semicircle,—for the river may be neglected,—with a quarter-mile radius from King William IV.'s statue as a centre, we should encompass as many as 35 of the 109 parish churches that were standing in the seventeenth century. Taking of this group those churches which were rebuilt after the Great Fire, one of the most conspicuous is that of St. Magnus the Martyr, just eastwards of New London Bridge. There was more than one saint of that name. He to whom this church is dedicated is supposed to be the martyr who suffered at Caesarea, in Cappadocia, during the reign of Marcus Aurelius Probus, A.D. 276. It is not mentioned in Raphael de Diceto's survey; whilst the earliest rector of whom we know is one Robert de St. Allamo, who, according to Newcourt, resigned the living in 1323. But we do know that a chantry was founded on this spot by Hugh Poorte, who was sheriff in 1302; and that hero was buried Jobn de Blount,—the first mayor to be actually knighted, though Stow gives that style to many before him,—who filled the chief civic chair during the interval 1301-1308. Another chantry in an attached chapel of St. Mary was founded towards the close of the fourteenth century by Henry Zenely. Zenely, or Yevel, as he is otherwise called, officiated as "Free-Mason" to three sovereigns,—Edward III., Richard II., and Henry IV. He is distinguished for having prepared the designs for King Richard's extensive alterations of Westminster Hall, as well as for his share in making that monarch's tomb in the Minster hard by. About this period the patronage of the church vested in the abbots of West Minster and Bermondsey alternately. Having passed to the Crown at the Dissolution, it was bestowed by Queen Mary, in 1553, upon the Bishop of London and his successors in the see. The original church, together with what we take for its tower, and the neighbouring churches of St. Margaret, New Fish-street (Fish-street-hill), and St. Leonard, Eastcheap, are clearly manifest in Wynngaerde's view,—*circa* 1550. But our subject makes us great figures in Agassiz's map, though its position would seem to be marked by a cross that stands on a raised platform *in situ*. It appears, indeed, to have fallen into decay, and not to have recovered from the untoward condition of affairs both in respect of its fabric and conduct, whereof a graphic account is to be found in Arnold's Chronicle, drawn up about the end of the fifteenth century. He describes, *inter alia*, how the church and chancel alike stood in great need of repair, and how the priests and clerks neglected divine service for the less seemly attraction of taverns and alehouses, fishing, and other trifles.

St. Magnus was one of the first churches to fall a prey to the conflagration which is commemorated by the monument that dominates this quarter of the town. Nothing remained thereof excepting, as we gather from Mr. Loftus Brock's paper, the portion which forms the eastern wall of the existing structure. This relic, he says, used to extend above the height of the now northern aisle, where the old masonry was visible, but was cemented over a few years since. Wren rebuilt the body of the new church in 1676; and this was declared by statute to serve for the united parishes of St. Margaret and St. Magnus.† In 1705 was added its noblest feature,—the steeple,—whose extreme altitude of 185 ft. is only 17 ft. less than that of the Monument. The whole fabric cost 9,579l. 19s. 10d. On the 18th of April, 1760, it suffered considerably from a fire which broke out in an oil-shop against the south-eastern corner. The story goes that a workman had left some oil boiling while he ran off to see Earl Ferrers return from his trial and conviction. Nearly

all the roof was consumed, the organ damaged and the vestry-room quite destroyed. At an expense of 1,200l. the parishioners made good their losses, rebuilding the vestry-room by the north-western end. But very shortly afterwards the two western angles of the church together with the new vestry-room, were taken down for the widening of Fish-street-hill, which had at last proved too narrow for the increasing traffic across old London Bridge. At that time the only entrance-way through the tower was from the west, where the steps, in descent now are. But hereupon the architect's presence came to light. Foreseeing the extending requirements of a later age, Wren had constructed the base of the tower in such a manner that the necessary passages might be made without imperilling the stability of his work. For in the tower walls, north and south, they found two arches already embodied in the masonry, and these are the arches of the present day. In this respect the tower shone he compared with that of Wren's Christ Church, Newgate-street, completed in 1704. It is to be observed, nevertheless, that the two openings no longer serve for their adopted purpose, since the space eastwards is now thrown into the churchyard, and the wharfs beyond are approached by a *détour* opening out of Lower Thames-street. In 1825 the church was repaired and beautified, its east window opened up, and the interior restored to the state in which Wren had left it.* Ionic columns separate the nave and aisles; the columns are slighter, and the intercolumniations wider than usual. They give an air of insecurity of support for the nave ceiling above. The organ is noteworthy as being the first to be fitted with a Venetian swell in lieu of the old echo organ. The gift of Sir Charles Duncombe in 1712, and originally built by the Jordans father and son, this fine instrument has been successively altered and renovated at the hands of Parsons (1825), Gray & Davison (1852), and Hill. The *Spectator* for February 8th, 1712, contains an announcement of its first use upon the following Sunday. The projecting dial-piece is a gift, too, of Sir Charles Duncombe, Alderman of the Ward, in the year of his mayoralty, 1709. Made by Langley Bradley for 455l. 5s. 4d., but shorn of much of its ornamentation, it now bears the date 1833. Duncombe is said to have presented the clock in fulfilment of a vow taken when, as a boy, he missed his master through not knowing the hour, and lost his time waiting on the Bridge.

The beautifully carved foliage and flowers beneath Thomas Collet's monument (1733), but apparently of somewhat later date, should not be overlooked; whilst against the eastern wall, by the altar-table, is fixed a Gothic panel (1837) bearing an open Bible, in memory of him under whose direction was published on October 4th, 1535, the first complete printed English version of the Bible. This was dedicated to King Henry VIII. and "his dearest just wife and most virtuous Princesse Queen Anne." The title ran "Biblia, the Bible, that is, the Holy Scripture of the Olde and New Testament, faithfully and truly translated out of Doche and Latyn into English, MDCXXXV." Miles Coverdale, bishop of Exeter, had been rector of the parish, and thither his remains were removed from St. Bartholomew-by-the-Exchange at the destruction of that church fifty years ago.

St. Magnus's stone tower, in three stories, with its octagonal composite lantern, also in stone, capped by a wooden and leaden lantern and spire, form together one of Wren's best designs. Mr. Andrew T. Taylor points out in his "Towers and Steeples designed by Sir Christopher Wren" (1881) that the entire Ionic portico on the western face of the ground story "interferes with what is so pleasing in most of his towers, the rising straight from the ground. One cannot get rid of the feeling that it is standing on the top of a pediment." He also remarks that the plate tracery balustrade over the tower cornice has rather a thin and weak appearance, hardly consonant with the solid-looking tower, the compact lantern, and the full-swelling cupola. These blemishes are not so evident, however, to a spectator looking at it from the south. There, from a river landing-stage, and seen through the opening between Adelaide and Fresh wharfs, this composition stands out in all its beauty against the clear sky over the rise of Fish-street-hill.

* See the *Builder*, April 25th and May 2d, 1885.

† With them was incorporated that of St. Michael, Crooked-lane, at the re-construction of London Bridge.

* The exterior stonework of the tower has been lately put into thorough repair. *Vide the Builder*, February 28, 1885.

This portion of London is so intimately associated with the memory of Wren and of the hours that we may revive a tradition thereof Mrs. Riddell makes signal use in her "Mitre Court." Scarcely 100 yards east from St. Margaret's Church,—and standing between Botolph-lane and Love-lane,—is a site whose venerable aspect does not belie the story that it once formed a home of the great architect. Having served for many years past the Billingsgate and Tower Ward Schools, the house has been somewhat changed internally. The spacious hall and noble staircase, the doors and carved doorways, the decorated ceilings, the painted panels (1696) of the parlour, and other valuable features are preserved. The first landing is the date 1670. The second landing is now thrown into the boys' school. The main entrance, facing a private road, locally known as Fenn's Gateway, is remarkable for its massive side-post and equally massive covered canopy.

RECENT EXCAVATIONS IN BEOTIA.

DISCOVERY OF STATUE OF APOLLO PTOOS.
 IN the last issue of the *Bulletin de Correspondance Hellénique* (January, 1886), M. Haric Holleaux gives the long-looked-for fruit of his important work, carried on last year at the village of Perdicovrysi, in Beotia. He has already briefly noted that his efforts, with a speedy reward. The excavations were but fairly begun when the workmen came upon a life-sized statue in whitish grey marble, very early archaic style, to which M. Holleaux does not hesitate to give the name of god Apollo Ptoos. This statue he now publishes in heliogravure, together with a fine archaic head, and the lower part of a still more archaic "Xoanon," inscribed with a dedication. A glance at the plate which accompanies the work will show the special importance of his discovery; the new archaic figure is obviously in consort to that long series of archaic statues which have till recently borne the name of Apollo, and which recent criticism has preferred to call by some less august name, seeing them not the representation of a god, but of a dead mortal, athlete or otherwise. We refer to the "Apollons" of Orchomenos, of Thera, of Ithaca, of Delos, of Naxos, of Tenea, and of the British Museum. Dr. Milchoffter has seen the "Apollo" of Tenea a funeral statue, and Dr. Loeschke attributes the same motive to the "Apollo" of Thera. M. Holleaux at once says that he has no intention of reopening the debate, which he rightly thinks merits of no categorical solution, but he distinctly states that in this new individual instance the place of "providence" does not indicate with exceptional precision the right attribution of the statue. It was found a few feet only from an undoubted sanctuary of Apollo, of high repute in ancient days. The ground around it was thickly strewn with fragments of pottery bearing inscribed dedications to the god. We can scarcely, therefore, avoid the conclusion that the statue itself is the age, votive or otherwise, of Apollo Ptoos himself. The supposition that it may have been the votive statue of a victor in the games at the Ptoia falls to the ground for lack of proof that at the manifestly early date of this time the games existed. Equally untenable is the theory that it may have been a funeral statue, as we know for certain that a sanctuary was served as a burial-ground. We think, then, that this particular statue is undoubtedly Apollo, but we repeat, with M. Holleaux, that it by no means follows that all the rest of the analogous series are also Apollos. The *juste milieu* is struck by Michaelis when he says that in the archaic period, whatever was the subject intended, god, hero, or athlete, the sculptor expressed it in the same terms; and in its beginnings was not concerned to vary its modes of expression in precise relation to the thought to be expressed. The long series of "Apollo" statues, though varying close general analogy, yet fall into two broad divisions, according to the type of feature and limb. Dr. Furtwängler has clearly shown that we have to group together on the one hand the "Apollons" of Thera and Tenea, on the other the "Apollons" of Orchomenos, Actium, and the British Museum. The question, of course, arises which of these broad divisions our new Apollo Ptoos belongs to. A long and detailed analysis brings M. Holleaux to a distinctly satisfactory conclusion.

Found in Beotia, the new Apollo ought to rank with the already Beotian specimen the "Apollo" of Orchomenos. In style he distinctly does, only in execution he is far superior. He now stands at the head of a series that enables us to mark step by step the advance of archaic art in modelling the human figure. The series is as follows,—the "Apollo" of Orchomenos, those of Actium, the Apollo of the British Museum, and lastly, the new Apollo Ptoos. The temple and oracle of Apollo Ptoos had its origin in Thebes; we may rightly, therefore, regard these statues as a chronological series of the archaic Theban school.

The inscribed fragment of a xoanon, also published by M. Holleaux, is scarcely of less importance,—its form recalls the famous Nikandre of Delos; it is little more than a board with indications of feet. The form of the letters of the inscription recall those of the Tanagra monument to Demys and Kilylos. Unhappily, the inscription is incomplete,—

... ον ἀνέθεκε τῷ Ἄρῳ
 Λοκί τῷ Πτοῦι
 ... ορος ἱμαίνεσθαι

unkind fate has left from us the name of this early sculptor, and literary record gives us no sculptor's name ending in "oros" to supply the deficiency. By order of the new director of antiquities, M. Kabbadias, both these statues, together with a head of archaic type, have been brought to the Central Museum at Athens, where the Apollo Ptoos stands side by side with his kinsman the Apollo of Orchomenos.

THE BUILDING OF STABLES.

It may be well to preface this article by saying that the following remarks are a brief summary of the desiderata in stable-building, as regarded from the point of view of the owner of the horses to be provided for. The subject is sufficiently important to make a non-professional opinion of some value.

It is surprising to observe how careful many persons are as to the construction and fitting-up of their houses,—how careless they are in regard to their stables. It is true that more intelligence is now shown in the management of horses than was visible even a few years ago, but that progress is still of a comparative character; so that the carelessness about the stables arises from a kind of popular ignorance in regard to the management of horses. Continually those who take a personal interest in everything which concerns their horses will be found to leave the stable management entirely to itself. Hence the construction and fitting of stables are often left altogether to the architect and builder. The former has quite enough to do with looking after the house without troubling much about stables, and in all probability he has seldom studied this question from a practical point of view. He will plan a picturesque and pleasing exterior, and then his task is over. But too often the owner of the premises does not give him free scope, even in regard to this. If he interferes, it is on the stables where the money is to be saved, and over and over again stables may be seen wholly inferior in architectural character to the house, simply because the owner, while feeling it necessary to erect stables, has thought it advisable to spend as little money upon them as possible. Badly-constructed stables are never economical, and in many cases a little extra money spent on them will repay itself in the better condition of the horses which will have to inhabit them.

A cardinal principle in the erection of stables is the selection of a site. Stables are too often put up in any hack region, but they should always be built in the warmest and sunniest aspect which is obtainable. Not warmed, as are houses, artificially, the warmth of the sun is most necessary to keep them as dry and warm as possible. Dryness is very essential for good stables, and, therefore, a site where drainage is easy and good should be selected. Damp stables will cause disease not only in the lungs and bronchial tubes of a horse, but also in his feet, and may cost the owner not only anxiety, but money. It has to be borne in mind also that both sunny and dry stables are requisite for keeping carriages in proper condition. Hence, no one should build a stable or coachhouse except on a dry site and with a warm aspect.

Another element in regard to the construction of stables of the highest importance is that

they should be built as substantially as possible. Warm stables in winter are absolutely necessary for horses if they are to look well and do their work well, and equally in summer they should be cool.

The aim of the builder of stables should in fact be to erect them so that they may be kept internally at a moderate and equal temperature throughout the year so far as that is possible. Horses come warm into a stable, and they cannot, as we can, stand with their backs to the fire. Hence, it is most necessary that in winter time they should not be received into stables which will chill them. On the other hand, too much care cannot be taken in regard to ventilation.

Many horses are lost every year owing to insufficient ventilation. The stables get hot and close, and a horse is stripped of his clothing and brought into the cold air. The human being, with much the same constitution, puts on an overcoat when he turns out. It is not surprising, therefore, that horses get cold, coughs, and sometimes die, sometimes become permanently injured in their wind. While, therefore, a stable should be temperate, it should not be hot, and accordingly the ventilating apparatus should be as effectual and as easily worked as possible. Barely one stable in ten is properly ventilated, and artificial warmth is never supplied, though most stables might obtain it from the harness-room fires by means of hot flues or hot-water pipes connected with the boiler, to be used according to the external atmosphere.

The fitting-up of the stable will hardly, perhaps, be considered as within the province of an architect, but it is a matter with which every architect should be acquainted. The great point to bear in mind is that loose boxes should be put up and not stalls. The common practice is to have about three stalls to one loose box, whereas the proportion should be reversed. The freedom which a horse has in a loose box is of vital importance. To point out the reasons for this would be to go into matters scarcely fitted for this journal, but, whether for actual general health or for keeping a horse sound in his legs a loose box is very necessary. There is no need to have them large, but loose boxes should be sufficiently roomy for a horse to turn in with comfort. There are many stalls which, with an extra foot of breadth, would make reasonably good loose boxes.

We may shortly summarise a few more hints. The harness-room should never be a passage-room, though, on the other hand, it should be directly connected with the stables. Where the stables are large it should be double, in the nature of a scullery and a kitchen, the outer harness-room for rough work, the inner for keeping saddles, &c., and for doing lighter and cleaner work. Large coach-houses are to be avoided; several smaller ones are better. To have several carriages packed in one coach-house causes them to be constantly knocked and bruised, whereas when one or at most two carriages occupy one house they are not so likely to receive damage. When stables are of any size there should always be one or more large loose boxes at a distance from the general range of stabling for the use of young horses, or mares with a foal, or for the purpose of summering hunters. If possible the stables should be planned so as to be connected with a small grass paddock; a mere plot of grass is sufficient. This serves as a place for a horse to be turned into in spring or summer for an hour or two occasionally, and as an exercising ground when a track is laid down with straw in hard winters. Again, every stable should be provided with one or two sleeping-rooms, which should be over the harness-room. As to the drainage, it goes without saying that it should be as perfect as possible. It may be said that the stables we have described are small, but the same principles are applicable to large ones, and, in all respects, the latter are but the small ones multiplied. Having regard to the great value of horses, to the carelessness, economical views, or ignorance of so many if not most horse-owners, architects should always do their best to insist on stables being erected on intelligent principles and in the best possible manner.

Alhambra Theatre.—Messrs. Archibald Smith & Stevens have received instructions to put in one of their improved hydraulic lifts at the Alhambra Theatre, London. This will be supplied by water from a tank at the top of the building, and will be available for use at all hours.

VICTORIAN PATENTS.

The Registrar-General of the Colony of Victoria, Mr. Richard Gibbs, issues a yearly list or index of the patents applied for. It is a most useful publication, in which a short abstract of each specification is given together with the necessary drawings. It is neatly got up, is of convenient size, and cannot fail to be of value to inventors, engineers, and others of the colony. Volume XV., which refers to the year 1885, has recently reached us, bearing date 1885. This seems a trifle late, a fact which somewhat detracts from the importance of this work as a book of reference.

During the year in question 176 patents were applied for. Of these 132 were granted, 39 lapsid owing to the absence of necessary procedure, four were refused, and one was withdrawn. In looking through the list of subjects we find electrically and railways occupy the greatest space. In the former section Mr. T. A. Edison has taken out no less than seven patents, and is, in fact, the largest customer to the Patent Office during the year, if we except Mr. E. Waters, a patent agent of the colony. In looking through the specifications we find that 92 patents were taken out by Victorians. Next in order come Great Britain and the United States, which make a tie for second place with 25 patents each, although, perhaps, our Trans-Atlantic kinsmen should have the preference, as two of the English patents are taken out jointly with inhabitants of France and Italy respectively. Next in order comes the neighbouring colony of New South Wales with 16 patents, while next on the list follow France, Germany, New Zealand, and South Australia with from five to two patents each; and, finally, Italy, Canada, Queensland, and Tasmania, each having a single patent credited to it. We do not find in the subject-matter of the specifications anything particularly distinctive of the colony, unless it is a "Portable Rabbit Sulphocator"; in fact, the list might be supposed to be taken hap-hazard from our own Patent Office Journal. There is the usual wide range of subjects, ranging from a brick-kiln down to an "improved candle-extinguisher." Agricultural machines of various types seem to have occupied a good deal of attention, although some of the most important patents are the result of foreign ingenuity. There are four patents for ice-making machinery, two from England and two from the United States. Mr. Beaumont, of Westminster, protects his compressed-air engine, and Sir John Coode an ingenious hopper-berge for delivering spoil by streams of water. We find no patent for a steam-engine on the list, neither is protection claimed for any new type of steam-boiler, although Mr. Wavish, of this country, receives a patent for what appears to be a form of his well-known "Economiser." Two patents for extracting precious metals are taken out by Americans, and one by a Parisian. An ingenious deep-lift pump is contributed by Mr. W. Watson, Ballarat, and a new form of rock-drill by Mr. John Mitchell, of Bendigo. A toggle arrangement applied to a stone-breaking machine, is considered a sufficient departure from previous applications of this device to the same purpose to merit protection. There are many other patents, doubtless, equally worthy of notice, but it would manifestly be impossible for us to go through the whole list. The illustrations are excellently lithographed, the printing is good, and, on the whole, the publication does credit to the office from which it is issued.

BRICKMAKING.

THE INSTITUTION OF CIVIL ENGINEERS.

At the ordinary meeting on Tuesday last, Sir Frederick Bramwell, F.R.S., President, in the chair, a paper on "Brickmaking," by Mr. Henry Ward, Assoc. M. Inst. C.E., was read. The author showed that many different systems of brickmaking were carried on in England. In some cases machinery was largely employed, while in others all the operations were done by hand. Similarly, many descriptions of fuel and many kinds of kilns were used. It was impossible to lay down any general rule which would suit all places. Probably the system of manufacture in each locality was less open to improvement than manufacturers in other places were inclined to believe. Doubtless there was much that was open to criticism, but generally the plan adopted appeared to have

been gradually adapted to the kind of clay and fuel, and to the labour and transport-conditions obtaining in each district. The process of brickmaking by hand consisted in working the clay to a plastic condition, moulding it, drying the bricks in the open air, and finally burning them in clamps or kilns. When burned in clamps, the fuel was generally hone-ashes mixed with the brick itself, but with kilns coal was employed. In hand-brickmaking as at present practised, machinery was utilised for the preparation of the clay. In the Home Counties the clay was first brought into a thin liquid in a wash-mill, where a certain proportion of chalk was added. This thin liquid was pumped into "backs" or pits, adjoining the pug-mills, during the winter. The water gradually drained away (often to be used again), while the clay settled and became sufficiently stiff to be worked in the pug-mills in the succeeding summer. In nearly all cases the wash-mills, pumps, and pug-mills were driven by steam-power. When the fields had a tolerably uniform surface, it was found best to use long lines of shafting to convey the power from point to point. Where, however, the surface, or the shape of the fields on plan, was irregular, it was preferable to drive the wash-mills and pug-mills by endless chains, running overhead, and supported by small pulleys or posts at intervals. Probably the most important of the applications of steam-power was that of driving powerful force-pumps, to force the liquid "slurry" through pipes, up and down hill, sometimes to a distance of two miles. In this way bricks could be made alongside a railway, canal, or river, while the clay could be pumped from a distance. In many brickfields all the clay had been worked out; but now that clay could be brought from a distance so economically, the old plant could be utilised.

Brickmaking by machinery might be roughly divided into two classes, namely, the plastic and the dry or semi-dry. In the plastic process the usual plan was to mix the clay and bring it to a soft state in a pug-mill, from which it was forced through a die, or opening, in the form of a column, the section of which was the same as that of a brick, viz., 9 in. wide by 4½ in. high, with a due allowance for shrinkage. This column of clay was divided into bricks by wires cutting through it transversely. The bricks were subsequently dried in the open air, or in sheds heated by fuel or steam. There had not been any great alteration in the process of manufacturing wire-cut bricks. These machines were now made stronger and more complete, with further crushing rollers, to enable them to deal with almost any kind of clay. The die, or mouth through which the stream of clay issued, required constant adaptation to particular clays to enable it to form a perfect column of clay. The difficulty was, that as the stream of clay flowed quicker in the centre and slower at the sides, similarly to a glacier or a stream of water, the sides and corners were apt to become ragged. This could be overcome either by putting friction on the centre of the stream of clay to retard its flow, or by helping the travel of the sides and corners, either by lubricating them or by forming the sides of large rollers. These rollers were either rotated by the issuing stream, or they might be driven by power faster so as to help the stream. The use of the exhaust steam under hollow floors, covered with brick, flagstone, or metal plates, had become general. By these means plastic brickmaking could be carried on to a moderate extent through the winter, as the bricks could be dried in sheds.

In the semi-dry process the clay was ground in a perforated pan-mill to fine particles without any admixture of water. This fine-ground clay was subsequently pressed into a brick, which was so hard and dry that it might be taken direct to the kiln without being previously dried.

Plans of works laid out by the author were shown, and also drawings of the various types of the machinery referred to. The Hoffmann-kiln, the gas-kiln, and the railway-kiln were described and illustrated. The Hoffmann-kiln remained much as it was when first introduced. Probably, as regarded economy of fuel, Mr. Hoffmann reached finality at one stride. The whole of the heat of the bricks that were cooling was carried forward by the current of air which supported combustion; and again, the heat of the products of combustion was absorbed

by the bricks which were being warmed and dried until there was not more heat left than was sufficient to cause the necessary draught. It had been attempted to abstract still more of the heat by passing the products of combustion through a greater number of bricks, and to obtain the necessary draught by a fan; this also saved the expense of building a chimney, but the plan had not been successful. Gas had been used as a fuel in these kilns in Germany and in France, not with a view to further economy, but mainly to improve the colour of the bricks. In order to save the cost of loading and unloading the kiln, Mr. Dueberg had introduced a method by which the green bricks were loaded on to a railway truck, which was run into the kiln, the bricks being burned while on the truck. The truck was formed without sides or ends, and the floor was covered with firebrick. The wheels and axles were kept cool by a current of air continually travelling under the floor of the truck. Communication was cut off between the space above and below the floor by lips of iron travelling in a sand-trough. In this system the fire travelled round the kiln, as in a Hoffmann kiln, and, therefore, the trucks were not moved while they were hot. In another type of railway-kiln the combustion-chamber was stationary, while the trucks of bricks were gradually pushed through it. This had not been a success.

THE SOCIETY FOR THE ENCOURAGEMENT OF THE FINE ARTS.

On Thursday, April 15th, at the rooms of this society, 9, Conduit-street, W., a lecture on "Old Engravings of the Italian Schools" was delivered by Mr. E. P. Loftus Brock, F.S.A. The chair was taken by Mr. H. H. Statham, who said that the lecturer, being his honorary secretary of the Society and a well-known archaeologist, needed no introduction. The walls were hung with a large and representative collection of engravings dating from 1508 down to the present century, and containing specimens of the works of Guido, the brothers Caracci, Diana of Mantua, Marc Antonio, and of Bartolozzi's early works. The lecturer said that the art of line-engraving in Italy sprang into vigorous life in the period of the Renaissance, and was greatly helped by the invention of the printing-press, to which, however, it was not indebted for its existence,—engravings in the form of wood blocks having existed anterior to the use of the press. The principal schools of engraving in Italy were those of Florence, Rome, Bologna, Parma, Padua, and Venice, which, on the whole, preserved their distinctive features to a comparatively recent date. The value of engravings as historical records of events, costume, contemporary life and manners, architecture, sculpture, and paintings, was strongly insisted on. Specimens of various schools and periods were compared and contrasted, and attention called to the gradual change from the hard, sturdy, well-defined outline of early art to a graceful artistic style.

An interesting discussion, in which the Chairman, Mr. Louis Fagan, Mr. Forbes Robertson, Mr. T. H. Maguire, Mr. G. A. Storey, A.R.A., and Mr. James Edmondson took part, gave additional force to the very able lecture, Mr. Fagan urging upon all the duty of giving attention to the magnificent collection of engravings in the British Museum, a collection unequalled in Europe.

The Parkes Museum.—An Extraordinary General Meeting of the members of the Parkes Museum was held on Friday, April 10th, Professor Berkeley Hill in the chair. The meeting was called to consider the desirability of amalgamating with the Sanitary Institute, and it was unanimously resolved, on the motion of Dr. G. V. Poore, seconded by Mr. Mark H. Judge, "That it is desirable that the objects for which the Parkes Museum and Sanitary Institute respectively were established, should, if practicable, be prosecuted in the future by one corporate body." Further resolutions for bringing about this amalgamation and for applying for a Royal Charter were considered, but it was decided to adjourn the meeting in order that amendments to the resolutions might be sent to the whole of the members.

THE TILBURY DOCKS.

THESE extensive deep-water docks, which have been constructed by the East and West India Dock Company at an expenditure of about 3,000,000l., were opened on Saturday. The principal works consist of a tidal basin and a main and branch docks. The tidal basin, with water area of nineteen acres, has at low-water spring tides a depth of 26 ft., while at ordinary high-water springs the depth is 45 ft., thus enabling the largest steamships to enter and depart irrespective of conditions of tide. In the basin there are two arrival and departure quays each 600 ft. long for discharging and loading all states of the tide. The north-western quay of the basin, named the transhipment quay, is over 300 ft. in length, and is chiefly intended for transhipments to and from Continental steamers. The coaling jetty at the north-western quay of the tidal basin is fitted with four 30-cwt. movable hydraulic cranes, with weighing apparatus, constructed by Sir G. Armstrong, Mitchell, & Co. (Limited), of Newcastle-on-Tyne, for discharging coal from main colliers into barges, and, by means of bridges connecting the jetty with the land, it can also be tipped into railway trucks. At the south quay of the tidal basin a shed has been erected for the accommodation of passengers and their baggage, comprising a waiting-room, Customs examination room, and two baggage warehouses, necessary baggage offices, and a booking office. The south side of this shed opens on to a railway platform, from which special trains can be run to Fenchurch-street and Liverpool-street stations. The hydraulic and other machinery for loading and unloading the vessels, and for opening and closing the docks, is very complete. The electric light has been employed throughout the whole dock system. The work has been done under the direction of Messrs. R. E. Crompton & Co., of London and Chelmsford, and the general arrangement of the lights has been such that a total of eighty arc lamps of 3,000-candle power each have been placed in various positions on masts or other convenient posts of stage in the outdoor part of the docks. The works have occupied four years. The principal contractors were Messrs. Manning & Baynes, and contractors who have completed the works were Messrs. Lucas & Aird.

The *Times*, in its account of the opening of the docks, stated "that the real commencement operations only dates from October 27, 1884, in the undertaking was taken over by Messrs. Lucas & Aird from the previous contractors, and that the total quantities of the principal works carried out from October 27, 1884, to April 17, 1886, were as follows:—Excavation, 3,275,000 cubic yards; concrete, 640,000 cubic yards; brickwork, 46,000 cubic yards; masonry, 260,000 cubic feet; shedding, 20 acres; permanent road laid, 22 miles. The materials used consisted of the following items:—Sand, 700,000 cubic yards; bricks, 19 millions; cement, 65,000 tons; stone, 230,000 cubic feet; ironwork, 1,056,900 square feet; ironwork, 4,100 tons; galvanised sheeting, 300,000 square feet; timber (hulk), 1,530,000 cubic feet; ditto (planks and boarding), 13,200,000 linear feet; coal and coke, 40,500 tons; and the machinery and plant used,—locomotives, 54; portable engines, 35; steam engines, 46; steam cranes, pile engines, 207; steam excavators, 6; dredgers, 5; cranes in steam, 250; wagons, 1,650; and 4,000 tons of sleepers, 76,000; temporary rails laid, 38 miles; timber, 2,000,000 cubic feet; and so on. The average number of men employed was 4,500, and the water pumped was (minimum quantity) 13,000 gallons per minute."

In reference to these particulars, however, Messrs. Kirk & Randall, the contractors who commenced the works, write:—"Whereas the site was put into our hands in July, 1882, situated marsh, if not a bog, it was forcibly, as we allege, wrongfully taken out of our hands two years afterwards as a well-drained site, from which we had removed considerably more than two millions of cubic yards of excavation, and in or upon which we had built a large amount of the most difficult portion of the quaying and other permanent works, and further, by putting in concrete at the rate of 2,000 cubic yards per day, or say 600,000 cubic yards per annum. The organisation of the plant, the merit of which is so complacently and by the present contractors, had been

completed, and upon this we had expended upwards of 200,000l. Of the thirty-eight miles of temporary road claimed by Messrs. Lucas & Aird, thirty-five miles were provided and laid by us. Of the total of 250 steam engines of all sorts, over 200 were put on the ground by us. To our pumping arrangements practically no additions were made. In short, of the total plant utilised in completing the docks we supplied, perhaps, 90 per cent., and Messrs. Lucas & Aird the remaining 10 per cent. Speaking generally, it may be said that when Messrs. Lucas & Aird went to Tilbury the chief difficulties of the work had been overcome."

Illustrations.

MONUMENT TO THE LATE ARCHBISHOP TAIT, CANTERBURY CATHEDRAL.

THIS monument was put up as a memorial to the late Archbishop, in Canterbury Cathedral, some months ago, as mentioned in our columns at the time. The figure is by Mr. Boehm; the architectural portion was executed by Mr. Brindley, from the design of Mr. J. Oldrid Scott, at a cost of 825l. The inscription is in gilt letters on a ground of deep red Rosso marble; the side panels being of a dark green porphyry. The other marbles used are mostly pavonazzo and breccia. The work is very richly inlaid and carved.

This engraving, and that of the Kemble memorial screen in the present number, are executed by Mr. J. D. Cooper, from photographs, assisted by the architect's drawings.

MEMORIAL SCREEN, BATH ABBEY CHURCH.

THE screen, which was erected as a memorial to a former Vicar, the Rev. Charles Kemble, divides off the eastern part of the south choir aisle, which will be used as a vestry. It has two brass plates on the lower part, with inscriptions, and the screen is surmounted by a shield bearing the Kemble arms, carried by two figures of angels. The cost of the whole was about 200l. The work was executed by Mr. Harry Hems, from the designs of Mr. J. Oldrid Scott.

It may be mentioned that Mr. Gill, an old inhabitant of Bath, has offered to give one of the side screens of the choir if the congregation will agree to give the remaining three.

DRAWINGS OF ST. MAGNUS, LONDON BRIDGE.

THESE admirably-executed measured drawings of Wren's steeple near London Bridge obtained for their author, Mr. E. H. Sedding, the first silver medal for architectural work of this class in the last Royal Academy Students' competition.

For some historical particulars in regard to the church and its site, see article in another column.

NEWCASTLE-UNDER-LYME PUBLIC BUILDINGS.

WE illustrate this week Messrs. Sugden's and Mr. Blood's design, to which the first premium was awarded by the professional referee in the competition which took place last year for this undertaking.

After some consideration, the Town Council decided to ask Messrs. Sugden and Mr. Blood to co-operate in the carrying out of the work with Messrs. Chapman & Snape, a local firm, whose designs, though unpremiered in the competition, contained features which commended themselves to the Town Council.

This arrangement having been agreed to, the further plans, which we also illustrate, have been jointly prepared by the architects named, after repeated consultations with the committee of the Town Council, whereas the practical advice of Mr. Thomas Lewis, architect, one of its members, has been of great value.*

These final plans show a very considerable development of the original scheme (as embodied in the instructions to competing architects), several features of public utility having been added, such as the large Council-chamber,

* It thus appears that this building has practically six architects. "In the multitude of counsellors there is safety."

school of art, refreshment-room, clock-tower, &c. The extent to which the outlay will have been thereby increased will be definitely known when the tenders are opened, after the 23rd inst.

The scheme divides itself into two parts, viz., the public baths (and caretaker's house) block in March-street, and the Ironmarket block.

The Ironmarket block consists of four departments,—the School of Art, the Free Library, the Council-chamber or Banqueting-hall and adjuncts, and the large Assembly-room, available for picture exhibitions, floral and horticultural shows, and other purposes.

The School of Art comprises elementary school, 25 ft. by 30 ft.; antique room, 25 ft. by 30 ft.; lecture-hall (and model-drawing room), with art-master's stores, 24 ft. by 44 ft. These are approached by a spacious corridor from which access is also obtained to the various students' cloak-rooms, conveniences, the modelling-room, storage, &c.

The Free Library has library proper, or book-stores, 24 ft. by 40 ft., divided into 8 ft. heights by open iron galleries round the walls, connected by spiral iron staircases, thus dispensing entirely with ladders. The reference, reading, and general news rooms are each 25 ft. by 30 ft., approached by an ample corridor, and with the necessary conveniences. These rooms are divided by lofty glazed screens, which denote at all times the extent of the apartments in this connexion, whilst affording facilities for oversight. The librarian has a capacious basement for the storage of useful but seldom studied literature; and his other requirements are fully provided for.

The Council-chamber is 50 ft. in length by 38 ft., formed into three embayed recesses, divided by columns and pilasters, and fitted up with window-seats on the street side. It has an ante-room on the same level, and in the basement, kitchen, scullery and larder, &c., from whence lifts ascend to the ante-room and to the assembly-room refreshment-room respectively.

The Assembly-room is 50 ft. in width by 90 ft. in length, exclusive of stage. It is lighted from the ceiling by clearestory lights in the ceiling cove, leaving the walls below clear for the hanging of pictures, &c. The ceiling is covered by plastered moulded beams. This room is approached by a double staircase rising from a crush-hall, having exits both into the Ironmarket and the carriage-way from the Ironmarket to March-street. There is a further staircase from the Ironmarket and separate stairs to the stage, all fireproof. The cloak-rooms, &c., for ladies and gentlemen are large and commodious, and the stage has ample retiring and dressing rooms. The refreshment-room opens upon a colonnade, which contributes very much to the effect of the front elevation.

Our reproductions of the plans clearly explain the extent of the baths accommodation, which, it will be observed, has been so devised as to allow of ladies using the swimming and Turkish baths, on the days set apart for them, from their own entrance, without crossing other corridors, &c.

The materials proposed for the building are thin dark-fired bricks for external facing. The stone dressings will be of mottled "Beggars Well" stone from Mrs. Mellor's quarries near Uttoxeter, and the roof tiling the best Broseley. The floors are all specified of iron and concrete, laid thereon with wood blocks in bitumen, ensuring security against fire, dry-rot, the presence of vermin, the transmission of sound, and other evils.

WINDOWS AT EASTHAMPTON CHURCH.

THESE windows, representing "Mary Magdalen at the Sepulchre," and "Christ and Mary Magdalen in the Garden," are placed in Easthampton Church, and are the design of Mr. Burne Jones, A.R.A. In the free yet strictly decorative treatment of the figures and drapery they afford an admirable example of stained glass style, equally free from archaistic stiffness and from any unsuitable degree of realism.

Railway Benevolent Institution.—The annual dinner in connexion with this Institution will take place at the Freemasons' Tavern, London, on Wednesday evening, the 12th of May, under the presidency of Mr. John Dent Dent, chairman of the North-Eastern Railway Company. The Institution has been established to provide for the necessitous members, orphans, children, and widows of the railway officers and servants in the United Kingdom.

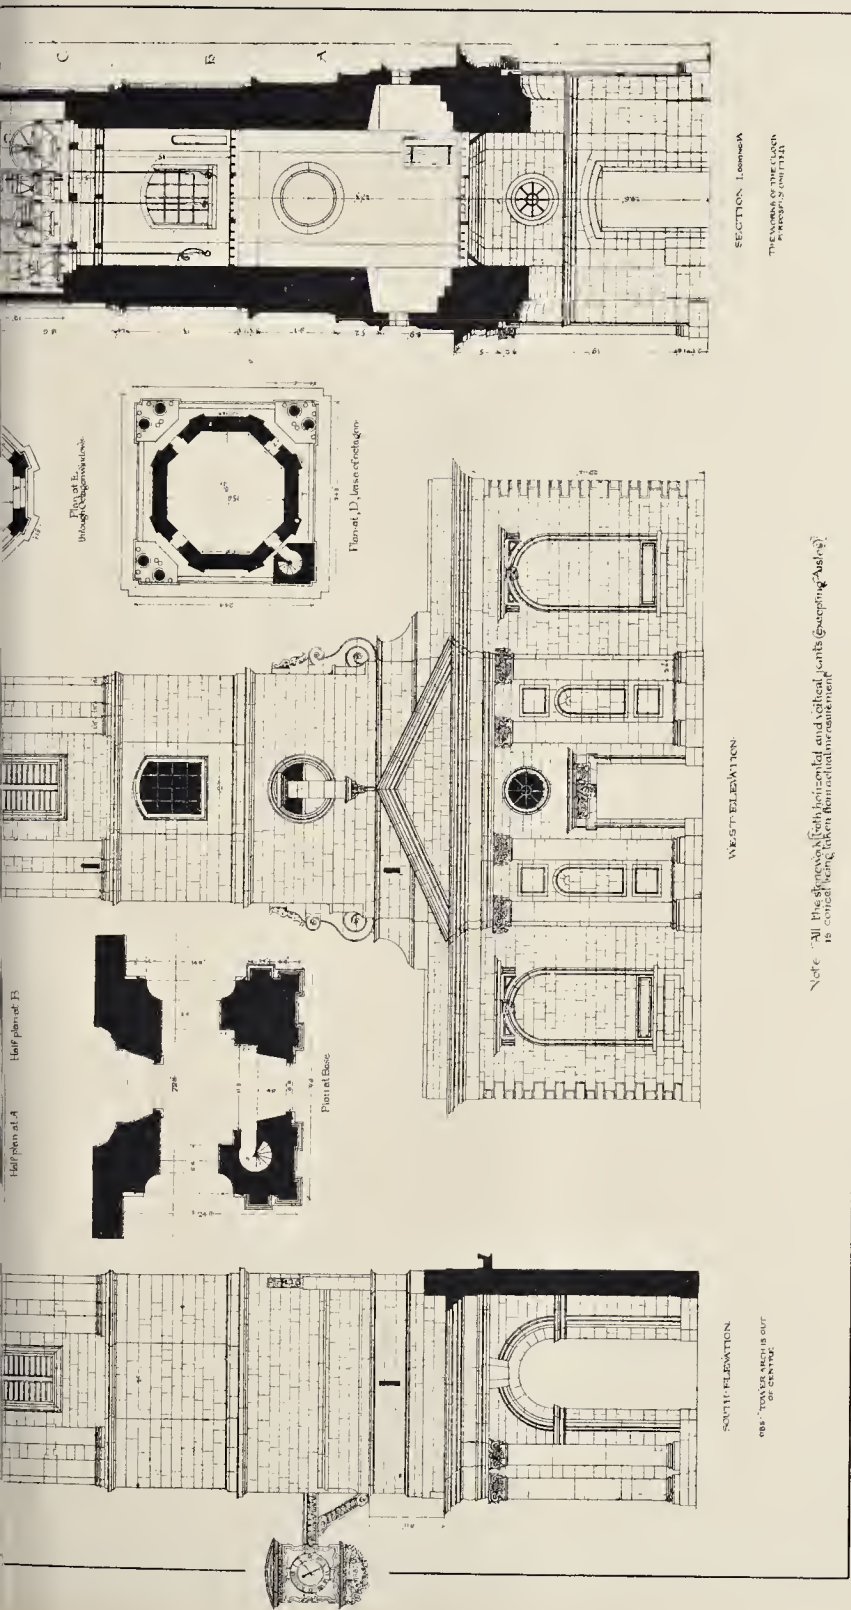

STAIRCASE, ETC., OLD HOUSE,
74, LOWER THAMES-STREET.

The staircase and fireplaces in this house (either pulled down or condemned) are excellent examples of the woodwork of the time of Charles II. Though a good deal of the panelling, &c., is destroyed, there is still sufficient left to be very instructive as to the internal decoration of a house of this date. The accompanying drawings were made some weeks ago, when the intended destruction of the house was first announced; but demands upon our space have compelled us to defer their publication.

Wall-Papers founded on Natural Forms.—Designed by Mr. C. F. A. Voysey, for Messrs. Woollams & Co.

DESIGNS FOR WALL PAPERS.

The accompanying cuts show two out of a series of designs for wall-papers exhibited by Messrs. Woollams & Co. at the recent Building Trades' Exhibition, and designed for them by Mr. C. F. A. Voysey, employing suggestions from natural forms of vegetation. The one on the right, if we mistake not, is based on some seaweed forms, a type of vegetation which may be found to supply some new suggestions in decorative detail.

CRYSTAL PALACE SCHOOL OF ENGINEERING.

The Easter term was brought to a close on Saturday last by presentation to the students of the certificates awarded by the Examiners. Mr. W. H. Barlow, C.E., F.R.S., presided, and addressed the students in an interesting practical address. From Mr. Barlow's address, and the reports of the Examiners, Messrs. R. Fogg, F.E., M.E., and W. B. Lewis, C.E., with the complementary speech of Mr. Fogg, it appears that the efficiency of the school is fully sustained, each of these experts bearing strong testimony to the value and thoroughness of the course of instruction given when taken fully, and its capabilities of usefulness if even taken for a single year. We notice that there has been a further expansion of the curriculum by the addition of a fourth term in the Civil Engineering Section, which is devoted to designing special and original engineering work. The students of the third term were, during the last term, exercised in "Design and Construction of Railway Dock." The creditable circumstance was mentioned by Mr. Wilson, Principal of the school, that of thirty-eight students who had attended during the term his course of lectures, which were on "Steam" for this term, all had earned a sufficient number of marks to make them eligible for examination except one, and he had unfortunately been prevented by illness. Mr. Wilson also stated that of 600 students who had passed through the school, 75 per cent. were known to be in good positions as civil, naval, military, and mechanical engineers, at different

places at home and abroad. Forty past students were now also Associate-Members of the Institution of Civil Engineers.

Of twenty-five students who received certificates for passing successfully the lecture examination, W. Bosman and F. Stewart were equal firsts, with 239 marks out of 273 marks attainable, E. J. Prow was first for work in the drawing office; B. Cadwell, for work in the pattern-shop; F. B. Dixon, in the fitting-shop. For students of the second year's course: Civil Engineering,—the firsts were, for first term, J. F. Harrison; second term, M. Mawson; third term, equal firsts, B. Marsland and C. H. D. Pettigrew; fourth term (third year), J. J. Croyle. Six certificates were awarded to students in the Colonial section.

ARCHITECTURAL SOCIETIES.

Birmingham Architectural Association.—The annual dinner of this Association was held at the Grand Hotel, Colmore-row, Mr. F. B. Osborn (President) in the chair. Mr. J. Cotton occupied the vice-chair, and among those present were Messrs. Victor Scruton (Hon. Sec.), Hughes, Wood, Newton, E. R. Taylor, T. Tonks, Jonathan Pratt, Hart, Churchill, and Hale. Mr. E. Wood proposed "The Profession," and, in speaking of the profession, said he was of opinion that they stood in a better position to-day than they had done for many years past from an artistic point of view, and also in the estimation of the public. Although pecuniary considerations could not be altogether overlooked, he thought it was to the advantage of every individual member of the Association to foster the love of art and the appreciation of the public foremost. Mr. Cotton, who responded, said, as a local body they might congratulate themselves that at least two practitioners out of five had their designs selected in the final competition for the Assize Courts, and it would be still more gratifying if a Birmingham man pulled off the prize. "The Association" was proposed by the President, who said, at the present time they had a greater number of members than at any previous

period of the Association, which deserved all they could do to advance it in every way. They numbered now something like sixty-five members. The classes of the society were eminently successful, and well attended. As they knew, the Royal Institute in London had now closed its doors unless applicants passed certain examinations, and the best way to gain the knowledge for those examinations was to belong to an Association like theirs.

Edinburgh Architectural Association.—The usual fortnightly meeting of this Association was held in the Professional Hall on the 15th inst. The President, Mr. G. Washington Browne, occupied the chair. After the usual preliminary business had been disposed of, the Chairman called on Mr. James Sellars, President of the Glasgow Institute of Architects, to read his paper on the "General Building and Sanitary Regulations for Scotland." Mr. Sellars began by stating that the Glasgow Institute had long held the opinion that such regulations should be eliminated from the various Police Acts, and embodied in a separate Act, in which all matters relating to the construction and sanitary arrangement of buildings would be dealt with, and which Bill should, in his opinion, be applicable to the whole of Scotland. His audience were aware that a Burgh Police and Health (Scotland) Bill had been before Parliament for some time, and it had now passed the House of Lords. He thought the Bill a very excellent one in respect of its sanitary regulations, but it was not, in his view, satisfactory as regards building regulations. Indeed, in his opinion, it might be said that the Bill did not contain building regulations at all in the proper sense. The details of building construction which could be clearly defined, and were so defined in the Metropolitan Building Act, were left indefinite and general. A building, according to this Act, was to be "of sufficient strength and stability," a phrase which would probably not be interpreted in the same way by any two persons. A similar indefiniteness ran through all the regulations relating to sanitary and building matters, and the probable unsatisfactory working of the Act was made all the more likely, as there was no proper provision made for the administration of

the regulations especially in very small burghs where the commissioners, who were to administer them, could not be expected to be properly qualified to judge of such matters themselves or able to afford to have properly qualified officials to advise them. Mr. Sellars described at some length the regulations as to drainage, widths of streets, heights of buildings in streets, and free space areas, construction of buildings, &c., contained in the Police Acts of the chief Burghs in Scotland, and the corresponding regulations in the Burgh Police and Health (Scotland) Bill, and also the existing provisions and those proposed in the new Bill for the administration of the regulations. He was of opinion that such matters were not in their proper place in a Police Bill which fittingly enough dealt with the regulation of hackney-coaches, pawnbrokers, fireworks, gunpowder, &c., and that the time had come when a separate Building Act was required. Mr. Sellars concluded by urging the Association to co-operate with the Glasgow Institute and probably other Architectural Associations in Scotland with a view to obtain a separate Building Act. If the Burgh Police and Health Bill passed in its present condition it would probably hamper legislation on the subject for many years to come.

Glasgow Architectural Association.—The Secretary's report for the eighth session (1885-86) says that the roll now shows a membership of fifty-one (this exclusive of hon. members), an increase of nine over last year; nineteen new members having joined and ten resigned. There have been seventeen meetings, with an average attendance of twenty. Eight papers were read and discussed at the general monthly meetings, and, as formerly, a series of lectures has been delivered during the latter months of the session, attended by architectural assistants outside of the Association and those professionally interested, as well as by members. The subjects were:—"Marbles, Mosaics, and Tiles," by Mr. William Gilfillan; "An Architectural Excursion," Mr. Thomas Gildard, architect; "Heraldry," Mr. John Baird, F.R.I.B.A., I.A.; "Foundations," Mr. David Barclay, F.R.I.B.A.; and "Architectural Detail," Mr. T. L. Watson, F.R.I.B.A., I.A. Interesting visits were paid to the following buildings:—Conservative Club, New Medical Schools, and Drumshugh Baths, Edinburgh; Mount Stuart House, Rothesay; Greenock Municipal Buildings; Linnithgow Palace, Kent road School, and Hillhead Public School. Honorary President's prize,—subject, Design for Memorial Chapel,—was gained by Mr. William James Anderson. Prizes presented by Mr. John Burnet, hon. member, F.R.I.B.A., I.A.:—Subjects, Measured Drawings of Atrium, gained by Mr. M. Gibson and Mr. Peacock; Measured Drawings of Old College, gained by Mr. Shanks; Best Collection of Sketches, gained by Mr. Charles Gourlay. The chief novelty of the session was the publication, in May, of the first Sketch-book.

A BUILDER'S CLAIM.

HASKELL V. BRADBEEER.

This case was tried before Judge Eldis, at the Clerkenwell County Court, on Thursday the 15th inst. Mr. Wills, barrister (instructed by Mr. Lowe), appeared for the plaintiff, and Mr. Popham, solicitor, for the defendant.

Mr. Wills stated that the plaintiff, Mr. W. J. Haskell, was a builder, of 38, Coldbath-square, and that this was a claim of 27*l.* 13*s.* for work and repairs done at the defendant's shop, 6, Great Bath-street, Clerkenwell.

Plaintiff stated that when the conversation first took place about the matter, defendant asked him how much it would cost to paint and grain his shop, inside and out, and he said about 20*l.*, but that he had better prepare him an estimate; the work was, however, commenced, and some extras beyond the work spoken of were done, and he sent in his claim for 27*l.* 13*s.*

Mr. W. F. Potter, architect, and Mr. C. R. Griffiths, architect and surveyor, gave evidence that they had measured and valued the work, and estimated it at 32*l.* 16*s.* 11*d.*

For the defence it was first alleged that it was a contract to do all the work charged for 20*l.*, and that the amount charged was excessive.

Mr. Irons, Surveyor to the Clerkenwell Vestry, was called to prove that the charges were high, but he admitted in cross-examination that he had not measured up the work.

His Honour, in giving judgment, said that he did not think the defendant's statement that there was a contract had been proved; on the contrary, he thought the plaintiff had fairly made out his case, and that his charges were fair and reasonable; he, therefore, gave a verdict for the plaintiff for the amount claimed, with costs.

SUNDERLAND MUNICIPAL BUILDINGS COMPETITION.

SIR,—I am a stickler for the observance of regulations in the present as in all such competitions. But I do feel that in disqualifying two of my fellow competitors for being a few hours late, the Committee have been rather too strict.

If they are equally strict in disqualifying all designs not done on their regulation "double elephant," and "without frames or bolts" or "colour," I fear others will have to share in the unfortunate fate of the two above-named.

As regards the style of getting up the drawings, the Committee ought to keep to their text, because, as we all know, that sort of thing does tell for or against a design very powerfully, even with comparatively skilled critics. But to disqualify the Edinburgh architect who posted his plans on Saturday, because they arrived a few hours after midnight, is really carrying things too far.

A COMPETING SUNDERLAND ARCHITECT.

STONE-SAWING MACHINERY.

SIR,—We observe in your issue of the 10th inst. [p. 563] a letter from Mr. Lewis Bale describing some Belgian stone-sawing machines which he considers to be "considerably in advance of any machines for the like purpose yet made in this country."

As we have manufactured, and made a special study of, stone-sawing machinery for several years past, we trust that you will allow us to state that we have turned out a number of machines constructed as described by Mr. Bale, in which the saw-frame is driven by a pair of side-levers instead of the one long connecting-rod or pendulum.

We also fit our machines with an improved self-acting downward-feed motion, and a self-acting gear for winding the saw up out of the stone when the block is cut through. We trust that your readers will be good enough to favour us with their inquiries before placing their orders for stone-sawing machinery with Belgian manufacturers.

E. P. BASTIN & CO.

West Drayton.

SIR,—I can only conclude your correspondent, Mr. Lee, can hardly have an accurate knowledge of facts, or he would not write as he does in your last issue [p. 593]. I am well acquainted with Cox's stone-sawing frame, and, I believe, with every other of any note made in this country, and many of those made on the Continent and in America. As Mr. Lee suggests Cox's frame has been copied in Belgium, for his information I may say that the firm whose machines were alluded to in the recent trial made crank-worked side-lever machines years before Cox's patent was taken out. In addition to this, however, the Belgian machines contain a most perfect sanding arrangement, and extremely clever automatic raising and lowering and adjustable downward feed movements controlled by one lever; in fact, the whole design is so good that it was, I think, the unanimous opinion of myself and the other engineers who went to Paris to witness the trials (several of whom are makers of stone saws) that these Belgian machines are far ahead of anything yet made in this country. I have no interest whatever in the Belgian machines,—rather the reverse,—but I think the time has gone by for us to sit at home "and fancy our little world making," in stone-working machinery as in other matters. I therefore wrote a short description of the machines, thinking it would interest your readers.

As from a user of machinery, Mr. Lee's opinion should doubtless be received with respect, but I think it highly probable that he cannot name the maker of these Belgian machines, and he certainly has never seen them at work; therefore, I take it, his dictum must be taken *cum grano salis*.

M. POWIS BALS,

Author of "Stoneworking Machinery," &c.

A QUESTION OF CEMENT PATENTS.

SIR,—As much has recently been published as to the alleged excellence of Robinson's cement, may we claim a portion of your space to ask Messrs. Robinson if they will point out the difference between their patent and the "cement or plaster" patent taken out by Mr. A. Francis in 1856?

Quoting from the recently-published patent of Mr. Thomlinson (Robinson & Co) we have as the essential part, the parentheses being our own:—"I find the calcined gypsum in the usual manner to a fine powder. I also in like manner, and separately grind (some) tinal (native borax). I mix the two powders in the proportion of about 40 lb. to 50 lb. of tinal to the ton of calcined gypsum; the proportions may be varied."

Mr. Francis's patent of May 6th, 1856, says:—"I first subject the gypsum to heat to calcine it, and then mix therewith dry borax. It is equally important to reduce the dry borax to a very fine powder, and in this finely-powdered state I mix it with calcined gypsum, reduced by grinding or otherwise to a fine powder. The proportions of the

compositions which I have found to answer well are 40 lb. of dry borax to 20 cwt. of calcined gypsum, but these proportions may be varied."

Mr. Thomlinson continues his specification:—"In some cases I mix other materials as well as tinal with the calcined gypsum, thus a good cement is obtained from the following materials:—

Finely-powdered calcined gypsum, 1 ton.
" " tinal, 45 lb.
" " alum, 15 lb.

The cement thus made I call Robinson's cement."

Finally, "I declare that what I claim is a cement consisting of calcined and powdered gypsum, mixed with powdered tinal, and with or without other ingredients, substantially as described."

The use of alum for the hardening of plaster is a very old expedient, well known to every plasterer. Subject to correction, we therefore claim that it is open to anybody to manufacture and sell an article identical with Robinson's cement as above described.

JOHN HOWE & CO.

Carlisle, April 20, 1886.

PROVINCIAL NEWS.

Accrington.—On the 5th instant, Major General Hutchinson, R.E., inspected the tramways recently constructed by the Corporation of Accrington, which extend for a length of nearly six miles through the borough, and into the adjoining townships of Church and Clayton-le-Moors. The General examined the depot and then went over the whole length of the line with an engine and car, accompanied by Mr. Alderman Hindle and Mr. F. S. Bnton, Borough Surveyor (representing the Corporation), Messrs. C. C. Cramp and A. C. Cubitt (directors), with Mr. Whyster Holt, C.E. (representing the Company who have leased the lines from the Corporation for a term of twenty-one years), and Mr. Rowley (representing the makers of the engines). Several slight alterations are required to be made before the lines are worked by the full complement of engines and cars; but the General gave his consent to the lines being worked at once on the understanding that the requisite alterations would be made. The certificate of the Board of Trade was received on Tuesday last, and the lines are now being worked by two engines and two cars, but the full number intended to be worked is eight engines and eight cars. The engines are built by Messrs. Green & Son, Smithfield Ironwork, Leeds, and the cars by the Falcon Car Company, of Longborough.

Birmingham.—Mr. James Kent, a well-known boot and shoe manufacturer, and the proprietor of a large estate at Olton, about seven miles from Birmingham, has, in order to open up the estate, commenced building operations. At the present time he has eighteen villa residences in course of erection. They recede a considerable distance from the road, and are replete with conveniences for this class of building. The front elevations are Gothic in style.—On the "Gillott" estate, also, near this town, Mr. Edward Airey, the contractor for the Artisans' Dwellings, has in course of erection twenty or villa residences. These houses are of somewhat similar arrangement and style to those just mentioned. The cost of the whole of the buildings will be about 10,000*l.* Mr. J. Stabat Davis, of Birmingham, is the architect.

Brighton.—The plans of the New Palace Hotel at Brighton have been approved by the Brighton Town Council, and shortly the work of constructing the hotel will be commenced. The site comprises the premises occupied by Matton's Hotel and Restaurant, 80 to 83, King's-road, Whitehall Yard-mews, and the premises held by W. Challen, jeweller, and Messrs. Savory & Moore, chemists, at the bottom of Russell-street. The building will be nine stories high, and will contain 400 rooms, and also contain spacious public rooms, baths, & a Bijon theatre, with *oyer*, on the plan of the Grand Opera, Paris, will be attached to the grand saloon, the whole illuminated by the electric light. The area to be utilised contains 24,450 superficial feet; the frontage on the King's-road will be 125 ft., and in Russell-street 238 ft. The capital required in 20,000 10*l.* shares is 200,000*l.*, and it is contemplated the hotel will be open in about eighteen months. The architect is Mr. F. T. Pilkington, of Russell-square, London.—Plans have been prepared for the erection, on the site of the Grand Concert-hall, in West-street (destroyed by fire two or three years ago), of a theatre and opera-house, to be called the "Grand Theatre," capable of holding over 3,000 spectators, at a

estimated cost of 36,000l. Messrs. Bucknall & Jennings, of Clifton, Bristol, have prepared the plans, which are before the Town Council, and the scheme is to be developed by a limited liability company.—We hear that active steps are being taken to erect a new Bijou theatre or the West-enders in the Western road.

Stourcliffe (Bournemouth).—A new chime is about to be cut at Stourcliffe, three miles to the east of Bournemouth Pier, where access to the beach is much required. A committee of neighbouring landowners having been formed to take the matter in hand, have appointed Mr. Reginald Pinder, F.R.I.B.A., of Bournemouth, as engineer, and plans are approved showing a road with a gradient of about 1 in 7 $\frac{1}{2}$, and a total difference of level of 100 ft., with surface-drains, foot-walls, &c.

STAINED GLASS.

Appleton (Yorks).—A Munich stained-glass window has just been erected in Appleton church, Yorkshire, in memory of the late Mrs. Handso-Pole. The subject represented in the window, which consists of two lights, is Christ in the house of Martha and Mary, while in the apse above is a bust of St. Catherine. The artists are Messrs. Mayer & Co., of Munich and London.

Rainhill.—On Sunday, the 18th inst., a large stained-glass window, by Messrs. Heaton, Butler & Bayne, was unveiled at St. Anne's church, the subject it illustrates being the situation of the Lord's Supper. It is of good sign, the figures being well drawn, and the general effect of colour pleasing and harmonious. The stained glass fills the east window of the church, which is a large one of seven lights, in a perpendicular style, by the late Mr. G. H. Duddle, of Liverpool, who was the architect to whom the enlargement of the church was varied out about seventeen years ago. The window is in memory of the late Mr. George Anderson, of Rainhill (who at the time of his death was a churchwarden), and is presented by his widow. During the last few years, the interior of this church has been greatly improved by memorial gifts, a richly carved and corbelled reredos having been contributed by Mrs. Clay, widow of the late Vicar, the Rev. Walter Clay; and also corresponding side panels—screens, by Mr. John Birchall, in memory of his wife and mother (both being among the designs of the late Mr. G. H. Duddle). These, with the addition of the handsome and costly stained-glass window just described, have converted a chance of somewhat faded and incomplete appearance into one possessing very considerable architectural merit.

The Student's Column.

OUR BUILDING STONES.—VII.
HARDNESS OF STONE.

HARDNESS is quite distinct from specific gravity. It applies more especially to the different minerals forming a rock, rather than to the rock as a whole. The scale of hardness in use among mineralogists is divided into ten degrees, each noted by the name of some mineral:—1, talc; 2, rock-salt; 3, calcite; 4, fluor-spar; 5, apatite; 6, orthoclase; 7, quartz; 8, topaz; 9, corundum; 10, diamond.

Many stones used in building are partly made up of the mineral calcite, and it is not always easy at first sight to distinguish this mineral from quartz. Calcite and quartz weather very differently from each other, and make a considerable difference in the cost of working the stone. The degree of hardness of these two minerals, however, is such that they can be easily distinguished from each other. If we use a pocket-knife, we shall find it is with the greatest difficulty that we are able to scratch calcite, but if the mineral should be calcite, it is very easily marked.

The brittleness of a stone as distinct from its hardness is an important factor in estimating the cost of working. Stones of the greatest durability are often largely made of silica, and are very brittle, breaking with a splintery fracture. Nearly all workable stones have a similar method of fracturing, which cannot be defined or found out, except by a practical acquaintance in shaping each kind.

THE EXAMINATION OF STONE BY THE MICROSCOPE.

We have seen that the weathering of stones, in a great measure, depends on their structure. Even where chemical composition would seem to indicate that certain kinds are unfit to withstand the destructive effects of the atmosphere, structure comes to their aid, and often produces good stones. The effects of frost, amount of absorption of water, strength and density, are all dependent on minute structure.

The minute parts of a stone are always the first to decay, and if, therefore, we can properly understand them, we shall strike at the very root of its weakness.

The instrument we propose to use in the investigation of these minute parts is the microscope. By highly magnifying pieces of stone, which are ground down to transparency, it shows what the structure is like better than any other means at our command. In many cases it directly points out the nature of the matrix of a stone, upon which the weathering might solely depend. It very largely shows the distribution of the chemicals in the rock, rigidly defining the crystals or crystalline particles composing it, which a chemical analysis of the aggregate totally fails to do.

But the microscope requires careful handling. It is only after considerable experience that anything like precision in the determination of good and bad stones is gained. This mode of investigation, although so much used by geologists to help them in unravelling the complex problems presented by igneous and metamorphic rocks, has been but very little introduced for the examination of aqueous rocks, — the chief building stones of our country. So that, whilst we will do our best to help the student to prosecute this part of the inquiry for himself, he must bear in mind that the principles we shall lay down are only the beginning of what will probably develop into an important part in the study of the selection of stone for building purposes.

Apart from the high character of the results obtainable by this method of investigation, and their very practical bearing, we have the element of cheapness,—a matter of considerable importance now-a-days.

When the microscope and its few accessories are purchased, the principal expense is at an end. If the student does not care to grind down his own pieces of rock for examination, there are several lapidaries, and mounters of microscopical objects, who would be glad to do so for him at 1s. 6d. per slide, and more cheaply if several slides are required. But we would strongly recommend that at first he should grind and mount his own specimens, for he then becomes more familiar with the stones, whilst practice teaches him the peculiar features consequent on bad mounting.

We will first treat of the microscope and its necessary accessories. The microscope required need not be of a very expensive character. A complete enough examination may be carried out with one capable of magnifying 100 diameters, whilst it is often found more convenient to use a much lower power,—60 diameters.

The stages of the more expensive microscopes used in examining rocks are usually made to revolve, as there are many advantages derived; and they have also rackwork for moving the object under examination to and fro, or up and down. A special contrivance for successively bringing various different magnifying powers to bear, without having to screw and unscrew them as required, and rackwork for fine adjustment have been invented, but none of these are absolutely necessary for our purposes, although if they are obtained, so much the better, as they save much time and trouble. The numerous small pieces of apparatus necessary for physiological work, are not needed in the examination of rocks and minerals.

The microscope, however, must have a polariscope attached. The polarising apparatus commonly employed consists of two Nicol's prisms,—one placed above the eye-piece of the instrument, or above the objective, which acts as the analyser; the other fitted under the stage of the microscope being the polariser. The polariser should always be placed so that it revolves freely when turned by the hand.

The Nicol's prism is constructed out of a rhombohedron of Iceland spar, about 1 in. in height, and $\frac{1}{2}$ in. in breadth. This is bisected

in the plane which passes through the obtuse angles. The two halves are then again joined in the same order by means of Canada balsam. It polarises light completely, and transmits only one beam of polarised light, the other being entirely suppressed.*

The field of the microscope appears clear and well illuminated when the shorter diagonals of the two prisms coincide in direction, but when they are placed at right angles to one another the field appears quite dark, light being totally extinguished. The intermediate positions exhibit different shades, either dark or light according to the relation of one prism to the other.

The use of the polariscope is briefly this. If the rock under examination contains any portions that are amorphous (that is, those in which no crystalline structure is developed), or crystals belonging to the cubic system, with, perhaps, too exceptions, they will be seen to become light and dark as the polariser is revolved. This is owing to their being singly-refracting, or isotropic substances.

If, however, the stone contains crystals belonging to one of the other crystallographic systems it will modify the polarised beam of light. All such minerals or crystals are said to polarise; in other words, they exhibit double-refraction, and are called anisotropic.

The direction in which the sections of the crystals is cut must be taken into consideration, because, under certain circumstances, as we shall presently see, they become singly-refractive. In cutting rock sections for our purposes of examination it would be quite an accident were any of these peculiar conditions to present themselves, as, generally speaking, the stone would be chipped at random, without any attention being paid to the direction of the blow.

Another test with the polarising apparatus, very useful in determining the mineral constituents of rocks, is in finding whether any pleochroism or dichroism is present. To do this the upper Nicol prism is removed, leaving only the lower. If, as we rotate the latter, no change in tint is observed, there is no pleochroic mineral present, or at least none which shows pleochroism at the angle at which it has been sliced; but very often the hue of certain crystals is changed, and they present many different colours. This is pleochroism. When, during the rotation of the prism, only two colours have been observed, the minerals presenting that appearance are said to be dichroic, or to exhibit dichroism.

Dichroism, or pleochroism, practically never occurs in crystals belonging to the cubic system. It is exceedingly useful in the determination of some common rock-forming minerals, enabling us, in most cases, at a glance to distinguish crystals in many other respects resembling each other.

A useful accessory to the microscope is a bull's-eye condenser, which is used to examine rock sections by reflected light. This is done by throwing the mirror, under the stage of the microscope, out of gear, and, by means of the condenser, directing a strong light on the surface of the section. The advantage of this method is more particularly noticeable in the case of minerals, which, when examined by transmitted light, are seen as black objects,—opaque.

Reflected light often enables us to discover the character of, and to define, opaque minerals. A lamp giving a good light may also be obtained specially for microscopic purposes.

Books.

The American Journal of Archaeology and of the History of the Fine Arts. Baltimore. Vol. I, No. 4.

THE fourth number of the American "Journal of Archaeology" completes the first volume of this very valuable publication. The great strength of the periodical is still its excellent summary of the archaeological news of the year and of the contents of current journals. In this matter it has no superior, and only one rival, the *Gazette Archéologique* of Lenormant and De Witte,—a publication which is, however, too costly to be in the hands of any but professionals. In the field of classical

* *The polarisation of light is well explained in Ganot's "Physics," 1853, pp. 581-6.*

archæology this fourth number has several original papers of interest. M. Salomon Reinach makes a timely publication (in phototype) of a small bronze basin, which, long known to archæologists, has gained fresh interest since the French excavations of last spring at Akraiphia, in Bœotia. The basin still supports two fragmentary feet of very delicate workmanship, but its great interest lies in the long inscription engraved upon it. The inscription runs as follows:—*Τιμασιφιλος μ' ανιθηκε τω 'Ηλοιο τω Ηρωι*, i.e., "Timasiphilos has dedicated me to the Ptoian Apollo." After this perfectly simple and easy dication there follow certain letters which no epigraphist has as yet interpreted, but, as M. Reinach wisely thinks, publication should and must often precede elucidation,—*primum edere, deinde philosophari*.

It will be seen that, in the present number of the *Builder* (p. 603, ante), we have noted the excavations carried out on the site of the ancient Temple of Apollo Ptoos, near Bœotia. M. Maurice Holleaux superintended them, and has had the good fortune to bring to light a number of votive inscriptions similar to that on the bronze, and also a quantity of architectural remains of the temple. He has also found a life-size archaic statue of Apollo Ptoos himself, which is to be published next year in the *Bulletin Hellénique*. The bronze published by M. Reinach is now in Paris in the possession of M. Eugene Piot. He bought it twenty years ago at Athens, but was told at the time that it had been found in Bœotia. Mr. Augustus Merriam publishes a long and interesting commentary on the Gortyna inscription, which we recently noted. This is the first detailed notice the inscription has received in the English language. M. Reinach also publishes a marble statue of Artemis, now in the Tchiny-Kiosk Museum at Constantinople. He thinks it possible that we have in this statue a small-sized replica of the Artemis Brauronia, seen by Pausanias on the Acropolis, and noted by him as the work of Praxiteles. Anyhow, this much is certain, that the Constantinople figure reproduces in a striking way the lolling attitude of the Praxitelean satyr.

For the next year we are promised papers by Mr. J. T. Clarke, the explorer of Assos, and notes and inscriptions collected by Professor Ramsay in Asia Minor; also, among a host of foreign contributors, Dr. Helbig and M. Ernst Bahelen have promised their help. Apart, however, from so promising a programme, we must repeat that, for the student as well as the expert who desires to be au courant with archæological news, the journal is simply indispensable.

A Manual of Greek Archaeology. By MAXIME COLLIGNON. Translated by JOHN HENRY WRIGHT. Cassell & Co. 1886.

We are glad to welcome the English translation of M. Collignon's excellent manual. Handbooks of Greek sculpture by this time abound, but M. Collignon's book remains unique in that it treats of Greek archæology as a whole, giving due weight to the evidence of minor arts such as vase-paintings, terra-cottas, coins, bronzes, gems. As we have discussed the merits of this and several successive volumes of the *Bibliothèque de l'Enseignement des Beaux Arts*, it only remains now to say a word as to the translation. In some respects distinct advance is made on the original, noticeably in the matter of the short bibliographies printed at the head of each chapter; here Mr. T. H. Wright has re-written the references up to date, and naturally due weight is given to recent English and American research; the references also gain much in clearness at small sacrifice of space by being printed in separate lines; in an elementary text-book no teacher of archæology will think those matters of small importance. Further, the illustrations have been enriched, e.g., in the chapter on terra-cottas, the interesting Berlin plaque showing miners at work at the base of a hill, cited before, is now reproduced in outline. With so much to recommend the book, we regret to have to say that the translation is always inelegant and sometimes inaccurate. The inaccuracies do not seriously affect the subject matter, but they just betray want of touch with the delicacies of the French language and want of close, sharp constraining. On the very first page, as we open the book, we find "Quelques rares mentions dans les documents écrits de l'Égypte" rendered "occasional scattered references in documents written in Egypt," a slipshod rendering which speaks sorry volumes for

the state of the translator's mind. The commonest care would have avoided Gallicisms like "Mythological scenes, where figure all the Olympian divinities," such sentences, irritating and distracting, occur by the dozen. Those who know M. Collignon's delicate, lucid French will feel that the translation can honestly be recommended as useful, but only (till revised, as we trust it will be in a second edition) to those wholly ignorant of the original tongue.

A Digest of the Law of Light. By EDWARD STANLEY ROSCOE, Barrister-at-Law. Second Edition. London: Reeves & Turner.

This excellent handbook is rightly named a digest, for it gives all that need be known upon the subject by a layman, in a concentrated form. The rationale of the law affecting this important easement has never, to our knowledge, been so clearly and concisely stated before, and the architect and surveyor will find in it a text-book of the greatest value in his dealing with the often complicated questions upon which it treats. The method of the work is not the least admirable part of it. First, the creation of the right by uninterrupted enjoyment, confirmed by prescription, is discussed, with all the essential particulars as to what that enjoyment consists in, and illustrations drawn from determined cases. Next the means by which an accruing right to light may be prevented. The effect of the abandonment or suspension of the right and the means of reassertion form the subject of a third section of the book, and following it is a clear exposition of the extent of the right with and without certain modifications. Finally, the means by which the right may be vindicated are duly set out, with forms of reservation to a grantee, of acknowledgment, of pleading, and of injunction. There are extracts from the Prescription Act,—which is the foundation of legislation on the subject,—the Common Law Procedure Act, Lord Cairns's Act of 1858, and the Judicature Act of 1873,—with the well-known clause 29, from the Metropolitan Building Act. Much practical advice on the whole subject of differences as to the right to light and its infringement is given by way of appendix, and a very useful series of what are called "plans," but which are really elevations, showing the result of decisions in cases where new windows have replaced old ones, identical in area and position, or varying in one or both of these particulars.

The vexed question as to how the value of obstructed light is to be estimated is very properly omitted, as beyond the scope of a work on the law of light. The author is very strong on the prudence of owners having plans (i.e., elevations) of their premises kept with their title-deeds, showing clearly and accurately every window; and he quotes approvingly Mr. Justice Baggallay's very pertinent remarks on this head:—"Having regard to the importance of the right to light, plans of the windows should always be made, even if there is no present intention of pulling down or altering a building. The small expense will always be many times recouped by the fact that a permanent record of the position of the ancient lights is in existence."

This is a book which really should be on every architect's shelves, for it is full of sound information and wise counsel on points with which any architect may at any moment be called upon to deal.

Bevis's Builder's and Contractor's Price Book, and Guide to Estimating. 1886. London: The Scientific Publishing Company, Limited.

This work, which is again edited by Mr. Bevis, introduces a new feature in the shape of "novelties," or new inventions; we note among these a push-and-pull lock of Chubb's; we thought this was the special patent of Kaye & Son; the locks of this latter maker seem the cheapest. Folding lavatories seem to be very useful where space is limited; the automatic electric speaking tubes appear to be rather too complicated to be efficient.

In Section I.—Plant, Machinery, &c.—the prices of plant, &c., are given much lower in many cases than in the last edition.

In the Excavator, page 50, concrete is given in gravel or burned hallast as being of the same value. This is an error: if the gravel or stone hallast is to be obtained on the site at the cost only of digging and screening, it is

then, of course, cheaper than burned hallast, whether you burn the latter yourself, or buy it, but if the stone hallast has to be bought the cost will be much more than in burned hallast.

The price of 1s. 3d. per foot run for strutting and planking 6 ft. deep is much too high, so is the list of drain-pipes, exclusive of digging or laying.

In the Bricklayer, page 59, the prices are materially lowered, though they are still too high. There is rather an odd error in the printing of extra facings in "picked stones" instead of stocks. We are pleased to see that the daywork prices for labour have been properly revised; the last edition had them a little below prime cost; the prices for horse cart, and man, have also been altered. There must surely be an error in the price of the Victoria stone damp course, 100 ft. super for tenpence.

The prices of lime that are given as including profit, &c., are only p. c., and the hair is less than p. c. The prices of glazed bricks are low. In Section V.—Slater,—there is an error in the second paragraph, the allowance for raves in inches slating is 12 in.; contes 10 in., and ladies, 8 in., the usual custom being both with slaters and surveyors to allow the width of the slate, and the method for measuring a slate cistern is not given quite clearly, the sides are usually about 4 in. longer (i.e., 2 in. each end) than the outside of the ends which are grooved into the sides. The slate shelves are too low in price; p. c. prices are given.

In Section VI.—Stonemason,—stone is given at p. c. prices. Bath stone sawing is given at 6d., and Portland at 7d. This seems very careless; Bath stone sawing is not worth half of Portland.

In Section IX. we are glad to see that the prices for floors have been increased. They are now in yellow deal, the best we have seen, at should only be used for pricing estimates at, they are close. The prices of doors, &c., are many of them still much too high, and need very carefully revising.

There is a useful list of the prime cost prices of deals, &c., and the note attached to it must be borne in mind in using them. This is the carting, profit, waste, and sawing to do in the hard woods this will increase the cost at least 2d. per foot super. in the inch. The prices given for "windows" are out of all question.

A very full list of ventilators is given under Section XII.

The prices of rolled joists on pages 158 at 15s. are very low, and really prime cost, by ton.

In the Plasterer, Section XV., page 170, the prices for cement work are low, and can be used in competition. The plasterer should get the same price per hour, daywork, as other mechanics. He is given at 10d.

The plate-glass is too high. Under Sundries, Section XXI., there are a good many useful outside prices.

The present edition is a great improvement on the last one, and is much more reliable.

The Artist's Manual of Pigments: Shows their Composition, Conditions of Permanence, Non-permanency, and Adulterations; Effluvia in Combination, &c. By H. C. STANDAGE. London: Crosby Lockwood & Co. 1886.

The author of this work considers that the deterioration in colour of many modern English pictures is due to the ignorance of the modern artist as to the actual nature of the materials he employs. One eminent modern artist, Mr. Holman Hunt, not long since stated the contrary as his own experience. He knew, he said, what pigments he ought to have, but could not get them. Mr. Standage supplies a great deal of very valuable information and methods as to the chemical qualities and the effect of the principal pigments used by painters; the tests to ascertain the purity of each, and general remarks on the best uses of each pigment, and what to do with it, and what to do with it. The book appears to be carefully done, and is very concise and brought in convenient compass, and ought to be practically useful. There are appended to it the questions set at the South Kensington School of Art examination in painting, with suggestions to the best books to go to for the answers to them. The author has also added lists of colours of various objects in landscape, and also of palettes of several eminent painters, commencing with that of the P.R.A. Such

to think of little use; they lead only to manerism and imitation. Every artist's palette results from his experience as to the means by which he can best produce the effect he aims at: and this experience must be sought; it cannot be borrowed second-hand.

Warts on Repoussé Work. Illustrated. London: T. J. Gawthorpe.

Mr. GAWTHORPE is apparently both author and publisher of this little pamphlet, which contains a useful description of the process of repoussé working in metal, with illustrations of the tools employed.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

7,707, Utilization of Slag. L. Perin, France. Molten slag is cooled slowly in moulds smeared with sandy clay to prevent adhesion, and sunk in hot bog covered with cinders. The castings may be used for paving and the like, and are suitable for bedding iron for fencing, posts, &c.

14,752, Ventilating Sewers. W. Paulson. The ventilating-pipe, in connexion with the sewer, air, &c., is led to a street lamp, where the foul air passed through the gas-flame or filtered through an arc placed in a compartment at the top of the pipe.

15,275, Making Bricks, Tiles, &c., from Slate (British). J. T. Welsh.

In order to utilise the debris from slate quarries in making bricks, it is pulverised, and, if intended for coarse work, it is mixed with fragments of slate of a somewhat larger size than the particles of pulverised slate. The pulverised material is slightly moistened with water, and is pressed by any of the means usually employed for moulding dry clay into bricks, blocks, or tiles. The moulded articles are then dried or burned, or, if they are required for fine work, they are dried and then pressed into a slip before being burned. (This test is opposed; the case is not yet decided.)

16,258, Water-waste Preventer. H. Wainwright.

The cistern is divided longitudinally by a partition in which is an opening closed by a check valve and a projecting arm. One of the compartments is supplied with the dividing partition is supplied with ball-cock in the usual manner. A weighted sliding-valve is so formed that the valve-spindle has a certain amount of vertical motion. Upon the spindle is a collar which, when in its lowest position, rests upon a projecting arm and keeps the check valve open. When the chain is pulled the first motion raises the collar and closes the check-valve, after which the flushing-valve opens and discharges the contents of the second compartment.

16,701, Planing Machine. P. R. Shiell.

In the driving-shaft of the machine are fixed two levers carrying bands of leather or metal, which pass round a pulley or pulleys, so mounted that the tension of the bands can be regulated by a screw. Strips of wood to be planed are stored in a box, sliding front of which permits only one board to pass out at a time. Strips of metal on the bands rest against the cutters. The boards are fed against the cutters by rods sliding in pillars supported by springs, the tension of which can be regulated.

16,888, Union Joint for Leadon Pipes. A. A. e.

The end of the leadon pipe is passed through a cone and is bell-mouthed by a turn-pin. A coned sleeve is then screwed into the socket, completing the joint. It may be constructed in two parts, cut screw together, and may be used for joining cast-iron, cast-steel, or leadon pipes.

NEW APPLICATIONS FOR PATENTS.

April 9.—4,943, T. Tryford, Manufacturing soft Basins.—4,951, J. Chapman, Planes.—4,953, Cleary, Flushing Water-closets.—4,954, J. & T. Mason, Planes.—4,955, C. Esting, Fasteners for Windows, Draught and Dust Excluder.—4,973, G. Per, Stop for Doors.

April 10.—4,937, C. Henderson, Heating and circulating Stove.—5,007, C. Hongst and J. Shake, Window-sash Fasteners.—5,022, H. Lako, Stove.—5,023, Weaver, Water-closet Apparatus.

April 12.—5,038, C. Esting, Fasteners for Windows.—5,054, A. Strubling, Obtaining Levels of Timbers of Roofs.—5,059, A. Tucker, Locks and Keys.

April 13.—5,110, W. Datsford, Window-sash Fastener.—5,124, W. Allen, Ladders.—5,127, R. Hunt, Stretch Traps, &c.—5,131, C. Gordon, Nest for Cradles.

MEETINGS.

THURSDAY, APRIL 23.
Edinburgh Architectural Association.—Mr. James Gordon on "Gothic Ornament." 8.30 p.m.

FRIDAY, APRIL 30.
Institution of Civil Engineers (Students' Meeting).—Mr. D. S. Capper on "Continuous Railway Brakes." 7.30 p.m.
Junior Engineering Society.—Mr. C. R. Harris on "Some Physical Considerations in Building Operations." 7.45 p.m.

SATURDAY, MAY 1.
Association of Public Sanitary Inspectors.—Address by Mr. Edwin Chadwick, C.B., President. 6.30 p.m.

Miscellaneous.

Science Lectures for the People.—The "Penny Science Lectures" at the Royal Victoria Hall, Waterloo-road, on Tuesday evening last, was delivered by Prof. H. G. Seeley, F.R.S., who took as his subject "Water and its Action in Earth-Shaping." The lecturer clearly explained the erosive action of the tides upon the land, and described the action of glaciers upon mountains. The lecturer's remarks were well illustrated by a number of large photographic views shown by means of a lantern upon a screen filling up the proscenium opening. The audience was very attentive and appreciative. The management of this place of entertainment is to be congratulated on this occasion for providing such excellent science lectures for the people.

Fire Engines and Escapes.—Messrs. Shand, Mason, & Co. have issued a large and elaborately illustrated catalogue of their very various contrivances for contending against, and escaping from fires, including fire-engines, hose, firemen's dress and accoutrements, fire-escapes of many descriptions. A great deal of information is contained in the descriptive matter, and the whole catalogue forms in itself a very useful manual and suggestion book for architects and house-owners in regard to the means for dealing with fires.

Decorations at the Italian Church, Hatton Garden.—The Italian (R.C.) Church in Hatton Garden, erected in 1862, has lately been undergoing internal decoration, the entire walls from floor to cornice, as well as the ceiling, having been painted and enriched by numerous figures representative of scriptural subjects and characters. The ceiling of the nave contains in its central panel a painting of St. Peter (to whom the church is dedicated) in glory, surrounded by angels holding the emblems of his authority and martyrdom. Over the sanctuary is a picture of Paradise, containing figures of the Trinity, the four doctors of the Church, founders of religious orders, and other saints. The apse over the high altar has for its centre piece the Ascension of Our Lord in glory, imparting his last blessing to the Apostles and his Virgin Mother. On either side are the prophets, Isaiah looking towards Christ, and Jeremiah sitting in the ruins of the Temple and weeping over its destruction. Underneath, in bas-reliefs, is seen Christ holding communion with St. Peter, and, in the counter panel, washing the feet of that Apostle. The apses of the Lady-chapel and St. Joseph's are also illuminated by angels hearing the emblems of the Queen of Saints. On either side of the transepts are large windows filled in with paintings. The subjects are the Transfiguration and the Agony in the Garden. These pictures stand 21 ft. high. The whole work has been carried out under the direction of Signor Arnaud, of Caraglio, Piedmont, who has likewise executed all the figures in chiaroscuro. The several paintings are by Cav. Gandi, of Saluzzo, Turin. It is stated that the cost of the decorations will be from 3,000l. to 4,000l.

Leipzig Bourse.—The new house at Leipzig has at length been completed, so far as the exterior is concerned, whilst the interior fittings will be opened for business on the 1st of July next. One portion of the structure has been specially reserved as the permanent offices of the Leipzig Chamber of Commerce. The estimates for the edifice were originally 920,000 marks, or 46,300l., but these have been considerably exceeded, and the total expenditure will ultimately amount to no less than 1,200,000 marks, or 60,000l. sterling. The latter sum, however, includes the outlay for a complete installation for illuminating the buildings throughout with electricity. There are several other architectural works of interest which will be opened in Leipzig during the coming summer, amongst the most important being the City Museum and likewise a magnificent monumental fountain. A deceased Leipzig lady left a considerable sum of money for the erection of the latter work, which it is proposed to construct on Augustus-square, in front of the City Museum.

An Archaeological Anniversary.—The Royal Historical Society has appointed a committee to make arrangements for the celebration of the 800th anniversary of the completion of the great survey of England contained in Domesday Book, which was, almost certainly, finished in the year 1086 A.D., and has invited the leading antiquarian and architectural societies throughout the country to take part in the celebration. The invitation has been accepted by most of the societies, including the Society of Antiquaries and the Royal Institute of British Architects, which have appointed delegates to serve on the committee. Any person interested in Domesday Book, or any learned society to which by chance an invitation has not been sent, may communicate with the hon. secretary, Mr. P. Edward Dove, barrister-at-law, 23, Old Buildings, Lincoln's Inn, London.

The Demolition of Lord Carrington's House.—The second and concluding sale of the materials of Lord Carrington's House, Whitehall, and the adjoining buildings in Whitehall and Whitehall-yard, took place on Tuesday, by Messrs. Horns, Son, and Eversfield, when the whole of the brick and stone work and other materials were disposed of. There was a large attendance, and high prices were obtained, the lead more especially being warmly competed for. This portion of the material on the main building was sold for 213l., whilst that on the stables realised 52l. The total proceeds of the day's sale amounted to 620l., which, added to 615l., the sum produced at the first sale on the 6th inst., brings up the aggregate sum realised for the whole of the materials to 1,235l. The buildings are to be taken down, and the whole of the site cleared, in six weeks.

New School of Art Buildings at Clapham.—A School of Art was some time since established at Clapham, and new buildings in connexion with the institution have just been erected, and are now nearly ready for occupation, on a site in a newly-formed road on the west side of High-street, the principal elevation to this road being 80 ft. in length, the building extending to a depth of upwards of 100 ft., and covering an area of about 8,500 ft. The whole of the central portion of the frontage, which is surmounted by a gable, is faced with Lawrence's red brick, the strings, window arches, and sills being in Brown's patent moulded brick. Immediately under the central gable there is an arched entrance, 8 ft. in width. The two wings on each side of the central portion of the frontage, are faced with stock brick, with red moulded bricks for strings, window-heads, &c. A parapet, running the entire length of the frontage, is decorated with large griffin panels in buff terra-cotta, supplied by Messrs. Stiff, of the Lambeth Potteries, and above these are vases, also in terra-cotta. The building is intended to be heated by hot-water apparatus, supplied by Messrs. Bailey & Co., of Gracechurch-street. Messrs. P. Anson & Son are the architects, and Messrs. Kynoch & Co., Limited, are the contractors, the works being under the immediate superintendence of Mr. Carmichael Kynoch, a member of the firm.

Independent Water supply in London.—Artesian tube wells are now being fixed at the following places in London:—For the supply of the flats and offices of the Albert Hall Mansions, South Kensington, and the Westminster Chambers, Victoria-street, S.W. The depth to be reached in each case, to obtain the required supply, will be over 400 ft. Ere the chalk-beds are reached thick layers of London clay and Woolwich and Reading beds will have to be penetrated. It is only of recent years that this system of obtaining supplies of pure water from deep sources has been so perfected as to almost entirely supersede the old and costly method of sinking dug wells. These artesian wells are protected by an even-sized tube, which is carried from the surface to the chalk beds, so as to prevent any of the polluted springs which are found in the upper beds to contaminate the lower springs. Messrs. C. Isler & Co., of Southwark-street, have had these works entrusted to them.

Association of Municipal and Sanitary Engineers and Surveyors.—The first examination held under the auspices of this Association was held at the Institution of Civil Engineers, Westminster, on Friday and Saturday, the 16th and 17th of April, when nineteen names were entered. The written and graphic examination was taken on the first day, while the *videlicet* occupied the greater portion of Saturday. The examiners were Messrs. R. Vawser, M.Inst. C.E., President of the Association; W. G. Laws, M.Inst. C.E., City Engineer, Newcastle-on-Tyne; E. B. Ellice Clark, M.Inst. C.E., Hove; and C. Dunscombe, M.A., M.Inst. C.E., Liverpool.

The Indestructible Paint Company, Limited, call our attention to the fact that it is now seven years since the Egyptian obelisk known as "Cleopatra's Needle" was protected with Browning's patent preservative solution. Dr. H. C. Bartlett, F.C.S., in a report on the subject, says that whereas on the arrival of the obelisk in this country, "the granite was precisely in that absorbent state that it would imbibed damp from our atmosphere, and become liable to exfoliate and throw off scale after scale under the influence of frost, until but little of the inscriptions would be likely to remain after one or two of our English winters" the obelisk is "sounder than when the solution was first applied, and all four faces are weatherproof."

A New Building Estate on Clapham Common.—What is known as the Clock House Estate on the south side of Clapham Common is about to be laid out for building operations. Several new roads are now in course of construction. The materials of the mansion and outbuildings, together with those of the adjoining mansion, called the "Lees," were sold on Tuesday last preparatory to clearing the site for building purposes. The two mansions and grounds cover an area of upwards of twenty-two acres, with a frontage to the common nearly 900 ft. in length. It is said that the estates will be laid out for the erection of between 300 and 400 high-class residences.

The Enlargement of the Junior Carlton Club.—An extensive enlargement of the Junior Carlton Club, in Pall Mall, which has been in progress during the last twelve months, is now on the point of completion. For the purposes of the enlargement the authorities of the club purchased Adair House adjoining, at the corner of George-street, at an outlay, it is stated, of about 25,000l. The club has now enlarged has a frontage to Pall Mall upwards of 120 ft. in length, with a frontage of about the same length in St. James's-square, together with a west frontage in George-street. The Pall Mall frontage has to some extent undergone reconstruction, the alterations consisting of a new entrance in the centre, 12 ft. in width, on each side double polished granite columns and pilasters surmounted by a balcony, which, it may be stated, is carried the entire length of the frontage at the first-floor level. Prominent bay windows have also been introduced in the ground-floor portion of the building, at the east and west ends of the frontage. The St. James's-square elevation is likewise undergoing certain alterations, bold bay-windows being carried up to the top of the first floor, surmounted by a balustrade. The entrance-hall is being richly ornamented with costly marbles. Internally the building has been to a large extent reconstructed, the alterations and additions including a new reading-room and library on the first floor, and a billiard-room on the floor above. The principal staircase has likewise been reconstructed, and the smoking-room enlarged, whilst a new strangers' smoking-room has been provided. The alterations are expected to be completed early in the approaching summer. The works are being carried out from the designs of Mr. J. Macvicar Anderson, architect. Messrs. Holland & Hannen being the contractors.

Assaulting a Clerk of Works.—At the Farnham Petty Sessions, William Waller was charged with assaulting John Stevenson, clerk of works, employed in the interest of the Farnham Local Board on the drainage works now being carried out in the town. The defendant, who is managing foreman of the Farnham drainage works, had some dispute with the clerk of works about the measuring-up of work and assaulted him, striking him on the head and knocking him down. Mr. Crundwell, who was instructed by the Local Board to conduct the case on behalf of the complainant, said the Local Board wished him to remind the Bench that this was not the first occurrence of the kind, and that there had been an organised opposition to the clerks of works and engineer. A clerk of works should be free and unfettered in his supervision. If he was not fully protected he would find his work very difficult indeed. The Chairman of the Bench said he saw the case in all its bearings, and inflicted a fine of 40s. and costs, and bound the defendant to keep the peace in the sum of 100l. *Surrey and Hants News.*

The Edinburgh International Exhibition.—Messrs. Field & Allan, of George-street, are presenting to the International Exhibition, Edinburgh, a handsome tile pavement, designed by Mr. H. Stephens, to be fixed at the entrance to the grand pavilion. The pavement, which is about 30 ft. long and 12 ft. wide, is treated in a style suitable to the building and in harmony with the surroundings. The pavement is 4 ft. square, and is composed of sixty-four 6-in. encaustic tiles, the groundwork of which is a rich dark blue, with the figure of a Cupid in the centre holding a ribbon bearing the word "Caledonia." On each side of the centre panel is a smaller one, 3 ft. square, composed of thirty-six 6-in. encaustic tiles, which have a very rich effect, though treated in somewhat different manner to the centre. The border is the same class of design, and is surrounded by a white marble strip, 15 in. wide. There is also a variously-coloured marble panel about 9 ft. long by 2 ft. 6 in. wide, in the doorway. The tiles have been manufactured by the Campbell Tile Company, of Stoke-up-Trent.

Westmoreland Green Slates.—In an account of the recent Building Trades' Exhibition at Islington, we omitted to mention an exhibit of green slating by the Buttermere Quarry Company, of Keswick. Both for its firmness of colour and strength this company's productions seem to meet all that is required of materials of this class. Messrs. Roberts, Adie & Co. are the agents for these slates.

CONTRACTS AND PUBLIC APPOINTMENTS.

Epitome of Advertisements in this Number.

CONTRACTS.

Table of construction contracts with columns for Nature of Work, By whom required, Architect/Surveyor/Engineer, and Tenders to be delivered.

PUBLIC APPOINTMENTS.

Table of public appointments with columns for Nature of Appointment, By whom Advertised, Salary, and Applications to be made.

BRMSGROVE.—For houses on the Shepley Hills Building Estate, near Bromsgrove, Worcestershire.

Table of tenders for Brmsgrove houses, listing names of builders and their respective bids.

CHATHAM.—For villa residence, Chatham, Mr. O. E. Bond, architect, Rochester.

CLIFTON (Bristol).—For additional buildings, Clifton College. Mr. Charles F. Hanson, F.R.I.B.A. architect.

Table of tenders for Clifton buildings, listing names and bid amounts.

GRAVEN ARMS (Salop).—For Lodge, the Grove, street, Redding.

Table of tenders for Graven Arms lodge, listing names and bid amounts.

HOLLOWAY.—For building three shops at Upper Holloway, for Mr. W. H. Chapman, Mr. J. W. Brooker, architect, Railway Approach, London Bridge.

Table of tenders for Holloway shops, listing names and bid amounts.

HORNSEY.—New sewer in northern portion of Hornsey District, for the Hornsey Local Board.

Table of tenders for Hornsey sewer, listing names and bid amounts.

HORNSEY.—New road work, for the Hornsey Local Board.

Table of tenders for Hornsey road work, listing names and bid amounts.

ISLINGTON.—For alterations and additions to the Duke of Cambridge Public-house, Peter-street, Islington.

Table of tenders for Islington public-house, listing names and bid amounts.

ISLEWORTH.—For alterations and addition to coach-house and stable at Caswell House, Isleworth, for Mr. Howard.

J. Beale, Westminster Bridge-road... £260 0 0

KENNINGTON.—For alterations and repairs to 115, Kennington Park-road, for Mr. W. A. Wall.— B. A. Lamprell (accepted) £182 0 0

LEWISHAM.—For the erection of the New Church of St. Laurence at Catford Bridge, Lewisham, for the Lewisham Church Extension Association. Mr. H. Boumian Gough, architect, Carlton-chambers, Regent-street, E.W.—

Table with columns: Church, Fence walls, Total. Rows include Kennard Bros, Banks, Staines & Son, Brown, Son, & Blomfield, Jerrard, T. Wontner Smith & Son, Chamberlens Bros, Belham & Co, J. Lister.

Table with columns: Church, Fence walls, Chapel, Total. Rows include Chamberlens Bros, Belham & Co, J. Lister.

LLANDAFF.—For the erection of a house at Llandaff, for Mr. H. M. Thompson. Messrs. Halliday & Anderson, architects, High-street, Cardiff. Quantities by Mr. Charles Taylor, Cardiff.—

Table with columns: Church, Fence walls, Chapel, Total. Rows include D. Davies, Cardiff, W. & T. Cox, Llandaff, C. Bird, Canton, H. Gibbon, Cardiff, J. Allen, Cardiff, F. Martin, Cardiff, J. Rhettson & Sons, Cardiff, J. D. Davies, Cardiff, T. Gough, Cardiff (accepted).

LONDON.—For additions and alterations at No. 4, Andley-square, W., for Mr. J. James. Mr. R. B. Marsh, architect. Quantities by Messrs. D. Campbell & Son.—

Table with columns: Church, Fence walls, Chapel, Total. Rows include J. Mowlem, Lawrence & Sons, A. Bush, Higgs & Hill, E. Conder, Nightingale, Brass & Sons, J. & J. Greenwood, Kilby & Gayford (accepted).

LONDON.—For rebuilding Nos. 31, 33, 35, 37, Worship-street, for Mr. Berliner. Mr. E. Street, architect. Quantities by Fowler & Higman.—

Table with columns: Church, Fence walls, Chapel, Total. Rows include Foster, Dickson, Downs & Co, Palmer, Mowlem & Co, Watson, Larter & Son, Nightingale, Kilby & Gayford (accepted).

LONDON.—For shops and residences, Mount-street, Grosvenor-square. Mr. J. T. Smith, architect. Quantities supplied.—

Table with columns: Church, Fence walls, Chapel, Total. Rows include Boyce, Higgs & Hill, Nightingale, Downs, Brass & Son, Perry & Co, Patman & Fotheringham, Peto Bros, Bywaters.

LONDON.—For shop and residence, Mount-street, Grosvenor-square. Mr. J. T. Smith, architect. Quantities supplied.—

Table with columns: Church, Fence walls, Chapel, Total. Rows include Boyce, Downs, Higgs & Hill, Patman & Fotheringham, Nightingale, Brass & Son, Peto Bros, Perry & Co, Morris, Bywaters.

LONDON.—For repairs and additions to No. 74, Wandsworth-road, for Messrs. Roy & Cartwright. Mr. G. Treacher, architect, Carter-lane, E.—

Table with columns: Church, Fence walls, Chapel, Total. Rows include J. Beale, J. Kinsey, Longwalk.

MOUNTAIN ASH (Glamorgan-shire).—For the erection of a Church at Mountain Ash. Messrs. Halliday & Anderson, architects, High-street, Cardiff. Quantities by Mr. Norman Wright, Cardiff.—

Table with columns: Church, Fence walls, Chapel, Total. Rows include S. Franklin, Cardiff, D. C. Jones & Co, Gloucester, C. Bird, Canton, Jenkins Bros, Swansea, W. & T. Cox, Llandaff, Ewan Thomas, Neath, Miss Edmunds, Mountain Ash, Edwin Parfitt, Cwmanan.

NEWBURY.—For building Oldfellows' Hall, Newbury. Mr. J. H. Money, architect. Quantities not supplied.—

Table with columns: Church, Fence walls, Chapel, Total. Rows include W. Wilkins & Son, Eryusham, G. Elms, Stockcross, C. Claridge, Busbury, S. Elliott, Newbury, Rottford, Newbury, R. Harrison, Newbury, T. Martin, Maidenhead, Simonds, Reading, E. James, Newbury.

POPULAR.—For alterations and additions to house, No. 1, Cuba-street, Millwall, Poplar, for Mr. Reeves. Mr. H. Hooper, architect.—

Table with columns: Church, Fence walls, Chapel, Total. Rows include Colman, Johnston, Salt, George Linn, Millwall.

STRATFORD.—For shop front and alterations for Mr. O.C. Wood, 11 and 12, Bridge-road, Stratford.—

Table with columns: Church, Fence walls, Chapel, Total. Rows include B. A. Lamprell, Clapham-road.

TUNBRIDGE WELLS.—For alterations and new shop front to houses, Colchester, Colchester, St. John's-road, Tunbridge Wells. Mr. W. H. Wright, architect.—

Table with columns: Church, Fence walls, Chapel, Total. Rows include G. Edwards, G. Winnifrid, H. Elwig (accepted).

SPECIAL NOTICE.—Lists of Tenders frequently reach us too late for insertion. They should be delivered at our office, 46, Catherine-street, W.C., not later than Four p.m. on THURSDAYS.

PUBLISHER'S NOTICES.

Registered Telegraphic Address, "THE BUILDER, LONDON."

CHARGES FOR ADVERTISEMENTS. SITUATIONS VACANT, PARTNERSHIPS, APPOINTMENTS, TRADE, AND GENERAL ADVERTISEMENTS.

TERMS FOR SERIES OF TRADE ADVERTISEMENTS, also for special arrangements on trade, competitions, contracts, sales by auction, &c. may be obtained on application to the Publisher.

FOUR LINES (about THIRTY words) or under 2s. 6d. Each additional line (about ten words) 6s. 6d.

PREPAYMENT IS ABSOLUTELY NECESSARY. Stamps must not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable at the Post-office, Covent-garden, W.C. to DOUGLAS FOURDRINIER, Publisher.

Advertisements for the current week's issue must reach the Office before THREE o'clock p.m. on THURSDAY. The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

SPECIAL—ALTERATIONS IN STANDING ADVERTISEMENTS OF ORDERS TO DISCONTINUE same, must reach the Office before TEN o'clock on WEDNESDAY mornings.

PERSONS Advertising in "The Builder," may have Replies addressed to the Office, 46, Catherine-street, Covent Garden, W.C., free of charge. Letters will be forwarded, if addressed envelopes are sent, together with sufficient stamps to cover the postage.

TERMS OF SUBSCRIPTION. "THE BUILDER" is supplied gratis from the Office to residents in any part of the United Kingdom at the rate of 10s. per annum. To all parts of Europe, America, Australia, and New Zealand, 20s. per annum. To India, China, Ceylon, &c. 30s. per annum. Remittances payable to DOUGLAS FOURDRINIER, Publisher, No. 46, Catherine-street, W.C.

TO CORRESPONDENTS.

Registered Telegraphic Address, "THE BUILDER, LONDON."

A. S. & S.—C. T. C. N. W.—W. D.—W. P. F.—M. H. K. E. O. F. Berle (thanks).—J. H. (more a matter for Notes Queries than for our column).—F. (thanks for photograph).—

All statements of facts, lists of tenders, &c. must be accompanied by the name and address of the sender, not necessarily for publication. We are compelled to decline pointing out books and job addresses.

Note.—The responsibility of signed articles, and papers for public meetings, rests, of course, with the authors. We cannot undertake to return rejected communications. Letters or communications (beyond mere news items) which have been duplicated for other journals, are NOT DESIRED.

All communications regarding literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

Best Bath Stone, for Winter use. WESTWOOD GROUND, Box Ground, Combe Down, Corsham Down, & Farleigh Down. Dried. RANDELL, SAUNDERS, & CO., Limit. Corsham, Wilts. [Ad.]

Box Ground Stone is the best for use in all exposed positions being a well-known and tried Western Stone. 50,000 ft. cube in stock. P I C T O R & S O N S, BOX, SO., WILTS. [Ad.]

Doubling Freestone. The stone from these quarries is known as the "Wheat Beds," and in a crystalline nature, and is doubtfully one of the durable stones in England. It is of the same crystalline nature as the Cleveley Stone, but finer in texture, and is suitable for re-moulded work. HAM HILL STONE.

Greater facilities have been provided for working these quarries, and the stone can be supplied in large quantities at short notice. Prices, and every information given, on application to CHARLES TRASK & SON, Norton-sub-Hamdon, near Ilminster, Somerset. London Agent—Mr. E. WILLIAMS, 10, Craven-street, Strand, W.C. [Ad.]

Doubling Free Stone For prices, &c., dress S. & J. STAP. HAM HILL STONE, Quarry Owners, E. & W. BLUE LIAS LIME and Lime Merchants. Stoke - under - Hill (Ground or Lump), Ilminster. [Ad.]

Ham Hill Stone! Ham Hill Stone. For Ham Hill Stone of best quality and workmanship, apply to JOHN HANN & SON, Quarry Owners, Montacute, Ilminster. Established 1837. Agents, MATTHEWS & CEARD, Albion Wharf, Regent's Park Basin, N.W. [Ad.]

Asphalte.—The Seyssel and Metallo Asphalt Company (Mr. H. Glenn), Office, Poultry, E.C.—The best and cheapest material for damp courses, railway arches, warehouse floors, flat roofs, stables, cow-sheds, and rooms, granaries, tin-rooms, and terraces. [Ad.]

Asphalte. Seyssel, Patent Metallo Lava, and White Asphaltes. M. STODART & CO. Office: No. 90, Cannon-street, E.C. [Ad.]

BANNER VENTILATORS.

The Strongest Exhaust Ventilators for all Buildings, Public Halls, Churches, Billiard-Rooms, &

HIGHEST PRIZES at all the most important Exhibitions.

BANNER SYSTEM OF SANITATION AND SANITARY APPLIANCE

WERE AWARDED AT THE

International Health Exhibition, 1884, One Gold Medal, Three Silver Medals, and One Bronze.

For further Particulars and Prices apply to

BANNER BROS. & CO. Sanitary and Ventilating Engineers

11, BILLITER SQUARE, LONDON, E.C.

Architecture at the Royal Academy.

OTES on the general contents of the Royal Academy exhibition of 1886 we defer till next week, only remarking here that, as far as paintings are concerned, we fear it will not be registered as a good year. There are two or three remarkable pictures, and a fair sprinkling of good ones, amid what seems to us so far to be a more than usual proportion of uninteresting and commonplace work. On the other hand, sculpture, in spite of the absence or very poor representation of some of the best names of the day, shows a good average, and includes some works of very high beauty, interest, and originality.

The standard of work in the Architectural room seems more generally up to a good average than any other department of the exhibition. Of course, it must be borne in mind that the number of these works is comparatively small: 202 drawings are exhibited, the total of works in the whole exhibition being 925; and equally, of course, architectural drawings, which are only representations of the work and not the work itself, do not stand the same category as paintings and sculpture, which are themselves the finished work. Nevertheless, the architectural visitor will, we think, find that there is a good standard maintained, and though there are few remarkable things, there are few which do not vindicate their right to be present. There is a considerable proportion of church architecture, and a rather larger amount than usual of decorative work, mostly of a good class. Public buildings any scale or importance are, as usual, in the minority; domestic architecture is fairly represented.

As we have sometimes done on former occasions, we will look through the churches first. Church architecture stands on different ground one respect from other branches of modern architecture, in that it is more, distinctly influenced by precedent than any other class of buildings. The days have gone by when it is considered by clients sufficient to have what was called a comfortable house, and when we even considered rather "had form" to wish to have a dwelling distinguished by any special effort at artistic effect from those of our neighbours. There is now, on the contrary, a desire on the part of men who build themselves and their families to have homes reflecting their own tastes, or, at all events, the taste of their architect; and the conditions of

plan and arrangement are more elastic in the case of a dwelling-house than in any other kind of structure except those which are purely monumental or decorative in character and aim. In the case of the church, on the other hand, the Mediæval plan, subject to modification within rather narrow boundaries, is still *de rigueur*. Orientation, the position of the chancel, of the baptistery (where there is one), of the choir, are settled by prescriptive custom or tradition, and the possible variety of plan is therefore very small; and practically style is, to a certain extent, also prescribed, though the latitude here is much greater than in regard to plan. It is still tacitly regarded, however, as a principle, that a church, to be acceptable, must be Gothic; it may be Gothic "with a difference," but it must, as a rule, fall within that category, and almost every one of the churches in the present exhibition does so. The matter of interest, therefore, is to find churches, designed within the accepted lines and in regard to plan and style, which present, nevertheless, some degree of originality in their details or in the variations played on the prescribed theme; and of this there are some interesting examples in the present exhibition.

Taking them in the order of hanging, the first we come to is Mr. Needham Wilson's Soane Medallion prize design for "a town church" (1,560); an exterior perspective view finely drawn in pen and ink, but taken from a point of sight rather too near to give the idea of the whole grouping, and producing a rather confusedly heaped-up effect, which is, however, picturesque, and was perhaps intentionally aimed at. The church is a brick one treated in a very severe style, with plenty of solid mass of wall, and large in scale; it realises its intended character as a town church,—it would be rather difficult to define what special characteristics go to distinguish a town church from a country one, but they are felt intuitively by most people who have any perception at all on such a subject. The placing of the tower at the angle where two streets meet secures one of the points of effect of which church architecture in streets is susceptible. Below this (1,561) is Messrs. Goldie, Child, & Goldie's interior of the church for Spanish-place, which has been illustrated in our pages, and of which we spoke at length at the time of the competition for the building. It represents the frank adoption of the Mediæval model, in detail as well as in general arrangement, and, as we have before said, a very successful example of that class of archaeological architecture which may be called mere imitation, but which, at all events, it requires no little knowledge, natural taste, and experience to

reproduce successfully. The same architects exhibit one of the exterior views of this church (1,696), a large pyramidal group, rising effectively above the houses surrounding it.

Mr. Seddon's competitive design for the memorial church at Paisley (1,567), we have also illustrated. It makes a very effective coloured drawing, and represents a spirited attempt to adapt Mediæval architecture to the special requirements of a Baptist church. It is a design practical for its purpose, as well as effective as a whole, but we cannot like some of the detail, which savours too much of "Dissenting Gothic" for our feelings, though, perhaps, thereby the more fitted for its object.

St. Paul's Church, Finchley (1,570), by Mr. John Ladds, shows no special originality, but has the merit of refinement and solidity at the same time: it shows a tower on the north side, nearly a solid mass of wall in the lower stages, with octagonal turrets and a short lucarned spire. There is no attempt at adapting Gothic, but there is a good feeling about the whole. Mr. Arthur E. Street's "Church of St. Paul, Worcester" (1,571), is an interior with a good deal of character. It is a very solidly-treated design with little ornament, of generally thirteenth-century character, but with a special type about it; the piers and arches, without caps or impost mouldings, are diversified with hands of red brick with black edging bands, alternating with a light-coloured stone; the roof is a plain solid-looking Mediæval roof, with heavy curved braces springing from timber corbels. The pulpit is too "stumpy" in appearance, and does not harmonise much with the rest of the design; but the whole is a good interior, and very monumental looking. "All Saints Church, Gosforth" (1,574), by Mr. R. J. Johnson, is a pen-drawn interior of a church in orthodox Late Gothic style, with nothing to find fault with or to comment on in particular. The "Church of St. Peter, Accrington" (1,577), by Mr. Henry Ross, is a plainly-treated edifice with a main roof running from end to end, the ridge only broken by a rather picturesque timber bell-cot and spirelet; there is a small transept much below the ridge of the main roof; plenty of solid wall, little ornament, square windows in aisles and pointed windows in clearstory. The employment of square-headed windows in church design, in conjunction with a style of Gothic not generally associated with that form of window-head, is one of the variations in which modern Gothic is indulging; with a low aisle it gives a greater proportion of light, and thus the great inspiring spirit of utilitarianism (for such it is, rightly regarded) is creeping into modern Gothic church architecture.

The "Interior of St. Bartholomew the Great,

Smithfield" (1,603), by Mr. Aston Webb, showing the proposed restoration of the east end, is one of the finest drawings in the room, and one of great interest, as showing the proposed treatment of the most interesting ancient church in London. We shall publish a reproduction of the drawing next week, together with some account of the church as it is and is proposed to be. We will only remark here that the architect has gone on the principle of restoring the Norman arcade on the ground story as a continuation of that part of the original design, and restoring the fourteenth-century story above, round the apse, so as again to make a continuous design; thus striking a balance between the claims of archaeological truth and architectural effect; and we believe this is the best course that could have been adopted under the circumstances; but there will be an opportunity of going into the subject more in detail next week.

Of Mr. Doyle's "Design for St. Bartholomew's, Liverpool" (1,606), the tower is the best portion. It shows an octagon rising, unsymmetrically, off a square mass in the lower stage, the square portion reaching to the height of the body of the church; the octagon has an upper stage of long window-lights, and is crowned by a smaller octagon stage and conical roof, very plainly treated. The effect of this is picturesque and rather unusual; the remainder of the building is rather bare and devoid of character. The "Interior, looking east, of Audlem Church, Cheshire" (1,612), by Messrs. Lynam & Rickman, is apparently an old church "done up," probably re-seated, but there is no indication what is actually new in the work; it is a plain, very solid, interior, of rather late date, with octagonal piers, with plain bell capitals and no carving.

Mr. E. C. Lee's design for "Proposed New Church, Teddington" (1,605) is hung too high to be well seen; it is a stately-looking church, in a Late Decorated style, with window tracery of Perpendicular type; a battlemented tower, with large angle turrets, at the crossing; it may be taken as a good specimen of the orthodox Gothic church. The "Trinity Presbyterian Church, Wimbledon," by Messrs. Potts, Sulman, & Hennings (1,615), is a pretty structure, with some original points about it; low walls and high roofs, with a very small clearstory, a tower at the south-west angle, with an octagon spire rather playfully treated, and a simple but elegant *niche* at the crossing; the details are Early Geometric Gothic in character. "Our Lady's Church, Wellingborough" (1,616), by Mr. S. J. Nicholl, is a pleasing example of a small town church, Late Gothic, with a tiled roof, a low transept not breaking the main lines of the nave, and a square low tower nearly detached from the church at the north-west angle, the tower kept very plain, except for an enriched story just below the battlemented parapet, and with a short spire over it. The shafts running past the centre of the tower windows and through the battlements, and ending in finials, are a little whimsical and out of keeping with the solidity of the general design. The "Woodberry Down Baptist Chapel" (1,627), by Messrs. Paull & Bonella, shows some originality of treatment; the large end window is flanked by bastion-like side masses projecting in semicircular form, which above the roof become complete octagonal turrets, but the small buttresses in three stages in this turret portion, radiating from the angles, produce rather confused lines, and seem out of scale with the rest, and do not sit very well on the sub-structure. If not already built, this portion is capable of improvement.

Mr. Leonard Stokes's drawing of a portion of his design submitted in competition for the Spanish-place Church is a very fine pen-drawing (1,635), showing the portion of the design with the semicircular vestibule, with a door and sculptured gablet at each extremity of the semicircle. The portion of the building rising above the porch is very severe and massive in style. We commented on it at the time of the exhibition of the competitive drawings; but the porch with its cingfoil

arcade hardly seems to belong to the rest of the building, and this, with the rather awkward manner in which the semicircular line of roof fits (or does not fit) into the angle of the main building, makes the porch look rather like an afterthought added by another hand. Otherwise, this is one of the best drawings in the room, showing a part of what as a whole was a very fine design.

Mr. Billing's "Proposed Memorial Church, Paisley" (1,638), an exterior perspective and, (like the last) a competition design, we cannot say very much for, save that it is large, elaborate, and ambitious, but incoherent, and not really effective, in spite of all its elaboration of detail. Messrs. Goldie, Child, & Goldie's "New Catholic Church, Mount Vernon, Liverpool" (1,644), is a simple Geometric Gothic church, with no tower, only a large octagonal turret at the south-west angle, and a porch the width of the nave, beneath the seven-light west window, which (the porch, namely) does not seem quite sufficiently connected with the rest of the design. The effect of the whole is quiet and picturesque.

Mr. J. D. Sedding's "New Church, Roche, Cornwall" (1,643), is shown in a bird's-eye view pen-drawing; it is apparently a church with all three aisles completely roofed with ridges, instead of the aisle roofs being treated as lean-to's; the design has a good deal of character of an unpretending kind, the porches are treated with variety and originality; the tower seems rather wanting in character. Mr. Sedding's other church, "New Church at Hayle" (1,709), is still more original, in fact defiantly so. The tower occurs in the middle of the north side of the church, a great square mass below, with an octagon lantern planted upon it; the square mass is cut into a deep square-headed recess on each of the visible faces, in the upper part of which recess windows lurk; the nave aisles are very low with broad single buttresses of one set-off, and in the centre of each wall-space between the buttresses is one very small window, square in two of the bays, circular in another, giving the idea that the aisle must be divided into cells internally. The clearstory windows, on the contrary, are long lancets piercing the wall midway between the buttresses, and with moulded relieving arches over them connecting the buttresses. Towards the east end the ground falls very much, and this portion has two full window tiers. The little windows dotted in to the nave aisle wall seem like a joke; but then it is a very amusing joke, and the whole design is exceedingly original and picturesque, and shows a determined effort not to continue in mere archaeological leading-strings, even while working in a spirit akin to that of Medieval architecture. Mr. Sedding's large and elaborate drawing for the restoration of the choir screen at Winchester we will speak of on another occasion.

NEW LIGHT ON THE EAST PEDIMENT OF THE ZEUS TEMPLE AT OLYMPIA.

THE Museum of Casts at South Kensington has made it possible to take an intelligent interest in the question of the restoration and interpretation of the Olympian marbles, without the, once indispensable,—journey to Berlin or to Olympia. If our readers will take the trouble to visit the museum, and study the "reduced copy of the east pediment group of the Temple of Zeus at Olympia" (in the catalogue No. 76a) they will find themselves easily in a position to appreciate the brilliant theory of interpretation which Dr. Loeschke has just sent us from Dorpat. To readers of the *Builder* Dr. Loeschke's name is familiar; his new theory is stamped with just the old impress, the hall-mark of constructive genius which stimulates the imagination as much as it convinces the intellect.

Mr. Perry, in his arrangement of the east museum, has selected the restoration of the east pediment made by Treu. From this restoration we have always dissented, and we are glad to see that Dr. Loeschke's theory sup-

ports, though quite incidentally, the riv restoration of Dr. Curtius. Into the merits of the two restorations it is not our purpose here to enter, except in so far as they necessarily affect the interpretation of the figures. We give a sketch of Dr. Curtius's restoration lettered so that the argument may be clear followed.

Dr. Loeschke begins by conceding that the question of the original arrangement of the twenty-one figures of the pediment is still part open. Only in part, however. If seventeen out of the twenty-one positions is fixed, either by their size in relation to the slope of the pediment, or by the description of Pausanias; or, again, by the exact spot which they were found. These seventeen are the five middle figures standing in an upright position (which, though, as we shall see, they may be interchangeable among themselves, must occupy the centre), F, G, H, I, K, the two groups of four horses, D and M, and, according to Dr. Loeschke, the much-disputed "brooding old man" (*sinnender greis*) and the "squatting or crouching boy" (*hockender knabe*) N and O. Of these last two, some authorities concede only the "brooding old man," who, common consent, takes his place immediately behind the right hand (fronting the spectators) horses. Dr. Treu, whose arrangement followed at South Kensington, places the crouching boy in front of the left-hand horse and fills his place behind the "brooding man" by the figure of the kneeling maiden.

First,—and here he acknowledges the leading of Dr. Studniczka, of Vienna,—Dr. Loeschke attacks the commonly-accepted arrangement of the centre standing group. It will be remembered that the pediment represents the preparations for the race between Pelops and Onomaoos, king of Pisa: the prince Pelops win is to be the hand of Hippodameia, daughter of Onomaoos; the umpire in the contest is naturally the Olympian Zeus himself. He occupies the centre, H; on his right-hand, G, stands the winning man, Pelops—in the lucky right hand place by his side, future bride, Hippodameia, F. On the left-hand (the losing place) stands Onomaoos, and by his side his wife, Sterope. We are bound to note, however, that it seems to us possible that conventional etiquette may have placed Onomaoos, the full-grown king, on the right-hand in place of the luckier, but younger Pelops; a glance at the diagram will show, however, that the outstretched arms of G. I would thus be turned inwards and create an unpleasant artistic effect. Dr. Loeschke holds that Pelops occupied the right-hand place, but, following Studniczka, he thinks wrong figure has been placed by his side, Hippodameia. He would transplant K, the called Sterope, and call her Hippodameia. Studniczka chiefly supports the change, considerations of dress; the simple D chiton of K he considers better fitted maiden figure. Dr. Loeschke, in addition thinks that on artistic grounds K occupied the place of F more harmoniously, and that folded arms and pensive droop of the figure suit the prospective bride. We cannot see the matter proven on either side.

We pass to the far more interesting, perfectly original, and, as we believe, convincing interpretation that Dr. Loeschke offers of the hitherto problematic figures intervening between the chariots and the river gods. The river gods, we should note in passing, are certain interpretation and position, the hand one, A, being the Alpheios, the right hand, P, Kladeos. Between the right horses, M, and Kladeos, P, are two figures, the far-famed "brooding old man," N, and the crouching boy, O. We begin with N. It happens no figure dug up at Olympia excited much surprise and such prompt controversy. Pausanias, never a very accurate observer, calls him for a groom; but if a groom, why his head resting on the hand, the furrowed forehead, the sunken, meditative eyes, the what seilic face? The fashion of grooms at that time have strangely changed if this is the type of the oster of ancient days. The type of the figure is so markedly realistic that its character cannot be unintentional, and it was the

deration of these well-marked characteristics that led Mr. Newton to see in the impossible room a seer, present as was fitting to precede over the rites that preceded the race. Dr. Loeschke gives the seer a name, a name of local might. From the beginning of time here dwelt in the plain the old god Kronos, and the crooked counsels (*ἀνελομήτης*); his bill (Kronion) it was that overhung the plain on

gracious to her lover, but bade her maidens pelt his face with mud; but the sculpture, if Dr. Loeschke's interpretation be true, adopts a milder version of the story. The goddess seems hending down to the ground, or it may be that in the space between her and Alpheus there was a stag sculptured, with which she played, while the river-god watched her as she lay.

of some of the subjects it dealt with, that it has done a great deal in calling attention to errors and neglect in such important subjects as sanitation, education, legal reform, &c.; and it is not too much to say that many of the most important improvements and advances which have been made in connexion with these and other departments of social organisation have had their initiative from the action of the

which the heroes raced, and he it was who his crafty soul decided the issue of the contest. We have no second contemporary representation of Kronos with which to compare N; known representations are of later Hellenic times; but, if an artist of the fifth century sized to depict the crafty ancient god, we can imagine no more likely embodiment than is "hooding old man." Any who may have followed us in recent discussions on the topographical interpretations of the east and west pediments of the Parthenon will find with us the great gain to the living interest the pediment in this interpretation of the merely accidental and abstracted groom into a seer or the local divinity who, in actual essence, superintended the race.

We pass to the crouching hoy, O. May he prove a local divinity? Was there any faithful god of local import whose shrine is nigh to the bill of Kronos? For we have not far to seek. On the very peak of Kronion towards the north, and not removed from the treasure-houses, Pausanias (20, 1) tells us he saw a shrine where was worshipped the hero Sosipolis, by whom men are in affairs of the greatest moment. The ans, at one crisis of their history, had been d-pressed by the Arcadians; the hoy Sosipolis as yet a child at his mother's breast, and mother dreamed the child should save the an state. They placed the child, naked, in at of their battle array, and, as the Arcadians tie up, the child was changed into a snake, panic-stricken at the omen, the Arcadians ke and fled. The Eleans consecrated a ne in their capital to their deliverer Sosipolis, saviour of the State, building it near the temple of the goddess Tyche (Fortune). doubt, the story hears the impress of an biological myth; but, none the less, he remains that on the hill Kronion was shipped the hero Sosipolis, and that by down to late days, the most solemn oaths taken: his worship has the appearance of old indigenous cult, and we may, with no ence to mythological chronology, suppose to have been present at the contest between pps and Oinomaos. The attitude of the ch seated crouching on the ground, and his ion between Kladeos and Kronion, suit lly with Dr. Loeschke's attribution.

To balance this local trio, Kronion, Sosipolis, Kladeos, on the right hand, we must have sth less vague than mere nameless pbs, and grooms, and seers, on the left. does Dr. Loeschke fail to give us again local ground whereon to set our feet. ing to the left end of the pediment, the -got (A) in the corner is already indis- bly Alpheios; names and personalities yet to be found for B and C, the maiden the full-grown seated man. For the en (B), Dr. Loeschke offers a charming ion. It had already been noted that she towards Alpheios, as if some marked con- were intended; she turns away from action in the centre as if the river-god to her more than all beside. There was maiden goddess much worshipped in pnia, and not over-prone to love, but she wooed by the river-god, Alpheios, and d a shrine with him; Artemis, who bore urname, Alpheiousa. According to the in Pausanias, the goddess was not over-

It will not be forgotten that much of the worship at Olympia centred round the taking of oracles, and all modern interpreters of the pediment have wished to see, in one or other figure, a representative local view. The figure C remains a figure of dignified aspect with a broad hand about the hair, and possibly having once carried a sceptre in the left hand. If the figure represents a seer, seated, as he is, on the ground, he must be of Chthonic origin. We scarcely need hesitate for the name,—Iamos, ancestor of the great race of seers, the Iamidæ,—Iamos, son of Apollo and Eradne, the haher whom, "by the counsel of the gods," Pindar tells us, two bright-eyed serpents nursed, and fed him with the harmless venom of the bee; and when he grew to be a youth, at night-time beneath the heavens, he cried to Apollo, and the infallible voice of his father answered and said to him, "Arise, my son, and come hither, following my voice, into a place where all men shall meet together." So they came to the steep rock of lofty Kronion; there the god gave him a twofold treasure of prophecy that, for the time then being, he should hearken to his voice that cannot lie. Thus Iamos was at home in Olympia before the coming of Herakles, before the contest of Pelops and Oinomaos; he completes the assemblage of the primeval local gods, Kronion, Sosipolis, Kladeos, Iamos, Artemis Alpheiousa, Alpheios. It will be seen at once that this scheme of interpretation, hanging closely as it does on questions of topographical juxtaposition, necessitates the arrangement of Dr. Curtius; it will be seen also what a lively and beautifully real background of local scenery it lends to the scene of contest in the centre. Did space allow, we might also dwell on another point which Dr. Loeschke emphasises, i.e., the close parallel which the pediment, thus arranged and elucidated, presents to the west pediment of the Parthenon. For this interesting question we must commend the reader to the original pamphlet, which is the last Dorpater programme, "Ad Sollemnia Casarea universitatis Dorpatensis."

NOTES.

THE Social Science Association, it is understood, is about to retire from public appearances for a time, and there can be little doubt, we suppose, that this is really a preparatory move to winding up the concern. Latterly, it has been evident to those who attended its congresses that the interest in its meetings has been declining; but this is no excuse for the kind of requiem which some of the papers have been singing over it. It is undoubtedly true that your typical Social Science man was a formidable bore; but then the congresses were not solely made up of typical Social Science men. The name in itself of the Association assumes a great deal, and incites in the critical mind the question, is there a social "science" properly so-called? And it impresses on the more mercurial temperament of the artist and literary man the feeling which Mr. Matthew Arnold expressed so delightfully when he alluded to "those hold, had men who attend Social Science Congresses." But with all this, there is no doubt, among those who know the past history of the Association and

Social Science Association; and that far more public benefit is traceable to the agency of the Association than some of its light-hearted critics of to-day have the least notion of. In fact, the Social Science Association might, we think, not unreasonably claim that, if it is *de trop* now, this is because it has done its work so well in compelling public attention to evils which, when the Association was started, really required that some such organisation should be established for inciting the public mind to action.

THE report of the Inspector appointed by the Local Government Board to inquire into the sanitary condition of the hamlet of Mile End Old Town practically finds that the Mansion House Council was right in pointing out certain sanitary defects, and that the defence of the Vestry fails. As regards the first point, that a large number of houses mentioned by the Council were without proper water-closets, the Inspector finds that 367 of them were of this kind, and he adds:—"As regards the closets in the hamlet the whole must be considered water-closets, and they should be provided with a suitable water-supply and with water-supply apparatus." We take it, therefore, that the actual number of houses with no proper supply of water-closets was greater than stated by the Mansion House Council. As to the second point he says:—"I found the large number of 365 houses in which dustbins were either entirely wanting or dilapidated." The Inspector also finds there has been a request on the part of the Vestry to put in force sanitary regulations, that further action should be taken under the Artisans' Dwellings Act, and that the staff of sanitary inspectors is insufficient. Lastly, his attention was directed to a new block of artisans' dwellings on Stepney Green. Of these he says:—"I consider them as to some of the rooms quite unfit for habitation, being deficient in light and air and the necessary sanitary appliances, but they do not contravene the provisions of the Metropolitan Buildings Act." We have done no more than give the Inspector's findings. These are enough to show that some parts of London are ripe for an outbreak of cholera, that vestries are negligent, that the Building Acts require alteration, and that it is clearly useless to pull down blocks of houses and replace them by blocks of artisans' dwellings, unless the latter are properly built on recognised sanitary principles. We regret we can at present give no more prominence to this report, which shows how much energetic action is required by the Government, by Local Boards, and by the Legislature, in order to put the metropolis and our large cities into a proper sanitary condition.

AN interesting statement is given in a recent number of the *Revue Scientifique* as to the great development of tramways in the different parts of the world, especially when we consider that, as far as the Continent is concerned, the commencement of the system only dates from 1856, when the tramway from Paris to Versailles was opened, followed, in 1863, by one at Copenhagen. In proportion to its size, Holland has been the most active in this matter, possessing at the commencement of last year 625 kilomètres (1 kilomètre = about 5 furlongs), employing 712 cars and 305 mer-

chandise-wagons. The number of passengers carried in the year was 24,270,000. In Germany there are 48 towns and cities with tramways, with a total of 903 kilometres, employing 8,100 horses and 69 steam-engines. The number of passengers was 190 millions, and in Vienna 36 millions. France is rather more backward in tramway development, there being only about 700 kilometres, of which Paris contains 250, employing 5,000 horses. Italy has made great strides in this direction, possessing over 1,000 kilometres, principally in Turin, Milan, Florence, and Naples. In Florence and Milan, more especially, steam trams are in use, not so much for town work, but for the accommodation of adjoining towns and villages, to which trains run along the high road at regular intervals, for distances up to ten miles or so. Belgium possesses about 150 kilometres, of which the greater portion is found in Brussels. Russia has 600 kilometres, Spain 100, while Portugal has only one tramway, at Lisbon; Turkey one, at Constantinople; and Greece one, between Athens and the Piræus. The United States are, of course, the great home of the tramway system, without which the inhabitants of the cities of magnificent distances would come badly off for inter-communication. In 1882 North America had 5,000 kilometres, of which 800 were in New York, while South America had 1,500, principally at Buenos Ayres. In the States, however, the mileage must be very largely increased by this time, considering that the first duty on founding a city (and sometimes before) is to lay the rails for a tram-car.

FROM a passage in the *Sunderland Daily Echo*, it appears that the corporation of Sunderland, having promised the competitors for the new Municipal Buildings to appoint Mr. Waterhouse as assessor, are now disposed to back out of their promise, it being found that "this concession to a little local feeling" will cost the rate-payers 100l. The frankness of the following quotation from the correspondent of the local paper referred to is amusing, and will no doubt edify the competitors:—

"I have seen the plans, and have conversed with those who have inspected them officially, and think it just as well to proclaim the fact that the feeling in favour of one set of plans is simply unanimous, the only question of doubt in the minds of some of the gentlemen relating to the possibility of the building being carried out for the sum stipulated. Granted a guarantee on that point, and there is no necessity for paying anything like 100l. to any professional man for simply endorsing what has already been decided."

The idea that the professional assessor may not endorse the decision does not seem to occur to the candid writer. As to the "little local feeling," the *Sunderland Echo* is apparently ignorant of the fact that a great proportion of English architects have decided not to enter into competitions unless a professional adviser is employed to adjudicate. If corporations and other public bodies choose to say, "We can judge for ourselves perfectly well without professional assistance," they have, of course, the right to say so, only in that case a large number of the most able architects of the day will not compete. If things go as they seem to be going, in this case and the Fulham Vestry-hall case and others, the practical effect will be to deal a blow at the whole system of architectural competition, which, perhaps, would be a result little to be regretted. It would be interesting to know whether the author of the plans so "unanimously" admired is a Sunderland architect.

IN reference to our review of the life of the late Mr. John Dobson, in the *Builder* of April 17th, under the heading "A Fine Old English Architect," Miss Dobson, the author of the biography, writes:—"It may, perhaps, interest you to hear something more about Seaton Delaval. The first fire was about 1752; the second fire, 1820; my father's restoration, 1814, when he also added a new wing. He sent a coloured drawing to the Royal Academy in 1815 of this work, which created great interest at the time, and, no doubt, introduced the present artistic treatment of architectural perspec-

tive drawings. Until that time I believe they were treated in a different manner. After the fire of 1820 the building remained roofless. Some years ago my father added a roof and strengthened the walls. Before his final illness Lord Hastings, who succeeded Sir Jacob Astley, requested my father to make plans for the restoration of the building, which were never executed. Lord Hastings also died. No doubt the building will never be restored."

LAST year M. Tourtay carried out a series of experiments bearing on the influence of mortar-joints upon the resistance of stone walls, which were described in the *Annales des Ponts et Chaussées*. He selected for trial three descriptions of stone, of which blocks and slabs were prepared, two of each being placed one upon another in the course of the trials. The spaces between were in some places not closed up, while in others liquid cement was poured into them, or they were filled with mortar (cement mortar or hydraulic lime mortar). In the tests the joints of cement mortar were $\frac{1}{2}$ in., $\frac{3}{4}$ in., and $1\frac{1}{2}$ in. in thickness, and those of hydraulic lime mortar $\frac{3}{4}$ in. The proportion for mixing was about 10 cwt. of cement or hydraulic lime to 35·7 cubic feet of sand. Blocks of the mortars themselves were tested after twenty-one days hardening, with the result that cement mortar showed a resistance to pressure of 1038·3 lb. per square inch, and hydraulic lime mortar 284·46 lb. per square inch. The resistance to pressure of the stone varied, according to its description, from 5689·2 lb. to 12801 lb. per square inch, and that of the masonry was found to be from 1422·3 lb. to 4266·9 lb. less per square inch. At a pressure of 1991·2 lb. to 4266·9 lb. per square inch, the mortar at the edges of the joints began to exfoliate and fall out, and this occurred sooner in proportion to the thickness of the joints. The blocks which had been united by pure cement (without any filling of mortar), preserved their condition as if they had been made of one piece. The following general principles are deduced by M. Tourtay from his experiments, but would doubtless require further investigation and testing before they could be accepted as final:—1. The destruction of mortar takes place in masonry at a much higher pressure than in blocks of the mortar itself, but at a lower pressure than in the case of the stone separately. 2. The pressure which causes the destruction of the mortar is in an inverse ratio to its thickness, so that (under conditions otherwise equal) it is advisable to make joints of mortar as thin as may be consistent with proper execution of the work. 3. Trial blocks, simply placed on each other, and without any filling of the spaces between, gave results as to resistance to pressure which were inferior to those of the separate stones, but superior to those of the slabs joined by mortar. 4. The trial blocks, between which a thin layer of pure cement had been placed, maintained their efficiency like complete blocks, and gave results far superior to those obtained in cases where mortar had been used. Although the strength of cement mortar was found, on separate testing, to be more than three times that of hydraulic lime mortar, there was no important difference found in the trials of masonry constructed with the two kinds of mortar. Attention is finally called to the necessity of the horizontal joints being very exactly worked, in order to render them suitable for the mode of construction referred to above in paragraphs 3 and 4.

IN regard to foreign water supplies, it may be noted that the City of Rome is supplied by 204,000,000 litres of water every twenty-four hours (1 litre = $1\frac{1}{4}$ pint), drawn from the following sources:—

	Litres.
Vergine or Trevi	80,000,000
Felice	24,000,000
Paola	40,000,000
Marcia	60,000,000
	204,000,000

The population of Rome being 345,036, the supply of water to each inhabitant per day is 591 litres.* Paris, which contains 2,240,124

* A litre is $\frac{1}{16}$ of a gallon.

inhabitants, only gives 58 litres per head for drinking purposes and 169 for domestic and other requirements, or a total of 227 litres. Berlin, with a population of 1,302,283, supplies 140 litres per head daily. Vienna, with 770,014 souls, gives 100 litres. Naples gives 200 litres to its 463,172 inhabitants, and Turin 98 litres to a population of 278,598. It will, therefore, be seen that if immunity from epidemic diseases depends upon the supply of water, the Italian capital ought to be the most healthy city in the world.

ON the site of the ancient Mantinea a colossal statue has been excavated, representing a discus-thrower. The statue is about to be taken to the Central Museum at Athens. Material and style are as yet unreported. We can scarcely venture to hope that it may be a bronze, and thus furnish us with some accurate notion of the style of the great discus-thrower of Myron.

THE *Berliner Philologische Wochenschrift* reports that Dr. Dörpfeld has undertaken (on behalf of the German Archaeological Institute at Athens) to superintend the excavation of the ancient Doric temple at Corinth. So far the remains discovered have been scanty, but enough has been laid bare to make out the ground-plan of the building, one door, and the pedestal of a statue within the walls. Dr. Dörpfeld thinks that the building is an instance of the not uncommon custom among the Greeks of a joint temple, dedicated to two gods at the same time.

A NEW 48-in. main has been laid from the Pultah waterworks to Calcutta, which will supply that city with 12,000,000 gallons a day by gravitation alone. The *Pioneer*, an Indian newspaper, says:—"Tenders were invited for the work, but they were so high that Mr. Kimber, Engineer to the Corporation, resolved to frame estimates of his own, and the iron pipes having been contracted for in England, he was allowed to do the work. The result is that the pipes have been laid at an expense less by five lakhs than the lowest tender sent in for the work; and, moreover, the total cost is $1\frac{1}{2}$ lakh less than Mr. Kimber originally estimated. This great saving has been due to careful management, and to some good fortune in the way of the physical difficulties of the ground being less than were anticipated. Mr. Kimber and his staff have well earned the gratitude of the Corporation, and of the ratepayers too; for the latter have to pay for works of this kind, and with heavy loans for other purposes having to be contracted, every lakh saved means so much less taxation. The five lakhs saved represent a sum more than sufficient to pay for the new pumping-engines, and the buildings to contain them, at Pultah."

THE series of articles in progress in the *Art Journal* on "The Revival of Decorative Needlework" and on "Suggestions in Decorative Design from the Works of Great Painters," are well worth the attention of architects and decorative designers. Among the illustrations to the former are four beautiful designs by Mr. Burne Jones for outline embroidery, emblematical of the four seasons. The second-named article is illustrated by engravings from portions of architectural designs from several pictures in the National Gallery, following out, in another branch of decoration, the idea embodied in Mr. Sydney Vacher's firm work on suggestions for textile fabrics from the same source, which we recently reviewed.

THE "Society of British Artists" exhibition has more of variety and originality than usual, though this arises chiefly from the presence of some of the more eccentric elements in modern art. The most noteworthy work is a life-size figure study by Mr. Whistler "Harmony in Blue and Gold" (298), which would send Mr. Horsley and the British Matron into hysterics, being a damsel leaning against the rail of a pier with a Japanese parasol over her head, but otherwise only a transparent film of gauze in the way of clothing.

the weight of the body is thrown on one leg, the other foot crossed over it; and the leg which carries the weight of the body is, as a bit of expression of anatomical construction and action, like the Princess Katishka's left shoulder-blade, "worth going miles to see," and shows that a master of the figure Mr. Whistler is when he takes it into his head to let people know it. Among the works of the religious school is Mr. Stott's "Kissing Ring" (341), some very sad ghosts of children in the midst of a still sadder expanse of shore; a picture which is a piece of pure affectation, only saved by being not altogether commonplace. Affectation reaches its climax in "A Portrait Sketch" (104), by Mr. Munn, where the lady's hand and arm die away into a mist. We remember critics laughing a few years ago at one of Smaike's pictures at a loan exhibition at Burlington House,—"Nutting," with figures which Punch called "Ghosts at Play"; this was the kind of thing, we were told, from which Pre-Raphaelitism delivered us; and now here are the new reformers in painting coming round to the very same thing again, and thus the whirligig of Time brings in his revenges. There are some very pleasant pictures scattered up and down the rooms,—chiefly small works in landscape and "seascapes." Mr. Fraser's "Fishing Boat passing Southend Pier" (464) is disappointing; it has his usual swing and movement of the sea, but is too muddy and opaque,—not without power of a kind, though.

WE have received the first number of a professional journal to be issued at Calcutta, under the title of the *Indian Engineer*. It appears likely to give a great deal of useful information as to what is doing in engineering work in India. The illustrations are executed with anything like the finish we are accustomed to in English engineering papers, and there may be difficulties we do not know of in the way of procuring well-executed locks in India.

CONCERNING Mr. Whistler's Exhibition of "Notes—Harmonies—Nocturnes" at Messrs. Dowdeswell's Gallery we must speak next week, being only able to testify from our own knowledge that on the afternoon of the private view day (Thursday) there was such a crowd that to penetrate through the narrow front shop to the harmonious sanctum was impossible, except for those who had unlimited means at their disposal. The catalogue shows that there are seventy-five "Notes" and "Nocturnes" and "Arrangements" and other artistic evolutions to be seen; but whether they are worth the rush that was made to see them is a matter whereon we suspend judgment.

LETTER FROM PARIS.

THE preparation for the Exhibition of 1889 is daily awaiting the vote of the Senate to pass into the stage of active execution so long waited for. The Chamber of Deputies has approved, by 300 votes against 131, the agreement entered into between the State, the Prefecture of the Seine, and the Guarantee Association represented by M. Christophle, Governor of the Crédit Foncier. Unfortunately, the vote of the Chamber is not definitive; the Senate must ratify it. Parliament is adjourned to the 29th of May, and we have only three years to prepare for this gigantic work. The decision of the Chamber gives a practical character to the project of M. Georges Berger at the Société Centrale des Architectes this week on the exhibition of it becomes every day more imperative. The project of the Government seems very well conceived, and such as to conciliate the interests of all quarters of Paris. It includes four distinct lines, an inner circle running to 20 kilometres of line, partly on a viaduct, partly in cross lines, and partly in open cuttings, and three Gare St. Lazare to the Gare du Nord; the second from the Square Dronot to the Avenue Daumesnil; the third from the Place du Strasbourg to the Place Denfert-Rochereau. These lines, which form one system, will have sixty-four stations at a distance of about 500 metres apart. Except in minor details, the project does not differ much from that which M. Haag, as mentioned in our last letter, has already traced out.

The military mind, formerly so adverse to the suppression of the fortifications, has at last accepted the decision for the demolition of the fortified enclosures between the Seine and the Porte de Roineville. According to the project submitted to the Municipal Council, and which will certainly be approved, the bastions will be replaced by a mere sunk fence between two large boulevards, which will mark also the limit for levelling the octroi rates. It is estimated that it will take three years to carry out the change, and to establish, with the results of the sale of the lands of the "Zone Militaire," new forts around the circumference.

The Ministry of War, which in this matter has shown itself very favourable to the true interests of Paris, deserves besides the recognition of artists, for it is credited with the intention of having some important paintings executed; first, to adorn the salons of the Minister of War with the portraits of all his predecessors up to our own day; and, secondly, to decorate the various barracks with mural paintings recalling the great military deeds of the French army.* A peevish critic might question the utility of this latter intention, which reminds one of the disagreeable frescoes with which Benedict Masson decorated the court of the Hôtel des Invalides. But, as we have hitherto had no instance of a Ministry of War playing the Mæcenæ, while giving the news with a certain spice of incredulity, we offer up our devout prayers that General Boulanger may indeed give this pasturage to hungry artists looking for the official commissions which are now becoming less and less frequent.

On the eve of the Salon artistic news is scarce; artists are reposing after their toils, and what there is going on may be briefly told. The competitors for the Prix de Rome, in the first place, are entering on their course of work. Here are the names of the ten young painters admitted by the Académie des Beaux Arts, and of whom six are from the atelier of M. Cabanel:—M.M. Lavalley, Danger, Tallet, Lohaye, Bourgonnier, Millocheau, Charpentier, Vender, Sinibaldi, and Cabane. The ten sculptors are M.M. Denan, Capellaro, Charpentier, Laroche, Ganquic, Gasq, Convert, Verlet, Desvergne, and Chavallard.

Speaking of the Académie we may mention that the architectural prize founded by Duc has been adjudged this year to M. Chancel, and that the subject was "a hall for lectures and public meetings."

The exhibition of the works of Baudry, opened at the Ecole des Beaux Arts since the commencement of the month, fulfils all that it promised, and draws daily a large concourse of visitors. It is truly a remarkable collection, and we regret we have not space to pass in review this assemblage of works for the most part of so fine and original a character and so powerful and masterly in execution. M. Leneveu has, we may observe, the commission to execute the work at the Panthéon which the State had entrusted to Baudry, and which still remains unaccomplished.

The equestrian statue of Etienne Marcel, which was the subject some years ago of a public competition, has, during the last few days, been placed in the garden of the Hôtel de Paris, on the Quai de Gèvres. The work has been completed by M. Marqueste, who received the second premium, the death of the original artist having prevented his carrying out his design. The statue, cast in bronze at the foundry of M.M. Thiébaud Frères, is a work of fine character and conception, and sufficiently decorative in style. But the pedestal erected

* When would the English Government think of appealing to the chivalrous sentiment of Tommy Atkins in such a manner?—Ed.

from the designs of the late M. Ballu is far from lending itself to the exterior decoration of a municipal palace. It is indispensable that the Service des Beaux-Arts should have it modified and brought into scale, so as not to break the outline of the building and the general harmony of its architecture.

The second exhibition which the Pastellistes are opening this month in the Georges Petit Gallery, is a kind of preface to the *Salon*. The public find there the works of some of their favourite artists, and the success of this little exhibition increases every year, the rather since pastel is a very charming form of art, which declines grave and serious subjects, and confines itself to coquetish and *spirituelles* compositions, fugitive impressions rendered without labour, pretty portraits in the glitter of variously-coloured robes. The new exhibition presents a collection very agreeable to look at, and from which it would be difficult to select any work as deserving of higher praise than the rest. We may mention, as equally worthy of note, the exhibits of M.M. Gervey, Guillaume, Emile Levy, Brune, Dnez, Jacquet; and, with certain reserves, M. Besnard, whose real talent runs a little wild sometimes into a rather over-acted "impressionism."

In this interval of artistic quietude, Parisian painters will rejoice at the news that the Department of the Seine is about to put up to competition the work of decorating the new Mairie of Pautin, a pretty good building from the designs of M. Guelorget. This decoration (of which a portion will be given to the artists obtaining the second and third premiums) will include three great rooms and the ceiling of the grand staircase. The competition will be decided next November.

As the *Salon* will have opened its doors by the time these lines appear, it may be of interest to give now the names of the jury of architecture for this year, which includes M.M. Bailly, Charles Garnier, Vandremere, Questel, Brune, André, Diet, Pascal, Hônard, Daumet, Raulin, and Sédille, with M.M. Normand, Dueswilwald, Gimain, Mayeux, and Deslinières, as "jurés suppléants."

We have to note, in conclusion, the death of M. Emile Laisné, architect, a modest and conscientious artist, who was a pupil of Blouet and of M. Questel. M. Bailly made him his collaborator in the construction of the Mairie of the Fourth Arrondissement and in that of the Tribunal de Commerce. He held an official position under the Municipality as a director in the third section of architectural work, and leaves behind him unanimous regrets at the Administration and among his colleagues.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

ANNUAL REPORT OF THE COUNCIL.

THE annual Report of the Council of the Institute, to be presented at the annual meeting on Monday next, and to which we briefly referred last week, contains the following paragraphs:—

"The proceedings of the past twelve months have possessed a more varied and important character than those of several previous years, and the Council believe that the Institute may congratulate itself upon the progress made in many matters which affect the profession of architecture quite as much as the corporate body of British Architects; though, at the same time, the official year has been marked by irreparable losses. A slight decrease, which is probably only temporary, in the total number of subscribing members, consequent upon the establishment of an educational test for admission to the class of Associates, was anticipated at the outset of the Obligatory Examination.

Five years ago (October, 1881) there were about 490 Associates; in October, 1885, there were more than 690 Associates; and at present (April, 1886) the number of Associates is 673. The number of Fellows has steadily increased from 370 in 1881, to 404 in 1885, and they are now 416. During the year 17 Associates have become Fellows; 27 new professional members have been elected, namely, 9 Fellows and 18 Associates; and 31 gentlemen who have passed the two recent Examinations in Architecture are eligible to become candidates for the Associateship.

The Hon. Associates elected during the year are Mr. Frank Holl, R.A.; Colonel Kingscote, a Commissioner of Her Majesty's Woods and Forests and Land Revenues; and Mr. William

Westgarth, well known in connexion with proposals for the amelioration of the poorer quarters of the metropolis. Eight foreign architects have been elected Hon. Corr. Members, two of them, MM. André and Danmet, being members of the Institut de France; and two being eminent Americans, Mr. Richard M. Hunt, of New York, and Mr. H. H. Richardson, of Brookline, Mass.; with Signor Boni, of Venice; Professor Fenger, of Copenhagen; M. Hermant, of Paris; and Herr Iane, of Berlin.

The losses by death among the Fellows are:—Professor Donaldson, the founder of the Institute, and his friend, George Alexander; James Fergusson, the historian of architecture; J. H. Good and Sancton Wood, two of the oldest members; Thomas Goodchild, of Teddington; and F. W. Ordish, of Queniborough. Among the Associates:—George Borer, Henry C. Harris, E. E. Hollis, and A. T. Ellison, the last named only recently elected, after passing the Examination in 1885. An Hon. Fellow, Edward Akroyd, is also deceased; and the decease of five Hon. Associates has to be recorded, namely, the Duke of Abercorn, the Lord Houghton, Henry Simmonds, the Rev. Benjamin Webb, and Sir Watkin Williams Wynn. Three Hon. Corresponding Members have died during the official year, one a distinguished archaeologist of Athens, Lysandros Kaftangiolon, a friend and contemporary of Professor Donaldson; another, Théodore Ballu, Member of the Institut de France, architect of the Church of the Trinity in Paris, and of other well-known works; and the third, Professor von Dehn Rofelser, of Berlin, and formerly of Cassel.

The death of Professor Donaldson,—the sole survivor of fourteen architects who met on the 13th of May, 1834, at 14, Regent-street, and passed a resolution that it was desirable to form an institution for the promotion of architecture,—occurred on the 1st of August, 1885, at a time when most of the members were out of town. The Institute, nevertheless, was represented at the funeral by the President, several members of the Council, and a large gathering of Fellows, Associates, and Hon. Associates. A letter of condolence with the family of the deceased was addressed by the President to Mr. T. Olinthus Donaldson, the eldest son, and at the opening meeting of the current session the Hon. Secretary took the opportunity of expressing a deep sense of the loss sustained by the Institute through the death of the venerable Professor, and of sympathy with his family in their bereavement. One of the ordinary meetings was afterwards devoted to the reading of two memoirs relating respectively to Donaldson's professional career and to his connexion with the Institute.

The death of Mr. James Fergusson took place on the 9th of January, 1886, and on the day of the funeral, the President, with Mr. Waterhouse, R.A., Mr. Penrose, M.A., Mr. Hansard, the Secretaries, and other members of the Institute, attended to pay a last tribute of respect to the deceased architect and scholar.

[The revenue accounts and balance-sheets, divided into ordinary and trust funds, of the receipts and disbursements for the year ended the 31st of December, 1885, audited by Mr. Banister Fletcher, M.P., and Mr. G. H. Blagrove, are submitted with the report, together with the estimate of income and expenditure for the current year. The estimated income for the present year is 3,650l.]

“Since the issue of the last Report two Examinations in Architecture have been held, to which forty-one applicants were admitted. The first was held last February at Leeds, under the charge of the Leeds and Yorkshire Architectural Society. Of the eight gentlemen examined, six have passed, and the remaining two were relegated to their studies, with the privilege of again presenting themselves without fee. The Questions set for this Examination were prepared by members of the London Board of Examiners, and the Chairman of the Board, Mr. Arthur Cates, who attended at Leeds during the whole week, presided at the Oral Examination. The candidates' answers to the several papers of Questions were distributed among Examiners (all members of the Institute) appointed by the Council of the Leeds and Yorkshire Society, namely, Mr. J. Wreghitt Connon, President of the Society, Messrs. E. Birchall, C. R. Chorley, J. B. Fraser, and W. H. Thorp, who ultimately reported to the London Board. For the Examination held in London all but one of the thirty-three gentle-

men admitted by the Board presented themselves. The Examiners who set the Questions and assigned the marks to the several candidates were Messrs. George Aitchison, E. A. Gruning, E. C. Lee, E. C. Robins, John Slater, Ernest Turner, and Aston Webb. The Moderators who superintended the written and graphic portions of the Examination, and two of whom were always present, were seven in number, namely, Mr. Walter L. Spiers, with Messrs. A. W. Anderson, F. R. Farrow, F. Hooper, H. Lovgrove, C. J. Tait, and E. P. Warren; and their report was of a satisfactory nature. The Oral Examination, which lasted three days, was conducted by the Board of Examiners, who reported that twenty-five of the thirty-two candidates had passed, and only one had not passed, while six were relegated to their studies for one year. No recommendation for the award of the Asphitel Prize, which is given to the candidate who most distinguishes himself in the Examinations held during one year, has yet been made, seeing that another Examination is to be held in November next.

A pamphlet containing the regulations and programme of these Examinations, with a Memorandum of Advice to Candidates, published last October, was widely distributed throughout the country. The first edition being exhausted, a second, to be shortly issued, will include the Papers of Questions set at the recent Examination held in London, the Council having adopted the recommendation of the Board of Examiners to publish such Questions.

During the twelve months elapsed from April 1st, 1885, to March 31st of the present year, the number of volumes presented to the Library was seventy-four and to the Loan Collection six, exclusive of periodicals, reports and transactions of societies, and parts of works issued in a serial form.

A handsome bequest of the late Mr. Fergusson, of all the architectural works in his library not being duplicates of those already belonging to the Institute, will bring in a sudden addition of perhaps 150 volumes, and occupy all the available space in the present bookcases.

The works purchased comprise ninety-nine volumes and one pamphlet for the Library, and five volumes for the Loan Collection, together with several Parliamentary papers.

The attendance of readers in the Library is given in a tabular form. The day attendances show an increase of over 15 per cent., but the evening attendances a falling-off of 5 per cent., as compared with those of last year. Last year's figures were, however, from whatever cause arising, exceptionally high; and that the numbers are by no means lower than might be reasonably expected is evidenced by the fact that they show an increase of nearly 46 per cent. for day and nearly 33 per cent. for evening attendances over those of 1884.

The resolution passed at the opening meeting of the present session, authorising the Council to take certain steps in the matter of the site for the proposed Admiralty and War Offices, and to memorialise the Government in the name of the Institute, should they think fit so to do, was acted on at once, and, owing to the election of a new House of Commons, and the subsequent change of Ministry, the memorial was not presented to the First Commissioner of Works until the 1st March, 1886, when a considerable number of members of all classes of the Institute waited on the Earl of Morley, who courteously received their views on the subject of the memorial. The Council therein referred to the fact that as far back as June, 1882, they had submitted a suggestion for the proposed offices, and that their further suggestion comprised a scheme embodying (1) The widening of Whitehall by the removal of the whole of the buildings between the Horse Guards and Charing Cross; and (2) The opening-up of the Mall to Charing Cross; and the memorial laid stress upon the desirability of effecting these two improvements. A block plan of the Institute scheme, and a lithographed copy of the official scheme, were presented with the memorial, which was afterwards circulated to members of both Houses of Parliament and others.

The resolution agreed to at a business meeting held in March, 1885, with reference to the present condition of the *disjecta membra* of the colonnade of old Burlington House, now lying exposed on the Battersea bank of the Thames, was duly taken into consideration, and it was found that the matter had almost at the

very same time formed the subject of a question in the House of Commons, when it was stated on the part of the Government that no use had yet been discovered for the colonnade, and no site for its re-erection had been even suggested. The representations ordered at the same business meeting to be made to the proper authorities on the subject of the old water-gates known as York Stairs, and of Temple Bar, the stones of which had been carefully numbered for the purpose of its re-erection, were addressed to the Metropolitan Board of Works and to the Corporation of London, and the answers received were published in the Journal of Proceedings on the 13th August, 1885.

Two special general meetings have been held to consider the draft of a new Charter, for the grant of which it is proposed in due course to humbly petition Her Majesty the Queen. The proposal was made at the beginning of Mr. Christian's presidency, and the appointment of a special committee, to take into consideration the practicability of a modification of the Charter, or the grant of a new Charter, was announced at a meeting of the Institute held on the 19th of May, 1884. The committee recommended that a new Charter, reciting the objects and maintaining the date and prestige of the original Charter, should be applied for, and a draft, submitted to the Institute on the 30th of November, 1885, was considered. This draft was then referred to a larger special committee composed of the Council and nine representative members of all classes, with instructions to report to another general meeting. The committee's report, together with an amended draft, were issued on the 25th of February, 1886, and considered by the Institute on the 5th and 6th of April, 1886, when the draft was further amended and, after two sittings of more than nine hours in all, was adopted, with certain reservations, which were intrusted to the care of the Council.

The report of a special committee appointed to consider the subject of Departmental Action suggested by Professor Kerr was submitted to the business meeting of the 29th of March, 1886, when a scheme was adopted for the establishment of four standing committees, for Art, Science, Literature, and Practice, to be elected at each annual meeting, whereby it is hoped that a large number of members may become increasingly interested in the work of the Institute.

The presentation of the Royal Gold Medal to Dr. Schliemann was made at the closing meeting of last session in the presence of a large assembly of members and their guests. The recent election of Monsieur Charles Garnier, the architect of the Opera House, Paris, as Royal Gold Medallist, has been graciously sanctioned by Her Majesty the Queen, and a letter has been received from Monsieur Garnier stating that he hopes to attend the meeting of the Institute at which the medal is formally presented.

The Metropolitan Board of Works having, in accordance with the provisions of the II. Section of the Metropolitan Management and Building Acts Amendment Act, 1873, given notice to the Institute that the Board proposed to apply to the Secretary of State for the Home Department to confirm certain new by-laws relating to the description and quality of concrete walls, and having forwarded a copy of the proposed by-laws, the Council appointed a special committee, consisting of Messrs. A. J. Bloomfield, Charles Fowler, John Slater, and Roger Smith, with Mr. Alex. Payne, as secretary, to consider the same; and the report having been adopted was in due course sent to the Metropolitan Board.

The Competitions Committee have diligently proceeded with their work, and are now gaged, with the assistance of the librarian, preparing statistics of competitions held during the last four years, with a view of ascertaining what amount of success has attended their efforts to procure the appointment of a professional assessor. The committee will report on this, and on other matters of interest connected with competitions, as soon as possible.

The expressions of confidence in the Institute, recently received from the various architectural bodies established in this country and in colonies, have been of a most gratifying character, more particularly those embodied in resolutions which have been passed by the Liverpool Society, the Nottingham Association, the Manchester Association, the Auckland (New Zealand) Institute, the Sydney (New So

Design for a Silk Brocade.

DESIGN FOR A SILK BROCADE.

THIS design is an adaptation of a Sicilian pattern of the fourteenth century, on a small and much-decayed fragment in the South Kensington Museum. It has been woven in four colors, viz., cream, two reds, and a green, and has been registered by Messrs. Hilditch, of Cheapside, to whom it belongs. They have brought it out to supply some of their customers who have become tired of the patterns of this character at present in the market.

The grandest of their present patterns was taken from the dress of one of the figures on the Southwold Screen (St. Peter's, I think), and was brought out many years ago.

This kind of brocade is chiefly used for altarcloths and vestments, but it is quite as adaptable for secular purposes.

SIDNEY VACHER.

ARCHITECTURAL ASSOCIATION:
ITALY EXCURSION.

A MEMBER of the party has forwarded us the following brief notes en route of their impressions of buildings visited:—

"The Italian excursion of the Architectural Association started on Friday, the 16th inst., from Charing Cross at 10.35, the total number of members joining being twenty-four.

The first journey was made to Milan via Calais, Laon, Terquin, through the St. Gothard Tunnel, Chiasso, arriving in Milan at 7.41 on the Saturday night. In Milan the buildings visited were,—first, the cathedral; the completion of the central lantern is still being proceeded with" [the proposed alteration of the Renaissance work in the west front is, as our

readers know, to be the subject of an important architectural competition]; "next, the churches of Sta. Maria delle Grazie, an interesting church, built externally with red brick and terra cotta; St. Amrogio, a twelfth-century church, with open atrium at the west end, with very fine bronze doors in the west end; St. Lorenzo, built on the site of the old church in Milan in the sixteenth century,—the plan of this church is octagonal, with four apses on the principal sides in two stories; the dome, being a regular octagon, does not fit very well, but the general effect is good; St. Eustorgio, an uninteresting church in itself, but with a chapel at the back of the choir, with some good fifteenth-century detail, which also contains a splendid fourteenth-century tomb; the Ospedale Maggiore, a fifteenth-century building, with splendid terra-cotta detail, certainly one of the most remarkable buildings we visited in Milan; the old Piazza del Mercanti, in the centre of which is an old thirteenth-century brick building, formerly the Palazzo della Ragione. The buildings surrounding this are of fourteenth and seventeenth century date. The tower and apse of the Romanesque Church of St. Gosardo were carefully studied, but the building can only be well seen from the roof of the cathedral. From Milan an excursion was made to the Certosa, near Pavia, reputed to be the most richly furnished church in Italy. The monastery has been closed some five years and the remaining monks removed to Bologna, the Government having taken over the building as a national monument. The buildings are most carefully preserved, and access is given to every part. The principal facade of the church is fifteenth-century work of the most elaborate kind, the whole of the work being executed in marble; the other parts of the exterior are principally red brick and terra-cotta. The interior is completely covered with fresco, the fourteen chapels being complete museums of works of art, marble inlays, ironzes, frescos, and pictures. The two cloisters have colonnades with marble shafts and terra-cotta arches; round the larger of the two are the twenty-four houses containing three rooms each, viz., dining-room and work-room on the ground floor and bed-room and dressing room on the upper floor; each room has a small garden.

The most striking modern building in Milan is the Galleria Vittorio Emanuele, the archway opening into the Piazza del Duomo being a very dignified piece of work.

On Monday the Association went to Piacenza. The Palazzo del Comune is a handsome building, in brick and marble, of the thirteenth century, with an open arcade with pointed arches. The cathedral is Romanesque, of the twelfth century, with a very dignified western porch. The original cathedral, now the Church of St. Antonio, contains some interesting work of the tenth and eleventh centuries. The next town visited was Bologna. The principal church, dedicated to St. Petronio, and built in the fourteenth century, is an example of the ambitious designs of that period in Italy which have failed to be carried to completion. It is said to have been commenced as a rival to the cathedral at Florence, the width of the nave being 66 ft., the extended length being 750 ft., but only 384 ft. of this has been built. In the "Reverenda Fabrica" of the church is an interesting collection of models and drawings for the completion of the building by Palladio, Giulio Romano, and Vignola. The church, though generally bare of ornament and void of interest, contains in one of the chapels an interesting early fresco, and on the pavement a meridian line, which showed that the church was not orientated truly. The Church of Sta. Maria Maggiore is an uninteresting Renaissance example, with some quaint canopied tombs built in the open square outside the church. The Church of St. Domenico contains little of interest beyond the tomb of St. Domenico, a Renaissance monument of the fifteenth century. The most interesting church in Bologna is undoubtedly the Church of St. Stefano, which is the name given to a group of seven churches. The first, on a level with the street, dedicated to St. Stefano, is a seventeenth-century church of no interest; the second, at a slightly lower level, built in the eleventh century on a very irregular plan, is dedicated to St. Sepolino; the third, the most interesting of all, is the well-known twelfth-century circular church with the tomb of St. Petronio, built in imitation of the Holy Sepulchre, the altar being built over the tomb; the fourth church, now being restored, of

Vales) Institute, and others, and forwarded to the Council. An intimation, almost generally expressed, that efforts should be made to strengthen still further the excellent relations already existing between such local bodies and the Institute, has led to the appointment of a special committee, consisting of Fellows and associates, and representatives, being members of the Institute, of the provincial societies, to inquire into the question of Federation. The consideration of the best means of furthering professional education, with particular reference to the Examination in Architecture, has been entrusted to another special committee, consisting of members of Council and members of the Committee of the Architectural Association, and others. The question of facilitating the admission of members of the Institute and of architectural students into public edifices, both at home and abroad, for the purposes of study, as engaged the attention of a committee of the Council, and a report has been received on the desirability of furnishing a form of credential testifying to the character of its hearers and to the objects in view, such forms to be in French, German, and Italian, as well as English, and to bear the insignia of the Institute."

Fulham.—The first stone of the Waste Land and Lygon Almshouses, Fulham Palace-road, was laid by the Lord Bishop of London on the 1st inst. They contain accommodation for the eight couples and six single persons, and there a large room for divine service and governors' meetings. The buildings are of brick, with one dressing, and the style is Tudor. Messrs. Simpson & Co. are the builders, the amount of the contract is 2,650*l.*, and the architect is R. J. G. Hall, of West Kensington.

SS. Pietro and Paolo, contains some interesting Classic columns and pilasters and a tomb of St. Vitale dated 382; the other churches are of little architectural interest. Adjoining the churches is a two-storied cloister of the tenth and thirteenth centuries. The interior of the Church of St. Petronius has some interesting ornamental brickwork. The Church of St. Alessandro is a Renaissance church effectively decorated in grey and gold. The numerous arcades, the peculiar feature of Bologna, afforded an unlimited field for the study of Romanesque carving.

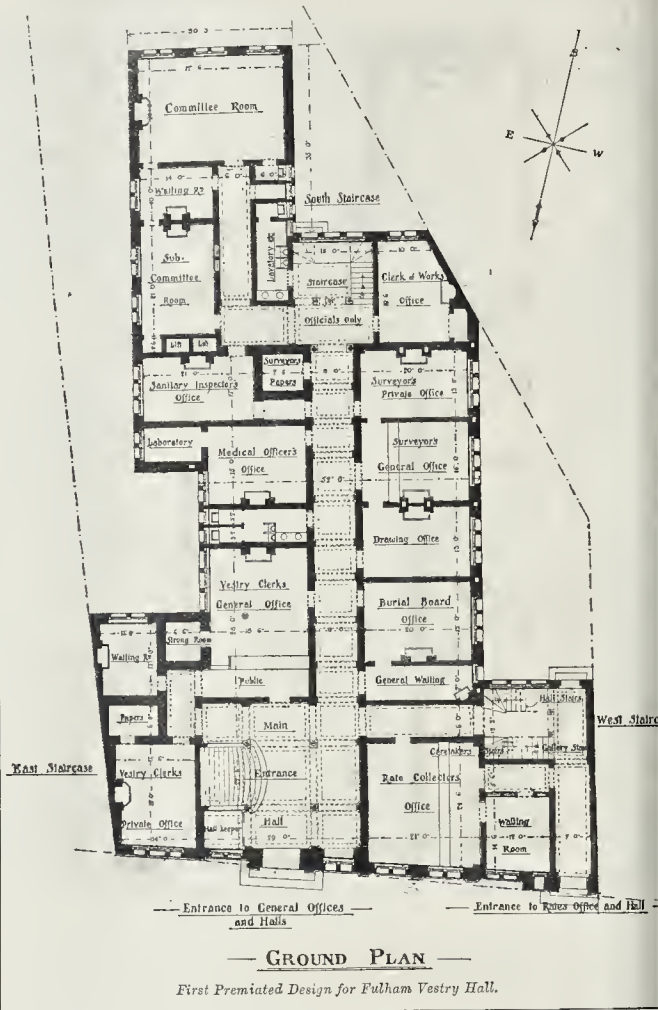

Florence was reached on the 21st, and a stay of four days gave a better opportunity of study than had hitherto been enjoyed. The first building visited was Santa Croce, which contains some monuments of great interest. The next building was the Duomo, the western façade of which has just been completed under the direction of Sig. Del. Moro, from the designs of the late Signor de Fabris, and is to be uncovered in about six months' time. The churches of Sta. Maria Novella, St. Lorenzo, St. Michele, St. Spirito, St. Mariato, and St. Annunziata, the Medici Chapel, the Baptistery, the Bigallo, the Bargello, the Palazzo Vecchio, and the galleries of the Belle Arti Uffizi and Pitti, the Palazzo Ricardi, Strozzi, Gondi, and Pandolini, were all visited and carefully studied. Excursions were made to Fiesole and the Certosa, and on Monday morning at 5-55 a.m. the train was taken for Siena."

TENDERING AT SWANSEA.

At the last monthly meeting of the Swansea Town Council, reported in the *Cambrian*, the Water and Sewers Committee presented a report stating that they had received a letter from Messrs. Baldry & Yerburch to the effect that in making up their tender,—which was accepted at the previous meeting of the Council,—for sewerage works they had calculated that the bricks could be made from the same clay as that which will be used in the middle trench, and that if the Committee insisted upon having a Staffordshire brick, a sum of 3,000l. must be added to their tender, making it 68,835l. instead of 65,835l., but that if a satisfactory brick could be made from the local clay, they were prepared to carry out the work for the lesser sum. Mr. Yerburch attended, and discussed the subject with the Committee, when the following arrangement was made:—That whatever sum be paid by the Corporation, calculated at 2s. per cubic yard, extra for brickwork up to 3,000l., the same is to be allowed by the contractors out of the price for any pugging of clay that may be required, calculated at a reduction in price of 2s. per cube yard up to the extra price paid brickwork, viz., to 3,000l.

Mr. Trew, Chairman of the Committee, in moving the adoption of the report, said he very much regretted to find that the firm whose tender had been accepted for the construction of the Upper Lliw reservoir had found some discrepancy in their tender. He believed this arose from the persistency with which some members of the Council had insisted that the amounts of the whole of the tenders should be read out at the last meeting of the Council. He had thought that was a most unwise course to pursue. The Council ought to have confidence in the committee in such matters as these, and that all the tenders should not be publicly reported. He said this because the next day after the amounts of the other tenders had been made public they received a note from the firm whose tender they had accepted, saying they had made a mistake with respect to the quality of the bricks required, and that if Staffordshire bricks were required the Council must give them 3,000l. more, bringing up their tender to within about a 1,000l. under that of the next tender. He believed if they had not read out the amounts of the other tenders (if they had only kept their own counsel) they would not have heard anything of this 3,000l. extra. The firm alleged that they had tendered on the understanding that the bricks which would be required could be made out of the clay found on the spot, and not Staffordshire bricks; and that if Staffordshire bricks were insisted upon, then they must have 3,000l. added to their contract price. They had taken care even then to come as near to the next tender as they safely could, and yet secure the contract. They had

* We believe it does!—Ed.

thus succeeded, but as a set-off they had agreed to a rebatement of 2s. 6d. per yard on as much "pugging" as would not be required out of the quantity stated; so that although the firm had taken an advantage in one respect they had given it in another way; and the committee knowing that they were a firm in every respect most competent to carry out the works in a most satisfactory manner, now recommended that the contract be accepted.

Mr. Alderman Daniel seconded the resolution adopting the report of the committee. Mr. Freeman inquired what was the price which the other parties who tendered required for the "pugging."

The Mayor put it to the meeting whether these details should be read out and made public or not, but not a single hand was held up in favour of the tenders being read.

Mr. Freeman said this to him was most unsatisfactory. He contended that when tenders were once before the committee, they became public property. He could not help expressing his surprise at the high tone of morality now taken by some members of the Council. Simply because of a clerical error which had been made by the firm whose tenders they accepted, they now wanted to cheat them out of this 3,000l.

The Mayor said such was not the case. Every contractor tendering for the work was shown a brick, and it was distinctly said to each of them, "That is the brick we require"; and yet, after their tender had been accepted, they wrote down to say, "We tendered for a brick

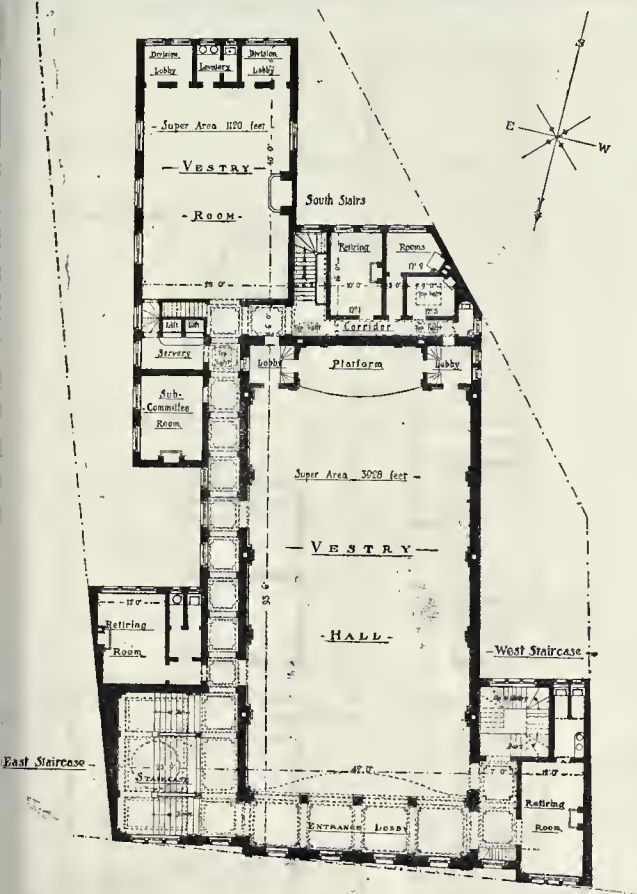

made of the local clay,"—a name of a Staffordshire firm being on the brick shown them.

In reply to a question from Dr. Rawlings, the Surveyor said that the word "Staffordshire" was not on the brick which was shown the first time.

The Mayor said that the firm whose tender had been accepted had taken three various samples of the clay found in the locality of the Lliw, and if they found that they could manufacture therefrom a sufficiently good brick for the purposes of the work, they would then save the additional 3,000l.; but if the Council insisted on Staffordshire bricks, then they would have to give them 21s. a yard more for as much quantity required.

The resolution adopting the report of the committee was then carried.

Japanese Art.—Mr. Ernest Hart will commence, on Tuesday next, May 4, a series of three lectures at the Society of Arts, under the title "Japanese Art Work," including metal work, old lac, porcelain, pottery, picture books, and drawings. The lectures will be illustrated by examples of the great Japanese masters, from the eleventh century to the present date, including many examples of the work of the Miöchin, Korin, Sosen, Hokusai, Kuzan, and others. A loan exhibition of specimens from Mr. Hart's collection of historic Japanese work of art will be on view in the library of the Society during the course of the lectures from May 4 to May 18th.

FIRST FLOOR PLAN

First Premiered Design for Fulham Vestry Hall.

builders, of Tredegar Works, Bow. In preparing the site to receive the superstructure great difficulties were encountered from the treacherous nature of the ground. To reach a solid foundation it was necessary to carry down the excavations for the principal walls to the unusual depth of 50 ft. A large quantity of running water was met with while these works were in progress, and this being traced was found to come from an old rivulet which had its rise in Highgate, and fell into the Thames about this point. To keep this in check, a 10-h.p. engine and powerful pump had to be kept at work night and day for six or seven months while a bed of concrete 6 ft. thick was being laid over the whole of the site. Before the walls had been raised much above the ground-floor level the works had to be suspended owing to the failure of the original company. Towards the end of 1884 the premises were acquired by the Building Securities Company, who arranged with Messrs. J. W. Hobbs & Co., of Croydon and Queen's Buildings, Southwark, to carry on the works. It had been the intention of the first company to erect an hotel with a frontage to the Avenue of 353 ft. On the failure of the company, however, 53 ft. of this was lost. The new owners retained the services of the architects, Messrs. Isaacs & Florence, from whose designs the building had already been commenced. To suit the contracted frontage of 300 ft. the original design had to be considerably modified and remodelled.

The building consists of nine floors and a lofty basement, and its roof rises to a height of 122 ft. above the roadway level of the Avenue. The front elevation is faced throughout with Portland stone, from the quarries of Messrs. Crickmay & Co. and Messrs. Steward & Co. The stone carving of the upper floors has been executed by Messrs. Daymond & Sons, and the whole of the remainder, including the central arch, which is surmounted by two emblematic figures illustrative of Day and Night, by Mr. Boekbinder. Of the ironwork used in the construction of the building, the cast-iron stanchions have been supplied by Messrs. Young & Co., and the wrought-iron girders and stanchions by Messrs. Dibley & Son. The ornamental iron balconettes to the front windows are from the Art Metal Works of Messrs. Starkie, Gardner, & Co. The floors throughout have been constructed of a concrete compounded of coke breeze and Portland cement, in the proportion of 4 to 1, and for all interior lintels solid slabs of the same fireproof material have been employed.

The internal planning has been devised to provide as compactly as possible all the accommodation required for a modern first-class hotel. The main entrance, which is in the centre of the building, leads into a large vestibule, and out of this a grand marble staircase, with return flights on each side, rises to the first floor. The upper floors can also be reached by a staircase at each end of the building, and by a double service of hydraulic lifts placed conveniently near the front entrance. In addition to the two passenger-cars, two additional cars have been provided for luggage purposes. These lifts will be worked by a Worthington pump in the basement; and the whole apparatus will be supplied and fixed by the American Standard Elevator Co. At a short distance from the entrance-hall, along the main corridor, an open vestibule affords access to the grand *salle-à-manger*, which is 100 ft. long by 42 ft. wide, exclusive of the space at the further end and the wings at each side. This room rises through two floors, and is about 30 ft. in height. In addition to this spacious dining-hall there has also been provided on the ground-floor a coffee-room, 56 ft. by 80 ft.; smoking-room, 53 ft. by 37 ft.; reading-room, reception-room, ladies' drawing-room, several private sitting-rooms, general lavatory accommodation, and a range of bed-rooms. Including those on the ground-floor there are about 500 bed and sitting rooms in the hotel. The electric light, in the form of incandescent lamps, will be used throughout the ground-floor and on all the upper floors. In some of the private sitting and reception rooms the Wenbam light has been introduced. Beneath the marble staircase a wide flight of steps leads to a billiard-room in the basement, which is 80 ft. long, 40 ft. wide, and 16 ft. high. In this room there will be ample space for five billiard-tables. In close connexion there is a bar, and also a lavatory, for the use of players. The other rooms in the basement include bed rooms, bath-rooms, general servants' quarters

Illustrations.

FULHAM VESTRY-HALL COMPETITION DESIGNS.

WE give this week illustrations of the design submitted by Messrs. Newman & Newman for the proposed new vestry-hall at Fulham, to which the first premium was awarded by the professional adjudicator, Mr. Currey, whose decision has been so creditably thrown over by the Vestry, with as injustice to those who had competed on understanding that the decision of the professional adjudicator would be acted upon. The design is a suitable one for the neighbourhood, though it cannot be said to exhibit any originality; it consists of that mingling of Ionic pilasters with mullioned windows which become fashionable of late, and which is here treated out with sufficiently neat and finished detail. But of the plan much more than this can be said. The authors have succeeded very well in dealing with a very awkward site, with the difficulty of lighting involved in arranging the ground-floor rooms under a large hall on the upper floor. The staircase is a good light, at the end of the long passage, very good point, and the committee-rooms well placed at the back and away from the eye of the street. The Vestry Clerks' general room would be rather deficient in light, and his are at a long distance from the Vestry-rooms; perhaps not a matter of much practical

importance. In the main, the authors are certainly to be congratulated on their plan, and on the credit of having been selected from so large a competition by so sound a judge as Mr. Currey. It is to be hoped this will afford them some gratification, as this seems to be all they are likely to get from it.

FIRST SELECTED DESIGN FOR PUBLIC BUILDINGS, NEWCASTLE-UNDER-LYME.

WE give the perspective drawing of the design for these buildings as first selected in the original competition, and which the architects, Messrs. Sugden & Son, had (very naturally) wished to have published along with the modified designs, of which we gave the geometrical drawings last week; but they did not contrive to make their wishes clear until too late for that arrangement.

As far as general picturesque effect is concerned, the original design by the one architect is certainly superior to that by the half a dozen architects, as given in our last.

THE NORTHUMBERLAND AVENUE HOTEL.

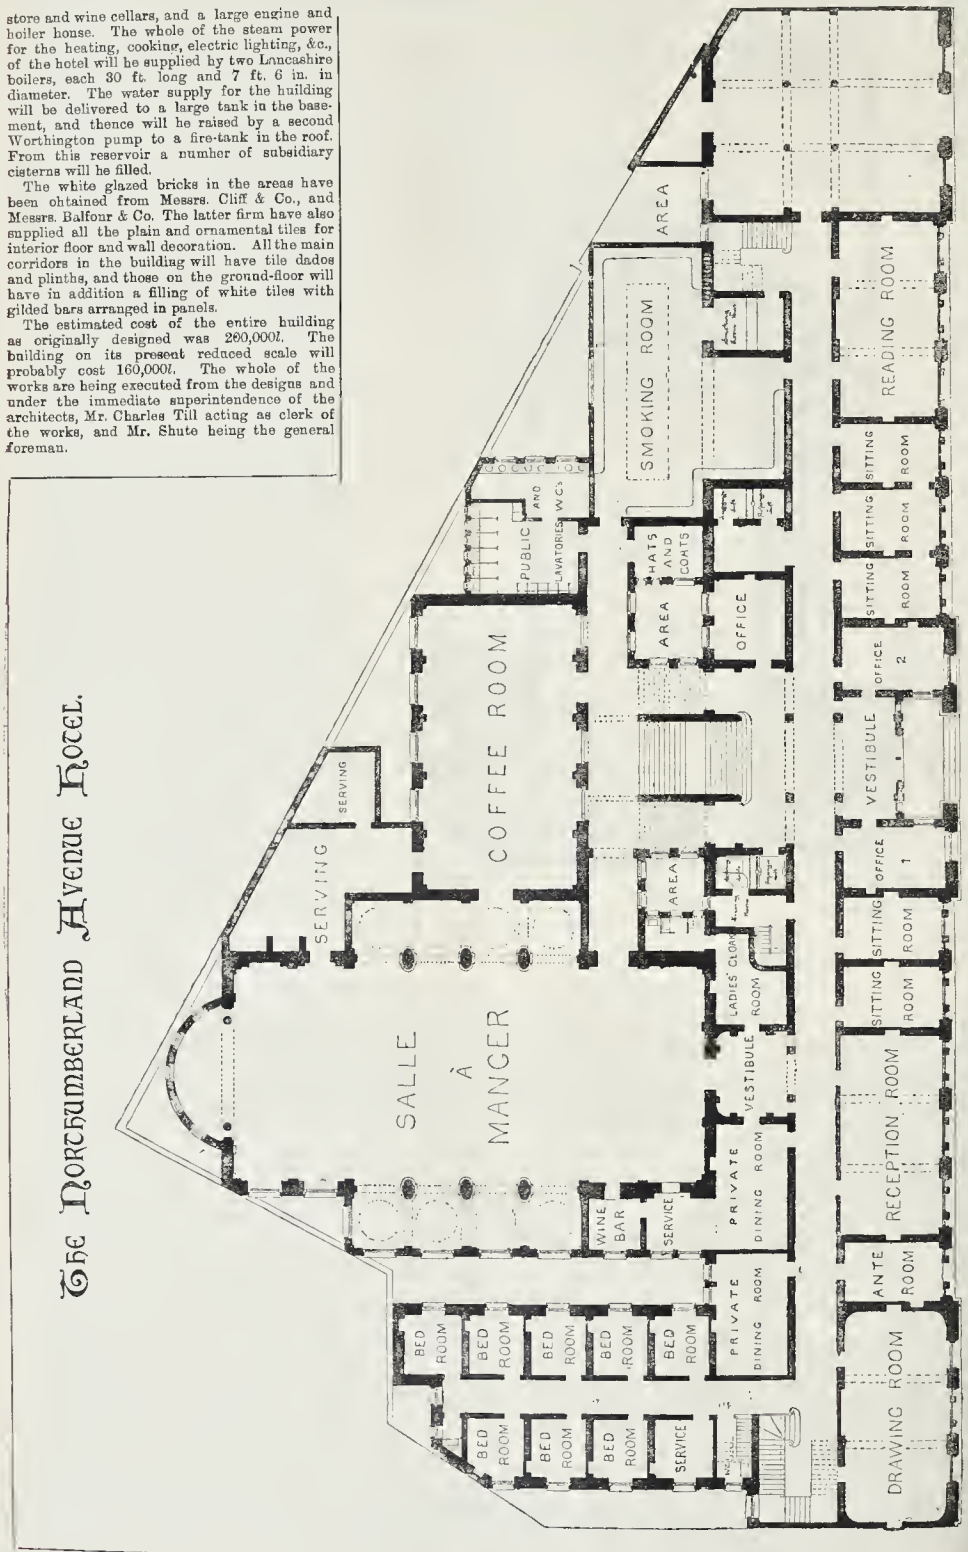

THE erection of this building was commenced by the Northumberland Avenue Hotel Company in the summer of 1883. A contract was then entered into with Messrs. Perry & Co.,

store and wine cellars, and a large engine and boiler house. The whole of the steam power for the heating, cooking, electric lighting, &c., of the hotel will be supplied by two Lancashire boilers, each 30 ft. long and 7 ft. 6 in. in diameter. The water supply for the building will be delivered to a large tank in the basement, and thence will be raised by a second Worthington pump to a fire-tank in the roof. From this reservoir a number of subsidiary cisterns will be filled.

The white glazed bricks in the areas have been obtained from Messrs. Cliff & Co., and Messrs. Balfour & Co. The latter firm have also supplied all the plain and ornamental tiles for interior floor and wall decoration. All the main corridors in the building will have tile dados and plinths, and those on the ground-floor will have in addition a filling of white tiles with gilded bars arranged in panels.

The estimated cost of the entire building as originally designed was 260,000*l.* The building on its present reduced scale will probably cost 160,000*l.* The whole of the works are being executed from the designs and under the immediate superintendence of the architects, Mr. Charles Till acting as clerk of the works, and Mr. Shute being the general foreman.

THE NORCUMBERLAND AVENUE HOTEL.

SKETCH SECTIONS OF DEERHURST CHURCH.

DEERHURST CHURCH.

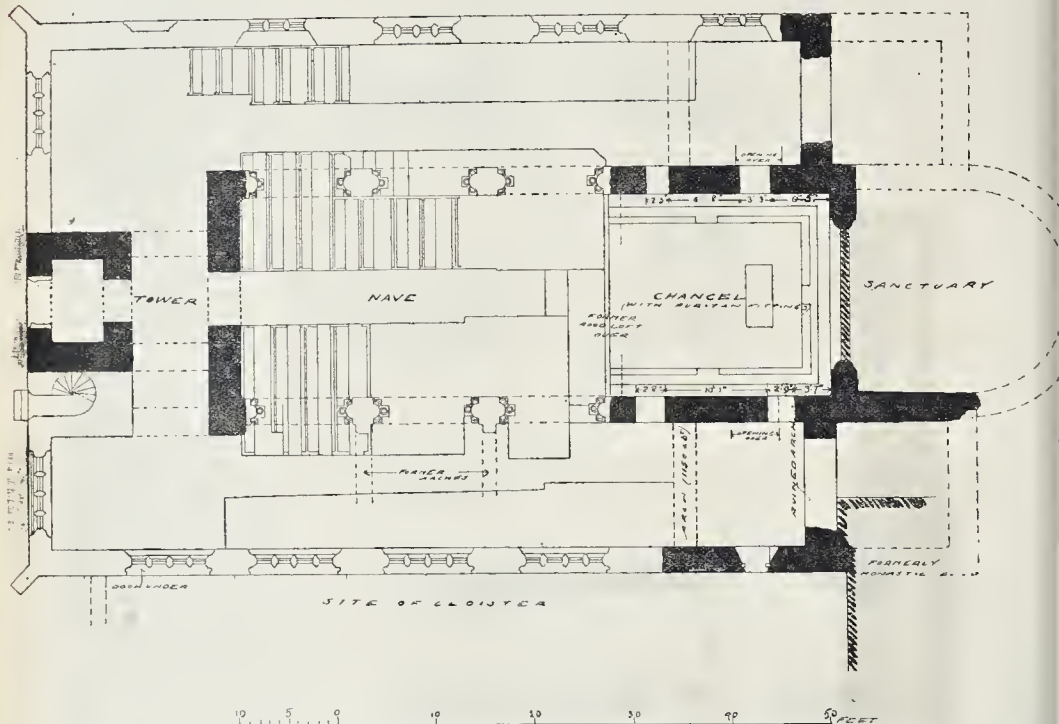

Str.—I read with much interest your description of the newly-discovered Saxon chapel, at Deerhurst, accompanied by a plan and other details [pp. 712, 819, last vol.]. In 1860, when plans were prepared by the late Mr. W. Slater for the restoration of the parish church of Deerhurst, situated not far from this chapel, I went down with a fellow pupil, Mr. S. Fry, and measured it, and afterwards made the drawings. I have referred to these, and have prepared a plan and sections showing the Anglo-Saxon work for purposes of comparison with the plans of the chapel.

It will be seen that this church is on a grand scale, and had in early days nave, chancel, apsidal sanctuary, western tower, and two aisles or chapels to the chancels. The proportions were also very lofty, as they are also in the Saxon churches of Bradford and Brigstock. The important question of the date is not easy to settle. Buckler is of opinion that as it now stands it was constructed about A.D. 1050, introducing features of earlier date; but the other theory commends itself more to my mind, viz., that "a restoration" only was carried out at that time, and that the lower part of the tower, and the nave and chancel and apse walls, are of an earlier date. I found in the course of the restoration of Brigstock Church that in the Saxon tower are numbers of hurned stones irregularly placed, pointing to a restoration after hurning by the Danes. The double window in the tower is, I believe (as does the Rev. C. Buterworth), *in situ*, and if, as Buckler thinks, the early church was low, this would have formerly been external.

There seems no doubt that the curious aisles or chapels belong to the early date, and Buckler thinks that formerly they extended eastward to the dotted lines. The doors are both pointed (like the tower windows) and flat-headed, and there is an arched opening each side above them into the chapels. The present arch in the south aisle is in the Saxon wall, and was an alteration of about 1150 A.D. There are remains of a ruined Saxon arch in the present east wall, and Buckler considers that the same place existed on the north side.

The Saxon chancel arch is removed, but evidences exist of its position. The sanctuary arch is well preserved, and was filled in when the apse was destroyed,

PLAN AS MEASURED 1860 (R. H. CARPENTER)
SEATS WERE 20" IN NAVE & AISLES

PLAN OF DEERHURST CHURCH.

—possibly the apse would be low, with windows over. The early church of Brixworth is a case in point, where the apse, with the sanctuary and chancel arch (or "arcus triumphalis"), all exist.

At Bradford and at Brigstock the chancel was narrower than the nave, proved at Brigstock by my finding the south-eastern quoin *in situ*. At Deerhurst they are equal in width, as at Brixworth.

The construction is an interesting point. The newly-discovered chapel has very fine narrowed angle quoins, as we find in most Saxon work, though they are not in the very regular "long and short" work, such as at Brigstock. The church, however, has the angles composed simply of small stones, like the walling stones, and one would infer an earlier date from this.

The existing clearstory walls are late in date, but there was evidently always a clearstory of great height, as indicated by the roof line in the tower and the windows in the east wall. The church at Bradford is an example of this Saxon lofty proportion.

The division of the tower into many floors and rooms would indicate that it was used for residence and defence, as that at Brigstock; it is likely a floor existed at the dotted line, and removed when the pointed arches were formed. The fourteenth century finish to the tower is very peculiar. The Saxon tower being oblong in plan, the Medieval architect arranged a square on it, with corbels for a spire, and covered the remaining space with a pointed barrel vault of stone, sloped on the outside with an eastern gable.

The plan shows the fifteenth-century seats which remained in 1860, and are now worked in to the new arrangement. It also shows the very singular Puritan arrangement of seats in the chancel, for receiving the holy communion sitting round the table. Mr. Slater retained this as a curiosity; but the eastern seats are not, of course, used. The others do duty for choir-seats. There was formerly a rood-screen,

and the doorway to the loft still exists through the south wall.

The nave roof is a grand fifteenth-century one of elaborate detail, and the arcades are beautifully moulded, with carved capitals to the detached shafts.

I must acknowledge kind help given me in these notes by the vicar, the Rev. C. Butterworth. I have visited the church since the restoration when rowing down the Severn, which runs near its west end, but have not yet seen the interesting chapel recently discovered.

R. HERBERT CARPENTER.

DRY-ROT.

HERR GOTTSCHAU, one of the leading German authorities upon building materials, gives a comprehensive summary of facts bearing upon the above question in a recent number of the *Centralblatt für Bauverwaltung*. He considers the question as one still to be solved, and suggests that the germs of the dry-rot may exist in the living tree, illustrating this supposition by quoting circumstances where apparently dry and sound wood was attacked. In Russia there are whole forests from which no building woods is now taken, experience having shown that it has always been attacked by dry-rot. A concentrated solution of common salt has often been found an efficient preservative, when applied to the beams in a boiling state. Airing with dry air has also been found efficacious.

In connexion with this subject the researches of Professor Polek are of interest. He instituted a series of experiments with a view of testing whether the germs of dry-rot become developed in wood felled during the winter. From three trees felled in January (grand pine) sections were taken on March 31st, in which were sown the germs of dry-rot. The sections were kept in covered vessels in a dark chamber at an average temperature of about 50° Fahr. The characteristic mycelium of the dry-rot became

visible during July and August in the three specimens. The wood of the previous winter had been found unsuitable for such experiments, although they succeeded with wood of the winter in question. A careful analysis of the wood showed that there was from 4 to 9 per cent. more potassium and phosphoric acid in the wood of the later season than in that of the previous one. The wood where the experiments had failed was supposed to have been floated wood, and experiments were consequently begun for the purpose of determining whether wood felled in the summer could be rendered safe against dry-rot by the removal of the bark, protracted drying, and steeping in water.

The *Industrie Blätter* refers to the experiments made with progressive success by Professor Farsky, of Tabor (Bohemia), in the application of salicylic acid as a remedy for dry-rot. At first he had used it in dry form (probably, therefore, in combination with some base), but since discovered that a solution of 5-25ths oz. salicylic acid in 22 gallon of alcohol, if afterwards diluted, was sufficiently efficacious to protect a flooring of 800 square feet from the spread of dry-rot, and to remove it from the places where it had appeared. Rough salicylic acid can be used, and the action of this antiseptic agent can be heightened by a slight admixture of carbolic acid.

Obituary.—We record with much regret the death of a promising young engineer, Mr. Edwin Southey Beale, at the early age of twenty-four, and after a very short and sudden illness. Mr. Beale contributed several very useful articles on some of the important engineering works of the day to our columns, on various occasions, which showed very full and accurate knowledge, for so young a man, on the subjects he specially undertook to deal with.

THE ATMOSPHERIC COWL COMPANY'S EXHAUST VENTILATOR.

This ventilator differs from an immense number of exhaust or updraught ventilators that have been made in not depending entirely on the action of wind (though that assists it), but on the difference between the temperatures within and without the apartment to be ventilated.

The ventilating-shaft on which the exhaust is placed contains air warmer, and therefore relatively lighter, than the outer air of the surrounding atmosphere, and this is turned to advantage in the ventilator under our notice by providing continuous slits at the angle of a spiral worm (projecting slightly in the interior of the shaft so as to be more affected by the heat) and by enclosing the portion of the shaft

Where the ventilator is exposed to the heat of the sun, the bottom of the jacket is to be closed, and a special supply of cold air is to be led into it by a pipe from a cellar or other cold-air reservoir. This is ingenious, but we should rather doubt the exhaust having as efficient action under these circumstances as when the normal temperature of the outer air is low. In fact, it would appear that the ventilator would have to be altered for hot or cold weather, so that to this extent it would be affected by varying temperature in the air, like other exhaust cowls.

It has the merit of being a small and unobtrusive-looking thing, without anything like the large and variously-shaped cowls which are to be seen on exhausts intended to act solely by wind force; and the idea is certainly ingenious and scientific so far as its action in direct relation to the heat of the apartment is concerned. As an assistance to the draught of a chimney, and a safeguard against down-draught, it ought always to be efficient, on its principles; and we have found it so on actual experiment. As an exhaust from a room, apart from the chimney-shaft, it would not be equally effective, we surmise, in all states of the weather; but it would be, or should be, superior to those exhausts which are actuated by wind-currents only.

WATER SUPPLY.

Leamington.—The Local Government Board have given their consent to the borrowing, by the Leamington Town Council, of 1,600*l.* for the extension of the water-mains and the driving of the addit in the new artesian well.

Stafford.—At the meeting of the Stafford Town Council on the 20th ult., Mr. J. C. Mycock moved "that the sanction of the Local Government Board be asked for the raising of a loan of 4,500*l.* to cover the outlay on the pumping shaft or well at Enson Moor, in carrying out the agreement entered into with Lord Harrowby, and for defraying the estimated cost of the proposed experimental boring from the bottom of the pumping-shaft." The Mayor seconded the motion, which was unanimously carried, the Town Clerk stating, in the course of the discussion, that, assuming water was found successfully, another 15,000*l.* beyond the amount already expended or sanctioned, would complete everything. That was altogether 25,000*l.*, and that meant practically a little over 30*s.* a head for the population of the borough and the fringe round it to be supplied. Statistics as relating to other towns showed that a water supply had seldom, if ever, been got at a lower rate.

STONE FOR THE NEW GOVERNMENT OFFICES.

SIR,—I do not know whether you will agree with me that the answer of the Government to the Member for the Forest of Dean, that the only reason for rejecting the stone he inquired about was that the colour is unsatisfactory, is not much to the point. In my own opinion, the answer was singular, if not absurd, as emanating from a practical department of the Government, the members of which are, of course, resident in London, and must, therefore, know from ocular demonstration and every-day experience that the natural colour of all freestones is changed immediately in the sooty and noxious atmosphere of the metropolis. If the building of the new offices must wait till a freestone is discovered that will not change colour, they will never be built at all. As you have more than once allowed me to urge, a material exists possessing this important quality, and another even more important,—durability in London. Granite has yet another recommendation. It can be obtained in all colours that the architect can possibly require,—from white through yellow, red, green, gray, blue, black. And taking into account the excessive and rather discreditable expenditure upon the restoration of recently-built Government structures in London,—70,000*l.* in one case alone,—its adoption for the New Government Offices would not cost an extra 6*d.*

Yet although this material,—in great variety,—is in daily use, the Government has not the enterprise to adopt it on a grand scale, and for ever set at rest the simple question, Is it possible to erect permanent edifices in London?

ARCHÆUS.

STAIRCASE, ALBANY CAPITOL.

SIR,—Will you permit me to correct an unintentional error of statement which occurs in a note accompanying the drawing of Mr. H. H. Richardson's design for the grand stairway in the new Capitol at Albany, New York, which is published in the *Builder* for the 17th of April [p. 574]. It is there stated that because of political action on the part of Government authorities, Mr. Fuller, whose design was chosen in open competition, resigned, and Mr. Eidlitz and Mr. Richardson were selected to carry on his work. I believe that for once in America, politics entered not at all into the consideration. The facts are these:—In accordance with a long-established custom in the United States, the terms of the competition were such as to prevent nearly all American architects of established reputation from having anything whatever to do with it. As a result the drawings submitted were of little value. Doubtless the design chosen was the best. When the building had progressed as far as the tops of the third story windows, the money already expended exceeded by several hundred thousand pounds the estimates of the architect himself for the entire structure. Moreover, it was seen that when completed the building would be a positive artistic offence, even in the country which counts more vulgar pieces of architecture than any other pseudo-civilised community whatever. Therefore, both by reason of pecuniary and artistic considerations, the entire control of the work for the future was given to three of the most prominent of American architects, Mr. Richardson, Mr. Eidlitz, and Mr. Hunt.

No attempt was made by the new architects to harmonise the new and the old work; any compromise was artistically impossible. Therefore, the entire interior was reconstructed and the exterior completed in a style of extreme originality and beauty. Instead, therefore, of the new work seeming out of place, it is the remnant of first work that is offensive. Should the time ever come when the exterior work of the first and second stories is replaced by something nobler and purer, the building will be a most harmonious and beautiful piece of design, although Mr. Eidlitz and Mr. Richardson were so handicapped at the start.

The original design may have been "Italian Renaissance," but in America we call it "American Renaissance," or "Builder's Classic." There is no English work with which it may be compared. The designs executed by Mr. Richardson and Mr. Eidlitz are Byzantine Romanesque, and a very rich round-arched Gothic, remarkably effective and of unusual originality.

RALPH ADAMS CRAIN.

ANCIENT GREEK SCULPTORS.

SIR,—In last week's issue of your paper, under the head of "Recent Excavations in Bœotia," p. 603, you state, in reference to an incomplete inscription on a fragment of a stele, that "Literary record gives us no sculptor's name ending in 'στρος' to supply the deficiency."

On p. 601 in the same issue, referring to a colossal statue found at Gortyna at Crete, you state that "the great interest of it lies in the fact that it is inscribed with the name of the sculptor, 'Ἐλεῖθρος Ἀθηναῖος τέλει.'" This seems to me to furnish the very clue which you require.

CHARLES G. CRESSWELL.

* * The first quoted remark referred to sculptors of the archaic period, of the Bœotian territory, and, therefore, likely to use Bœotian characters. Evidently, especially with his affix, Ἀθηναῖος, could not come under this category. There are several known sculptors of the classical period whose names end in "στρος." It was not, we admit, put quite as clearly as it should have been.

STONE-SAWING MACHINERY.

SIR,—I see in your issue of the 24th ult. p. 624, a letter from E. P. Bastin & Co., stating they are makers of side lever saw-frames, but they omitted to state that they were using my patent under a royalty from me.

With regard to the statement of Mr. Powis Bale that side lever machines were used in Belgium years before my patent came out, that I question, or why was not my specification challenged when I brought it out in 1874, or when I renewed it in 1881?

Park Foundry, Weymouth.

RICHARD COX.

SIR,—My letter to you of the 10th ult. [p. 583, ante] will not bear the construction which Mr. Powis Bale puts upon it. I should be the last person to advocate "sitting at home." In the course of my business it has been my lot to travel through Belgium, France, and Italy, and I have spent many months in the examination of the manner in which marble and stone are sawn and worked in these countries. I do not know who are the manufacturers of the machines which Mr. Bale mentions, but I do know that the description of them given by Mr. Bale himself exactly answers the description of the machines made by Mr. Cox under his patent. If they are not

SECTION.

PLAN.

finished with the spiral worm in a jacket open at the bottom, so that the external air forces its way in at the bottom of the jacket to supply, through the slits, the partial vacuum in the shaft, and, coming in contact with the comparatively warm metal, expands and rises in the jacket, entering the slits with greater force and consequence, and giving the effect of a continuous jet into the interior.

Care is taken to give a special direction to the incoming jets of air, so that they pass one after the other near the centre of the shaft (as shown in the plan), and communicate to its contents a rotary ascensional motion, whereby the draught is quickened, and the vitiated and heated air attracted in greater proportion than the mere difference of temperature between the shaft and the outer air would effect. This is, therefore, theoretically at all events, an automatic haul, calculated to draw more rapidly the higher the temperature rises in the room to be ventilated.

the same, will Mr. Bale tell us what the difference consists? In his description of the Belgian machines, he says they are driven "by a crank attached to a countershaft in the usual manner; but in place of the connecting-rod being attached to the end of the saw-frame a pair of side levers are arranged to take hold of the frame at about the centre on either side, thus giving a longer connecting-rod, and increased steadiness in working." The conclusion which will be naturally drawn from such a statement is that this principle is peculiar to the Belgian machines. This is not the case, and in justice to our own manufacturers it should be so stated. If I have misunderstood Mr. Bale's description, I should be exceedingly glad to be put right. I can assure him that English manufacturers are only too anxious to learn from any source open to them.

ARTHUR LEE.

ROBINSON'S CEMENT.

SIR,—With reference to the letter from Messrs. John Howe & Co. (plaster makers) on the above subject, which appeared in your columns on the 23rd inst. [p. 624], we are not disposed, for obvious reasons, to give them any further information than that which they have already obtained or can obtain from the patent. We also decline to be drawn into a correspondence on the subject, but take this opportunity of stating that if they or anybody else do manufacture or sell "Robinson's Cement," or an article identical with "Robinson's Cement," they infringe our patent, and do so at their risk. JOSEPH ROBINSON & CO.

Knott Hill Cement Works, Carlisle,
April 28.

"HASKELL v. BRADBEER."

SIR,—My attention has been called to the excellent report of the trial of this action in your paper of the 24th ult. [p. 624]. There is, however, one little error which perhaps you will kindly allow me to correct, i.e., the name of the learned counsel who appeared for my client, the plaintiff, was "Willes," and not "Wills." F. A. WHITMORE LOWE.

The Student's Column.

OUR BUILDING STONES.—VIII.

THE PREPARATION OF MICROSCOPIC SECTIONS OF STONE.

As before mentioned, in order to examine stones with the microscope it is necessary that they should be ground down until they are transparent. As so much depends on the proper treatment of sections, considerable care and delicacy of manipulation must be bestowed on them. If the section is not uniformly ground,—one part of it being thicker than another,—or not reduced thin enough, the accuracy of determination is much impaired.

It is not so difficult to cut and grind sections of granite, and such hard rocks used in building, thin enough for the purpose, as they are so compact. But with some sandstones and limestones it is quite another thing. Many fairly durable building-stones are not so compact as to enable sections to be made thin enough by the ordinary method, for examination. Just as the final stages are being completed, they frequently break up and go to powder. We shall point out, however, how these refractory stones are to be dealt with, in order that they may be successfully investigated.

The method of preparing thin slices of rock for the microscope is well explained by Messrs. A. Geikie* and F. Rutley.†

The preparation of a great number of sections for the purposes of these articles, however, enables us to see that the special circumstances of the case require a somewhat different method from that usually practised.

No very costly or unwieldy set of apparatus need be procured, every appliance used being of the simplest character.

The first thing to do is to select the usual average piece of stone, which is to be ground down. A dexterous blow with a hammer should sever a thin chip from it. If the stone is very hard, this chip should be as thin as possible, as it saves a great deal of work in grinding; but if, on the contrary, it should not be very compact, a piece not less than ¼ in. in thickness, should be struck off, as thinner pieces are liable to be fractured internally. Much trouble might be saved if the stone be taken to a lapidary, who, for a penny or two per section, is willing

to slice it with his machine. This produces two even surfaces on the thin piece to be ground, besides making it of a uniform thickness. The following is a list of the apparatus required in the grinding and finishing:—

1. Two zinc plates ¼ in. thick, 10 in. square. Iron is sometimes recommended, but we prefer zinc because it does not rust. One zinc plate is used for coarse emery, the other for flour emery. It is particularly necessary to keep these plates apart from each other, as, if any of the coarse emery finds its way to the flour plate, the section on being rubbed on the latter will be cut to pieces.

2. A Water of Ayr stone, 5 in. square ¼ in. thick. The sides of the stone should be painted with oil colour to keep the wet out, and so prevent the stone from rotting. Water of Ayr stones 6 in. long by 2½ in. broad are generally used, but the fact that they soon become worn by the rubbing process into hollow surfaces is a sufficient reason for using a larger stone where the rotary motion causes it to wear away more evenly.

3. Emery powder for rough grinding. That known as No. 60 is very suitable.

4. Flour emery.

5. Canada balsam. This is often used for fixing the specimen whilst grinding as well as finally mounting it, but for the former process we have found a shellac cement more useful. This cement is made of about ½ lb. shellac to ¼ lb. Venetian turpentine. Put the shellac in an earthenware pot and place it in an oven. When about half melted, add the Venetian turpentine and mix both together. It may be stirred with a stiff wire, with a loop at one end. When sufficiently mixed, pull the wire out and when cool enough, catch hold of the cement adhering to it and roll the cement between the hands into a stick, like sealing-wax.

6. Two American wooden paper clips, forceps, and some needles. One of these last should be stout and strong.

7. Some pieces of thick glass, 1½ in. or 2 in. square.

8. Glasses with ground edges, 3 by 1 in., may be obtained of almost any optician. They are for finally mounting the ground slices upon.

9. Thin covering glasses, shape immaterial. Square ones are cheapest.

10. ¼ oz. oil of cloves, and a small bottle of spirits of wine.

11. A small spirit-lamp, and a nest of small saucers.

a. The first part of the process is to grind the chip of stone flat on one side, rubbing it on one of the zinc plates with emery powder (3). Then wash the chip in water, taking care that all the emery is removed. Next, grind the same side of the chip with flour emery on the other zinc plate, which should remove the rough scratches made with the emery powder. Wash it again. By this time the piece of stone should be quite smooth on one side.

b. Then polish it on the Water of Ayr stone, using a little water. Wash again. It will be found that many soft sandstones and limestones will not polish well. This does not particularly matter, but in all cases they should be ground as smooth as possible.

c. The polished side should now be fixed to one of the pieces of thick glass mentioned (7). This is done by clasping the glass with one of the paper clips (6), and holding it over the lighted spirit-lamp (11), gently moving it to and fro, until it is warm. A stick of shellac (5) should then be rubbed on the warm glass, when it will be found to melt. As the shellac melts, a rotary motion is applied to get an even surface, and distribute it fairly over the centre of the piece of glass.

d. The smooth side of the chip should then be warmed a little, and placed on the piece of glass with the shellac. A paper clip may be used at this stage to press the chip firmly on the glass, and care should be taken to see that the part of the shellac which cements it is equally distributed. Throughout the whole of this part of the process, the glass with the chip affixed should be slightly warmed, and if any air-bubbles appear,—as they very often do,—the chip should be moved about until they disappear.

When a few minutes have elapsed, and the one side of the chip is firmly cemented to the glass, the other side should be ground down in exactly the same manner as described in a, b. This time, however the chip requires more watching, to see that the stone is being evenly ground, no one part being thicker than another.

It must be remembered that the object is to be made as thin and transparent as possible. So hard stones may be reduced to as thin as, if thinner than, a sheet of tissue paper; but others are attempted to be so finely ground before stated, they go to pieces. No rule can be laid down as to what the actual thickness of each chip should be: nothing but a little experience can determine it.

Heat should now be applied to the glass, so the shellac cement re-melted, the object being to remove the chip from the glass. This may be done by gradually sliding it off the edge, with the stout needle, but great care must be exercised, or the slender piece of stone will break. The slice of rock is now gently placed in alcohol spirit (10) in a small saucer (11), and allowed to remain some hours. It should then be taken out with a small brush, and placed in a saucer with some fresh spirit, where it may remain some hours. Take it out again, and place it in a saucer, with a little oil of cloves (10), keeping it there five minutes only.

The section is now ready for the final mounting on the glass with ground edges (8). (One of these pieces of glass should be cleaned, a little Canada balsam dropped on the centre of it. The thin section should then be very carefully placed on the balsam, and under influence of the heat of the spirit-lamp, mounted gently about to ensure the removal of any air-bubbles which may appear, and to firmly cement it to the glass. A little balsam may then be drawn with a needle over the section, and the thin glass coverings (9) carefully fixed to prevent dust from spoiling it.

A label is afterwards affixed to the slide, with the name of the stone, quarry, and bed written on it.

As before stated, many stones used in building are very soft. Sections of them cannot be handled about in the manner just described. We treat them partly by the method recommended by Mr. E. T. Newton, F.G.S.* They rub the chip on an ordinary grindstone, and polish as well as possible with the Water of Ayr stone. It should afterwards be soaked in a solution of shellac in spirits of wine. This shows this mixture, and, when dried, becomes very hard. It is then cemented with the marine glue to a piece of thin glass, with ground edges (used in the final stages of the method). The other side must then be ground in a similar manner, and the section reduced to the required thickness. In consequence of the soft nature of the stone it should not be removed from the glass. This latter will be likely be scratched in the grinding process, but look a little negligently, but heavy must in the instance be sacrificed to utility.

Instead of fixing one of the thin glass coverings on the section at the final stage, as before the best plan is to put it away in a place where the dust will not get at it. To fix the glass covering heat must be applied, consequently unless extreme care is taken, the section will be spoiled by falling to pieces.

All this may seem rather tedious, but it is astonishing how practice facilitates the operation. A good plan is to have several pieces of stone ready at each stage of the process. In instance, a few hours may be employed in grinding several, as described in a and b, the whole of the pieces are then ready for c, d, so on. In this way, twelve sections can be ground, and mounted in about the same time as four or five done separately.

RECENT PATENTS. ABSTRACTS OF SPECIFICATIONS.

17,011, Conduits for Underground Work.
J. B. Paise.

These conduits are constructed of glazed earthenware in sections, and coated internally with paraffin and shellac. The sections fit together with gaskets and socket joints, and have longitudinal lines, which are provided to receive pipes to carry brines, &c. The conduits are about two-thirds filled with water, the remaining portion being left for ventilation produced by the air being drawn through enclosed fire at the base of a suitably constructed shaft.

16,893, Furnace Bricks and Concrete Work.
J. Gillespie.

These bricks or their outer faces only are of clay, and for the purpose of affording a holganiser or other silicious lining, they are provided with projecting pins or ridges, which may be

* "Outlines of Field Geology," 1882, pp. 202-211; and "Text-book of Geology," 1882, pp. 182-187.
† "The Study of Rocks," 1883, pp. 59-74.

* See Rutley, *op. cit.*, p. 71.

oid with the brick, or made separately and afterwards inserted. In the latter case, when the ridges are longitudinal, they take the form of tiles inserted in grooves; this may be modified by letting the tiles lie between the bricks instead of into a groove, re- sults being formed so that the tile enters half into each brick, or the rebate may be dispensed with, and the tiles fastened on entirely through the joint, in place of the projecting pieces, holes in the bricks may be employed to effect the same object, these holes may be extended right through, and the bricks then by using only one hole are caused to take the form of tubes. Linings built of these tubes in connexion with tiles, consist of a skeleton, which is filled in with the plastic lining. This use of hollow bricks is also applicable to the building of concrete walls.

16,111, Door Locks. J. Edwards. The tumblers of the lock engage with a pin upon longitudinal slot. In the act of locking an extension of the tumbler passes over the keyhole and prevents the insertion of any pointed instrument or the purpose of picking the lock.

April 16.—5,286, E. Staples, Attaching Door Knobs to Spindles.—5,316, W. Allen, Syphon for self-flushing Water-closets.—5,317, W. Wesley and J. Peers, Ventilators.—5,321, M. Hussey, Roofing Systems, &c.—5,324, G. Oulton, Syphon Flushing Systems.—5,343, G. Johnson, Machines for Making Gouge and Groove Flooring. April 17.—5,351, R. Bradshaw, Carrying of able for Brick Machines, &c.—5,371, J. Macneil, Fan Ventilators.—5,387, A. Seefils, Rendering Wood, &c., Fireproof. April 19.—5,391, W. Baldwin, Waste Prevent- ing Syphon.—5,438, W. Green, Lifts and Ladders.—5,438, J. Lorrain, Chimney Flues, &c. April 20.—5,442, J. Stacey, Turning Nibbed Valves, &c.—5,454, C. Meyer, Combined Ward- robe, Bookcase, and Secrétaire.—5,457, J. Pflüging, Leads for Stained Glass. April 21.—5,504, G. Newman, Sash or Window Washers.—5,516, W. Walker, Cooking-ranges.—5,516, W. White, Paving Blocks. April 22.—5,553, J. Dyson, Cows, Chimney-tops, &c.—5,556, J. Smith, Stoves, Firegrates, &c.—5,574, H. Glendinning, Springless Locks and Latches.—5,581, R. Rastrick and G. Hughes, Mitrering and Jempeeting Machine.

PROVISIONAL SPECIFICATIONS ACCEPTED.

3,259, H. Penrice, Rock Tunnelling Machinery.—3,420, S. Jarvis, Bastic Bricks.—3,421, S. Jarvis, Bastic Bricks.—3,480, G. Newman, Pneumatic Door presses and Checks.—3,544, J. & J. Mason, Hang- ing Window-sashes.—3,569, J. Dyson, Wall Bond- ing Bricks for Damp Walls.—3,567, J. Lawson, Self-acting Water-closet.—3,628, W. Burridge, Water- closets, Urinals, &c.—3,694, H. Pennell, Window fastening.—3,874, T. Ford, Suspended Hydraulic Differential Power Lifts.—4,153, T. & J. Holt, Flushing Apparatus for Water-closets, &c.—4,435, F. Rows, Frough and Sash Pullster Plane.—3,364, T. Price, Sash fasteners.—3,944, T. Humpage and J. Shaw, Scaffolds.—3,961, S. Fraulkinberg, Cement or Mosaic Work, Wood Paving, &c.—4,288, J. Walker and H. Worsey, Sash Casement and Door fasteners.—4,361, J. Walker, Door Knobs, &c.—4,489, J. Sharp, Chimney Cow and Ventilator.—4,500, C. Wharton, Automatic Window-sash fastener.—4,603, J. Rawlings, Bench Plugs and Pins.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to opposition for two months. 7,208, A. Hogg, Adjusting and Attaching Door knobs to Spindles.—7,483, J. Hamond, Mortising Machines.—7,748, T. Worthington, Imitating Wood, Marble, &c., on Painted Surfaces.—7,834, J. Smmond, Door Fastening.—8,094, G. Andrews, Sash for Hydraulic Lifts.—8,138, H. Williams, Window-sash Fastener.—8,254, W. Shorland, Weather Board and Draught Excluder.—13,247, I. Headland, Chimney Pot.—1,912, G. Woolhcraft and T. Freeman, Ties.—3,283, S. Mower and T. Fowler, Machines for Making Saws.—3,459, J. Bentley, Glazed Structures and Skylights.—8,364, J. Wood, Producing a Glazed Surface on Stone.—10,514, E. Wood, Ventilators.—3,065, H. Allison, Door and Wall Covering.

RECENT SALES OF PROPERTY. ESTATE EXCHANGE REPORT.

April 15. By DEE, SON, & HILTON. 11tham, High-street—Turrington Lodge and Meadow View, freehold £3,760 By REYNOLDS & EASON. 1/1alhamston — 2 3 and 4, Hope Cottages, freehold 410 1/1apham — Loats-road — Holly Lodge, 22 years, ground-rent 2l 545 1/1ngland — 38, 40 and 42, How-street, 18 years, ground-rent 6s 510 1/1nch Town — 2 and 3, Lewis-street, 49 years, ground-rent 9l 480 By RICHARDSON & BOOTH. 1/1reewich — 4, Lorne-terrace, 78 years, ground-rent 4l 8s 220 April 22. By TOLIS & HARDING. 1/1ethal Green-road — Nos. 120 to 128 even, and I, George-street, 70 years, ground-rent 65l 810

Table of property sales with columns for location, years, and ground-rent. Includes entries for Dulwich, Brixton, Pepler, Notting Hill, Claygate, Egham, Wandsworth, Elmfold, Chislehurst, Notting Hill, Hyde Park, St. George-in-East, Mile End, St. George-in-East, Limehouse, Poplar, 23, Rook-street, 22, Tetley-street, Bromley, 28, 24, and 26, Whitehorse-street, freehold.

MEETINGS.

SATURDAY, MAY 1. Association of Public Sanitary Inspectors.—Address by Mr. Edwin Chadwick, C.B., President. 8.30 p.m. St. Paul's Ecclesiastical Society.—Visit to the Church of West Ham. 3.45 p.m. MONDAY, MAY 3. Royal Institute of British Architects.—Annual General Meeting. 8 p.m. Surveyors' Institution.—Professor W. Freeman on "The Geology of the Surface in its Practical Aspects." 8 p.m. Society of Engineers.—Mr. W. A. Martin on "Induced versus Forced Draught for Marine Boilers." 7.30 p.m. Clerks of Works' Association.—Mr. J. R. Cruickshank on "The Decoration of Public Buildings." 8 p.m. Inventors' Institute.—8 p.m. Society of Chemical Industry (London Section).—(1) Mr. A. C. Selmon on "The Purification of Water." (2) Messrs. Macnab and Beckett on "The Treatment of Water for Technical Purposes." 8 p.m. Society of Antiquaries of Scotland.—Mr. J. Romilly Allen on "Early Christian Symbolism in Great Britain and Ireland" (Rhind Lectures in Archaeology), Masonic Hall, Edinburgh. 4 p.m. TUESDAY, MAY 4. Art Union of London.—Annual Meeting and Distribution, Adelphi Theatre. 11.45 a.m. Institution of Civil Engineers.—(1) Mr. Francis Fox on "The Mersey Railway." (2) 30 Mr. W. E. Birch on "The Hydraulic Passenger Lifts at the Underground Stations of the Mersey Railway." 8 p.m. Society of Antiquaries.—Anniversary Meeting. 2 p.m. Society of Biblical Archaeology.—8 p.m. Society of Arts (Special Lectures).—Mr. Ernest Hart on "Japanese Art Work."—I. 8 p.m. WEDNESDAY, MAY 5. Society of Arts.—Adjourned Discussion on Dr. C. Meymott Tidy's paper on "The Treatment of Sewage." 8 p.m. British Archaeological Association.—Annual Meeting. 4.30 p.m. Civil and Mechanical Engineers' Society.—Annual General Meeting. 7 p.m. Builders' Foremen and Clerks of Works' Institution.—Ordinary Meeting. 8.30 p.m. Society of Antiquaries of Scotland.—Mr. J. Romilly Allen on "Early Christian Symbolism in Great Britain and Ireland." 4 p.m. THURSDAY, MAY 6. Royal Archaeological Institute.—Mr. R. S. Poole on "The Value of Archaeology in the Study of the Bible." 4 p.m. Society for the Encouragement of the Fine Arts.—Conversations at the Galleries of the Institute of Painters in Water Colours. 8 p.m. Institution of Mechanical Engineers.—General Meeting. 7.30 p.m. FRIDAY, MAY 7. Architectural Association.—Mr. W. J. N. Millard on "Architectural Training." 7.30 p.m. University College.—Professor G. T. Newton, on "Greek Inscriptions."—I. 4 p.m. Institution of Mechanical Engineers.—General Meeting continued. 3 p.m. Lincoln Diocesan Architectural Society.—12.15 p.m. SATURDAY, MAY 8. Architectural Association.—Visit to the National Liberal Club, Victoria Embankment. 3 p.m. Edinburgh Architectural Association.—Visits: (1) to Ancient Chapel, Church, and Rosend Castle, Burntisland. (2) to Sincilshirst Waddoth and Lincolnton Works.

Miscellaneous.

Plumbers' Company.—The Ordinances of this Company, dating from A.D. 1365, fix St. Mark's Day as the first quarterly meeting of the year. The observance of this Ordinance has continued unbroken since that date, and by reason of St. Mark's Day falling this year upon the Bank Holiday, arrangements had to be made for holding the meeting at the Guildhall Tavern, Gresham-street, which was opened specially for the purpose. The Court assembled at half-past three, Mr. George Shaw, G.C. (the Master), presiding, supported by Mr. Alderman Knill, Prime Warden; Mr. F. Machin, Bentor Warden; Mr. W. Digby Seymour, G.C.; Mr. Philip Wilkinson, Mr. Chas. Hudson, Mr. R. Cooke, Mr. W. H. Bishop, Members of the Court. Among the aged women admitted to the annual pension, and relieved by a grant of 5l. 5s., was Charlotte Hardcastle, who produced the indentures of apprenticeship and freedom of her father, a Liveryman of the Company, dated 1765. It was reported to the Court that the registry for qualified plumbers, opened by the Company at the Guildhall on the 1st of March, was very generally approved, not only by the plumbers of the London district, but that plumbers (both masters and journeymen) in various parts of England and Wales, as well as Scotland and Ireland, had applied to be admitted to the London Register pending the establishment of offices of registry in the provinces. The quarterly returns of the United Operative Plumbers' Association of Great Britain and Ireland (numbering 3,000 plumbers in various parts of the kingdom) were submitted to the Court, with a communication from Mr. Geo. B. Cherry, the General Secretary (Sheffield), expressing the satisfaction of the Executive Council of the Association with the system of registration established by the Plumbers' Company.

The Resistance of Building Stone to Frost.—Herr Frangenheim (in the Deutsche Bauzeitung) remarks that most books upon tests of building materials recommend the glauher-salt process for arriving at the resistance of building stones to frost. He disputes, however, the analogy between a test applied to a sample of stone and the actual effect of frost upon large stones exposed to humidity, and with surfaces which have been more or less affected in their structure by dressing with various instruments. From Professor Tetmjer's investigations it would seem that contraction takes place during the crystallisation of glauher salt instead of extension, so that the value of this test has become much depreciated in technical circles. The Berlin testing station has tried the actual effects of frost by a comprehensive series of experiments, the results of which have been indicated by the loosening of the structure of the stone, as illustrated by diminished resistance to pressure. Herr Frangenheim considers, however, that further experiments are necessary before conclusions of definite value can be arrived at. His own investigations have led to the result that stone of acknowledged and tried durability has been injuriously affected by glauher salt, while inferior tests hitherto made are not sufficient for arriving at a reliable opinion as to whether the structure or the composition of the various descriptions of stone experimented upon has led to the conclusions arrived at.

The Hunting Castle of the Empress of Austria.—This new structure, near Spessing, is described by the Vienna Gekuerbe Zeitung as doing credit to the artistic skill of Baron Haesenauer, who has been entrusted with the work. The relative simplicity which characterises the other Imperial residences has in this instance given place to rich decoration, in which architecture, painting, and sculpture, have been fully employed. The roof from the station of Spessing is illuminated by 115 electric lights. The castle stands on the site of a wood which had to be removed, the excavations being performed by the Union Building Association. Mannersdorf and Almus stone have been principally used. In the flooring of the entrance-hall polished white slabs of Belgian and Carrara marble have been employed.

Nineteenth Century Art Society.—Thursday, the 29th inst., has been appointed for the reception of works of art intended for the Summer Exhibition of this Society, at the Conduit-street Galleries.

British Archaeological Association.—On Wednesday, April 21st, Mr. Thos. Morgan, F.S.A., in the chair, a series of ancient views of Rheims were exhibited by Mr. Loftus Brock, F.S.A., illustrative of the visit of the Leland Club to that city, which is to take place in course of the present week. These views indicate the aspect of many of the buildings which have since been demolished. Among these was the Church of St. Nicaise, an elegant building of the thirteenth century, of which a view of the west front was exhibited, while an ancient plan showed the positions of a singular group of churches close to it, also a similar group around the neighbouring Church of St. Remi. The division of the city into squares of unequal size appears to show the continuance of the plan of the Roman city to Medieval times, similar in this respect to Gloucester and some other cities in England which were referred to. Mr. Romilly Allen, F.S.A. Scott, exhibited a remarkable powder-disk of horn illustrated with quaint subjects of most archaic design, representing scenes of New Testament history. The workmanship is Scandinavian, and the date that of the seventeenth century, showing a singular survival of older forms. A paper was read by the Chairman on Haslemere and its locality, and another by Mr. J. T. Irvine, on the Saxon Tower of Barnack Church, the architectural features being described in detail. The meagre historical evidences were referred to, and a late Saxon date was assigned to the work, the tower having been added probably to an older wooden church, an opinion which was demurred to by some of the members.

St. Alban's and Milan.—There is a splendid chance of more distinction for the amateur architect who is said by the curious to have made himself noble by making the west front of St. Alban's Abbey ignoble. One of the most magnificent cathedrals in the world, the Duomo of Milan, is to be provided with a new façade. The prize-jury appointed by the conscript fathers of the old Lombard capital offer four premiums of considerable amount to the senders of the four best "projects of restoration." The competition is open to architects of all nations. A programme, with the conditions and a set of illustrative plates, at the cost of four francs, including postage, may be obtained by any applicant who will send his name and address to Signor Uricio Hnepli, bookseller to the King of Italy, Milan. Possibly the Italians might like to have their church of St. Ambrose, like our church of St. Alban's, subjected to the process wickedly known as "a Becketting."—*Pall Mall Gazette.*

Edward Alleyn's Almshouses.—The foundation-stone of Alleyn's Almshouses was, on Monday last, in the presence of a representative gathering of the inhabitants of Southwark, laid by Mr. F. Sandman, the Colledge Warden, at Hamilton-road, Lower Norwood. The buildings provide accommodation for ten persons, each of whom will have a suite of rooms, consisting of living and bed room, kitchen with sink and dust-shoot, and water-closet and coal-cellar. The plans have been prepared by Mr. C. N. McLutye North, of 15, Borough-street, S.E., and the buildings are being erected, under his superintendence, by Mr. Wm. Marriage, of Croydon.

The Atmosphere of Railway Carriages. A contemporary expresses a preference for death by "asphyxia," to death by cold from sitting in a draught. We are not quite sure that, even granting the somewhat shaky use of a technical term, this preference is well grounded; but, however that may be, there is no sort of reason for making a selection. It is not necessary to choose between closed and open windows in travelling by rail. Nothing could possibly be easier than to ventilate a carriage moving rapidly, by a very simple and obvious contrivance of air-chambers in the roof. There need be no down-draught, and certainly no difficulty exists in providing effectually for the egress of impure air and the introduction of pure air. The fact of movement overcomes the obstacle to ventilation which exists in the case of a fixed chamber.—*Lancet.*

New Railway Station at Norwich.—On Monday next, May 3rd, the Great Eastern Railway Company intend to open the new passenger station at Thorpe for traffic. This station is, next to Liverpool-street, the largest owned by the company. It has been constructed by Messrs. Youngs, contractors, Norwich. The building has long been felt in Norwich. The old one, it is stated, is to be turned into a goods station.

Board Schools, Clyde Bank, Dumbartonshire, N.B.—The School Board of the parish of Old Kilpatrick recently decided to erect a new school at Clydebank, and invited architects to send in competitive plans. Fourteen architects responded, and sent in twenty designs. At a meeting of the Board held on the 23rd ult., these were carefully examined, and the design marked "Science" was adopted. This school will be one of the largest and most complete in the West of Scotland, and has accommodation, on the ground and first floors, for 1,500 scholars. The upper floor is specially designed and arranged for technical classes, and accommodates between 300 and 400 pupils. The class-rooms are large, lofty apartments, thoroughly well lighted and ventilated. The stairs are broad and easy, the steps all radiating to one common centre. There are masters' and pupil teachers' rooms on each floor, and convenient cloak-rooms for the children. The janitor's house is at the principal entrance. Messrs. A. Thomson & Turnbull, of Glasgow, are the architects, and they have been instructed to proceed with the work.

Utilisation of Gas Residuals.—At a recent meeting of the Stafford Town Council, the Gas Committee reported that they had instructed the manager to use the tar for heating the retorts in lieu of coke, and to purchase Mr. Simon's apparatus for manufacturing sulphate of ammonia and to erect the necessary buildings, the total cost not to exceed 600*l.* Alderman Dudley, in moving the adoption of the report, referred to the great fall that had taken place in the value of these residuals, which would amount at the present market price to no less than 1,400*l.* during the next twelve months. They had been selling the tar for five years at 3*s.* per ton, and the liquor at 1*s.* 5*d.* Now, in answer to their advertisement for tenders, the highest tender received had been 8*s.* for tar and 3*s.* 11*d.* for the liquor. If they had accepted this price, the amount they would realise would only be 400*l.* instead of 1,837*l.*, which they received last year. The committee, therefore, felt this was a matter of such serious importance that they deferred its consideration until they had ascertained if there was any better method of using the residuals than selling them at so low a price. After careful consideration of the whole matter the manager was now in a position to assure them that by adopting the manufacture of sulphate of ammonia he could realise a profit of about 450*l.* or 500*l.* a year over and above the present market price for the article. With regard to the tar, after careful study and testing they had ascertained that the tar would be worth 12*s.* 9*d.* a ton to them to burn, whereas they had only had an offer under pressure of 10*s.* a ton for it, and therefore they intended to burn it instead of selling it at that low price. The opinion of the committee was that no tar should be sold for less than 20*s.* a ton. They would not have much to dispose of after burning what they required, and he had no doubt if every gas-works adopted the same plan they would soon see the price go up to something like its old figure. The reported was adopted.

The Turners' Company.—This Company is offering, and has before offered, various prizes for the best examples of turning in wood and pottery, in special classes. Works in competition are to be sent in during the week ending October 23. Particulars may be obtained on application to Mr. Edgar Sydney, the honorary secretary to the Competition Committee, at 4, Hare-court, Temple.

Artists' Benevolent Fund.—Lord Chief Justice Coleridge will preside at the seventy-seventh anniversary dinner of the Artists' Benevolent Fund, on the 4th of June next, at the Freemasons' Tavern. The fund was founded in 1810, and incorporated by Royal Charter in 1827, and has given to widows and orphans of artists above 50,000*l.* since its foundation.

Lectures at the British Museum.—Miss J. E. Harrison intends to give a course of four lectures on the "Topography and Monuments of Modern Athens," in the Archaic Room of the British Museum, on Wednesday, May 12th, and the three following Wednesdays, at 11*h.* 45*m.* precisely. Letters in regard to admission to the lectures can be addressed to Miss Wilson, No. 45, Colville-gardens, W.

Lincrusta-Walton Decoration.—Some important exhibits of this class of work are in preparation for various rooms or stands in the Edinburgh, the Liverpool, and the Indian and Colonial exhibitions.

Horwich New Railway Works.—Rapid progress is being made with these extensive works, in course of construction by the L. & C. and Yorkshire Railway Company, to relieve the great pressure at their large establishments in Miles Platting. Two-thirds of the locomotive erecting shops have now been completed, and the building will be 1,520*ft.* long by 115*ft.* wide, and 30*ft.* high, and will be furnished with a score of travelling cranes, each of 30-ton lifting power. The contract for these has been let to Messrs. Etherington, Manchester, at an estimated cost of 18,000*l.* and the delivery of the cranes is expected to commence almost immediately. Mr. Meadfoot of Stockport, is the contractor for the locomotive works. Half-a-dozen exceedingly large carriage-sheltering sheds, of corrugated iron with semicircular roofs, have been erected. Messrs. Fish of Preston; and Mr. Riley, Fleetwood, is engaged in the construction of a large range of offices for the Company. These will have a frontage to the highway of 350*ft.* Since the Railway Company commenced to lay down their works here, the little village has developed by leaps and bounds upon rows of house and shop projects springing up in all parts of the township, meet the demand the Local Board are expected to largely increase their water supply and they are also engaged in an extensive sewerage scheme, the cost of which is estimated at 10,000*l.* Mr. James Lomax, of Bolton, is engineer for the latter, which will be carried on his quiescent precipitation principle.

The Battersea Dust-yard.—We are glad to learn that there is at last a prospect of a scandal of the Battersea Dust-yard, against which we have so often inveighed, being satisfactorily and finally settled. After having more than once been made to get rid of the nuisance, and the Southwark and Vauxhall Water Company in particular have striven to free their filter-beds from the danger involved in the too close proximity of the dust-yard to them. In the Water Company's Bill of this session is a clause authorising the compulsory purchase by them of the dust-yard site, the object, of course, of abolishing forthwith the storage of refuse there. An agreement, however, now being entered into between the Water Company and the London, Brighton and South-Coast Railway Company, by which the railway company, being anxious not to part with the land, have undertaken to discontinue in perpetuity the use of the land for dust-stuffing any other noxious purpose, upon condition that the compulsory powers are withdrawn from the Bill. The Local Government Board, it is understood, have agreed conditionally to this arrangement, as it permanently removes the danger which they complain.—*The Sanitary Record.*

The Corinth Canal.—The work of cutting a ship canal across the Isthmus of Corinth making fair, though not very rapid, progress. At the present time there are upwards of 1,000 workmen employed on the excavations. The total quantity of earth which it was necessary to dig out was over twelve million cubic feet, and of this two and a half million cubic feet have already been removed. The depth of the canal will be 8 metres, or 26*ft.* The width of the surface of the water will be 22 metres, 72*ft.*, except at the entrance, where it will be from two and a half to three times the width. Already the water of the adjacent sea penetrates to a distance of about 1,600*ft.* on the land on each side, the depth being near 17*ft.* At the rate at which the work is being accomplished, the canal will be completed within five years from the present date.

Burma.—With a view to encourage commerce among the indigenous races in Burma the Local Government have been pleased to offer a scholarship of Rs. 60 per mensem, available for five years, to persons of Burmese or Indo-Burmese origin. Applications from suitable candidates to be sent in to the Director of Public Instruction before the 31st of May 1886. The successful candidate will be sent to the Engineering College at Calcutta, there to be trained in the profession, and ultimately join the superior service of the D. P. W. Burma.—*Indian Engineer.*

Indian and Colonial Exhibition.—Understand the Wilkie's Patent Metallic Pavé Company have received instructions to pave the Indian Village at the Colonial and Indian Exhibition at South Kensington, the paving to be the same as that laid in the Old London Street at the Inventions Exhibition last year.

Gift of Pictures to the Wolverhampton Art Gallery.—At the last meeting of the Wolverhampton Town Council, the Mayor read a letter stating that Mr. P. Horsman, the donor of the art gallery, had authorised the inscription on some valuable paintings he had acceded to the art gallery to be altered from "Presented" to "Presented."

More Exhibitions.—We shall soon witness an opening of three large exhibitions almost simultaneously, viz., the Colonial and Indian South Kensington; the "Shippers" at Liverpool; and the International Art and Industrial Exhibition at Edinburgh. In connection with the "Shippers" Exhibition at Liverpool, or, as it is officially styled, the International Exhibition of Navigation, Travelling, Commerce, and Manufacture, it may be mentioned that Mr. Frank Leslie, one of the Honorary Secretaries, engaged in delivering lectures in Liverpool, Manchester, and other neighbouring towns, descriptive of the building and its chief exhibits. These lectures are illustrated by lantern views, and are free with the exception that a charge is made in some cases for front seats. The course of the exhibition is intended, of course, to whet the appetite of possible visitors to the exhibition to such an extent as to induce them to go there to feast their eyes on its contents. But there are other exhibitions to come. We have received the prospectus of the Decorative Art Exhibition, which will be opened on July 12th at the Royal Aquarium, Westminster, and will remain open till the 31st of that month. There are to be only two classes, each of which will comprise sections, "trade and professional" and "amateur." We must also acknowledge the receipt of the preliminary prospectus of the Newcastle-upon-Tyne Mining, Engineering, and Industrial Exhibition (International and Colonial) which is to be held next year. It is envisaged that "a complete full-sized working model of a mine shall form a special feature" of the Exhibition.

TIMBER (continued). Table with columns for timber types (Wainscot, Deal, Pine, etc.), quantities, and prices per unit.

METALS. Table listing various metals (Iron, Steel, Lead, etc.) and their prices.

PRICES CURRENT OF MATERIALS. Table listing various materials (Timber, Cement, etc.) and their current market prices.

OILS. Table listing various oils (Linedseed, Coconut, etc.) and their prices.

TENDERS.

ACTON.—For the erection of Parish Hall at South Acton, W., for the Rev. A. Hunter Dunn, M.A. Mr. Edward Moman, jun., Groveshoe Farm, Acton, architect. Quantities supplied: F. Bray, Acton; F. & Co., Ealing; Steel Bros., Dalston; T. Nye, Ealing; S. Huet, Chertwick; E. L. Green, Holborn; W. Woodward, Finsbury; T. Anthony, Brentford; H. Brown, Southall; Hann & Co., Windsor; G. Lifford, Shepherd's Bush; G. Hooper, Acton (accepted).

BREDE Sussex.—For alterations and additions and part rebuilding the Rectory, Brede, Sussex. Mr. J. W. Ridge, architect, London. W. Ridge, Northiam; W. Conkors, Brede; A. Reeves, Edinboro; H. J. Rodda, St. Leonard's-on-Sea; J. Longley, Crawley; G. Harmer, Hurslemere; Eldridge & Co., nard's-on-Sea; W. Colman, Stone Kiln, Brode; W. E. Warman, Hastings.

BRENTFORD.—For making-up and sewerage Spring-grove, F. W. Lacey, A.M.I.C.E., surveyor, Brentford. Treherne & Co.; Brundson & Co.; William Parker; Nowell & Robson; Mowlem & Co. (accepted).

BRISTOL.—For the erection of the Parish Church, Ashton Gate, Bristol, from the finished level of the foundation work. Mr. John Bevan, architect, Unity-street, Bristol. Section 2. Section 3. Total. Brock & Bruce; W. Cowlin & Son; H. A. Forse; E. Walters; A. J. Beaver; W. Church; Stephens & Bastow; R. Wilkins & Sons; J. Wilkins (accepted).

CARDIFF.—For additional buildings at existing tramway depots, for the Provincial Tramways Company. Messrs. Davis & Emanuel, architects, London. C. Fox; Jones Bros.; C. Barton; Shepton & Son; F. S. Lock (All of Cardiff).

CARDIFF.—For new tramway depot at Cathays, for the Provincial Tramway Company. Messrs. Davis & Emanuel, architects, London. C. Fox; Jones Bros.; C. Barton; Shepton & Son; F. S. Lock (All of Cardiff).

CROYDON.—For finishing Tower House, Birdhurst Rise, Croydon. Mr. F. West, architect. F. R. Docking; T. Bristy; S. Page; Goulter & Glasscock; M. Taylor; J. Horrocks; Bridger (accepted) (All of Croydon).

CROYDON.—For the erection of house at the junction of the Kidderminster and Stanton roads, Croydon. Mr. F. West, architect. W. Marriage, Croydon; Smith & Bullard, Croydon; Smith & Sons, South Norwood; B. J. Saunders, Croydon; M. Taylor, Croydon; S. Page, Croydon.

CROYDON.—For alterations and additions to premises, North End, Croydon, for Mr. D. H. Weston, Mr. F. West, architect, Coombe-road, Croydon. Smith & Sons, South Norwood; W. Marriage, Croydon; S. Page, Croydon; M. Taylor, Croydon; F. R. Docking (accepted).

CROYDON.—For the erection of house in the Waddon-road, Croydon, for Mr. W. P. Wenham, Mr. R. W. Price, architect, Cedar-road, Sutton. Smith & Bullard (accepted); M. Taylor, Croydon; W. Marriage, Croydon; S. Page, Croydon; Smith & Bullard (accepted).

DUTTON (Cheshire).—For alterations and additions to the Union Farm at Dutton, near Preston Brook, Cheshire, for Mr. Algeron Charles Talbot, Messrs. C. E. Link, & S. Davis, architects, Frodsham. S. Talbot & Carter, Northwich; Executors of late John Heave, Frodsham (accepted).

CONTRACTS AND PUBLIC APPOINTMENTS.

Epitome of Advertisements in this Number.

CONTRACTS. Table with columns: Nature of Work, By whom required, Architect, Surveyor, or Engineer, Tenders to be delivered, Page.

PUBLIC APPOINTMENTS. Table with columns: Nature of Appointment, By whom Advertised, Salary, Applications to be in, Page.

EALING.—For re-laying curb and channelling and making-up road and tar-paving footpaths called the Wood-vile road, for the Ealing Local Board:—
 Seward, Hanwell £1,018 0 0
 Bath & Blackmore, Clapham 1,615 0 0
 Nowell & Holton, Kensington 952 0 0
 Oldridge, Kew 955 0 0
 Kallet, London 835 0 0
 Pizzev, Hornsey 834 0 0
 Constable & Co., Dulwich 846 0 0
 Mowlem & Co., Westminster 841 13 4

FRODSHAM.—For the restoration of the tower of Frodsam Parish Church. Mr. Samuel Davies, architect, Frodsam:—
 Thomas Davies, Frodsam* £1,625 0 0
 * Accepted.

FROME.—For erecting new boys' school and classrooms at Holy Trinity Church, Frome, for the Rev. W. E. Daniel, Vicar. Mr. W. G. Brown, architect, Frome:—
 W. Norris, Frome £720 0 0
 Charles Barnes, Frome 663 0 0
 F. P. Brown, Frome 676 0 0
 Joseph Bird, Radstock 658 0 0

 William Jarvis, King's Lynn 650 0 0
 S. Bradley, Sutton Bridge 645 0 0
 Thomas Gilder, Boston 640 0 0
 Henry Hicks, Peterborough 630 3 0
 [Architect's estimate] £650.
 * Accepted.

LONG SUTTON (Lincolnshire).—For the erection of shops and houses in the Market Place, for the trustees of the late Mr. Hainesworth. Mr. Joseph Sawyer, Chancery-lane, architect. Quantities supplied:—
 Bardell Bros., King's Lynn £2,411 0 0
 W. Emerson, Stamford 2,280 0 0
 S. Sherwin, Boston 2,217 0 0
 Girling Bros., Wisbeach 2,196 15 0
 Henry Hicks, Peterborough 2,050 0 0
 Messrs. Bateman, Sutton Bridge 2,040 16 4
 W. Greenfield, Boston (accepted) 1,654 8 4
 [Architect's estimate] £2,000.

NEWCASTLE-ON-TYNE.—For additions to Christ Church Schools, Newcastle. Mr. Arthur B. Plummer, architect, Newcastle:—
 Walter Boston, Newcastle (accepted) £400 0 0

RODDEN.—For alterations and additions at Easthill Farm, Rodden, for Mr. T. F. Parkinson. Mr. W. G. Brown, architect, Frome:—
 F. J. Seward, Frome £304 0 0
 S. Chislett, Frome 287 0 0
 F. P. Brown, Frome 267 0 0

TEDDINGTON.—For foundations for new church at Teddington, Middlesex. Mr. W. Niven, architect, Dean's Yard, Westminster. Quantities not supplied:—
 J. Shillito & Son, Bury St. Edmunds £1,866 0 0
 F. Collinson, Teddington 2,217 0 0
 T. H. Adamson & Sons, Putney 1,385 0 0
 Dove Bros., Islington (exclusive of pumping) 1,325 0 0
 * Accepted.

SPECIAL NOTICE.—Lists of Tenders frequently reach us too late for insertion. They should be delivered at our office, 48, Catherine-street, W.C., not later than **Four P.M. on THURSDAYS.**

St. Bartholomew the Great, West Smithfield.

HE works designed for the preservation of this noble church form an important incident in current architectural history, partly on account of the intrinsic beauty and high antiquity of the

fabric, and partly because they bring to a head many of the vexed questions which perplex those who are engaged in rescuing the works of our forefathers from desecration and decay, while respecting their present and future usefulness.

To begin at the beginning,—the history of the foundation of the church is unusually clear and singularly interesting. By a most fortunate chance, a Latin MS. entitled, "Liber Indacionis Ecclesie Sancti Bartholomei, Londoniarum," written between the years 1174 and 1189,—and probably more exactly about the year 1180,—by a monk of the priory, who had himself talked with those who remembered the founder, is still extant. It covers eighty-six leaves of vellum, measuring 10½ in. by 7½ in., and is preserved in the British Museum, and numbered "Vespasian B IX." An English translation was made about the year 1400,—the date, it will be noted, of Chaucer's death,—and this is almost more interesting than the original, as being an example of English prose at a time when it was first assuming a settled form. The translation is much contracted, and has recently been most carefully and learnedly edited by Dr. Norman Moore, Warden of the College of St. Bartholomew's Hospital.

To recite shortly the material part of the record it is only necessary to say that the founder of the church and hospital was one Rahere, or Rayer, who, born of humble parents, possessed a pleasant wit, by the exercise of which he gained admittance to the households of princes and nobles, diverting their leisure by his antics and buffoonery, and "annoying thir eerys with jaysys and atternynges," pandering in fact to all their follies. From this useless,—perhaps sinful,—life he was miraculously called, and like so many others in those strange times when vice and virtue, like sun and shadow, stood out in old contrast, he became first an exemplary tenant, and afterwards almost a saint, pious, contemplative, and devoted body and soul to works of practical charity. During a visit to some "weyngs hys dedis, and reducing to wynde the scapis of hys youth," he fell into a serious illness and vowed to the service of

God whatever might remain to him of life. He recovered, and most religiously kept his vow. Of course he had a vision, which is set out by his admiring biographer with elaborate detail and devout unction. The blessed Apostle appeared to Rahere, and counselled him to build a church in a certain spot "yn the subbarbis," which should be more particularly indicated; while for the due performance of the holy work the needful help, he was assured, should not be wanting. A whole chapter is given to the "exposicion" of this vision, over which we must not linger.

Rahere prudently disclosed his purpose to his bishop, and secured that prelate's good offices with the king. The chosen site was in Smithfield, which was then so very much "yn the subbarbis" that it was a waste marsh,—a sort of no man's land,—"dunge and fenny," defiled with all manner of ordure, and hearing aloft the common gallows whereon were hanged "theyvs and those damped by iudiciale auctoryte." He called to his aid a certain old man named Alfane, who had in his youth been employed in the building of St. Giles's Church in Cripplegate, and set valiantly to work. Church builders appear from the first to have met with their share of discouragement and opposition. Envious men conspired to thwart and annoy him, destroying nightly his daily work. The critic of the period was down upon him heavily, some "hegiled hym with synulate frendschippes," and others "provoked hym with despitis," while from others again he went in fear of his life. Nevertheless, he struggled manfully against all difficulties, and gradually attracting to his side many faithful souls, he at last successfully accomplished his self-imposed task. The foundation-stone was laid in the month of March, 1123. The first portion of the work was consecrated in 1133 by Richard of Beauvais, and Rahere was elected the first Prior of the Community of Augustinian Canons, who were then and there established. On the 20th of September, 1144, their founder passed peacefully away, "forsaking the cley house of thys worlde that in the house of his fadir he myghte he crownyd." He ruled his convent with firmness and discretion, and it grew and prospered under his wise guidance: some at least of his solid, sturdy work may still be seen pretty much as it left his hands: it has survived most of the additions of his successors, and will, with reasonable care, endure for centuries, a witness at once to the good prior's simple faith and ardent charity.

The full extent which the ecclesiastical and monastic buildings eventually assumed may be seen in the plan on the following page.

The order of their edification appears to have been somewhat as follows:—

First the choir and choir aisle, the north and south transepts, and the tower at their intersection, and an eastern Lady-chapel. As this is referred to in the MS. as an "oratory," it was probably of much less extent than the handsome Lady-chapel afterwards built, the enclosing walls of which remain. Even the original Lady-chapel would appear to have been somewhat of an after-thought, for its junction with the choir aisle is marked by a certain awkwardness in the apsidal groining, which was evidently no part of the original scheme. A point of some interest is connected with the central tower, which was not a perfect square, owing to a variation in the widths of the nave and transepts respectively. The arches carrying the tower have, however, their springings and crowns level, and as the wider arches are semicircular it follows that the narrower ones are pointed,—and thus we see the pointed arch adopted *ex necessitate* by Norman builders. It is perhaps doubtful whether a Norman nave was ever built, the one Norman eastern bay having probably been erected as a counterfort to the thrust of the tower arches. The excavations now in progress or contemplated, will no doubt throw some light on this question. In any case an Early English nave was built in the succeeding century, and the earlier choir clear-story was replaced by one of later date. A fine Early English doorway still stands exactly in the prolongation of the south aisle; but whether this formed an entrance to the church or to the precincts it is not easy to determine at present. The fourteenth century was one of great building activity at St. Bartholomew's. A new Lady-chapel of splendid proportions was erected. The apsidal east end of the choir was converted into the square east end, which was always the favourite with English architects, a wall being built from the foundations upwards at the points in the side slightly east of the full diameter of the apse. This of course hid the Norman piers, and the space between them and the new east walls was used as a receptacle for human remains, and long known as "Purgatory." Early in the fifteenth century further extensions of the priory were in progress,—the cloisters, chapter-house, refectory, dormitory, and accessory buildings were erected, and the fortunes of the convent appear to have reached their zenith. Prior Bolton, 1506-32, effected some further alterations and embellishments which cannot all be with certainty traced. He raised the whole floor of the church some 2 ft. 6 in., altered in some way the central tower, and added the watching chamber on the south side of the

choir, which has ever since formed one of the peculiar features in the church. With the close of his rule the clouds began to gather about the priory, and its dis-edification but too quickly followed. Robert Fuller, the last prior, surrendered his charge into the hands of the king on the 15th October, 1540, who thereupon devised the prior's house, infirmary, dormitory, chapter-house, hall, kitchen, stables, &c., to Sir Richard Rich, the Lord Chancellor, for the sum of 1,064l. 11s. 3d. The nave of the church was destroyed, and the choir was decreed to be used thereafter as a parish church "for ever."

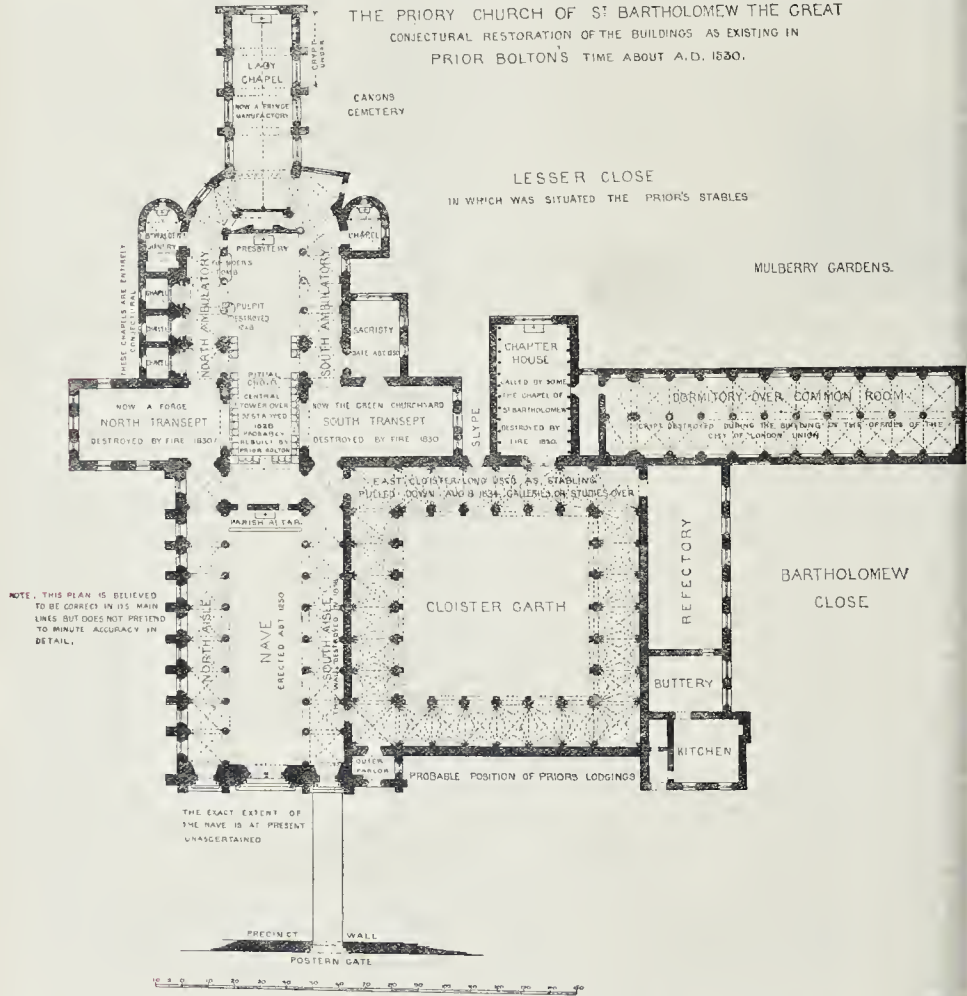

A change in the fortunes of the Priory took

custodians of the church have reduced it to a sorry plight indeed. Secular buildings of all sorts have clustered round the exterior walls so thickly that the casual visitor might pass within a few feet of this fragment of this noble but desecrated church without suspecting its existence. A blacksmith's forge occupies the site of the north transept, and, as a crowning calamity, a fringe factory, which has usurped the site of the Lady-chapel, has been allowed to protrude westward into the sanctuary itself and overhang the very altar. The force of indignity cannot further go!

Strenuous efforts were made about a quarter of a century ago to remedy this scandalous condition of things, and, although something

trustees, who hold it in reversion to the church authorities if within a reasonable time the purchase-money is forthcoming. So that the prospects of the church, if not very bright, are yet fairly hopeful. Its structural condition calls for immediate action, for the rain pouring through the roof, which has been patched until it can be patched no more, and the contiguity of the disused factory, with its complicated network of floors and partitions, is a standing risk of fire, a cause of destruction from which the church has already frequently suffered.

The work of preserving what remains of the sacred fabric, and adapting it more perfectly for its proper use, has been entrusted to Mr. Aston Webb, and his proposals may be ascer-

place in Mary's reign, and the Dominicans, to whom the church was granted, commenced to restore the nave, but little appears to have been accomplished by them. In 1622-8 the steeple was pulled down and a western brick tower was erected, wherein the bells, which are of special interest as being the only pre-Reformation peal in London, have been fortunately ever since retained. About this time, or possibly a little later, the large and handsome eastern windows were, for some inscrutable reason, destroyed, and the present characterless semicircular headed openings substituted. Since then the course of degradation and spoliation has been continuous and rapid, and the greed or supineness of the

was done in the right direction, the bulk of the evils were at that time insurmountable. A recent effort has met with more success. The fringe business appears to have gone hoddily to France, and the vested interests which stood in the way of improving the choir became purchasable. By the generous aid of the patron, the Rev. F. P. Phillips, and the energy of the rector, the Rev. W. Panckridge, and churchwardens, assisted by the parishioners, and in a limited sense by the public, those interests have been in part acquired. The freehold of the factory has been purchased and the accretions which conceal the north wall of the choir have come into the hands of the committee. Further, the blacksmith's shop has been bought by

tained from his published Report to the Executive Committee. They are divided in sections in the order of urgency:—

1. The completion of the apse, consequent upon the removal of the intruding factory.
2. The re-roofing of the church (which should have thought should have come first but he has no doubt good reason for giving a second place).
3. The removal of the boys' school, now he in the north triforium.
4. The removal of the forge and of the present vestry, and the rebuilding of shall north and south transepts.
5. Repairs to the west end, and uncovering the remains of the nave.

6. Re-seating and furniture.
7. Restoration of the Lady-chapel, which it is hoped may some day be used as a Guild Chapel in connexion with a community associated with the hospital.

The interior view, which is reproduced in this number from a drawing in the present Royal Academy Exhibition, shows the general effect of the proposed works so far as the choir is concerned. The jambs of the fourteenth-century east window have been retained, and an elliptical arch turned from side to side, carrying a wall, and preserving the tradition of the square east end. The polygonal triforium and clearestory are carried round behind this sanctuary arch, and revive what must have been the general effect of the original design, — thus preserving "all the present traces of the architectural history of that portion of the building."

The laying bare of the remains of the nave would, no doubt, "add very greatly to the architectural and historical interest of the church"; and it might be formed into a pleasant approach, a bright and quiet spot in a crowded and noisy neighbourhood.

We confess that, looking to all the conditions of the problem, we cannot see a better solution of it than that proposed by Mr. Wehh. It is, of course, arguable that, having obtained possession of the church and its more immediate surroundings, we should leave it to tell its own tale of the changes and vicissitudes through which it has passed; that everything about it is of historic interest, and, therefore, sacred. This is an intelligible view of the case. But it is attended with some inconveniences. For it would not only extend to be ugly and incongruous cast-iron columns and wrought-iron girder, erected with an obviously temporary object a quarter of a century ago; but to be quite logical, to the dust deposited yesterday, and the rain-stains on floor and walls. They have now all become historical, and there would appear to be nothing for it but to enclose the whole in a huge case, protect it from the weather, and let it sink into, by no means "unperceived," decay.

But there is another side to the medal. This arch is far from being a mere curiosity fit only for a museum. It is the centre of a remarkably active ecclesiastical life. Shall its power for spiritual good be paralysed out of a sentimental regard for the structure as a mere work of art, or, rather, of those portions which we have no art to recommend them? That would, indeed, be giving the devout parishioners stones for bread. The builders of the church did not do thus. They never hesitated to destroy the material church if they could enlarge the sphere of its spiritual usefulness, and we find fragments of their Norman choir built to the body of the Lady-chapel, which they tried to do.

We take the common-sense view of the situation to be that which the responsible authorities have adopted. To maintain every ancient feature; to repair what is repairable, and to replace what is not; and to fit the whole, according to our lights, to the needs and decencies of Christian worship.

The present proposals do not appear to sturb the really ancient work. The new work will be distinctly new, and carefully differentiated from the old, and it can scarcely be contended, in the face of Mr. Wehh's designs, that we or our posterity will be the loser by substitution of his nice art for the uncouth barbarisms which it will replace.

It happens that in 1791 Mr. Thomas Hardicke prepared a series of careful drawings, showing the then existing state of the church and its allied buildings, and these drawings have been preserved in the library of the Society of Antiquaries. The present state of the buildings has been delineated with equal accuracy, and these drawings will be placed in the same study. The history of the church will thus be preserved and recorded with exceptional care.* It is very sincerely to be wished

* On the 3rd of May the Lord Mayor, sheriffs, and a distinguished company visited the church, and listened to a short lecture on its history and peculiarities. Immediately after that, it was handed over to Messrs. Dove, well-known church builders, for the commencement of the first portion of the work.

that the works now happily commenced may not languish for want of funds, which are sorely needed if all is to be done which it is desirable to do. St. Bartholomew was once very popular, dear to all Englishmen, and especially mariners. His life and martyrdom were the constant theme of preacher, painter, and moralist, and countless churches throughout the land are dedicated in his honour. May we, without suspicion of profanity, commend the work to the particular consideration of the Worshipful Company of Skinners, and in sober seriousness to every worshipful City Company whatever. There are many reasons why Englishmen of all shades should combine to help the work. Associations of all kinds cluster round the spot. Hogarth was baptised here, and Milton lived in the close hard by. It was not his wont to join in public worship, but the solemn swell of the organ and the melody of the bells must have fallen gratefully on his ear in his time of trial and seclusion. We have, however, not half the necessary space to touch upon all that might be said on this side of the subject. We heartily sympathise with those who are engaged in this difficult work, and hope at no distant date to congratulate them on its successful accomplishment.

THE INDIAN AND COLONIAL EXHIBITION.

CONSIDERING the unfinished state, or even almost uncommenced state, of the arrangement of a great part of the Exhibition only two or three weeks ago, the stage of completeness which it had reached on the day of the opening speaks strongly indeed for the energy and industry of those who have been occupied in the preparations for the opening ceremony, which has been fully described in the daily papers. Those who have already visited it will, we have no doubt, consider that our prediction as to its high interest and beauty is fully borne out, as regards the Indian section to which we especially referred, and which forms by far the largest department of the Exhibition. The Colonial courts contain an immense amount of matter of practical interest, with which, so far as it touches on the subjects in which our readers are specially interested, we shall be able to deal from time to time during the progress of the Exhibition. The section of primary interest, however, is the series of Indian courts, which in themselves include a wealth of objects of art of all kinds, many of which it is impossible even to glance at in a general article; and perhaps the best thing we can do this week is to devote a few remarks to the exceedingly interesting series of screens which line the great avenue of the Exhibition, and which approach more nearly to the subject of architecture than anything else in the Exhibition, except the Indian Palace, of which a word hereafter.

The main avenue is entered through the arcade of a transverse screen or gateway, contributed by the Maharaja of Jeypore, and carved by his subjects; a wooden erection, of which almost every portion of the construction is covered with carved ornament, and side ways filled in with carved open work of foliated patterns. Among inscriptions carved on the beams is one, on the side facing the avenue, "Ex Oriente lux," a motto which comes in appropriately in face of the array of varied and beautiful work stretching before the spectator.

The avenue is classified into "courts" of the districts represented, but not divided by any cross lines of screens except those at the top and bottom. On the left, after entering through the gateway, we find the Jeypore side screen, an erection of Saracenic character (which character naturally pervades a good deal of the work exhibited in the architectural screens) of dark wood elaborately carved, and further decorated by tile paintings let in as panels. The various workmen, we are told, were left to exercise their own individual taste in the portions on which they were employed, subject to general control of a master-workman, being only directed to employ as great a variety of

patterns as possible, and to work on traditional lines. Opposite to this is the Kotah screen, of a general design copied from old buildings in the city of Kotah, a beautiful piece of work, with ivory inlay on dark Shisham wood; the main feature is a many-foliated arch, with the spandrels filled with inlaid flower-work of rather naturalistic type; the whole forms a charming example of modern Hindu work, delicate and graceful in its detail, and very rich in its general effect. Returning to the left, we find next the Bhartpur, Karauli, and Dholpur screen, a red sandstone architrave and false arch (there comes in the "false note" of so much Eastern architectural detail), a low-centred arch with small foliations near the springing only; over this is a frieze of pierced panels of geometrical design. The style is the result of a combination of details from various buildings in the neighbourhood, "a representation of local architecture in details, but not as a whole." It is of red sandstone from the quarries near Karauli, and is executed by local masons under the supervision of the State Public Works Department. The Ulwar screen, next to these, is of marble, with bracket capitals, of Hindu design, and taken from the Ulwar Palace. A dark-veined marble lintel supports a frieze of marble panels of perforated designs.

Returning to the north side, the next screen to that of Kotah is that of Ajmere, a model, and carved in wood and painted white to represent as nearly as possible the ordinary street architecture of the town, which is in marble or plaster, the special feature being a two-storied over-hanging cornice, with rows of pendent bud-like ornaments. Executed as it is and painted, it looks rather grimy, and the forms and details are not very beautiful. Below this comes the Bikanir screen, a wooden structure, which shows a brilliant effect of gold arabesque on white and red grounds, of the method of forming which the following description is given in the catalogue:—

"On the surface of the wood, which had been previously well scrubbed with liquid clay and allowed to dry, the outlines of a flower-pattern were stencilled with a bag of powdered charcoal through perforated paper. Successive layers of liquid clay were then applied with small squirrel-hair brushes within the outlines of the pattern, each layer being allowed to dry before the next application, until a raised surface bringing out the stalks, leaves, and petals with sufficient distinctness had been produced. The whole surface was then fixed by a coat of paint, and when this was dry, gold leaf was applied over all. The ground-work, black, with a red border, on the portion intended to face the central avenue and the adjacent courts of Central India and Ajmere, and red, with a black border, in the interior of the Bikanir bays, was then painted in, the flower-pattern standing out in gilt relief."

After this we come to Central India, whose screens appear on both sides of the avenue. This embraces a district of about 75,000 square miles, but does not send contributions of proportional interest to its area. The screen is in a mixture of styles, exhibiting a good many figures in niches, some of them Buddhist, some Hindu in style; the supports and lintels are of wood, but on these are carried carved marble panels, containing some beautifully-executed floral ornament, intermixed with figures of a rather primitive kind. Attached to the side portions of this screen on the right are perforated panels of stone from Gwahor, better, on the whole, in design than in workmanship, which does not seem to represent the best that Indian carvers can accomplish.

The Bombay screen, next to this, which was constructed from a general design made by Mr. Griffiths, the Superintendent of the Bombay School of Art, was designed to illustrate the wood-carving of the Bombay Presidency; it is very flat work, constructionally, containing panels of geometrical ornament and also some very beautiful and delicately carved open-work panels of floral design; it is rather bare in appearance, and one of the least architectural looking of the screens. The contrary may be said of the Bhavnagar screen, which is a solid erection of rather a "lych-gate" type, with details taken from the mosques of Ahmedabad; the superstructure is a tolerably massive erection overhanging the supporting columns boldly, and steadied by straight-lined brackets

projecting on either side transversely from the pillars; these brackets, however, though constructional features, are one mass of carving, rich to look at, but entirely destroying their expression as pieces of construction: the "false note" again. The Baroda screen, opposite, is very similar in general character, but the brackets are not straight-lined; they are curved members, branching out into buds, and remind one rather of the ordinary bracket-capital placed transversely. On the Bhavnagar side should be noticed the curious and effective cornice ornaments, evidently suggested by the elephant's trunk as a hint, but conventionalised into a very effective and suitable feature of ornamentation. From Bengal comes a screen of imitation brickwork, arranged in an arcade form, and decorated with plates of *repoussé* metal-work fixed on the walls at intervals, and according to a symmetrical scheme; the effect is rather unsatisfactory, the metal decorations seem an afterthought. On the right-hand side, opposite this, Bengal is also represented by an imitation brick erection of very peculiar but also clumsy type, at least as far as the piers are concerned, which are nearly all cap and base projections; the archivolt is decorated with a triple row of cusped ornamentation; the whole is lined out in white on the background. Next, on the left side, come the screens of Agra and Lucknow, of dark, elaborately-carved wood with foliated arches, and the open panels of the frieze decorated by richly-coloured stuffs draped on them. Opposite to these, on the right, the Nepal Court shows one of the most beautiful of all the screens; columns with capitals of quasi-Classic form, with angle volutes, the shafts ornamented with vertical bands of delicate and minute carving; the panels above finely carved, especially two which show designs formed of intertwined "dragons" in low relief. Near this stands, in the centre of the avenue, the Baroda pigeon-house, which attracted so much admiration from "Robert" in *Punch*; an erection carried on a tapered octagonal column covered with carving, the base also carved; the pigeon-house is an arcaded erection, very pretty in design, steadied by long brackets from the column, which are, as in other cases, too much carved for true constructional expression. But the whole affair is a remarkably fine piece of work, and one is not surprised to learn that it is not intended as a mere piece of farmyard furniture, but for the decoration of pigeons which have the good luck to be considered "sacred"; in fact its elaboration springs from just the same pious fervour as that which led to the beautifying of our own mediæval shrines.

In the Punjab screens, which occupy both sides of the way below this point, is to be seen some very rich and beautiful work. The screen on one side is in Shisham wood, and that on the other hand in deodar. Both are the work of Sikh carpenters; they are carried on elegant columns, with brackets, and the upper portion presents a long series of very delicately-wrought panels perforated in geometric patterns, almost exactly like Arabic work. Some of the other wood-work exhibited in this Section is splendidly rich; there are one or two doors fixed on the walls behind, showing arch over arch, spandrel over spandrel, all covered with rich and minute carving. The Kashmir screen is similar in general style, but not quite equal in design, except the brackets, which are the weak point of the Punjab screen. The following details in regard to it are extracted from the catalogue:—

"The screen for the Kashmir and Frontier States' Court is copied from the verandah of an old wooden mosque near Chakoti, on the Kashmir Murree Road, to which the attention of travellers is invited in Ince's handbook. The date of its erection was not, as far as I could find, anywhere marked on the building, but tradition and the character of the carving seem to point to the earlier part of the last century. The pillars, brackets, and architrave beam of the screen are almost an exact copy of the original, both in design and proportion. The side bays, 6 ft. 3 in. each, are identical, and the front bays differ only in that the original arches, each 5 ft. 2½ in. span, have become pillars 10 ft. apart, surmounted by brackets. The railing at the top is

pinja work, such as is commonly made and used throughout Kashmir at the present day. The material is deodar wood."

After this follow the screens of the central provinces, carved in wood, and the work of Nagpur native carpenters. These are very rich, heavy, and elaborate erections, in teak, supported by what may be called square rusticated pillars (only that the rusticated surfaces are carved), with graceful columns in front of them; the upper part is carried on very heavy brackets, both transverse and longitudinal (as in Japanese construction), in double tiers, and with carved lions between the upper and lower brackets; the cornice contains some beautiful floral carving in low relief.

The Assam screen is an exception to the rest in being rustic work, formed of bamboo supports grouped in fours, with light woven cane patterns in the superstructure. Burnah shows a peculiar and barbaric-looking structure, on red and gold columns with black bases; carved brackets forming a straight line, parallel with the lintel, at the top; the frieze is decorated with embroidery and figures on a red ground. The best part of this screen is the carved floral ornament, which is fine and bold, and with a remarkable resemblance to good Renaissance work in feeling. Madras, which, like Burnah, occupies both sides of the avenue, shows a curious type of column, octagonal, and with no projections beyond the shaft line; just beneath the capital the shaft is cut into a round knob form with pendant wreaths leaving clear-cut open spaces behind them: rather fragile looking. The columns are fluted, interrupted by bands of carved ornament; the cornice is very elaborately carved; the whole is intended as a representation of the Dravidian style of architecture. It is executed in teak by Madras carpenters, from a design prepared by the Superintendent of the Madras School of Arts.

On the left, below this, comes the sumptuous screen of Hyderabad, the least architectural of all, as it is only a framework carried by plain gilded stiles and transoms. The interspaces are occupied by panels, some showing dwarf foliated arches, some square, some with a circular dished panel in the centre, all filled with metal or lacquered flower ornament of varied and beautiful detail. The second and sixth arches are of Bidri ware, blackened pewter inlaid with gold, silver, and copper; the third and fifth are entirely of lacquer work. The Mysore screen, opposite to this, is a curious contrast, mostly of plain wood surfaces, the frieze ornamented with paintings. Hyderabad furnishes the screen closing the vista, an erection gilt all over, of very Moorish character, on columns ornamented with chevrons in red, green, and gold; the spandrels of the foliated arches are ornamented with, on the contrary, very Renaissance-looking scroll wreaths on a light blue ground. The thing is a little gewgaw, and there is a made-up look about it.

The central point of the Indian work, opposite the end of Old London, is the Indian palace and courtyard, entered by the splendid marble gateway, originally designed by Major Keith for the Calcutta Exhibition, and executed under his superintendence by native masons, at Gwalior. It is a large archway, with carved engaged columns, and an archivolt decorated by pendent bud ornaments, the spandrels filled with elaborate conventional floral ornament, with an elephant in bas-relief, as if entangled among the ornament, in each spandrel. Within this is the courtyard, surrounded by an arcade, and from this a pillared porch gives entrance to the octagon hall, formerly occupied by the water companies' exhibits, but which is now seen in a subdued but rich glory of beautiful textiles, not only on the walls but overhead, a soft light being admitted through thin hangings covering the centre space. In the centre is a fountain or cistern, the water bubbling up in the centre, but always kept at a level with the star-shaped rim, so that it looks like a large crystal set in an ornamental border in the centre of the apartment. Steps lead from this to the highly-decorated room overlooking the courtyard, the elaborate woodwork of which

was made by two natives of Bhera (Punjab) in the Exhibition. We must describe this more in detail another time. The whole makes a singularly beautiful interior, conveying a sense of repose which cheats one into the belief of being far away from the rattle and bustle of London.

NOTES.

THE railway companies are, to say the least, ill-advised as to the tactics they are adopting in order to defeat the Railway and Canal Traffic Bill. They persist in speaking of the measure as an attack upon their property, while it is really directed against their method of management. Indeed, it may fairly be said that the long-felt desire for reform, which has at last found definite expression, is not so much of an attack as it is represented to be. It is certain that Mr. Mundella never had that idea in framing the Bill, but desired rather to legally remedy an unsatisfactory state of things which has grown up through the vague and insufficient character of previous legislation. It appears that railway *employés* have been told that the Bill is aimed against them, as well as the proprietors, and mass meetings have recently been held at various stations protesting against it. It is very certain that the passing of the measure would not reduce the volume of traffic, and, as the reverse of this would, in all probability, happen, and the staff would have to be increased rather than reduced, the talk about their employment, being imperilled is altogether beside the mark. If it should unfortunately happen that the directors considered it necessary to reduce the rate of wages, such a step would certainly emphasise their statement that this measure would follow the passing of the Bill, but it would be no proof that such a result was "aimed at," or even contemplated. Indeed, Mr. Mundella takes every opportunity of repeating that his aim is justice to all; and Lord Henniker, who is one of the foremost champions of the Bill, has, like Sir B. Samuelson, a considerable stake in the railways, and will not be likely to uphold anything of a "confiscatory" nature.

THE Queen's Bench Division has just decided that Sec. 156 of the Public Health Act 1875, does not apply to new buildings upon land never before built on. That section enacts that it shall not be lawful, "without the written consent of the urban authority," to bring forward any house or building forming part of any street or any part thereof, beyond the front wall of the house or building on either side thereof, nor to build any addition thereto beyond the front of the house or building on either side of the same." In the case of *Williams v. The Wallasey Local Board*, which we are now noticing, the Local Board approved of a certain line on plans for the erection of a new street as its frontage line. Some of the houses were built further back than such line, and the next proprietors built his up to the line. He was then proceeded against under this section, and the justices convicted him of offending against it. This decision the Queen's Bench Division has reversed, on the ground that if it were upheld "the person who first erects buildings in such a place as this can, in fact, prescribe the line frontage to be followed by other persons who may begin to build at a subsequent time. This decision seems to be reasonable, for if a local authority fix the frontage line, but if a person chooses to build at a distance behind such line, that is clearly no reason why his neighbours should lose the advantage of a ground which is available for their buildings."

WHEN a Local Board gives over a road or highway, or any part of it, for any purpose of, and during the time it is, to be repaired under contract, that Board very properly does not relieve itself for one moment of the responsibility to the public for any accident or damages which may arise in consequence of the condition of the road. The Board must, and very often does, specify that the contract

shall be liable to the Board, and indemnify it against loss through any carelessness on his part. Matters would, indeed, get into a very confused state if a Board could delegate to a contractor for any time its duty to the public of maintaining in a good and safe condition the roads within its jurisdiction. But there is in the Public Health Act another point interesting to contractors, but evidently not generally well known, and that is that no action for damages through accident on a road against a Local Board can be instituted if six months have expired from the date of the occurrence of the accruing cause in the case. The application of this provision was illustrated in a case which was entered for hearing in the Brentford County Court. A butcher in Chiswick claimed damages from the Local Board for injury to a horse which had, in February, 1885, slipped at a hole in the road, which was being repaired by the contractor. At the last moment it was discovered that he had failed to comply with the requirement of the Public Health Act, viz., to institute proceedings within six months of the accident or accruing cause, and he very wisely, on the advice of his solicitor, withdrew the case. Not a few persons are acquainted with the law's delays; but here the danger or fault lay in delaying to set the legal machinery in motion.

A CORRESPONDENT of the *Times* last week attacked strongly the reality of Dr. Schliemann's pre-historic discoveries at Mycenæ and Tiryns, quoting in support of his views Mr. Penrose and a mysterious "Oxford man," whose connexion with that University seems to have been considered conclusive as to his archaeological infallibility. From what we have heard direct from Mr. Penrose, however, we gather that he considers there are good grounds for questioning the antiquity attributed to the walls uncovered at the top of the hill or citadel of Tiryns. The chapter on these in the work on Tiryns was not written, as our readers may remember, by Dr. Schliemann himself, but by Dr. Dörpfeld, who is one of the most learned architectural archaeologists in Germany, but probably liable to be carried away by that desire to make remarkable discoveries to which German archaeological enthusiasm is somewhat prone. We declined to accept some of his theories about objects found at Tiryns at the first, though regarding him as a safe and credible witness in the main. Mr. Penrose's reason for doubting the Pelagic date of the Tiryns excavated walls is founded on the nature of the masonry, containing many small stones mingled with bricks, the presence of sawn stone instead of the rough-hewn finish of the undoubted Pelagic structures, and the evidence of the use of iron tools in drilling holes in the stone. We are certainly ready to accept Mr. Penrose as an exceptionally competent and unprejudiced witness, with probably a much cooler judgment than Dr. Dörpfeld; and the idea that the walls of a pre-historic palace have been unearthed must, at all events, be held to be matter for a suspension of opinion. It does not necessarily follow, however, that the plan of the habitations at Tiryns may not be in great measure in accord with that of an older structure previous to the walls that have been uncovered, the remains of which may lie deeper. Dr. Schliemann and Dr. Dörpfeld had better excavate to a lower stratum, and see what that produces.

THE subject of Dr. Dörpfeld's essay was taken up by Dr. Jehb in an able paper read before the Hellenic Society on Thursday afternoon, not in regard to the archaeological questions of date, nature of the walling, &c., but in regard to the degree in which Dr. Dörpfeld's plan and explanation of the Tiryns remains could be reconciled with the description of the Homeric house in the *Odyssey*. By a series of carefully-arranged quotations Dr. Jehb made out a very strong, if not unanswerable case, in favour of the idea that the women's apartment in the archaic Greek house opened from the back and directly out of the great hall or men's apartment, and not by the circuitous route neces-

sary on Dr. Dörpfeld's theory. Eurycleia is called out from the women's apartment, for instance, by a speaker in the hall, and immediately appears; Odysseus, at the entry of the hall (while still in disguise), is summoned to the presence of Penelope, as a humble guest who has been wronged, and scruples to pass the crowd of insistent suitors in the hall,—as if he must do so to get to the women's apartments. These were only one or two of the passages cited, the whole of which go to make up a very strong body of evidence in favour of Dr. Jehb's view.

THE scene at St. Bartholomew's Church on Monday afternoon, where the Lord Mayor went to give the countenance of the municipal authorities to the project for the preservation and partial restoration of the old church, was a very interesting and striking one. The church was crowded, and Dr. Norman Moore gave a short account of its foundation and history, and the names of some of those who had been connected with or interested in it, including that of Henry Fitzwillin, the first Mayor of London, whose signature is appended as a witness to the ordinance of Richard de Ely, Bishop of London, in the year 1198, laying down rules for the guidance of the master or proctor of the hospital connected with the priory. Mr. Aston Webb then gave a short lecture on the architectural points in the building, explaining what was proposed to be done. A collection for the fund was made at the conclusion. We hope that the Rector, who has shown so much energy in endeavouring to arouse public interest in the safety and preservation of this remarkable church, is about to see the reward of his labours.

IN reference to the threatened destruction, or partial destruction, of the Roman Baths at Bath, the Leicester Literary and Philosophical Society has passed the following resolution:—"The members of the Archaeological section of the Leicester Literary and Philosophical Society have with surprise and regret that the Roman Baths at Bath are threatened with partial destruction in consequence of some scheme of public works; and they beg most earnestly to express a hope that the Corporation of Bath may be able to modify their plans, and save these unique and interesting memorials of their Roman predecessors." We entirely agree with the spirit of the resolution. It is not always desirable or possible to allow ancient remains to stand in the way of modern improvements, but the Roman remains at Bath are of such peculiar and almost unique interest that every effort should be made to preserve them, even at the cost of some sacrifice of public convenience.

THE restoration of the beautiful cloisters of St. Juan de los Reyes at Toledo, in Spain, which were brutally mutilated by the French, is progressing most satisfactorily, under the skilful supervision of the architect, Señor Arturo Melida. The north wall, which suffered more than any other part, is already completely restored, the workmen now being busy on the north and west arcades. In one of the bays on the western side, an important addition has been made in place of the present projecting eaves, viz., an elegant traceried balustrade, with pinnacles running up at each of the buttresses between the openings. When this is carried round all four sides, as Señor Melida intends to do, and the carving and tracery of the other sides are completed, these cloisters will be able to vie with any others in the world for grace of composition and beauty of detail. The stone being used for the new work is a dazzling white limestone, which, when fresh from the quarry, is of a soft chalky nature; but the architect is confident that it will harden by exposure to the air, asserting, as his opinion, that the old stone was as soft when first carved,—a theory which is supported by the extreme delicacy of the original carving.

WE learn from a paragraph in the *Venice News* (an English newspaper published in Venice) that the crypt of the Basilica of St. Mark is showing signs of serious injury

from the infiltration of water, and a committee of architects has been appointed to investigate the circumstance and provide some remedy. It is proposed to undertake the restoration of the central portion of the pavement of the crypt, preserving, it is said, its ancient character, in order to repair the settlements, which have become, it is alleged, both serious and dangerous. The editor of the *Venice News* reports that he has made a careful examination of the pavement in question, and that he can find no ground for the apprehensions entertained by the Restoration Committee; the well-known undulations of the flooring resulting, in his opinion, from settlements which are not recent, and which do not appear to be increasing to any serious extent. He further points out that if the pavement is taken up and relaid, its ancient character must be necessarily destroyed, and that, if it is to be tampered with at all, it may just as well be replaced by a pavement of entirely modern design,—an opinion in which we concur.

THE "Société Centrale des Architectes" of France has formed a commission for inquiry into the causes of the present unfortunate condition of the Building Industries in France. The President of the Society is M. Bailly, and the chief secretary M. Paul Wallon; MM. Hamant and Paul Sédille are the vice-presidents, and the Commission includes other well-known French architects.

IT is proposed to erect a large block of residential chambers on the south side of Piccadilly, between the Bath Hotel, at the corner of Arlington-street, and the Green Park, extending back to Arlington-street, on ground belonging to Lord Walsingham. Mr. W. O. Milne is the architect.

THE exhibition of the Royal Society of Painters in Water Colours, in spite of the gap made by the absence of any contributions by Mrs. Allingham, is one of the best which the Society has ever opened. Mr. Alfred Hunt sends several works in his highest style; two especially to be noted, "On the North-East Coast" (120), and "Warkworth Castle" (80), a distant view of the castle, with a wonderful hit of distant sea; the idea of space and distance conveyed in these two small drawings is remarkable. Mr. G. P. Boyce has two or three scenes from Vézelay and its neighbourhood, which are in his best manner. Mr. Eyre Walker's drawings, especially "The Edge of the Combe" (21), are among the finest he has exhibited. Mr. Poynter has a very interesting study of a riverside town with a picturesque entanglement of buildings of all kinds, under the title "The Ferry" (62). Mr. Naftel has surpassed himself in various small but exquisite drawings, "A Golden Dream" (87), and two drawings framed together, "Bridge on the Road to Idwall" and "Duncheon Ghyll" (56). Mr. Herbert Marshall has an exceptionally fine London picture of St. Botolph's churchyard, Aldersgate. Among others may be mentioned, "At the Foot of Ben Nevis" (72), and "Sunset Glow on the Torridon Hills" (161), by Mr. Colin Bent Phillips, a new name to us, and that of an artist of power, with a style of his own. "The Jungfrau" (190), by Mr. W. Collingwood; "On the Cliffs, Cornwall" (194), by Mr. Otto Weber; "The Ponte alle Grazie before its Demolition, Florence" (121), by Mr. Albert Goodwin; "Early Morning at the Bathing Ghâts, Benares" (100), by Mr. Walter Duncan; "Holiday Folk" (69), figures in a garden full of poppies, by Mr. E. K. Johnson, with much more character and refinement in the figures than we have often noticed in this artist's works; "Pont Aberglaslyn, North Wales" (150), by Mr. Clarence White, a little theatrical in effect of light, but a remarkable drawing. It is interesting to find Mr. H. Moore appearing on this occasion as a flower-painter, with two or three very good examples. Many more might be mentioned; the exhibition is full of good work.

If things go on at their present rate, there will soon be an end of national artistic style, and we must be content to see the art of the whole world little by little Europeanised. Japanese art was hailed, not so many years ago, as a hitherto neglected source of fresh, spontaneous, and indigenous art. It soon appeared that the Japanese, in some matters, were as ready to imitate us as we were to imitate them; but it would hardly have been expected a few years ago that the Japanese Government would have taken such a revolutionary step as to invite architects from Berlin to design and plan their new public buildings and palaces. This, however, we are informed, is the case; so we presume that is the knell of Japanese architecture as a national style. It is possible, however, that local developments from Classic and Gothic materials may arise in different countries in time. This appears to be, to some extent, the case in America already.

HAVING looked into the Whistler Exhibition, at Messrs. Dowdeswell's, which, as we said, was too crowded to get into last week, we can record that the "Harmony in Brown and Gold" in the decoration of the room is exceedingly tasteful and pleasant to the eye, and that the frames of the drawings are uniformly tasteful and well executed, and ample in size. For the drawings themselves, there are some pretty outline sketches of figures from the life, and a number of ideas for landscapes in a very inchoate state. What the crowd who rushed and struggled to see these thoughts of them we, of course, can only conjecture; but we could imagine that Mr. Whistler, who to his other gifts adds a fine sense of humour, is laughing at them in his sleeve.

ARCHITECTURE AT THE ROYAL ACADEMY.—II.

WE passed over in our previous review an interesting pencil drawing of the interior of South Marston Church, as restored (1,600) by Mr. J. Belcher. We like to meet a pencil drawing sometimes; this medium of drawing is getting neglected. As in some other restoration drawings, there is nothing here to show how much has been restored and how much is original; we presume that the roof, with its shaft member in the place of a king-post, and apparently supported on the cambered tie-beam, is ancient. Passing on to where we broke off in our first article, we find,—

1,644, "New Catholic Church, Mount Vernon, Liverpool"; Messrs. Goldie, Child, & Goldie. This, which is hung too high to be well seen, is a good monochrome drawing of a church in geometric Gothic style, with a large traceried west window and long porch narthex-wise under it, hardly, to our thinking, sufficiently tied into the main design, architecturally speaking. A large octagon turret or small octagon tower, attached to the south-west angle, solid below and with a window-stage at the top, groups well with the rest. The whole design, without any special originality, is solid in appearance, and composes pleasantly.

1,647, "All Saints' Church, Gosforth, Newcastle-on-Tyne"; Mr. R. J. Johnson. A freely executed pen-and-ink drawing of a rather peculiar church design, all the windows, except those in the tower and east end, being fat-headed; the aisles in the style of the late Gothic Domestic windows, and coming close up to the string-course under the cornice. The clearstory windows have a tracery less late in character, but fitting in well enough with the square heads. The parapets of tower and nave are battlemented. The design looks like an experiment to show that, as a matter of practical adaptability, the square-headed window in a Gothic church may have its advantages and may be introduced with good architectural effect as the prevailing form of window-head.

1,654, "Church Schools and Presbytery of St. Joseph, West Hartlepool"; Messrs. Dunn and Hanson. Hung high; apparently a solid-looking brick angle, which is rather spoiled by the stoppage of the buttresses at a marked horizontal line halfway up, which cuts the tower into two stages not sufficiently connected in their anatomy, and the projections for the

staircase hang on to the tower in a rather accidental manner. We like to see such adjuncts look as if they were a necessary part of the whole scheme of design, inseparably connected with it, not as if they might be taken away and put on another side at pleasure and just as conveniently. The deep buttresses on the west front give force to this part of the design, the whole of which is of the solid and massive character suitable to a church of size and importance.

1,655, "View of a New Church, with Schools, &c., below it, about to be erected in a poor part of West Ham, Essex," Mr. J. Oldrid Scott. We presume the statement as to the "poor part" is intended as an explanatory comment on the plain and unadorned character of the work. There should have been a small plan and section appended (why do architects neglect this so much in their Academy contributions?), to show the arrangement of the building, the design of which is rather peculiar. The hint of a nave and aisle arrangement is kept up, but the aisle is very narrow, and massive buttresses rise above the whole width of its roof, against the clearstory-wall, and are presumably carried down to the ground. We presume, therefore, that these apparent aisle windows are really the windows of the "Schools below," divided into shallow bays by internal buttresses, and that the church is on the upper floor and lighted by what appear to be clearstory windows externally; but it would have been better if this had been shown by drawings. The church is apparently a brick one, very plain; the school (?) windows are of Perpendicular tracery type, with low straight-lined pointed arches in brick; the church windows lancet shape, with a centre mullion and tracery in the head, and placed beneath pointed relieving arches carried from buttress to buttress. The real church has apparently, from the perspective view, two aisles of equal height, with an arcade between; at least, there is a hold projecting buttress at the centre of the west end, which can have no other meaning. The building is apparently brick, very simple, but not ineffective, and very suitable in design for its purpose and position.

1,664, "Eight architectural designs:—(1) Screens, Whiston Church; (2) Grafham Church tower; (3) American Church, Paris; pulpit; (4) St. Mary's, Southampton: west front; (5) American Church, Paris: vestry-room; (6) Wendover Church: screen; (7) St. Peter's, Manscroft: fêche; (8) St. Thomas's, Salisbury: pulpit." Mr. Arthur E. Street. Of these, No. 5 is a drawing of an apparently large room, with an open-timber roof, effectively treated; there are, however, no figures introduced to scale it, and the apparent size may be deceptive. The sheet of sketches is generally in true Gothic feeling, but a little heavily drawn; not effective, at all events, at the height at which they are hung.

1,668, "St. Andrew's Church, Willesden Green: North-east View," Mr. Jas. Brooks. This charming church is shown in an equally charming drawing, a reproduction of which was published in the *Builder* for January 2 last. It is to students a valuable illustration of the satisfactory architectural effect that may be produced by the simplest means, and with almost the entire absence of what is called "ornament," by the carefully-studied arrangement and proportion of windows, string-courses, and buttresses, so as to form a harmonious whole. The east end, with its five-light lancet window included under one wall-arch, and the development of the ends of the north and south walls, above the string-course, into shallow buttresses ending in simple gables, is quite Greek in spirit, in its combined simplicity and elegance.

1,672, "Sandby Church, near Gainsborough: Interior View." Messrs. W. S. Wenherley & F. E. Jones. This is a small pen-and-ink interior of a chancel with a panelled wooden ceiling with massive moulded and braced principals, and an open-traceried wooden screen of somewhat elaborate late Gothic character; good work, not calling for any special comment, however.

1,684, "St. Peter's Church, Streatham: Third scheme for completion of West End Exterior," Mr. G. H. F. Prynne. This shows an octagon-ended baptistry applied to the church so as form a kind of west-end apse, in two stories, the lower story forming a meeting-room, the back portion would not be quite well lighted. On either side of the baptistry projection is a

porch, the two portions producing the impression of a narthex cut in two by the baptistry. We complain that the porches, as in one or two other instances we have noticed, are not connected with the main design; merely abutted against the west wall, without any architectural relation or connexion,—otherwise the contemplated additions may be said to be picturesque and practical.

1,689, "Additions and Alterations to St. Ignatius Church, Preston," Messrs. M. E. Hadfield & Son. This is a brilliant coloured drawing, not however conveying any information as to what the additions and alterations consist in. We presume they are in the seating, the stained glass, and the reredos. The general effect is rich and brilliant; the water-colour drawing hardly makes out the details.

1,703, "Church in Gordon-square: West Elevation." Mr. John Belcher. This is an elevation of a west end and a lofty tower and spire with octagonal angle turrets, in orthodox English style, and presenting little either fit criticism or comment.

1,712, "A Suburban Church" Mr. E. J. Tarver. This drawing, which has been published in our illustration pages, is a clever attempt to assimilate the architectural style of a suburban church to the style of the suburban villa, by way of producing an effect of architectural unity or uniformity. Whether the proceeds tend to the elevation of church architecture, "the wise may make some dram of a scruple or even a scruple itself."

1,713, "Tolly Cross and All Saints' Church, Warley, Essex," Mr. F. W. Tasker. A view of the chancel of an Early Geometrical church, so high to be properly seen. We shall, however, publish some illustrations and a description of this church and what has been done to it shortly.

1,730, "Parish Church, Wootton, near Liverpool," Messrs. Grayson & Ould. Hung high. Apparently a good modern Gothic church, a fourteenth-century style, with a large solid-looking tower.

1,735, "Church of St. James, Spanish-place Exterior View," Mr. John Kelly. The description ought to have run, "Competition Design for Church," &c.; it is rather misleading to put the title in the catalogue as if it were a executed building. This was the half-French half-Byzantine design with a dome, which was noticed fully at the time of the competition. It is what may be termed a clever design, but not beautiful; externally, at all events, would probably have made a good interior.

THE ROYAL ACADEMY EXHIBITION.

ALTHOUGH the works of the President this year are few in number, the two principal ones must rank among the best contributions which Sir F. Leighton has ever made to the Academy. The large painting at the top of Gallery III., "Decorative Painting for a Ceiling" (164), is intended, we believe, for the same house in New York for which Mr. Tappan has designed some of the furniture. It is a triptych, representing on a gold ground the figures of Mnesomyne, Melpomene, and Thalia in the centre compartment, while the side compartments contain, on the right, figures emblematic of the poetry of Revolver or of the Dancé and on the left figures typifying Amatory poetry; Mnesomyne is a seated figure, with a tripod on each side; Melpomene and Thalia are standing, the one draped in blue, the other in red. On each side of the central figure hover winged genii representing Music and Poetry, chubby children, but youthful boy figures whose delicate nude limbs make a lovely contrast with the gold ground: and in this purely ideal work Sir Frederick's manner of painting flesh with an enamelled smoothness of texture seems quite keeping. The whole work is full of grace and beauty, both of form and colour, and one can only regret that it should be destined for a ceiling, where it can never be seen so well as to so much advantage as on the wall on which it now hangs. We have always considered that to paint high-class ideal figures on a ceiling is a mistake; no one can look at them comfortably, and from one side of the room they may always be seen wrong way up.

A certain regret also is mixed with our admiration of the other work referred to, the statue entitled "The Sluggard," in the lecture room. This is a life-size figure of a finely formed man, stretching his arms and somewhat out

toring his body in an expression of physical leanness. The figure is splendidly modelled; nothing could be finer in its way; but it is almost a pity to see so much artistic power expended on a subject so little elevating or inspiring to the mind; nor, we may add, would a habitual sluggard show the fine muscular condition of this figure. There is, indeed, a certain moral point given to the work by the incident of the laurel wreath trodden under the foot of the figure; but, after all, it is the sluggard that we are to admire, and we do not admire him with a clear conscience. A little statuette in the same room (like "The Sluggard," a bronze) entitled "Needless Alarms," is another contribution of the President's, and a very clever and unusual work, showing a young girl in the attitude of shrinking from and looking over her shoulder at a toad. Like the Sluggard, it is mainly a study in modelling of the figure in a difficult position, and a remarkable success in its kind.

One of the finest and most original works in this year's exhibition is the sculpture group (terra-cotta) in the Central Hall, "The Enchanted Chair," by Mr. Gilbert. As the work of a young sculptor, nothing finer or of greater promise for the future has been seen here for a long time. The "chair" is a mysterious one, resting on dragons, coils, and wings, and in it is a fine female figure, of full contour, in the heaviness of sleep, the head drooping on the right shoulder. The peculiar attitude of the feet also, one of them bent inwards, as if the heel had slipped and unconsciously pivoted round the toe, intensifies the expression of sleep. On the back of the chair stands an eagle, his beak bending forward over the sleeper, his outstretched wings spread grandly on either side of her. This imaginative production is more than a mere piece of fine modelling; it is a real poem in sculpture, such as we seldom see amid the generally prosaic ranks of Royal Academy sculpture.

Mr. Orchardson has distinguished himself this year by a powerful sequel to a former powerful work. This is entitled "Mariage de Convenience: After!" (136). Here the elderly gentleman who sat at one end of that miserable dinner-table in the former well-remembered painting is seated aimlessly before the fire, after dinner (the table now laid for one only) musing on the wretched past, while from the wall behind the portrait of the wife who has deserted him seems to regard him with scorn. Even his favourite Lafite has palled upon him; only one glass has been taken from the decanter on the table. The room and all the accessories are painted with the greatest care, with a realism which never degenerates into hardness or over-finish. The figure itself is an admirable study. There is the history of a wasted life in it. What various critics mean by the faint praise with which they condescend to notice such a work we cannot understand. Here is not only a fine and learned painting, but that kind of insight into human character which makes painting what Mr. Arnold has said poetry ought to be, "a criticism of life," and of how very few pictures in this or any Academy exhibition can that he said? Take Mr. Tadema's principal work, for instance, which hangs back to back with this on the wall of the next room, "An Apodyterium" (235). This is, perhaps, the best painted work in the whole exhibition. Mr. Tadema's principal work usually is. The marble floor of the dressing-room, the figures ascending the stairs to the bath-room, the lady in foreground putting the last touch to her costume, the nude seated figure who stoops to unfasten her sandals, the architecture in the sunlit court seen through the door, all these are represented to perfection, but there is not a suggestion of any feeling, any idea, below the brilliant treatment of superficialities. The gifts of art seem capriciously bestowed. To some, who have great gifts in technique, soul and spirit are denied, and others strive to express deeper meanings without the technical power to convey them adequately.

Among the pictures that will be remembered in this year's exhibition is Mr. Bryne Jones's first contribution since he accepted membership, "The Depths of the Sea" (314), where a mermaid is dragging a drowned man down to her cave, with an expression of vicious triumph on her countenance, which is all the more striking because it is in such strong contrast to the placid faces of a certain type to which this remarkable artist has too much confined himself. The fishy portion of the mermaid is painted in a

masterly manner; her tail, which would touch the pearly bottom if extended, is turned at right angles so as to clear it, in a way which oddly reminds one of the movements of fish as one can watch them in an aquarium. The drowned man is rigid in her arms; the last remains of his breath send up bubbles to the surface above. As a realisation of a world-old fable this is a remarkable work. The same room contains Mr. Dicksee's principal painting, and, in regard to the manner in which it tells its story, the best he has ever contributed to the Academy. Under the title, "Memories" (374), it shows an interior where a widow with her child sits, stirred to sad recollections by the music played by a young woman at the piano-forte. The face of the principal figure is full of pathos; the accessories are carefully studied; the garden seen through the window adds an incident to the scene. This is one of the works in which there is an appeal to the feelings as well as to the eye. Near it hangs one of the best of the class which are addressed only to the eye, Mr. A. Moore's "Silver" (323), a "young person," lightly clad, seated on a sofa covered with a charming pattern, and with an equally effective wall-pattern behind, which we have seen in other works by the same painter. The decorative effect of the whole is lovely. On the opposite wall is Mr. Brett's principal work, "An Argyll Eden" (340), a Scottish coast scene bathed in a flood of almost impossible sunlight, which makes blue shadows everywhere behind the angles of the rocks and among the dense foliage of the hills; a schooner slips quietly along in the middle distance, with scarcely wind enough to stretch her canvas. The sunlight effect we certainly think exaggerated; the foreground (or forerwater) with its jutting rocks, is painted with wonderful reality.

Touching on sea paintings, the exhibition contains two masterpieces. Mr. Hook has seldom done anything so fine as the wave about to curl and break in the picture entitled "The Broken Oar" (65); we are conscious of the weight and momentum of the water, and expect to hear the roar it will make in breaking the next moment: the whole picture is full of wind and freshness, and of that smell of salt water which we always seem conscious of in looking at Mr. Hook's sea-pieces. Mr. Moore's "Moun's Bay, early Morning, Summer" (1094), is an expanse of sea gently undulated by the morning breeze, cold, dark, and wonderfully liquid-looking; he does not give us the briny air which flows over Mr. Hook's seas; but the depth and the movement of the water are splendidly conveyed, and there is a fascination about the picture, partly arising from the boldness of the attempt to make a large picture out of nothing but water; not the first time Mr. Moore has done it, of course, but he has never been more successful.

Sir John Millais's one contribution (unfortunately) is an admirable and most characteristic portrait of Mr. Barlow, the engraver (190), who was also the central figure of the now well-known picture of "The Ruling Passion." Among other noteworthy portraits of the year are Mr. Holl's "Lord Carrington" (203) and the "Duke of Cleveland" (210), the latter rather exaggerated in manner and expression; we have before remarked that when Mr. Holl gets a sitter with any peculiarity of manner his endeavour after strong character leads to over-accentuation. His portrait of Mr. Chamberlain (274), however, is admirable. A very successful portrait, without any such exaggeration, of a well-marked and well-known physiognomy, is Mr. Onless's "Dr. Burdon Sanderson" (243). Mr. Sargent's exceedingly clever and expressive group of three sisters (709) is a good example in what we venture to think a vicious method; the style verges on "impressionism," the flesh is not like flesh; yet there is no denying that the individual character, manner, and personality generally of the three sitters is very ably conveyed, and the group very well composed and contrasted. Sir John Gilbert's contribution is "The Slain Dragon" (179),—the dragon of the first book of the "Færie Queene," lying at his length in the landscape: a very good dragon as dragons go; the knight is too rugged and mature-looking a man for Spenser's hero. In the large gallery also is Mr. G. F. Watts's principal picture, "The Death of Cain" (158), one of a series on this subject, we believe; a painting which, like another already mentioned in the Grosvenor Gallery, tends too much towards the mystical

school; Cain, a dark brown figure, fallen forward on his knees, seems more like a rock than a man; an angel rushes past him, pointing onward amid a conensation of light. It is fine; it is a picture one must look at; but it is rather too much what might be described as a serious *extraneousness*. Another painting near this (to come from the mystic to the realistic), before which every one must pause, is Mr. Filde's "A Daughter of the Lagoons" (288), a powerful painting of a magnificent dark-eyed brunette in a crimson dress.

Mr. Riviere's principal work, "Rizpah" (268), is one of many examples of the painting of pictures mainly for the sake of depicting animals, and then giving them the title of a subject which ought to overpower all animal interest whatever. The real objects of Mr. Riviere's picture are the lion and lioness and jackals; Rizpah is quite a secondary matter; but so tragic a subject should not be made subservient to animal painting. Mr. Waterhouse's "Magic Circle" (450), an antique sorceress going through incantations, is a success, because the central figure is of real interest and originality, there is something exceedingly uncanny about her; she is a sorceress all over. Mr. Logsdail has a very brilliant and clever work, utterly prosaic, but uncommonly true to nature, "A Venetian *al fresco*" (1047), a party of pleasure of "the lower orders" in a boat going along one of the canals; it is superior in force and ability to anything that artist has previously exhibited; the personages are evidently closely studied from life, and stand out in strong relief as so many individual types of Venetian life. A much higher interest belongs to Mr. J. R. Reid's one work, "The Shipwreck," a scene on a quay or "hard" in bad weather, where an old man who has hardly survived the cold and exposure before he was rescued is supported, half dead, by two stalwart fishermen, a crowd of more or less sympathetic bystanders gazing on him. This is one of the best things Mr. Reid has done, and differs marvellously from many a commonplace shipwreck scene that is painted; it conveys the idea of being a real scene as it happened or might have happened. Among the older *habitués* in the Academy, Mr. Frith has made a successful revival of Dr. Johnson, in the painting of the incident of his attending Madame du Boufflers to her coach; the painting is hard, but the figure of Johnson, as described in Boswell's narrative of the incident, with his little wig, too small for him, on the top of his head, his "rusty-brown morning suit," and his shuffling gait and embarrassed politeness, may be taken as a realisation of the personality of the great man which probably comes very near the truth. As for the works of another old Academician, Mr. Herbert, who, as usual, indicts on us the full tale of eight, they are quite beyond criticism, and must be seen to be appreciated.

Among battle pictures, the one with most point and the most stirring subject is Mr. Gow's "Cromwell at Dunbar" (412), showing the incident when "the Lord General made a halt and sang the 117th Psalm, till our horse could gather for the chase." The painting of a troop of men all singing with their mouths open is a difficulty which has been finely grappled with; Cromwell, at the head of the troop, is rather a weak figure, but there is an old Ironsides in the foreground, shouting the Psalm with all his lungs, who would have been an awkward partner to come across. If we remember right, Dunbar was fought in a gale of wind, which the Royalists had in their faces, and which contributed to their discomfiture: there is no hint of this in the picture. To go from grave to gay: Mr. Collier has sent a large picture representing a group of "Ménads" (757) running through a wood with leopards and snakes in their hands, and looking generally sprightly in their pace and attitudes; but they are obviously only acting the part in a set scene; Ménads who were worth anything, from the point of view of a Mænad, were, we are convinced, a great deal madder than this.

We have endeavored to indicate the main points of interest in this year's exhibition, which make a respectable total in themselves, but are weighted with a great numerical proportion of uninteresting work. We shall have space for some further notes on painting and sculpture another week.

United Service Club.—Mr. R. St. Anbyn Romien has been appointed architect and surveyor to this club.

THE GROSVENOR GALLERY.

The exhibition this year is by no means of equal interest with many of its predecessors, though it contains some fine ideal works and some very good portraits. The most remarkable work is "Hope" (61), by Mr. G. F. Watts, a very strange and melancholy, though poetic, treatment of the subject. Hope is represented by a blindfolded figure seated on a globe, and trying to string a lyre, towards which she bends her ear to listen what can be drawn from their sounds. A peculiar and indescribable tone of colour pervades the whole, and in composition the figure rising in a pyramidal form from the globe is very fine; there is a grand monumental character about the painting, in spite of its faint and nearlily colouring. Mr. Watts's other contribution, "The Soul's Prison" (10), illustrating, or illustrated by, some lines of Mr. Walter Crane's, might almost have been painted by Blake. It is a half-length female figure of dark brown colour, whose eyes scintillate strangely from the dark face, and who appears surrounded by ray-like flames. Like some others of Mr. Watts's works, it is an attempt to express what it is hardly within the possibilities of painting to express adequately.

Mr. Burne Jones sends three works: of these "Sibylla Delphica" (161) is a decorative painting in his best manner, of a figure heavily draped in terra-cotta-toned garments, standing beside a tripod, and holding up some leaves on which she gazes. As a work to give pleasure to the eye it may rank high, even among its author's works; the colouring is beautiful, and the drapery very finely treated. "Flamma Vestalis" (1) is a less ideal picture, a three-quarter length of a beautiful chaste-looking female figure, seen in profile, the face and hands only visible; as an expression of the idea conveyed in the title, it is very beautiful in conception. His third and largest work, "The Morning of the Resurrection" (96), is a total failure in conception, to our thinking: it may please pious children and child-like souls.

The most remarkable works after these are the portraits. Mr. Tadema sends a very fine one, "a portrait" (67), not at all recognisable at first sight as his work. It is a life-size three-quarter length of a lady in a brilliant green dress, standing in a rather dark staircase apartment, from the upper portion of which a gleam of light only is seen through the top of an archway. The face and hands are painted with the clearness, firmness, and delicacy of finish which marks all the artist's work, whether on a small or a large scale. In this respect it may be instructively compared with Mr. Orchardson's large painting, "Master Baby" (31), which may also probably be regarded as a patient. Here a merry child is lying on its back on a cane-backed settee, laughing at its mother who bends over it. Mr. Orchardson's peculiar tones and texture in the painting of flesh, though one has to get used to and allow for them, do not mar the intellectual interest of the paintings on his usual scale; but here, when we come to life-size figures, the effect is certainly unhappy, and the face of the mother is quite unlike any healthy flesh-tones or texture, it looks flabby and not clean. The baby's laugh is well rendered. Mr. Collier's portraits of "Ria and Frida, daughters of Col. Kennard" (53) is an admirable portrait of children, forcible as a pictorial effect also; white frocks "carried off" (as the old school of critics used to say) by a profusion of white flowers in one corner of the picture; the faces are full of healthy glow, and most delicately painted, that of the younger child especially. The same artist's portrait of Mr. Henry Irving (41) is a great success. His "Miss Nettie Huxley" (108) we hardly like so much.

There are, as usual, a considerable number of portraits by Mr. W. B. Richmond, all of them delicate and harmonious schemes of colour; all conveying the impression that the production of such effects, rather than the portraying of the real character and personality of the sitter, has been the primary aim; unless we must take another alternative, and conclude that Mr. Richmond's sitters have mostly been people devoid of any marked character or expression. The portrait of Miss Burne Jones, seated in a landscape, is the most pleasing view, in which respect they are indeed all pleasing in their way, but are more or less weak in the matter of character. A small portrait, — a cabinet picture, — of "Mrs. Henschel" (84), by

Professor Grosse, should be looked at. In the east gallery we have, in the way of portraits, Mr. J. T. Shannon's "Miss Annie A. Beebe" (150); one of the attempts which have been made, since Mr. Herkomer's brilliant experiment in last year's Academy, to paint white draped portraits on a white background, and not an unsuccessful one; and Mr. Richmond's "Mrs. Warren de la Rue" (163), which, by the way, forms an exception to what we said a few lines back, for it is a brilliant and powerful portrait, with a good deal of character. Mr. Sturt Wortley, in the "Rector's Daughter," a portrait" (165) has not quite equalled his great success in portraiture (we forget the title) in a previous Grosvenor Exhibition; but this one, a quarter length, has character, and a certain originality in colour, besides good flesh-painting.

Among ideal figure subjects not well alluded to, is a "Hermes" (80) by Mr. W. B. Richmond, a brown figure standing between the columns of an Ionic temple, leaning one hand against a column while he fits to one of his feet a rather too-realistic winged sandal. The figure is a fine one, but hardly reaches the ideal character which should belong to such a subject. Mr. Calderon's "Ænone" (74) is hardly perhaps equal to the Tennysonian figure, "Forlorn of Paris," which it is intended to illustrate; but it is a very graceful and expressive figure, seated, nearly nude, on a bank, and gazing wistfully before her; the flesh is very delicately painted, and the attitude and lines of the figure most graceful, — perhaps too much so for the true expression of Ænone's sorrow. In a very different way a picture by Mr. J. D. Batten should be mentioned, "Life's Recompense" (145), an artisan leaning over the back of the chair in which sits his wife with their infant; the painting is life-size, and might have told all its story more effectively on a smaller scale and with less expenditure of canvas, but there is real feeling in it, and the group is finely composed, and has that unity of expression which makes a picture a composition and not a mere assemblage of figures. Of Mr. Sturdivick's archaeological productions, ancient styles made over again, we have never been enamoured; they are among the clever affectations which have always found a place in the Grosvenor Gallery. There is more point and purpose in Mr. Walter Crane's small and brilliantly-coloured work, "Venice, Florence, Rome" (16); a collection of personages characteristic of the three great Renaissance cities, arranged under three arches of an arcade. Among the Venetian group is seen Titian, stately in his long robes, and Paris Bordone's well-known blind lady; Florence is typified by Cimabue, stooping over Giotto, who kneels on the pavement sketching, and Dante; Rome by Michelangelo, Raffaele, and Julius II. Other characteristic figures make up the groups, at the back of which appear, in their respective places, the St. Mark's column, the tower of the Palazzo Vecchio, and St. Peter's. Miss Kate Gardiner Hastings gives us Elsie weaving shirts of nettles to destroy the spell which had changed her brothers into swans, according to Hans Andersen's tale (147); pretty enough, but Elsie seems to take to the nettles with great equanimity, and there is not a sign in her action or expression that she is handling anything so uncomfortable. Miss Pickering's "The Dawn" (184) is an eccentric but rather powerful work representing the dawn by three crimson-robed angels blowing trumpets, the figures of Day and Night beneath, the former wreathed in flowers, the latter departing, as she always does in such paintings, under the protection of a heavy, dark-hued mantle. The three crimson angels, however, are a new idea, and produce a rather striking effect. Mr. R. Barrett Browning has availed himself of a supposed incident in the early days of Joan of Arc (179), to paint a nude figure in a landscape; the figure, with her back to the spectator, falls in so far with the subject that it represents that kind of nervous and well-strung body which one might imagine the soul of Joan of Arc to have inhabited. There is another and more orthodox Joan of Arc picture by Mr. Harold Rathbone, representing the heroine kneeling, in armour, to receive the sacrament; the face is a noble and expressive one.

The finest landscape at the Grosvenor is Mr. J. W. North's painting (7), with a complement from Spenser as a title. This wonderfully delicate

harmony of greens and warm browns, a rich bank of earth with a mass of foliage over it, and a grass foreground, is an admirable example of that peculiar phase of nature which Mr. North has made his own, or, rather, which he has elaborated into a system in which, beautiful as the results are, there is, perhaps, more of art than nature. The effort to harmonise the sheep in the foreground, for instance, in the present case, leads to painting them of a dull nondescript colour nearly blending with the landscape, as sheep certainly do not blend in nature. Mr. Keeley Halswell's "Scaur on Gillean, Isle of Skye" (35), is a rather middling picture of a magnificent scene; his other landscape, "The Island of Loch Marce" (298) is a fine example of his special and rather restricted powers. Mr. Hamilton Macallum's "A Kiss from the Sea" (81) is a good example of his peculiar and very effective manner of representing the reflection of light on rippled sea water. "In a Cider Country" (122), by Mr. Alfred Parsons, is worth study for its strongly-marked local colour and character, whether the "local colour" of the grass is not too pronounced a green may be questioned. "Sunset after Storm" (142), by Mr. Henry Moore, has a grand rolling mass of cloud warmed by sunset light; there is a wild storm feeling about the whole scene, but it is not one of the artist's great works. Mr. Hemy's "The Boat came Home" (149) is a spirited work such as only a painter who has been constantly among boats and by the sea could have painted; the boat, preparing to heave in rough weather, is on the curl of a breaking wave, her bow projecting in the air in front of the wave; you can anticipate with what a thud she will come down on the beach next moment, and what a kick-up her stern will get from the breaker as she does so. Another work by the same painter, "Falmouth Natives" (192) consists chiefly of the stern of an oyster craft swinging up and down on the green water. It is pleasant to look at scenes like these painted by an artist who is really at home in what he paints, and whose pictures smell of the sea and of fishing craft.

Among other works, Mr. Nettleship has a very good lion picture (185), Mr. Spencer Stanhope has a large stained-glass kind of picture, "Why See ye the Living among the Dead?" (189), which like Mr. Burne Jones's "Resurrection," will do very well for grown-up children; Mr. J. W. Waterhouse exhibits "A Flower Market" (109), a pleasant bit of cheerful realism amid an exhibition too much pervaded by affectations; Mr. Leslie has "The Garland" (50), woven by some young girls on a sunny lawn, who look rather as if they knew they ought to be at the Royal Academy and not at the Grosvenor; and Mr. John O'Connor has "St. Peter's from the Vatican Gardens" (24), in which the architecture is so forcibly painted and the foreground so deficient in force that the building seems to come close up to the spectator, and consequently only looks half its real size from want of aerial perspective, nor would any one at first glance take it for a building on the scale of St. Peter's, — a caution to architectural painters.

Among the sculpture exhibited is Mr. Madlean's life-size group "Spring," a very clever translation into marble of two figures from one of Mr. Tadema's paintings, of which we have before spoken in praise when it was in a small exhibition of Mr. Maclean's works in Piccadilly. This is the principal work in sculpture. Among the others we may mention a very pretty bronze statuette by Mr. Gilbert, a study of a head by Mr. Mullins, and a good portrait bust of the Abbé Lizez, by Mr. Boehm.

A Social Reform Conference. — The Fabian Society has made arrangements for a Conference, which will be held at the South Place Institute, Finsbury, London, on three consecutive evenings in June next, in order to afford an opportunity for those interested in the labour question to discuss the present economic system, and the better utilisation of national wealth for the benefit of the community; and the following is the proposed order of discussion: — (1) "The Utilisation of Land" (Wednesday, June 9th); (2) "The Utilisation of Capital" (Thursday, June 10); (3) "The Democratic Policy" (Friday, June 11th). On each evening the Conference will sit from 5.30 till 7.30, and, after an adjournment for half an hour, will continue the sitting at 8 o'clock.

THE EDINBURGH EXHIBITION.

In 1859 an attempt was made to get up an International Exhibition in Edinburgh. Designs for a Crystal Palace were prepared by the late Mr. David Rhind, architect, and a site selected on the ground which then formed the Experimental Garden, now the pinnerium, attached to the Royal Botanic Gardens. This attempt having proved futile, a suggestion was made, in the pages of the *Edinburgh Guardian*, that the buildings for the National Gallery and Royal Scottish Academy, then recently completed, might be utilised for the purposes of an art-treasures exhibition, on a limited scale. This suggestion was acted upon, and in 1861 an exhibition was opened in the buildings on the mound, which was mostly confined to the display of furniture, textile fabrics, and ceramic ware. This exhibition, although on a small scale, was most interesting, showing as it did that the Great Exhibition of 1851 had even then had an influence upon the art manufactures of the country. It did not, however, prove a success financially.

The Fisheries Exhibition of 1883, held in the Fruit and Vegetable Market, and the more ambitious Forestry Exhibition, of 1884, held in specially-designed buildings erected in the grounds of Donaldson's Hospital, both proved successful, and led to the suggestion that an International Exhibition, upon an extensive scale, might reasonably be ventured upon. A small committee was formed and proceeded to action in the most energetic manner. According to Dean of Guild Gowans, chairman of the Executive Committee, they met with little encouragement at first, but in course of time the guarantee fund, which was originally fixed at 25,000L, was subscribed, and it went on increasing till it now stands at 96,000L. Plans were advertised for, and those submitted by Messrs. Burnet & Lindsay, of Glasgow, were adopted. The building is now completed, and the Dean pronounces it to be perfect as regards the requirements, and the cost, 30,000L, to be small. The space originally intended to be set apart for exhibits was 78,000 square feet, but the applications by exhibitors were in excess of what was expected, and the space has been extended to 112,000 square feet.

Part of the buildings is intended to be permanent, and is constructed of concrete, iron, and glass. The plan is based on the simplest lines, forming a central avenue, 970 ft. in length, with courts on each hand, 135 ft. each. The permanent portion has a central court at right angles to the temporary buildings, with aisles and transepts, the latter being in continuation of the central avenue, and the aisles are appropriated as art galleries. The principal entrance is in the west façade, under a deeply-recessed semicircular pediment, flanked by square towers, from between which appears a dome, with a lantern, surmounted by a winged figure, gilt, and the angles of the great court are surmounted by small domes. This façade is approached by a flight of steps, 120 ft. wide, composed of long blocks of Stewart's granolithic material, and the main doorway, a satisfactory architectural design, richly moulded and decorated, is formed of the same material, as are also two detached Corinthian pillars, surmounted by vases, on each side. This material is close in texture, and has stood the test of time most satisfactorily. The present example is of a rich red colour, but we have seen specimens of it of a glittering white and a sober grey. It can be formed in blocks of considerable thickness and of greater length than stone can readily be procured, and the mouldings are sharp and clean. This material bids fair to be of much use to the builder, especially where long lengths are required without joints, as in staircases, &c.

Taking a hint from South Kensington, an "Old Edinburgh" has been formed at the east end of the central avenue. Its design was entrusted to Mr. Sydney Mitchell, who has arranged some of the ancient edifices which have disappeared from the old town, in a remarkably picturesque and effective manner. Entering by the Netherport, we find ourselves in an irregular oblong court, with quaint gabled and turretted houses having outside stairs, projecting windows, and moulded doorways, surmounted by armorial bearings, texts, &c. This portion of the buildings cost about 4,000L, but the rents received for the shops therein reach to within 700L of that amount.

One of the most interesting adjuncts of the Exhibition is an original conception of Mr.

Gowans', to whose unwearied exertions and enthusiasm the existence of the Exhibition is in great part due. He has designed two pillars, which are placed at the north-western entrance of the Meadows where the Exhibition buildings stand. They are constructed of freestone,—red, white, and yellow,—procured from all parts of Scotland and the north of England, contributed by the quarry-masters. The workmanship is the gratuitous contribution of operative masons, and shows the various modes of tooling in use. The names of the quarries from which the specimens are procured are carved on them, and they will thus form a useful source of reference in time coming of the durability and texture of the materials. The pillars are octagonal in form, 33 ft. in height, having moulded panels, and are decorated with the armorial bearings of the principal Scottish cities, and surmounted by unicorns supporting shields and banners.

The exhibition was opened on Thursday by Prince Albert Victor of Wales.

THE ST. PAUL'S RAILWAY STATION.
LONDON, CHATHAM, AND DOVER RAILWAY.

ON Monday next the new City Station of the London, Chatham, and Dover Railway, in Queen Victoria-street, immediately opposite the *Times* office, will be opened for traffic. The station, which extends for some distance over the river on the new five-arched railway-bridge which has been built immediately to the eastward of the existing lattice-girder bridge, has been named the "St. Paul's Station," and its opening seems likely to do much to alleviate the lot of the long-suffering residents south of the Thames who have been obliged to use the Ludgate Hill Station. The new station, by the bye, is almost immediately contiguous to the south end of Ludgate Hill Station, the two stations being in communication with each other by the girder-bridge which spans Queen Victoria-street. Seeing that, just to the north of Ludgate Hill Station,—literally within a stone's throw of it, in fact,—there is the Holborn Viaduct Terminus of the same railway, and beneath this terminus the low-level Snow Hill Station for the through traffic to Moorgate-street, King's Cross, and beyond, the London, Chatham, and Dover Railway Company have practically four stations all adjoining each other. It was pointed out in our columns some years ago that this company lost a great opportunity in not placing its city terminus on the eastern side of Farringdon-street, where adequate room might at one time have been obtained for a large high-level station. The local or suburban passengers could have entered the station from the north side of Ludgate-hill or from Farringdon-street, reaching the platforms by steps as at the present Ludgate-hill Station, while cabs and carriages could have entered the station from Holborn Viaduct, as in the present Holborn Viaduct terminus. Had the latter been four or five times its present size, it would have afforded all necessary accommodation for the City traffic of the Company, and while the low-level station at Snow-hill would still have been necessary, two of the four stations which the Company will now possess in this part of the City might have been dispensed with, greatly conducing to simplicity and economy in working the traffic, and saving a great outlay in station buildings, signalling arrangements, &c. But, recognising the fact that it is of no use to cry over spilt milk, the Company has perhaps, by the present important supplement to its station accommodation, done its best to meet the ever-increasing requirements of its traffic, and the addition has been well planned.

The works have been in progress since the spring of 1883, and have thus occupied about three years to complete. The new bridge crosses the river on five arches, three of which are of 185 feet span each, and two of 175 ft. span each. It carries seven lines of rails over the river, and with the four lines over the lattice girder bridge the company are in possession of eleven lines of rails between the Middlesex and Surrey sides of the Thames. The arches and superstructure of the bridge are of wrought-iron, the arch principals springing from massive granite piers. Between 6,000 and 7,000 tons of iron have been used in the erection of the structure. The bridge was originally designed to carry four lines of rails only, and its estimated cost, according to those dimensions, was about 300,000L, but it having subsequently

been determined to widen it to a capacity of seven lines, the outlay on the structure will approach 500,000L. A special feature in the construction of the bridge consists in its commencing to widen out on approaching the Middlesex shore, at the third pier from the Surrey shore, and thus on reaching the Middlesex side a considerable extended width is obtained, which is devoted to station purposes, as before mentioned. The new booking and other offices of the station constitute a prominent building, faced with red brick and Corschilli stone, and having a frontage of 140 ft. to Queen Victoria-street, there being square towers at each angle. On the street level in Queen Victoria-street is a large central hall, containing the booking-offices, together with refreshment-rooms and waiting-rooms. The station and booking-offices are admirably planned and lighted. The screen of the ticket-office (which has seven windows), and the doors and other woodwork, are well and solidly constructed in oak, and arrangements are made for keeping the streams of passengers leaving and entering the station distinct. From the central booking-hall three spacious staircases, 12 ft. in width, and fitted with Hawksley's patent treads, lead up to the station area and railway level above, a large landing being provided midway. That portion of the station area immediately adjoining the booking-offices, and extending to the margin of the river, has, to a large extent, been constructed on arches (available for cellarge purposes), and is covered in by an angular iron and glass roof, rising to a height of upwards of 40 ft. above the railway level; the platforms, which are four in number, being nearly 400 ft. in length, and extending, as already stated, beyond the Middlesex shore arch of the bridge, the greater part of the over-river portion of the station being covered in by a roof of patent zinc and glass. It should be added that the booking-offices are immediately over the Blackfriars Station of the Metropolitan District Company, and provision is made for communication between the two stations. The works were designed jointly by Mr. J. Wolfe Barry, Mr. H. M. Brunel, and Mr. W. Mills, as engineers, and have been carried out by Messrs. Lucas & Aird; the ironwork of bridge and station being made and supplied by the Thames Ironworks and Shipbuilding Company, Millwall. The three terminal "bays" or "train-docks" of the station are provided with Langley's ingenious hydraulic stop-buffers, made by Messrs. Ransomes & Rapier, for the prevention of accidents in case the trains run in too sharply towards the "dead-ends." Mr. Crutwell has been the resident engineer; and to Mr. Turner, the courteous representative of the contractors, we are indebted for his kindness in showing us over the works. Messrs. Saxby & Farmer have supplied the signals; whilst the lighting of the station and works in connexion has been entrusted to Mr. W. C. Cannon, of London-road, Southwark.

The Gravesend extension line of this company, which will also be opened on Monday, places the Chatham and Dover Company in competition with the South-Eastern Company for the traffic to Gravesend. The new line commences by leaving the main line at a point between the Farningham-road and Fawkhams stations, and thence, proceeding in a north-easterly direction, it arrives at Gravesend immediately on the banks of the Thames, where a pier, which has been erected, will place the railway-trains in communication with the large steamers at Tilbury.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

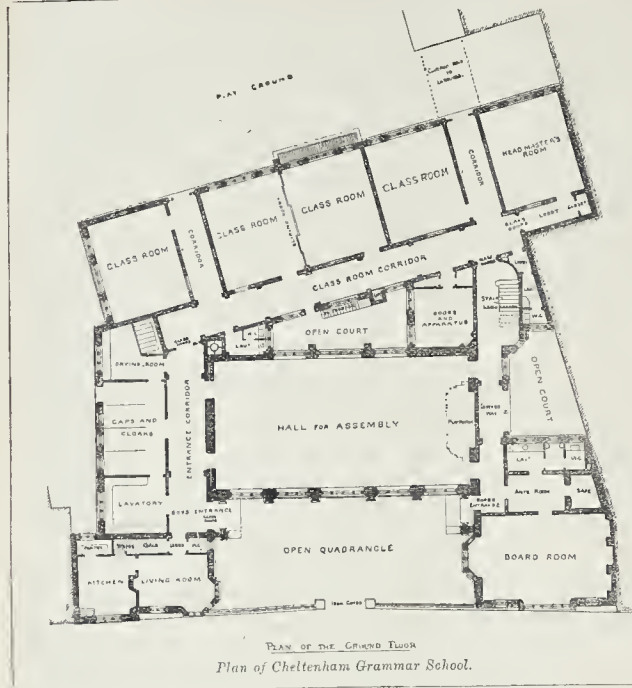

ELECTION OF PRESIDENT AND COUNCIL.

At the fifty-second annual general meeting of members, held on Monday evening last, the Council for the ensuing year of office were elected, viz. —

President.—Mr. Edward P. Anson, F.G.S.

Vice-Presidents.—Messrs. Alfred Waterhouse, R.A., Thomas Worthington (Manchester), and Arthur William Blomfield, M.A., F.S.A.

Council.—Messrs. George Aitchison, A.R.A., James Brooks, Arthur Cates, Charles Roberts Chorley (Leeds), Henry Curry, Robert William Edis, F.S.A., William Emerson, William Milner Fawcett, M.A., F.S.A. (Cambridge), Charles Fowler, Edward Augustus Gruning, Octavius Hansard, Charles Richard Pink, John Slater, B.A., Thomas Roger Smith, and Aston Webb.
Honorary Secretary.—John Macvicar Anderson.
Secretary.—William Henry White.

Illustrations.

THE CHURCH OF ST. BARTHOLOMEW-THE-GREAT.

IOR a description of Mr. Aston Webb's proposed restoration of the interesting old Church of St. Bartholomew-the-Great, West Smithfield, see the article on p. 663. We give an interior view, with transverse and longitudinal sections.

THE ATKINS MONUMENTS, CLAPHAM.

In the *Builder* for January 2nd last we gave an account of the circumstances attending the remarkable discovery, just then made, of sculptured figures beneath the old parish church of St. Paul, Clapham,—a discovery due to the insight and perseverance of Mr. J. W. Grover, F.S.A. The figures, five in number, are those of some members of the Atkins family. We illustrate three of them. The recumbent male figure is that of Sir Richard Atkins, Lord of the Manor of Clapham, who died in 1689. The other recumbent figure is that of Lady Rebecca Atkins, wife of Sir Richard. The seated figure, abnormally clad in Roman costume and with full-bottomed wig, is that of their son, Henry, who died in 1677, aged 24. The other figures discovered were those of two daughters, Rebecca, who died in 1661, in her ninth year, and Annabella, who died in 1670, in her nineteenth year. The figures are all in exceedingly good preservation,—no doubt because their existence had been so utterly lost sight of,—and, as we mentioned a few weeks ago, Mr. Grover, assisted by some friends, is collecting funds for placing the figures in a suitable and protected position in the church. Many who have seen the monuments incline to the belief that they are the work of a foreign sculptor or sculptors.

PORCH AT EAST SHEEN, SURREY.

The porch, designed by Mr. T. Colcutt, forms part of an addition to a house at East Sheen, and is constructed in terra-cotta, the roof being covered with Hartsbill tiles; the inside is lined with red Staffordshire tiles.

The alterations were carried out by Messrs. Peirce & Lansdown; the terra cotta was supplied by Mr. George Jennings, from his Parkstone potteries, and is of an excellent colour. The drawing is in the Royal Academy exhibition.

CHELTENHAM GRAMMAR SCHOOL.

The accompanying plan shows the arrangement of the ground-floor. The assembly-hall is set back from the line of the street, and forms one side of an open quadrangle, 55 ft. by 25 ft., having on the right the board-room and entrance for the governors, and on the left the caretaker's residence and entrance for the scholars. The class-rooms are placed in the rear, and have a north-west aspect, facing directly down the playground. The whole of the accommodation, with the exception of the chemical laboratory and lecture-room, which are on the first floor, is on one level.

The cloak-room and lavatory, and also a room for drying coats in wet weather, are provided adjoining the entrance-corridor, and there is a way from the cloak-room direct to the playground. The old buildings on each side of the playground can be retained, and are proposed to be utilised as recreation-rooms or workshops for the boys. The latrines are detached from the schools, and are to be approached by a covered way.

The schools were originally founded by Richard Pate, in the reign of Queen Elizabeth; the style prevalent at this period has, therefore, been adopted.

The exterior is proposed to be faced with Bath or Doulting stone, and the roofs covered with Broseley tiles. The assembly-hall has an open-timbered roof, with a lofty bell-turret (utilised also for ventilating the room) rising from the centre. The walls are lined with wainscoting below the windows, and there is a gallery at the end opposite the platform.

The building is proposed to be warmed by an apparatus in the basement, and the chimney in connexion with this is constructed with a hollow space all round, into which the ventilating flues are carried.

The estimated cost of the buildings, exclusive of the school fittings, is 5,560l.

The architect is Mr. Henry Hall, whose design was selected in competition.

WEST WINDOW, TICKHILL CHURCH, YORKSHIRE.

The west window in Tickhill Church has recently been filled with stained glass, which has been designed and executed by Messrs. Powell Brothers, of Leeds.

The ten chief openings contain the following subjects from the Book of Genesis:—The Fall,

Abel's Acceptable Offering, Rainbow Covenant, Abraham meeting Melchizedek, the Destruction of Sodom, Abraham's Sacrifice, the Meeting of Isaac and Rebekah, Jacob obtaining the Blessing, Joseph sold to the Ishmaelites, and the Death of Joseph.

The tracery lights contain the Days of Creation, presented to the church by the Misses Alderson, of Tickhill.

The church was partially restored some years since under the superintendence of Mr. J. D. Webster, of Sheffield.

ARCHITECTURAL SOCIETIES.

Edinburgh Architectural Association.—The fortnightly meeting of this Association was held on the 29th of April, in the Professorial Hall, George-street, the President, Mr. G. Washington Browne, in the chair. After the usual preliminary business, a paper on "Gothic Ornament" was read by Mr. James Gordon architect. The author traced the characteristics of the Romanesque and Byzantine expression of art in ornament, and showed their combined influence in the rise and development of the Gothic style in the end of the twelfth century. Celtic art, he said, attained to a high degree of perfection in Ireland as early as the sixth century, and was carried thence by the early Christian missionaries to Britain and the Continent, where it influenced very largely the subsequent phases of ornamental art. The Norman period, which preceded the advent of Gothic, was an age of great artistic vigour, when every form of decorative art suddenly assumed a degree of perfection unapproached for thousands of years. The various changes in Gothic ornament, corresponding to the architectural styles, were described,—those exhibited in the arts of sculptured ornament, stained glass, ornamental metal-work, and MS. illumination receiving chief consideration. Conventional treatment in foliage and figure representative marked the earliest and best periods of Gothic ornamental art. Towards the end of the fourteenth century, and even earlier in Continental Gothic, naturalistic foliage which did not suit the material used, and which had little sympathy with the purpose, began to assume the ascendancy over the conventional. This tendency soon led to the decadence of Gothic ornament. The paper was illustrated by numerous photographs, cartoons, and drawings several of the drawings being the work of the talented draughtsman, the late J. G. Lamb. After the customary discussion, a hearty vote of thanks, proposed by Professor Baldwin Brown, and seconded by Mr. Bonnar, was given to the lecturer.

Northern Architectural Association.—The first of a series of out-door meetings of the members of this Association took place on Saturday last, when they visited the New Town-hall at Municipal Buildings at Middlesbrough, which have been in course of erection for the past three years, and will occupy at least two years longer to complete. The members were met by their President, Mr. G. Gordon Hoskie, F.R.I.B.A., the architect of the buildings, who acting as *cicerone*, conducted them over the works. The existing stage of operations is perhaps, for members of the profession, the most interesting, inasmuch as the greater portion of the vast scheme is laid bare, and such vital subjects as construction, heating, ventilating, and the sanitary arrangements are more thoroughly grasped than when in more advanced stages. We may mention the description of the building, accompanied by a double-page perspective view, appeared in the *Builder* for January 13, 1883. After a very complete inspection, occupying upwards of two hours, the members accepted the invitation of the President to refreshments at the Corporation Hotel, after which they left by train for Dlington, where they went over the Free Library and the New Hospital, both recently completed works of which Mr. Hoskins was also the architect. The majority of the members ultimately returned to Newcastle.

Newcastle-upon-Tyne.—Messrs. R. & Hawthorn Leslie & Co. are now erecting extensive range of offices, pattern-shops, and stores at their St. Peter's Works, also a new approach to the existing offices from St. Peter's Station, from plans prepared by Mr. W. Glover, architect, 16, Market-street, Newcastle.

Rye.

CHAIR, ST. NICHOLAS CHURCH, RYE.
With some of the faults of decorative style pertaining to its date,—the apparently constructive weakness, for instance, of the backrest,—this is an example of a late Renaissance chair worth commemoration for elegance and richness of effect. We can give no information as to its history.

COMPETITIONS.

Hospital for Children, Shadwell.—We are informed that Messrs. H. Saxon Snell & Son have been requested to advise the Board of Management of the Shadwell Children's Hospital as to the merits and probable cost of four designs selected from those sent in in competition for the proposed new wing to the East London Hospital for Children and Dispensary for Women, Shadwell.

Board Schools, Clyde Bank, Dumbartonshire. In the old Kilpatrick School Board competition, held last week (p. 650), the designs of Messrs. J. & G. Holme and James S. A. Mercer, joint architects, Liverpool, were placed second out of thirteen competitors.

EXHIBITION OF JAPANESE ART-WORK.

In connexion with Mr. Ernest Hart's course of lectures on "The Historic Arts of Japan" at the Society of Arts' rooms, there is being exhibited in the library of that institution a collection of old Japanese metal-work, pottery, lacquer, "kakemonos," &c., exhibiting the various manners and styles of the several schools of Japanese artists, from the foundation of the first native school in the ninth century.

The objects, with few exceptions, are from a private collection of Mr. Hart, and are arranged in historic sequence. Among the "kakemonos," or hanging pictures, we noticed particularly a figure of the Buddha, by Kanooka

(ninth century?), in quiet neutral colours which seem to harmonise with the serene and expressionless countenance of the god. Another, which hangs close by, represents the Buddha surrounded by a heavenly choir playing, singing, and dancing among the clouds; it looks beautiful in the midst of beautiful objects, and in its gold and dark-blue colouring inclines one to wonder whether "the unknown artist of the twelfth century" may not have been Cimabue in a previous phase of existence. On the opposite side of the room may be seen a representation of a Japanese æsthetic exquisite carrying a branch of "the poet's tree" (the plum), and with a beautifully embroidered border of chrysanthemums on his dress. A picture of dogs by Okio, which hangs near, surpasses anything we have hitherto seen in delicacy and tender colouring, and has besides a touch of that humour so characteristic of Japanese art. By the popular modern master, Hekusai, there is a representation of the domestic goddess, Ofuku, casting out the demon of dirt and disorder by throwing beans—the Japanese equivalent for holy water—at him, a kind of "spring cleaning" supposed to be performed in every household upon New Year's day.

Among the swords and sword-guards exhibited, it is curious to notice how little the artists who decorated them thought of sparing their labour, and how they spent it equally upon the basest and the most valuable materials—the hardest iron, and even the steel hilts of the weapons, are chased with delicate and beautiful ornament, and the guards and scabbards are damascened, enamelled, carved, lacquered, and inlaid with almost every material that could be procured—mother-of-pearl, coral, ivory, crystals, and metals, chiefly gold, silver, copper, and alloys. These materials are not, as a rule, used in their crude state, but are carved into flowers and leaves, insects, reptiles, &c., and are stained in delicate tints, with the proper veins and marks drawn upon them. The beautiful early sword-guards of cold

hammered iron must also have been wrought with an amount of labour and patience difficult to realise.

We have no space left to speak of the pottery and the bronzes and the works in lac, but we were as much delighted as ever with the delicacy and humour, as well as with the loving patience, the spirited freshness, and the broad sympathies of the old Japanese artists. No work of nature is too great or too small for them, from a mountain to the petal of a flower, from a human being to a tiny insect, everything is studied and drawn, carved and coloured with equal care, accuracy, and feeling.

ARCHITECTURAL ASSOCIATION: ITALIAN EXCURSION.

The following further notes of this excursion (see p. 637, ante) have been forwarded to us:—"We reached Siena on Tuesday, the 27th April, and visited the cathedral, studying the large mosaics in the west façade and the interesting incised outline pictures in the marble pavement. In the fourteenth century a far larger building was commenced, it being the intention to make the present cathedral a transept of the new one, but only a portion of this building was carried out, and the original cathedral was completed as it now is in 1348. The library is celebrated for its frescoes. The baptistery under the choir contains a curious font with a ciborium in the centre. The Opera del Duomo contains some interesting plans of the larger cathedral and cartoons of the pictures on the pavement, and a splendid collection of needle-work, consisting of altar frontals, chapel hangings, &c. The Church of St. Domenico is a striking brick building of the fourteenth century, consisting of a nave and transepts, 70 ft. wide, with open timber roof of king-post construction, with chancel and six chapels at the east end, a striking feature in the church being the small window space required to light it, only four windows being left open in the nave, though the church has the appearance of being well lighted. Under the east end of St. Domenico, which is built on the side of a hill, is the celebrated fountain of Fontebranda. The Church of St. Caterina de Siena contains some good majolica tiles and carved and inlaid stalls. The Palazzo Pubblico, with the adjacent tower and the other interesting buildings in the market-place, make it one of the most picturesque places seen on the excursion. The Loggia of the Casino de' Nobili, with its handsomely-carved benches, and the various large private houses, with their quaint iron brackets, were all carefully studied. The next town visited was Orvieto, which was reached on Tuesday afternoon. The cathedral, as is well known, is similar in style to Siena, though not so large. The west façade contains splendid mosaic pictures, and a marvellous wealth of carved marble. The roof of the nave is now being restored, the present roof, erected in 1826, showing signs of decay. The roof is of king-post construction, and is being reinstated with fir, similar to the roof that is being taken off. Whether it will last more than fifty years is rather doubtful. The span is 62 ft. A great deal of the detail in the cathedral, and the other buildings in the town, shows strong resemblance to our Northern Norman work. There are several churches with interesting fragments of old work, and one or two private buildings. One of the curiosities of the place is the well in the fortress, which is 203 ft. deep, and 43 ft. wide, with a double spiral staircase 6 ft. wide from the top to the bottom. Rome was reached on Wednesday, the 28th of April, and under the guidance of Mr. Russell Forbes, the remains on the Palatine Hill were examined, and the Roma Quadrata (the so-called Wall of Romulus), the house of Livia, and the Flavian Palace. In the afternoon the Church of St. Paolo Fuori le Mura was visited. This church, which was rebuilt after a fire in 1523, is one of the most elaborately-decorated churches in Rome. The upper part of the façade is completely covered with mosaic, and the interior is gorgeous, decorated with marble and gilding with a very unsatisfactory result."

The excursionists return to London this week.

Rainhill Church.—In our notice in the *Builder* of April 24th, the records of this church should have been stated as having been subscribed for by the congregation.

THE FIREMAN'S EXHIBITION.

UNDER this title a small but interesting exhibition of appliances and materials for extinguishing fires and preventing loss of life by fire, and of constructive materials and solutions for rendering buildings and woven fabrics fireproof, is now open at the Royal Aquarium, Westminster. Of course the well-known firms of Merryweather & Sons and Shand & Mason are represented; as also are Spong & Co. and James Sinclair with chemical fire-extinguishing engines. Perhaps the most striking feature of the exhibition is the evidence which it appears to afford of the increased resort to chemical means of fire extinction, if we may accept as evidence the great number of exhibits of that kind. Here are to be seen hand "grenades" for fire extinction, made in the form of indiarubber bladders, in glass bottles and tubes, and even in the form of artistic glass and pottery vases for display on mantel-pieces and sideboards, or in cabinets,—all these receptacles being filled with chemically-charged liquid. One ingenious application of this liquid consists in filling the glass or earthenware base or stem of paraffin oil lamps with it, the idea being that, should the lamp fall and set light to floor or curtains, the fire would be immediately extinguished by the liberation of the chemical anti-fire fluid. Of mechanical and electrical appliances for use by fire brigades and the public, there are a few good things to be seen. Amongst these we must include the electric alarms and other fittings exhibited by Mr. Julius Sax, and a very good instantaneous hose-coupling (without spring, screw, or rivet) exhibited by Mr. Edward Nunan. The automatic and other sprinklers for fire extinction are also represented by one or two exhibits.

The ordinary type of street fire-escape, as used in London, is exhibited in action by Messrs. E. H. Bayley & Co., of Southwark; and a very good and simple fire-escape for domestic use, called "The Dreadnought," and consisting of a canvas tube and folding-ladder combined, is exhibited by Messrs. Piggott Bros. It folds up into a small space, and is always ready for use. Of course, the canvas and ropes are rendered unflammable by a chemical process. Another canvas escape, the "Ever Ready," exhibited by the patentee, Mr. H. T. Bailey, consists of a canvas tube with indiarubber hands inside it to check the descent of the persons using it. The practical use of these two escapes finds no lack of illustration, for the more juvenile portion of the male visitors to the Exhibition are not slow in availing themselves of the opportunity for pastime which they afford. A noteworthy exhibit is Woolven, Kade, & Co.'s rocket life-saving apparatus for saving life and property at fires. It is an adaptation of the rocket life-saving apparatus as used on our coasts. By it a line can be thrown over a high building and secured on the other side when other means of ascent or descent would be impossible. When we were at the Exhibition on Wednesday, the Friberg fire-escape (a German invention, apparently, and telescopic in action) was still lying on its side in the position in which it toppled over on Saturday last, when it unfortunately killed a poor man. It is evidently too lumbering, heavy, and cumbersome for hurried locomotion.

The gallery is mainly occupied by models of fire-engines and fire-escapes; one of the latter is devised so as to be extended or raised on the principle of the "lazy tongs," but we question whether it would answer in practice. In the gallery also are to be seen some very good portable fire-escapes invented by Col. Wethered, of Woolwich, as well as M. C. Duffy & Son's wood-black flooring as applied to fire-proof construction; Hitchins's fire-proof plastering; Wilkes's metallic flooring; Johnson's wire fire-proof lathing; Wright & Co.'s patent fire-proof fixing-blocks in a variety of their applications; and other exhibits connected with construction.

The archaeological aspect of the subject is represented by an old manual fire-engine exhibited by Messrs. W. Rose & Co., and described as dating from 1575,—a very doubtful ascription of antiquity, we think, in spite of certain traces of those figures having been painted on the engine at some time or other; and by a larger manual engine exhibited by Messrs. Spong & Co., and which is, no doubt, of the date assigned, viz., 1780.

The exhibition is worth a visit, and will remain open until the 15th inst.

EXAMINATIONS FOR MUNICIPAL AND SANITARY ENGINEERS AND SURVEYORS.

THE Association of Municipal and Sanitary Engineers and Surveyors, established in 1873, now numbers about 250 members, all of whom are necessarily, by Rule III., "civil engineers and surveyors holding chief permanent appointments under the various Municipal Corporations, or Sanitary Authorities within the control of the Local Government Board." The objects of the Association are, by Rule II., defined to be: "(a) the promotion and interchange among its members of that species of knowledge and practice which falls within the department of an engineer or surveyor engaged in the discharge of the duties imposed by the Public Health, Local Government, and other sanitary Acts; (b) the promotion of the professional interests of the members; (c) the general promotion of the objects of sanitary science." These objects are fulfilled by the holding of seven or eight district meetings over the country during the year, which afford valuable opportunities for interchange of ideas and views between the members, while the visits to works which constitute part of the programme of each meeting are fraught with many practical lessons. With a view to the improvement of the professional status and education of the holders of such appointments as those which qualify for membership, the Council some time ago came to the conclusion that it was desirable that the Association should take upon itself, as the most fitting body for such a purpose, the duty of instituting voluntary examinations and the granting of certificates of competency to candidates for appointment as borough surveyors and surveyors to local boards and other sanitary authorities, and after some consideration decided to hold two examinations in each year,—one in April, in London, and one in October in some provincial town. The April examination has just been held, the examiners being, as we announced a fortnight ago (p. 628, *ante*), Messrs. R. Vawser, M. Inst. C.E., President of the Association; Mr. W. G. Laws, M. Inst. C.E., City Engineer, Newcastle-on-Tyne; Mr. E. B. Ellice Clark, M. Inst. C.E., Hove; and Mr. Clement Dunscombe, City Engineer, Liverpool. The following gentlemen who satisfied the examiners have been granted certificates of competency by the Council of the Association, viz.:

Aggell, J. H., Leytonstone.
Ashmead, H., Clifton.
Coates, H. G., King's Lynn.
Fenton, W. C., Sheffield.
Grestorex, A. D., Toxteth Park.
Harland, A., Charlotte-street, W.
Osborne, F., Dover.
Saunders, E. C., Walthamstow.
Watts, J. W., Skelton-in-Cleveland.

LOAN EXHIBITION OF PICTURES AT THE WALKER ART GALLERY, LIVERPOOL.

IN catering for the entertainment of the numerous visitors whom Liverpool is expecting next week, among other things a very good loan exhibition of pictures and water-colour drawings has been opened in the Walker Art Gallery.

This collection has been contributed almost entirely by collectors in and about Liverpool, and is a very extensive one. It occupies seven rooms in the Gallery, and numbers about 850 works of art, many of them of great excellence, and comprises examples of most of the best-known British artists of the present and past generations.

One room is entirely appropriated to foreign pictures, belonging principally to Messrs. Medley, Oakshot, and J. Davies. Another is also set apart for drawings by the members of the "Liverpool Society of Painters in Water-colours"; while a third contains works of "The Liver Sketching Club," which latter society, consisting, when first established a few years ago, exclusively of amateurs, has lately been joined by some local artists, and their combined efforts show very creditable results.

The pictures lent by Mr. Edward Sammelson, chairman of the Liverpool Art Committee, also in themselves fill one room.

Among the works exhibited we may mention "Nansicaa," by Sir F. Leighton, P. R. A.; "Ariadne," by the same artist; "Rosalind and Celia" and "Flowing to the Sea," both by

Millais; "Othello and Desdemona," by Dicksee; "A Street in Venice," by J. Holland; Bridell's fine landscape "The Temple of Venus, from the Faerie Queene"; and other fine works are contributed by Mr. A. G. Knitz, of Liverpool.

Mr. Ralph Brocklebank lends, amongst others, Wilkie's "Letter of Introduction," Pynce's "Heidelberg Castle," Turner's "Blessing of the Adriatic," "Somers Hill," by the same artist; "Baalbeo," by David Roberts, R.A., &c.

Mr. David Jardine, of Liverpool, sends "The Cherry Seller" by W. Collins, R.A.; "Coast of Normandy," by Clarkson Stanfield; an English landscape, by Calcott, R.A., &c.

Mr. Malcolm Guthrie contributes "A Summer Storm," by Constable (a charming example of the artist); "View near Llangollen," by David Cox; and a number of other fine pictures.

Mr. Arthur East, also of Liverpool, sends "View on the Surrey Downs," by W. Linnell; "Wharfedale, Bolton Abbey in the Distance," Copley Fielding, &c.

Millais's "Fringe of the Moor," the property of Mr. T. H. Ismay, is also here.

The works of Rossetti, Burne Jones, &c., are also strongly represented.

In addition to the gentlemen already named, the following should be honourably mentioned as contributing largely from their collections to this interesting exhibition:—Messrs. F. R. Leyland, G. W. Moss, Chas. Langton, J. G. Livingstone, James Pezram, A. T. Squirey, Jas. Barrow, George Rae, Benson Rathbone, G. C. Dobell, John Temple, William Coltart, and others.

The display of works of art in these rooms is highly creditable to Liverpool, and worthy of the occasion which it is designed to help to celebrate, and cannot fail to attract considerable attention on the part of all connoisseurs and lovers of art.

It is worthy of note how many pictures of the highest class, which have appeared upon the walls of our exhibitions of late years, have found final resting-places in the galleries of the wealthy citizens of Liverpool and its neighbourhood.

DELAYS IN SANITARY LEGISLATION.

IN closing the session of the Association of Public Sanitary Inspectors, Mr. Edwin Chadwick, C.B., its President, delivered an address of Saturday evening at the rooms of the Association, Adam-street, Adelphi. The veteran sanitarian is displeased with the monopoly of that time of the House of Commons by political problems and the consequent exclusion of sanitary legislation. He says that by these continue political pre-occupations the advance of preventive sanitary measures is delayed, while silently and unheeded, ravages of life, strength, and working energy are permitted, which are more disastrous than the most terrible war. Even in the interests of Ireland he thinks that existing pre-occupations are to be condemned, since they cause measures to be overlooked that are essential to the relief of the most distressed of the Irish population, and which might provide increased wages in the execution of productive and profitable sanitary works. The poorest and most mud-hovelled districts of Ireland were ever the most disturbed, murdered, manslaughters, and other crimes of violence being as characteristic of such districts as epidemic disease. The proportions, comparing the best and worst districts from the sanitary point of view, were, as he had pointed out in 1852, as 61 to 29 in epidemic diseases, and as 20 to 32 in crimes of violence and passion. Ireland being wetter than England, was in greater need of sanitary relief. The only measure that he believed would be effectual, that of affording relief by remunerative outdoor labour, as successfully carried out on occasions of great manufacturing distress in England, had not been adopted, and the measures now proposed appeared to offer no means of relief for the most distressed and troubled of the Irish population. Were all the rents and taxes given to the Irish people, it could be shown that it would only bring the wages up to about half the derivable from high culture on a large scale, such as prevailed in Scotland. The delay in preventive legislation created intolerable even in one of the least afflicted districts of the metropolis, Greenwich, which even when represented in Parliament by the Premier himself. That district displayed an annual excess of more than 500 preventible deaths, between 300 and 400 of which affected the bread-winners chiefly

The loss, valued in money, he estimated at from 60,000l. to 80,000l., and more than 14,000l. annually in a medicine bill, besides a loss of at least ten years of life. The seventy-seven miles of main thoroughfares of the metropolis were administered by sixty-eight independent local authorities, and the leading thoroughfare alone from Hammersmith to the East India Dock was under fourteen different boards, of which the Corporation of London was but one. Under a system of administration now would have been removed to side streets, footways would have been systematically cleaned by the "squeegee," and the jet would have been used for asphalted surfaces as in "clean-streets Paris," and all this would have involved the expenditure of only one-eighth part of the water wasted by the present system of distribution. The purification of the air which took place after a thunder-storm indicated the increased purity of the air that would result from complete cleansing, and the annual death-rate might be reduced by at least 20,000. The principle of hydrating the streets, and putting the hose in charge of the police on the beat, had in Manchester and Liverpool, reduced the losses of life and property by fire to one-third what it was in the metropolis; yet, notwithstanding the proposals of Sir Selwin Ibbetson's Committee in 1877, no relief had been afforded, loss of life and property had gone on increasing in all its pre-ventible excess as well as in cases attributable to design or to pure accident. Had the plan proposed in their report on the water-supply of the metropolis been adopted, the cost would not have been less by very many millions than would have been necessary, and every year of further delay was adding about a million sterling to that cost. Notwithstanding the expenditure of 6,000,000l. on the purification of the Thames, estimated originally to cost 1,000,000l., its condition had been justly pronounced by Lord Bramwell's Commission as "a disgrace to the metropolis and to civilisation," and 4,000,000l. more were about to be spent, in order to throw into the sea the means of producing the milk of 200,000 cows. In the concluding part of Mr. Chadwick's address the members of the Association were adjured to make themselves masters of every detail connected with the practical use of the smoke-tester or proving the drainage of houses throughout the United Kingdom. By it they could make mental darkness visible, and show, better than any previous method, how many millions of people are living, eating, and sleeping in the midst of invisible gases, fraught with disease and death.

At the meeting, a report of the proceedings of the 8th of April was distributed, when a resolution of the Association had an interview with Mr. Stansfeld, the new President of the Local Government Board, on the introduction of Mr. Chadwick. In addition to the above-mentioned points, brought before the Board by Mr. Jerram, the Chairman of the Council, as points unanimously adopted by the Association, — papers on sanitary statistics, the position of the "Sanitary Inspector," and "Tenure of Office" were presented to Mr. Stansfeld, who, in reply to the spokesman of the deputation, expressed his satisfaction with the comprehensive treatment of the subject by the speakers. The points submitted by the deputation were:—

- 1. That the powers, responsibilities, and emoluments of Sanitary Inspectors should be largely increased.
- 2. That a minimum rate of salary for Sanitary Inspectors should be enacted.
- 3. That Sanitary Inspectors shall be duly qualified, and removable from their appointments for proved misfeasance or incompetence.
- 4. That Sanitary Inspectors shall initiate proceedings on behalf of the Local Authority for the abatement of nuisances by serving notices requiring all necessary works to be done for that purpose. All such notices to be read and approved, or otherwise by the Local Authority, or shall, if satisfied thereon, order proceedings to be taken against the offenders.
- 5. That the position of the Metropolitan, Urban, and Rural Inspectors be assimilated.
- 6. That in order that the position of the Sanitary Inspectors be strengthened, it is expedient that the appointment of all officers should be approved of by the Government Sanitary Authority, and no officer dismissed by any Local Authority without final appeal to, and approval of, the Government Sanitary Authority.

The proceedings of Saturday last concluded with a vote of thanks to Mr. Chadwick, on the motion of the Chairman of the Council, Mr. Jerram, seconded by Mr. Rains, and supported by Mr. Alexander (Shoreditch) and other speakers.

In replying to the vote of thanks, Mr. Chadwick said that a proposition had been submitted

to Lord Granville to send out to the Australian and other colonies some of the instructions on sanitary matters issued at a former period in this country, and the suggestion had been favourably received on the understanding that the information given would be brought up to date. The home death-rate of 10 or 12 per 1,000 for the nobility, 20 per 1,000 for the middle, and 30 per 1,000 for the working classes, was enormously increased in the colonies, the death-rate, with every advantage of pure air and genial climates, exceeding even the rate of 40 and 45 per 1,000 of the slums of great cities. It was a terrible fact that in Australia and some other colonies more than half the children born were in their graves before their fifth year.

THE GEOLOGY OF THE EARTH'S SURFACE IN ITS SANITARY ASPECT.

From an interesting paper read by Professor W. Fream at the meeting of the Surveyors' Institution on Monday evening last, on "The Geology of the Surface in its Practical Aspects," we call the following passages:—

"A full knowledge of the nature and distribution of the superficial deposits is a necessary preliminary to a thorough comprehension of local conditions favourable to water supply and drainage. Water derived from surface springs is always more or less open to suspicion, and the recent progress of medical and sanitary science has indicated clearly enough the nature of the dangers which may lurk in drinking-water obtained from such sources. The growing density of the population is, even in rural districts,—perhaps I ought to say particularly in rural districts,—calculated to increase rather than to diminish this source of danger. Cases in which shallow wells have run dry when adjacent cesspools have been abolished are by no means hypothetical, and filtration through a few feet or yards of porous, sandy, or gravelly rock is utterly inoperative against organic poisons. The establishment or maintenance of ponds is another important matter, especially in agricultural districts; it is a circumstance which is largely dependent on the character of the soil and subsoil, and on the nature of the available sources of water supply.

The unhealthy character of some districts is associated with the nature of the soils, and it may be regarded as an established fact that certain classes of diseases are specially addicted to certain soils. On soils pervious to water the prevailing diseases are of the enteric or typhoid type; on impervious soils they are consumption and other lung diseases, and rheumatism. In the former case foul drinking-water obviously suggests itself as the medium of contagion, for when the level of the ground water is low, percolation is free, and then it is that most of the zymotic diseases are rife. Professor Pettenger's continuous daily observations on the height of the ground water at Munich demonstrated that when the ground water fell the death-rate rose, typhoid fever in particular inducing fatal results. Not long ago Mr. Baldwin Latham prepared a diagram showing the connexion between low ground water and typhoid fever at Croydon. The ground air, moreover, is as important from a hygienic point of view, particularly in relation to dwelling-houses, as is the ground water. The quantity of ground air varies with the nature of the soil, being least in clays, more in loams, and most in sands or gravels; it varies also with the quantity of moisture in the soil, and, in any given soil, it approaches the maximum when the ground water is at its lowest. The circulation of air in the soil is greatly influenced by the temperature and pressure of the atmosphere, and a falling barometer is a danger signal, bidding us beware lest the offensive gaseous emanations from defective drains and cesspits should be given off at the surface of the ground, and, perchance, beneath the dwelling-rooms of a house, where the draught caused by fires will aid in determining the course of the effluvia. Dr. J. W. Tripe, Medical Officer of Health for Hackney, has traced the path of injurious gases through more than 30 ft. of loose soil. Some years ago, Mr. G. J. Symons, F.R.S., Secretary of the Royal Meteorological Society, advocated the collection, by a commission of experts, of a complete statistical record of the health-rate, death-rate, geology, climate, water-supply, drainage, and general conditions of all our mineral water, sea-bathing, or pure-air resorts; and he maintains that the collection of such

statistics would have both direct and indirect beneficial effects infinitely beyond the cost of the inquiry. The temperature, both of soil and of ground water, is obviously a matter of importance.

The reason that sandy and gravelly soils have usually received town populations before clayey ones,—a fact which was well illustrated during the settlement of the metropolitan districts,—is that, on the former, water was as easy to obtain as, on the latter, it was frequently difficult; the sanitary differences between the two kinds of soil are branches of very recent knowledge. So intimate is the relation between the geology of the surface and the conditions controlling health, that the University of London in its 'Examination in Subjects relating to Public Health,' which is open only to its Graduates in Medicine, requires candidates to give evidence of a knowledge of 'Geology, as regards general knowledge of Rocks, their conformation and chemical composition, and their relation to underground water, and to drainage and sources of Water supply.' Among legislative enactments, the Rivers Pollution Prevention Act is not without interest and significance in the same connexion."

THE PROPOSED MUTILATION OF THE CHARTERHOUSE BUILDINGS.

A PUBLIC meeting, convened by the Society for the Protection of Ancient Buildings and the Commons Preservation Society, was held on Thursday afternoon last in the hall of the Society of Arts, John-street, Adelphi, to protest against the proposed mutilation of the Charterhouse and the destruction of the open space. The Right Hon. G. Shaw-Lefevre, M.P., presided.

Mr. H. N. Story-Maskelyne, M.P., proposed the first resolution, as follows:—

"That, in the opinion of this meeting, irremediable injury will be inflicted on the metropolis by the mutilation of the Charterhouse in the manner proposed by the Bill promoted by the Governors of Sutton's Charity, and now pending in Parliament."

Mr. James Bryce, M.P., seconded the resolution, which was supported by Mr. Henry Maudslay; and, after some remarks by Mr. Lee, of the Charterhouse, in defence of the Governors of Sutton's Charity, was carried unanimously.

Mr. William Morris next moved:—

"That the open land within the bounds of the Charterhouse, situate in a crowded district of the metropolis, the condition of which has recently been shown to be highly insanitary, is of the greatest value, as conducing to the health of London; and its devotion to building purposes, in order to add to the funds of an already wealthy charity, would be a scandal."

The resolution was seconded by Mr. T. J. Cobden-Sanderson, supported by Mr. Richard Chamberlain, M.P., and carried without a dissentient.

The third resolution was proposed by the Hon. Walter H. James, M.P., as follows:—

"That no sufficient reason has been shown for the abolition of the hospital founded by Thomas Sutton in the Charterhouse, or for setting aside the expressed wish of the Founder, and the Act of Parliament passed to give effect to that wish, that the Charterhouse should be preserved as the home of the charity, and should not be turned to profit."

Mr. J. T. Micklethwaite, F.S.A., seconded the resolution, which was supported by the Hon. R. Grosvenor, and unanimously carried.

Lord North moved the fourth resolution, which was seconded by Mr. Hunter:—

"That the chairman be authorised to sign and present to the House of Commons a petition against the Bill, and that a deputation wait upon the Vice-President of the Council to enforce the views expressed at this meeting, and to solicit the aid of the Government in securing the withdrawal or rejection of the Bill."

Mr. Rowlands supported the resolution, which was also unanimously agreed to.

Proposed Monument to Abraham Lincoln.

The Bill recently introduced at Washington by Mr. Cullum to appropriate a sum of 500,000 dol. for the erection of a monument to Abraham Lincoln in that capital has been reported upon very favourably in the Senate by Mr. Sewell on behalf of the Library Committee. In the course of a speech respecting the Bill, Mr. Cullum said that the provisions of the measure, except as to the amount and name, were precisely similar to those in the Bill referring to the monument in memory of General Grant.

THE ART-UNION OF LONDON.

ANNUAL MEETING AND PRIZE DISTRIBUTION.

The fiftieth annual meeting of the Art-Union of London was held on Tuesday last, in the Adelphi Theatre. The chair was taken by Mr. James Hoggdon, J.P., in the absence of the President, the Earl of Derby, who wrote regretting that his duties as a Commissioner at the opening of the Colonial and Indian Exhibition would prevent his taking the chair on this the first annual meeting of the Art-Union since he had been elected to the office of President.

Mr. Hallett read the annual report, from which we extract a few paragraphs:—

"In announcing to the subscribers the total amount of contributions of the year at 7,273.7s., though it shows a considerable decline from the amount of last year, the Council do not feel called upon to take a desponding tone, for, looking at the general depression prevailing in this country,—which greatly affects every kind of enterprise,—as well as the loss occasioned by bad harvests and the low prices of wood in Australia, they think they are justified in regarding the amount as a satisfactory contribution to the encouragement of art; and, from the reports received on all sides, they have no hesitation in stating that with the return of more prosperous times, the Art-Union may fairly be expected to show that general level of income which has prevailed for above forty years.

The amount to be expended on prizes will be thus allotted:—1 work at 100*l.*; 1 work at 75*l.*; three framed original drawings, by the late E. M. Ward, R.A., being replicas of frescoes in Westminster Palace, viz. The Last Sleep of Argyle, The Execution of Montrose, and 'General Monk declaring for a Free Parliament,' valued at 70*l.* each; 1 work at 60*l.*; 2 works at 50*l.* each; 3 works at 45*l.*; 3 at 40*l.*; 4 at 35*l.*; 5 at 30*l.*; 4 at 25*l.*; 20 at 15*l.*; 20 at 10*l.*; 80 sets of designs from English history; and 47 portfolios of 'Animal Life,'—making, with the prizes given to the unsuccessful members, 336 prizes.

The following is a brief summary of the receipts and expenditure:—

Amount of subscriptions	£7,273 7 0	
Allocated for prizes	£2,113 0 0	
Set apart towards providing works of art for accumulation	472 0 0	
For print of the year, exhibition, report, and reserve	1,975 12 6	4,560 12 6
Agents' commission and charges, advertisements, printing, postage, rent, &c.	2,712 14 6	
	£7,273 7 0	

In August last, the Art-Union found itself without a president by the death of Lord Houghton. As Mr. Monckton Milnes, his lordship had been, for many years, a member of the Council, and on the death of Lord Montagu in 1886 he was elected President. His lordship took the chair at the annual meetings whenever he was in England and his health permitted him, and frequently presided at the meetings of the Council.

In succession to Lord Houghton as President, the Council, having ascertained his lordship's willingness to accept the post, unanimously elected the Right Hon. the Earl of Derby, who had been one of the Vice-Presidents since the year 1869, and to whom, from his interest in all undertakings tending to the intellectual development of the people, the Council feel justified in looking for an active co-operation.

In August last died Professor Donaldson, at the ripe age of ninety-one. Professor Donaldson was the sole survivor of fourteen architects who, on the 13th of May, 1834, met at 14, Regent-street, and passed a resolution that it was desirable to form an institution for the promotion of architecture. After various meetings, a well-digested scheme was drawn up and adopted. The Institute of British Architects was incorporated on the 16th of June, 1835, with Lord de Grey as President, and Mr. Donaldson as one of the Vice-presidents. From the day of its formation, Mr. Donaldson was one of the leading spirits of the Institute. . . . He was one of the founders of the Art-Union, and remained one of its most useful and active supporters to the last. He was one of a small committee which drew up an admirable report on the possibilities of the Association, which was of great service in shaping its course."

After alluding to the decease of Mr. James Fergusson, the historian of architecture; of Mr. Thomas Thornycroft, sculptor; Mr. Randolph Caldecott, and Mr. R. Thorburn, the Report referred to the question of copyright in the following terms:—

"A measure of great importance, not only to artists and authors, but to all those who take an interest in art, and desire to secure to authors the benefits resulting from the works of their own brains, is a Bill to amend and consolidate the laws relating to copyright. It has been prepared by the Incorporated Society of Authors, and there is every prospect that it will be shortly embodied in an Act of Parliament. The Bill proceeds mainly on the lines laid down by the Commission of 1873. It consists of six parts, of which the first four,—that is, copyright generally, dramatic and musical copyright, artistic copyright, and foreign and colonial copyright,—are so far complete themselves that they could, if occasion required, be readily dealt with *separately*. The remaining divisions affect registration and procedure. The Bill does not merely patch up the old Acts, and pretend to render them workable by providing new machinery, it makes a clean sweep of the whole of them, substituting an intelligible code of regulations for their uncertain rules. It proposes to bring the distinct classes of work to which copyright attaches, for the first time, within the operation of analogous legal principles. The Bill consists of rather more than 100 clauses, and it has some to rank as a new Act. We shall refer particularly only to the law relating to fine art.

At present copyright in engravings lasts for twenty-eight years from publication, in painting for the artist's life and seven years; in sculpture fourteen years from the first

'putting forth or publishing' of the work, or if the artist lives so long, for another seven years. The artist's distributions if now proposed to abolish in favour of one uniform term for the life of the author, and thirty years after his death; a period which seems well calculated to meet the necessities of the case, and is recommended by the Commissioners of 1873. This illustration will suffice to indicate the sweeping character of the new Bill.

Another instance of the confusion resulting from the present state of the law is to be found in the distinction as to registration. In the case of books and paintings the effect of registration differs, since it is only in the former case that the owner can take proceedings for an infringement prior to registration. The Bill deals summarily with these distinctions, establishing a copyright registration office, where any copyright can be registered. The artist is to have copyright both in his work and in the design or original, and this right includes that of reproducing the design in any way. It would, for instance, give a sculptor the power of prohibiting the photographing or engraving of his work.

An important declaration is made of the law as to copyright in photographs, which is to belong to the taker of the negative. In the case of *costes-de-vaite* taken on commission, however, it is very properly proposed, irrespective of copyright, to prohibit their being sold or exhibited in shop windows without the consent in writing of the person for whom the work was executed.

It is proposed that the measure shall extend to the whole of Her Majesty's dominions, so that it is a serious attempt to deal with the vexed question of copyright in the colonies as well as at home.

Such are the main features of the forthcoming Bill, and they will suffice to show that it is a praiseworthy piece of work. Much, of course, yet remains to be done before it can be regarded as wholly satisfactory in point of detail, but it goes far to render the speedy settlement of this great question at any rate possible."

Having referred with approval to the work of the Home Arts and Industries Association, the Report spoke of the courses of lectures on the Egyptian and Assyrian antiquities in the British Museum which have been given of late years by Mr. Newton and others making tours of the galleries, and illustrating their discourses by reference to the several objects exhibited, and asked whether it might not be worth while to establish something of the same sort in connexion with the National Gallery and other collections:—

"Suppose some competent person were selected who should take some special painting, and give to those standing in front of it a 'catalogue raisonné' of its elements. He would indicate the general intention of the work, whether the symbolical meaning of some masterpiece of Beaufield or Murillo, or the more homely but still subtle and intensely realistic representation of interiors of De Hooch or Van Ostade; explaining the manner in which the master grouped his figures to produce a harmonious composition,—how one part was made to lead up to and give force to another,—the modification of effect produced by direct and reflected light,—the simpler principles of perspective,—the force due to the contrast or harmony of different colours,—the skill displayed in foreshortening the figures,—the effect of solidity acquired by the play of light and shade,—the principle which regulates the reflection of objects on water,—and shortly, all those points which illustrate the genius and technical skill of the artist, apart from the mere 'motif' of the work, which as a general rule is all that the average spectator takes in. Who can doubt that, having picked up some at least of these elements, the visitor will be enabled to go on to other pictures, and to retail for the benefit of his companions, those points, few perhaps, and but roughly comprehended, but which may have the effect of making him ponder on them as far as they go and seek opportunities of learning more. At any rate, it cannot be said that the experiment is not worth making.

As bearing on some degree, on the foregoing subject, of highly deserving of recognition is the fact that the Dean of Westminster, every Saturday afternoon, personally escorts a party of ladies and gentlemen to the museum, to explain to them the design and intention of the several monuments."

In reference to the presentation work for the coming year, the Report, in conclusion, says:—

"It is long since the Council provided for the subscribers an English landscape engraving, and, believing that such a subject would be acceptable, especially to those dwelling in distant lands, they commissioned Mr. Leader, A.R.A., one of the most popular landscape painters of the day, to paint a picture for the purpose. The artist chose for the subject a view at Streatley, a village on the Thames, and a very favourite haunt of artists from the charming combination of river scenery, hills, and woods, which diversify the spot. . . . The painting has been introduced in black and white with marked power by Mr. Willmore, and the Council feel no doubt that it will be very popular with the subscribers. The oil painting, worth 300*l.*, will be the chief prize in the next distribution."

On the motion of the Chairman, seconded by Mr. Zouch Troughton, and supported by Mr. Henry Maudslay (who made a few suggestions with the view of making the objects of the Art-Union better known), the Report was unanimously adopted.

The Chairman next moved a vote of thanks to Mr. Zouch Troughton, the honorary secretary, for his services during the past year, and expressed the deep regret which he felt having to announce that the senior honorary secretary, Mr. E. E. Antrobus, J.P., died on the previous day (Monday). This was seconded by Mr. Gooden, and briefly acknowledged by Mr. Troughton.

Votes of thanks were also given to the auditors (Messrs. G. J. Fearis and J. Walker); to Messrs. A. & S. Gatti for granting the use of the theatre for the meeting; and to the ladies

who rendered assistance in connexion with the drawing of the prizes.

It may be added that the principal prize (value 100*l.*) fell to Mr. W. G. Judge, Dorking, and the three drawers by the late E. M. Ward, R.A., to subscribers at Oporto, Lenhard (Victoria, South Australia), and Peterborough (Canada) respectively.

AN IMPROVED BATH.

The object of the form of bath shown in the accompanying sections is to prevent the running up of water over the edge and on to the floor, which constantly and inevitably happens when a large bath is used with any depth of water, and the water is agitated during the use of it. It is an odd instance of the way in which so many things are made according to custom rather than common sense that large standing baths, which are always emptied by a plug at the bottom, and never can be emptied by pouring over the rim, are nevertheless, habitually made with a curve over at the rim, in the same way as a wash-hand basin, which (when not a fixture) is always emptied by pouring over the rim. This curved-over rim is therefore the natural and proper way of making the latter; whereas in large fixed bath it is an object that the water should not get over the rim. Reverse the curve, therefore, and the water,—however it may run up the side during use,—will not run over the edge and give the household extra work in mopping up floors, or occasionally percolate through the ceiling below.

The reverse curve is so made that it does not project inward beyond the line formed by the side of the bath in its ordinary form, a presents no edge or angle internally. It is patented by Mr. H. H. Statham, and the right to the patent is made over to Mr. Jennings, Lambeth, who is prepared to make and supply the bath.

Cutting of Glass by Heated Air.—*Centralblatt für Glas Industrie* remarks that heated air or gas is now frequently used in place of the former methods of cutting glass. A pipe leads the air or gas against the object to be cut, which is fixed close before the pipe and rotates on its axis. In this way a small circle of heated glass is produced, which is damped, and the glass can then be cut with relative ease at the place desired. The process is described as being rapid and effectual, and likewise surer than any hitherto employed.

A NEW DISCONNECTOR.

This new drain or sewer disconnecting chamber and syphon trap combined is invented and patented by Mr. Marsh Simpson, C.E., who describes its objects as follows:—

“It is a development of and improvement upon the ‘Kenon’ air-chamber first introduced by Professor Corfield and Mr. Mark H. Judge one year back. The object of the design is to provide chamber sections in stoneware, with or without branch channels, as required, complete, thus dispensing with separate channel pipes and cement-rendered floors. The plan and sections given above with the following notation from the registered description of the design fully explain it.

- “The design is to be made of glazed stoneware consisting of eight different sections, all fitted together so that they may be used either separately or in any combination, and is applicable to the shape or configuration thereof, viz. —
1. Syphon trap and floor.
 2. Floor with three channels of equal size.
 - 3 and 4. Floor with two channels of equal size, right and left hand.
 5. Floor with three channels of unequal size.
 - 6 and 7. Floor with two channels of unequal size, right and left hand.
 8. Floor with one channel only.”

We may add that the disconnector is manufactured by Messrs. John Bolding & Sons, of 10, South Molton-street.

NEW BUILDINGS FOR POOR LAW ADMINISTRATION.

Workhouse Schools for the Edmonton Union.—The Chase Farm Schools, erected by the Guardians of the Edmonton Union on the Ridge-way, Enfield, have lately been opened. The buildings have been erected at a total cost of £10,000, which includes the sum of 12,000*l.* the cost of the site, which is 44 acres in extent. The architect of the building was Mr. T. E. Updeley, of 106, Cannon-street, E.C., and the builder Mr. Charles Wall, of Chelsea. The buildings comprise a lodge with long porch for the protection of new comers, whilst the necessary formalities of admission are being observed; then of two separate buildings, which may be termed quarantine buildings, as in each, each child will pass fourteen days before being received into the family. The main building consists of a centre and three surrounding wings. In the front of the centre are the committee and master's rooms, and sleeping accommodation for domestic servants; behind are bakery, work-rooms, kitchen, dining-hall, swimming-bath, landrises, and washrooms, arranged with subsidiary kitchen and landrises to be used for training the girls and fitting them for domestic service. The wing on the left is for girls, that on the right for boys, and that in the rear for infants. In the front of these the school, class and play rooms, 12 lavatories are below, with dormitories, wash-rooms, and water-closets above, arranged so that the case of fire or epidemic a floor or block, part of it, may be isolated, as the dormitories are divided and have separate staircases.

The buildings are on what may be called the subdivided pavilion system. Beyond these are two cottage homes, each for two foster parents, and a family of thirty children, the man teaching the boys, and the woman instructing the girls. In the distance is an infirmary for infectious cases, with separate laundry. Provision has been made for future enlargement to any required extent without having to hem in the existing buildings,—an important point not always secured, even where it might be.

The Holborn Union Workhouse Buildings at Mitcham.—The large and costly new workhouse, which has for some time past been in course of erection at Mitcham for the Guardians of the Holborn Union, is fast approaching completion. The buildings are situated in Merton-lane, opposite the Mitobam and Wimbledon Gasworks, and occupy an area of about eight acres. They are built on the pavilion principle, and contain seventeen blocks, twelve of the blocks consisting of the inmates' wards. These are arranged on each side of the site, and are three stories in height. All the blocks are connected by covered and glazed corridors. The administrative blocks are in the centre of the site, and are three in number, the front block of two floors facing Merton-lane, containing the master's residence, the board-room, and committee-rooms. At the rear is the block containing the dining-hall, a large apartment 100 ft. by 50 ft., which is also intended to be used as the workhouse chapel. The kitchen, immediately adjoining, is 63 ft. by 24 ft. Adjoining is the laundry block and engine-house, whilst at the extreme rear is the infirmary, a separate and distinct block, three stories in height. The porter's lodge and the receiving-wards are at the entrance in Merton-lane. The inmates' wards, facing the Merton-lane elevation, are surmounted at each angle by towers, whilst the central administrative block is entered by a bold pedimented doorway in Portland stone. The whole of the buildings are faced with stock brick, on blue Staffordshire brick bases. The buildings have been erected from the designs of Messrs. H. Saxon Snell & Sons. Messrs. Wall Bros. are the contractors. Mr. J. H. Caine is clerk of the works, and Mr. Saunders is foreman. The whole of the wards will be heated by hot-water apparatus, furnished by Messrs. May Bros., of Holborn, who are also supplying the general engineering work. The gasfittings are by Messrs. Perry & Sons, of Westminster. The whole of the stone paving will be executed by Mr. Alfred Walker, of Colindale-square, in Walker's granolithic pavement. A water-tower, with tank to hold 25,000 gallons of water, is to be erected, at a cost of 2,500*l.* The estimated cost of the buildings is upwards of 60,000*l.* In connexion with the new workhouse, and the industrial schools in Mitcham-road immediately adjoining, new gasworks are about to be erected.

Ranmoor, Sheffield.—Stained glass has been inserted in another of the windows in the eastern apse of the Church of St. John, Ranmoor, Sheffield. Messrs. Powell Bros., of Leeds, are the artists, and the window is to the memory of members of the Ellison family, and represents some of the chief events of the Passion.

“ROBINSON'S CEMENT.”

SIR,—Referring to the correspondence in your recent issue between Messrs. Howe and Messrs. Robinson [pp. 624, 658, ante], we are surprised to learn that the latter claim a patent right in the admixture of borax or thiod with calcined gypsum, it being widely known that for the past thirty years we have manufactured and largely sold a cement called “Parian,” which is a combination of the above ingredients; and, as Messrs. Howe point out, our late senior, Mr. A. Francis, took out a patent as far back as May, 1856. We also agree with Messrs. Howe that alum is a very old ingredient in the manufacture of marble cements.

It is admitted by practical plasterers that Parian cement, made under the process we have described, is more reliable than any other cement of its kind, being free from liability to efflorescence even when on a backing of Portland cement, and being capable of taking paint, paper, or polish within forty-eight hours of being used.

FRANCIS & CO.

NEWCASTLE-UNDER-LYME PUBLIC BUILDINGS.

SIR,—The authorship of the first premiated design for the above buildings is, in last week's *Builder*, attributed in error to us solely, whereas it was shared by ourselves, Mr. W. H. Sugden, and Mr. John Blood.

The plans as now adopted certainly do not present themselves to great advantage in your illustrations of the 24th ult., owing, doubtless, to the fact of their reproduction from ordinary tracings. But we hope in due course to place the later design in perspective in a better light.

W. SUGDEN AND SON.

Leek, May 3, 1886.

*** This is the first intimation that has reached us that any other architects than Messrs. W. Sugden & Son were concerned in the first design of this poly-architect building.

TRURO CATHEDRAL CENTRAL TOWER FUND.

SIR,—Will you allow me to make one final appeal for the fund now being raised for the purpose of carrying up the lower stage of the above?

In answer to my two former appeals, a sum of £66*l.* has been promised, but this is far short of the amount required, viz., 2,574*l.* We have now reached such a point in the work that it must at once be decided whether we carry up this portion or carry the transept roof through, thus entirely obliterating this essential feature from the design. I am the more anxious to do this work now to avoid paying off a good many men (who have now been with us from four to six years), in the present time of slackness and difficulty of getting work.

Will not some influential person take the matter up, and try and raise the 2,000*l.* required, by collection or otherwise. Or, failing this, surely there are 2,000 persons amongst your numerous readers who, without much self-doubt, could contribute 1*l.* each, and the amount would be at once raised. Let me press upon all who see this at once to act on this suggestion; let no one hold back and say there are plenty without me. If each will look upon himself or herself as the important one, and kindly send me only 1*l.*, I shall soon have the pleasure of writing to say the amount has been made up and the work going on.

ROBERT SWAIN,
Clerk of Works.

BREWERY CHIMNEY-SHAFT.

STR.—Having to design and draw up specification of a large shaft for an extensive brewery, will you kindly allow me to ask through the medium of the *Builder*, the following questions, in the hope that some of your subscribers will give me their practical opinion:—

1. Some architects specify that for every yard in height a course or two shall be built in Portland cement; what advantage is there in so doing?
 2. Have any large shafts been built throughout with concrete?
 3. If exhaust steam is turned into a chimney-shaft, will it injure the brickwork?
 4. What are the binding clauses for the supplying of best Portland cement? I should like one from some well-known company or corporate town.
 5. Is any instance known of a chimney-shaft standing any length of time when out of the perpendicular?
 6. When subject to great heat, will brickwork in mortar or brickwork in Portland cement stand best?
- I have the book lately advertised in the *Builder* on "Tall Chimney Construction," by Messrs. R. M. & F. J. Bancroft. As they have studied the subject, perhaps they would favour me with a reply, which would benefit your numerous readers as well as
- J. H. G.

The Student's Column.

OUR BUILDING STONES.—IX.

MINERALS COMMONLY FOUND IN STONE.

BEFORE proceeding to examine the sections of stone which have been cut and ground, it may be well, perhaps, to describe briefly a few of the minerals which most commonly occur in them in considerable proportions; for it is quite evident, as most rocks are made up of a variety of minerals, that unless we are able to distinguish the principal minerals under the microscope, we shall be able to make but little progress in microscopic analysis.

Minerals crystallise in different forms, and in such characteristic manners that their identification often rests, to a great extent, on what is called their crystallographic forms. The axes of crystals are referred according to their number, relative position, and relative lengths, to six different systems. It does not come within our province to describe these systems. The student will find information on this point in any elementary treatise on mineralogy.

The mineral which will be found to form a large per-centage of many sandstones and granites is

Quartz.

In its purest form, quartz is white, being composed wholly of silica. As a constituent of building stones silica may occur as,—

1. Crystallised quartz, forming, with other minerals, a thoroughly crystalline mass, having no glassy matrix, as in granite.
2. In crystallised particles or little grains, as in sandstone.
3. Filling minute cracks, or performing the part of the matrix or cementing material of a sedimentary rock.
4. Taking the place of a pre-existing mineral, as in a stone containing silicified shells.

Quartz may be crystalline or non-crystalline. Where it is found filling veins and cavities in rocks, and so does not form one of the original constituents of them, it is called "secondary quartz."

Flint consists of an intimate mixture of crystalline silica, which is insoluble, and of amorphous silica. Chalcedony is silica, having an obscure or minutely crystalline structure. Practically the quartz found in stones used in building operations is insoluble, and if a stone containing it decomposes, it is owing to the inferiority, in point of durability, of other minerals of which it is made.

The destruction of a stone may be somewhat retarded by the manner in which the silica is disseminated throughout. If it exists in the form 2, described above, the weathering depends on the character of the matrix. If silica itself should form the matrix, by enveloping particles which might be more susceptible to weathering, it, to a great extent, preserves it. In time, however, the exterior of the stone might become pitted with little holes, by reason of the decomposition of the particles exposed to the atmosphere. Such a stone would be quite unfit for any delicate mouldings.

If we get conditions 2 and 3 together, the stone would be almost wholly, if not quite,

composed of silica, which, although it would last for ages, would be exceedingly difficult to work, breaking with a conchoidal or splintery fracture.

Quartz appears clear under the microscope, and polarises in strong brilliant colours. Minute enclosures of foreign substances, little specks, and thousands of minute cavities are frequently seen dotted over the crystal. Its appearance is so characteristic, however, that it cannot be easily mistaken for any other mineral.

Chalcedony looks granular, and often shows a minute concentric radial structure, with a black cross between crossed Nicols.

The hardness of quartz is 7, and it cannot be scratched with the point of a knife. When in a granular condition the little grains may sometimes be detached, giving the mineral the appearance of being scratched.

Felspar.

This mineral exists in a variety of forms, and is important enough for us to describe in some detail.

The following table shows the principal felspars, and their average chemical composition:—

Name of Felspar.	Silica.	Alumina.	Potash.	Soda.	Lime.
Orthoclase	64.80	18.50	16.50
Albite	68.42	19.68	...	11.83	...
Oligoclase	63.71	22.95	1.22	8.11	27.5
Labradorite	(52.9)	30.3	...	4.50	21.75

Orthoclase often contains small proportions of lime, iron, magnesia, and soda. Its colour is a dirty white, grey, or pink. It crystallises in the monoclinic system. The other three felspars crystallise in the triclinic system.

Felspar is one of the essential constituents of granite, and on the power of its resistance to weathering the durability of that stone mainly depends. We are sometimes apt to consider granite as a good weathering stone, without inquiring into any particulars concerning it, and although as a rule it is exceedingly durable, as a matter of fact, unless the felspar be of a durable character, it may weather quite as easily as a bad limestone or sandstone. For instance, much of the granite used in the buildings of Dublin is of inferior quality, being so rotten as to become quite worthless; whilst other kinds are durable.

In the decomposition of felspars, which may be represented as silicate of alumina combined with silicates of potash, soda, and lime, the alkali or lime is removed in combination with a portion of silica, and there remains as the final result of the process a hydrated silicate of alumina, or clay. The potash felspar orthoclase is, under ordinary conditions, much less subject to such a decomposition than the soda felspar, albite, or those which, like labradorite, contain both lime and soda. Both Mitscherlich and Bischof have remarked that where albite and orthoclase are associated, the former may be found decomposed and friable, whilst the latter is still unaltered. This change of felspar is favoured by mechanical division, which multiplies the surfaces exposed, so that when a felspathic rock is triturated with water, small portions of silica and of alkalis are taken into solution. If the decomposing rock contains, like many granites, both potash and soda felspar, the latter, being first attacked, will be rendered friable, and eventually reduced to the condition of clay.

Under the microscope orthoclase can be recognised by its characteristic cleavage, rectangular cross-hatching, strong colour, and dirty turbid-looking appearance. It often presents a very irregular crystalline form, and commonly occurs in twins, which ordinarily polarise in different colours on either side of a median line.

Triclinic felspars in polarised light usually show a series of parallel bands, or twin lamellae as they are called, which polarise in various colours. The student will find excellent information on the microscopic determination of felspars from Fouquet et Michel Lévy, "Minéralogie Micrographique," pp. 209-227; Rutley, "Quarterly Journal of the Geological Society" (1876), p. 479; and "Study of Rocks," pp. 86-104.

* See the *Builder*, vol. xxi. (1873), p. 1021.
† See "Geol. of Canada" (1863), p. 570.

Mica.

The two commonest forms of mica are termed muscovite and biotite. The former crystallises in the rhombic system, is optically biaxial, and consists principally of silicates of alumina and potash. Oxide of iron, soda, fluorine, and water are usually present in variable quantities. Its ordinary colour is silvery white, but occasionally dark brown or black specks of the mineral may be seen. Muscovite stands the weather very well, and little plates of it may be found on decomposed granite, apparently unaffected by the action of the weather; whilst the felspar has rotted away. This mica is often found in sandstones. The fissility of many flag-stones is frequently due in a great measure to its presence along certain lines, so that the surfaces of paving stones are often covered with this glittering mineral. Under the microscope, muscovite exhibits clear colours and is transparent. At in the case of most minerals distributed promiscuously throughout a rock, the section for microscopic examination being cut in any direction, it is not easy to give all the rules for the determination of this mica. Under ordinary circumstances the sections do not often coincide with the cleavage of the mineral, but cut the planes of cleavage at different angles, which causes thin parallel lines to appear in two different directions.

When, by design or accident, the section is cut parallel to the basal cleavage a tolerably strong chromatic polarisation is shown, that differing from biotite, which, under the same conditions, appears dark between crossed Nicols. Dichroism is faintly exhibited.

Biotite is also called the magnesian mica and crystallises in the hexagonal system. Its chemical composition is silicate of alumina and magnesia, with a little potash and iron. It may be either black or dark green. It is not so durable as muscovite, assuming a white, soft crust under the action of the weather. Ordinary sections of the crystal are strongly dichroic.

Mica is very elastic; its degree of hardness is so variable that it cannot be stated with any pretensions to accuracy.

Hornblende.

This mineral crystallises in the monoclinic system. Its chemical composition is "silicate of protoxide of iron, magnesia, alumina, lime and protoxide of manganese, with frequently a little hydrofluoric acid and water."

There are two principal varieties of hornblende; one has a considerable proportion of alumina, and the other contains very little; sometimes none.

The former is generally of a dark green, black, or brown; the latter of a pale green, white, or grey colour.

The non-aluminous hornblendes do not often occur in stones largely used for building, but the aluminous kinds are found in syenite and granite, where, in weathering, the silica, lime, magnesia, and a portion of the alkalis are removed, with conversion of part of the earth, and the iron into carbonates. The further oxidation of the ferrous carbonate is shown by the yellow and brown crust, so commonly to be seen on the surface, or penetrating cracks in the hornblende. The change proceeds until a mere internal kernel of unaltered mineral remains, and until the whole has been converted into a ferruginous clay.

Under the microscope, hornblende is strongly dichroic, and this is its principal feature. It is often longitudinally striated, in addition to which the cleavage planes form a sort of lattice work. The mineral is so irregular in form that very little reliance can be placed in its determination from that point of view.

Its degree of hardness is between 5 and 6.

Calcite (or Calcespar).

This is an important mineral for us to consider, forming as it does the basis of the most prominent limestones used in building.

It presents a great diversity of crystalline forms, but crystallises in the hexagonal (rhombohedral) system, the cleavage being very perfect. Its chemical composition is carbonate of lime. We have previously described the principal cause of the decomposition of this carbonate on p. 459.

Under the microscope, sections of calcspar, if the analyser alone is used, exhibit strong double refraction. It is very faintly pleochroic, and

* Rutley's "Mineralogy" (1876), p. 121.
† See Geikie, "Text-book of Geology," p. 75.

the intersecting cleavage planes are often well marked. When the polariser is used, it is frequently found that the crystals are made up of separate granules, which have different tints, and their boundaries are well defined. Each granule has a characteristic series of parallel lines running across it,—called twin lamellae,—and the direction of these lines is quite independent of those of the surrounding granules. Sections of statuary marble show this structure of perfection.

In calcitic freestones the carbonate of lime appears to have formed round grains of sand or other nuclei, in concentric layers like an onion, and sections often show radiating lines.

Calcite is the principal petrifying mineral. Shells, corals, and other organic remains found in rocks are commonly made of it. Take such stone as Portland, for example. A microscopic section of this will show that the abundantly matter contained in it is almost exclusively made of calcite. The iridescent zig-zag appearance of the mineral forming the shells at once proclaims the fact.

Many very compact limestones need as marbles owe their dense structure to calcite, a mineral not only forming the whole of the matrix remains contained in them, but also forming the matrix or cementing material. The carbonate of lime forming the organic remains, sometimes of a more durable character than the matrix, hence, on weathering, the fossils,—they are termed,—stand out from the surface of the stone, but often the reverse is the case. The importance of correctly ascertaining the nature of the carbonate of lime composing the shells of a limestone, it is only necessary to point to the many buildings now standing, where the stone is completely riddled with cavities formed by the decay of the shells, being not only a source of weakness in the walls of the buildings, but an unsightly appearance.

Both large and minute cracks in stones are often filled with calcite. The mineral is often taken for quartz, which, at first sight, it is very much like. If the cracks are filled with quartz and not calcite, there is a considerable difference in quality, and when the limestone is being rubbed down and polished, the minute quartz veins are a nuisance, causing a deal more work.

Calcite is very easily distinguished from quartz. The former, when treated with acid, effervesces, and, having only a hardness of 3, is easily scratched with a knife; whilst quartz produces no effect on, and the knife cannot scratch, the latter.

Aragonite.
This mineral crystallises in the rhombic form. Its chemical composition is exactly the same as calcite, but it weathers very differently. The fact that it is harder and stronger than that mineral would lead one to suppose that it is of a more durable character, such is not the case. The shells of many fossils are made of aragonite. The action of water containing carbonic acid, in percolating rocks, has removed to a great extent those shells which were imbedded in them, but, fortunately, the mineral is not so monotonous as might otherwise be. The cavities on the removal of the shells are often frequently filled up by calcite. When this is the case the calcite is seen under the microscope to be more or less coarsely crystalline, the original structures of the shells being obliterated, they present a different appearance to the original calcite shells which may be found them.

Microscopic sections, aragonite may be distinguished from calcite by its biaxial polarisation in convergent light. We may pause to mention this. When there is one direction in a crystal, along which a ray of light can proceed without bifurcation, that crystal has one optic axis, and is called uniaxial. Iceland spar (calcite) is an example. When a crystal has two such axes, it is termed biaxial,—quartz, for example. On reference to the laws of optics relating to uniaxial and biaxial crystals, it will be seen that they respectively issue in a distinctive manner.*

Patent Work.—An exhibition of amateur metal-work is proposed to be held at Long Acre, in December next, under the patronage of Mr. T. J. Gauthorpe, to whom design exhibitors can apply for particulars.

* Ganot's "Physics" (1883), pp. 572-575 and 583, for further information on this subject.

RECENT PATENTS.
ABSTRACTS OF SPECIFICATIONS.

23, Opening and Holding Hinged Windows, Ventilators, &c. D. Aubert.

A worm, actuated by hand by means of a pair of bevel wheels, or in a similar manner, causes a worm-wheel to revolve. To the worm-wheel is fixed one arm of a jointed lever, which raises or lowers the window when the wheel is turned. The worm wheel and bevel wheels retain the lever and the window in any position.

60, Roofing Tiles. H. W. Robinson.

The object is to produce a tile which may be effectively used on roofs too flat to allow the use of ordinary roofing tiles. The front of the tile is pointed, and its surface is grooved with a number of channels deepening towards the point, and serving to conduct the water away from the joints. On the back portion of the tile projecting ridges are formed, over which fit the points of the tiles in the course above, corresponding grooves being made on the under sides. Nibs are sometimes formed on the under sides of the tiles and cemented into recesses in the tiles below.

101, Hinge. T. Greenwood.

This is a hinge particularly adapted to screens, but which may be used for other purposes. Toothed sectors attached to the panels of the screen, are held together by a bar pivoted at the centre of each sector.

117, Chimney-tops. J. Bennison.

Above the lower part of the chimney-top is fixed a canopy, surmounted by a cap. The upper part of the outer surface of the lower part and the whole of the inner surface of the canopy are fluted or grooved, and the outlets of both are arranged so that a free current of air carries up the smoke without draught.

217, Wood Block Flooring. W. Court.

Round the lower edge of each block is a semi-circular groove. The blocks are laid on a foundation of concrete, in a composition consisting preferably of Stockholm tar, pitch, and resin. Before being laid, the blocks are dipped into the melted composition.

230, Street Orderly Bin. W. K. Sidgwick.

A cast-iron shell has a sand-box formed on it. The dust-bin is braced diagonally at the bottom, and fitted at the top with angle-iron and sliding handles.

331, Door-fastening. M. P. Ismay.

A box, fixed on the door-frame, contains a sliding block, which is formed with teeth on its upper surface, and the block is pressed upwards with springs. A pawl on the door engages one of the teeth when the door is shut, and prevents its opening until sufficient pressure is applied to compress the springs. Very little pressure is required to close the door.

NEW APPLICATIONS FOR PATENTS.

- April 24.—5,638, J. Russell, Cooking Ranges.—5,661, W. Williams, Portable Scaffold.
- April 27.—5,678, J. Mitchell, Water-regulating and Waste-preventing Apparatus.—5,680, J. Jackson, Flushing Cisterns for Water-closets.—5,689, N. Locke, Self-locking Bolts for Doors.—5,706, J. Macleish, Water Fittings for Baths.—5,710, C. Porter, Dust Bins, &c.
- April 28.—5,748, W. Pilkington, Plate Glass.—5,749, J. Howorth, Ventilators.—5,752, J. Parsons, Sanitary Pipe.—5,795, C. Gannaway, Ventilator.—5,803, C. Hardy, Fire Grates.
- April 29.—5,812, J. Hill, Securing Knobs to Spindles for Door Locks and Latches.—5,820, J. Warwick, Manufacture of White Lead.—5,843, C. Howe, Cement or Plaster.—5,844, C. Howe, Cement or Plaster.

PROVISIONAL SPECIFICATIONS ACCEPTED.

- 1,363, T. Payne, Miter Frame Clamp.—4,065, S. Cerish, Spring Hinge.—4,160, J. Osmond, Holding Doors or Casement Windows Partly Open.—4,223, M. Ismay, Double Swing Doors.—4,245, J. MEETINGS.

- SATURDAY, MAY 8.
- Architectural Association.—Visit to the National Liberal Club, Victoria Embankment. 3 p.m.
- Edinburgh Architectural Association.—Visit to Kirkton and Burnside Parish Churches, and Rosend Castle.
- MONDAY, MAY 10.
- Society of Antiquaries of Scotland (Edinburgh)—Dr. Daniel Wilson, LL.D., on "Illustrations of Early Celtic Christian Art." Three other papers. 3 p.m.
- TUESDAY, MAY 11.
- Institution of Civil Engineers.—(1) Further discussion on Mr. Francis Fox's paper on "The Mersey Railway," and of Mr. W. E. Hill's paper on "The Hydraulic Passenger Lifts at the Underground Stations of the Mersey Railway." (2, time permitting) Mr. W. H. Hulce on "Modern Machine-Tools and Work-shop Appliances for the Treatment of Heavy Forgings and Castings." 8 p.m.
- Society of Arts (Special Lectures).—Mr. Ernest Hart on "Japanese Art Work."—II. 11 p.m.
- WEDNESDAY, MAY 12.
- British Museum (Archeological Room).—Miss J. E. Harrison on "The Topography and Monuments of Modern Athens."—I. 11:45 a.m.
- THURSDAY, MAY 13.
- Torres Museum of Hygiene.—Mr. R. Warrington, F.R.S., on "Recent Investigations on Well-waters." 8 p.m.
- Society of Antiquaries.—8:30 p.m.
- Society of Telegraph-Engineers and Electricians.—Mr. W. H. Preece, F.R.S., on "Long-distance Telephony." 8 p.m.
- Employers' Liability Assurance Corporation (Limited).—Annual Meeting. 2 p.m.
- Edinburgh Architectural Association.—Annual Meeting. President's Valedictory Address. 8:30 p.m.
- FRIDAY, MAY 14.
- University College.—Professor C. T. Newton, C.B., on "Greek Inscriptions."—II. 4 p.m.
- British Museum (Archeological Room).—Miss J. E. Harrison on "The Technique of Greek Vases."—I. 11:45 a.m.
- SATURDAY, MAY 15.
- Artists' General Benevolent Institution.—Anniversary Dinner, Freemasons' Tavern. 6 p.m.
- Society of Arts (Special Lectures).—Professor George Forbes, M.A., on "Electricity."—V. 3 p.m.

Society of Arts.—The papers to be read at the ordinary meetings of the Society of Arts, after the Easter recess, will include the following:—May 26th, "The Purification of Water by Agitation with Iron, and Sand Filtration," by Mr. William Anderson, M. Inst. C.E. In the Indian Section, Mr. B. H. Baden Powell's paper on "Indian Manufactures from a Practical Point of View," will be read on May 7th. The fourth, fifth, and sixth lectures of Professor George Forbes's course of Elementary Lectures on "Electricity" will be given on Saturday afternoons, May 8, 15, and 22; and Mr. Ernest Hart's second and third lectures on "Japanese Art Work" will be given on May 11th and 18th.

Miscellanea.

The Institution of Civil Engineers.

At the ordinary meeting on Tuesday, the 4th of May, Sir Frederick J. Bramwell, F.R.S. (President), in the chair, it was announced that Mr. George Hodson had been transferred from the class of Associate Members to that of members, and that the following candidates had been admitted as Students:—Messrs. Joseph Edward Davies, David Morgan Jenkins, James Newcome Matthews, Walter Bishop Purser, and Arthur Henry Wakeford. The monthly ballot resulted in the election of two Members, viz.:—Messrs. Joseph Hobson, Grand Truck Railway, and James Young, P.W.D., Bombay; of fifteen Associate Members, viz.:—Messrs. Arthur Beckwith, Stud. Inst. C.E., Chislehurst; Philip George Brunton, D.P.W., Sydney; George Murray Campbell, Westminster; Charles Dick, London and North-Western Railway; Grewe; John Gill, Bangor; Edward Rainford Jackson, Stud. Inst. C.E., Jamaica; John Arthur Dayrell Lloyd, South Indian Railway; Richard Loch, Hereford; James Meldrum, Kensington; Karl Emil Nahholz, Dublin; Robert Robertson, B.Sc., Stud. Inst. C.E., Glasgow; Alexander Charles Schönberg, Westminster; William Charles Ernest Smith, Stud. Inst. C.E., Lodi, Italy; James Thropp, Lincoln; and John Alexander Warren, Stud. Inst. C.E., Glasgow; and of Mr. George John Armytage, Brighouse, as an Associate.

The Proposed Mining Exhibition at Newcastle-on-Tyne in 1887.

It is stated that the Newcastle Corporation will grant the Bull Park as the site for this Exhibition, to which reference was made in our last. At a meeting of the Building Committee last week, Mr. William Glover, Vice-president of the Northern Architectural Association, attended, and showed a sketch-plan of the mode in which he proposed to utilise the seven acres and a half of the Bull Park site. The committee carefully considered the plan, and some alterations were proposed, after which Mr. Glover was formally appointed architect for the Exhibition, and instructed to prepare a detailed plan to lay before a future meeting. The plan prepared by Mr. Glover shows about six-acres of covered-in space in the Bull Park, all arranged so that there will be no need for any visitor to go out into the uncovered ground at all to get from one department to another. It is proposed to reserve the reservoir in the ground for use in connexion with marine working models, diving-bells, and hydraulic appliances. It being thought that the Bull Park area will not be large enough to allow mining operations to be illustrated there, it is very probable that that department of the Exhibition will be accommodated on a portion of the recreation-ground to the north of the Bull Park. This would leave about five to five and a half acres to be covered in, and the remaining portion of the Bull Park will be laid out as an ornamental garden, in which will be erected band-stands, refreshment-rooms, &c.

Walhamstow.—From the Surveyor's annual report to the Walhamstow Local Board we learn that important works have been executed for the completion of the drainage of the district, and for the better disposal of the sewage. These works comprise the underdraining of about thirty-five acres of land on the Low Hall Farm; the construction of 1 mile 180 yards of concrete and earth carriers for the distribution of the effluent water over the south-westerly portion of the sewage farm; so that now over 100 acres of land of good and suitable soil are available for the purpose of deodorising the sewage in addition to the oxidising influences which are exercised in the effluent water over two miles of open carriers, before it is discharged into the Dagenham Brook. The works for the sewerage disposal also comprise the erection of brick mixing-shed, offices, boiler, and engine houses, with machinery for grinding the chemicals, and automatic arrangements whereby the varied flow of the sewage regulates the inflow of the proper amount of chemicals by night, as well as by day, thereby securing a regular and even pureness of effluent sewage; another important feature has been the construction of machinery whereby a more convenient disposal of the sludge is accomplished, which is now pumped into troughs and thereby passed on to the virgin soil at the rate of one acre a month, and there dug or ploughed into the land at the south-easterly portion of the farm.

Royal Institution of Great Britain.

The annual meeting was held on Saturday last, Sir Frederick Bramwell, F.R.S., Honorary Secretary and Vice-President, in the chair. The annual report of the Committee of Visitors for the year 1885, testifying to the continued prosperity and efficient management of the Institution, was read and adopted. The real and funded property now amounts to above 85,000*l.*, entirely derived from the contributions and donations of the members. Twenty-six new members paid their admission fees in 1885. Sixty-three lectures and nineteen evening discourses were delivered in 1885. The books and pamphlets presented in 1885 amounted to about 354 volumes, making, with 464 volumes (including periodicals bound) purchased by the managers, a total of 818 volumes added to the library in the year. Thanks were voted to the President, Treasurer, and the Honorary Secretary, to the Committees of Managers and Visitors, and to the Professors, for their valuable services to the Institution during the past year. The following gentlemen were unanimously elected as officers for the ensuing year:—President, the Duke of Northumberland, K.G., D.C.L., LL.D.; Treasurer, Henry Pollock, Esq.; Secretary, Sir Frederick Bramwell, F.R.S.

Risks of Intermittent Water-Supply.

The dangers of the intermittent system of water-supply to houses is well illustrated by an event which recently happened in Marylebone, and of which Mr. Wynter Blyth gives account in his last report. When the water was turned off by the water company's officer, a vacuum was created in the water-main, and a quantity of coal-gas which had escaped from a leak in the gas-pipe in the ground was sucked in; when the water was again turned on, coal gas was delivered into the house with the water. In houses where the ground becomes saturated with filth by defective drainage, it is probably of no uncommon occurrence for the water to be polluted in the mains by filth of this nature. Coal-gas is easily detected, but it would be quite possible for more dangerous gases to enter the main without recognition. The risk is most easily avoided by the adoption of the constant system of supply, but even constant service must be occasionally interrupted when necessity arises for the repair of water-mains. The provision of a stop-cock to every house would go far to obviate this danger.—*Lancet.*

Railway Enterprise in India.—A section of the Indian Midland Railway from Cawnpore to Kalpi was recently inaugurated by the Hon. T. C. Hoop. Starting from Cawnpore, the main line of the railway runs via Kalpi, Jhansi, and Etawah, to Bhopal, a distance of about 320 miles, joining the Grand Indian Peninsular main line about midway between Khandwa and Jubbulpore. A distance of fully 120 miles is thus saved for traffic proceeding from Cawnpore to the port of Bombay for exportation. In addition to the main line direct, however, from Cawnpore to Bhopal, there are several other connected lines, namely, Jhansi-Gwalior, Jhansi-Manickpur, and Etawah-Saugor, which, when completed, will raise the mileage of the system to some 700 miles. The survey of the line from Cawnpore to Kalpi was commenced early in the year of 1884, so that the whole of the operations involved in the construction of the forty-two miles of railway have been accomplished in the comparatively short time of two years. The total expenditure is estimated at about thirty lakhs of rupees, which is on the average 70,000 rupees per mile.

Birmingham.—An interesting exhibition is being organised to be held at Bingley Hall during the month of September next, in connexion with the visit of the British Association to Birmingham. The Midland Manufacturers' Exhibition is to be confined strictly to articles manufactured in Birmingham and in the district embraced by a radius of fifteen miles, while it is further intended to limit the exhibits to the productions of leading manufacturers and to the makers of specialities, in order to be able to illustrate the great variety of manufactures carried on in the Midland district. Among the twelve classes into which the manufacturing section is divided, one will, as a matter of course, be devoted to hardware of every description. A second class will be devoted to heating and lighting, and will include stoves, fenders, and fire-irons, gas and electric light fittings, and oil lamps and candle fittings.—*Martineau and Smith's Hardware Trade Journal.*

A Warehouse Roof in Fore-street.

We have had an opportunity of seeing a glazed roof which has been erected on MacKenzie's patent system (the British Patent Glazing Company's) over the new premises at present being erected by Messrs. W. Brass & Son, contractors, of 47, Old-street, for the Fore-street Warehouse Company in Fore-street, from the plans of Messrs. Ford & Hesketh, architects, Aldermanbury. The roof consists of five spans of ironwork, 26 ft. long each, and these are covered with polished plate-glass in sheets 10 ft. long each, which are placed in Mackenzie's patent bars, fitted up at centres of about 20 in. We are informed that sheets of polished plate-glass of such a size have never before been fitted up on a roof, and from the small size of the bars the shadows are reduced to the minimum. The roof has a very good appearance. One point worth mentioning is the admirable way in which the architects have arranged the plan of the warehouse so that the top-light from the skylight will be effectively available on all floors of the building.

Automatic Control of Temperature of Rooms.

—A novel device for controlling the temperature of rooms heated by natural gas has lately been made by Mr. Westinghouse, and has been patented in the United States. It consists of a brass tube filled with alcohol fastened to the wall of the room. This tube connects with the gas-pipe leading to the grate where it is attached to an automatic valve. Attached to a tube of alcohol is a check-oscillation arrangement which can be set at any desired temperature. If the temperature rises above this, the alcohol thermometer records the fact and communicates it by an electric wire to the valve, which is closed. As soon as the temperature commences to fall below the desired degree the valve is opened by the same method. Should the weather grow warmer, the instrument gradually shuts off the gas sufficiently to maintain the proper temperature.—*Invention.*

Torch for Paint Burning, &c.

—Messrs. G. Farnillo & Sons draw our attention to the Wellington Automatic Torch, invented by them for burning off paint, soldering joints, brazing, tempering tools, &c., and for any purpose where a powerful flame is required. It consists of a strong brass reservoir, to which is attached a burner and needle-valve; a small air-pipe is also provided. The reservoir is charged, not filled with two pints of benzoline. A small quantity of air is forced in by a few strokes of the air pump, which forces the spirit forward to the burner. On opening the valve, a small quantity of spirit is allowed to run into a cup under the burner. This is lighted to warm the burner. The valve is again opened, and the spirit, reaching the hot burner, is formed into a powerful gas, which is consumed as fast as made by unscrewing the valve; the size and intensity of flame can be regulated as desired.

Enlargement of the Prudential Insurance Company's Buildings.

—The extensive buildings in Holborn and Brook-street which were erected a few years since for the Prudential Insurance Company, from design by Mr. Alfred Waterhouse, R.A., are at present undergoing still further additions by an extension at the north end in Brook-street, carried as far as Greville-street. The extension is 140 ft. in length, and when the enlargement now in progress is completed the company's building will have a frontage of 340 ft. to Brook-street occupying nearly the whole of the east side of that thoroughfare. The new buildings contain five floors, and are architecturally uniform with the original structure, faced with Edwardian Ruabon red bricks, and terra-cotta, Mr. Waterhouse being the architect of the extension, and Messrs. Holland & Hannen the contractors.

Stoke Newington.

—The fourth of the series of stained glass windows in the Sanctuary of all Saints' Church (Mr. F. T. Dolman architect), has just been added. The subject are illustrative of the passages from the "Denm."—"The Goodly Fellowship of the Prophets," and "The Noble Army of Martyr Praise Thee," being a part of the general scheme of adoration of "All Saints." The window as well as the three eastern lights are from designs by Mr. Daniel Bell, and executed by Mr. R. Davison.

The Atmospheric Cowl Company.

—Our notice last week of the exhaust cowl made by this company, it should have been stated that Mr. Wery is the patentee, and the cowl is known as "Wery's Patent."

Colonial and Indian Exhibition: Reception Committee.—After consultation with the Agents-General of the Colonies, the Reception Committee have adopted a classification of the visitors who may be expected to come within the range of their operations, and for whose benefit accordingly special excursions are arranged. Besides a limited number of representatives of the different Executive Commissions, the classification includes:—Colonial governors, ministers and ex-ministers, members of the legislatures, mayors of cities, heads of government departments, secretaries to the high commissioner and agents-general, judges of the higher courts of justice, officers in the colonial forces, who have held command down to and including the rank of lieutenant-colonel; residents of railway companies, principals of railway companies, principals of universities, and heads of religious denominations, and of ex-governors and administrators of governments. The wives and daughters of these visitors who are comprised in the above list will be considered as being included in the classification. The names of distinguished visitors from the colonies not included in any of the above classes will be added to the committee's list on the recommendation of the agents-general, and as the arrangements of the committee permit.

Beech Wood as a Paving Material.—The above subject has recently been treated in detail by the *Deutsche Bauzeitung*, and the special interest manifested by Prince Bismarck in the adoption of this system has gained for it relative amount of notoriety. During last summer trials were simultaneously at Berlin and Hamburg, a superficial area of nearly 1,000 square feet having been in each instance laid with beech-paving. The height was partly 1 in. and partly 3/4 in. The forests of Friedrichrich, near Hamburg, and Prince Bismarck's vast estates furnished the wood, which was treated according to Roeper's patent process. His method comprises impregnation under high pressure with chloride of zinc, and subsequent immersion of each single block in a heated solution of pitch. Various other trials have been arranged for both in and out of Germany.
