FOUR Lines (about THIRTY words) or under 2s. 6d. Each additional line (about ten words) 9s. 6d. PREPAYMENT IS ABSOLUTELY NECESSARY. * Stamps must not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable at the Post-office, Covent Garden, W.C. to DOUGLAS FOUNDRY, 10, Abchurch-lane.

Advertisements for the current week's issue must reach the Office before THREE o'clock on THURSDAY. The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

SPECIAL.—ALTERATIONS IN STANDING ADVERTISEMENTS or ORDERS FOR CANCELLATION must reach the Office before TEN o'clock on WEDNESDAY mornings.

PERSONS Advertising in "The Builder" may have Replies addressed to the Office, 46, Catherine-street, Covent Garden, W.C. free of charge. Letters will be forwarded if addressed in envelopes as sent, together with sufficient stamps to cover the postage.

TERMS OF SUBSCRIPTION. "THE BUILDER" is supplied gratis from the Office to residents in any part of the United Kingdom at the rate of 19s. per annum. Foreign, to all parts of Europe, America, Australia, and New Zealand, 25s. per annum. To India, China, Ceylon, &c. 30s. per annum. Remittances payable to DOUGLAS FOUNDRY, Publisher, No. 46, Catherine-street, W.C.

TO CORRESPONDENTS.

Registered Telegraphic Address, "THE BUILDER, LONDON."

F. J. (Mableth)—W. O. S.—W. G. D.—G. H.—J. W.—W. G.—G. W. S. (you will see the misapprehension set right in a note to letter in our last number).—T. R.—R.—T. R.—J. W.—C. I. & Co.—G. F. & Son.—W. B. (shall have consideration).—A. H.—L. & G. (should send full list and amount).

All statements of facts, lists of tenders, &c., must be accompanied by the name and address of the sender, not necessarily for publication. We are compelled to decline pointing out books and public addresses.

Note.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors. We cannot undertake to return rejected communications. Letters or communications (beyond mere news items) which have been duplicated for other journals, are NOT RETURNED. All communications regarding literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

Best Bath Stone. WESTWOOD GROUND, Box Ground, Combe Down, Corsham Down, And Farleigh Down, RANDELL, SAUNDERS, & CO., Limited, Corsham, Wilts. [ADV]

Bath Stone. BEST QUALITY OF ALL KINDS. PICTOR & SONS, Box, Wilts. [ADV]

Doubling Freestone. THE CHELYNCH STONE. THE BRAMBLEDITCH STONE. HAM HILL STONE.

Greater facilities have been provided for working these quarries, and the stone can be supplied in large quantities at short notice.

Prices, and every information given, on application to CHARLES TRASK & SON, Norton-sub-Hamdon, near Ilminster, Somerset. London Agent—Mr. E. WILLIAMS, 16, Craven-street, Strand, W.C. [ADV]

Doubling Free Stone For prices, &c., address S. & J. STAFFORD, Quarry Owners, Stoke and Lime Merchants, Stoke-upon-Trent. (Ground or Lump). Ilminster. [ADV]

Ham Hill Stone! Ham Hill Stone! For Ham Hill Stone of best quality and workmanship, apply to JOHN HANN & SON, Quarry Owners, Montacute, Ilminster. Established 1837. Agents, MATTHEWS & GEARD, Albion Wharf, Regent's Park Basin, N.W. [ADV]

Asphalte.—The Szeysel and Metallo Asphaltic Company (Mr. H. Glenn), Office, Poultry, E.C.—The best and cheapest material for damp courses, railway arches, warehouse floors, flat roofs, stables, cow-sheds, and mill rooms, granaries, tun-rooms, and terraces. [ADV]

Asphalte. Szeysel, Patent Metallic Lava, and White Asphaltes. M. STODART & CO. Office: No. 90, Cannon-street, E.C. [ADV]

BANNER VENTILATORS.

The Strongest Exhaust Ventilators for all Buildings, Public Halls, Churches, Billiard-Rooms, &c.

HIGHEST PRIZES at all the most important Exhibitions.

BANNER SYSTEM OF SANITATION AND SANITARY APPLIANCE

WERE AWARDED AT THE

International Health Exhibition, 1884, One Gold Medal, Three Silver Medals, and One Bronze.

Architecture at the Paris Salon.

It is strange and not a little discouraging to witness the absolute indifference of the French public and press to the architectural exhibits at the Salon. While the representatives of the journals avail themselves of "varnishing day" to promenade their readers through all the paintings and sculpture, they seem not even to know the place where, at the extremity of the Palais de l'Industrie rooms, architecture awaits patiently, in her deserted galleries, the few critics whom professional duty calls there. The causes of this neglect are the same in Paris as in London. Architecture is an austere art, and does not captivate the masses. Plans, sections, and elevations leave them unmoved; and the most learned of archaeological restorations is worth nothing beside flesh-painting and rapery.

It must be admitted that the architectural exhibition this year is inferior to that of the year preceding. The number of exhibitors is diminished; and the list of 173 drawings does not show any work of such boldness and originality, or of such beauty of detail, as to leave a very striking impression on the memory. As usual, there is a heterogeneous assemblage of various elements, sketches *en route*, public monuments projected or in course of execution, private houses, restorations of ancient monuments, &c. As usual, also, there is a proportion of school designs from young men anxious to figure in the great art show, and whose classical projects are in art what themes and size poems are in literature.

The sketches taken in course of travel increase every year in number and importance. These collected studies from here and there, selected by the chance of travel, and in the enjoyment of first impressions, please us much. While some of them reveal considerable practical and artistic capabilities in the young architects who are mostly their authors, they have a certain stamp of personality which the more regular academical studies do not reveal, and enable us to make a kind of anticipatory classification in order of merit, with which it will be curious to compare the future work of the same men.

In this class of work M. Breffendille holds an honourable place. His easy and unpretentious pencil gives us lightly but truthfully sketched views from the South of France. The sketches of M. Ch. Normand are interesting,

but a little dry and precise in style. M. M. Ch. Giraut and Goutier take us on a full career of Arabian architecture, while M. Julien has directed himself towards Venice, and M. Lechatelier brings from the Campo Santo of Pisa an agreeable drawing of the monument of Ph. Decio. M. F. Kaheun, a Londoner by birth, but of French parents, shows a pretty water-colour drawing of the church of Offranville, a curious monument of the sixteenth-century, not far from Dieppe. But the palm must be given to M. Courtois-Suffit, who, under the title of "notes and sketches of a traveller in Italy, Algiers, and Tunis," gives us in the first place a very careful coloured restoration of a mosaic fountain from Pompeii. This highly-finished water-colour shows great technical ability. He has also, in one frame, about forty water-colour sketches from Italy, beautiful both for colour and for freshness of observation. His details of the cloisters of San Gregorio, at Venice, are especially remarkable, and we note also some details of Pompeian architecture which show their author to be a close student as well as a facile sketcher. Nor must we forget to mention the view which M. Ballu has brought from Algiers of the mosque of Djama el Djedin.

The restorations of ancient monuments are very few in number this year. We only half complain of this, for archaeology, which is a little overdone in France at present, ought not to take too prominent a place, interesting as it is in the light of a study. It is chiefly valuable as a means of educating and purifying the taste of the more advanced students. In the same room, and in the same place where we noticed last year the fine restoration of M. Laloux of the Altis of Olympia, we find this year a restoration of the Megaron at Eleusis, executed by M. Blavette; not a work equal to that of the preceding year, but we cannot deny the talent and learning of this young pupil of M. Givain. In a very complete plan, which accompanies the elevation of the actual state of the ruins, he distinguishes the excavations carried out successively in 1814, by the Society of Dilettanti; in 1860 by François Lenormant, who discovered the two propylæa; and then those made in 1882, 1883, and 1884, by the Archaeological Society. The restored elevation and section of the sanctuary should also be noticed. In the section the interior decoration is minutely drawn with details, interesting but a little fanciful. It is unnecessary to describe the heavy and uninteresting studies in Greek architecture by M. Thierry, or M. Pauline's water-colour of the Baths of Diocletian, executed to complete a monograph.

If the utility of reconstructing, from uncertain documents and descriptions, monu-

ments which have disappeared, be very contestable, there is a different kind of interest attaching to buildings which make part of the history and national art of a country. There is a real and immediate interest in some of the works of this class exhibited this year, especially in the careful drawings of M. Zéquier from the Château d'Anet, that marvellous residence of Diana de Poitiers. The drawings made by M. Macaigne, in collaboration with M. Vassilief, after the portion of the Château de Blois dating from the time of Louis XII., are equally careful and conscientious.

M. A. Lafon exhibits a complete restoration of the Hôtel de Bourgherolles at Rouen, and has given the details of that lace-work in stone with a patience and fidelity which almost bids defiance to the photographer. The Francis I. Gallery and the five bas-reliefs representing the Field of the Cloth of Gold are particularly well treated in the drawings. M. Steinheil, a worthy follower of his father, gives us drawings of the sixteenth-century windows which decorate the Church of St. Julien du Sault, and M. Suasso has sent six sheets of studies from the villa of Pope Julius at Rome, an interesting piece of work, especially the longitudinal section of the palace, and the ground plan. But, however fine, conscientious, and learned it may be, a restoration is not completely the work of the artist who makes it. It is when we come to the designs for public buildings in which the architect has marked out a new idea entirely from the commencement, that we come to the most interesting part of the Salon architecture.

In this respect one cannot deny a certain merit to M. Akermann. The monumental fountain which he has designed for New York wants neither style nor elegance. An abundance of water plays in cascades into a series of superposed basins, over which is a loggia recalling the form of the "Fontaine des Innocents" in Paris, and forming a shrine for a deity armed with a trident. But too many bas-reliefs, columns, and allegorical figures are heaped over the structure, the decorative effect of which would have gained by being simplified. This is the great fault of the young architects who, taking the work of the Renaissance for their models, always wish to amplify and elaborate it.

M. Albert Ballu, who has from the Roumanian Government the commission to design the Palace of Justice at Bucharest, exhibits a collection of drawings and perspective views of incontestable merit. The design, which is in course of execution, is in a broad and severe style, and of great simplicity of lines; it shows imposing façades and very sober decoration. The charge of being too simple, which might be brought against this work, is certainly

not a fault with which we can charge M. Ostermann, a Swedish architect, and author of a design for a colossal theatre, intended probably for Stockholm, and the terraces and columns of which are shown reflected in the waters of the Mœlar Lake. The design is an ill-digested agglomeration of Classic reminiscences, and this magnificence of porticos, statues, and bas-reliefs will seem little in place under a grey northern sky. We could understand it better on the banks of the Mediterranean.

In that latter region M. Paugoy has erected a building of strange enough aspect. Without the assistance of the catalogue one would certainly not guess that this construction bristling with turrets, was a laboratory of marine zoology. And then to think that this Marseilles architect is a pupil of M. Questel! Another southern architect, M. Boussac, has done better with a design for a library for Narbonne, his native town.

Next is a Lycée, which M. Ridet is constructing at Laval, a sober and well-studied design; and the same praise may be given to the Lycée for girls, with which M. Baudot proposes to replace the calcined walls of the Cours des Comptes. This will be more suitable than the proposed Musée des Arts Décoratifs; but, Musée or Lycée, the great point is to substitute something as soon as possible in place of these melancholy ruinous remains of civil war.

M. Achille Hermant merits special notice for his design for the reconstruction of the Mairie of the eighth arrondissement, Rue d'Anjou St. Honoré, opposite the English embassy. This is a remarkable and beautiful design, and shows a very good plan, arranged in perfect accordance with the requirements of the public service. The design has also the great merit of breaking through the regulation style of Paris municipal buildings, and maintaining a character harmonising with the high-class mansions in its neighbourhood.

M. Hénard, a veteran architect, whose talent at all events does not seem to age, shows a little further on a design for a grand fireplace and mantel for the "Salle des Fêtes" of the Mairie of the twelfth arrondissement (Avenue Daumesnil). The general effect is fine; the artistic portion (figures and ornaments) has been entrusted to MM. Barrias, Delaplanche, and Caïr. The plans and designs made by M. Roussi for the firemen's barracks on the Boulevard Diderot, complete all which relates to municipal architecture in Paris; of this last building some account was given in our last "Letter from Paris."

The religious edifices restored or simply reproduced in their actual state, are not numerous this year: a sign of the times. The tendency to secularisation, which is spreading in every direction, has made itself felt in architecture also. Nevertheless, what a vast field of interesting study for young architects, and how much better for them, instead of shutting themselves up among the dead works of past ages, to apply themselves to reviving the national art, the study of which was the education of such men as Viollet-le-Duc, Lassus, Magne, Ballu, and Constant Dufeü. In this class of work we may note the drawings of M. Bertrand (restoration of the Church of Banyuls), M. Châme (elevation of the Church of Ydes), the views of Vezelay, by M. Degeorge; five sheets by M. Petelgrand, devoted to the Church of Gallard; a curious interior of the Cathedral of Puy, by M. Gautier; and the drawings by M. Rapine of the Church of Grand Brassac.

In consequence of the too exclusive direction given to architectural study in France, the annual exhibitions count a very small number of projects having for their object the everyday requirements of modern life. Since public monuments are exceptional things, and the number of theatres, libraries, palaces, and museums is necessarily restricted, it is vexatious not to see a more decided effort at the architectural treatment of dwelling-houses and private properties.

With M. Lheureux, however, we are in the full tide of modernism, and, which is more, of modern utilitarian construction. This architect, who has been commissioned by the Municipality to construct the immense wine

warehouse at Bercy, shows a design for a restaurant forming an annexe to that establishment. This building, intended for the use of the wealthy business men at Bercy, is perfectly appropriate to its purpose. The façade is gay with ornamental brickwork and coloured tiles, while the vine twines about the porticos which extend along the river front. The general aspect is fresh and pleasing, and the drawings are executed with great care.

The design by M. Cuvillier, on the other hand, has nothing of the industrial about it. We have here the aristocratic abode which M. Le Marquis de B— has had built in the Avenue de Wagram, in the best quarter of the Plaine Monceau. If the general architectural splendour of the building is borrowed entirely from the Renaissance, the pavilion roofs, the finials of the dormers, the armorial trophies of the pediments,—in a word, almost all the exterior decorative treatment, has been copied from the similar details of the Marquis's château at Angerville. M. Cuvillier merits high praise for his contribution to the exhibition, and special mention should be made of a design for the ceiling of the dining-room, a remarkable piece of decorative work. We cannot like so well the work sent by M. Saint-Ange, and the Shahovskoy-Streetneff Palace at Moscow may be an imposing building, but is cold and heavy in its architectural style.

We pass over without notice the commonplace villa buildings of MM. Ménuel and Coquelin, only noticing, without very much sympathy, the turreted hotel built by M. Sanvestre at Neuilly-sur-Seine.

We have not classed among designs for public buildings some schemes which belong entirely to the domain of fancy, such as the compositions, which M. Monie proposes to place at the four angles abutting on the dome of the Pantheon, in honour of Hugo, Voltaire, Corneille, and Rahelais. M. Monie, to whom Paris is partly indebted for the very bad monument on the Place de la République, has the idea apparently of completing after his own manner the work of Soufflet, which does not stand in need of any such completing; but young architects are so presumptuous in these days. In the matter of fancies, the car which M. Fornigé had designed in view of the great historical procession (indefinitely postponed for want of funds) is shown in a water-colour drawing, in a light and free style; a very original design, much superior to the allegorical car exhibited further on by M. Dumesnil for a public celebration at Lyons. The first is the fancy of an artist, the latter a hippodrome "property." Very bad also is the fantastic universal exhibition palace which M. Mussignann proposed, but unsuccessfully, to erect at Vincennes. As might have been expected, the exhibition building for 1889 has tempted more than one exhibitor; but we come here into the region of pure insanity. There is the scheme of M. Jules Doré, for instance, who proposes to engulf in one immense bazaar the Champs de Mars, the Invalides, the Place de la Concorde, the Champs Elysées, and the Tuileries! There is also a municipal tower designed by M. Lantermier for somewhere in America,—a grotesque achievement.

There are a few sepulchral monuments this year; a less number than usual. The best is, undoubtedly, that to Dr. Fauvel at the cemetery at Passy, designed by M. Girette.

Passing over, for want of space, a good many things, we have, nevertheless, noticed the best of the exhibits, as well as some few of the worst. The exhibition of works, as observed, is inferior to that of last year, and in every way less interesting. This is partly owing to the absence of some eminent architects who, for want of time or other causes, have not lately troubled themselves much about the annual exhibitions. The field, therefore, remains open to the younger men, who misuse it by making the *Salon* a kind of chapel-of-ease to the Ecole des Beaux Arts. It thus happens that while the other sections at the Palais l'Industrie, especially that of sculpture, present a sustained interest, and bear witness to efforts continually renewed, one is conscious, in the architectural room, of an atmosphere of indecision and want of enter-

prise. We do not take this as any indication of a decline in the art of architecture in France. Convincing proof of the contrary is given by the interest always excited by the public competitions organised by the Municipality of Paris, and the high merit of a large proportion of the designs submitted on these occasions. The intended competition for the 1889 Exhibition building, in spite of the absurdities to be found in the *Salon*, will no doubt awaken again the same kind of interest, and evoke the same proportion of talent.

MORE LIGHT ON THE LAW OF LIGHT.

O branch of law has been more completely created by judicial decisions in recent years than that concerned with the law of light. Let any one compare Mr. Latham's work on the "Law of Window Lights," published in 1867, with the most recent publications on the same subject and the superstructure of case law which has engrafted itself on to the third section of the Prescription Act, will be very apparent. The recently reported case of *Scott v. Pape* (Law Reports, 31, Chancery Division, p. 554), is the most recent of the cases which has thrown further light on the subject. It is reprinted at length in the May number of the Law Reports, and we are thus enabled to see exactly its extent and its bearings. It will be found on perusal to decide once for all that bringing a wall forward or rather by building a new wall in advance of the line of the old one, and placing in it a new window, for the present we will say substantially the same as an old one, the light is not lost. The putting back of a wall was for the first time in 1888 declared not to cause a loss of a right of light. That was the effect of *Bullers v. Dickinson*; and there is no doubt that in principle, the right is preserved when the wall is brought back, it is equally preserved if it is pushed forward. But arguing as to the result of a case from principle is one thing; to have a decision of the Court of Appeal, as we now have, is quite different. But, in commenting on *Bullers v. Dickinson* at the time of its decision, we expressed our difficulty in saying where the line was to be drawn as to the extent to which a wall might be thrown back without the loss of a right of light. The recent decision of the Court of Appeal in *Scott v. Pape* enables us for the future to have some guide in the matter, and let us also point out that *Scott v. Pape* may be looked on as affirming *Bullers v. Dickinson*, the principle of the two cases being in effect the same. We must quote the judgment of Lord Justice Cotton as giving in words clearer than we can find the explanation of this difficulty. I says:—"Then will moving back the plane of the wall deprive the plaintiff of his right? In my opinion, no! It is difficult to see how the mere fact of moving back can do so, and, in fact, there is authority against such a proposition. [The Lord Justice no doubt referred to *Bullers v. Dickinson*, which had been cited in the argument.] Then if moving it back will not, will simply moving it forward have the effect? In my opinion, both the moving back and the moving forward may destroy the light, because the new building when constructed may, either by being substantially advanced or substantially set back, be placed that the light which formerly went in the old windows will not go into the new. If a building is set back, say 100 ft., it will not enjoy the same one of light that was enjoyed before, but will have an entirely different one, and it may be moved so far forward that it will not enjoy the same light as that enjoyed by the old building. In my opinion, the question to be considered is this, whether the alteration is of such a nature as to preclude the plaintiff from alleging that he is using through the new apertures in the new wall the same cone of light, or a substantial part of the same cone of light which went to the old building. It is true that these semi-scientific propositions about cones of light are not altogether satisfactory in practice, because the angle at which

the one of light" may be regarded as entering the window, must make all the difference as to what is a substantial moving forward or setting back of a window. Of the three windows the subject of the action in *Scott v. Pape*, the one which was the most moved was put 2 ft. 3 in. more forward than the old one, so that there was no question that it had not been substantially moved forward. Thus *Scott v. Pape* settles clearly enough that a wall may be put forward or backwards, and yet retain as to windows in its right to light. It seems also pretty clearly to promise a considerable crop of litigation, because until a judge has said in each particular case whether a window has been substantially moved backwards or forwards, it will be well-nigh impossible to say whether it retains the right to light or not.

We will now touch on the no less important second point which this interesting case clears up.

The point may be best put in an interrogative form, and it is this: how much of the space of old window in a new window will give the latter a right to light? We assume, of course, that the old window has obtained a prescriptive right to an enjoyment of light for the statutory period. The well-known case of *Wapping v. Jones*, in the House of Lords, "gave rise to a not unreasonable impression, that wherever small part there might be of an old window in the new one, it was sufficient to give a right to the light in respect to the new window." Then came *Newson v. Pender*, in 1841, in which Lord Justice Cotton explained that this was not the case, that he understood it to mean that the new light must contain the area of old light, or substantially area. But as in *Newson v. Pender* there were some new apertures quite the same as the old, it was unnecessary to decide the point, and an injunction was granted in respect of these. But if the quotation already given in *Scott v. Pape* be referred to, it will be seen that it includes the words, "substantial part of that cone of light which went to the old building."

Therefore it seems to show that it is not necessary to have the entire area of the old light in the new, but only a substantial part of it. How much is a substantial part of it? The woodcuts illustrating two decisions to be found in the appendix to Roscoe's "Digest of Law of Light" will serve as examples of how much is not a substantial part. The facts in *Scott v. Pape* show how much is.

Old window No. 1 was 3 ft. 6 in. high, 9 ft. wide, and divided into two parts by a 9-in. partition. One of the new windows contained more than one-half one of these parts, and more than one-third of the other; the second new window more than one-third of one part and more than one-half the other part of old window No. 2, which was about the same size; and the third new window one-third of one part and three-fourths of the other part of old window No. 3. All these examples show that everything must depend on the application of the words "substantial part of the old area" to the circumstances of each particular case. Here, again, is a fine field for disputes and lawsuits, which are the more difficult to avoid because the issue depends on the way in which individual judicial minds apply what is now a clear rule to widely differing facts.

An International Statistical Institute. The preliminary meeting of the officers of the International Statistical Institute was held at Bologna at the beginning of the present month. Messrs. Rawson W. Rawson, K.C.M.G. (President), Professor von Neumann-Spallart, and Mons. E. Vassier (Vice Presidents), Signor Luigi Bodio (General Secretary), and Mr. John Biddulph Martin (Treasurer), were present. It was decided, on the invitation of the Italian Government, to hold the general meeting at Rome on the 23rd to the 29th of September next. It was announced that the members nominated at the preliminary meeting of the Statistical Society in London had accepted their nominations, and the first business of the Institute at Rome will be to complete the list of Members and Associates.

NOTES.

THE rejection of the Charterhouse Bill on the second reading, or, rather, its withdrawal to avoid a probable rejection, is an indication that Parliament is becoming somewhat more alive to the interest and value of "Old London" than it formerly was; and if the Governors of the Charterhouse have not altogether dropped their project, they will have at least an opportunity of giving it fuller consideration. Although we are among those who would regret to see any such alterations carried out as were proposed, we do not think the arguments used against the scheme, when compared with one another, make up a very logical assemblage of reasons. One critic twists the body with mismanaging their own property in having sold a few years ago to the Merchant Taylors, for 90,000*l.*, land which was now worth 620,000*l.*; while another urges that the sales proposed now will not be by any means as lucrative or advantageous as is supposed. Those who are interested in preserving the buildings speak rather too contemptuously of the idea that a larger number of pensioners might be provided for if larger funds were acquired, and wish to persuade us that the founder preferred benefiting a small number of men to a large number. No doubt Sutton contemplated the establishment of the charity on its present site in perpetuity, but then he did not contemplate the changed condition of London, and it may be very much doubted whether he would not have approved of the idea of providing for a larger number of pensioners in a neighbourhood where land was cheap, by selling property which has now acquired a very high commercial value; and there is a certain point in Mr. Courtney's remark that "it was hard on the Governors that they should be constrained to keep up a historical monument at the cost of a number of poor brethren who might otherwise be provided for." We, and many others, would regret to lose one of the oases of London,—fast becoming fewer and fewer,—but somewhat question whether the essential object of the founder would not be more truly realised by the sale of the property for the purpose of giving larger accommodation elsewhere.

THE Home Secretary has called the attention of the Metropolitan Board of Works to the circumstance that the House of Detention, Clerkenwell, and Coldbath-fields Prison are no longer used as prisons, and inquired whether the Board has any intention to negotiate with Her Majesty's Prison Commissioners for the purchase of the two sites or either of them, with a view to appropriating them to the erection of dwellings for the working classes. This appeal looks like a cheap bid for popularity on the part of the Home Secretary, who ought to be aware that the Board's powers are strictly limited by Act of Parliament, and that they have no authority to purchase land for the purpose of housing the working classes as suggested.

WE report in another column the result of the Sunderland Municipal Buildings Competition so far. The Town Council accepted Mr. Waterhouse's award by a large majority of votes; and though there was a good deal of opposition on the part of certain members, and the discussion on the subject, as reported in the local journals, is somewhat amusing reading, it is satisfactory to observe that, generally, the Council seemed to be quite convinced that they had done a wise thing in calling in Mr. Waterhouse to assist them in forming a judgment on the designs. One speaker on the occasion admitted that he had been opposed originally to what he regarded as the unnecessary cost of calling in a professional adviser, but that he had not listened for ten minutes to Mr. Waterhouse's exposition of the merits and demerits of the various designs before he was convinced that the money had been well spent. A question, we observe, was raised in the discussion which has been raised before in similar cases, viz., whether the professional assessor was invited to adjudge the premiums,

or only to aid the Council in doing so by his advice. Practically it seems to have been decided that they were bound to accept his award. It is a point, however, on which it is better in such cases to have a distinct understanding beforehand. We should recommend any one who is invited to become assessor in a competition to put the question plainly beforehand to the Committee,—“Do you ask me to adjudge the premiums, or only to assist you by advice?” and in the former case to obtain a definite undertaking that they will abide by his decision.

THE representatives of the railway interest in Parliament did not press for a division on the second reading of the Railway and Canal Traffic Bill, which has accordingly passed that stage. The speeches of the opponents of the measure formed a marked contrast to the extravagant utterances which have been heard outside the House, and the discussion was reasonable and instructive. It has been recognised that the 23rd clause, which so alarmed the directors, would not, as it stands, afford a satisfactory settlement of the rates and charges difficulty, and that part of the Bill will be amended in Committee. The assurance that the Government were willing to join with the Companies in arriving at a decision which should be just to all concerned removed the main objection, and the railway officials must feel as great a desire as any one for the question to be dealt with without more delay and controversy. The irritation produced by uncertainty has a mischievous effect upon all concerned, and as this uncertainty would be perpetuated by any weakness or insufficiency in the clause regulating the charges, it is clearly essential that this should be clear and definite. It is very satisfactory to find the House so unanimous in agreeing with the principle of the Bill as to permit the second reading without a division; but there is a strong feeling upon certain points,—such as the preference rate clause,—which will probably lead to an animated discussion in Committee. The agitation among the railway employees, to which we referred last week, resulted in a number of petitions against the Bill, one of which Mr. Mundella presented himself.

WE have received a pamphlet on Freehold Disfranchisement, by Mr. G. Beken, published by the Liberty and Property Defence League. It is a counter-blast to the publications in favour of Leasehold Enfranchisement, and states the opposing case clearly and well. Together with this question that of the taxation of ground rents is also dealt with, though the connexion of the latter with the enfranchisement of leaseholds is not altogether apparent. The amount of bad arguments which are advanced in favour of any particular change are usually as numerous as the sound ones, and, therefore, Mr. Beken has no difficulty in showing that some of the arguments in favour of leasehold enfranchisement can be confuted. For example, ground landlords have been accused of hiring parties to build when there is no demand for houses, and, therefore, it is said, Abolish ground landlords! Of course, it is easy to show that this is a ridiculous charge. The perusal of this little publication will certainly help any one who wishes to form a definite opinion on this subject to arrive at this desirable end.

THE Alcázar, Toledo, now used as a training school for officers of the army, is in the hands of the restorer. The important rooms restored or redecorated lately, are the chapel, reception saloon and ante-room, and the library for the use of the students. The chapel, absurdly out of proportion to the number of students (more than 400) is more the size for a small private chapel than for such a large institution as the Alcázar. It has been richly decorated, both with paintings and wood-carving, giving a very satisfactory result. The new stained glass in the windows on the east side is, however, very disagreeable in colour, being both garish and inharmonious, especially noticeable after the incomparable windows in the cathedral. The unpardonable

fault has also been made of painting sham windows in the north and south sides of the chapel. The reception saloon and ante-room and library are on the first floor, and occupy the centre part of the principal façade. The reception saloon is a fine spacious apartment, but an inadequate supply of money has induced the architect, Señor Pablo Vera, to paint the whole of the dado in chiaroscuro to represent the mouldings and high-relief ornament in the panels, and this, as can be imagined, destroys, to a great extent, the otherwise grand effect of the room. The ceiling is, in section, a very flat semi-ellipse, and, in the almost vertical portion immediately above the cornice, Sans, a clever Spanish painter, has represented, in fresco, scenes from Spanish history, arranged as much as possible as a procession, the rest of the ceiling being blue to represent the sky. The ante-room is extremely well decorated in the Moorish style of the Alhambra. The dado, 4 ft. in height, is of azulejos or tiles, the walls in the diaper stucco richly coloured, and the wood ceiling worked in a somewhat intricate geometrical pattern, and supported by honeycomb stalactical pendentives. The library is a large room fitted up with bookcases against the walls, and with comfortable reading-desks for the students, the material used being varnished pitch-pine or some equally resinous wood. Altogether the new work at the Alcázar would have been a great success if only Señor Vera could have resisted the temptation of trying to obtain a more grandiose effect than was possible with the money at his command.

THE *Æria Adriatic* (No. 481) reports the accidental discovery, in the island of Syros, of three graves, the structure and contents of which would point to very early prehistoric date. The discovery was made during the digging for the foundations of a new building in the town of Hermonopolis. The vessels found in the graves are in good preservation, and are, with one exception, of wood or earthenware; the one exception is a vase of metal, in which are the ashes of a dead man. The other graves show, without exception, unburned bones, thus pointing to a mixed cremation and burial. Votive offerings are disposed about the skeletons in every case, those of greatest value being placed near the dead man's hands.

EVERY one should see Mr. Albert Goodwin's collection of "drawings of city, town, and hamlet" at the Fine Art Society's Rooms. It was at first intended to be an Exhibition of cathedral cities alone, but the scope was a little widened, apparently because the artist was unable to resist the temptation to paint the pleasant spots he met with elsewhere. The sketches are on a very different level in regard to finish: some are slight enough, some finished drawings; but all have their own individuality and their own effect; Mr. Goodwin has no patent system of producing landscapes of a given pattern as if they were turned out by machinery, like some of the heroes of the Academy walls. Among the drawings is a very powerful one of Boston Tower in twilight, dark against a deep-glowing remains of sunset; "The Miller's Garden, Winchester," is shown as laid out in little tapering parterres on the piers between rushing water; Abingdon furnishes several charming subjects; "Durham, Autumn," is seen from a new point of view and in new light; "The Bishop's Garden, Wells," is all in a shimmer of summer light; "Whitby in Gloom" and "Whitby in Gladness" are contrasted. There is not a drawing in the collection that is not worth looking at, and that does not make us share the enjoyment the author must have had in producing it.

RIPOLL, a town of Catalonia, not far north of Barcelona, suffered greatly in the first Carlist war by the sacking of the famous monastery of Santa Maria, founded by Wilfredo el Velloso, and for some time the pantheon of the independent Counts of Barcelona. The already ruinous state of the monastery was increased in 1860 by the falling in of considerable portions of the internal vaulting, and shortly afterwards a project for

restoring the church was prepared by the architect, Señor D. Elias Rogent, who for the next seven years carried out extensive works to preserve the fabric from further ruin, the expenses of such works being borne by the Commission of Monuments at Gerona. Last year the Spanish Government conceded the monastery to the Bishop of Vich, who has confined the task of complete restoration to Señor Rogent, conjointly with Señor Artigas, another well-known Spanish architect, giving them instructions to complete the works by 1888, so that Catholic worship may be resumed in that year, the millenary of the foundation of the monastery by Wilfredo. The inauguration of these works took place on the 21st of last month, under the patronage of the Bishop of Vich, who celebrated high mass among the ruins in the morning and presided at the banquet in the afternoon. Considerable interest has been taken by the Spanish papers in this movement for restoring one of the most interesting and dilapidated ruins in Spain, and, if all goes well, in two years' time the reproaches of many travellers in Spain condemning the apathy of the Spaniards as to the condition of their monuments of art will no longer be justified in the case of St. Maria at Ripoll.

THE Government recently announced that there was no intention of laying-out the waste land on the western side of the Law Courts as public gardens, as it might be wanted for an enlargement of the Law Courts. It is quite certain, however, that there is no immediate intention of such enlargement. Therefore, although it may not be advisable to lay this bare space out as regular gardens, it might well be gravelled over, and benches should be placed about it, and the public allowed to use it. The use of a space such as this adjoining the crowded courts of that part of London would be an immense boon to the children and poorer inhabitants of the district in the approaching summer. Hundreds of children daily throng the Temple Gardens when they are opened in the evenings, and so far as space is concerned they would have equal enjoyment on this piece of ground. The Board of Works could, no doubt, also supply a few scores of geraniums and shrubs in pots which could be placed on stands and would add to the enjoyment of those who frequented the place. The delight with which children who have never seen flowers will look at them cannot be appreciated until a child from the slums is taken into the country. As that, in most cases, is an impossibility, the world of flowers should be brought as much as possible to the children in the towns.

AT the last meeting of the Académie des Inscriptions, Paris, M. Ravaisson announced that the Museum of the Louvre had received the addition of an interesting statuette of Mercury, from Entrains, in the department of Nièvre. The statuette is in bronze, of small size, and is considered to be a copy of the colossal statue of Phœnix of Rome, executed by Zenodorus, under Nero. Zenodorus, it will be remembered, was famous for the fabrication of colossi. The one ordered by the Averni took ten years to make, and cost a sum equivalent to about 335,000*l.* The statue of Nero himself had to be moved by the help of twenty-four elephants. This colossal tendency will scarcely be perceptible in a small copy, but, happily, Zenodorus was equally famous for his tereutic skill.

THERE is a small and very good collection of Dutch pictures to be seen at Messrs. Boussod and Valadon's. It contains two very fine works by Israëls, "The Shipwrecked Mariner" and "The Sewing Class." The latter is one of the painter's most finished works. The face of the old preceptress cutting-out is an admirable study of human nature. She has been cutting-out shapes all her life, and has no intellectual perceptions beyond that. There are two or three fine works by Artz, and a remarkable landscape by Mauve, "The Return of the Flock;" another by De Bock, "Evening." Both these are,

it must be admitted, unlike nature in their tones, but the painter's object is obvious enough, and the works become what may be called landscape-fantasies, expressions not so much of the landscape itself as of the feeling with which the painter saw it, and which he wishes to convey to others. Too much of this kind of landscape-fantasy is not good for people; we need to come back to unadulterated nature from time to time for a breath of unsophisticated air; but there is more intellectual interest in it than in some of the realistic or would-be realistic landscape so popular in England.

THE Vestry of St. Martin-in-the-Fields have intimated to the Metropolitan Board of Works that they approve of the suggested alteration in the plan of the site of the new Admiralty and War Office, as proposed by the Institute of Architects, and illustrated in our pages (see p. 367, ante).

WE regret to see, on the agenda for the meeting of the Metropolitan Board of Works this Friday, May 14, that among the communications received by the Clerk, and to be brought before the Board, is a "letter from Mr. G. Vulliamy tendering his resignation of the office of Superintendent Architect in consequence of failing health." Our readers will remember that in our issue of the 13th of March we referred to Mr. Vulliamy's illness, and we can now only renew our expressions of regret, coupled with the hope that in his retirement he may yet be able to find some measure of renewed health.

THE eleventh annual exhibition of painting on china, at Messrs. Howell & James's, is a considerably larger one than usual, but does not otherwise differ much from the usual nature of these exhibitions. There is a great deal of clever work, a large proportion of which consists of subjects totally unsuited for china-painting, such as landscapes, interiors, wigs, figures, &c.; all which can no doubt be done up to a certain point on china, but with the result which only serves to remind us how much better the same thing could be done on paper or canvas. China painting calls for decorative work, not realistic figures or landscapes; head with a certain degree of conventional treatment, may be made something of. The judge Mr. Marks and Mr. F. Goodall, seem to be very little alive to the true decorative nature of china-painting, if we may judge from the award of the *Queen* newspaper prize for "the best decorated pair of panels"; the two panels rewarded (Nos. 61, 770) being not "decorated at all in the true sense of the word, but representing simply hard paintings of interiors, each with a common-place looking figure. This is no 'decoration'; it is only rather bad painting." Among the contributors who seem to know what china-painting is for are Mrs. W. Smith of Woodclyffe, who sends two plates in the Persian style (34, 78), which gained the Crown Princess of Germany's gold badge; Miss Izon (conventional design of honeysuckle, 31); Miss Anderson (roses and stephanotis, 14); Miss Alice Brady, who gains a silver medal for an acacia design (186); and Miss Welby, who has gained a silver badge, presented by the Crown Princess of Germany for the best work by a lady professional, her two Renaissance dishes (195, 201), which are the best things we saw in the collection, and show a true feeling for decorative design. A great majority of the examples exhibit what, from an artistic point of view, would rather not see at all. What lover of landscape art would ever purchase a china painted landscape, or even accept it as a gift.

New and Latter House of Israel, No. Brompton, Kent.—A further contract (the first being now completed) has been signed between Mrs. J. J. Jezreel and Messrs. Nay & Son, of Rochester, for the completion of the superstructure of the Temple now in course of erection at Chatham Hill, Chatham, at a further estimated cost of about 40,000*l.* The external dimensions of the building are 124 ft. square and 124 ft. high.

ARCHITECTURE AT THE ROYAL ACADEMY.—III.

ONE of the most important drawings exhibited is that by Mr. J. D. Sedding (1,553) for the restoration of the great screen at Winchester Cathedral; the drawing is hung higher than it ought to have been, and the details cannot be well made out at the Academy. The screen has been terribly pulled about, partly by conoclastic enemies, partly by restoring friends, and the sculpture is entirely gone. Mr. Sedding's drawing shows a restoration of the whole; a good deal of the canopy work existing now is modern patchwork, some of it in plaster; the restoration of a portion of the canopies in 1820, under the direction of Dr. Nott, one of the Janons, is, Mr. Sedding considers, very good or the time at which it was done, and some portion of it, at all events, will be retained. According to the Dean's report, published a little while since, the work required to be done to complete the screen, amounts to this:—"Two large pedestals for statues, and six larger canopies; all the pedestals and canopies for the thirty-four smaller statues; and if the picture West be removed, the ornamentation of the large space so left bare." The removal of the picture forms a part of Mr. Sedding's design, and the space is shown filled up by a series of small niches and statues, and canopy work. The removal of West's picture is, to our mind, a thing to be thought twice about. It represents the contribution to religious art of a painter who was certainly not contemptible in his day, and has a historical interest; and it may be questioned whether an assemblage of modern decorative Gothic detail to fill the space will have as much interest, after all. We only suggest it as a point to be considered. The restoration seems very finely carried out in the drawing. The figures were drawn by Mr. Westlake, and Mr. Onslow Ford is doing the first portion of the sculpture; the part of the work at present undertaken being the middle portion, including the cross and the six large figures adjoining it. The sketches for a picture above the altar, and on the altar, and on the doors on either side, shown in the drawing, are by Mr. Burne Jones. Mr. Sedding has so much knowledge of and sympathy with Late Gothic detail, that the architectural portion certainly could not be in better hands.

We now proceed to some notes on the secular public buildings, institutions, &c., represented, giving them in the order of hanging.

1,547, "Beckenham Public Hall," Mr. George Sedding. A brick building apparently, with a very large hipped roof over the whole, and lantern (probably for ventilation) in the middle of the ridge. The lower story has round arches with square mullioned windows under them; upper story, pilasters standing out on corbels, overhanging the lower portion, a very foolish and logical use of the plaster, sanctioned by fashion. The hall is on this floor, lighted by long mullioned windows. The angles are decorated by octagonal angle turrets, also corbelled out at the first-floor line, with good effect; an angle turret is a different thing from a pilaster. The building is solid-looking, but not beautiful. The author is to be commended for spending a plan.

1,551, "Dining Hall, Middle Temple," Mr. John Crowther. A beautifully-executed water-colour drawing, combining fine effect with the most minute representation of detail; as an example of illustrative architectural drawing it deserves the highest praise. Too often water-colour drawings of this class lose detail and a general glitter.

1,552, "Bedford Grammar School," Mr. Basil Champneys. A simple piece of Queen Anne architecture; mullioned windows with horizontal cornices below and sharp-pitched pediments to the windows in the upper story, broken at the apex, but the angles covered by shields with scroll supporters. The festooned webs sculptured on the wall above these windows are, of course, a feature of the style chosen, but a very absurd one, which it is a pity to see repeated by modern architects who, these days of æsthetic enlightenment, should know better than their "rude forefathers."

1,557, "New School of Science and Art, Dublin,—Portion of South Front," Mr. George Sedding. A tinted drawing of a main entrance with a bay window over, a boldly-treated piece of Jacobean work, with a deep shadow under the recessed elliptical-arched doorway; the only

point we dislike is the obelisk-like spikes on the gable; another instance of modern imitation of bad detail.

1,562, "Proposed New Building for the University of Oxford, adjoining the Schools: High-street Front," Mr. T. G. Jackson. A very pleasing and picturesque design, which is Gothic in feeling, though only partially so in detail. It has mullioned windows, some of them with pedimented gables over, some without, the window compartments with circular heads without cusping, a point which is repeated in the design of the open balustrades. In the left-hand side of the building (which is in two marked divisions), the manner in which breadth is given and the whole connected together by carrying the window divisions over the wall in the form of panelling, and by the rich carved first-floor string-band confined round this portion under the panelling, is most effective and artistic. Though containing details borrowed from different periods, this is no piece of *maro Jacobean* or Elizabethan copyism, but a combination of details into a harmonious whole with a considerable amount of originality. No plan is given, nor is it stated what is the purpose of the building.

1,569, "Northern Assurance Company's Offices, Dublin: Design in Competition," Messrs. T. N. Deane and Son. A water-colour drawing of a red brick building with stone dressings, the portion at the angle of the street forming a kind of massive tower with a pyramidal roof, and a large open archway on the ground story. No plan is given; the design is successful in giving picturesque effect to "business premises"; it looks a trifle heavy, but this may be due to the drawing, which is somewhat loaded, and wants brightness.

1,572, "New Building for Corpus Christi College, Oxford: Garden Front," Mr. T. G. Jackson. A very simple and pleasant bit of Domestic Gothic, looking rather like an ancient building, and probably intended so, to harmonise with others in the vicinity.

1,576, "Entrance to a London Hall," Mr. E. H. Sedding. Hung high; a "Classic" block, with a level skyline, pilasters on either side of arched entrance, with balconied windows between.

1,583, Mr. T. G. Jackson: apparently the south front of the same building "adjoining the Schools" at Oxford, of which another face is shown in No. 1,562; but hardly recognisable as such. This is a sepia drawing, showing windows of similar design to some of those in the other drawing, but the general style and feeling much more tame and uninteresting, perhaps because the author was more influenced by adjoining buildings on this side. The different method of execution makes the difference still greater; no one looking at them apart from the catalogue would guess the two drawings representing the same building.

1,587, "Municipal Buildings, now being erected," Mr. W. Young. A large and carefully-finished pen drawing of the Municipal Buildings, Glasgow; the rusticated ground-story, with pilasters and pilastered windows let into it, so to speak, is effective; but in the main it is a piece of pompous and well-elaborated commonplace.

1,588, "Prudential Assurance Offices, Dale-street, Liverpool," Mr. A. Waterhouse. A Gothic red brick and terra-cotta building, with an angle entrance, and projecting angle bay on heavy corbels; the ground-floor shops are treated with heavily-moulded segmental arch windows with solid piers between. The whole resembles so much other buildings designed by the author in the method of plain solid Gothic, with certain specialities of detail which are at once recognised as his, that detailed description is unnecessary.

1,595, "Design for Board Schools, Northampton," Mr. W. Doubleday. Hung too high to be well seen; a coloured drawing of a building in which the departments into which the school is apparently divided are picturesquely expressed in the design; no plan, however, is given.

1,625, "The Constitutional Club, Northumberland Avenue," Mr. R. W. Edis. A large and careful water-colour drawing, showing very well the effect of the red terra-cotta dressings against the lighter-tinted wall-spaces, as intended, we presume, though it hardly appears so rich in effect as this. The three large gables and two smaller ones a little separated from them, with variously-curved outlines, make a highly picturesque sky-line; the rounded end

of the building, with open loggias, and the shallow rounded bay-windows within the columns of the projecting bays, are other effective incidents in the design, which will certainly be one of the most sumptuous of London clubs in architectural appearance.

THE EDINBURGH EXHIBITION.

A VISITOR to the Exhibition possessed of architectural proclivities naturally gravitates to "Old Edinburgh." After passing down the central avenue, where everything is intensely modern, he finds himself outside the eastern doorway in the open air, and before him, as if raised by the skill of a magician, stands the gateway of an ancient city flanked by battlemented walls, over which appear the tops of gabled houses. To this and the rest of the reproduction a remarkable degree of solidity and truthfulness has been imparted; corbels, string-courses, gargoyles, &c., stand out in bold relief; different kinds of masonry and varieties of stone are wonderfully imitated, and the effects of time and weather are rendered with artistic finish. The gateway represented is the Nether Row-Port, built in 1606 and demolished in 1764, the easternmost of the six principal gates which pierced the wall built after the battle of Flodden, and which led from the city to the burgh of Cannongate. The design of it is said to have been taken from the Porte St. Honoré at Paris, and it was as massive and picturesque a structure of the kind as could be found in any ancient city. The archway was flanked by circular towers similar to those existing at Holyrood, and over the archway arose a square clock tower with a spire. Passing under the gateway, which is guarded by members of the ancient city guard in quaint costumes armed with halberds, we find ourselves in what may be considered the market-place of the ancient city.

The whole of the buildings represented no longer exist, and, of course, did not occupy the contiguous positions here shown. To the left appears "The Twelve Apostles' House," to the east wing of which tradition has ascribed the name of "The French Ambassador's Chapel." This building was taken down in 1829 to make way for the erection of the George IV. Bridge. It is an example of the semi-fortified Scottish town house. The upper floors are reached by a staircase situated in a strong square tower corbelled out in the upper stage, and having a circular turret with pointed roof at one side. Above the doorway is a shield bearing a werewolf and a crescent between two stars in chief, with the motto "*Speravi et inventi*." The house next to this is of a different character entirely, being one which stood in Dickson's-clos. The basement is of stone, and the upper stories, which project over it, are of wood and plaster. It must have been built after 1608, when James IV. granted, by charter, the Burgh Muir to the Town Council of Edinburgh. The ground was greatly occupied by oak trees, and, in order to encourage the citizens to purchase the timber, permission was given to project new fronts to the houses in the town to the extent of 7 ft. With each story of height the projections increased, till in some of the closes opposite neighbours could shake hands. These projections were generally closed in by lath-and-plaster walls between oak uprights, but in some instances they were open, forming galleries, which were used for recreation. The house in question was occupied in 1786 by David Allan, artist, "the Scottish Hogarth." Passing on, we reach another timber-framed house, which was taken down, as being unsafe, so recently as 1878. It stood at the angle of the West Bow and Lawn Market, and had an open piazza on the ground-floor towards the west. The ground-floor was occupied as a shop or open booth, to which the piazza formed a useful adjunct. The second floor was decorated with fluted pilasters, and the windows glazed in lattice work. It was here that the Messrs. Nelson laid the foundation of their famous publishing house. Turning northwards, we see Major Weir's house, through which there is an exit to the Meadows. The house stood in a small courtyard entered by a close from the West Bow. Over its doorway was inscribed the legend: "*Soli Deo honor et gloria, 1604.*" This was one of the haunted houses of the city, and is associated with the name of Major Weir, in respect to whom we refer the reader to a book named "Satan's Invisible World Discovered,"

by George Sinclair, Professor of Philosophy, in the College of Glasgow, published at Edinburgh in 1655. Major Weir was burned at the Gallows, between Edinburgh and Leith, in 1670.

The next house was the residence of the Earl of Selkirk, and afterwards of the Earl of Hyndford, Ambassador to Frederick the Great, and at a subsequent period it was occupied by Sir Walter Scott's grandfather. It was a stately edifice, the most remarkable feature of which was a tower supported upon massive pillars and round arches, under which there is a continuation of the footpath. Then follows a house which stood in the Cowgate, between the College Wynd and Horse Wynd, remarkable for its double row of dormer windows and high cross-stepped gable containing the stair. The "Lans Deo" house adjoining, bearing the date 1591 below the motto, stood on the Castle Hill; it is supposed to have formed part of the Palace of Mary of Guise, the hack portion of it having borne evidence of being erected at the same time as the Guise Palace, although the street elevation was of more modern character. The interior was richly decorated, and so lately as 1840 a beautifully painted ceiling in wood was discovered. The ceiling was arched and the painting in distemper. The Mint or Canzie Nook was destroyed in the siege of 1573, and another erected in the following year bearing the legend "Be Merciful to Me, O God, 1574." It is approached by an outside stair and arched wooden porch. The Charity Workhouse at the foot of Leith Wynd, which was erected by the Magistrates in 1619 in place of "The Hospital of our Lady in Leith Wynd," is a picturesque structure, with a fine row of dormer windows; it was removed by the North British Railway works. This completes the north side of the Market-place. The east side is occupied by the house of Simpson the printer and Mary of Guise's Oratory. The former is a timber-fronted house, the first floor of which is approached by an open stair. Above its massive oak door was an elliptical architrave with rich mouldings bearing two inscriptions: "Gif ve deid as ve would ve myght hail as ve vald," and "Get and saif and ve sal hail, 1515." The oratory of Mary of Guise stood on the Castle Hill, and was removed to make way for the Free Church College. It was erected after the English invasion of 1544. The palace of which it formed a portion was, as a whole, the finest as regards internal decoration in Old Edinburgh. It contained richly-carved stone and oak mantelpieces, panelled and arched ceilings, having emblematic and heraldic paintings, &c. After the death of the Queen Regent in 1560 the buildings were occupied by wealthy tenants, but, like all the fine mansions of the old town, it was at last divided into small dwelling-houses. *Sic transit gloria mundi.*

Entrance is obtained to Old Edinburgh at the south-east by the royal porch (1430-1753),—a finely-groined Gothic gateway, surmounted by a high-pitched gable, and having on one side a circular battlemented tower, and on the other a corbelled turret. It formed the chief entrance from the city into the courtyard of the Abbey of Holyrood, and was erected by Abbot Bollanden, who also "brecht hame the gret bellis, the gret basin fownt . . . he theikit the kirk with leid, he biggit ane brig of Leith, ane other our Clide, with many other grude works." This fine example of Gothic architecture, as well as the good abbot's house which adjoined it, was remorselessly demolished in 1753 by the Duke of Hamilton, Hereditary Keeper of Holyrood House. Proceeding westward, we find the Tolbooth,—"The Heart of Midlothian,"—towering aloft, and projecting its huge bulk obtrusively forward. It stood between the Church of St. Giles and the High-street, and was removed in 1817 as an obstruction to the thoroughfare. There was good reason for its removal, for although its loss may be lamented in an historical and romantic point of view, its condition as a prison, as described by Hugo Arnot, was most disgraceful. In front of the west elevation of the Tolbooth, Mr. Sydney Mitchell has reproduced an earlier version of the Market Cross recently restored by him. On the site now occupied by Melhorne-place stood a house and chapel which belonged to the Abbots of Cambuskenneth. These were acquired by Mr. Robert Gourlay, a city merchant and messenger-at-arms, in 1569. He utilised the carved stones in erecting for himself a

house, which was one of the most massive and striking in the city. The manner in which one half of the gable is corbelled out is exceedingly bold, and there is a most effective turret, which contained a spiral staircase leading to a room used as a cell for State prisoners of gentle blood, which tradition names as the apartment where occurred "The Last Sleep of Argyll." The house was planned so as to be easily convertible into several distinct residences approached by separate flights of stone stairs leading from one point. When taken down in 1834 a secret chamber was discovered between the ceiling of the first story and the floor of the second. Cardinal Beaton's house stood at the south-east end of Blackfriars-wynd at its junction with the Cowgate. It was built by James Beaton, Archbishop of Glasgow, afterwards of St. Andrews, and was remarkable for a bold octagonal angle turret. The attempt to reproduce the Parliament Stairs was too daring a one to be successful in the circumstances. This great flight of stairs reached from the low-level of the Cowgate to the high-level of the Parliament Close. They are produced in miniature, and form a pleasing feature. At their head is a corridor, the open timber-work of which is a *fac-simile* of that of the Old Hall at Lintithgow, recently taken down, which once belonged to the Knights Hospitaliers of St. John of Jerusalem. The adjoining building is a copy of the Assembly-rooms in the West Bow, where used to meet the rank and fashion of the city. It is a lofty building with high-pitched cross-stepped gables and long slender chimney-shafts rising from the eaves, very unlike any modern structure appropriated to similar purposes. It was erected by Peter Somerville, a bailie of Edinburgh, and bears his initials with the date 1602 and the motto "In Domino confido." A representation is given of a portion of "The Black Turnpike,"—a massive structure of large extent and great height which stood to the westward of the Tron church, and which was taken down in 1788. It is Gothic in style, and has an ogee-pointed doorway and niches, which have an affinity with late French Domestic Gothic. Tradition ascribed its erection to Kenneth III. (994), but the later date given, 1461, is obviously nearer the mark. The last *fac-simile* to be noticed is that of a Cowgate house of very pleasing form, which was removed a few years ago. It was one of the timber-fronted burgher dwellings, with a piazza on its ground-floor and an open gallery on the first floor.

A word of commendation is due to Mr. Sydney Mitchell for the admirable manner in which he has performed the task entrusted to him. Were one placed amidst these quaint surroundings, with none but the members of the ancient city guard, in the scarlet coats, cocked hats, and black leggings, who supersede the modern policeman, and the damsels who attend to the open booths attired in the costume of the time of Queen Mary, appearing as inhabitants, the picture would be complete, but the hex-hat, billicock, dress, "improver," and parasol of to-day everywhere appear, and dissipate the illusion.

Glasgow University: Gatasway Buildings.—The opening of the Underground Circular Railway having enabled the North British Railway Company to vacate the College Station, Messrs. Morrison & Mason, the contractors, are now engaged in carefully taking down the Old University Buildings in High-street, and removing the original archway, escutcheon with royal arms, and other historical stonework (temp. Cromwell and Charles II.) to Gilmore-hill. They have at the same time commenced the erection of new gateway buildings at the north-eastern entrance to the grounds of the present university, in which the materials and decorative features of the old façade are to be embodied, thus conserving a valuable link with the past. The new buildings are in the Scottish Domestic style of the period, with a blending of French and of Scottish Baronial architecture. They are the gift of Mr. Wm. Pearce, M.P., the eminent shipbuilder; and the architect is Mr. Alexander George Thomson, I.A., who, in a letter published in Nov., 1883, suggested this application of the ancient stonework. The lower floor is to be occupied as the janitor's dwelling-house, and the two upper floors as class-rooms in connexion with the Elder Chair of Naval Architecture and Marine Engineering.

FURTHER NOTES ON ACADEMY PICTURES.

We give some further notes on pictures in the Academy Exhibition, taking them now in the order of hanging. In Gallery I, is a charming little work by Mr. Marks, "A Delicate Question" (29), submitted in the shape of a manuscript of some kind to an elderly gentleman in a white wig and blue coat, who holds the paper before him with an admirable expression of puzzled responsibility. The colour is on a delicate and carefully-arranged scheme, waning gradually from left to right of the picture, from the blues and greys of the old gentleman's dress to the pale saffron of the girl's dress, who is the messenger, and finishing with the warmer orange in a bunch of flowers on the extreme right; giving quite a decorative value to a painting of realistic life. Mr. Doolman's "Warranted Quiet to Ride or Drive" (42), where an old man is getting taken in about his purchase, is a capital bit of humour along with a very good painting of a horse. Mr. Calderon's "Ruth and Naomi" (21) is the largest work in the room, and seems an earnest attempt to give new life to an old story; but the expression of Ruth is rather stary and exaggerated, as if she were playing to the gallery. Mr. J. Farquharson's "In Cairo" (41), a street scene with the figures in conversation, is animated certainly, but does not go to show that the author would be wise to desert the field of landscape in which his real power lies. "Choosing a Summer Gown" (66), by Mr. Woods, is a brilliant and very lifelike painting of a group of figures on a quay in Venice; each figure tells its own story well—the incident is of the slightest. Mr. Sargent's portrait of "Mrs. Harrison" (78) commands attention by its original style and peculiar costume, but for a portrait it aims too much a sensation. In this respect it may be contrasted with Mr. Pettie's carefully studied and manly portrait of "W. Bailey Hawkins, esq." (20), a very good example of portraiture. Mr. L. Jeune has one of his pretty combinations of child-life and landscape, "Water-Lilies" (80), and near this is a large, flashy, clever, and very vulgar painting, by Mr. A. M. Rossi, "A Solo by Request" (82), showing a drawing-room full of very vulgar and commonplace people, who have no possible claim to be painted at all.

In Gallery II. the largest work is Mr. Long's "Pharaoh's Daughter" (115), on steps above the water's edge, inspecting Moses and his cradle, and accompanied by various handmaidens, all in a state of more or less undress. This is one of those rather exasperating works which are very well painted, and yet totally fail to interest one, or to suggest anything but a scenic effect of grouping. Mr. Goodall's "Puritan and Cavalier" (87), where a girl in soldier grey hides behind a screen from the pursuit of a gallily-dressed little boy with a bunch of mistletoe, is bright and amusing, and the screen, which occupies the largest portion of the canvas, is a fine piece of Renaissance decorative work. Mr. Farquharson has done finely in his landscape, "And Winter's Breath came Cold and Chill" (94), if we except rather too hard and metallic look on the water; it is a snow landscape with the sunny light reflected from a stream not yet frozen; a peculiar and striking effect. Mr. Wyllie's "The Estuary of the Thames" (103), is a small but really fine landscape; the estuary with the tide low, and its mud banks dotted with coasting vessels aground, is seen from height, the line of hills sloping across the picture from the left contrasting with the low levels of the estuary; a very artistic composition, in which the art is not obtruded. Mr. Woods has done something new in his small painting of "The Water-Wheels of Savanna" (114), where we look up a flight of subterranean steps, the water-wheels on the left. An interesting example of an out-of-the-way subject turned to pictorial account, "Worship a-day England" (123), also by Mr. Wyllie, is a sunset picture over a river golden beneath but bordered by factory chimneys and clouds of smoke; we do not recognise the locality; it is a very effective picture, suggesting matter for thought too, in the contrast between the glory of nature and the work of man. We have never seen anything better from Mr. Wyllie than these two small and unassuming landscapes, both of which are hung on the line. Mr. Marcus Stone's "A Peacemaker" (140) is a pleasant picture, with three figures in the

background of a landscape, where a girl is interposing to conciliate two lovers, who have quarrelled; the costumes (of the Jane Anstey period) are carefully studied, and the figures expressive in their action; the face of the offended young lady is very handsome, and not sufficiently expressive of anger not to spoil her good looks.

In the large Gallery, Mr. A. B. Donaldson as a work in his richly-coloured but rather stiff manner, of Pope Alexander VI. deciding between the claims of Spain and Portugal to the Indies by drawing a line across the map; the Pope's is a characteristic head, and worth looking at; the other figures rather fill up the canvas than aid in the story. Mr. Pettie's "The Musician" (189) is a pathetic picture of a man of refined and *spiritual* features, on which the light is concentrated, evidently dying of consumption, looking on a sheet of the music which he will never hear performed; chamber-organ, a violoncello, and other accessories, fill up the apartment; a well-contrived picture as well as a pathetic one. Mr. Boughton's "The Conciliators of Peter the Great" (225) is a humorous scene from the early history of Prussian New York, not very interesting. "A Violin Player" (231) is a half-length portrait, by Mr. Storey, of a very handsome young woman clad in a very effective robe, and filled up to her chin; it is a pleasant picture to look at, but the face is a little too polished and wax-like for flesh. "Sacred to Pash" (253), by Mr. Long, is really a study of Persian cats, or the type of it commonly so called; as such, it is good, and attracts the interest of the many lovers of those animals. Mr. Joseph Knight's large landscape, "The Summit of the Great Orme" (263) is rather a puzzle; the tones of the grass suggest moonlight, which is obviously not the intention; it is an unreal-looking work.

In Gallery IV. we passed over (expressly, as our previous comments, the remarkable landscape by Mr. A. W. Hunt, his one contribution, Dunstanborough" (334); but, indeed, Mr. Hunt's landscapes are so far out of tune with the regulation Academy key, that they at last amid the more strongly-lined and self-asserting works amid which they are hung, his is a view showing the "iron coast and angry waves" in the foreground, and the castle in the centre, the setting sun behind it; to the right, over the reef beyond, comes one beam of wonderfully real and luminous light, there might be a little more force in the foreground rocks, perhaps, with advantage; though possibly any such attempt would have spoiled the unity and solemn effect of the whole. Mr. Pope's portrait of "Mr. Pfeiffer" (312) is an exceedingly good likeness; Mr. Holl's "The Reverend the President of St. John's College, Oxford" (335), is one of his best portraits in regard to force and power of characterisation. Mr. Leader's "When the West with Evening Lows" (340), is an effective work in a hard and unimaginative manner. Mr. F. Hamilton has tried a very good subject (352), the endearing hour of a man who, like Tannhäuser, had dwelt in the Venus cave, to obtain resolution from the Pope, when the figure of the goddess appears behind the Pontiff's hair as if to claim the suppliant as her own. The subject is not treated with the power it demands, but so many trumpery subjects are put before us at the Academy, that the effort to rise to something higher merits recognition. The like praise may be given to Mr. W. F. Calderon's attempt at Dante in the Valley of Terrors" (364), the poet and the three animals that dispensed his path. It may be doubted, however, whether this kind of pure allegory can be successfully dealt with in painting; in verse it is very well brought in animals as allegorical of certain feelings or certain States (for the meaning of Dante's leopard, lion, and wolf, is disputed by critics), but when you come to paint the actual animal on canvas, the symbolical meaning seems to disappear behind the mere question of animal painting. Mr. John Fæd's "Still Life" (372) is a brilliant production in its kind, except, perhaps, the grapes, which are a little odd in appearance.

In Gallery V. Mr. H. Moore's "The Sound of Sea after Sunset" (404) is a beautiful sea-piece, with a quiet swell on the water such as is seen when a breeze has gone down; the waves are golden when the fading of sunset light strikes them. Mr. Holl's portrait of "Sir John

Millais" (405) is certainly not one of the most favourable specimens of his work in portraiture, and confirms us in an opinion we have long entertained, that Academicians select for their diploma works those which are of least value to themselves. Mr. Riviere's "Union is Strength" (428) is a good painting of sheep preparing to retaliate on an over-hold half-grown dog, whose sudden alarm is very ludicrously portrayed. "The Handmaidens of Siva preparing the Sacred Bull at Tanjore for a Festival" (434), by Mr. Val Prinsep, though not beautiful, is interesting as a transcript of fact, as we presume it is. "Across the Moor" (445) is the best of Mr. Peter Graham's contributions, which are in the usual order of things,—Highland cattle, hills, and a mist. There is a special point in this one from the brilliant and very real way in which a passing gleam of bright sunlight is shown, almost glittering, on the side of a middle-distance hill. Mr. MacWhirter's "The Three Witches" (455) is a very expressive painting of three trees which have probably all suffered by lightning, stretching their withered arms about over the heath, but there is too much lightning in the picture; not from the storm which decapitated these three trees (for they are evidently old victims) and, therefore, not to the point, and lightning is an eminently unsatisfactory thing to paint, and should be indulged in as little as possible.

In Gallery VI., "Domino," by Mr. Frank Bramley, is a capital specimen of what may be called the modern "white school," where no details are made out, and as little colour used as possible. Two girls are playing at dominoes; white table-cloth, white dress, white muslin "work" thrown down, and a nearly white wall; the only hit of positive colour is in some flowers in a vase; but the attitudes of the two girls playing, and the face of one of them (the other has her face nearly turned away) are full of character and expression. There is little else in this Gallery to pick out for mention beyond what is mentioned already. "The Squire's Daughter" (508), by Mr. Margesson, is a life-size study, rather intended to be, we should say, after the manner of Mr. Boughton; it is rather dubious in colour, but not unpleasing. There are some other pretty things, and some very bad ones, in the same room.

Gallery VII. contains two works by Mr. Machett, from his favourite fen country; "Sodden Fen" (508), a very dreary-looking spot with a faint red sun going down behind a dreary-looking building; and as this dreariness and melancholy was probably what the painter wished to convey, he must be held to be successful so far, though it may be questioned whether the result was worth the canvas. The other work, "A Fen Lode" (604,—what is a lode?), where two picturesque-looking country girls are walking along the grass dyke by a canal or cutting, is a brighter and more pleasing work, and is one of the artist's most successful things in regard to both landscape and figures. Mr. Peter Graham's "Ramblers" (610) may be noted as a subject somewhat distinct from his ordinary run; the usual cattle are there, but their *habitat* this time is a sand-hill locality by the sea, and the sand-hill scenery is very well painted. Mr. Shaw's "Ramsey Island" (614), is, of course, a sea-painting showing much of the sea and little of the island; it is not equal to some previous works of his. Mr. MacWhirter has two small companion pictures in this room; a "Winter Morning" (625), a beautiful painting of a hick-tree whitened with snow, in a snow landscape, and "Autumn Evening" (630), a nearly similar scene under different light and different circumstances. The "Winter Morning" is the finer work of the two. Mr. Seymour Lucas's "Peter the Great at Deptford" (653) is a work which covers too much canvas for the degree of interest it includes; the group of figures in the foreground have a good deal of character, especially Peter himself, in workman's apron, who sits looking at a drawing of the framework of a ship, and who is well contrasted with the figure of a conventional part of the day, who forms one of the group; in fact, Peter looks a great deal more respectable than he probably ever did look in reality; but a great part of the canvas is filled up by the hull of a ship in progress behind, which, to say truth, is not painted with such an amount of force and realism as to be of much interest, and the large canvas has a somewhat blank appearance. Mr. Joseph Knight's "An October Day" (605) is a little gem: an evening scene, with a green turnip-

field in the foreground, and the folds of meadow going back from the eye in gradually deepening shades,—a very poetic little landscape made from simple materials.

Mr. Goodall's "Susannah" (688) is the principal nude figure in the Academy, the only one of any consequence or pretension; and, to say truth, does not justify its existence on so large a scale. It is a commonplace affair in conception, and not of the first order in execution.

Mr. Perugini's "Tempora Mutantur" (697) is a pretty idea,—a modern girl standing in a Renaissance interior amid a circle of caryatides, who seem as if they returned her contemplative examination. "Nature's Conquest" (711), by Miss Florence Small, is a pretty picture of a young girl who has fallen asleep reading; the colour of the work also is pleasing and harmonious. Mr. Blashfield's "Inspiration" (716) is a startling effort, rather of the old school; a female seated in a theatrical attitude on a gorgeous throne with a scroll in her hand, receives "inspiration" from an angelic visitant who comes on in a cloud; the draperies are all as if agitated by a strong wind. It is impossible not to smile at this piece of bombast, which, for all that, has a certain merit. How different is the next picture, "Relics" (717); a simple portrayal of a mother gazing on the toys and other little possessions of her departed child; the attitude and expression unaffected, the colour very refined. Mr. Ludovici's "Letters from Home" (732), a girl's school in the early part of the century, has some character and humour; and Mr. Bryan Hook, in "Cornish Fishers" (735), which are, in fact, cormorants in front of a stretch of sea, is showing himself a promising follower of his father. "The Tennis Match" (740), by Mr. J. Lavery, is a lively work of the impressionist school,—figures and faces which are only phantoms, but phantoms with grace and nature in their characters. "Flowers and Fruit" (770), by M. Charles Verlat, is a great bravura piece of flower-painting, not in the highest style, but brilliant and powerful in its way.

In Gallery IX., mostly occupied by small works, is Mr. Tadema's other contribution, "Rose of all the Roses" (818), a figure in a marble alcove, with a bright look-out over a distant landscape, on the right of which is discernible a rock-out temple with the square pillars coloured a strong red. Mr. Fæd's "Sunday Afternoon" (806) is a pleasant painting of a country girl, reclining in blissful ease on the ground. "Gathering Limpets" (824) is one of the best of Mr. Hook's pictures, with a breezy sea and breakers flashing in the sunshine. Mr. Tom Lloyd, in "Take us, Daddy" (893), has been rather poaching on Mr. Hook's marine preserves. The picture is full of aerial effect, but it recalls the older painter rather too strongly.

In Gallery X., "Twixt Power and Duty" (959), by Mr. John Bowie, should be looked at as a really original and striking work, both in composition and colour. It shows an ecclesiastic in red, in a dimly-lighted room, hesitating about signing a paper. A friar is seen in the background. The story of the picture is only vaguely hinted at, but it is done in a powerful and suggestive manner. Mr. Leader's "With Verdure Clad" (964) is a large, bright, mountain landscape, with a great deal of realistic force in the foreground. Among others in this room may be mentioned Mr. Eyre Crowe's "Hongkong" (976), a larger picture than usual for him, showing a group of wounded French soldiers, listening to an oration from another who has elevated a small tricolour standard, and points up to it. There is a novelty in the subject, which is given with considerable dramatic force. Two admirable pictures of the relation between humanity and dogs are found in this room: "In Diagræ" (1,008), by Mr. Burton Barber, where a dear little child, put to sit in a corner, is consoled by her favourite dog, looking up to her with a touching expression of sympathy; and "The Welcome" (1,020), by Mr. Riviere, where a very large working man is greeted at his door by a very small white puppy. The action of the dog is perfect. In "Iris" (977), Mr. Grimshaw has succeeded in giving a wonderfully luminous effect of light in the halo round the head of the figure. "Off to the Fishing Ground" (1,021), by Mr. Stanhope Forbes, should be looked at for the character of the figures in the boat, but the water is not painted at all, only a grey expanse—a very easy way of painting marine subjects. Mr. Ernest Croft's

"Return from a Raid" (1,027) is a kind of Walter Scott business, looking more real than such things sometimes do in painting; not one of the artist's best works, however.

In Gallery XI. Mr. B. S. Marks's "Jewish Bihloppoe" (1,039) is a fine little work, and Mr. David Murray's "Glen Falloch" (1,041) vindicates the position the Academy have accorded him better than some of his works which we have seen there: Mr. Vicat Cole's "Great Marlow" (1,052) is the best of his usual series of Thames pictures which are turned out regularly year after year, and by which the simple-minded might be persuaded that Thames scenery never had any but one aspect and one colouring. It is the successful manufacture of a certain type of landscape, rather than landscape art in the true sense. Mr. Waterlow's "Sunny Hours" (1,100) is a brilliant foreground and figures with a poor sea behind it. Mr. Annonier has sent a beautiful "June" (1,108), a scene under great trees through which the sunlight comes with a subdued glimmer. M. Fantin's large picture "Antour du Piano" (1,093), is obviously a group of portraits; the pianist, whose action and expression are very true, reminds us of Herr Jaell, but we have no information as to the personalities. The picture is better in expression than in colour; the flesh tints are unpleasing and muddy in effect. Two good portraits may be mentioned in this room, Colonel Lionel Barton, by Mr. Wirgman (1,095), and "The Duchess of Buckingham and Chandos" (1,109), by Mr. Arthur S. Cope; the latter a beautiful work, and an advance, to our thinking, on anything this artist has previously done.

The sculpture we will notice separately.

THE McLEAY MARBLES.

It is not generally known that the McLeay marbles exhibited for a short time some years ago in the South Kensington Museum during the absence of their owner in India have now passed into the hands of Sir Charles Nicholson, and are beautifully arranged with several additions in his house, The Grange, Tottenham. Last month, on the occasion of his receiving from his own University, that of Edinburgh, the honorary degree of Doctor of Laws, mention was made of the conspicuous services rendered by Sir Charles Nicholson to the cause of Egyptology. He twice visited Egypt for purposes of research, and there made a large and valuable collection of antiquities which he presented to the University of Sydney, in the inauguration of which he had taken a conspicuous part. More recently he has done good service to Greek archaeology. The valuable collection of marbles given him by his friend, Mr. George McLeay, he has not only suitably housed, but has had them photographed, and it is hoped that a selection of them will by his kindness shortly be published in the "Journal of Hellenic Studies." When we consider the vast stores of ancient marbles scattered in the town and country houses of England, when we remember that it needed the advent of a learned German, Dr. Michaelis, among us, to note and catalogue these national treasures, we feel that Sir Charles Nicholson sets an example valuable from its rarity. We do not intend to anticipate the discussion of the marbles in the "Hellenic Journal," but we may note that the provenance of the marbles is, for the most part, Asia Minor, and their date post-Alexandrian. Marbles of this late date and graceful style are specially fitted to adorn a private house, and when by the kind courtesy of Sir C. Nicholson we visited them in their present home we felt that they gain greatly in charm by their present scattered disposition instead of the usual massing in a museum. In the entrance-hall, on either side of a door, stand two female figures dressed in long chitons, with the high post-Alexandrian girding, and ample himation; the light from a side window upon them makes their position singularly favourable. In the same hall below the window is a small Greek grave-tablet, of a type already familiar: the young warrior leading his horse, a tall draped figure, followed by miniature figures, leading a sheep to sacrifice. Underneath the staircase is a group of Ganymede and the eagle, interesting from its close analogy to the group of Ganymede and the Eagle at Bonn. Ganymede, in Phrygian cap and high boots, leans against a pillar, on which the eagle is perched. A

relief, standing on the right hand of the hall door, is interesting as having been found in the Amphitheatre at Pergamon: it represents a gladiatorial scene, a man in boots and short chiton, with a whip in the right hand, faces a tiger about to spring upon him. The collection includes several grave reliefs, a number of heads, some of portrait type; a life-sized and well-preserved statue of Flora; and many others of interest. As a rule, we regret the existence of private collections, but where, as in this case, the owner is willing and eager that they should, by publication, be made available for scientific purposes, we are able to enjoy, without scruple, the added charm of beautiful and natural surroundings.

THE SURVEYORS' INSTITUTION EXAMINATIONS.

THE Council announce that the following candidates, whose names appear in alphabetical order, have passed the Professional Examinations held on the 5th to 9th April last:—

CANDIDATES FOR PROFESSIONAL ASSOCIATESHIP.

Students:

Burrows, Alfred John.	Lansdown, Harold W.
Callendar, William J.	Lowe, Charles Robert.
Carter, Frank W.	Perkins, Walter Frank.
Hilton, Harry Russell.	Physick, Walter F.
Jones, Samuel M.	Turrer, Percy.
King, William Isaac.	Vale, Henry.

Of the foregoing candidates, A. J. Burrows passed at the head of the list with a high aggregate of marks, but being precluded by age from competing for prizes, the Institution Prize, of the value of fifteen guineas, falls to W. F. Physick, and the Special Prize, of the value of ten guineas, to W. F. Perkins, these candidates being respectively second and third in order of merit.

Non-Students:

Birkett, Tom.	Hill, Alfred.
Bonsfield, Edwin V. D.	Isimey, Alfred.
Briggs, John.	Lee, John Wilfrid.
Campbell, Colin.	Maxwell, Francis Wm.
Crosland, Walter.	Peterson, Andrew T.
Drew, Henry Alban.	Pelham-Clinton, H. E.
Ellis, Ralph Staples.	Prater, Thos. Hubert.
Gibb, William Pashley.	Roods, Alfred.
Golightly, Charles H.	Ruddle, Frank J.
Green, Thomas Joseph.	Woolnough, John W.,
Henderson, Richard.	

of whom A. Roods obtained the highest aggregate of marks, and receives the "Driver Prize," of the value of Fifteen Guineas.

EXAMINATION FOR THE FELLOWSHIP.

The following have passed the Examination for the Fellowship:—

Day, William, jun.	Jones, Henry Arthur.
Godfrey, Robert.	Paul, Alan.
Hasluck, Lancelot G.	

SOME THOUGHTS ON ARCHITECTURAL TRAINING.*

IN offering you a few stray thoughts on architectural training, a question which has for a long while interested me, I certainly cannot claim originality as to the subject chosen, nor perhaps for many of the ideas I have attempted to string together; but I trust you will allow the apparent staleness of my subject to be outweighed by its importance to us and its peculiar fitness for discussion by such a body as our Association. Since, moreover, it seems to be a question on which the last word has not yet been spoken, by any means, we may possibly still find one or two points worth considering or even reconsidering, in spite of everything that has been said and written concerning it. In fact, regarding some points, one is half tempted to ask, "What has all the attention given to the matter of late years really amounted to, so far?" To say nothing of the destined victims themselves, the pupils-to-be, standing, so to speak, on the brink of the profession, about to take their great "leap into the dark," are the parents and guardians, up to the present time, any better informed or enabled to inform themselves much more clearly than hitherto, about what is involved in an architect's training and subsequent career, what are the main requirements and the chief conditions essential to success—or, at least, to avoidance of failure,—in such an undertaking?

* A paper by Mr. W. J. N. Millard, read before the Architectural Association on the 7th inst., as elsewhere mentioned.

Here, to begin with, I would submit, lies the possible source of much mischief which might be rendered more preventable than it is, by us architects.

The immense importance of any reliable information that can be obtained with regard to an architectural career, before committing a youth to it for life, must be obvious; and surely it rests with us, and us alone, to enlighten the outside public in this respect. As yet, however, I fall to see where the parent is to turn with certainty of obtaining anything more than the most meagre hints to help him to a decision in such a case; and still, it seems to me, it ought to be quite possible to afford him ample means of fully weighing a step so grave in its consequences for his protégé before letting him take it.

For instance, a Students' Manual or Text-book might be drawn up, one would think, and issued under the joint sanction of the Institute and the Association; embracing the entire training of an architect, and setting forth in detail all the various branches of study, with the order in which they could be best taken up, according to circumstances, as well as the other items of information hearing on the subject. To accomplish this effectually, would perhaps call for a little more unanimity than seems to have prevailed until now, as to the main lines to be laid down for an architect's training, but I hope we may really take it that all the interest recently exhibited about the whole question is evidence, at least, of a genuine desire for some more general agreement.

The project of a Students' Text-book to be published by the Institute, was put forward in a paper by Mr. Phene Spiers so long ago as the General Conference of 1871, but, for some reason or other, it seems to have fallen flat. Perhaps vested interests in the pupil-farming system were too powerful in those early days for any so radical an attempt at reform.

It is true, the A.A. "Brown Book" and its lately-issued Institute "Kalendar" do give particulars of many things a student may wish to know, such as our classes and the Examination, thus fulfilling their purpose well enough in its way; but we seem to be in need of something far more comprehensive in its aim—a production that should, if possible, be the outcome of the united counsels of all those best qualified to advise, and so be rendered valuable as a guide to parent, principal, and pupil alike.

Since the feelings and opinions current amongst juniors of the profession would, as a matter of course, have to be taken particularly into account in preparing any such work, it occurs to me that we could not be doing amiss this evening to quietly discuss a few matters of which it might treat.

With this object I proceed to throw out suggestion or two for your consideration.

To begin with, then, it would not be inappropriate, by way of an Introduction, to call to mind what is usually comprised in an architect's practice,—to which his training is professionally preparation,—and to afford some conception of the wide range of subjects he is expected to deal with. How, for instance, he is of course supposed capable of designing almost anything from a Christmas card to a cathedral; and liable at any moment to be appealed to as an authority on nearly all conceivable matters from a leaking gas-pipe to a question of Charlemagne's ritual-arrangement; or again, to be called upon from playing the part of a building detective to decide upon a doubtful point of archaeology; or, to mention other things innumerable; showing clearly that, although architecture is the work of architects, the converse will scarcely be good invariably.

It might be interesting and instructive, at the next place, to follow this up with a sketch of the means commonly taken to equip the aspiring youth for an enterprise of such magnitude, giving a brief unvarnished recital of the time-honoured course of procedure so familiar.—I will not say endeared,—to most of us of recounting how the raw pupil, all-unprepared, he is, gets pitchedforked into an office,—the brass the better; and how only too frequently the wasted years of innocence are terminated by a rude awakening to what he ought to have been learning all the time, on finding himself, at the expiration of his articles,—helpless.

This, to anybody of an inquiring turn of mind, must bring home the question,—supposing it has never occurred to him before, whether no improvement is possible, whether no saving of valuable time can be effected in

pupil's usual course of training; and if it can, how?

Even so much as to put him into the way of teaching himself, to show him how to use his eyes and pick up what he can on his own account, is not unfrequently to do him quite a good turn, as elementary instruction for architects goes now-a-days.

Hitherto, a lurking sort of idea seems to have possessed parents, architects, and pupils alike, that for about the first year, at any rate, it cannot really matter so very much how a pupil is employed, and—as I have even known it to be said, by an architect too,—that "a year or so of office drudgery will do him good!" Will it? May we feel quite certain it will do no harm?

Herein, possibly, lies a clue to the mystery of that spectral apparition, we so often see, calculated to touch the conscience of architects,—if anything will,—I mean the late-time-expired pupil, wandering round disconsolate in search of his first berth as an assistant; whilst his good friends and relations are growing every day more and more concerned about him, marvelling how it is he does not manage to "do something." Poor fellow! as, generally speaking, it is so very little he can do. He tells you naively how he would like to get with some "good man," where he could "learn something." That alone speaks volumes.

He finds, in fact, he has just come to a most critical turn in his course. For a last resource, perhaps he goes, out of sheer desperation, as an "improver," in hopes of learning something. Save in certain exceptional cases, I can seldom see of an instance of that nondescript,—the "improver," without suspecting there must be something wrong somewhere, and, not improbably, as much of misfortune as fault on his side.

Altogether, is it not enough to suggest a doubt, whether the ordinary architect's office is invariably the best possible place for a boy fresh from school; and whether the practising architect, he be prosperous or struggling, is precisely the man to undertake the responsibility of such a charge?

Almost any head-draughtsman can tell you how young pupils are usually regarded as a nuisance in an office, secretly or openly, until they have proved themselves to the contrary; it how they must, of course, be tolerated for so sake of their premiums and the dim hope of some making themselves useful some day before a term of articles is "up"; and how it is time ought to trouble much about them, when (if or before then) they become, somehow or other, sufficiently advanced to be trusted with the work of any consequence.

To slightly vary the well-worn metaphor,—as the boy is to the man,—so is the pupil to the architect." We do not find the question of bringing-up" lightly regarded by the majority of thoughtful parents in respect of their children,—not, at least, so long as they are still young to take to architecture as a profession, and seeing that, in other branches of education, the art of teaching is generally held to require some sort of special training, and even special gifts, for it to be followed with success, we wonder is how intelligent men of the world, who have to decide on a career for their sons, can go on supposing that corresponding conditions may be dispensed with in an architectural location. But, as yet, how are they to be rare, whether or not they ever incur any risk at all of such conditions being unfulfilled, less, indeed, the architects they treat with could themselves say as much; a course of occurrence only conceivable on the assumption, the first place, that even they are firmly persuaded to that effect.

Happily, at last there does appear a tendency, faintly amongst architects, towards agreement thus much, at any rate, viz., that a regular course of distinctly preparatory training is most essential for a pupil, before being nudged straight into an office, if he is to derive full benefit from what he sees going on there. This point, finally accepted, would involve a further one, as to what should be the nature of such preparatory work; in short, how best begin an architect's training. Or is this ever remain a case for "toss up"?

By no means the least part of the difficulty deciding on any course arises from the very variety of studies the pupil might begin with, ranging under the four main heads of Art, Science, Literature, and Practice. One thing,

at any rate, is pretty certain,—he cannot plunge indiscriminately into them all, just at first.

No sensible man, with a dozen important affairs to attend to, will attempt to take them together in a lump, but will at once set about arranging them in some suitable order.

No beginner at architecture can be reasonably expected to acquire a dozen branches of professional knowledge all at the same time; he needs careful guidance,—now-a-days more than ever,—as to the best order in which to proceed; even supposing the economising of time be his sole object.

Then, another difficulty meets us in the fact that the same course may not be equally well suited to varying capabilities.

Yet, surely, it ought to be possible to indicate a path which no one could be any the worse for pursuing, a certain distance at least, to begin with; that is, if he is ever to be an architect at all.

Doubtless we shall hear plenty of excellent and powerful arguments in favour of a preliminary course of technical education or applied science rather than purely artistic training.

I venture, with all respect, to put in a plea for the latter being made, much more than it is, the basis and backbone, as it were, of an architect's education and whole career, the very foundation to build up from.

I should like to see an architect commence oftener with a sound artistic training, including geometry and perspective, in a school or studio side by side with other art students.

It is rank heresy, of course, to breathe the shadow of a doubt as to the immense advantages of a so-called practical training; but it may be at least permissible to discuss whether this is always the best way of beginning; and whether a thorough knowledge of what comes under the head of practical work might not be acquired by a student just as well, or even better, and in shorter time, after he had advanced somewhat and there was a likelihood of his perceiving the bearing of such studies and of then realising the unquestionable necessity for his mastering them, as one main condition of ever being able to practise his profession.

It will be allowed, I think, that no more potent influence was ever invoked in aid of successful teaching of any sort, than the infection of the pupil himself with a desire to learn. This, if possible at all, is most likely to be brought about with work he most cares for at the time.

If, therefore, an architectural beginner's own inclinations lean, ever so slightly, towards art rather than science, would it not be a trifle unwise to disregard them, and to confer failure, by putting him through the "mill" of a scientific or practical training from the first,—beginning, as it might prove, at the wrong end? The consideration of what he himself may want to be taught, will perhaps be hardly worth neglecting entirely, for the sake of compliance with some supposed infallible programme of cut-and-dried correctness.

Rather, I would say, let the loose rein, given in the first place to his natural tendencies, be used as a means to lead him little by little. All in good time, no doubt, he will want to know about practical matters, and will be far more disposed to devote himself to the intelligent pursuit of them,—in view of their absolute indispensability to him as a practising architect,—when he is old enough to feel clearly convinced of this fact. And it is a fact, the full weight of which, he will never be made to feel by mere reiteration.

Again, even in the case of those who may not, so far, have given unmistakable indications of genius, or whose natural bent still rests undefined; just a verger young beginners,—say,—with all their inherent imperfections, carelessness, ignorance, laziness, or stupidity; a preliminary trial of artistic instruction is still as likely as anything else to enlist their better qualities, and has at least the recommendation of leaving no unpleasant distaste or harmful results,—supposing it should, after all, fail to disclose latent talent. Nor need it be lost time, since every architect, to be worthy of the name, must at some period or other attain to a certain amount of proficiency in freehand drawing,—as distinguished from mechanical,—and the earlier he does this of so much the more service will it be to him. It is something he can apply in his everyday work, and thus, at the same time, ensure from becoming rusty and useless, as

may easily happen with some kinds of knowledge if acquired sooner than need be. How an architect can gain command of his pencil too soon is difficult to make out.

But beyond all this, is it not also worth our while to consider, for a moment, the positive harm that may be done to any youth blessed with so much as a single spark of artistic fire, by deferring the careful and systematic development of such a gift until after he has been wearied and nauseated with what may well appear to him, at first, as the less attractive and less stimulating side of his profession?

If there be one thing more than another that needs, and at the same time repays, skilful tending, from boyhood upwards, it is surely this lamp of art; whereas, on the other hand, its flame is by no means to be kindled at will, just any moment a man may decide to "go in for the artistic." The comparative rarity of a wild plant may sometimes be apparent only, rather than real, owing to its general unobtrusiveness; but granted, that, in this case, the shoot might be but a feeble one,—the smaller the growth, the greater the need, perhaps, to prevent its being blighted and hidden for ever; and the season for bringing it forward to good purpose, once let pass, may never recur. In such an instance, it would seem, anyhow, to be running a smaller risk to postpone awhile the taking-up of some other branches of study.

Every now and then, in looking at executed designs, one cannot help feeling that the authors might easily have been made so very much more of as artists, by other training; to judge from the evidences of considerable artistic power,—somehow strangely undeveloped,—marking their work which differs, at the same time, distinctly from that of the simply feeble designer, destitute of any ideas of his own, and only just sufficiently clever to ape the art of better men. Ask many a worthy practitioner whether, in his heart of hearts, he does not deplore his lack of early artistic encouragement and guidance, and feel that this might have made just all the difference.

To save even a single student from the fate of turning out, in an artistic sense, a dwarf or a cripple for life,—if it can be prevented,—appears well worth the attempt.

To catch hold of him and bring his brighter side to the light; to draw out his finer feelings, whilst yet unclouded; to arouse in him a healthy enthusiasm through the sympathy of fellow-workers in a congenial pursuit, just at an age when he is most impressionable,—may be doing a truer kindness than to ply him with all the most admirable instruction in the world, before he can half-appreciate the good of it.

As I believe in a good art school for the beginning, so, I must say, I know of nothing equal to a good office for the finishing of an architect's training,—out-door study and travel coming in very largely between whiles.

I am not prepared now to talk about these latter, among many other things I should have liked to touch on; but I will just allude,—with your permission,—to a proposal I made here, on a former occasion, for obtaining the privilege of a seat in a good office, by way of a "finishing;" for such as should distinguish themselves in preliminary study.

Might not the Architectural Association set an example of founding scholarships entitling the holders to serve, for a period, a sort of advanced pupilage in one or another of the leading offices, where they would have the advantage of doing good work along with other picked men?

Any number of poor students would, I suspect, regard such a prize as indeed something to aim at; and further, we should be thus helping, in a way, to bring on a more accomplished race of architects. For, whatever is gained from any course of instruction depends, not only on whom it is the pupil works under, but quite as much on those he has to work with; figuratively speaking, they constitute the very atmosphere he breathes. Indeed, oftentimes in after-life, on looking back to such days, a man may be able to trace some decided change of direction in his career to the fact of his having then chanced to come in contact with certain other minds of different calibre from his own.

A paper on "Architectural Training," however limited in scope, would be incomplete without some reference also to the Examination. Now, the architect's calling may be said to combine the pursuit of an art with the practice of a profession. No man may lawfully set up as an attorney, a doctor, or even a druggist

without first satisfying an examination test. Anybody may dub himself "architect" who chooses to, but so can anybody proclaim himself a painter, a sculptor, or a musician, without, however, any other folks taking it very seriously to heart. In these cases an abuse of the title corrects itself in the long run. May not a like result be looked for in architecture, if only the standard in it of artistic attainment be more and more raised?

But yet, on the other hand, how is it that people do not, as a rule, seem to put such implicit faith in their architect as they will, for example, in their legal or medical adviser? Is it not mainly because these latter can invariably offer a sound guarantee to begin with, of proficiency in their work, up to a certain point?

If, then, this be the true reason it must manifestly tell to the architect's advantage also,—as well to his client's satisfaction,—to have a similar assurance to give, so far as any examination test can be fairly applied and without prejudice to his position as an artist, still leaving that point to be determined in the same way as in the sister arts.

I make no apology for assuming all along the possession of artistic ability to constitute one of the truest claims to the title of "architect." To some, of course, it may seem but a small matter for regret if by clumsy nursing we do manage to "choke off" or maim so many "budding artists" a year, leaving only the harder survivors to flourish in spite of it; but do not let us forget that in the training of our pupils lies the key to the future of British architecture; and even for the present one does not hear many serious complaints of our poor profession being actually glutted with artists, whatever other forms of depression it may be labouring under.

It is to be hoped there may ever continue to be pupils who, by force of talent, with or without good training, will in due time win credit to themselves and their profession; but we are dealing with a matter affecting, not a small minority only of exceptionally clever men, but that vast majority of average mortals like ourselves, who, whether or no, are some day to adorn or disfigure with their works our streets and suburbs and fair country-side.

It is not my object to pursue the subject further, though much might be said, of course, about a student's more advanced work and his preparation for practice. Important and interesting as these questions would be found, they must sink into insignificance beside the great initial one, of how the training of an architect should be commenced; since in this, as in many another undertaking, it is the first move,—the easiest one to make,—which may influence so incalculably all that follows.

And together with this point goes the one,—at the root of the whole matter,—whether some means or other cannot be devised for putting things a little more clearly and fairly before parents and guardians.

In pursuance of my endeavour throughout to regard this subject in as broad a light as possible, rather than in detail, I will conclude with a proposition that may now appear to many self-evident,—but, nevertheless, one, if true, whose more universal and loyal acceptance by architects in days past might perhaps, among other results, have rendered needless, not only this evening's discussion, but the very existence of the Architectural Association itself,—viz., that our whole profession, as a body, is responsible for the training of its pupils.

SAN VICENTE, AVILA, SPAIN.

THE restoration of the Church of San Vicente, in the picturesque old town of Avila, in Spain, is not being unnecessarily hurried on, having already been in progress for three years and a half, and, unless funds are forthcoming sooner than are expected, it is computed that the church will not be completely restored until the end of at least three years hence.

The work is under the direction and supervision of Señor Don Enrique M. Repullés, who is architect to the Ministerio del Fomento (freely rendered, Department of the Minister of Fine Arts), at Madrid; all his drawings are, however, subject to the approval of the Academy of San Fernando, also of Madrid, so that no vandalism can be perpetrated without the full cognisance of the most competent authorities of Spain.

The restoration, however, as yet completed, is extremely satisfactory, viz., the whole of the south façade, with the exception of the roofing in of the blue granite loggia, which extends from the south porch to, and slightly beyond, the west façade, the whole of the exterior of the apse with the cimborio, the porch of the north façade, and the south tower of the western façade. Before the north front a terrace, 18 ft. wide, of the same level as the west entrance, has been thrown up so as to prevent any chance of the earth falling away, and so endangering the structure.

The restoration of the magnificent west porch, recessed between the two towers, will shortly be commenced; and if the same standard is kept in this, as in the work already completed by Señor Repullés, there need be no anxiety as to a satisfactory result; especially as the Academy require a careful drawing to be submitted of the proposed rendering of any portion of the carving which is so broken or worn away as to give no tangible clue as to the original design. And this in backward Spain, while we allow a Parliamentary lawyer and newspaper controversialist to "during off-hours exhibit his powers" on one of our finest abbeys, and then, forsooth, place a coronet on his learned brow for the benefit he has rendered to his fatherland!

But, to return to Avila. Señor Repullés has submitted two proposals for the completion of the western towers,—one is for the demolition of the later date portion of the existing north tower, i.e., from the point where it becomes entirely detached, and the substitution of another story and spire of his own design, in the style of the same epoch as the rest of the façade; the alternative is to preserve the present north tower intact, and add another story to the southern tower, which shall bring both to the same height. The Academy have not yet given their decision, but, should they decide on the former proposal, the loss of the upper part of the northern tower need not be deplored, as its only beauty is the colour that the granite has acquired, and there is abundance of the same stone round Avila. The three windows now blocked up in the north front are to be opened out, and the grass-green blue granite buttresses, which are a later addition, are to be cleared away.

Nothing is yet settled about the restoration of the interior of the church, but, fortunately, there is little that calls for the chisel of the nineteenth century.

The whole of the exterior of the church, with few exceptions, is built of the red granite so plentiful around Avila, the new stone required for the restoration being quarried from La Colilla, a small village about one mile and a half from Avila. This red granite weathers into most delightful and various tints, from bright reds and burnt sienna to deep purples, as may be seen especially in the picturesque old hattle-mented walls or in the Church of St. Pedro. The exterior of the apse of this church, with a bright sun shining on it and with groups of the brightly-clad and picturesque peasants leading their mules about the plaza as a foreground, would be as delightful a subject for the water-colour painter as he could well wish for.

The blue granite round Avila is, perhaps, more plentiful than the red, and, although it has not the special charm of colour, it can be quarried in extremely large blocks, and many fine effects are produced in the town by the great dimensions of these stones.

Illustrations.

WE this week illustrate various buildings by Messrs. Ernest George & Peto, the drawings of which (except those of the cottages) are now on the walls of the Royal Academy.

HOUSES IN CADOGAN-SQUARE, S.W.

The first of these is a large house for Mr. T. A. De la Rue in Cadogan-square.

The front is of red brick, with buff terra-cotta dressings from Messrs. Donlton & Co. The quaintly-shaped bay-window forming the porch underneath is a specially picturesque feature. The roof forms one large gable, and is covered with red tiles. The interior of this house will be finished with fine oak panelled rooms, which we hope to illustrate in a later number. On the ground-floor is an entrance-hall with

millioned windows down one side and a large stone fireplace carried up to the ceiling. In the front of the house, on the ground-floor is the quaintly-shaped drawing-room, with small boudoir or music-gallery looking down into it from a higher level.

At the back of the house, and beyond the arched oak staircase, is placed the dining-room, and beyond the dining-room are the stable-buildings, with access from the house. On the first-floor are a billiard-room, library, and Mr. De la Rue's own suite of rooms.

The hall has an oak-beamed ceiling, and solid the dining-room. The billiard-room has an open-timbered roof with a lantern light.

The house will be fitted with electric light. All the kitchens and offices are lined with white tiles from floor to ceiling. Messrs. J. Simpson & Son are the builders.

CHAMBERS, MOUNT-STREET, GROSVENOR-SQUARE

The range of buildings next to the Vestry hall, in Mount-street, Grosvenor-square, is a stack of very complete chambers, giving various amounts of accommodation, which are here built for Mr. W. Warner, commodious and being arranged on the ground-floor, with separate entrance for the chambers. These are ranged round an amply-lighted court, of white glazed brick. These chambers obtain excellent light at the back as well as the front, and great care has been taken to make every suite, however small, as convenient as possible. The style chosen for these buildings is the French Flamboyant.

Adjoining these is another stack of chambers by the same architects, for Mr. J. Andrew, containing flats of very ample dimensions, each with their own kitchen and offices, these flats in each case being on a floor higher than the respective chambers, and having their own little private staircase leading thereto in addition to the entrance from the main stairs.

The design for these chambers is Late Renaissance, the terra-cotta architraves and mouldings being ornamented with egg and tongue and other Classic enrichments.

This building is also of terra-cotta, from Messrs. Edwards; that for Mr. Warner being from Messrs. Donlton.

Messrs. Stephens & Bastow, of London & Bristol, are the builders for Mr. Warner's buildings; Mr. Andrews (of Mount-street) being his own builder.

"BUCHAN-HILL," SUSSEX.

These drawings illustrate some portions of the interior of this house, which Messrs. George & Peto have been building for the last three years for Mr. P. Saillard.

They show the two ends of the great hall, of the fireplace end, and the other of the gallery across the hall and opposite the fire. The gallery, like much of the rich work in this house is of oak, very beautifully carved.

The grand staircase is also shown. It is the tower and is arranged round an open well with a massive oak post at each corner, carrying the flight overhead.

Each step is moulded from a solid block of oak.

Above the panelled dado the walls are lined with stone, which is obtained on the estate.

COTTAGES AT LEIGH, KENT.

Our fourth sheet shows a group of cottages for Mr. Samuel Morley, which are ranged round a small open green, with a red brick path leading to the different cottages.

The gables and other portions are oak timbered. Two of the cottages are of the local stone; some have their upper stories of oiled shingle; and a portion of the work is thatched the buildings thus forming a quaint and quiet group.

Proposed Public Baths in St. George's, in the East.—The Rector of St. George's, in the East, the Rev. C. H. Turner, has made an offer to the local Vestry to the effect that, on behalf of himself and friends, he is ready to erect public baths in the parish provided the Vestry will undertake the maintenance and management of the same, including the payment of the ground-rent of the land on which the baths are proposed to be erected, at which amounts to 52l. 10s. per annum. The Vestry having taken the matter into consideration have decided to accept the rector's offer.

Church of St. Laurence, Catford.

CHURCH OF ST. LAURENCE, CATFORD.

The foundation-stone of this church is to be laid to-day by the Viscountess Lewisham. The church is founded under the auspices of the Fisham Church Extension Association, the object of which is to provide additional church accommodation for the parish of St. Mary, now numbering a population of 15,000, by building churches at Catford, Hither Green, and Sley. The Catford Church, of which a sketch is enclosed, is designed by Mr. H. Rounie, architect. For the present requirements of the site it has been considered sufficient to erect a nave and aisles, a portion of the transepts, and a temporary chancel, providing accommodation for 500 persons, at a cost of about 3,500. The plan has been given by Major Foster.

THE "SHIPPERIES" EXHIBITION, LIVERPOOL.

The International Exhibition, which was opened by the Queen on Tuesday, the 11th inst., is probably on the largest scale that has ever been attempted in a provincial city. The building itself, as is well known, is the same which was formerly used for a like purpose at Antwerp, and it has been re-erected on the present site under the superintendence of Mr. Sumner, architect, of Liverpool. The building is built on land on the south side of Edgehill, and in close proximity to Edgehill Station, which a new road has been opened for the convenience of visitors. The Exhibition building itself occupies twelve acres; and the grounds around it, which have been laid out and planted with considerable care, are in all about forty-two acres in extent. The interior consists of a vestibule and main hall, running from west to east, and intersected at right angles by other wings and aisles. There is a central cupola or dome, at the intersections, rising to a considerable height; and under these is placed a very conspicuous "trophy" of Donlon's manufacture, of which we shall have more to say hereafter. There is also another large "trophy" at Liverpool exports and imports at the further end beyond which there is a large concert-

room which terminates the building eastwardly.

The general decoration of the interior is pleasing. The walls are stone colour, relieved by attached columns at intervals. The iron-work of the roof is a pale blue, while below the sky-lights are ornamental panels with figures and geometric devices. The principal colours of these are grey and brown, picked out with gilt, the whole being relieved by crimson draperies. The vista from end to end of the main avenue is very effective.

Little attempt is made at external ornament, and what there is is confined to the principal entrance.

On entering the grounds from the north end the first object that attracts attention is an exact facsimile of the Eddystone Lighthouse, and from this the electric light is intended to be exhibited.

The immediate objects of the promoters (to use the words of the Mayor's address to the Queen) are "to illustrate the art and science of navigation in ancient and modern times, the means by which the achievements of modern science are abridging the distances between the nations of the world, and the beneficial results which have followed therefrom, viz., the extension of commerce and commercial industry, the development of trade and manufacture, &c."

The Exhibition is at present in a very unfinished state, and in a note to the first edition of the Catalogue, the Executive Council say, "that in consequence of the many alterations necessitated by the official opening being performed by Her Majesty in person, and the number of season-ticket holders requiring to be accommodated, it had been found absolutely necessary to defer the installation of a great number of important exhibits until afterwards."

These exhibits were on Wednesday being busily brought in; and we hope to return to the subject next week, when we shall be able to give a tolerably full description of the Exhibition.

Society of Arts.—The loan collection of Japanese art at the Society of Arts, John-street, Adelphi, will remain open during the ensuing week. Admission by presentation of visiting card. A classified catalogue by Mr. Hayashi has been printed, which is of unique value for the study of the periods of Japanese art.

ARCHITECTURAL SOCIETIES.

The Architectural Association.—A visit was made by this Association last Saturday afternoon to the National Liberal Club, now being built at the bottom of Northumberland-avenue from the designs of Mr. A. Waterhouse, R.A. The building (of which we published views and plans a year ago) has been carried up to the level of the second floor. The general arrangement of the plan is as follows:—On the basement floor are the smoking-room, storage space for members, and men-servants' dining-room and bedrooms. On the lower ground-floor are the billiard-rooms, seven in all; card-room, dressing and bath rooms, conference-room, and entrance to the club, and public entrance to the Gladstone library and chambers. On the upper ground-floor the grill-room, dining-room, serving-room, and Gladstone library,—the dining-room communicating with the terrace over the billiard-rooms. On the first floor the reading and smoking rooms, drawing-room, private dining-room, and committee-room, and secretary's office. The second, third, and fourth floors are devoted to chambers,—the kitchen being also on the fourth floor. The foundations, which are on an average 25 ft. below the surface of the ground, are on a bed of gravel. The whole of the stonework is brown Portland, and all the bricks are gault, which have been tested to a pressure of 48 tons. The floors are all fire-proof, of steel decking and concrete; and all the lintels and fixing-blocks are of breeze concrete.

Exeter Diocesan Architectural Society.—The quarterly meeting of this Society was held on Thursday, May 6th, in the hall of the Vicar's College. The Ven. Archdeacon Earle was in the chair. The report, read by the Rev. E. V. Freeman (secretary), dwelt principally on the recent decease of Lieut.-Col. Harding, of Upcott House, Barnstaple, at a very advanced age. Allusion was made to the various papers contributed by Col. Harding from time to time to the Society's Transactions during his Secretaryship from 1851 to 1865. These papers, which were enumerated, were chiefly upon old churches and their monumental effigies, chapels difficult to find, and matters of antiquarian interest in the diocese. Mr. Ashworth, architect, then read a paper illustrated by many

plans and drawings of portions of Exeter Cathedral not generally known. It chiefly described two opposite chapels in the choir aisles, St. Andrew's and St. James's, of good Decorated work, each having an arch-chamber over its vaulting, also vaulted, and floored with encaustic tile work of the fourteenth century. Under the latter chapel is an interesting crypt of Early English character, scarcely accessible before the improvements carried out some years since under Sir G. G. Scott. The ancient Chapter-house was described, erected on a portion of Bishop Bruner's garden, given about 1230, the lower portion good Early English, and the upper Perpendicular, with a highly decorated roof, dating in Bishop Lacey's episcopate 1430-40. The absence of an effigy or memorial of Leofricus, the first Exonian bishop, was remarked, with the supposition that a monument of pyramidal form in St. James's Chapel, enclosing a cinquefoiled arch, must have been to his memory. Grandison's work in the nave from 1327 to 1369 was described, and his place of sepulture, a small chapel within the western screen, of sixty-five niched statues of apostles, prophets, English kings, crusaders, &c. In concluding the proceedings, the Archdeacon observed that it would be well if greater facilities were given for visitors to view the cathedral by abolishing the fee of 6d. for seeing certain portions, also that it would be an excellent thing if arrangements could be made by which eminent authorities might give lectures (in the north transept) on the history of the cathedral, which really meant the history of the church,—that such lectures would be much appreciated, especially by working men, and that much good would result from them.

Edinburgh Architectural Association.—On Saturday last the members of the Edinburgh Architectural Association visited Kirkton and Burntisland parish churches, and also Rossend Castle, under the leadership of Mr. Hippolyte J. Blanc, architect. After giving some historic notes of the ancient burgh from the Roman Invasion under Agricola, who camped on Duncarn Hill, down to recent times, Mr. Blanc described the features of the parish church, which is recorded to have been built in 1592. It is of rectangular outline, and bears a strong resemblance to the North Kirk at Amsterdam, at that time the chief mercantile city in Europe. Within the edifice are four massive pillars connected by semicircular arches. The walls resting on these are solid to the roof, and, rising above it, terminate in an octagonal tower. There are arches of masonry between the external angles of the tower and the inner angles of the exterior walls, intended as buttresses. An outside stair gives access to one part of the gallery, probably for private use; the wainscot panelling contains some interesting specimens of decorative emblems suggestive of ship's cabin design, dated 1608. The church was erected by the inhabitants, not by the heritors. The party then visited Kirkton, about half a mile to the westward, where are the ruins of the pre-Reformation Parish Church, which consisted of a nave and chancel. They then passed to Rossend Castle, in the neighbourhood, built by the Durio family in 1382, Abbots of Dunfermline. Its form is that of the old Scotch peel. It is now occupied by Mr. Shepherd, and is well cared for.

Leeds and Yorkshire Architectural Society.—The members of the Associates' Sketching and Art Club held their first meeting for this session in the Society's Rooms, Albion-street, on Monday evening, when a series of drawings and sketches produced by the members during the last month were on exhibition, the most interesting works being "Sketches from Lincoln," Mr. J. W. Twist; "Old Oak Chest," Mr. H. P. Buckley; "St. Michael's Church, Coxwold," Mr. Frank Haigh; "Riddlesden Hall," Mr. Alfred Whitehead; and "Wall Arcading, Lincoln," Mr. F. W. Bedford. The evening was spent in criticising the sketches and transacting the business of the Club.

The Old Workhouse at Lambeth.—The Lambeth Guardians, at their meeting on Wednesday, adopted plans submitted by their architect, Mr. T. W. Aldwinckle, for reconstructing and partially rebuilding the old workhouse in Prince's-road, and adapting the same as a test house for the able-bodied poor of both sexes, at a cost of 16,000l.

ARCHITECTURAL ASSOCIATION: ITALIAN EXCURSION.

We have received the following further notes: "Before leaving Rome the party on Thursday visited the Forum, the Colosseum, the Arches of Titus and Constantine, the Nymphæum of Marcus Aurelius, the Church of St. Stefano Rotundo, the Basilica of Constantine, and St. Pietro in Vincoli.

Friday morning was spent in the Vatican, and in the afternoon St. Peter's, St. Maria in Trastevere, the theatre of Marcellus, the temples of Hercules and Fortuna Virilis, the House of Rienzi, Sta. Maria in Cosmedin, the Arch of Janus, and the Arch of the Goldsmiths were seen. On Saturday morning the Museum on the Capitoline Hill and in the Tabularium, and the Mamertine prison; and in the afternoon the Baths of Caracalla, the Arch of Drusus, the Porta Appia, the Circus of Maxentius, and the tomb of Cecilia Metella were visited. On Monday the following buildings were visited, viz., Sta. Maria degli Angeli, Sta. Maria Maggiore, the Porta Maggiore, the tomb of the baker Eurysaces, Sta. Croce, and St. John Lateran; and in the afternoon we left Rome for Pisa, which was reached at 10 p.m. on Tuesday morning. The cathedral tower, Baptistery, Campo Santo were visited, and the train taken for Lugano; and on Wednesday for London, where we arrived at 5.30 p.m. on Thursday.

The excursion of twenty-one days was carried out on the following time-table, and proved to be a great success. The estimated cost of 25l. was found to be fairly correct. Several of the members of the excursion started on Monday, the 12th of April, and included Venice and Verona in their programme.

Time Table of Architectural Association Italian Excursion.

April.
Friday, 16.—Left London, Charing-cross, 10.35 a.m.
Saturday, 17.—Arrived at Milan, 7.40 p.m.
Sunday, 18.—Milan.
Monday, 19.—Left Milan, 9.40 p.m., arrived at Piacenza.
Tuesday, 20.—Left Piacenza, 9.5 a.m.; arrived at Bologna, 1.45 p.m.
Wednesday, 21.—Left Bologna, 2.20 p.m.; arrived at Florence, 8.1 p.m.
Thursday, 22.—Florence.
Friday, 23.—Florence.
Saturday, 24.—Florence.
Sunday, 25.—Florence.
Monday, 26.—Left Florence, 5.55 a.m.; arrived at Siena, 9 a.m.
Tuesday, 27.—Left Siena, 9 a.m.; arrived at Orvieto, 1.25 p.m.
Wednesday, 28.—Left Orvieto, 3.39 a.m.; arrived at Rome, 9.20 a.m.
Thursday, 29.—Rome.
Friday, 30.—Rome.
May.
Saturday, 1.—Rome.
Sunday, 2.—Rome.
Monday, 3.—Left Rome, 3.40 p.m.; arrived at Pisa, 10.30 p.m.
Tuesday, 4.—Left Pisa, 9.44 a.m.; arrived at Lugano, 10 p.m.
Wednesday, 5.—Left Lugano, 9.44 a.m.
Thursday, 6.—Arrived in London, 5.30 p.m."

It may be said that it was hardly worth while to see a number of great monuments in such a hurry, and of course real study of them was out of the question. But we sympathise with it as a spirited effort for which much credit is due to Mr. Blashill, who originated the idea and conducted the party; and it is better to see the real thing with your own eyes, if only for a few minutes, than not to see it except in books.

ARCHITECTURAL ASSOCIATION.

The thirteenth ordinary meeting of this Association for the present Session was held on the 7th inst. at 9, Conduit-street, Mr. C. R. Pink (President) in the chair.

Messrs. J. C. Anderson and S. C. Arding were admitted as members.

Mr. H. D. Appleton (hon. secretary) read the House List nominating the officers for next session, Mr. J. A. Gotch being put down as President; and Messrs. J. Slater, E. J. May, and Henry Lovegrove as Vice-Presidents.

A vote of thanks was accorded to Mr. R. W. Edis for permitting the members to visit the Constitutional Club, Northumberland Avenue, and for kindly conducting them over the building.

The Chairman referred to the Examination in Architecture commencing on the 22nd of November next. This had been arranged to enable many who had been preparing to have another chance of qualifying this year for the Associateship of the Institute. Papers and rules could be had on application to the secretary of the Institute. It would be

observed that the questions set at the last examination had been published in these papers, which they would all agree was a very necessary and welcome improvement. (This announcement was received with applause.)

Mr. Appleton, at the request of the Chairman, made a few remarks on the Italian excursion of the Association, which started on the 16th of April, and consisted of twenty-four members. The whole of the programme had been carried out without the slightest hitch, Milan, Bologna, Florence, Siena, Orvieto, and Rome having been visited. Although it was impossible to "do" these cities thoroughly, still they had seen enough to make them wish to return again next year.

Mr. W. J. N. Millard then read a paper entitled "Some Thoughts on Architectural Training," which we print on another page.

The Chairman, in opening the discussion, referred to the fact that the Committee of the Institute appointed to consider the question of architectural education was doing its work with great earnestness, and he hoped it might bring about the publication of the text-book they had been so long looking for. There was no doubt that the student required some direction much better and more definite than he at present possessed, to indicate what would be required in the practice of his profession. Anything that could be devised which would inform parents and guardians as to the nature of the profession would also be of the greatest possible value, as many boys entered it knowing nothing of what would be required of them. Some preliminary training was very essential, and without going into details, it should include the grammar of art-expression, which could be gained at an art school, besides a knowledge of mechanics and of applied mathematics generally, without which artistic knowledge would not be of any great practical advantage. When fairly hunched as a pupil, he should be encouraged by his principal to make use of his eyes, and observe what was going on both inside and outside the office. Many years since the Institute published a suggestive pamphlet, entitled, "How to Observe." He did not think it was of much practical use now, but at the time it directed the student, when on the building, what he should look for; therefore, some such guide might be devised which would be valuable to the boy on his first entering the office. There he should see "how it was done" from inception to conclusion, as this was the only way in which he could obtain intelligent knowledge. He would like to enter a strong protest against giving the pupil office-work merely to kill time; it would be better rather to send the lad to study some building. The architectural examination, as it was and would be further developed, might be regarded as the true diploma of the profession. The supposition that the profession would ever be made a close one by statutory powers was a mere chimaera; he did not think the thing was possible, and he was not sure, in the true interests of art, that it was to be desired. But it was advisable that the architect should be able to show a direct certificate of competency; therefore let science go with art, for in architecture it was impossible to divorce the two. He was not sure that there were not more "artistic" architects than really scientific ones at the present time, and unless science and art were studied together there could be no possible progress in the future for the architecture of this country.

Mr. Cole A. Adams proposed a vote of thanks to Mr. Millard, who he thought took a rather too despondent view of the whole question of architectural education. The advantages enjoyed by students in the present day, were large in comparison with those enjoyed not so very many years ago, though, no doubt, capable of improvement, and he had always urged the importance of this. This improvement was the more necessary because while the standard of education had advanced in the other professions that of architecture was the only one which seemed to have held back. The Architecture Association was doing good work, but there was a demand for something higher, and the question of how it was to be met was an exceedingly difficult one to answer, owing to want of funds. Last session the matter was brought before the members of the Association, and a proposal made to raise the subscription, but this was out-voted. Thus, the sinews of war were cut off, though he believed the Association would some day see how essential it was to supply

them, and another effort would have to be made, if they wished for higher education. Doubtless the Institute would have voted hands for the endowment of "Chairs" had they possessed the means, but the figures of its balance-sheet did not give much hope of any assistance from that quarter. Parents and guardians who wished to put youths into an architect's office would surely make some inquiries before doing so, and therefore he failed to see that any pamphlet would have much chance of reaching them; still, such a work as Mr. Millard advocated would have its use. All would agree that the artistic was the higher side of the profession of architecture, but he concurred with the Chairman as to the great importance of studying the scientific side. If our present system was so thoroughly bad, how was it that his country had turned out such excellent work during the last fifty years? Many of the fine designs which were published in the professional journals were a source of wonder to our Continental brethren. The drudgery of the pupil was not at all a bad thing for the pupil, and had its use; if he had good stuff in him he could hardly fail to rise in his profession if he seized and made use of his advantages.

Mr. W. H. Atkin Berry, in seconding the vote of thanks, thought that Mr. Millard's remarks would be useful to many a parent and guardian who were asking the well-worn question,—"What shall I do with my boy?" Mr. Millard carefully weighed the relative importance of art and science in making a start, and had indicated art as the more important. But it was not always a matter of choice with the pupil as to which he should adopt. Before taking out his course of training, the pupil could ask himself two questions.—1st, Why be an architect? 2nd, What were the duties of an architect? If a man were an architect from a sheer love of his art, he would doubtless follow art first; but if he had to follow the common-place pursuit of making his living, he would be careful before disregarding the science of his profession. Now-a-days there seemed to be no profession which was not included in that of architecture,—a knowledge of law, science, and "business" being necessary for the protection of the client. A knowledge of science was much more capable of being adequately tested in an accomplishment in art; the first, therefore, should form the principal basis of test for diploma. He would like to know where the scientific knowledge of some of the profession could be, if the practical man behind the scenes were withdrawn?

Mr. Leonard Stokes did not understand that Mr. Millard had pooh-poohed the scientific side of the question. He had merely said that the artistic part should be taught first, for if a man is first taught his art the scientific part would follow with it hand-in-hand. All pupils should attend an art school before entering the office, and as to the troubles of parents and guardians they were much the same in connexion with all other professions. Then, again, it was an possibility to teach everything in three or five years, when men who had been twenty years in a profession felt they had still much to learn. The question was, how much could be taught, and the architect should, therefore, give his full as much attention as he possibly could. Though many architects were to blame for the manner in which they treated their pupils, yet many pupils were sure to blame for the way in which they treated themselves.

Mr. Sydney Vacher would like to see the Institute lay it down as a law that the manner in which pupils should do so with the object of teaching them something for their own use. If this course had been pursued, there would have been no necessity for such a paper they had heard that evening. Mr. Brodie believed that the proper place for a pupil was in an office rather than in a school, and the practical side of the question would be so thoroughly intertwined with the artistic that they could not be divided. At the same time, the pupil should have some knowledge of drawing before he entered an architect's office.

Mr. Appleton thought that Mr. Millard's object of contention in regard to art-training was not the pupil, if he wished to learn, must be able to express his ideas with the pencil. It was one canon of taste in regard to art, and that was appropriateness. Indeed, an artist must have a certain amount of scientific training to make a design appropriate.

Mr. J. F. Carwen said he wished they had preparatory examinations, as in the Law. The vote of thanks was then put and carried, and Mr. Millard having made a few remarks the proceedings terminated.

COMPETITIONS.

Proposed Municipal Buildings, Sunderland.—At a special meeting of the Sunderland Town Council, held last week, a report was received from the Corporation Buildings Committee as to the award of prizes for competitive plans in connexion with the proposed new municipal buildings. The Mayor (Alderman Preston) occupied the chair, and there was a large attendance of members. The Town Clerk (Mr. Bowey) read the report to the committee from Mr. Alfred Waterhouse, R.A., who had been appointed to advise as to the merits of the plans, and who stated that he had gone through the designs submitted by the twenty-three competitors, and had carefully examined them, both as regarded their compliance with the conditions laid down and their merits of arrangement and design. He was of opinion that the plan sent in under the motto "Stabilitas" was the best. It complied with the conditions, and was in every way deserving of the first premium, it being of unusual merit and showing great care and skill in design. The second premium he awarded to the plan bearing the motto "Nineteenth Century," and the third to "Time and Tide." Taking into consideration the lowness of prices at the present time, he thought that all the above-mentioned designs could be executed for the sum named by the architects. The Corporation Buildings Committee accordingly recommended that the premiums be awarded as follows:—First prize, 100*l.*; second prize, 75*l.*; and third prize, 50*l.*—On the motion of the Mayor, the report was adopted by 33 against 2.—The sealed envelopes being opened, the respective competitors were found to be as follows:—"Stabilitas," Mr. Highbury Binyon, Ipswich; "Nineteenth Century," Messrs. Grayson & Ould, Liverpool; "Time and Tide," Messrs. Doubleday & Caws, Wolverhampton.

THE CHURCH OF

ST. BARTHOLOMEW THE GREAT.

SIR,—In your able notice of the restoration of the ancient church of St. Bartholomew the Great, you make an appeal to the City companies to aid in the carrying out of this important work; nor do I doubt that the appeal will be generously responded to. There is, however, an important profession to whom an appeal should also be made. To the founder of this noble church the medical profession are indebted for the foundation of St. Bartholomew's Hospital; to the energy and piety of Bakers the two buildings owe their existence. There is no church in London which would probably be so interesting to the members of this great profession, and I doubt not they would come forward liberally to aid the fund for its restoration. *Belham, May 12th.* W. H. S.

BREWERY CHIMNEY SHAFT.

SIR,—Replying to some of the questions of your correspondent "J. H. G." [p. 694, ante], I consider that no good, but rather harm, results from using Portland cement in occasional courses of the brickwork, as it expands differently under the influence of heat to lime cements. Exhaust steam does no harm to the brickwork of the shaft, but the condensed water which falls down will, in time, soften the foundations unless special provision is made to carry it off.

I know one or two instances of chimney-shafts standing for some years slightly out of the perpendicular.

I consider mortar the better of the two for chimney-shafts. Portland cement seems to crack so readily under heat.

The flues from the boilers and coppers in a brewery should be so arranged that the heat is absorbed in doing useful work,—producing steam and boiling the worts,—so that what remains enters the chimney at a moderate temperature. Neglect of this will crack your chimney, besides being a great waste.

C. R. WILSON
(Brewers' Engineer).

SIR,—With reference to "J. H. G.'s" questions on the construction of a brewery shaft, I consider the only courses in cement should be at each "offset" in the shaft where the brickwork is reduced

in thickness, and should be about four courses above and three courses below the offset, making seven courses in cement. I have not heard of shafts being constructed entirely of concrete. I should consider it a risky experiment to try. Brickwork in lime mortar is about the best construction. There is an elasticity in lime mortar that is an advantage over cement mortar, for such work as this. It is not advisable to discharge much steam into a shaft, because it tends to keep the brickwork damp, ruins the mortar joints, and there is likely to be trouble in keeping the tube clean. W. J. S.

SKYLIGHTS GLAZED WITH PLATE-GLASS.

SIR,—In your issue of the 8th inst. (p. 696), you say, re "a warehouse roof in Fore-street" that the skylights are glazed with polished plate-glass in sheets 10 ft. long, and add that you have been informed that sheets of polished plate of such a size have never been fitted up in a roof before. I have frequently glazed in sheets of this length. T. W. HELLIWELL.

The Student's Column.

OUR BUILDING STONES.—X.

ON THE ORIGIN AND STRUCTURE OF THE STONES.

To properly understand the structure of rocks, which, as we have pointed out, is a very important element in considering their eligibility for building purposes, it is desirable that we should know something of their origin.

The principal rocks used in building have been formed (1) by the cooling of masses which were once in a molten condition; (2) they may have been gradually laid down as sediment in water; or (3) by the petrification of organic remains on a large scale.

The rules which apply to the selection of building stones formed in the manner firstly described, will be quite different from those made in the second and third manners, and we ought, therefore, to be able to distinguish at once the stones belonging to either group. We will first consider

Granite.

This rock has been formed at great depths within the earth's crust, and the reason why it is now found at the surface is because the rocks which once overlaid it have been removed by denudation. It seems at first sight almost incredible that so many thousands of feet of strata could have been worn away by the action of rain, frost, and other atmospheric agents, but that such is the case has been proved beyond the shadow of a doubt. Nature works slowly but surely. From an examination of ancient volcanoes in various stages of denudation, it is found that the rock which flows out at the surface as a lava, when traced downwards, generally becomes more and more thoroughly crystalline in character as it approaches its reservoir. If we examine a lava we shall find that it is by no means crystalline. Minute crystals may be seen enveloped in a matrix, and crystals which it detached from the sides of the "neck" of the volcano on its way up may be found in the lava, but its structure is more like that of glass, with various impurities in it, than that of a crystalline rock. The reason why lavas are not crystalline rocks is simply because they have cooled at the surface of the earth, and so, under very little pressure. If the same materials had consolidated at greater depths within the crust of the earth the superincumbent rocks would have exerted a much greater pressure upon them, and they would consequently have become more crystalline. This condition of things would go on until the materials, being very deep-seated, would, on solidifying, form a thoroughly crystalline rock, i.e., one having no glassy matrix whatever. Granite is a good example of such a rock, and thus we see how it is that, having once been in a molten condition, it contains no fossils or organic remains.

The following illustration is a microscopic section of a typical granite, magnified about twenty-five diameters.

The white portions marked *a* are quartz, with fluid cavities and inclusions dotted over it. It will be observed that the dots sometimes occur in lines. The unbrid-looking mineral *b*, irregularly striped, with lines running across it, is felspar. The mica, *c*, is finely striated, presenting a ragged appearance. Parts of it,

especially near the edges of the mineral, are very frequently seen as dark, almost opaque, patches. Any one looking at this section will see at once that in their endeavours to crystallise out, the different minerals have become

interlocked with each other in such a manner as to present very irregular outlines, and they have crystallised so closely together, as to leave no room whatever for a matrix to form. The quartz is often seen wrapping round the other minerals.

Seeing that the intensity and amount of heat and pressure, rather than chemical composition, so much influence the state of crystallisation of the minerals of rocks which were once in a molten state, we must not wonder that there is such an intimate connexion between the chemical composition of a rock that is crystalline and one that is non-crystalline. For instance, there are numerous examples of granitic rocks having precisely the same composition as lavas in their immediate vicinity. We need hardly remark that such lavas are not, as a rule, by any means so durable as their crystalline representatives, another instance in which structure greatly conduces to the durability of a stone. Lavas are only used locally as building materials in this country, but at several places on the Continent they are very extensively employed.

From what has been said, it appears that granite is the consolidated reservoir of a volcano; but all such reservoirs are not granites; some of them are syenites, gabbros, &c.,—equally crystalline rocks. Neither is it absolutely necessary that a volcano should be involved in the construction of granite. The fact that the molten mass is of the necessary composition, and that it cooled under sufficient pressure, is quite enough for the purpose. It may not have had any vent to the surface at all. The depth at which granite may form depends on a variety of circumstances. It would only be when a considerable proportion of the pressure (which kept the mass in a liquid condition) had been removed that it would solidify, and as this removal would be very slowly effected, it follows that it would cool with extreme slowness.

We know that the general directions along which mountain ranges run are lines of weakness in the earth's crust, and that the ranges themselves have been formed by tremendous lateral pressure. We will not now inquire into the causes of this pressure, but at once state that, under these circumstances, the conditions for the formation of granite are present.

Strata which were originally laid down in water have often been squeezed to such an enormous extent in the elevation and formation of mountain ranges, that they have been unable to withstand the pressure and consequent heat; so they have been melted up, and on re-consolidation formed granite. Subsequent dissection of the mountains in various stages, by atmospheric agents, shows us this, and also the innumerable veins springing from the granitic mass, filling cracks in the surrounding rock.

As might be expected, the rocks through which such veins run present an altered and baked appearance, and the compressing forces have frequently been so great that thousands of feet of strata have been twisted, contorted, and inverted like so many sheets of paper crumpled up.

Since the overlying rocks have been denuded and the granite brought nearer the surface of the earth, the cracks and interstices which existed in them have often been filled with secondary quartz, calcite, and other minerals.

The variations in colour presented by different granites are due, to a great extent,

to the predominating tint of the felspar. Some Aberdeen granites are of a bluish colour when seen from a little distance. This, in the majority of cases, is due to the presence of dark mica in minute flakes showing up against the clear quartz. When iron is present, felspar would be different tints of red, occasionally approaching a dull yellow colour.

The large flesh-red felspar crystals seen in the granites of Galway and Shap Fell are shown so prominently that these stones are appropriately called porphyritic granites.

Syenite.

Respecting the rock known as syenite, we have only a few words to say. According to the majority of British authorities, its essential minerals are quartz, felspar, and hornblende. The rock, both in origin and crystalline structure, has many of the characters of granite. Indeed, it is not easy to draw the line in some cases between the two. Much of the stone largely quarried for architectural purposes at Mount Sorel, in Leicestershire, and known as syenite, contains a considerable proportion of mica in addition to the above-mentioned minerals, and would, therefore, be more correctly called hornblende granite. We get syenite from Guernsey and Jersey, but as it is mostly used for road metal and similar purposes, it does not concern us at present.

Porphyry.

The rocks included under this heading vary greatly in chemical composition, colour, &c., because, as we have before stated (p. 459), it is from their physical characters that they are so-called. Quartz porphyry and its ally, elvan, are used principally as ornamental stones. They are also in some measure used in building, especially locally. In mineral composition they consist of a felsitic ground mass, in which orthoclase felspar and quartz are porphyritically developed.

The following remarks by (Sir) H. T. de la Beche are of interest:—"For durable stone the harder lavas of Devon and Cornwall, particularly when of good cream and other light colours, may be considered the best building materials (in those counties). . . . Occasionally the felspar crystals may have been decomposed and have been washed out, but the siliceo-felspathic base has remained firm, thus preserving the sharp character of the work. . . . When, however, in an incipient state of decomposition, and then too frequently prized by the mason for his work, they cannot be trusted for durability, though they often have a good appearance. They would sometimes be mistaken for fine light-coloured sandstones."*

The origin of elvan is very similar to that of granite, being, in fact, mainly offshoots or veins from that rock.

Porphyries are principally used for causeway stones and road metal, and, as a rule cannot be raised in large blocks from the quarry.

Slate.

When strata originally made of clay have undergone great pressure, but not quite enough to cause them to melt, we get the conditions necessary for the formation of slate; for that useful roofing material is simply clay in another form. Pressure has caused a molecular rearrangement of the particles which composed the clay. A microscopic examination would show that the longer axes of these particles have assumed a position at right angles to the direction of the pressure. Thus a fissility was produced in the mass, the fineness of which, for the most part, depended on the purity and structure of the argillaceous deposit. For instance, if the clay when originally deposited was not intermixed with many impurities, such as sand, pebbles, &c., it would assume a more minute "cleavage" character, as it became highly compressed, than when those impurities were present. Consequently we find in slate quarries that beds of sand which were mingled with the clay have not taken on a "slaty cleavage," whilst all the surrounding clays, free from such impurities, have.

Large cubical yellow crystals of iron pyrites are sometimes found in slates. If marcasite is present in the pyrites, they may decay, leaving holes in the slate; if, however, this mineral is absent, the pyrites yield very slowly to weathering, and some Scottish slates may be seen which

have been exposed to the atmosphere for centuries with the pyrites still sticking up from them, as fresh as on the day they were built up. Slates for roofing should be compact, and absorb but little water.

VARIORUM.

VISITORS to the International Exhibition of Industry, Science, and Art, now open at Edinburgh, will, as a matter of course, purchase the Official Catalogue, a copy of which has been sent to us. It is a well-printed and clearly-arranged guide to the contents of that interesting display. So far as we have been able to test it we find it free from errors than is usually the case with such compilations. Quite as necessary as the "Official Catalogue" to all visitors who wish to bring away with them an agreeable souvenir of the Old Edinburgh Street (which has been designed by Mr. Sydney Mitchell, architect, and is a worthy rival of the "Old London" at Kensington) will be found "The Book of Old Edinburgh," by Messrs. John Charles Dunlop and Alison Hay Dunlop, containing seventy-eight illustrations, drawn by Mr. William Hole, A.R.S.A. The book, which is published under the auspices of the "Old Edinburgh Committee," contains sketches and pleasantly-written archaeological notes of all the buildings represented in the street, and many picturesque and humorous sketches, accompanied by amusing anecdotes, besides. In typography, paper, and general get-up it is a marvel of cheapness, being obtainable at the same price as the Official Catalogue, viz., one shilling. Both these indispensable handbooks are printed within the Exhibition by Messrs. T. & A. Constable.

—Two or three books of reference which came to hand recently deserve mention. "Whitaker's Almanack" (London: J. Whitaker, Warwick-lane) in its latest edition, with supplement, contains a fund of information, carefully collated, arranged, and indexed, on a great variety of matters, and its value and usefulness are so well known that we need not say more about it here.—"The Electrician's Directory and Handbook for 1886" (London: *Electrician's Office*, Salisbury-court, Fleet-street), is exactly what its name states it to be. The information which it gives is very complete and varied, and an interesting part of the work is the biographical section, in which are given short biographies (in some cases accompanied by portraits) of most of the leading electricians and electrical engineers of the day.—"Sell's Dictionary of the World's Press for 1886" (London: H. Sell, 168, Fleet-street), contains a variety of interesting information concerning the history and development of the Press, and it exhibits some commendable improvements in arrangement as compared with last year's edition,—improvements which make it much more convenient for reference. It is a very useful volume for the office or library table.—Handbooks of a kindred character to the foregoing, are "Successful Advertising" (published by Mr. Thomas Smith, of the Mutual Advertising Agency, 132, Fleet-street) and the "Advertiser's Guardian," issued by Mr. Louis Collins, of Wine Office-court, Fleet-street. Both of these hand-books contain some entertaining reading.—From the *Buxton Advertiser Office* we have received a well-got-up and usefully illustrated supplement forming a guide to that pleasant Derbyshire watering-place.—"The Life and Teachings of Joseph Livesey," comprising his autobiography, with an introductory review of his labours by John Pearce (London: National Temperance League, Depot, 337, Strand), contains some interesting particulars of the life of a well-known social reformer. The late Joseph Livesey was one of the "Seven Men of Preston" who initiated what is known as the Temperance movement, but he was by no means "a man of one idea." On the contrary, he was possessed of broad sympathies, and more than fifty years ago, in a periodical publication he edited (the "Moral Reformer"), he called attention to the wretched way in which the poor were "housed" in Liverpool and other towns. He exposed the exactions of the house-farmer and middleman, and asked the question "Shall the bitter cry of woe never cease?" So that some of the gentlemen who raised the "bitter cry" a year or two ago at the East End of London were anticipated even in the title which they gave to their agitation. Mr. Pearce has done his part of the work well, and the volume will

* Rep. on Geol. of Cornwall, Devon, and W. Somerset (1839).

and to contain a great deal of suggestive matter.—Mr. B. T. Batsford has in the press now edition of Mr. Banister Fletcher's *Night and Day*, in the revision of which the author has had the valuable assistance of E. Edward Uttomare Bullen, barrister-at-law.—*The Journal of the Royal Historical and Archaeological Association of Ireland*, No. 60 (London: Williams & Norgate), contains an illustrated paper by Lieut.-Col. W. G. Woodruff on "The Battle-ground and Ancient Monuments of Northern Moytirra" (co. Mayo), which remains in question are megalithic. A second paper comprises "Notes on Sligo Abbey," by Mr. Richard Langrishe, V.P. Mr. Langrishe says that a great deal has been done by the owner of the abbey, the Hon. Evelyn Ashley, by building buttresses and coping the walls to preserve it from further dilapidation; he adds, "it is very desirable that it should be made a national monument, and placed under the care of the Board of Public Works, so that these interesting remains may be preserved in further destruction. The only reason, it is stated, why this has not been already done is the dislike of the local *illiterati* to give long-used burial-places, and to forego the well-established custom of digging up the bones of their predecessors." Another interesting paper (also by Mr. Langrishe) is on "Irish Church Bells."

Papineau, Door Closers.—6,061, L. Groth, Roofing Tiles.
 May 5.—6,082, T. Potter, Machinery for Building Concrete Walls.—6,086, J. Martini, Draught preventing Appliances.—6,091, C. Sliwyerman, Preventing Shocks in Water-supply Pipes.—6,099, R. Mason, jun., Valve Apparatus for Lock-closets.—6,100, W. Macfarlane, Water-closets.—6,103, E. Flint and W. Knowles, Hinges.

University College.—Professor C. T. Newton, C.B., on "Greek Inscriptions."—III. 4 p.m.
British Museum (Archæological Room).—Miss J. E. Harrison on "The Technique of Greek Vases."—II. 11.45 a.m.
SATURDAY, MAY 22.
Architectural Association.—Visit to the National Agricultural Hall, Kensington. 3 p.m.
Society of Arts (Special Lecture).—Professor George Forbes, M.A., on "Electricity."—VI. 3 p.m.

Miscellaneous.

County Surveyors' Society.—The annual meeting was held at the Holborn Restaurant, on Tuesday afternoon last, Mr. C. H. Howell, County Surveyor, Surrey, in the chair. The members were engaged for a considerable time discussing the proposed by-laws for regulating the business of the society, as drawn up by the honorary secretary, Mr. T. H. B. Heslop. These were agreed to, and ordered to be printed and circulated amongst the members. The honorary secretary was requested to obtain certain particulars as to the duties, &c., of county surveyors in England and Wales, the cost of main roads, bridges, county buildings, &c., and to prepare a tabulated statement for the use of members of the Society. A general discussion, which was of a very interesting character, took place as to the scope and working of the Society. The members dined together in the evening, the Vice-President, Mr. F. H. Pownall, Middlesex, being chairman, in the unavoidable absence of the President.

Unemployed Fund.—At a meeting last week of the Committee of the London District Government Building Employed's Unemployed Fund, a matter relative to the balance in hand was taken into consideration. The accounts show that the total amount received from the six weeks' subscription amounted to 1681*l.*, of this amount the Government contractors, Messrs. Perry & Co., generously contributed 60*l.* Consideration had been given to 135 applications, of which only ten were disqualified from participating from the fund. The total number of cases relieved after full investigation was ninety-eight first, twenty-two second, four third, and one fourth application, the third and fourth being in extreme distress, and very deserving cases, each applicant receiving 1*l.* The expenses incurred in the management and distribution of the fund over a period of nine weeks amounted to 3*s.* 8*d.*, leaving a balance in hand of 43*l.*, which was unanimously ordered to be invested in the Post-office Savings Bank, in the names of the three officers of the fund as trustees, which will form a nucleus for a like purpose should the necessity arise in the ensuing winter.

Kingsbury.—The proposed restoration and additions which will be carried out at Kingsbury Church, from the designs and under the superintendence of Messrs. Newman & Newman, in conformity with the views of Mr. Ewan Christian, the architect to the Ecclesiastical Commissioners, will consist of a thorough restoration upon the most conservative principles of the church, as it now stands. The present modern gallery will be removed; the ancient arch on the south side of the church, which has for many years been bricked up, will be opened out, and an open-timber porch erected to correspond in all respects with the original, of which engravings have been found. Upon the north side, it is proposed to erect a vestry and organ-chamber, under which will be placed the heating apparatus. The seating, which is unfit for re-use, will be removed, and replaced with new; and it is hoped that the funds will permit of the erection of a roof-screen, which appears to have formerly existed, and which no doubt formed a great feature.

An Australian Railway Viaduct.—The Werribee Viaduct, which has just been completed in the colony of Victoria, is the longest work of the kind in Australia. The structure consists of lattice-girder work. It is 1,230 ft. in length, and runs to a height of 125 ft. above the level of the Werribee river. The viaduct has fifteen spans each of 60 ft., and thirteen spans each of 30 ft. The total cost of the bridge was 120,000*l.* On completion the structure was submitted to a severe test, which it stood with perfect success.

Appointment.—By a unanimous vote, the appointment of Clerk of Works to the Chapels and Mortuary of the new Cemetery at Edmonstone has fallen on Mr. Thos. Peto Ward, of Hornsey.

Rebuilding of the "Horns" Tavern and Assembly Rooms, Kennington.—That well-known hostelry, the "Horns" Tavern, Kennington, and the Assembly Rooms adjoining, are about to be rebuilt. The new structure will have commanding frontages towards Kennington-road and Kennington Park road. The assembly-room portion of the premises as rebuilt will form a principal feature in the building. On the level of the first-floor, in the rear of the tavern, with its frontage to Kennington-road, will be the large and chief assembly-room, an apartment 76 ft. in length, and 40 ft. in width, containing a floor area of about 3,000 ft. At the northern end there will be a stage, whilst at the opposite end there will be a gallery. In connexion with the hall, and on the same level, there will be two supper-rooms, a waiting-room, and lavatories. Under the large hall, on the ground-floor, there will be a minor hall with a public room for use in connexion with the tavern. It is calculated that the large assembly room will seat an audience of about 1,000 persons. Messrs. Crickmay & Son are the architects.

Staircase Construction.—At the meeting of the Metropolitan Board of Works on the 7th inst., consideration was given to the subject of the disagreement between Mr. H. Jarvis, District Surveyor, and Messrs. Oliver & Leeson, relative to the construction of staircases at Alcey's Boys' School, Dulwich. The Superintending Architect presented a report, showing that the staircases in question are 3 ft. 9 in. wide, and of solid oak. A representative of Messrs. Oliver & Leeson stated that the stairs, being of solid oak, were as safe as though they were of stone, and reminded the Board that the matter was within their discretion by the 90th section of the Act. Mr. Jarvis, the District Surveyor, said he had objected to the wooden stairs on the ground that the 22nd section of the Act required that they should be of some non-combustible material. On the motion of Mr. Selway, the Board decided the point in dispute in favour of Messrs. Oliver & Leeson. We think the Board has decided wisely.

The Fireman's Exhibition.—The account which we gave last week of this exhibition did not pretend to be exhaustive; it was only intended to give some idea of the nature of the exhibition, and consequently we only mentioned a few typical exhibits. Among others which we might have noticed then had time and space allowed were Cullen's patent nozzles for fire-hoses; Feist's swing-joint for hydrants; and the "Phoenix Automatic Electric Fire Extinguisher and Fire Alarm," exhibited by Messrs. Thompson & Ritchie, and shown in action above the seal-tank between the hours of two and six p.m. The exhibition closes this (Saturday) evening.

Portable Fountains.—An apparatus has recently been constructed by Messrs. Merryweather & Sons for exhibition at Lisbon on the occasion of the wedding of the Crown Prince of Portugal. It consists of a complete set of portable fountains, the water being supplied by two steam fire-engines, and the jets will be illuminated at night by powerful electric lights placed underneath, the effect being similar to that which was to be seen at the Inventions Exhibition last year. The lighting part of the arrangement is undertaken by Messrs. Siemens Bros. & Co. The fountains will be fixed in a barge moored in the Tagus, the engines being placed in another boat.

Church Clocks.—A large clock has just been erected upon Blyth Church Tower, Notts. It shows time upon one dial, 6 ft. across, strikes the hours and chimes the quarters. It is fitted with all the latest improvements brought out by the makers, Messrs. John Smith & Sons, of Derby. The same firm have also just completed a large church clock at Dinton, Wiltshire, which shows time on a skeleton dial 5 ft. across, and strikes the hours on a ton bell.

The New Theatre at Derby was burned down last week. Two lives were lost. The coroner's jury found that the fire arose from a portion of the raw edge or shred of cloth accidentally catching fire at the gas hatters. The theatre was only first opened a few weeks ago.

A New Cathedral at Ballarat.—At the celebrated gold-mining centre of Ballarat, in the colony of Victoria, it has been decided to erect a cathedral for the Anglican Church. The estimated cost of the body of the building, exclusive of tower and steeple, is 35,000*l.*

A Reredos at Stonehaven, N.B.—A large and elaborate reredos has just been erected for St. James's Church, by Messrs. Earp, Son, & Hobbs, of London and Manchester. It is of stone, marble, and alabaster, in five divisions with crocketed and gabled canopies, supported by marble columns, enclosing statues in white alabaster,—that of Our Lord occupies the centre, and in the side niches are the figures of St. Peter, St. John, St. Andrew, and St. James. The work was designed by Mr. Sidney Gambier Parry, architect, London, and was executed under his personal superintendence.

Robinson's Cement.—In reference to the comments made on this patent by some correspondent, Messrs. Joseph Robinson & Co. write to us to repeat emphatically that their cement is a new material not before made, and intended to supply the place of common lime plastering where something better than that is required at a lower price than has been charged for other substitutes previously used. We must leave the manufacturers and patentees concerned to settle it further among themselves.

Table with 5 columns: Nature of Appointment, By whom Advertised, Salary, Applications to be in, Page. Lists public appointments.

TENDERS.

Table of tenders for various projects including detached residences, semi-detached houses, and construction work.

Table of tenders for various projects including music-hall, public-house, and alterations to existing buildings.

EXNING (near Newmarket).—For building new stables, &c., at Exning, near Newmarket, for Mr. Matthew Dawson. Mr. John Flatman, architect, Newmarket.

HOLLOWAY.—For the erection of three shops in Upper Holloway-road, for Mr. W. H. Chapman. Mr. J. W. Brooker, architect, Railway Approach, London Bridge.

KENSINGTON.—For the completion of the fabric of the Church of St. Cuthbert, Phillimore Gardens, Kensington. Mr. H. Roumieu Ough, architect.

LEE (Blackheath).—For various works in altering seven private houses (situate in the High-street) into shops, for Mr. S. Jobbins. Mr. A. Smith, surveyor.

LONDON.—For alterations, repairs, and bar fittings at the carpenters' Arms public-house, King's Cross-road, for Messrs. Bacon Bros. Mr. Charles Young, architect, Rochester. Quantities applied.

LONDON.—For rebuilding No. 25, Clara-street, Strand, for Mr. J. R. Church. Messrs. Bray & Webb, architects. Quantities by Mr. R. Fehlan Russell.

LONDON.—For repairs to No. 43, Fribst.-street, for M. Ludovic Noel. Mr. J. William Stevens, architect and surveyor, New Bridge-street, &c.

LONDON.—For alterations to the Victoria Hotel, King's Cross, for Mr. W. A. Baker. Mr. Arthur W. Saville, architect. Quantities supplied.

LONDON.—For the erection of a billiard-room, &c., as an addition to No. 12, St. John's Park, Blackheath, for Mr. W. Pantin. Mr. Joseph B. Wall, architect, Welbrook.

LONDON.—For the rebuilding of Nos. 3 and 4, Portland-street, Lincoln's Inn, W.C. Mr. Edward Street, architect. Quantities by Mr. Charles Poland.

LONDON.—For new premises, Warwick-lane, City. Mr. Gen. Pearson, Warwick-court, architect.

MOSBOROUGH (Derbyshire).—For the erection of a village club and caretaker's house, for Mr. J. F. Swallow. J. P. Messrs. Rollinson & Son, architects, Chesterfield.

RICHMOND.—For laying a running-path for the Richmond Athletic Association, at their new ground, Old Deer Park, Richmond. Mr. J. F. Brewer, architect.—
 F. Sims, Richmond..... £593 0 0
 Austin, Battersea..... 460 0 0
 Pierce & Lansdown, Richmond..... 423 0 0
 C. Maton, Kew (accepted)..... 419 0 0

RICHMOND.—For building a pavilion for the Richmond Athletic Association. Mr. F. J. Brewer, architect.—
 Street & Lansdown, Richmond..... £574 0 0
 Pierce & Lansdown, Richmond..... 497 0 0
 F. Sims, Richmond..... 440 0 0
 C. Maton, Kew (accepted)..... 439 0 0

ST. MARY CRAY (Kent).—For alterations to the shop of Mr. F. Stanger, St. Mary Cray.—
 Wood, Chislehurst..... £112 0 0
 Hart Bros., St. Mary Cray..... 96 0 0
 Jas. A. Taylor..... 86 0 0
 Goodwin, Edenbridge (accepted)..... 80 0 0

SANDAL (near Wakefield).—For two cottages, road-forming, and drainage of Church View-road. Mr. Abraham Hart, architect, Wakefield. Quantities supplied by the architect:—
Excavator, Bricklayer, and Mason.
 J. W. Woults, Belle Vue (accepted)..... £171 10 0
Carpenter and Joiner.
 G. Ashton, Sandal (accepted)..... 55 0 0

SOUTHALL (Middlesex).—For two pairs of cottages at Hayes Bridge, Southall, for Mr. W. Minet. Mr. Geo. Hubbard, architect, Finsbury-circus. Quantities by Mr. Sergeant, Holden-lane.—
 W. Hunt..... £999 2 0
 C. F. Kearley..... 927 0 0
 J. Elder..... 832 0 0
 A. & B. Henson, Southall..... 858 0 0

STOKE NEWINGTON, N.—For alterations and additions to the Black Bull, No. 192, High-street, Stoke Newington, for Mr. A. Hart. Mr. John Waldram, architect. Quantities supplied by Mr. H. J. Trevellick.—
 Morter..... £4,352 0 0
 Sharman..... 4,296 0 0
 Rider & Son..... 3,979 0 0
 Stimpson & Co..... 3,873 0 0
 Robt. Perkins..... 3,857 0 0
 Hicks..... 3,856 0 0
 Grover & Son..... 3,532 0 0

TROWSE (Norfolk).—For widening road and widening and altering bridges, for the County Magistrates. Mr. T. H. B. Heslop, Assoc. M. Inst. C.E., County Surveyor, Norwich.—
 G. E. Hawes..... £647 0 0
 Horace Lacey..... 465 0 0
 W. North (accepted)..... 446 10 0
 [All of Norwich.]

TOXTETH PARK.—For the completion of Maple Grove, for the Toxteth Park Local Board. Quantities by the engineer, Mr. John Price:—
 Sayce & Handle, Widnes..... £342 13 3
 W. F. Inglis, Castle-street, Liverpool..... 236 17 8
 Ireland & Hurley, Liverpool..... 222 10 3
 C. Burt, Wellington-road, Liverpool..... 220 0 0
 J. Nuttall, Moss-lane, Manchester..... 208 7 6
 Lomas, R., Alma-street, Eccles..... 212 16 0
 L. Marr, Aspen Grove, Liverpool..... 193 19 4
 McCabe & Co., Liverpool..... 194 6 3
 Anwell & Co., Park-road, Liverpool..... 189 1 9
 W. F. Chadwick, Liverpool..... 186 10 1
 Walkden & Co., Bransnose-road, Liverpool..... 167 0 0
 [Engineer's estimate..... £185.]

TOXTETH PARK.—For the completion of Moss Grove, for the Toxteth Park Local Board. Quantities supplied by the engineer, Mr. John Price, Assoc. M. Inst. C.E.:—
 Sayce & Handle, Widnes..... £536 3 8
 Ireland & Hurley, Liverpool..... 361 1 0
 W. F. Inglis, Castle-street, Liverpool..... 319 10 0
 C. Burt, Wellington-road, Liverpool..... 310 0 0
 L. Marr, Aspen Grove, Liverpool..... 300 2 3
 J. Nuttall, Moss-lane, Manchester..... 283 3 9
 E. Lomas, Alma-street, Eccles..... 283 5 3
 W. F. Chadwick, Liverpool..... 254 2 7
 Anwell & Co., Park-road, Liverpool..... 272 2 0
 Walkden & Co., Bransnose-road, Liverpool..... 245 19 0
 [Engineer's estimate..... £280.]

TOXTETH PARK.—For the completion of Sefton Grove, for the Toxteth Park Local Board. Quantities by the engineer, Mr. John Price, Assoc. M. Inst. C.E.:—
 Sayce & Handle, Widnes..... £273 8 1
 Jas. White, Alburgh Vale, Liverpool..... 211 2 11
 C. Burt, Wellington-road, Liverpool..... 210 0 0
 Ireland & Hurley, Brax-street, Liverpool..... 209 17 9
 R. Lomas, Alma-street, Eccles..... 207 13 0
 W. F. Inglis, Castle-street, Liverpool..... 206 18 0
 Jas. Nuttall, Moss-lane, Manchester..... 203 8 9
 McCabe & Co., Lambeth-road, Liverpool..... 199 11 3
 Anwell & Co., Park-road, Liverpool..... 192 7 3
 L. Marr, Aspen Grove, Liverpool..... 181 8 4
 W. F. Chadwick, Howard-street, Liverpool..... 177 18 4
 Walkden & Co., Bransnose-road, Liverpool..... 165 15 0
 [Engineer's estimate..... £195.]

TUNBRIDGE WELLS.—For alterations and additions to Ferne Hill House, Tunbridge Wells, for Mr. W. H. Walley. Mr. D. Banks, architect. Quantities supplied by Mr. J. H. Pitman.—
 Bower & Son, London..... £4,562 0 0
 Jones, London..... 4,540 0 0
 Ellison, London..... 4,522 0 0
 Sharp, Margate..... 4,510 0 0
 Brass, London (accepted)..... 4,500 0 0

VAUXHALL.—For making alterations and additions to the John Bull public-house, Taver-street, for Mr. M. Bennett. Mr. J. W. Brooker, architect, Railway Approach, London Bridge:—
 W. & F. Croaker..... £279 0 0
 W. Downs..... 767 0 0
 R. O. Bartley..... 727 0 0
 J. Beale..... 687 0 0
 A. Garratt..... 681 0 0
 Burman & Sons (accepted)..... 663 0 0

WILTSHIRE.—For the supply of 1,000 tons of Mendip Mountain stone (quarry No. 1), at per ton, broken to a 2-in. gauge, and delivered free at Woodborough and Pewsey stations, Wilt., for the Everleigh and Pewsey Highway Authority. Mr. James Pease, surveyor.—
 W. B. Beauchamp, Osammore, Shepton Mallet (accepted)..... 6 8 7 2

SPECIAL NOTICE.—Lists of Tenders frequently refer us too late for insertion. Tenders will be delivered at our office, 46, Catherine-street, W.C., not later than Four p.m. on THURSDAYS.

PUBLISHER'S NOTICES.

Registered Telegraphic Address, "THE BUILDER, LONDON."

CHARGES FOR ADVERTISEMENTS.
 SITUATIONS VACANT, PARTNERSHIPS, ADVERTISEMENTS, TRADE, AND GENERAL ADVERTISEMENTS.
 Six lines (about fifty words) of under..... 4s. 6d.
 Each additional line (about ten words)..... 6d.
 Terms for Series of Trade Advertisements, also for special Advertisements on front page, Competitions, Contracts, Sales by Auction, &c. may be obtained on application to the Publisher or Surveyor.

NOTICES WANTED.
 FOUR Lines (about thirty words) of under..... 2s. 6d.
 Each additional line (about ten words)..... 6d.
 PREPAYMENT IS ABSOLUTELY NECESSARY.

* * * Stamps must not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable at the Post-office, Covent Garden, W.C.
DOUGLAS FOURDRINER, Publisher.

Advertisements for the current week's issue must reach the Office before THREE o'clock p.m. on THURSDAY.
 The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to ADVERTISEMENTS, and strongly recommends that of the latter COPIES ONLY should be sent.

SPECIAL.—ALTERATIONS IN STANDING ADVERTISEMENTS OR ORDERS TO DISCONTINUE same, must reach the Office before TEN o'clock on WEDNESDAY mornings.

PERSONS Advertising in "The Builder," may have Replies addressed to the Office, 46, Catherine-street, Covent Garden, W.C. Letters should be forwarded in addressed envelopes are sent, together with sufficient stamps to cover the postage.

TERMS OF SUBSCRIPTION.
 "THE BUILDER" is supplied direct from the Office to residents in any part of the United Kingdom at the rate of 12s. per annum. Foreign, to all parts of Europe, America, Australia, and New Zealand, 26s. per annum. To India, China, Ceylon, &c. 30s. per annum. Remittances payable to DOUGLAS FOURDRINER, Publisher, No. 46, Catherine-street, W.C.

TO CORRESPONDENTS.

Windows.

OUR earliest forefathers got on without windows, and only went indoors to sleep or to protect themselves from storm or danger, so that their indoor occupations must have been very limited.

We have better use to make of our time, most of which is spent indoors, and the admission of light and air into our buildings has been the chief consideration amongst all civilised nations.

The word "window" is used a few times in the Bible, but there is not much indication of its origin, except such as we may gather from the description of Jabez looking out of one, proving that the sill must have been near enough to the floor for that purpose, and the opening large enough for Jabez to be thrown out of. The ancient Egyptians seem to have used all windows, as may be seen in the Pavilion of Amenhotep, and in a wall painting, both illustrated in Fergusson's "Hand-book of Architecture," pp 247-248. There is also a most interesting model of an Egyptian house in one of the glass cases at the British Museum. This model contains a range of first-floor windows, divided up by mullion and transome; and the second-floor windows (?) contain an indication of something that looks unaccountably like diagonal quarry glazing.

The palace of Darius at Persepolis, B.C. 521, contains a range of rectangular windows; but the neighbouring country of Assyria there does not appear to have been such windows. Indeed, in Egypt, Persia, and Assyria, the admission of light and air into the temples and palaces seems to have been usually obtained through the interstices between the columns and piers of a raised superstructure. As to the ancient temples, the absence of any actual remains of windows,—except in the Erechtheum, the great temple at Agrigento, and that at Paestum,—has provided food for endless discussion as to the means of lighting their interiors. The Romans used arched windows in their public buildings, but do not seem to have used much for them in their houses, being satisfied with the doors looking into the atrium and peristyle; the dining-room, however, or triclinium, was sometimes provided with a large window. The Saracens used windows certainly, but only to admit a subdued light through trellised openings.

Thus the constant and regular provision of windows in ordinary buildings for everyday

purposes, and with the special object of providing abundance of light, seems to belong to a comparatively modern period of architecture.

It is observed by Viollet-le-Duc in his article on windows (*Dic. Raisonné*, vol. v.), that the daylight introduced through an opening into a building is pyramidal or conical in form, diminishing inwards. This is so contrary to the divergent appearance of the light that it is difficult to believe the statement. The proof of it lies in the fact that a small opening admits a shorter pencil of light than a large opening. This is easily proved by holding a sheet of paper farther and farther away from a small opening until the light fades away and ceases to illumine it. Then, by enlarging the opening, light will reappear on the paper. The distance travelled by the light, therefore, depends upon the area of the opening forming the base of a cone or pyramid.

This is a most important fact as abolishing the notion that two quite separate windows of, say, one square foot each will admit as much light as one window of two square feet. And it opens up great possibilities in the arrangement of light. Some light there must be in every part of a building, but equal light diffused over every part of it is "flat, stale, and unprofitable." Keep the greater part of an interior just sufficiently lighted for practical purposes, and cast a brilliant flood charged with the rays of the sun, on to the most important feature in the building, and there will be seen an effect worth living for.

To this calculation of effect Viollet-le-Duc attributes the huge rose-windows occupying the gable ends of Mediaeval churches; their superior lighting power overruling the clear-story, and casting shadows without which all the moulding and carving in the world would be mere waste of labour. The interior of Polebrook Church, not far from Peterborough, is one that leaves an indelible impression on the mind, owing to a most artistic disposition of the windows.

It seems to have been a fate common to all styles of architecture, not excepting Greek, to become lighter and slenderer in construction as they went on; and partly from this cause, and partly from the fascination of crowding more and more stained glass into the wall surface, Gothic buildings became, as has been said of "proud Hardwick Hall, more window than wall." It is needless to repeat here that, so far as circumstances allowed, civil architecture went hand in hand with ecclesiastical, and that, so far only as requirements demanded, they differed, but no farther; it being reserved for the imitative architecture of recent times to adopt one style for churches and another for civil buildings.

The artistic effects of lighting must have

arisen from this rage for glazing, though a redeeming opportunity was given by the various tones of the glass itself.

There is a danger just now of our using more stained glass than we really want. One of the most original and refined churches of modern times, Christ Church, Streatham, is, from this cause, dependent upon gas for its light, and the fashion for stained glass in our houses has deprived many a family of the wholesome view of the sky by substituting in the upper panes such glass as the speculative builder will get at the "lowest quotation." If we would only put stained glass where we want it,—and it is undoubtedly useful in many situations,—we should be better off, and the cost of the useless glass could be concentrated into the price of the right glass in the right place.

As an instance of misplaced light, a London church may be mentioned where a little spare and elaborate fittings have recently been added at a cost that would pay for two or three complete and handsome churches. Here every pennyworth of the pains taken by the designer is wasted by the glare of two brightly-coloured windows that strike the eye from every point of view, and cast the costly materials, the delicate carving, and the rich painting into chaotic shade. If these two windows were blocked up, and the next pair, which are almost out of sight, were filled with white glass, the money's worth would be seen.

Many people, even those of such a practical turn of mind as the eminent architect to the Ecclesiastical Commission, like clear quarry glazing in their own houses, and there is undoubtedly a great charm in the comfortable "indoor" feeling produced by the visible network of lead lines between us and the outer air. Great care is, of course, needed in properly cementing the quarries into stout lead-work. To go to the other extreme, and to use huge sheets of plate glass, simply because such can be purchased for money, seems to be illogical reasoning.

The advantages of plate glass are its strength and clearness: no one wants to see a distorted image through a window; but having secured these advantages, all other practical requirements are best fulfilled by dividing the window into panes with sash-bars. They materially strengthen the sashes, and the panes are more easily and cheaply replaced if broken. If kept at least 12 in. apart, they do not materially obstruct the view; at all events, the slight obstruction is more than compensated for by the sense of indoor comfort that they supply. Let any one who doubts this try the experiment of living in a room fitted with both kinds of window.

Bearing in mind Viollet-le-Duc's demonstra-

tion as to lighting power, it will be seen that the size of the windows of a room will be regulated by the dimension of length or width that sustains them, and that an end light must be made more powerful than a side light. This, of itself, will furnish a variety of window size or window spacing that will at once relieve a building from slavish (so-called) Classical monotony. While using windows enough, and being duly thankful that we do not live in the days of the window-tax, we have to avoid the danger of too much window-surface, especially in a moderate-sized living-room, otherwise the occupants will have no choice between "melting moments" right over the fire and freezing moments in other parts of the room. The right amount of light, in the right place, not forgetting a well-lighted wall or two for pictures, and the avoidance of a blinding glare in the eyes as one enters the room, are the items of a problem that has to be solved. There is a prevalent rage for "French" windows, leading into the garden, of which fashion one can easily have too much. The draught from such windows is sharper than from an ordinary window, and if any other way can be contrived to go from a smallish room into the outer air, by means of a side lobby, so much the better.

Many people like the complete opening that can be obtained by means of French and other casement windows; but the difficulty of using sunblinds if they open outwards, or of using inner blinds, shutters, or curtains, if they open inwards, seems to give the balance of advantages in favour of the more modern double-hung sash-window. Modern ingenuity has been devoted to rendering this form of window perfect, and the contrivance for raising the bottom sash so as to introduce an upward current of air between it and the upper sash, and yet without opening the window at the bottom, is surely an achievement. If this be done by means of a deep bottom rail to the lower sash, we may look for another of those many new features that are slowly accumulating towards the formation of a recognised style; and it may be added that there is more designing to be put into a sash window than is generally supposed.

The weak point in double-hung sashes consists in the danger of the sash-lines giving way, and in the amount of "cradling" which has to be made for these weights to work in, to the detriment of real solidity and honesty of construction. Any one who could invent a vertical sash-hanging without pulleys, and applicable to large and heavy window-sashes as well as small ones, would do the world a service.

The Swedish windows, described and illustrated by the Librarian of the Institute in a former number of the *Builder*, could also be used where double-hung sashes are undesirable. Their water-tightness appears to be marvellous, and their construction far cheaper than the more complicated arrangements made in England.

Much ingenuity has been displayed by architects in combining stone transoms or mullions, or both, with wooden casements or sashes, and many of us will remember the regret expressed by one of our leading practitioners at the adoption of eighteenth-century windows, "just as we were getting Gothic work into practicable shape" (or words to that effect). Except, however, in a very lofty room, there is really no need for stone transoms to strengthen the window-opening, and, while admitting the convenience of stone mullions for subdividing a fine large window, one cannot help being sensible of a certain grittiness in the presence of a stone surface in the midst of the joinery and upholstery of a truly modern house. In halls, passages, and other thoroughfares the discordance is not felt, as a rule, and the windows themselves, owing to their positions, often assume various odd shapes to the design of which stone mullions are welcome aids.

In all periods of architecture, before the imitative styles gained the predominance, windows, where seen in position, have formed unerring indications of the purpose of the buildings in which they occur, and, unless they have been inserted in older work, are an

equally sure indication of date. Doorways, arcades, buttresses, walling are blank pages as compared with the information conveyed by windows in their successive developments from the eleventh to the sixteenth century, and even then the Early Renaissance architects preserved a manly independence, selecting and adapting just what ideas they wanted from the revival of Classic art, and thus creating a recognised style.

We have a still wider field for selection and are taking a longer time in casting aside that which, to us, is archaeological dress; but when we have consented to a convenient, practical, and beautiful set of windows, appropriate to the respective buildings in which they occur, something very near to a recognised modern style will have been formed.

GREEK PLAYS IN LONDON.

THOUGH the term "Renaissance" is generally applied to the historical period of the fourteenth and fifteenth centuries, when classical learning and taste were revived in Italy, the term might, in a new sense, be applied to our own immediate time. For, whereas classical, more especially Hellenic, culture, was, in the fifteenth century in Italy, restored through the channels of Roman history, art, and literature, the new feature of the revival lies in the directness with which we go back to Greek culture itself, as well in the study of art as in history and literature. This tendency has led not only to the modification of the ordinary university studies, and to the introduction of branches of study (such as classical archaeology) which were hitherto neglected, but it has extended its influence beyond the ordinary bounds of university work to a wide circle of lovers of Hellenic culture, who are endeavouring to reproduce what is best in the great past of Greece.

Of late, the efforts of these Hellenists have been chiefly directed toward the reproduction of the Greek drama. Oxford undergraduates led the way with the performance of the "Agamemnon"; Harvard University followed with the "Edipus"; smaller attempts were made at various places, especially at Bradfield College, while at Cambridge the performance of the "Ajax" was followed by the production of the "Birds" and the "Eumenides," and the Greek play has become a regular institution, if not officially academical, at least a part of Cambridge life.

Two similar attempts in London within the last few days show that the metropolis is also moved by this spirit of Hellenic revival, and all who recognise the good that dwells in things Greek will hail such signs of awakening and will be grateful to the promoters of such laudable enterprise. There is always some fear lest good movements may not evoke reaction when once they become "fashionable"; for this is often the price at which metropolitan publicity is bought. Yet the pure profit to be derived from such efforts will, we hope, remain, however numerous the imperfections in the work produced, and however strong the reaction which exaggeration and sham may call forth.

The first of these revivals in London was the performance of the *Story of Orestes* at Prince's Hall on Thursday, May 13th. Prof. Warr here endeavoured to condense the Orestean trilogy of Æschylus (Agamemnon, Choephoras, and Eumenides) into one drama. As the three Greek tragedies are continuous and strongly hound together, it was an experiment well worth making to produce the whole in one performance. But the copious cutting which this necessitated interferes so much with the continuity of action that we believe the experiment has proved such attempts to be futile. On the other hand, we must draw attention to Prof. Warr's translation, which is masterly in the proximity with which it follows the Greek, and the freedom and heauty of the English.

The performance itself was, chiefly owing to the very cramped space given to actors and chorus, not as impressive as previous performances of Greek plays have proved to be.

Considering these disadvantages the chorus (Argive and Athenian elders and maidens) performed its part very creditably. The drapery both of men and women was not always successful, sometimes even mediæval, and not Greek in character. Two attempts at "archaising" accurately were not successful. The first was the attempt to give masks to the Furies. The masks in the Greek drama had chiefly a *constructive* origin. The conditions of space in the Greek theatre, both with regard to sight and sound, called for the Greek masks and the *cothurnus*, the mask acting as a speaking-tube. In reproducing masks we should have also to reproduce the other conditions of the Greek stage, and the whole "make-up" of the Furies themselves, as well as of all the other actors, and the character of the accessories in the play would have to correspond. Unless complete accuracy is aimed at and a strictly and primarily archaeological spirit pervades the whole performance, it is better to give up such attempts at archaising and to adapt the plays in the less essential features to the requirements of modern taste. The same holds good with regard to the music which was composed by Mr. Walter Parratt. We cannot reproduce Greek music, and even if we could the great development of that art in modern times has affected our very organs of hearing, and the consequent requirements of our taste. The effect which the more rudimentary music produced upon the ancient Greeks, and its importance as a feature in their dramatic performances, can only be adequately represented in a modern performance by a much more elaborate form of lyrical art. The chanting of the chorus in the *Story of Orestes* was not even effective by its simplicity. Greater simplicity might have been maintained in the acting, especially of Clytemnestra, who evidently admires some of the mannerisms of Sarah Bernhardt. On the other hand, Miss Dene's rendering of Cassandra was not only intelligent, but, in the weird and visionary pathos of her prophecy, caused many a student to realise, more fully than he could from the mere reading of the Greek, the solemn grandeur of Æschylus.

No doubt the most interesting and successful features of this performance were the tableaux. The first of these represented the "Sacrifice of Iphigenia." It was designed by Mr. G. F. Watts, the background representing the coast of Aulis, painted by Mr. Arthurs Severn. There was a famous picture in antiquity representing this scene, by Timanthes of Kythnos, of which Pliny, Cicero, and Quintilian give us an account. The picture is said to have been remarkable for the success with which the artist presented the rising scale of pathos; Kalchas was sad, Ulysses deeply grieved, Aias distressed, whilst the artist refrained from painting the face of the father, Menelaos, and thus represented him as covering his face with his cloak. In an extant mural painting from the Casa del Poeta Tragico at Pompei, as well as on a relief on a small drum in the Uffizi, at Florence, we no doubt have modified reproductions of the picture of Timanthes. Mr. Watts followed these to some extent in the general arrangement of figures, as well as in the action of Agamemnon, which Lessing praises as showing how well the Greek realised the limitations of his art. Iphigenia, with head upraised, has sunk back before the altar, supported by the attendant of Kalchas, the priest, who raises the knife above the altar to deal the fatal blow. On the other side, Agamemnon covers his face with his cloak, and behind him a fury with a torch stands beside the altar as a presage of the fate which is to befall the house of the Atrides, and which governs the whole of the trilogy. Greek warriors are grouped round these central figures.

The other tableaux, designed by Mr. Walter Crane, were Nemesis, or the Return of Agamemnon; the Dirge at the Tomb of Agamemnon; and Orestes before the Areopagus. Of these the Dirge before the Tomb of Agamemnon was the most successful. Electricity, seated before the sepulchral pile of Agamemnon, with her attendants grouped about her and a background of cypress trees, was most im-

pressive. The smallness of the stage made the last tableau less impressive, especially to those who had seen the last act of the *Emmenides* at Cambridge.

The same painful feeling concerning the smallness of the stage and the imperfections of stage arrangements was certainly not experienced by those who witnessed the performance of Mr. Todhunter's play "Helena in Troas" at the Greek Theatre in Argyle-street on Monday last. It was certainly one of the most beautiful sights ever offered to the London public, and Mr. E. W. Godwin, who was responsible for the stage arrangements, may be heartily congratulated upon his successful accomplishment of a very arduous task. Upon entering the theatre, usually known as Hengler's Circus, it required no great stretch of the imagination to fancy oneself transported to ancient Greece, and this in spite of the modern audience and the galleries and boxes. For the eye was immediately attracted by the theatre proper, in which the hold attempt had been made to solve by demonstration the vexed question of the actual arrangement of the Greek stage. What was formerly the ring of the circus, was covered by boards and canvas representing the tessellated marble pavement of the orchestra, in the centre of which stood the thymele or altar of Dionysos. This orchestra or chorus was one of the earliest parts of the theatre, as the choric dances formed the earliest feature of the Dionysiac festival long before the drama itself had become properly developed. Thus we have the explanation of the introduction of the altar to Dionysos in combination with plays which make no reference to the "cult" of that deity. At one side a segment of the circle of the orchestra was cut away by the stage proper, the *scenae frons* with a background, and three entrances for the principal actors. We are told that Mr. Godwin chose as his model for the palace of Priam the so-called Temple of Empedocles of Selinus, a Sicily. Be this as it may, no fault can be found with his attempted restoration, though the mural decoration points to a later period than the age of Sophocles, which we were to expect as the supposed date of the performance. But he was right in not attempting at restoring the building in accordance with the very slight indications of early Greek art, the rather as in all probability no such archaeological realism would have been attempted on the Athenian stage. The distant view of the coast in the background, beyond the walls, was very effective, and not out of keeping with what we have reason to believe the scenic decorations in the period of the developed drama was like. No doubt in the earliest times the arrangements as regards scene-painting were very rudimentary, but towards the close of the fifth century B.C. the important position of scene-painting in the development of pictorial art, beginning with the painter Polygnotus, and the minuter drawing of characters and action in Sophocles and Euripides, must have called for a far more elaborate system of scene-painting than antiquaries have hitherto admitted in connexion with the problematical *επίσκηνα*. On a level with the orchestra, just where the extension of the stage beyond the orchestra (the *παράσκηνα*) begins, the doors through which the chorus enters the orchestra, while marble steps lead up the centre to the stage proper. These steps in the Greek theatre were probably of wood, and movable. We were glad to find that Mr. Godwin introduced polychromatic decoration into his architecture, and also used curtains freely. Without these important adjuncts Greek architecture loses much of the life it undoubtedly possessed. He might even have been bolder and more decided in the application of colour. So also the colouring of the reliefs added much to the effect. In the front of the stage slabs from the amazon-frieze of the *bigata* were let in, and these were given a dark red background, while the figures were left. Perhaps some reliefs of Dionysiac import might have been more appropriate. Even the modernness of the galleries and boxes was alleviated by the introduction of casts from the Parthenon frieze, to which a blue background

was given, while the relief remained white, giving them a little too much of a Wedgwood appearance.

The dresses were very good and appropriate. The fifteen Greek maidens of the Chorus were draped in white, with the long *himation*, and a kind of *diplois* like the figures from the frieze of the Parthenon. As they entered in procession, and swayed rhythmically to their own singing, or while the action was proceeding on the stage, sat in graceful attitudes below the stage, one realised how the Greeks with the Chorus presented to the Greeks the living and moving sculpture which has been lost to us with the introduction of the gauzy petticoat and tip-toe rope-walking of the *corps de ballet*. The dresses of the actors were also very successful. The best, perhaps, was the Tirewoman to Hecuba (Mrs. Jopling), who also, it appears to us, was most graceful in attitude and most perfect in gesture. The dress of Paris, the archer, was effective and correct according to ancient representations. He wore the close-fitting garment which distinguished the Oriental archer, and the Phrygian cap. Perhaps he might have held his bow, or worn a quiver, instead of the sword, which became singularly obtrusive in the superfluous business of kissing it before he dies. Throughout the acting was very good.

But in both these plays a deficiency, not only of the modern stage, but of modern life, became most manifest, namely, the universal awkwardness in walking and in standing. It is certainly due to our dress, but actors in Greek plays ought to study it carefully. Ancient reliefs and statues will show each phase in the act of walking. When the one foot is advanced the other foot turns outwards while rising on the ball and is then moved in an outward circle forward, whereas modern walkers keep the foot at one angle and raise it at once. This Greek walk must not be confused with the ordinary abrupt stage-walk. In standing, the modern Paris dress, especially in its treatment of the waist, has caused women to bend their back in too much. In Greek dress the outline of the figure, when the modern attitude is maintained, is decidedly ugly. One slim and fair lady in the Chorus was very graceful in her attitudes, and might easily have been taught to walk as the most graceful figure from a Greek frieze would have walked in life. Ignoring these slight defects, we must feel that we witnessed a sight never to be forgotten, and one which seemed to take us for the moment far away from London and modern life.

NOTES.

THE principle of Mr. McLaren's Purchase of Land Compensation Bill, which was read a second time last week (May 12), is sound enough. Practically its object is to enable those bodies which take land compulsorily to set off any advantages to the property left, against the disadvantages arising from taking land compulsorily or from their undertaking. It is quite clear that if without doubt the undertaking will improve the value of the property it is not right that credit should not be given, so to speak, by the arbitrator for this advantage when he comes to assess the compensation which is payable. The difficulty in regard to the scheme is in carrying it into practical effect, because while the disadvantages to the property are clear, the advantages are very often problematical, or such that they will not be a benefit to a property in its existing state. Suppose a piece of land near a house and grounds were taken, cutting off access to a river or home farm, the loss to the owner of the property as a residential one may be clear, the gain in the proximity of a station may altogether depend on the future train service. Still, if the principle of a Bill is sound it should pass its second reading, but whether this particular one if it becomes law will be found to have much practical effect seems very doubtful. However, the chance of such small fry as this obtaining the royal assent during the present session is not very promising.

THE statistics of deaths by fire, as recently set forth by Dr. Choquet, are of very considerable interest, and especially those cases which have happened in theatres and places of public resort. The latter, indeed, have been extremely prolific in this kind of calamity, no fewer than 7,000 persons having been burned between 1751 and 1885. The first ten years of this period showed only 179 victims, of which Paris supplied 21,—a proof that places of entertainment were relatively few and far between; and things went on pretty quietly until between 1790 and 1800, when it mounted up to 1,100, of whom 1,000 were burned to death all at once at a place in Istria, probably the largest human hecatomb on record. America took the lead in the next epoch from 1801 to 1830, although the total number of deaths was only 227. In the following decade, St. Petersburg had more than one large fire, by which 500 persons came to their end; but this number was greatly exceeded between 1841 and 1850, the total of deaths amounting to 2,144. Of these, 1,670 were carried off at one swoop in a Chinese theatre at Canton, and 200 more in a Canadian theatre at Quebec. The next twenty years showed a relaxation in the roll of deaths from this class of accident, there being only 345; but there was a great increase in the next fifteen, the total amounting to 1,845. It must be remembered, however, that there has been within that period a great development of theatrical entertainments in all the large cities of the world, though, on the other hand, the means for providing for the safety of visitors have been very much more attended to than formerly. Paris, with its numerous minor theatres and *café-chantants*, has been, on the whole, remarkably free from deaths by fire, not more than 71 in twenty-five years. This is not bad, considering that the theatres number 32 and the *café* concerts 56, which are visited yearly by at least eight million people. Considering, too, that the Porte Saint Martin has been burned twice in the present century, and the *Ambigu-Comique*, the *Gaieté*, the Italian, and the *Vaudeville* each once, it is surprising that the total deaths at these occurrences only amounted to five, the fires fortunately happening when the theatres were empty.

WE in England are generally credited with an undue degree of Philistinism as regards art matters. It may, perhaps, be some consolation to know that other countries are as bad as ourselves, and that even Italy, with her professedly artistic life, is not always free from blame. A proof of this is shown in the art history of Florence. In 1431 Lucca della Robbia built a beautiful singing-gallery for the Duomo, while two years afterwards, Donatello made another to match it, the bas-reliefs on these being objects of the deepest admiration. In 1688, when the wedding of Prince Ferdinand with a Princess of Bavaria was celebrated, these galleries were taken away to make more room, and placed in one of the rubbish chambers belonging to the cathedral works, and there they remained until 1845, when they were taken to pieces and put into one of the magazines of the fortress, whence they found their way into a cellar in the Chapel of the Medicis. Finally, Professor De Fabris found them in 1870 in another cellar, covered over with mud brought in by the Arno, which had overflowed into it. The bas-reliefs, however, had been taken off the galleries and were stored away in a dark room forming part of the building occupied by the *employes* of the Duomo, not only utterly unknown to the public, but as described in a current document "*Mala mente visibili*,"—scarcely to be seen, at all events, without the aid of a lantern. Proud this ignoble position they were eventually rescued, and placed where they are now in the national museum known as the Bargello. The ten bas-reliefs of Lucca della Robbia, the subjects of which are singing and dancing boys and girls, are probably some of the most exquisite groups, both in design and execution, that can be found all the world over. The whole story has a striking resemblance to that of the underground marbles in the British

Museum, though with the difference that there seems to be no immediate prospect of delivery for the latter.

A GAIN the old, old story. Such may explain any one who takes note of the case of *Botterill v. The Ware Board of Guardians* just decided by the Court of Appeal. It is the old story of a contractor suing his employer, going into an expensive litigation, and being held not entitled to recover, because there was no final certificate from the architect or the engineer as the case may be. "It is common," said Lord Justice Bowen, "for contractors who put themselves in the power of the engineer, or surveyor of the employers, to bring actions under a sense of supposed wrong, in the wild hope of somehow or other getting a decision contrary to strict law." That law is, that without a certificate, a contractor is not entitled to be paid, unless the certificate is withheld by fraud and collusion. It is true that in the case of *Pawley v. Turnbull* (Roscoe's "Digest of Building Cases," p. 27), a builder was held to have a right of action, because the architect in regard to the certificate had acted "improperly and unfairly." But such impropriety and unfairness must be by the light of the last case in the Court of Appeal and other decisions of tribunals of less authority, clearly be such as in the eye of the law would be equal to fraud. The lengthy and expensive litigation, the cost of which will be borne by the plaintiff in this case, should be a warning to all contractors not to enter on these forlorn hopes. We have over and over again pointed out the sanguine recklessness with which contractors enter into contracts by which they are absolutely at the mercy of engineers and architects, and how futile it is at the eleventh hour to try and escape from the bonds they have made for themselves. The cost of an arbitration of twenty-two days, or of a trial before a judge, and an appeal to the Court of Appeal are the substantial items to set on the debit side against the sum of 670*l.*, which the defendants were willing to give the contractors, not as their legal right, but simply from good nature.

THE *Daily News* of Monday last admitted to its columns what can only be described as the despairing wail of a confirmed and unreasoning "Anti-Scraper," in the form of a letter from a correspondent "N. M." He writes:—

"There remains in London one ecclesiastical building of the twelfth century yet unrestored, and lovers of early Medieval art have been hoping that this one had been overlooked by the destroyer, ycleped restorer. It appears now, however, that the fiat has gone forth. To-morrow, perhaps, an army of irreverent scrapers will be turned loose in the venerable church of St. Bartholomew the Great, with instructions to obliterate every trace of antiquity from its walls. There is, perhaps, only one way of preventing this dreaded consummation, which is to withhold the supplies; and it is devoutly to be hoped that the subscriptions to the restoration fund will be only sufficient to meet the really necessary repairs, so that the restorers may be restrained by lack of means from undertaking any works tending to rob the church of its venerable appearance."

We wonder whether the writer of these rabid sentences saw the interior of the church as it was up to within a week or so ago? The idea that "lovers of Medieval art" could have indulged the hope that the church would be allowed to remain in its deplorable and despoiled condition is absurd to a degree only equalled by the audacity with which it is assumed that "an army (!) of irreverent scrapers" will be instructed "to obliterate every trace of antiquity" from the walls of the building! The writer either does not know what is proposed to be done, or he wilfully misrepresents the proposals of the Committee and their architect. His diatribe would not be worth notice in these columns except as a specimen of the length to which some of the neck-or-nothing "anti-restorers" can go in the direction of wild and baseless assertion.

THE project for the erection of a St. Gothard monument, in commemoration of the piercing of the tunnel through that mountain

has now taken a definite form. It was originally intended to place the monument in some prominent position on the mountain, either at Göschenen, on the Swiss side, or at Airolo, at the Italian end of the tunnel, but this has been abandoned, and it has now been determined to erect the work at Lucerne. A model of the monument has already been executed by the well-known sculptor, M. Richard Kissling. According to the new plan an artificial island is to be constructed in the Lake of Lucerne, not far from the quay, and near the Schweizerhof, which is to serve as the pedestal. The sculptor's work represents a young man, mounted upon winged wheels, personifying the genius of the age of steam travelling. On two of the sides of the socle will be medallions, containing the busts in relief of the engineers of the tunnel, MM. Louis Favre and Alfred Escher.

POLITICAL disturbances in Greece happily do not seem so far to have retarded archaeological work; the excavations of the French school have begun again at Delos, and the *Δελφών της Έστίας* (No. 474) reports that the American school is just about to set to work at a systematic exploration of the ancient theatre at Thoricus. "Thoricus et Brauronia, olim urbes, jam tantum nomina," so wrote Pomponius Mela in the first century A.D., and it is noticeable that Pausanias makes no mention of the place: probably the ruins were inconspicuous. Since then the fortunes of Thoricus (now Port Mandri or Tberiko) have looked up again. Important mining operations from the Laureium mines are carried on there. To some of us the place still owes its sanctity to Makronisi, the "Long Island" which shelters its harbour. There Helen rested when she fled with Paris. The theatre, which is to be the scene of the American excavations, is noted for its unusual form; it has also a pointed gate similar to the one at Tyrus. On the promontory of the town the ruins of the fortifications built by the Athenians in the Peloponnesian war still remain. There is also, on the west side of the theatre, a Doric building, the purpose of which is uncertain.

SOME "Proposals for Antiseptic Drainage" made in a pamphlet, sent to us by Dr. J. M. Lownds,* indicate that he has not much practical acquaintance with the subject, although he writes of sewage, sewage-farms, reservoirs, and pumping-stations as if he had. The working of his proposed system would come to a deadlock in a hundred places at once, in a town even of the 20,000 population he mentions, to say nothing of London, of which he makes further mention. There is one saving proposal, and that is all. Where a cess-pool must be made for the reception of liquid sewage, Dr. Lownds proposes to cover the surface of the liquid with a film of layer of "oil containing about ten per cent. of an antiseptic such as terebinte oil, crude creosote, carbolic acid, &c." He has for eighteen or nineteen months preserved urine in a glass vessel exposed to sunlight, air, and heat in a conservatory, "free from decomposition and smell, as at first, and the mucus is just as it appeared when it settled down." Where it may be proper to prevent this decomposition the method might be tried, as it seems to effect the purpose.

THE drawings made for Mr. Ruskin for a screen in the same room with Mr. Goodwin's drawings of the Fine Art Society's galleries, are exquisite specimens of what illustrative drawing of architecture should be, a large portion of them being of architectural subjects. The artists are Signor Alessandri, Mr. Frank Randal, Mr. Fairfax Murray, Mr. T. Rooke, and Mr. W. G. Collingwood. Mr. Rooke's drawing of one of the richly-coloured stained-glass windows from Chartres is a splendid piece of work, with almost the deep sombre glow of the glass itself. Mr. Randal's drawings of the porch and of the lion and dragon sculptures at the cathedral of

Bergamo, and the Tabernacle at Santa Maria Maggiore at the same place, are models of illustrative architectural water-colour drawing. The whole of the small collection shows the most conscientious work, with a desire to realise the effect of the original, at whatever cost of labour and patience. Architectural draughtsmen and students should not miss looking at them.

AT the International Art Exhibition to be opened in Berlin on Sunday, the 23rd, more than a hundred English artists will be represented. The total number of their works, to be shown in a separate compartment, will be about 130, of which sixty are oil-paintings, fifty water-colour drawings, and twenty sculptures. The Exhibition is expected to represent the best work of the leading German artists of the day.

THE Burlington Fine Arts Club have had on view for the last fortnight in one room in their house a small but very interesting and valuable collection of illuminations from manuscripts, principally Italian and French. These include some very large, fine, and elaborate pictorial initials, letters enclosing paintings, &c.; there is very little of mere decorative borders or letterings, but there are one or two very beautiful Arabesque borders. The examples of the Venetian School include some cuttings from Ducal commissions ("Ducates") from the Venetian Senate to individual persons, officers, &c., in which the portrait of the Commissioner was usually introduced. These are very fine in execution, and, being as they are, mere ornaments to a State document, are worthy of the city of Titian.

FROM the *Berliner Philologische Wochenschrift* (May 15) we learn that Dr. Schliemann intends to crown the romance of modern archaeological enterprise by the excavation of the oracle-cave of Trophonius. We were not aware that the exact site of this wondrous cave was known, but no doubt Dr. Schliemann holds the clue. The memory of Trophonius and his brother Agamedes is, not doubt, enshrined in the heart of every architect, so we need not recall the excellent stories that Pausanias tells of their buildings; they were at work before Dædalus himself, they were men "dear to the immortal gods," men "wonderful at building temples for the gods, and palaces for mortals," and above all things they built "strong treasure-houses" for Minyas at Orchomenos, for Hyrieus at Hyria, for Augias at Elis. It is at Lebædia (Livadia) that Dr. Schliemann intends to set to work, where the oracle of Trophonius was consulted by Croesus, and again by Mardonius. It kept up its prestige long after the other oracles of Æolia were dumb. It may be that the cave still holds strange treasures of curious idols and quaint votive offerings. Anyhow, the exploration is the fitting sequel to Dr. Schliemann's work on the semi-mythical sites of Troy, Mycenæ, and Orchomenos.

AT Messrs. Tooth's gallery in the Haymarket there is opened to-day a collection of paintings by M. Tissot, entitled "Pictures of Parisian Life." These consist of sixteen paintings all of the same size, and arranged round the room as a series. They are not on the small scale and in the highly-finished manner in which M. Tissot used to paint London Society when he lived in England; he paints on a larger scale now, and artistically in a far inferior manner; the flesh tones are in too many cases crude and untrue; the texture hard; the figures on all the planes of the picture painted up to the same degree of force and brightness, at least in some cases, as in "The Amateur Circus," where the ana-tour down in the ring seems to be on the shoulder of the lady in the foreground. Artistically, this is a great declension from the artist's old style; but, in some other respects, the pictures are exceedingly clever and bitterly satirical. We are shown the "fashionable beauty,"—a soulless doll walking calmly between two rows of admirers; the girl "without dowry," also a doll, and evidently waiting to

* No publisher's name.

catch some one; the "political woman," who has married an old man she expects will become a Minister; the woman of fashion brooking herself in the hall for her next rendezvous; "painters and their wives" sitting down to lunch after "varnishing morning"; the "provincial women" with their father, who have come too early to the Prefect's reception, and are open-mouthed at the splendour of the empty rooms. The manner in which the various shades of society are discriminated is worth note; the banking society in "the fashionable beauty" who is only in a certain set) is quite distinguished from the style and manner of the personages in "The Woman of Fashion," who belongs to the best set. This is all very clever, but it is not pleasant, and the painter is no more in earnest than his personages. He has been producing a popular picture show; that is all. It is not a very high use of art; but the whole set of paintings is a curious commentary on Feuillet's recent novel, "La Mortie."

ARCHITECTURE AT THE ROYAL ACADEMY.—IV.

No. 1,628, "New Offices, Legal and General Life Assurance Society, Fleet street," is another building by Mr. Edis, an example of the application of terra-cotta to street architecture, though the fact of the employment of terra-cotta is not indicated in the uncoloured pen-drawing in which it is shown. The ground-work, with a Roman triglyph cornice, is very boldly treated; the porch of the principal entrance is carried on fluted columns with the lower portion of the shaft covered with unplastered or rather modelled ornament; a plain massive rusticated pier between the two windows gives further value to the decorated surfaces. The building serves to show how much decorative effect the employment of terra-cotta gives scope for, without extravagant cost, and (which is more important) in a material far less affected by London atmosphere than an ordinary building stone.

1,630, "Cheltenham Grammar School: accepted Design," Mr. Henry Hall. We published this drawing recently. The plan is not completed, as it should have been. The school, with large square mullioned windows, is set back from the road, a courtyard being left in front of it, flanked by residential blocks. It is a pleasing-looking building, suitable for its purpose.

1,631, "Almshouses at Charlton, Kent, built by Trustees of the Dutch Church, Anstifnians, C." Messrs. T'Anson & Son. A plain brick building of Late English type, the centre apparently an administration block, higher than and projecting beyond the wings, which are plain in their neatness." No plan.

1,632, "Business Premises, Foregate-street, Chester," Messrs. Grayson & Onld. An attempt to do something in keeping with the old Chester architecture, but in a more massive style. The ground-floor has round arches with no impost, is bay an open loggia, after the Chester fashion; two bays forming shop-windows. The windows above are mullioned, and the gable ends are filled up with scrolls. Generally picturesque, but rather wanting refinement in detail, and a by no means good drawing, in this respect certainly not vindicating its favourable position on the walls.

1,636, "Premiated Design for the New Baths, Stockport." Mr. W. G. B. Lewis. A neat, domestic-looking building, with no show-out, but, nothing in its character to indicate its object; it looks rather like a private house, with a one-story addition for billiard-room at the side. No plan.

1,639, "National Liberal Club: Whitehall-front," Mr. A. Waterhouse. A powerful rather loaded water-colour drawing, giving an effective view of this part of the building, with the polygonal angle tower seen on the left, the effect of the balcony on heavy corbels running under the second-floor windows, and coping against the sides of the projecting gables, tying the whole together, is well shown in this drawing, which generally conveys very well the massive character of the building.

1,641, "New Premises for the College of Receptors, 2 and 3, Bloomsbury-square," Mr. Finches. A building rather heterogeneous

in detail; panelled pilasters à la Renaissance with Gothic cusping in the middle as an ornament; square-headed windows with mouldings receding as in Gothic work, but, nevertheless, with (apparently) the outer moulding standing out beyond the wall-face, as in a Classic architrave; the whole suggests an effort after originality by combining details not generally combined. The combination is not unsuccessful in itself; at least, it is not owing to that peculiarity that the building is not very pleasing, but to a want of general refinement.

1,646, "Council House and Art Galleries, Birmingham," Mr. Yeoville Thomason. The sort of architecture that delights the heart of your Birmingham man *pur sang*: large, costly, and respectable, without a spark of artistic feeling or originality. A good water-colour drawing of the architectural draughtsman style, with a sufficient number of carriages and people.

1,648, "Harrow School: New Museum and Class-rooms," Mr. Basil Champneys. A brick Queen Anne building, with the usual illogical details, which the fashion for a particular epoch alone makes people admire, but with a good many pleasant points of treatment in spite of this. The corbelled balcony running along part of one side, with the picturesque bay windows at each end, is one of these; also the open arched staircase in the angle of the other front. No plan; so that we cannot tell the least how far these architectural features lend themselves to the arrangement of the plan, or express or emphasise it.

1,655, "The Guildhall School of Music, now being erected at Backfriars for the Corporation of London," Mr. Horace Jones. We gave the elevation of this building some time ago. It is a square Italian building, with rusticated ground story, very plain, the only special feature being the insertion of carving in the spaces which would otherwise be the second-floor windows, excepting the end ones; this portion of the building being raised higher than the rest, and we presume marking the concert-hall. No plan. The building is, we very little doubt, practically suitable to its purpose, nor does the exterior sin against good taste in any way; but its purely architectural merits are certainly of too negative a description to have been worth all this paper and colour and wall-space.

1,656, "Design for the Mappin Art Gallery, Sheffield," Mr. J. D. Webster. This, we imagine, should have been labelled "competition design." It is not the selected one, but, as far as exterior architectural design, it is as superior to the selected one as light to darkness. No plan; and therefore we cannot form any judgment as to whether the arrangement and practical treatment of the building would or would not have justified its selection. The building has something the look of a Classic church in outline and composition. It has a very picturesque octagonal turret and a large semicircular annexe, the lower story of which forms an open porch. The remainder of the building is apparently in a three-aisled form, with clearstory windows, which would not be much seen from below and are plainly treated, with the practical object of giving as much light as possible. The outer side walls are solid and plastered, with statues in niches between the pilasters. It is shown in an admirably-executed pen-drawing. It is a great pity the author did not add a small plan and section to indicate his practical treatment of the building. The exterior treatment is very pleasing and original.

1,662, "Chelsea Vestry-hall," Mr. J. W. Brydon. A large elevation of this Queen Anne vestry-hall, the centre portion of which seems to be modelled on details from St. Martin's-in-the-Fields. We illustrated the design at the time of the competition.

1,665, "Cheltenham Grammar School: competition design," Messrs. P. Thicknesse & W. E. Willink. A design showing the same general arrangement as the accepted one, the school thrown back, and accessory buildings flanking the space in front, so that, we presume, this general arrangement was part of the programme; but in this case the end of the school building is turned to the road, instead of the side. The building is a great deal more picturesque one than the accepted design, but as no plan is given with either, it is impossible to give any judgment as to their real practical merit for the purpose for which they were intended.

1,667, "Salcombe College, Loughton," Mr. James Cubitt. We presume a girls' school, treated in a picturesque, homelike style; an attractive building to arrive at, as a girls' school should be. No plan.

1,663, "London and County Bank, Kensington; New Premises," Mr. Alfred Williams. A richly-treated elevation of Late Gothic detail; the bank only marked by large mullioned windows on the ground story. Some of the details are of Early Renaissance type, but mixed with details more decidedly Gothic than are usually found in this combination. It is not refined architecture, but it is a creditable attempt to give something more of architectural effect and interest to a bank than bankers usually care for; this class of professional men being in general, for some reason, more utterly and stolidly opposed to architectural beauty or picturesqueness than any other class; the bad effect on the mind of continually handling money, we presume.

THE "SHIPPERIES" EXHIBITION, LIVERPOOL.

As the various sections of this Exhibition are got more into shape, the real scope and interest become more apparent. But there is still an immense amount of work to be done before the display can be said to be complete. The workman's hammer is heard in all parts of the building, and empty stalls are gradually filling. But the annex set apart for "machinery in motion" remains almost a chaos, and it must be some weeks before the whole of its contents can be in working order.

The most conspicuous, perfect, and not the least interesting section of the exhibits is that of the marine models, which are arranged on each side of the central main avenue; and from a scientific point of view, as illustrating the history of shipbuilding in Great Britain, and, indeed, also in Europe and America, during the last century, this collection is highly instructive, not only to the shipbuilder and engineer, but to all men of intelligence. The list of exhibits in this department occupies fifty-six pages of the printed catalogue. These models are for the most part of excellent workmanship, and are contributed by the Royal Naval College, Greenwich; the Bureau Veritas, Paris; Messrs. Laird Bros., Birkenhead; Sir W. G. Armstrong & Co., Newcastle-on-Tyne; the White Star Line, Liverpool; Messrs. Henderson Bros., Liverpool; D. J. W. Henderson & Co., Portico, Glasgow; the Cunard Steamship Company; Imman Steamship Company; National Steamship Company; Cayzer & Co., Glasgow; Guion & Co., Liverpool; Denny Bros., Dumbarton; John Reid & Co., Port Glasgow; R. Napier & Sons, Glasgow; G. L. Watson, Glasgow; Messrs. Alex. Richardson and St. Clair Byrne (both naval architects, of Liverpool); the Liverpool Model Yacht Club, &c.

The specimens of naval architecture thus brought together of course form one of the chief features of an exhibition whose very name implies that the illustration of the shipping of the civilised world and its appliances is its almost main object.

This series of models comprises nearly every known class of vessel. The iron-clad man-of-war (in many instances accompanied by drawings and sections explanatory of the construction), the ocean liner, the cargo-carrying sailing ship, the Channel passenger steamer, the steam yacht, the river-ferry and towing steamer, and the most modern type of outer and schooner yachts. Along with these are many examples of our now-obsolete wooden sailing frigates and other wooden ships, down to the collier brig of a century ago. There are also excellent models of past and present light-ships, lifeboats, &c., showing all their arrangements and equipments. A more complete marine show has probably seldom been got together.

As connected with steam navigation, Mr. John Dickinson, engineer, of Sunderland, exhibits a patent crank shaft, made of separate pieces and fitted together with screw bolts, and thus capable of repair at sea. It is essentially, he says, a "built shaft," being more easily taken to pieces and put together than any other shaft extant; and in the event of a flaw taking place in any part of the shaft, that part may be replaced at a fraction of the cost of the whole shaft. By carrying a spare web and pin and two shafts, should a breakdown occur at sea, the faulty part could easily be replaced by the

engineer and assistants without the expense and risk of taking the ship into port. A sound forging is ensured in the shafting owing to its being made in short, straight, easily-handled lengths. The shaft exhibited is a very fine piece of workmanship. The web and pins are cast-steel, and the forgings of iron or steel. We are informed that several steamers have been fitted with this shaft.

Messrs. Vicars & Co., of Sheffield, exhibit two screw-steamers blades of cast steel, duplicates of those supplied by them to the Cunard steamers *Umbria* and *Urania*, of 7,000 tons. Messrs. John Brown & Co., Atlas Works, Sheffield, have a Siemens steel furnace-front, flanged by hydraulic pressure in one heat, as made for the steamers building for service at Queenborough. The same firm also show an Ellis's patent steel-faced armour-plate, tested by a twelve-ton service gun with chilled cast-iron Palliser projectiles (256 lb. weight each), charged with 50 lb. of powder, at a range of ten yards. The result of three shots in different parts of the plate is an indentation in each instance about half way through, but scarcely any bulge or crack is visible at the back of the plate, which is a 10-in. one. Had the plate been of iron only, it is said it would have been pierced completely through; or if of steel only, it would have been broken up into pieces.

The "Mersey Forge Company," and Messrs. C. Cammell & Co., of Sheffield, show some massive iron forged-work for cranks and main shafts for large ocean-going steamers.

Messrs. Doulton's Trophy, which we mentioned in last week's notice, next attracts attention. This structure, which is in itself an exponent of the use to which Doulton ware may be applied in decorative art, is a pagoda-like design, square in plan, and entered by arched doorways from all four sides. There are also four detached stands, ornamented with porticos, &c., situated at each corner of the area formed by the dome of the Exhibition Building, under which the whole group stands. Their furnishing is not yet completed, but the centre trophy is intended to contain samples of Doulton ware in all its applications, besides some specimens of stained glass produced by a new process; while the corner stands are to exhibit stone-work, fire-proof flooring, chemical ware, sanitary appliances, &c. It will probably be a fortnight before these stands are really finished.

The New Perry Brick Co. exhibit some good moulded brickwork, of a uniform brownish-red colour, the decorative devices being generally sharp and well formed. The "lock-jaw" roofing tiles patented and manufactured by Mr. Charles D. Phillips, of Newport, Mon., have been chosen by the Aylesbury Dairy Company for the roof of their extensive building.

Among the exhibits from Douglas are specimens of a fine-grained grey limestone from Castletown. It is stated that Castle Rubin was built with stone from the same quarry 900 years ago, and that it is in almost as perfect a state as when first erected. Messrs. Stone Brothers, of Bath, have on view specimens of a Bath stone which they claim to be specially durable. They quote a report of Mr. J. L. Pearson's upon work completed twenty years ago with it, and which had been exposed to the direct action of the sea. Mr. Pearson says:—"I found it had acquired a hardened surface on which the weather seemed to have had no influence, and I found it had deepened in colour to a rich yellow tint, toned down in places by a grey lichen which had grown on its surface, and which is a sure sign of a good weather stone."

Messrs. Fred. Jones & Co., of London, devote a stall to their patent silicate cotton, or "slag wool," for making walls, partitions, ceilings, and floors fire and sound proof,—the best material for the purpose which has been brought out; and Mr. T. I. Constantine shows specimens of his "Treasure Cooking Ranges." Messrs. Pendleton & Co. exhibit Wright's patent "As you Like it" grate, which we described and illustrated in our issue of Oct. 17, 1885. Mr. Muller, of Birmingham, has a gas apparatus for lighting places where coal-gas is not attainable. This gas being produced without fire or heat, he calls it "The Alpha patent Air-gas Apparatus." It is a compact and portable machine.

In the machinery department proper, the most striking objects at present on view are locomotive engines. One, called the "City of Liverpool," manufactured at the Crewe works of the London and North-Western Railway, is a remarkably fine piece of workmanship. It

is one of the three-cylinder compound passenger engines, on Webb's system, which we before noticed in the Inventions Exhibition, and has two high-pressure cylinders, 14 in. by 24 in.; one low-pressure ditto, 30 in. by 24 in.; and coupled driving-wheels 6 ft. 3 in. in diameter. Among other locomotives is the "Victoria," by Messrs. Sharp, Stewart, & Co., of Atlas Works, Manchester, made for the Lancashire and Yorkshire Railway; and one by Messrs. Black, Hawthorne, & Co., Gateshead-on-Tyne, made for the Brazil Great Southern Railway. This latter is fitted with elaborate iron "guards" back and front, for removing obstructions.

In strong contrast to these powerful modern machines is their neighbour, "Locomotive," said to be the first that ever drew a passenger train on any railway, and which is the type of engine which led up to the construction of Stephenson's "Rocket," which figured at the opening of the Liverpool and Manchester Railway a few years afterwards. Certainly in its small size and feeble and elementary appearance it sets off to advantage the modern work among which it stands, and illustrates the enormous strides which have been made in mechanical engineering during the last half-century.

Messrs. Schaffer & Budenberg, of Glasgow, exhibit their patent pressure and vacuum gauge, patent hydraulic gauges, automatic expansion regulator with governor for steam-engines, and other inventions.

Messrs. Moser & Sons, of Borough High-street, London, have their patent fan-forges and fan-blowers on view. Their improvement on others consisting in the construction of the fan, and the method of driving it, by which they are said to be the most powerful yet produced, the use of bands being avoided, and fly-wheel and multiple-wheels substituted.

Messrs. Henry Pooley & Son, of Liverpool, exhibit a variety of their weighing-machines and weigh-bridges, but their most important exhibit is a set of their locomotive engine balancing tables, fixed in the main avenue. These tables are eight in number, arranged in pairs, and so adjusted as to give separately the weight distributed on each wheel of an eight-wheeled locomotive engine.

Messrs. Lockwood & Carlisle, of Eagle Foundry, Sheffield, have their "patent double-acting metallic piston packing-rings and spring" on show. With these they claim to secure thorough steam-tightness with the least possible amount of friction; springs that are not liable to break or lose their action, and may be simply and easily adjusted when required; in conjunction with a system of packing-rings which are at once strong, elastic, and durable.

It is almost premature to enter into any detail as to the foreign contributions to the collection, for the galleries in which the Italian, French, and Belgian treasures are to be displayed are only just beginning to fill up their empty spaces. What is already to be seen gives great promise, however, that in productions of art, bric-a-brac, and articles of vertu generally, this portion will perhaps be the most attractive in the Exhibition.

In the Italian Court, for instance, A. Bancer, of Florence, has a beautiful selection of ebony inlaid with ivory, carved work in oak and walnut, &c., and in both the French and Italian Galleries some apparently fine marble sculptures are in course of arrangement.

Among the miscellaneous exhibits, which it is impossible now to particularise, there are many of great interest and value. The Liverpool trophy of imports and exports is a commanding and interesting object. Messrs. Elkington & Co. have an extensive collection of silver and plated goods, including two large shields executed in *repoussé* work. The principal pianoforte and other musical instrument manufacturers are largely represented. Messrs. Gruisen & Son, Dreaper, Cramer & Co., Metzler & Co., and others have each exhibitions of pianos, chamber-organs, &c., showing the most recent improvements in their construction. Messrs. R. J. Ward & Son, of Liverpool, exhibit brass instruments and flutes in the actual course of making. Messrs. Charnot, of Vardour-street, London, have also a good show of stringed instruments.

In the grounds outside the Exhibition building an "Ashantee Village" an "Indian Pavilion," and a "Settlement of Laplanders" are in course of preparation.

The late bad weather has, however, greatly impeded the outdoor operations; but with the

return of sunshine and the result of a few days' labour, both the exterior and interior of this very extensive Exhibition will no doubt wear a greatly improved aspect.

VINEGAR-YARD AND AN OLD PLAY-HOUSE.

A MEMORIAL OF DICKENS.

For shouts were heard mid fire and smoke,
And twice ten hundred voices spoke,
"The Haybones is in flames!"
And lo! where Catherine-street extends,
A fiery tale its lustre lends
To every window pane.

REFLECTED ADDRESSES.

The offices of the *Builder* in Catherine-street look out towards the back on to a little plot of ground, barely one rood in extent, which had apparently escaped the notice of London topographers. Whatever may be its previous history, this piece of land now belongs to the Metropolitan church of St. Mary-le-Strand, whilst its elevation above the surrounding level indicates how freely it was used for interments. A long-neglected and, until recently, noisome open space, it some time ago came to the notice of the Metropolitan Public Gardens Association, and a faculty having been obtained, the rector of St. Mary-le-Strand, the Rev. Canon Tagwell, gladly giving his consent, the space has, at a cost of 180*l.* been made presentable by being covered with tar pavement, a small flower-bed being provided and a couple of trees planted, though the space is so hemmed in that any attempt at anything ambitious in the way of horticulture or arboriculture would be futile. A number of seats have been placed about the ground, and an appeal is made by Lord Brabazon for funds for the erection of "a handsome drinking-fountain in memory of Charles Dickens," for this burial-ground is by many people believed to be the one so graphically described in "Bleak House," where poor Jo's only friend "Nemo" was interred, and at the gate of which Lady Dedlock was found dead.* Dickens describes the graveyard in question as,—

"A hemmed-in churchyard, pestiferous and obscene, whence malignant diseases are communicated to the bodies of our dear brothers and sisters who have not departed, while our dear brothers and sisters who hang about office backstairs,—would to Heaven they had departed!—are very complacent and agreeable. Into a beastly sort of ground which a Turk would reject as a savage abomination and the Caffre would shudder at, they bring our dear brother and departed to receive Christian burial. With houses looking on on every side, save where a reeking little tunnel of a passage gives access to the iron gate, with every sillary of life in action close on death, and every poisonous element a death in action close on life,—here they lower our dear brother down a foot or two; here sow him in corruption; he is raised in corruption, an avenging ghost at many a sick bedside; a shameful testimony to future ages how civilization and barbarism walked this howling island together. Come night, come darkness, for you cannot come too soon or stay too long by such a place as this. Come straggling lights into the windows of the ugly houses; and you do us no injury therein do it at least with this dread scene abroad. Come flame of gas burning so sullenly above the iron gate on which mentioned airy deposits its white-cintments slimy to the touch."

This is no very exaggerated picture of the condition of many town graveyards thirty-five years ago, and it is asserted that Dickens's graphic pen had much to do in hastening the closing of urban burial-grounds. While speaking of the alleged associations of the place with Dickens's "Bleak House," we may be permitted to point out that the Metropolitan Public Gardens Association, with the *Daily Telegraph* and the *Morning Post*, are incorrect in assuming that Dickens's appellation of "Tom-all-Alone's" was given by him either to the burial-ground or to the courts immediately surrounding it. At the end of chapter xvii of "Bleak House," Jo, having had a piece of gold given him by Lady Dedlock at the gate of the burial-ground, is described as "setting off for 'Tom-all-Alone's,' stopping 'in the light of innumerable gas-lamps' to look at the coin." This passage alone justifies the inference that it is Dickens's mind the burial-ground and "Tom-all-Alone's" were some little distance apart. We believe that it is the opinion of many students of the topography of Dickens's London that "Tom-all-Alone's" was situated in Great Wild-street, a street a little to the eastward of Drury-lane, and the description given of the locality in the chapter already mentioned seems to confirm that view. The

* But it is to be observed that Hawdon, the law-written and the "Nemo" of the tale, died at Krook's house in the court off Chancery-lane. This is not in the parish of St. Mary-le-Strand, and, therefore, his burial should not have been located in the ground under notice.

† Since these lines were written we notice that the *Daily News* has called attention to the mistake.

point is of interest because Dickens's descriptions of some of the scenes of his stories are realistic word-pictures capable of identification by those whose knowledge of London forty years ago was, like Sam Weller's, "extensive and accurate."

This small, but, to the poor children of the neighbourhood, very acceptable playground, was formally opened on Wednesday afternoon by Lady George Hamilton, and amongst other gentlemen and gentlemen present were Lord Rochester, Lord Fortescue, Col. Burges, the Rev. Canon Tugwell, Mr. J. T. Bedford, C.C., Mr. F. H. Fowler, Mr. Cross, Mr. Augustus Harris, Mr. A. M. Broadley, and a large number of ladies and gentlemen interested in the beneficent work of the Association. The formal part of the proceedings being concluded, the children of the neighbouring courts and alleys were admitted to the ground, and large numbers of them remained there until the closing-hour (eight p.m. this time of the year), exercising their limbs and their lungs. Before passing from this part of our subject, we may mention that of the few remaining headstones which are visible, one marks the burial-place of "Mrs. Betty Hadrill, many years housekeeper to the Royal Academy," who died April 28, 1803. This is of interest as recalling the fact that at that time the Royal Academy was located in Somerset House.

Separated from this neglected and well-nigh forgotten burial-ground by Vinegar-yard and rose-court formerly lay, to the north-east, Vinegar-yard Garden. Until the building to which we shall hereafter refer, the Garden was wholly represented by the space between Wren's-lane Theatre and a curtain-wall, which, varying from what is known as Lady Burdett's door, abutted against Marquis-court. At the Drury-lane end of Marquis-court remains a pretty name-tablet, of the date 1763, as may be found in the town. At one time Vinegar-yard was a title frequent enough in London; in a few cases, — as in the district under review, — and also in St. Giles-in-the-Fields, in Aldgate, and in Bermondsey, it is most likely a corruption of the earlier and here and there still extant Vinegar or Vinegarden-yard, — marking the vicinity of a conventual pleasure-ground. Peter Cunningham says it was built *circa* 1621, and that from St. Martin's-in-the-Fields register an entry of the burial (probably in the adjacent Wren's-lane ground) of "blind John out of Vinegar-yard," on 4 February, 1624.* But he does not mention the one name which should see it from oblivion. For in our Vinegar-yard was born Fanny Barton, — daughter of, it is said, a guardsman, — who, succeeding to Pritchard's and Clive's comic muse, was such Miss Prue and a Lady Teazle as the world has never since seen, and whose face is familiar to us in the many portraits of Mrs. Abington by Reynolds.

In an essay of Elia, written *circa* 1825, Charles Lamb describes his first visit when a child "not past six years old" to Drury Lane theatre. "My First Play" begins thus:—"At the north end of Cross-court there yet stands a portal, of some architectural pretensions though doomed to bumble use, serving at present for an entrance to a printing-office." He goes on to say that this old doorway was the identical entrance to old Drury, — Garrick's Drury, — being all of it that was then left. Garrick's muse was the second to occupy this spot, having been erected from Wren's designs, and, as Cibber recounts, opened on the 20th of March, 1714, with a prologue and epilogue from Dryden's pen. The poet had joined with Killgrew, Moham, and others in the venture for this "new play-house." Its predecessor, burned down in January, 1692, formed the "King's House" so often mentioned in Pepy's theatrical gossip, which Killgrew opened on Thursday in Easter week, March 8, 1663, with Benniont & Fletcher's Humorous Lieutenant, "the play beginning three o'clock. Shortly after the Restoration rode, a bookseller, rebuilt for the third time a notoriously offending Cockpit or Phoenix, a private" house on the further side of Drury-lane, just southwards of the old Devil's Gate company, however, comprising Hart and other officers in the Civil War), Burt, and Misses Betty Marshall, joined Tom Killgrew's, being their house to Davenant's troupe. These, after with Kynaeton and Botterton, removed in 1662 to the "Duke's Play-house," in

Portugal-row, Lincoln's Inn-fields. Pitt-place, in Great Wild-street,* long preserved a memory of the Cockpit, which had shared more than once at Puritanical hands the fate of certain other houses, the neighbourhood's *dustænon oncidens*, which it was deemed to resemble in repute. Pitt-place, Prince's-court,† and Stewart's-rents (*antique*, Holford-court), together with Orange-court and Wild-passage, marked its site. These pestiferous alleys were demolished in 1881 for the Artisans' Dwellings erected by the Trustees of the Peabody Fund. Thus is gone every trace of a house where, before Commonwealth men gained the upper hand, were brought out Marlowe's "Jew of Malta," Heywood's "Woman Killed with Kindness," and, above all, Maesinger's "New Way to Pay Old Debts." Closely associated with the dramatic triumphs of Dryden, Lee, Wyeherley, Congreve, and Farquhar, Wren's house was licensed in turn to Rich, Steele, Doggett, and Booth. Here Garrick first performed, under Fleetwood's management, in 1742, earning a salary of 500*l.* a year, and the nickname of the Whitefield of the stage. On September 15th, five years later, he opened the season, as Lacy's co-partner, with "The Merchant of Venice" and Dr. Johnson's incomparable prologue. Here he continued as actor, author, and manager, until, having sold his moiety for 35,000*l.* to Sheridan, Linley, and Ford, he finally took leave of the public on 10th June, 1776.

Together with Charles Lamb's delightful essay should be read, for the sake of contrast, that by Cumberland *à propos* of a same occasion, when taken under proper convoy to Drury-lane from Westminster School. His attention is riveted by Quin as Horatio, dressed in a green velvet coat, an enormous full-bottomed wig, rolled stockings, and high-heeled shoes, pouring forth his heroics, so diverse from his ordinary delivery, with dignified insouciance. Mrs. Cibber as Calista sings in sweet recitative Rowe's harmonious strains. Mrs. Pritchard, as Lavinia, is so different, yet so much more varied, for however "ungenteel" in figure, she could pace with facile excellence from Doll Common to Lady Macheth. Little Garrick, striving to reconcile his audience to naturalness on the stage, then young and alive in every feature and in the muscles, electrifies the house as he bounds on to the boards as Lothario. Heavens! what a transition! A noteworthy comment, too, on that day's fashions is afforded by Lamb's "Reminiscences,"† and a foot-note to the bill of June 10, 1776, being the very last play-bill in which Garrick's name is printed. It is the last night of the season; his final course of Shakespearean character is concluded, and as Don Felix in "The Wonder" he is to bid farewell to the stage. The doors open at 5:30, the curtain rises at 6:30; "ladies are requested to send their servants a little after five to keep places to prevent confusion."

Referring to J. Gwynne's plan of 1766, we see that the theatre at that time was co-extensive with the auditorium of the existing structure. Four approaches severally opened through Vinegar-yard, Drury-lane, and the then Brydges and Little Russell streets. A passage ran from Little Russell (now Russell) street into Vinegar-yard. The front of Garrick's house had a handsome elevation, resembling somewhat Wren's Middle Temple gate in Fleet-street. A pediment, carrying at its two corners the royal supporters, enchanter, and at the apex a trophy of arms, was sustained by five fluted pilasters resting upon a Palladian basement story having five spacious doorways. Destroyed by fire, the theatre was rebuilt by Henry Holland on an enlarged scale as to accommodate 4,000 spectators. But this—the third—house met with a similar fate; for on the night of the 24th of February, 1809, after a brief life of but fifteen years, it was totally consumed. The existing house, designed by Benjamin Wyatt, was finished at a total cost of 150,000*l.* The Russell-street colonnade, of cast iron, and the portico in Catherine-street, surmounted by a leaden figure of Shakespeare, are more recent additions. The opening on the 10th of October, 1812, with a prologue by Lord Byron, is memorable for the publication in a thin 12mo.

* So named after Humphrey Weld, who built (1651) over the Aldwych Field property that had belonged at divers times to the Holford, Drury, Stradling, and Digby families.

† Part of Drury-lane, *temp.* James I, was called Prince's-street, but that style really belonged to the now newly-christened Kemple-street, a thoroughfare dating from the days of the Holford and Drury in Elizabeth's reign.

‡ His first visit was made in 1781.

volume that year of the wittiest parodies, by the Brothers Smith, in the English language. Just within the semicircular wall, and facing Cross-court, stood the pit entrance spoken of by Charles Lamb. All traces of that relic have been removed for new "property" and store rooms, lately constructed under the superintendence of Mr. C. J. Phippe, F.S.A., architect.

SCULPTURE AT THE ROYAL ACADEMY.

To the works in sculpture by the President in this year's Academy we have already alluded, as also to the very remarkable and original work by Mr. Gilbert, "The Enchanted Chair." Among the other leading works in the exhibition, perhaps none will attract more attention than the figure of "The Sower" (1,921 in the lecture-room), by Mr. Hamo Thornycroft, of which we have the pleasure of giving in this number a sketch, made specially for our pages by the sculptor. As to the entire suitability of such subjects as this, and the well-remembered figure of "The Mower" by the same artist, to sculptural art, we have our reservations. We should scarcely like to see them executed in marble; the material seems too fine to bestow on such details as boots and gaiters. But, in plaster or terra-cotta, these life-size and life-like representations of figures in the garb of their every-day vocations have a very high interest; and "The Sower" is, perhaps, superior in artistic expression to its predecessor. The long, swinging stride with which the sower walks over the furrows is admirably given; there is no burry in the action, which is sufficiently quiet and subdued to come within the proper domain of sculpture; the expression of the face is fine and dignified; the whole reminds us somewhat of the feeling of the figures in some of Walker's paintings of rustic life; like them, it seizes the best and most dignified phase of rustic character.

Taking the other sculpture exhibits in the order of numbering, we notice first Mr. Mulline's marble bust of "the late W. C. Worthington, F.R.C.S." (1,750), notable for the bold treatment of the marble, which is not polished up, but left with its crystalline surface and visible tool-marks. The bust of Dr. A. Carpenter (1,754), by the same sculptor, has the same characteristics. Whether the real object of a portrait bust in marble would not be better fulfilled by the old-fashioned treatment, showing the head and partly nude bust without any of the details of coat-collar and shirt-front, is a question to be asked. We have no particular fancy for the execution of crumpled shirt-fronts in marble. But in both cases the treatment of the countenance is in true sculptural feeling. Of Mr. Pomey's design, submitted in the students' competition for "Cain an Outcast" (1,751), we have already given an illustration (*Builder*, April 17) and commented on its high merits and promise as the deservedly successful design in the competition. Mr. Adams-Axon has a good portrait-statue of "David F. Carmichael, Esq., of Madras" (1,753), a seated figure so full of life and character that the drawback of the modern dress, so unsuitable for sculpture, is half forgotten. This in its way is one of the most successful works of the year. Mr. Nelson Maclean's marble statuette of "Comedy" (1,755) we have before noticed in speaking of a special exhibition of his works. Mr. Gilbert has a plaster bust of "Mr. Cyril Flower, M.P." (1,757), another of the realistic busts, which has a great deal of "go" about it; it is what old-fashioned people used to call "a speaking likeness." Miss Lipscomb's terra-cotta bust, "Day-dreams" (1,759), should be looked at as a very expressive head, slightly angular in contour, not strictly beautiful in feature, but with a beauty of a higher order than mere physical form.

Mr. Carl Müller's "George Burnard, Esq." (1,761), is another of the terra-cotta portrait busts, in which there seems to be an attempt to idealise the costume with some effect. Miss Susan Canton is a rising sculptor; her work this year is much in advance of what she has previously attempted. Her group, "What hast thou done?" (1,764), which seems to represent the Cain and Abel legend, and shows the instant of remorse after a murder has been committed, is, perhaps, over-accounted in the anatomy of the figures; but it is a fine and expressive group on a small scale. Mr. Mark Rogers, jun., exhibits a marble "Caryatide for Chimney-pieces to the Saloon at Ashridge"

* Singularly to say, in one or two maps of about 100 years ago this yard appears as Woburn-street.

(1,766), appropriately placed so as to flank the door into the picture-gallery behind; it is a male figure, with head bent on the right shoulder, the left shoulder sustaining the cornice; a stain on the marble has an unfortunate effect on the nose and left eye, and the position of the figure is rather painful, conflicting, in our eyes, the doubt we always have had as to the advisability of employing figures in this semi-constructive office, respectable as is the precedent for it. The figure itself, however, and the manner in which the vertical weight is taken by the left leg, is fine and sculptural. Miss Chaplin's "Lioness and Cub" (1,767) is an animal study of a larger size than usual with her, but quite equal in natural action to any of her smaller animal groups with which we are so familiar. Mr. Albert Toft is a name we do not remember before; but his "Study of a Young Man" (1,769), a terra-cotta bust, showing head and neck only, without any realistic adjuncts, is a very spirited thing; and so is his portrait bust of "Nelson Dawson, Esq." (1,801)—lecture-room). He is a sculptor of whom one is likely to hear more. Signor Fontana's "Il mio fedele" (1,770), a girl and dog, is one of the "pretty-pretty" order of things, which delight children.

Mr. Brock's statue of Sir Erasmus Wilson (1,772), to be executed in bronze, and erected in front of the Infirmary at Margate, is a fine and very dignified example of portrait sculpture. The great authority on skin diseases is represented standing with clasped hands, and holding a book, the official gown which he wears furnishing the sculptor with a means of giving a broad "drapery" effect to the figure. Mr. Pinker's statue of "John Hunter" (1,781), a bronzed plaster cast of a statue presented by the Queen to Oxford University Museum, is, however, perhaps the most successful work in this class as regards energy and expression. The great physiologist is leaning with one elbow on something,—we cannot well make out what,—and looking forward with compressed lip and an eager face, something like that of the monk in the "Sentimental Journey," that "looked as if it looked at something beyond this world." Hunter's studies were prosaic enough certainly, yet he must have had the kind of persuasion of future fame which is so well expressed in this work.

Mr. Havard Thomas's "A Slave Girl" (1,774) is a realistic marble study of the figure, with little beauty, but not without pathos. The expression of the face is in keeping with the attitude of the hands, half extended, as if in deprecation of her position and treatment. Mr. H. Christie's "Spring" is a pretty plaster sketch of a girl playing with lambs, which may be instructively contrasted with the girl and dog group above referred to; the action in "Spring" is really natural and unaffected. Mr. Birch's colossal statue of "Major-General Earle" (1,786), which occupies a central place opposite the entrance, is only half successful. The figure is represented as advancing to or leading on an attack, sword in hand; but the action savours too much of stage warfare; there is not the energy of real combat in it.

The lecture-room contains a great many small things of merit which we have not space to mention in detail, and of course a certain proportion of commonplace. The most important works in it next to those we have already mentioned are the bas-reliefs by Mr. Harry Bates. The first of these is "Homer" (1,811), who is represented by a figure not quite dignified enough for the ideal of the ancient bard, seated at one end of the panel, bent over a harp, while at the other end are two beautiful women, one seated, the other reclined, listening to him. "Socrates" (1,827), a marble relief, by the same sculptor, is the finer work. Socrates is seated on the right, in attitude and manner as if arguing and laying down a proposition; opposite to him a nearly nude young man sits in an attitude of deep thought, the bands clasped over one knee; two other figures are behind him; a young man also stands behind Socrates, leaning over him. The composition, from a decorative point of view, is beautifully balanced, the expression of the two principal figures, in countenance and attitude, very good. On the opposite wall is a cast of the first of the sculptured panels of St. George's Hall, Liverpool, which has been executed (1,872), and about which there has been some foolish depreciatory local criticism. It is by Mr. Stirling Lee, and represents "Justice as a Child of the Poor, led by Understanding

into the Way of Wisdom, Joy following, strewing her Path with Flowers." So much meaning may be said to be a "rather large order" for one panel, and the nude child figure put to represent Justice is rather too young to have come to any years of discretion or any beauty of person; but the main treatment of the panel, with its broad surfaces and flowing draperies, is very sculptural, and eminently fitted to contribute to the decorative effect of the great Modern-Greek building for which it was designed. We presume the sculptor's intention was to show in further panels the stages in the growth of Justice; and we hope some more of them will be commissioned before long.

Looking round the room we note the design for the sculpture portion of the Sir John Goss Memorial, by Mr. Hamo Thornycroft, a panel in very low relief representing kneeling choristers. Mr. C. Calderon's "Fiore diprimavera" (1,794), a very pretty female bust, should be looked at; and Mr. Onslow Ford's "A Hop-picker" (1,814), a bronze model of an old, seamed, weather-beaten face, pathetic to look at in connexion with the title. Mr. Lawson's "Summer" (1,823) is a piece of real sculpture. Like his "Spartan Dancing Girl" of last year, it is an expression in sculpture of a moment of repose in a body of strong and healthy physique, only this time it is a young lad who is the subject, who has evidently been bathing and is lying on his back on the bank, with his feet banging down, in a moment of blissful indolence and enjoyment of warmth and sunshine. The figure is very finely modelled, and the work is altogether original. Miss Ada M. Palmer has made a success with her "Paolo and Francesca" (1,816), an alto-relief of the two beads only, very fine and passionate in expression, appearing to emerge from a background of drapery and flying figures.

Among the figures in the centre of the room, Mr. Onslow Ford's "Folly" (1,925), a bronze nude statuette, a little light-headed creature balancing herself on a bit of rock, with foolish gestures of her hands, is a very clever and original bit of invention. Among other works which we can only just mention as not to be passed over are "Contemplation," a bust (1,818) by Mr. Maclean; bust in marble of Sir James Paget (1,825), by Mr. Boehm; "The Young St. Timothy" (1,831), a nude child poring over a book, by Mr. A. G. Atkinson; "F. Johm, Esq." (1,851), by Mr. A. Drury,—a bust showing the head and neck only, with no artificial accessories, very spirited expression; "Portrait of a Lady," terra-cotta bust (1,865), by Mr. S. Fry; "Felicità" (1,871), a peasant girl from Cava di Tirreni, by Mr. Amendola; "A Study" (1,891), a bronze bust of a calm female head, by Mr. E. Onslow Ford, a very good likeness in marble (bust) of the late Mr. Macdonald, of Marble (1894), by Mr. Lawson, a reminiscence of a familiar figure who will now no longer be seen in his wheelchair on private view days, welcoming the friends who clustered round him; a Dalecarlian peasant-woman (1897), by Miss Henrietta Montalba; "Diana after the Chase" (1,911), a new figure in an attitude of repose, by Mr. G. C. Cowell. There are some good little works among the smaller exhibits, which we have no space to particularise. There is certainly a high average in the sculpture work of this year.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE ninth ordinary meeting of the present Session was held on Monday last, Mr. A. W. Bloomfield, M.A., F.S.A. (Vice-President), in the chair.

Obituary.

Mr. William H. White (Secretary) announced the decease, on the 28th ult., of Mr. H. H. Richardson, of Brookline, Massachusetts, Hon. and Corresponding Member of the Institute. Mr. Richardson, who had only quite recently been elected an Hon. and Corresponding Member of the Institute, died very suddenly, having been at work twenty-four hours before his death. He was a native of New Orleans, but he went before the American War to Harvard University, where he graduated in 1859. At that time he was so good an American that he would not fight against the national flag. He, therefore, went to Paris, entering the Ecole des Beaux Arts, where he took some

honours, and was ultimately employed on the works of the Tuileries and the Louvre, when the two buildings were being joined together. Returning to the United States, he settled in New York for three or four years, and afterwards went to Boston, where his principal works were erected. Photographs of many of these were lately exhibited at the Institute. Mr. Richardson's reputation was not only great in the United States, but also in Europe. One of his chief friends was Mr. Hubert Herkomer, for whom he designed a house.

On the suggestion of the Chairman it was agreed to send a message of condolence to Mrs. Richardson.

Mr. R. Phené Spiers, as a personal friend of Mr. Richardson, said that his works had been described at the time of his election as a Corresponding Member of the Institute. He (Mr. Spiers) had placed in the library a design for a cathedral prepared by Mr. Richardson, which, although it had not been carried out, would show his great power of design, and careful study of French Medieval work. His acquaintance with Mr. Richardson commenced when that gentleman came to Europe in 1859 to attend the Ecole des Beaux Arts. Mr. Richardson came over to Paris, as most Americans did, with sufficient money to enable him to live at his ease, and take his studies as it suited him. On the breaking out of the American War, however, he was left without means, and was compelled to enter into some office to *faire la place*, as it was termed. This would have interfered with his studies, had he not devoted his evenings to continuing them in the atelier. Mr. Richardson had told him that the misfortune which came upon him in Paris was really in one sense the making of his fame, as he would probably never have taken a serious aspect of practical work unless he had been forced to obtain his living. The work he did in the Tuileries and Louvre also gave him a position when he went to New York, and helped him to a lucrative practice. Mr. Richardson was one of the few architects who were able to charge more than the ordinary 5 per cent., for so great was the demand on his artistic powers that he was obliged at last to confess that he could not do work properly unless he obtained the best possible assistance. He, therefore, would not undertake work for less than 8 per cent., and for many years he worked at that remunerative price. Mr. Richardson's last work was a very important one, and he hoped at some later date to be able to give more information as to this and other works of so eminent an architect.

The Charterhouse.

Mr. John Webb.—With respect to the Bill lately before Parliament with regard to the Charterhouse, it was announced at a public meeting held at the Society of Arts the other day that the scheme then before Parliament had been approved by the Institute. It was a Member of Parliament who made this statement, which, I hope, so unlikely to be correct, that I think the Institute would be glad of the opportunity to give it some sort of denial. It may possibly have arisen from the fact of an individual member of the Institute, who, being also a member of the committee to which the question was referred, did not consider it incompatible with his duty as a member of that committee to further a plan for building on the site, for running a road right through it, and entirely mutilating the buildings. It is a question of individual taste, and I suppose the Institute cannot help the action of its members individually; but, I think, in its corporate capacity the Institute would be rather chary of expressing any opinion with regard to proposals of this kind, and perhaps you may be able to say whether there has been any action taken by the Institute with regard to the Bill.

The Chairman.—I think, in regard to a question of this kind, that it would be more convenient if notice were given beforehand, so that one might have all the facts of the case ready. I am rather new to the post I occupy this evening, and was not present at any meeting of the Council,—in fact, I was not on the Council, when this question was considered.

Mr. J. Macvicar Anderson (hon. sec.).—I may say that no definite action whatever was taken by the Institute in the matter. The subject was brought before the Council by a member of the Institute, who is also an old Carthusian, but inasmuch as they did not seem to be entirely at one amongst themselves as to what was the

best course to adopt, the Council deferred any action, and no advice was given or action taken in the matter by the Institute.

Mr. Hebb.—I am extremely glad to hear it.

Roman Remains in North Africa.

Mr. Alexander Graham then read an exceedingly interesting and copiously-illustrated paper, entitled "Remains of the Roman Occupation of North Africa, with special reference to Tunisia." The following is an abstract of the paper:—

The author referred to the vicissitudes the Agency of Tunis has undergone since the Phœnicians from the Syrian coast formed their first settlement on its shores, and to the myths that surround its earliest history. It is supposed that Carthaginian literature was very limited, Greek being the language of educated Carthaginians, and that the principal records of Punic times passed to the library at Alexandria, and were destroyed by fire in the sixth century. There is nothing to show that the style of architecture introduced by the Romans into North Africa was influenced by the style of the buildings they found at Carthage, and explorations have favoured the supposition that the fine arts never flourished among the Carthaginians. This is the opinion of Winkelman. The architecture in Tunisia during the five centuries of Roman occupation is as Roman as that of Rome herself. There is dearth of inscriptions of the time of the first emperors, owing to the colony having been at first principally agricultural, but with the advent of Hadrian and Trajan and their immediate successors commenced a long era of wealth and prosperity. Roman Carthage no longer exists, but its treasures of marble and onyx may be seen in the principal mosques and palaces in North Africa, and in Europe as far north as Pisa. The older Carthage of the Phœnicians is about 40 ft. under the surface, awaiting systematic exploration. The antiquity of Utica, one of the oldest known towns in the world, was then referred to, and a contrast was drawn between the present appearances of Bou-Chater (its modern name) and the city in pre-Roman times, with its massive walls and its strong position. The Punic and Roman methods of building, as exemplified by the remains of Utica, were then compared, especially with reference to the early use of *opus pisce* and of rubble. The Roman roads from Carthage were then traced, and reference was made to the remarkable natural harbour at Bizerta. The town of Thabraca and the castle of Charles V., on an island off the coast, were then mentioned, and a brief account given of the beautiful country of the Khomair tribes. The Roman road along the banks of the Bagradas were traced, and the remains of Balla Regia, the residence of Numidian kings long before the Roman occupation, and of Imbita, with its magnificent marbles, were then referred to. Further eastward, along the banks of the same river, where the great conduit of Carthage, having a total length of sixty-one miles, crosses the plain, a full description of this stupendous work was given in detail, as well as a history of the development of the science of water supply in North Africa, and of the construction of cisterns in that country from the earliest times. The Roman road south of Carthage was then traced, and mention made of the ruins of Aphrodisium, and of the great city of Uthina, commencing southward, the mountain of Zagouana was reached, and a description given of the ruined temple, with its colonnades, which the Romans built over the spring that supplied water to Carthage. Reference was then made to the holy city of Kairouan or Kairwân, and to the Roman shafts and capitals that form the chief ornament of the Great Mosque.* Thysdrus, better known as El-Djem, was described, and a detailed historical account given of the great amphitheatre there, its materials, its mode of construction, and its size compared with other well-known examples. Turning northward to Carthage, the remains of towns on the south bank of the Bagradas were described, and special reference to Thugga, remarkable for its numerous monuments as well as for the beauty of its position. Continuing along the Roman track, the site of Aghia was reached, where are the remains of an immense Byzantine

fortress. Some account was then given of these strongholds in North Africa, and their development in the sixth century into Monasteria for soldier-monks. The walled enclosure at Teheffa in South Algeria was referred to as a striking example of this kind of building. Passing close to the fatal plain of Zama (where Hannibal was signally defeated), the great ruins of Assuras were described, as well as the remains of Siccaveneria, now known as El-Kef, signifying "the rock," occupying a remarkable position at a considerable elevation. The ruins of Mactar were then reached, and following the Roman road by Sufes, a town that once covered an area of nearly three square miles, but is now a mass of stones,—the last town on the western frontier, named Ammadara by the Romans, but better known by the modern name of Hydra, was described. The remains of Scillium were then referred to, and a full description given of the mausoleum of M. Flavius Secundus, with its quaint inscriptions. East of Scillium are the remains of Sfetula, the most important as well as the most interesting in Tunisia. These were fully described, special reference being made to the remarkable enclosure, commonly called the Hieron, on account of the three temples within the walls. Passing allusion was made to the sites of other towns farther south on the borders of the Desert that have not yet been explored, but no mention is made by travellers through this region of any architectural monuments now standing. The monuments of a country, such as those in North Africa, where written records fail, may be considered as so many pages of history, and the architect and the historian may walk, hand in hand, rebuilding the ruins, re-editing the fragments, and giving them their proper place and value in the records of the country. The principles of law and order were exemplified in Roman architecture in a remarkable degree, resulting in a national style that can be recognised in any of the monuments of the Roman Empire.

In the discussion which followed, The Chairman expressed the pleasure with which he had listened to Mr. Graham's interesting, scholarly, and suggestive paper. It raised a great many subjects for discussion and question, and he hoped they would have some remarks from visitors present who were familiar with Tunisia.

Mr. H. S. Ashbee, F.S.A., said that perhaps there was no country in the world where we could better appreciate the power and grandeur of Rome than in North Africa, and especially in Tunisia,—not so much from the monuments that had been left, as from a comparison of the desolate and terrible state of the country at the present time with what it must have been in Roman times. That country, which then supported a vast population of its own, and which was, in addition, the granary of Europe, had now become a mere waste, scarcely affording food for its sparse population. In one of the vast plains, for instance, one travelled for miles without finding any population except a few nomads, and no agriculture or even a tree was to be seen, nor was there shelter of any kind. Yet they were told by the ancient Arab historians that when the site for a city was chosen there it was an impenetrable forest, infested with venomous serpents and wild beasts, and that the interposition of Allah was necessary to make those enemies of the human race retire. The vast cisterns or reservoirs to which Mr. Graham had referred were of undoubted Roman workmanship, as was shown by the niches to be found in the interior of some of them. Mahomet forbade the erection of statues, and those niches were doubtless intended for nymphs or other images, and had rounded arches, not the horseshoe ones of Arab construction. In the great plain in which Thysdrus stood there was the same absolute desolation; the ground was furrowed by neglected water-courses which had broken up the country in every direction, so that no one could pass for three miles in a straight line. The amphitheatre would never have been put up on the plain unless there had been a population there. Thysdrus was, no doubt, a minor place, but doubtless the whole plain was at one time covered with homesteads and villages, the well-to-do cultivators of which would fill the amphitheatre at the time of the games. For over a thousand years the Arabs held this beautiful country, which had a climate little short of perfection. They found it numerously populated by a cultured and active people, and adorned with magnificent monuments, the

drawings of some of the remains of which were upon the screen. The Arabs drove out or slaughtered more people than the whole country now contained; they cut down the forests without replanting; and they neglected the rivers and water-courses, allowing the roads to disappear and the bridges to decay, and they let the land go out of cultivation. In short, they turned a fruitful country into a desert, a garden into a wilderness. When it was considered that they had left no literature worth speaking of, and no monuments of their own; that no development of science or of commerce was to be found, it was permitted to them to turn their thoughts from such a people back to those grand times when Rome was dominant in North Africa,—to the times when those magnificent monuments were erected, the drawings of which, thanks to the faithful and facile pencil of Mr. Graham, they were able to admire upon the walls.

Mr. F. W. Pervin remarked that, having travelled over a large portion of the country described by Mr. Graham, he had listened with great interest to the paper. Tunis could be easily reached, and was an extremely interesting centre from many points of view. If the district were thoroughly examined, he believed that discoveries of great architectural interest would result.

Mr. R. W. Edis, F.S.A., Member of Council, proposed a vote of thanks to Mr. Graham for his exceedingly interesting paper. The subject was one in which they all took a very great amount of interest. He had no idea that there was so much Roman work in a part of the world which he had always believed consisted chiefly of sand.

Professor T. Roger Smith seconded the vote of thanks, and referred to the great excellence of the paper and its illustrations. It was only when one attempted to do anything of the sort that one understood how much pains and labour went to the creation of such illustrations. It was well that we should from time to time be reminded of the great debt we owed to the Romans, of whom we were architecturally the descendants. All the architecture of Europe, both Christian and Renaissance, traced back to a Roman origin, and when we found in a hitherto-unexplored country a fresh proof of the vigour and energy with which the Romans colonised, and the orderly manner in which they erected monuments and buildings of the highest importance, we could only feel that here was a great people whose mission it was to supply a kind of energetic stimulus, the results of which had remained to the present, and the influence of which would remain for many generations yet to come. Therefore, we were specially indebted to any one who showed us the works of those who were in a certain sense our forefathers, in the way Mr. Graham had done that evening.

The resolution was then put, and cordially received.

Mr. Graham, in replying, said it was a pleasing task to prepare a paper of this kind, which went a little out of the beaten track. It might be that some of them might think the information he had brought together could be found in that usual resort of the thirsty *Littérateur*,—the encyclopædia. But in order to obtain reliable information on the subject he had not only traversed the country and seen many of the remains described, but had traced back all the statements he had made as far as he possibly could to the original Latin authors of the first, second, and third centuries. Under these circumstances they might fairly rely upon his statements,—not only those which he had read, but those which, for want of time, were left unread, but which he hoped many of them would peruse when the paper was published in its entirety in the Institute's "Transactions."

Rodney Stoke.—The parish church of Rodney Stoke, near Wells, Somerset, has just received some important and much-needed decorative additions to the chancel. An oak panelled and boarded ceiling, with richly-carved bosses and ornamental cornice has superseded a common lath-and-plaster ceiling. An entirely new east window, with handsome tracery, harmonising with the fifteenth-century architecture of the church has been added. It contains three lights, and is filled with painted glass, by Messrs. Lavers & Westlake. The architect is Mr. B. Edmund Ferrey, F.S.A. The window superseded was a very poor one, inserted about thirty years since.

* Some particulars of this Mosque, by Mr. Herbert Carpenter will be found, in the *Builder* for Feb. 24, 1883, p. 237, and in the Institute "Transactions" for the same year.

COMPETITIONS.

The Fulham Vestry Hall.—A special meeting of the Fulham Vestry was held on Tuesday evening, the Rev. F. H. Fisher, M.A., in the chair, to consider the report of a committee stating that several letters were read from competitors re the Vestry Hall plans, pointing out the hardship they would be subjected to in consequence of the resolution of the Vestry deciding to adjudicate themselves on the plans, and recommending the rescinding of so much of the resolution relating to the non-appointment of a professional adviser to assist the Vestry in the examination of the amended plans for a Vestry Hall.—The adoption of the report was proposed by Mr. Hamer, and seconded by Admiral Sullivan.—Mr. Walden maintained that they were practical men, and quite competent to decide upon the plans.—Mr. Easton expressed an opinion that Mr. Currey made a mistake in his award. The Vestry had acted in a manner which he thought was for the benefit of the parish. He felt sure that the vestrymen were capable of forming an opinion as to the plans.—Mr. Cardwell said a professional adviser should be called in for the benefit of those vestrymen who were unable to form an opinion as to the plans. He regretted that Mr. Currey's award was not accepted.—Mr. Hamer thought the proposition to ask their surveyor to act as adviser would prove impracticable and undesirable. What was their object in appointing a professional adviser in the first instance? In order to obtain the best design, and, further, that they should have an independent man. He also regretted that the award was not accepted. They had set aside Mr. Currey's award, and, if they adopted the report, they would be excluding the best men of the profession from joining in the competition. Not having a professional adviser, they practically excluded members of the Institute. The best thing they could do was to obtain the advice of a man of equal standing to Mr. Currey. He hoped they would rescind the resolution, so as to enable members of the Institute to participate in the competition. The motion that the report be adopted was put to the meeting, and lost. (A letter referring to this subject appears on another page.)

Illustrations.

ST. JAMES'S (R.C.) CHURCH,
SPANISH-PLACE.

WE publish this week two views of the design Mr. Leonard Stokes submitted in the recent competition for the above church. The drawing of the exterior is now in the Exhibition at the Royal Academy, and has been already noticed by us. The interior we criticised at the time of the competition. The plan is arranged so as to give as far as possible an uninterrupted view of the altar and pulpit, and a low triforium has been introduced in order to obtain as much accommodation as possible on a somewhat cramped site. The materials proposed were red brick and stone throughout both the interior and exterior.

THE NEW HOMEOPATHIC HOSPITAL,
LIVERPOOL.

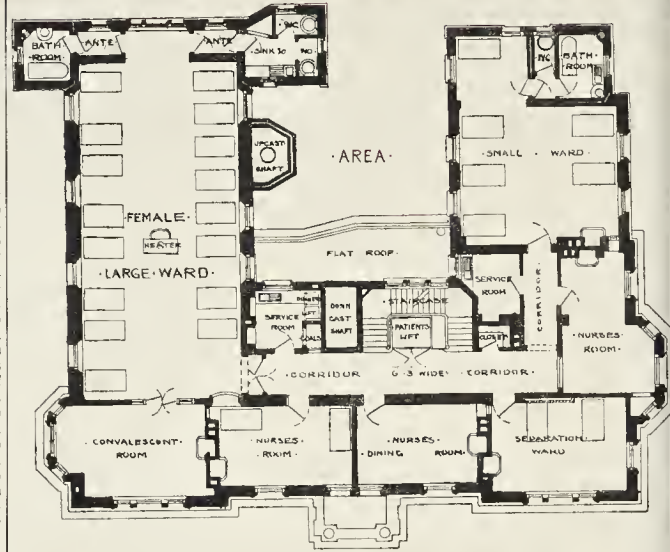

This building, of which we give an illustration this week, occupies a prominent site at the corner of Hope-street and Hope-place, Liverpool. The illustration shows the exterior from the north-east angle.

The building is designed to accommodate fifty beds at present, and is capable of being enlarged, on the south and west sides, so as to provide twenty or thirty more.

The basement is arranged as a dispensary, to take the place of the present one in Hardman-street.

The building is upon the red sandstone rock, and stands high in what is considered to be the healthiest part of the city.

The wards are arranged to have a southern aspect, and in the case of the three larger ones, cross lights, and large windows at the west ends. The large wards (male and female) on the first and second floors are 69 ft. by 24 ft., and have each a convalescent-room, with large bay window at the east end. A

Liverpool Homeopathic Hospital.—First Floor Plan.

smaller ward is provided on the first floor, and two infectious wards, completely isolated from the rest of the building, on the second floor. Two separation wards are arranged on the first and second floors, and five private wards, with a convalescent-room on the third floor, all being lofty and well lighted. Service-rooms, with hot plates, sinks, dinner-lifts, &c., are placed next the wards, and nurses' rooms, with inspection-openings commanding all the beds. The latrines and bathrooms at the ends of the wards are completely cut off by an air-space and double doors from the wards adjoining; they have a separate system of warming and ventilation, and will be lined throughout with glazed tiles, and have polished cement floors.

Nurses' bedrooms, and dining-rooms, an operating-room with north and top light, servants' bedrooms, &c., occupy the remainder of the upper floors.

The main staircase is of granolithic stone; and the whole of the corridors are of fireproof materials. On the ground-floor are the kitchens, sculleries, larders, stores, servants' hall, pantry, and service-room, in the south wing. The board-room, stores, office, porter's room, boys' room, and entrance-hall, are to the front. The House-Surgeon's sitting and bed room and spare room; the matron's sitting and bed room, bath-room, &c., and large store, with hoisting doors to yard, in north wing.

A hydraulic lift for patients will be provided from the ground to the third floor, in the well-hole of the stair; and a coal-lift from the basement to the top of the building.

With the exception of a large store-room, the wine and beer cellars, and the mortuary, the whole of the basement floor is devoted to the dispensary requirements. A large waiting-hall, with latrines at the west end, is provided, with porter's room overlooking it, and communicating with a spacious corridor, off which are seven well-lighted consulting-rooms, a waiting-room, with dispensing-room and exit door, completes the arrangement of this floor. Dados of glazed brick are provided in the hall and corridors.

The sub-basement is devoted to the heating-chamber, coal-places, air-shafts, and chambers of the heating and ventilating apparatus.

The exterior of the main front is faced with red Raahon brick, the strings, cornices, window dressings, &c., of stone from Stourton quarries. The ridges, hips, and finials are of terra-cotta, and the roofs are covered with Welsh slates. The drainage of the building has received special attention, and the soil drain-pipes will be flushed out by means of a large self-flushing tank (Bowers Scott & Reid's patent) placed at a point where the soil-pipes from the closets join the drain. The ventila-

tion and warming are arranged on the "suction power" principle, as successfully applied by Drs. Drysdale and Hayward, Liverpool, to several dwelling-houses in the neighbourhood, and may be briefly described as follows:—The foul air is extracted from the wards and rooms by flues situated near the ceilings, carried up through the walls to a horizontal foul-air chamber in the roof. This chamber is intended to cause all the foul-air flues joining it to be drawn on equally by the central downcast shaft, with which it is connected, and which conveys the foul air to the bottom of the great upcast-shaft, which actuates the whole system, and is then carried up the same, rising some distance above the ridge of the roof, and finished with an iron hood, having side openings for the escape of foul air. The centre of this shaft is occupied by an iron flue from the kitchen fireplace and heating apparatus boiler, and also connected with a large Cockerle stove for use when the boiler is not required.

By this means a powerful current will be induced in the upcast and consequently in the downcast shaft and its connecting system of foul-air chambers and flues. Regulating valves will be fixed at both the upper and lower ends of the foul-air flues to admit of their being accurately adjusted. Central fireplaces are provided in the large wards, if iron or earthenware, with separate air supplies, water trays, marble tops, &c.

The fresh air is introduced into the various rooms and wards, &c., by means of flues in the walls, connected at their lower ends with a chamber heated by rows of hot-water pipes, and running round the whole of the building under basement floor. A perforated wall allows the fresh air from an adjoining air-chamber to pass over the hot-water pipes so as to enter the various rooms at a temperature of 60 deg. in the coldest weather.

Fresh air is supplied to the air-chamber by means of seven "Eolus Water-spray Intake Ventilators," which suck the air from some height above the ground.

By means of these appliances and the regulating valves at the upper ends of the fresh-air flues, the supply of heated or cooled fresh air can be regulated with the greatest nicety, or shut off from wards not in use.

The hospital, the first contract for which amounts to over 13,000*l.*, is being erected at the sole cost of Mr. Henry Tate, of Park Hill, Streatham, and Liverpool, on the freehold site recently purchased by him from the Liverpool Corporation.

The contractors are Messrs. Holme & Green, and the architects Messrs. J. & C. Holme, of Liverpool. Mr. W. Bell is clerk of works.

St. Bride's Vicarage.

ST. BRIDE'S VICARAGE.

publish to-day a view of this new London house, of which Mr. Basil Champneys is the architect, and a drawing of which is in the possession of the Academy. The house is built on ground granted to the Ecclesiastical Commissioners, and occupies a site of 1,000 ft. super. The owners are the Rev. Mr. Bridewell, who were the owners of the house which commanded light and air, and that the house should occupy the frontage at the northern end of Bride-place. Hence the considerable extent of frontage compared to the depth of the plot. The material is red brick throughout. The contractor was Mr. Nightingale; the architect, Mr. Goodchild; the railing in the garden is by Mr. Ribbard Crittall.

THE RECENT MUNICIPAL WORKS IN ROME.

SURVEYORS' INSTITUTION.

At the ordinary general meeting of the Surveyors' Institution, held on Monday evening last, Mr. F. Vigers (Vice-President) in the chair, the President (Mr. E. P'Anson*) read an interesting paper on "The Recent Municipal Works in Rome." We are permitted to extract some portions of it:—

Of all the cities of Europe,—may I not say of the world?—there is none which excites more interest than the City of Rome, the Eternal City.

For the last three winters I have had the opportunity of seeing the extensive works which are in progress; it is these municipal works and their initiation which I now propose to describe.

When the seat of the Government in 1870 was transferred to Rome, the city was found insufficient to fulfil the requirements of its new destination. The considerable increase of its fixed population and probable increase had to be provided for.

The necessity that the modern city should have well-planned and well-drained streets, the example of what Florence, which for five years was the seat of Government, had already accomplished, immediately engaged attention, and whilst it was felt desirable to initiate works of urgent necessity without delay, it was equally felt that some general plan should be settled to regulate the development of the city, with a view to which, within ten days after the formation of a provisional government on the 30th of September, 1870, a Commission was appointed.

* It is worth remark that Mr. P'Anson at present enjoys the dual and unique honours attaching to his position as at once President of the Royal Institute of British Architects and President of the Institution of Surveyors,—the two leading professional societies connected with architects and surveyors.

of which Signor Pietro Campanesi was President, the veteran archaeologist, Signor Rossa, was vice-president, with nine other members, architects or engineers, all Romans, and well acquainted with the topography, the local difficulties, and the many questions which had to be considered in designing a plan for the development of the city.

This Commission, although the members were soon agreed on the general principles of a plan, did not so easily agree as to the details of the extensive and complete scheme they were appointed to carry out.

When the Commission commenced its labour the members had before them plans which had already been prepared, namely, a *piano regolatore* de *Massima*; a second plan, proceeding from a section of the appointed Commission; a third plan, presented by the Roman Communes, prepared by the engineer Merotte; and a fourth plan, by an architect named Paniconi.

A Council of the Roman Commune was called on to deliberate on these plans on the 3rd of June, 1871; they appointed four engineers to examine and report on the merits of the plans produced, who reported in favour of the plan of the Government Commission, but suggested various alterations, whereupon an amended *piano regolatore* was prepared.

At this stage of the inquiry another engineer, Alessandro Viriani, was called in, when, after the lapse of several months, the *piano di Massima* was recommended for adoption, and provisionally approved by the Council on the 28th of November, 1871, when, pursuant to a law passed in 1865, the plan was publicly exhibited, so that it might be fully known and criticised; and on fifteen consecutive days this plan was examined by a daily average of 120 persons, in all about 1,800. The objections made were neither serious nor numerous, but all objections made, either by individuals or by the public press, were carefully recorded, so that any amelioration to the plan which might appear necessary as the result of the objections offered could be made.

This plan seems to have been divided into sections, for on the 14th of September, 1871, the Council approved of the plan for the Esquiline Quarter.

The Commune, on the 13th of November, approved of the plan for alterations in the Piazza Sta. Maria Maggiore and adjacent streets; on the 20th of February, 1872, of the plans of the Pretorian Camp and of the Viminale Quarter; on the 20th of March, of the Industrial Quarter of Testaccio; and on the 6th of April, of the Quarter of the Celio.

Finally, at the sitting of the 19th of August, 1872, the project was approved of continuing the Via Nazionale direct to the Fountain of Trevi and to the Piazza Sciarra, and for which the necessary powers of expropriation were obtained.

The Commission had proceeded thus far in the summer of 1873, by which time the *Massima* plan, which was then partially approved, contained all the fundamental requirements of a first design, and it was again presented for the sanction of the Council, who, before having a definitive consultation, on the 9th of July, 1873, appointed a third Commission composed of four engineers, with instructions to re-examine the plan and also ten other plans, which by that time private engineers had laid before the Municipal Administration.

Two months afterwards this Commission published their Report, dated the 3rd of September, 1873, which determined that neither of the ten new plans was better than the official *piano regolatore*, or capable of being combined with it.

The Commission classed the proposed works under three categories:—1. Those they thought indispensable. 2. Those they thought relatively useful. 3. Those they considered ornamental and not absolutely necessary.

On this report further discussion took place, the opinion of the public was invited, and several meetings took place to consider the objections and criticisms on the plans, which were read to the Council on the 6th of October, 1873, Francesco Nobili Villatasse, President; and on the 18th of the same month the *piano regolatore* appears to have been accepted, and a further commission was then named, who published it in April, 1882, and this seems to have been the final Report. It was signed by Villatasse, President; Marco Ottoboni Duca de Tiano, Giovanni Ballista de Rossa (the veteran archaeologist), Salvatore Bianchi, Emidio

OLD WOODWORK AT THE CHARTERHOUSE.

give some measured drawings of the case in Howard House, part of the Charterhouse property, about the possible fate which there has been so much discussion of. The portion of the building in which the case is, was not, we are assured, ever to be touched or removed; but it may be interesting to those who do not know the Charterhouse interior to have this example of work to be found there.

CULPTURE AT THE ROYAL ACADEMY.

give this week a sketch by the artist, Mr. Thornycroft, of his principal work at the Academy this year, "The Sower." We commented on it in another column, and remarks on the Academy sculpture of

Renazzi, Andrea Brachi, Gaetano Pompiano, and Antonio del Vecchio, Secretary.

The *piano regolatore*, after passing through the various Commissions which had succeeded each other, received the approval of the Parliament, when a law was passed to enable the State to contribute to the rebuilding and extension of what had become the capital town of the country.

So early as 1873 it had become apparent that without the assistance of Government the city had not the power to meet the exigencies of the new position, and that it was not reasonable that the Commune of Rome should without assistance be required to provide for the expense of the proposed works, which were for the advantage of the whole nation. Nevertheless it was then decided to continue the works in the new Esquiline Quarter with the Via Nazionale, delaying other works for the time, and until Government assistance could be procured.

The Committee found, by reference to the statistics of the decennial period anterior to 1871, that the annual increment of the population had been 3,000; from 1871 to 1881 the increment had been 80,000, perhaps one-half of which was occasioned by transporting the seat of Government to Rome. In 1879 the increase was 7,100; in 1880, 9,000; in 1881, 6,500; and it was considered that, during the next twenty-five years, the annual augmentation might be reckoned at 5,000, or in all 125,000, which, added to the 300,000, the population at the time of the last census, would amount to a population of 425,000. Then, taking it as a basis that a well-arranged city contains 500 inhabitants to the square acre, including buildings and streets, the extension of the plan should be such as to provide for 850 square acres; and, as the inhabited part of the city in 1871 covered an area of 500 acres, it followed that the additional area required in the new quarter was 350 acres.

Additional spaces, conveniently placed, were also considered necessary for docks, markets, slaughter-houses, and above all for studios, workshops, and other buildings in connexion with the fine arts, one of the staple industries of Rome. The principal streets, it was determined, should be 25 metres wide, and the others should vary from 20 to 12 metres. It was more difficult to decide about the enlargement of the old streets on account of the difficulty of removing various old buildings of archaeological interest and artistic value which it was desirable to preserve. It was considered that the bridges should not be more than 300 to 400 metres apart, and that they should coincide with important streets already formed or contemplated, and the retention of gardens and public promenades, the committee considered, should not be neglected.

After making these general observations the Commission refers in considerable detail to various parts of the plan.

What may be gathered from this relation is, that vigorous efforts were made as soon as Rome became the seat of Government in 1870 to devise a plan for forming new streets and altering old ones, so as to effectually provide for the anticipated increase of population and the public buildings necessary for State and municipal purposes. The relation states that in 1865 a law had been passed to enable the compulsory acquisition of land and houses for purposes of public utility. It sets forth the various steps which were taken, the apparently thorough and conscientious study and publicity which was given to the subject, and concludes with recommendations as to the order of time in which the various works contemplated should be carried out.

The conception of the plan appears to me truly magnificent and of great public utility, because it is a *piano regolatore*,—that is, a plan which, after the largest opportunity for inquiry has been given, is the plan adopted by the governing body, the strict adhesion to which will ensure the development of a great and well-arranged city.

As I understand it, the Government takes the initiative, and requires the Commune to execute such works as the Government thinks necessary, leaving, however, as I gather from the relation, great latitude to the Commune as to the details; that thereupon the Commune studies the subject, and prepares its scheme and plan, and the approval of this plan is considered equivalent to a declaration of public utility, on which may follow the expropriation or acquisition of such property as may be

required for carrying on the work. It also appears that after the plan for the intended improvements, or probably after the order of the Government is given to take the matter into consideration, that a period of twenty-five years is allowed for the execution of the work, and the Commune has power to levy taxes so as to provide for the expenses of carrying them out.

The development of the new city commenced in close proximity to the termini of the railway, which, after skirting the east side of the city, enters it on the north-east, near the Porta Maggiore. Close to the railway station are the ruins of the Baths of Diocletian. Opposite these ruins a fine crescent has been formed, and from the centre of this crescent the important Via Nazionale has now been constructed, running in a south-westerly direction for nearly 1,000 yards towards the Piazza Venetia, which is at the southern end of the Corso, the great street of old Rome. This is a noble street; it falls pretty gradually towards the Piazza Venetia until at the lower end, where the street has an inconveniently steep gradient, and an awkward bend. At the present time the work of the demolition of the buildings which it is necessary to remove in order to extend the Via Nazionale towards the Castle of St. Angelo is actively going on.

From the Baths of Diocletian to the Piazza Venetia the Via Nazionale is now completely formed, lined on both sides with either new buildings (entirely so in the upper part) or with old buildings in the lower part of the street, the façades or enclosures to which have been altered so as to adapt them to the line of the new street. Some gardens also shut on the street, causing open spaces to be left; but the aspect of the street is on the whole highly satisfactory, and in parts even picturesque.

In the upper part is one of the large modern hotels of Rome, the Quirinale, not far from which, in a parallel street, is another modern hotel, the Costanze. On the upper part of the Via Nazionale stands a charmingly-designed church, built for the Americans,—who frequent Rome in large numbers,—by the late Mr. Street, in the Medieval style, with such modifications as the locality and the climate suggested to the mind of that most able architect. In the lower part of the street is a somewhat imposing building, called the Palazzo degli Belle Arti; the other buildings are private houses or shops. The street is of ample width, and planted as a boulevard, with trees on either side.

Not the least interesting work now in course of execution is the embankment of the Tiber, which is being carried on on the Trastevere side, in the prosecution of which scheme the embankment has been or will be advanced, and in one part the land at the back of the Palazza Farnesina, which projected into the stream, and narrowed it very inconveniently, has been removed. This work appears to be going on with considerable rapidity, and when completed will be a most important work.

THE SUPERINTENDING ARCHITECT: METROPOLITAN BOARD OF WORKS.

At the meeting of the Metropolitan Board of Works on the 14th inst., the Clerk, Mr. J. E. Wakefield, read the following letter:—

"Metropolitan Board of Works,
Spring gardens,
May 10, 1886.

To the Chairman and Members of the Metropolitan Board of Works.

GENTLEMEN,—I beg to inform you that I find myself compelled by failing health to tender my resignation of the position of Superintending Architect to the Board, which I have held for more than twenty-five years. It is with great reluctance and deep feelings of regret that I have resolved to withdraw from this high and honourable position, and from the performance of professional duties in which I have taken a very lively interest for nearly half a century (having entered my profession in July, 1830).

In doing my long connexion with the Board, I trust I may be allowed to express my grateful sense of the kindness and consideration which has always been extended to me by all the Members of the Board, the Chairman, and officers, the recollection of which will ever be a great comfort and consolation to me in my declining years.

In tendering my resignation I desire at the same time to say that I shall be prepared to continue the conduct of the business of the Department until the Board shall have made such arrangements as they may think necessary in consequence of my retirement, and shall also be willing and ready to place my services at the disposal of the Board on all occasions when the Board may think fit to honour me with their confidence.—I have the honour to be, Gentlemen, yours very faithfully,
GEORGE VULLIAMY."

Mr. F. H. Fowler said he was sure that he expressed the unanimous feeling of the Board,

which was one of regret that in consequence of declining health Mr. Vulliamy had felt himself bound to send in his resignation as Superintending Architect to the Board. No one knew more than those who were connected with him the high character of Mr. Vulliamy. He had served the Board for twenty-five years. A pupil of Sir Charles Barry, and for some sixteen years engaged in the practice of his profession on his own account, he was elected from among twenty-two competitors as Superintending Architect in the place of Mr. Marrable on the resignation of that gentleman in 1861, and since then had been actively concerned, under the direction of the Board, in carrying out some of the most important street improvements which the metropolis had witnessed, and in his retirement he would carry with him the respect and esteem of every member of the Board with whom he had been associated. He moved, in the first instance, that Mr. Vulliamy's letter of resignation be referred to the Works and General Purposes Committee.

Mr. Freeman said that, as the oldest member of the Board, he was able to endorse to the full all that had been said by Mr. Fowler as to the regret which the Board would feel at Mr. Vulliamy's retirement. He seconded the motion, which was unanimously agreed to.

Mr. Vulliamy some time afterwards entered the Board-room, and presented his usual weekly report on applications under the Building Acts. At the meeting of the Board to be held this Friday, the 21st, the Works and General Purposes Committee will present a report recommending that Mr. Vulliamy's resignation be accepted as from the 29th of September next.

It may be mentioned that Mr. Frederick Marrable, the first Superintending Architect to the Board, was elected on Feb. 4, 1855, when there were fifteen other candidates, viz., Messrs. W. Hosking, E. W. Lower, J. Blore, J. H. Taylor, G. L. Taylor, C. Leggs, H. Harrison, J. T. Wood, C. W. Pined, Thomas Young, John Barnett, E. C. Hawksill, William Young, F. W. Stent, and S. C. Gant. At the last moment, however, Mr. G. L. Taylor wrote withdrawing his candidature, as he considered the salary offered for the duties too small. A member of the Board moved that the appointment should be deferred, and the question of salary reconsidered, but this proposition was negatived, and the election was proceeded with. Four of the candidates (viz., Professor Hosking, Mr. Marrable, Mr. Hawksill, and Mr. Barnett) were first selected by show of hands to go to the final vote, and ultimately Mr. Marrable was elected.*

Mr. Marrable resigned in 1861 under the following circumstances:—The Covent Garden Approach and Streets Committee presented a report to the meeting of the Board held on Feb. 9 of that year, recommending that the salary of the Superintending Architect be increased from 800*l.* to 1,200*l.* per annum, but to this recommendation an amendment was moved, and carried by twenty-seven to nine, that Mr. Marrable's salary be increased to 1,000*l.*† At the following meeting of the Board, Mr. Marrable sent in his resignation, on the ground that when, in 1856, candidates were invited for the office at a salary of 800*l.* per annum, nothing was said to induce a belief that he would be expected to perform such onerous and responsible services of a professional character as had been demanded of him, relating to the survey, valuation, and purchase of property for the new streets undertaken by the Board, and he regarded the increase of salary now offered as inadequate. The resignation was accepted, and it was referred to a committee to consider the duties and salary of the office.‡

At the meeting of the Board on March 1, 1861, Mr. Vulliamy was elected by thirty-two votes as against twenty-nine given for the late Mr. Sanction Wood, twenty-seven for Mr. J. Kerr, twenty-six for Mr. Isaacs, twenty-six for Mr. J. Billing, and twenty-three for Mr. Fowler. There were seventeen other candidates, viz., Messrs. Sandders, J. Young, F. Wilson, Hart, C. Eales, Salter, H. B. Richardson, Liddiard, T. Goodchild, T. Morris, Blore, Dixon, T. D. Barry, Cooper, J. Hansom, Kirkland, and Salmon.§

In February, 1877, the Board determined to elect an Assistant Architect and Surveyor,

* *Vide Builder*, 1856, p. 78.
† *Builder*, 1861, p. 108. ‡ *Ibid.*, p. 130. § *Ibid.*, p. 1.

salary of 500*l.* per annum, and it was remitted to the Works and General Purposes Committee to select six candidates from among those who applied for the appointment. There were only eight applications. The committee submitted the following names:—Messrs. D. R. Dale, W. Ogerty, John Hehh, George McDonell, W. Hilton Nash, and Jasper Wager. Mr. Hehh was elected, and continues to hold the office.

ARCHITECTURAL SOCIETIES.

Edinburgh Architectural Association.—The annual general meeting of this Association was held on the 18th inst., Mr. Geo. Washington Rowne, President, in the chair. Mr. J. Fairburn, Hon. Secretary, read the report of the twenty-eighth session, which the Council stated at they regarded as one of unobtainable progress in all departments. The gentlemen admitted as members during the session numbered thirty-seven; twenty-seven names had been withdrawn, owing to various circumstances, and there were now 303 on the roll. The report having been adopted, the office-bearers for the ensuing session were elected, viz., Mr. Hippolyte Blanc, president; Professor Baldwin Brown and Mr. John Kinross, vice-presidents; Mr. T. Fairbairn, hon. secretary; and Mr. John Whiteley, hon. treasurer. On the motion of Professor Baldwin Brown votes of thanks were given to all office-bearers. The Chairman then read continuation of a paper on Monastic Architecture in Scotland.

Glasgow Architectural Association.—On Tuesday afternoon last a party of the members visited the Cathedral, and were conducted over the building by Mr. John Honeyman, R.I.B.A. Under his guidance the various portions, from crypt to tower, were seen, and in details of erection learned, a running commentary on the purposes of the different parts, and the intention of the builders where these appear to be departed from or unfulfilled, rendering the inspection a most interesting and instructive one.

Liverpool Architectural Society.—The annual report of this Society, read at the meeting on the 3rd inst., shows a slight diminution in the number of members, the number now being 35, as compared with 121 at the close of last session. This number is made up of 42 Fellows, 27 Professional Associates, 27 Associates, 23 Students, and two Corresponding Members. There had been eight resignations, viz., two Professional Associates and six Students. Among the members deceased, mention is made of the report of the late Mr. Samuel Huggins, many years a member of the Society, which is indebted to him for many contributions to the proceedings. Seven members had been elected, viz., one Fellow, five Professional Associates, and one Student. In the early part of the session the Council received, with regret, the resignation of the Hon. Sec., F. W. Hornblower, whose devotion to, and interest in, the welfare of the Society for past eight years had contributed in no small measure to its continued existence. Mr. C. W. W. has undertaken the duties of the office, subject of the federation of architectural societies had frequently engaged the attention of the Council, who had given their support to a committee formed by the Royal Institute of British Architects, upon which Mr. C. W. W. was placed, and Mr. Parslow has been nominated as the representative of the Society.

OBITUARY.

Sancton Wood.—Mr. E. C. Robins, Sancton Wood, whose office I entered in 1846, I have long requested by his representatives to write a few words about him. He died on the 2nd of April last, within a week of his seventy-year, and was buried on the 24th at Putney cemetery. He had resided in a house of his design on Putney-hill for the last thirty-years, and was formerly District Surveyor of Putney and Roehampton, but for the last twenty years he was District Surveyor of St. George's, Chelsea. He was a Fellow of the Royal Society of British Architects, and was a member of the Examining Board for District Surveyors. He was also a Fellow of the Institute of Architects of Ireland, and an Associate of the Institution of Civil Engineers. He was

* Builder, 1877, p. 189.

articled to Sir Robert Smirke, but was turned over to Sydney Smirke, and remained Classical in his architectural taste and practice. He was engaged by Mr. John Braithwaite to design the station buildings on the Eastern Counties Railway, and was the architect of the old termini at Shoreditch. He was the successful competitor for the Great Southern and Western Railway buildings in Ireland, and erected the Kingebridge Terminals and the stations from Dublin to Cork. He was also architect to the Limerick Junction line, and, living at a time when architects were not quite elbowed out by engineers, he became architect of the Rugby and Stamford Railway, and the Syston and Peterborough Railway buildings in England. He was subsequently architect to several building estates, and built many private houses and London offices, notably those at the southwest corner of King-street and Gresham-street. In his later years he was much employed in arbitrations, and was an able administrator. He was married, and had two sons, who preceded him to the grave.

We are asked to add to the above that in 1846 Mr. Wood received a premium of 100*l.* for his designs for the Blackburn Railway Station, offered by the Blackburn and Preston Railway Company.

BUILDERS' BENEVOLENT INSTITUTION.

An election of pensioners on the funds of this Institution took place on Thursday afternoon, at Willis's Rooms, St. James's, Mr. Arthur C. Lucas, J.P. (President), in the chair. There were three vacancies,—two for men, and one for a woman,—for which there were six candidates, five of whom were men. The following is the list of the candidates, with the number of votes polled for each, according to the report of the scrutineers (Mr. Thomas Stirling and Mr. Keeble), viz., John E. Rowe, Croydun, aged sixty-three, builder, 1,661 votes; Samuel Walton, Holloway (formerly a subscriber to the Institution), aged sixty-eight, builder, 1,283 votes (including 140 allowed for subscriptions); Ebenezer Robinson, Camberwell, aged seventy-two, builder, 353 votes; James Picking, Clapham, aged sixty, builder, 74 votes; and Thomas Norton, Brook-green, aged forty-six, 330 votes.

John E. Rowe and Samuel Walton were therefore declared to be the successful male candidates, and Mrs. Caroline Cleary, of Highbury Quadrant, widow of Joseph Cleary, builder, being the only female candidate, was elected as a matter of course.

Votes of thanks to the chairman, proposed by Mr. Foxley, and to the scrutineers and other gentlemen who had taken part in the proceedings brought the meeting to a close.

CASES UNDER THE METROPOLITAN BUILDING ACT.

NEGLECT TO SUBMIT PLANS TO DISTRICT SURVEYOR.

At the Hammersmith Police Court on Saturday, Mr. Harris (Harris & Wardrop), contractor, was summoned for omitting to produce to Mr. Knightley, the District Surveyor, plans and sections showing the constructions of proposed stabling for Messrs. Carter, Paterson, & Co., in Glenthorne-road, Hammersmith.

Mr. Knightley said he sent formal notice to the builders for plans, but without effect.

The defendant said his foreman called one day at Mr. Knightley's office. He only saw a junior clerk, and refused to leave the drawings. He (the defendant) added that Mr. Knightley could have seen the drawings at the building at any time.

Mr. Knightley contended that the production of the drawings meant in such manner that he should have time and a fair opportunity to examine them. The Magistrate, Mr. Bennett, expressed a similar opinion, and imposed a penalty of 3*l.*, with costs.

WHAT IS A PARTY-WALL?

At the Worship-street Police-court, on Wednesday, Mr. James Stone, a builder, of Walthamstow, was summoned under the Building Act, for so irregularly building a certain party wall that it did not rise 15 in. above the roof.—Mr. Jutsum, solicitor, appeared on behalf of the prosecuting surveyor, Mr. Meeson, of the District of East Hackney North; and Mr. Adam Burn, barrister, defended.

The defendant, it appeared (we quote from the report in the Daily Telegraph), was the contractor for certain buildings being erected in Theydon-road, Hackney; and the point of the case was whether the wall in question was or was not a "party" wall within the meaning of the Act. If a "party" wall it was necessary that it should be carried up above the roof at least 15 in., whereas the evidence of Mr. Meeson showed that the wall was covered by the roof. There was no contention as to the facts, and it was shown that the buildings in question

were intended for "block dwellings," and are being erected in eight "blocks."

The defence was that the total area of the "block" in question was only 1,200 ft. super, whereas 3,600 ft. was the allowance under the Act for areas without party walls.

Mr. Meeson's contention was that the wall, being the boundary of the "separate dwelling," as model dwellings" are let, was a "party" wall, and a long discussion as to the bearing of the Act took place on the point; the Act, it was submitted by Mr. Jutsum, being sufficiently clear in its definition of a "party wall" by stating that it should "apply,"—a word which Mr. Hannay remarked was very oddly used in that connexion,—"to any wall separating a building from another building occupied by different persons."

Mr. Hannay said that if that view of the matter was to be held good, a set of chambers would require a "party" wall.

The solicitor submitted that they did, and that the "flats" of "model dwellings" were "separate dwellings" was clear from the Representation of the People Act, which treated them as dwelling-houses.

Mr. Hannay said that it was well known that separate occupation was a "separate dwelling" for voting purposes; but if a separate occupation was a "separate dwelling" within the meaning of the Building Act no person could let a portion of a house to a lodger without putting up a party wall from roof to basement.

Mr. Burn cross-examined to show that for every "separate" dwelling, District Surveyors under the Act were entitled to a fee about six times greater than that allowed for a mere survey of so many floors, &c. Therefore, if Mr. Meeson were to succeed in his contention, it would be greatly to his benefit.

Mr. Hannay thought that point need not be pursued.

Mr. Burn having addressed the Magistrate for the defence.

Mr. Hannay said that he could not go with the contention for the prosecution, that a set of chambers or "rooms" was a separate building; and he was helped to that opinion on reading the 27th section of the Act, which said that every building should have its "external or party wall." In his opinion the wall in question was not necessarily a party-wall; therefore the defendant was not bound to carry it above the roof, and the contention for the Surveyor must fail. He dismissed the summons, and ordered the Surveyor to pay the defendant two guineas costs.

TALL CHIMNEY CONSTRUCTION.

SIR,—Your correspondent "J. H. G." (page 694, ante) having put six queries to the readers of your paper, and especially asked me to reply, with your permission I will endeavour to do so, taking them *seriatim*, embodying in the answers the opinion and experience of men who have practically superintended the erection of this class of work, both in England and America, for many years.

Cement Rings.—The whole of the chimney should be built with good lime-mortar, and not with cement rings every yard in height. Some shafts have been built with cement rings; probably it is thought this prevents cracking, but I know chimney-designers and builders in the counties of Lancashire, Nottinghamshire, and Kent who use good lime-mortar throughout because they are convinced it is better to preserve the homogeneous character of the structure.

Concrete Chimney.—I only know of one shaft being built in concrete,—that is at the Chain Cable and Anchor Teeting Works, Sunderland, and is described and illustrated in our book. If any of your readers know of other examples I hope they will communicate the same to the Builder.

Exhaust Steam.—The discharge of exhaust steam into the chimney cannot always be avoided, but it is very rarely done. I know a case in the City of London where the exhaust steam is conveyed into the chimney-shaft, but this was arranged to avoid causing a nuisance to the opposite premises. The responsible person in charge considers it detrimental to the brickwork. Some chimney-builders say that exhaust steam injures the draught when discharged up the shaft, as the steam forms itself into a column and takes up the centre of the chimney, and saturates the smoke. The vapour clings to the chimney sides and causes a wet lining of soot on the brickwork, and so affects the mortar that it falls from the joints every time the fires are stopped. The face of the brickwork will peel off when touched, similar to plaster on a damp wall. The whole length of the flue from where the steam enters is wet and slimy on all sides, and there is a constant downpour of soot and grit accumulating at the

base, which causes 25 per cent. more dirt than if no steam entered, and the damp and dirt in the flue make the chimney more unhealthy and laborious to the men employed.

Portland Cement.—The Liverpool Corporation specify their cement as follows:—It must be of uniform quality and capable of bearing the following tests to the satisfaction of the engineer:—

1st. Samples of the cement being sifted through a No. 60 gauge wire sieve, must not leave a residue of more than 10 per cent.

2nd. Samples of pure cement will be gauged with water and placed in brass moulds used by the corporation. Within twenty-four hours the casts thus made will be immersed in still water, in which they will remain until the expiration of seven days from the date of moulding, when they will be taken out of the water and tested to ascertain their tensile strength, which must not be less than 1,000 lb. on the sectional area of 2½ square inches.

3rd. In ordering the cement it will be distinguished as quick-setting or slow-setting. In order to ascertain the time of setting a modification of Vicat's needle will be used, having an area of 1/400th part of a square inch and a total weight of 2½ lb. The slow-setting cement must take an impression from the needle when standing vertically upon it at any time within three hours after moulding. The quick-setting cement must take the impression only during the first half-hour.

"J. H. G." should not overlook the important provision as to the amount of water to be used in moulding briquettes for testing. An excess of water will adversely affect the result; the right proportion is 9 oz. to 40 oz. of cement, as given in Grant on the "Strength of Cement."

Shafts out of Perpendicular.—There is a chimney in Lincoln upwards of 140 ft. high from the ground-line, which stands considerably out of plumb, and has been so many years. Inspections have been made two or three times during the last twelve years, and it shows no alteration. Some years ago I saw several moderate-sized engine-house shafts in the Staffordshire mining district, a little out from the vertical, owing, I suppose, to the subsidence of the ground from removing the minerals.

Mortar or Cement, when exposed to great Heat.—I presume that "J. H. G." asks this quite apart from the question of fire-brick lining, which, of course, is always set in fireclay. I have found that practical chimney builders consider that brickwork in mortar will stand greater heat than brickwork in cement. Your correspondent will also find the following authorities agree with this:—

Hurst's "Surveyor's Pocket-book," twelfth edition:—"Mortar is generally preferred to Portland cement in the erection of chimneys, as the latter does not stand the heat well."

T. Box on "Heat," fourth edition:—"Mortar should be used for the most part, because cement is destroyed by a strong heat; the 4½ in. work at the top, however, should be in good cement. With so thin a wall the heat is rapidly carried off by the external air, and the cement will not be injured."

R. Wilson, on Boiler Chimneys, says:—"Cement, owing to its crumbling when exposed to a high temperature, cannot be recommended except for the top of the chimney, where it may be usefully employed."

R. M. BANCROFT.

ARCHITECTURAL ASSOCIATION.

SIR,—For the benefit of those who were unable to attend the supplementary lecture on the History of Architecture last Saturday, and who have written to me for information, I would say that, after looking at Assyrian, Persian, Egyptian, Greek and Roman work at the British Museum, we visited the following buildings:—St. Bartholomew, Smithfield, for Norman; the Temple Round Church for Transitional; the Temple (eastern portion) and St. Bartholomew's western doorway for Early English; St. Etheldreda's, Ely-place, for Geometrical; Austin Friars church for Curvilinear; Great St. Helen's for Rectilinear; Lincoln's Inn gateway for Tudor; Middle Temple Hall for Elizabethan; Whitehall for Inigo Jones; Bow Church for Wren; the Adelphi for Adams; and Somerset House for Sir W. Chambers.

It would have been easy to begin with the Confessor's work at Westminster, and to have filled up many gaps in the list, as London is still capable of showing a connected series of styles from Anglo-Saxon to the beginning of this century, but the above had to be seen in the course of an afternoon.

EDWARD J. TARVER, Lecturer.

ARCHITECTURAL ASSOCIATION EXCURSION TO ROME.

SIR,—Those of your readers who have taken an interest in the scheme which I brought forward several months since for short excursions to Rome will have gathered from the notices you have printed during the last few weeks that the first of these excursions has been successfully carried out. It happened that I was at Rome at the time of the visit, and saw the party at other places, and I feel extremely gratified with the result. The labour of getting up this excursion and of conducting it was undertaken by Mr. H. D. Appleton, one of the Hon. Secretaries of the Architectural Association, and while I shall be very glad to promote any further excursions made with the view of seeing the best examples of the architecture of Italy, Mr. Appleton will be happy to place the experience he has gained at the service of any students who may apply to him.

The party that has recently returned will combine to put on record in some suitable way the impressions they have received during their short visit to Italy.

THOS. BLASHILL.

FULHAM VESTRY HALL COMPETITION.

SIR,—We have received the following letter from the Vestry in reply to our inquiry as to whether they would appoint a professional assessor for the so-called second competition, for which, with our reply, we shall be glad if you can spare space in your next issue.

NEWMAN & NEWMAN.

19a, Tooley-street, London Bridge,
May 20, 1886.

[COPY.]

"Vestry Offices, Walham-green,

May 19th, 1886.
DEAR SIRS,—I beg to inform you that at the meeting of the Fulham Vestry held last evening, it was resolved to adhere to their resolutions of the 6th of April last not to appoint a professional assessor to examine the amended plans, and to make no alterations in the date for depositing the amended plans.—I am, dear Sirs, yours faithfully,
CHARLES J. FOAKES,
Clerk to the Vestry."

"DEAR SIR,—We are in receipt of your letter of yesterday, and are not at all surprised at the course your Vestry have taken, as it fully confirms our views as to the 'straightforward' way in which this competition has been conducted, and also confirms the report we have heard upon good authority that the work was from the first intended for a local architect."

In answer to your Vestry's advertisement, about seventy-five architects have expended their time and money needlessly, and as neither the designs under the mottoes 'Clavus' or 'Truth' (the authors of which are known to us) were considered by Mr. Curry worthy of notice, the Vestry has now given them an opportunity of altering and amending their designs at the expense of the other competitors, and has reserved to itself the rights of final selection. After this we will say no more in the matter, but will leave those interested to form their own opinions.—We are, dear Sir, yours truly,
C. J. FOAKES, Esq. NEWMAN & NEWMAN.

BELPER UNION INFIRMARY COMPETITION.

SIR,—Accompanying the "Instructions" for this competition is a drawing comprising plan of site, levels, and an elevation of the present infirmary. This drawing bears the name of a Belper architect, and it would be well for intending competitors to ascertain (if they can) how this gentleman stands with reference to themselves.

Many of your readers will remember that a few months ago the Birmingham Guardians advertised for designs for an infirmary to cost 60,000*l.* There were only six competitors. And why? Simply because it oozed out that a local man had already prepared designs, and inspected other infirmaries in company with the guardians. Moreover, it was stated that it was only by the casting vote of the chairman that a competition was decided on. May not the Belper case be a parallel one?

Competitors are asked to give "an accurate estimate" of the cost of carrying out their designs, but the Guardians give no indication whatever of the amount they intend to spend. Doubtless this is one point, among others, in which outsiders will be heavily handicapped.

The Guardians deserve credit, however, for being quite clear on one matter. The last clause of the "Instructions" reads:—"The Guardians do not intend to appoint an assessor."

NOT A COMPETITOR.

The Statue to Mr. Samuel Morley at Bristol.—We are informed that Mr. Havard Thomas has secured the commission for the Samuel Morley memorial statue, which is to be erected at Bristol. The figure is proposed to be of heroic size, and will be placed upon a pedestal of granite. Mr. Thomas's commission is the result of a competition in which his model was successful.

PROVINCIAL NEWS.

Abingdon.—The Corn Exchange here was formally opened on the 5th of May. It occupies a prominent site in the Market-place, and is built of red pressed bricks, with white bands, &c. The interior is 80 ft. by 45 ft. The interior walls are of white bricks from Bridgewater, relieved by red brick dressings. There is also some effective ornamental brickwork introduced, by Poulton, of Reading. The roof is open, with wood principals and iron trusses of special design. There are four openings on one side and out of the hall, forming shops. The platform is specially designed for concerts and other performances, and has two retiring-rooms below, with separate entrances. The main entrance is in the front, with an extra one at the side. Over the entrance is a gallery for ladies. The roof lighting is by Rendle's patent glazing on the north side. The front gable is surmounted by a stone figure of Ceres, by Mr. W. Frith, of London, the gift of Mr. J. Heher Clarke, who was mayor of Abingdon when the building was commenced. The architect is Mr. Charles Bell, of London, whose design was selected in a limited competition on the award of Professor Hayter Lewis. Mr. Williams, of Abingdon, was the builder. The contract sum being 1,840*l.*

Aylesbury.—A new wing has been built at Messrs. Hazell, Watson, & Viney's extensive printing works at Aylesbury. The working-space now afforded is nearly an acre in extent, and consists of eight floors, each measuring 100 ft. by 40 ft., and some additional ground-floor space. Access to both buildings is obtained from a stone staircase, built in a tower between the two buildings. There is scarcely a partition in any of the floors, so that each floor forms a light and cheery space for each department of the business. Would that this could be said of all printing-offices! The architect was Mr. P. H. Watson. The building work was done by the firm without contract, Mr. Jesse W. Landon being the building foreman; and the whole of the details were carried out under the immediate superintendence of Mr. Jowett.

Brooklands (Cheshire).—On the 13th inst. the Bishop of Chester opened the parish room recently erected at Brooklands from the designs of Mr. Charles Heathcote, architect, Manchester. The room is in connexion with the church of St. John the Divine, is cruciform in plan, and will accommodate 325. The two arms of the cross can be separated from the remainder of the building by folding-screens. A vestry, a room for the preparation of refreshments, and two retiring-rooms complete the plan. The porch, containing two sets of folding-doors, is warmed, like the remainder of the building, with high-pressure pipes. The heating apparatus chamber and a large store-room are in the basement. The building is lined above the wooden dado with bands of red and buff Rushton bricks. The roof is open-timbered and wood-lined, and the internal fittings and floor are in pitch pine. The extract-ventilator, with current induced by gas-jets, is in a turret at the west end. The floors of the porch and tea-room are laid in mosaics. The builders were Messrs. Wilson, Toft, & Huntley, of City-road, Manchester.

Glamorganshire.—At Gower-road, in the county of Glamorganshire, a Conservative club has just been erected. The main structure, except the joiner's work, has been built by the workmen of the Elha Steel Works, under the direction of their foreman, Mr. George Beynon. The walls are built of slag from the works, and on the first story half timber-work is introduced. The slag, which is simply burned cinders from the furnaces, is put together with Aberthaw lime, the outside of which, between the timber, is covered with rough-cast. The building contains reading-room, billiard-room, and a large telles recess, card-room, and bar-parlour; and these rooms is a large assembly-hall with open timber roof, and approached by a distinct entrance. Two class-rooms are provided. Adjoining the club is a cottage for the caretaker, Messrs. Brown, Thomas, & Johns, carpenters of Llanelly, executed the woodwork, and the building was designed and carried out under the supervision of Mr. J. Buckley Wilson, architect, Swansea.

Newport (Salop).—At a recent meeting of the Newport Town Council, the General Purposes Committee recommended for approval plans of four streets submitted to them by the architects to the Newport Cottage Company, Limited.

and of two other new streets, one of which was in Caerw Park, for Mr. J. A. Herbert. The Deputy-Mayor congratulated the town upon its prosperity, as indicated in the spread of building operations. The four new streets for the Cottage Company would provide 390 dwellings suitable for the poorer classes, and at rents within their reach. The recommendation was adopted.

Stoke-upon-Trent.—At the last monthly meeting of the Town Council, the Cemetery Committee reported that, having considered Mr. J. Forsyth's account for laying out the cemetery, and the report of Messrs. Milner thereon, they found that a deduction of 769l. 7s. 10d. out of the claim of 1,194l. 3s. balance of his contract and for extra work had been made by Messrs. Milner, who had certified a sum of 424l. 15s. 2d. as being due to Mr. Forsyth. The committee having considered the statement of accounts and Messrs. Milner's report, and the unnecessary difficulties Mr. Forsyth had had to contend with, owing to the unanticipated rocky nature of the ground, recommended that he be paid the sum of 500l. in total discharge of all claim. It was explained that besides the 424l. 15s. 2d., there was 30l. due for shrubs, so that the proposal was to pay only 46l. beyond the certified sum; and Mr. Milner had informed the committee that Mr. Forsyth had had unexpectedly to contend with difficulties by reason of stone strata in many places not having been revealed by the borings. The Council, however, decided to adhere to the certificate of Mr. Milner, and to pay so much as 500l.

ROMAN CATHOLIC CHURCH BUILDING NEWS.

Ford (near Liverpool).—On the 9th inst. the foundation stones of a new church for the benefit of the Good Shepherd, Ford, near Liverpool, were laid and blessed. The new church, which will be dedicated to the Sacred Heart, is designed to accommodate three separate congregations, who will be present at Mass in the building at the same time, all of whom must see the altar, but without any of them seeing either of the others. To carry out this idea there are two naves, which will be separated by an arcading filled in with screens, one to be occupied by the nuns, and the other by the penitents, while the third, the "externs," will be provided with commodation in the transept running at right angles to the chancel. Near the chancel will be two arches, which will be connected by five arches with the chancel, supporting an octagonal tower 30 ft. in diameter, and rising to a height 54 ft. The total length is 88 ft., the internal width 52 ft., and the height will be 40 ft. Red brick, with dressings and Bootle stone, is being used in the construction of the building, for which Messrs. Pugin & Pugin are the architects, and Messrs. Roberts & Robinson, of Liverpool, the contractors. The cost of the building will be between 6,000l. and 7,000l.

Trays (Essex).—The first stone of a new school-chapel, &c., at Grays, was laid on the 6th ult., by Cardinal Manning. The new buildings are being erected from designs by F. H. Pownall, architect, Montagu-square, London, and comprise, on the ground-floor, schools capable of holding over 400 children, and a church above, to seat from 500 to 600 persons. The buildings are Early Gothic in character, and faced externally with stocks, of local manufacture, relieved with red bricks.

Greenhill (Swansea).—A new Roman Catholic church at Greenhill, Swansea, in the Diocese of Exeter and Menevia, for the Very Rev. Canon Hardey, O.S.B., has just been commenced. It is a most picturesque site, and will be seen in all parts of the town. The architects are Messrs. Pugin & Pugin.

The Laet of the Old "Cock" Tavern, Fleet-street.—The historical Cock Tavern in Fleet-street will shortly be replaced by the buildings about to be erected by the Bank of England, and on Tuesday last the materials for the ancient hostelry were sold by Messrs. G. Son, & Everfield. The new structure of the Bank authorities intend to erect on the site will have a frontage to Fleet-street of 90 ft.

STAINED GLASS.

Bexley.—The five chancel windows in the new church of St. John the Evangelist, Bexley, Kent, have recently been filled with stained glass by Mrs. Layton, of Bexley, in memory of her late husband, Edward John Layton, through whose instrumentality the building was erected and to which he was a munificent donor. The centre window represents the Crucifixion, and in those on each side, the subjects of the Good Samaritan and Our Lord blessing little children, have been respectively illustrated. The extreme north window contains the figures of St. Peter and King Edward in niches under rich canopies, and on the extreme south St. John the Evangelist and St. Paul similarly arranged. In the quatrefoils of the centre window is the *Agnus Dei*, and in the four others the emblems of the four evangelists. The windows are all two-lights, and have been executed by Messrs. Burlison & Grylls under the supervision of Mr. George Low, the architect of the church.

Penn (Bucks).—The parish church of Tyler's Green, Penn, Bucks, has just received two Munich windows, one representing St. David, in memory of Mr. James Plaistowe, of Land-water, and the other containing a figure of St. Margaret, in memory of Margaret Amelia Rose. The work has been designed and carried out by Messrs. Mayer & Co.

Westwood (Coventry).—Westwood Church has been enriched by a stained glass memorial window to the Vicar's wife, who died last year: the window was unveiled on Easter-day. The subject represented is Our Lord meeting Martha and Mary. In the tracery is an emblem of the Trinity. The window was designed and executed by Messrs. F. Holt & Co., Warwick.

Winchester.—A memorial window to Lord Chief Justice Erie, who was a devoted Wykehamist, has been placed in a window of the south aisle of the cathedral nave, directly before the south face of the chantry of Wykeham. It is by Messrs. Clayton & Bell, and has been provided by Lady Erie. It is of six lights, with trefoil heads, in which are the college arms, the Erie arms, and an angel with an open book. The six lights are filled with figure subjects. In the upper tier are Wykeham, in full pontificals, and Bishop Ken, vested in the robes of the Protestant bishops. Between these two is the Virgin, to whom the two colleges are dedicated, holding the Divine Child. The second row includes figures of Faith, Charity, and Justice, with their conventional symbols and attributes.—*Hampshire Independent.*

The Student's Column.

OUR BUILDING STONES.—XI.

ON THE ORIGIN AND STRUCTURE OF SANDSTONE.

THE rocks included under this heading constitute a large class of building materials. They are composed mostly of grains of quartz cemented together by various kinds of mineral matter.

Sandstones are essentially aqueous rocks,—that is, they were formed in water, and the great majority of those used in building were laid down in the sea not far from land; for the quartz grains of which they are composed were derived from the denudation of the land. In the first instance, the grains were no doubt obtained from the wearing away of crystalline rocks containing quartz, but the majority of the sandstones formed at later periods were largely made from the destruction of pre-existing arenaceous rocks. Many sandy deposits now in process of formation, for instance, have obtained the materials of which they are made from the denudation of the sand-cliffs along our coasts.

Suppose we follow out the formation of a sandstone the quartz in which has been derived directly from a crystalline rock, such as granite. The felspar, as previously stated, would decay, and, being borne out to sea in the form of mud, would form clay. Part of the mica would also be removed, thus leaving the remainder of the mica and the quartz loose. These the sea would eventually seize hold of, the mica being carried away some distance from the beach at an early stage in the process, but the quartz crystals would be rolled to and fro on the beach, knocked together and broken, their rough, jagged edges

being worn off whilst being made into pebbles. The pieces resulting from this fracturing would be of various sizes, and the smaller pieces or grains of quartz, being small enough for the water to hold in suspension, would then be carried away from the shore. If we still follow these little grains up we shall find that as the velocity or drifting action of the water became insufficient to suspend them, they would fall to the bottom, being quietly deposited there. It often happens that flakes of mica are deposited with the quartz, and are so arranged in thin layers that, when the sand becomes hard, it assumes a fissile character, which renders it capable of being split up into flagstones (see ante, p. 694).

Little pebbles would be frequently deposited in the coarser sand.

As molluscs and other organisms living in the sea died, their remains would be covered up by the deposit of sand, and unless subsequently removed, would be handed down to us as fossils. The accumulation of sand in time might become very great when the upper part of it, exerting considerable pressure on the lower, would cause it to become compact.

Although it has been shown that pressure alone is sufficient to make particles of sand cohere into a hard mass, yet by far the greater quantity of sandstone quarried for building purposes has a matrix or cementing material. This in most cases has been introduced into the stone after the sand has been laid down, for water in percolating it has left behind some of the chemicals which were held in solution, and these, forming round the grains of sand and filling up little spaces, made the mass hard,—in other words, made the sand into a sandstone.

A microscopic examination of sandstone imparts a considerable amount of useful information. Then it is seen that a specimen, which from outward appearance was not suspected to contain any grains but those of quartz, is made up also of minute particles and fragments of other minerals. This is a feature of much interest. If the specimen contained a more than usual quantity of silicate of alumina with potash, lime and soda, there is just the possibility that minute particles of felspar are present, but as the analysis would only give the aggregate chemical composition, we could not be quite sure in what form those chemicals occurred. An examination of a thin section of the rock would go far to settle points like these.

Little opaque grains of some form of iron are frequently seen under the microscope. These are waiting to be attacked by the atmosphere, and by their decay cause unsightly ferruginous lines to run down the surface of the stone when built up. The microscope is also useful in pointing out the state of cohesion of the quartz grains, and to some extent the nature of the matrix. If, for instance, the grains are rather far apart, and the mineral calcite appears between them, the stone would not be very durable, but more so than when the carbonate of lime existed, as it very often does, in an earthy form. If, on the contrary, the small quartz grains are close together, and the little matrix present looks firm, that is, does not present a decomposed, woolly appearance, the stone would be durable and easy to work. It would be still more durable if little veins, presenting the granular structure peculiar to chalcodony, or secondary quartz, were seen running here and there between the grains of quartz, although we should remember that the more siliceous the matrix is, the more difficult the stone becomes to work up.

If the sandstone under examination contains many shells, the mineral composition of those shells should be ascertained. Their original composition is often replaced by silica, but occasionally they are made of some form of carbonate of lime, and might then be submitted to the method of microscopic analysis for the determination of the particular form as described on p. 695.

LIMESTONE.

This class of stone is raised extensively for building purposes in many parts of the country, but often occurring in the midland and northern counties close to sandstones of better quality, limestones are not so generally used as they might otherwise be.

We will first consider the origin of limestone. Although sometimes deposited chemically, the greater quantity of carbonate of lime derived from the denudation of rocks, which is

rought to the sea by rivers, is eliminated by the agency of molluscs and other organic life. These organisms having died, and their shells being covered up by other shells, after a lapse of time such an accumulation takes place, and the deposit becomes so thick by the augmentation of shell sand, that the underlying portions are subjected to such a pressure as to make them tolerably compact. The deposition of different minerals from percolating water, subsequently aids the whole in becoming a limestone. The shell-sand is formed of broken up and pulverised shells. It is not difficult therefore to see why limestones contain so much shelly matter. One of the best known limestones is chalk, which is often used locally as a building material. On examination with the microscope this rock will be found to be almost wholly made up of the broken, and more or less perfect shells of marine organisms.

Several limestones found in this country and elsewhere, were evidently at one time coral reefs, as they are composed of the skeletons of those animals built up one upon another. In some instances, the character of these reefs has been gradually obliterated by the passage of percolating water through them, which has dissolved and re-deposited the carbonate of lime, of which the corals were made. In this way a crystalline structure, formed of organic remains, has been set up, without the agency of subterranean heat.* Other limestones appear to have been similarly affected.

The microscopic structure of the little spherules which, together, help to form oolitic freestones, was described on p. 695. These little egg-shaped bodies were probably formed in water charged with a considerable proportion of carbonate of lime, and under the influence of gentle currents which drifted along the grains of quartz or fragments of shells now forming their nuclei. The carbonate of lime would be deposited on any surface suitable for its reception, such as that presented by these grains and fragments, and continual motion being kept up during deposition, it would form in layers round all sides of them. Such an action is proceeding in some parts of the globe at the present day.

The fact that grains of sand often form the centres of these oolitic spherules, and that sand frequently also occurs distributed throughout the rock, accounts no doubt in some measure for the silica which a chemical analysis shows is present in some limestones. We may remark that where this is the case the silica has no preservative action whatever, as, directly the oolitic grains forming the rock decompose, and the carbonate of lime is removed, the grains of sand, being loosened, simply fall out, having nothing to support them.

The microscope, however, often shows us that all the silica present is not confined to the grains of sand, but that some of it is distributed in a vein-like manner between the spherulitic bodies. When this is the case, the stone would show rather a high "crushing weight," and although, perhaps, it might not be a very good freestone, it would be much more durable than the ordinary limestones used in building.

Those rocks which are largely composed of carbonate of lime and carbonate of magnesia are called dolomites or magnesian limestones. They are often crystalline in character. In some instances, dolomites appear to have been formed by an original chemical precipitate from the saline water of inland seas.† In others, the rock has been altered to a great extent by heat and pressure, and a crystalline structure thus set up. Thirdly, they have been formed by the abstraction of carbonate of lime from those which contained but little carbonate of magnesia, and they may then have had their proportion of magnesian carbonate increased by the action of percolating water. It has been shown that shells and other organic remains originally made of calcite or aragonite have been converted into dolomite in this manner.

Limestones of fresh-water origin have been used in some districts for ecclesiastical ornaments. Parbeck marble, for instance, was much employed in this manner, in many of our cathedrals and churches for slender shaftings, tombs, &c. This stone is sometimes also known as "paldina" marble, from the fact that it is largely made up of the fresh-water shell of that name.

Although a large number of limestones are comparatively free from foreign matter, it is

* See Dana's "Coral and Coral Islands," p. 354.
† See Berry Hunt, "Geology of Canada" (1863), p. 575.

evident from their origin that such must to some extent occasionally be present. Unless formed under very favourable circumstances, clay, iron, and bituminous matter, in addition to the sand, before referred to, will be more or less prevalent in them. The methods of detecting these impurities have been described on p. 491.

FLINT.

This material is largely used for chnrcebs, &c., in districts where it is abundant. Most of it comes from the upper part of the chalk, the lower chalk containing but very little. As it hardens on exposure to the atmosphere, it is more easily dressed when fresh from the chalk-pit than when it has been lying about for some time. It is composed of silica, but frequently contains impurities such as iron.

Flint has been formed in various ways. It is often found enveloping sponges and other organic remains in such a manner as to leave but little doubt that much of it accompanied the deposition of the chalk, though why it should have a tendency to form in lines as it does is not very clear. It is certain that some flint at least was not formed until the chalk was made compact, because it is found filling cracks which were not in existence before the chalky deposit was considerably dried, the cracks being formed during the contraction, consequent on drying. Water holding silica in solution appears to have permeated the chalk, leaving that oxide behind in the cracks and joints.

Unless flint is very impure it will last for ages when built up. The principal thing to look to in constructing a building of flint is the cementing material or mortar.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

609, Ventilating Buildings. E. Tomlinson.

A series of outlets are made from the rooms, &c., into the various chimneys, the smoke being collected by suitable cowls fixed on the ordinary chimney-stack. In the case of a single building the cowl may be continued over the roof or down the side in such a manner as to cause the condensation of the smoke. An artificial exhaust is employed, and after treatment of the smoke the gases are discharged by an up-take-pipe, into the atmosphere above the roof.

531, Measure. W. R. Lake.

Along the side or upon the back of the tape measure or scale is printed a corresponding logarithmic scale, so that calculations of cubical contents, &c., may be readily made.

843, Disinfecting Apparatus. J. Robertshaw and J. T. Turner.

Consists of a vessel, round the rim of which is a channel or gutter, and inside of which is suspended, from suitable supports, a metal plate, wire, or disc, or other suitable flat surface, on which sulphur may be burned or volatilised.

881, Hardening Stone, Cements, &c. B. J. B. Mills.

This invention consists in economising cements, &c., in the formation of agglomerates not of a merely earthy nature, permitting the employment therein of vegetable matters, such as hay, algae, sawdust, &c., and hardening, without baking or compression, by the addition of rock alum and a suitable sulphate. The materials are mixed and shaped, dried, and immersed for twenty-four hours in a solution of any suitable sulphate, preferably zinc sulphate, with the addition of rock alum. The compound may be dried and again immersed in a bath of greater density than the first, or the immersions may be replaced by three or four waterings at intervals with the same fluid. Vegetable materials thus bound together may be made into partitions, hollow vessels, boats, &c. The mixture of rock alum and a sulphate may be applied for the preservation of public monuments, &c., for hardening soft stones, plasters, &c., for incombustible coatings for wood-work, &c., for coating ships' hulls, conduits, &c., and for other purposes.

896, Strengthening Wooden Mallets. A. J. Bonlt.

The working surfaces of mallets, the wooden handles of tools, &c., where the surface of the wood is at right angles to the grain, are strengthened by strips of tough wood, raw hide, indiarubber, &c. (but not metal), which are bevelled at the ends, bent round to a circular form, so that the ends overlap, or to a spiral form, and, lastly, glued and pressed into circular recesses in the article to be strengthened.

897, Manufacture of Tiles. A. J. Bonlt.

An hexagonal receptacle or basket is mounted on a vertical shaft by which it may be rotated at a

high speed. Moulds having glass backs for the purpose of producing a smooth surface are arranged on the interior of each of the sides. The sides are hinged so that they may be opened outwards for removing the moulds. The material which is to form the surface of the tile is fed in first while the shaft is rotating, and the material to form the back is fed in afterwards. When the tiles are of sufficient thickness the basket is removed and a fresh one substituted. The apparatus may be modified to render it applicable to other articles than tiles.

Miscellaneous.

The Proposed New Bridge at Battersea.

At the meeting of the Metropolitan Board of Works, on the 14th inst., the Clerk read a letter from Mr. Geo. B. Godfrey, whose tender for the erection of a cast-iron bridge across the Thames at Battersea for the sum of 130,000, was provisionally accepted at a previous meeting of the Board, stating that since his tender was before the Board he had gone more minutely into the details, and, for certain reasons which he had stated to the Board's Engineer, he found that he should require 135,000, instead of 130,000, for the execution of the work, and that he should not feel justified in undertaking the contract unless the amount was raised to that sum. On the motion of Mr. Shepherd the subject of these tenders was referred to the Works and General Purposes Committee. The list of tenders for the work was given by us last week (p. 731).—At the meeting of the Board to be held this Friday, the 21st, the Works Committee will present a report recommending that Mr. Godfrey be informed that the Board is not prepared to entertain his suggestion for an increase in the amount of his tender; and also recommending that the next lowest tender, namely, that of Messrs. Williams, Son, & Wallington, amounting to 143,000, be accepted, subject to the same conditions as were attached to the acceptance of Mr. Godfrey's tender.

The Planning of Cow-houses.—Mr. P. McConnell, in his "Dairy Lectures," now appearing in the *Agricultural Gazette*, writes, with reference to the planning of cow-houses:—"The arrangement of the buildings is a point of the most vital importance, seeing that on this depends much of the success of the dairy management. It is advisable to have the cow-houses ranging north and south, with the barns, mixing-houses, food-stores, &c., across the northern end, while the dairy should be separate from the cow-house and as far away from sources of smell or taint as possible,—a northern exposure being the best. The system of 'concentration' is the best, whereby the buildings are all contiguous and open into one another. This saves space, cost of erection, and labor of attending to stock. On the dimensions and arrangement of the stalls depend much of the comfort and cleanliness of the animals. The manger should be on the level of the ground, so that the animal could lie down without requiring to hack into the gutter behind. The bed should be of the exact length to suit the cow, so that she may stand and lie in the same place. The gutter or channel behind for the droppings should be at least 2 ft. wide, and 8 in. deep at the side next the cow. The passages may be lower than the beds, so that the gutter need not be so deep at this side, but the bottom should have an incline away from the cows. Cows standing in a stall fitted up in this style, and with this wide and deep gutter behind, will always be clean,—a state of matters we seldom see in cow-houses constructed in any other way. A wide gutter-passage must be provided, but it is a matter of taste whether there be a feeding-passage in front or not. If there is, the stall-fronts must be so arranged as to prevent the cows from sticking their heads through."

The Jumna Viaduct.—In connection with the Cawnpore and Kalpi Railway, of which we spoke in the columns of the *Builder* of the 8th inst., there is a very important bridge now in course of construction over the Jumna River. According to the designs, the bridge will consist of girders covering ten spans of 250 ft. each. The piers are 76 ft. high from the level of the water to the lower flange of the main girders, and are to be constructed on well foundations, each pier having two wells, 27 ft. external diameter, and sunk to a depth of 50 ft. below the bed of the river. Up to the present time the work has been almost solely confined to sinking the wells. Some difficulty was experienced in the sinking of one of the pier foundations on account of a well having got 8 ft. out of plumb in going down 50 ft. A steady pair of two to three hundred tons, however, was brought to bear on the upper section of the well, and under the continued strain thus applied the cylinder has been gradually brought back to its proper position as the sinking progressed. The bridge is expected to be open for traffic in about two years. The entire cost, including the approaches, is estimated at thirty-four lakhs of rupees, or 340,000, sterling.

MEETINGS.

- SATURDAY, MAY 22.
 Architectural Association.—Visit to the National Agricultural Hall, Kensington. 3 p.m.
 Society of Arts (Special Lecture).—Professor George Forbes, M.A., on "Electricity."—VI. 3 p.m.
 The Institution of Civil Engineers.—Annual General Meeting to consider the Report, and to elect a President and Council. 8 p.m.
 WEDNESDAY, MAY 26.
 British Museum (Archeo Room).—Miss J. E. Harrison on "The Topography and Monuments of Modern Athens."—III. 11:45 a.m.
 THURSDAY, MAY 27.
 Society of Antiquaries.—Ballot for Election of Fellows. 8:30 p.m.
 Society of Telegraph-Engineers and Electricians.—Papers by Captain P. Cardew, R.E., and Captain H. B. Sankey, R.E. 8 p.m.
 FRIDAY, MAY 28.
 University College.—Professor C. T. Newton, C.B., on "Greek Mythology Illustrated by Fictile Vases and other Monuments."—I. 4 p.m.
 British Museum (Archeo Room).—Miss J. E. Harrison on "The Technique of Greek Vases."—III. 11:45 a.m.

The Brick-making Industry of the Metropolis.—The Works and General Purposes Committee of the Metropolitan Board of Works have recommended to the Board that the Society of Medical Officers of Health be informed, in reply to their letter urging that legislation is needed to control the brick-making industry in the metropolis, that the Board, having given careful consideration to the question, are not prepared to take any action in the direction indicated.

Sales of Building Land at Fulham and Surbiton.—Last week Messrs. Baker & Son submitted to competition, at the Red Lion Hotel, Walham-green, thirty freehold plots on the Bishop's-road and Salisbury estates, fronting on Bishop's-road and Munster-road, Fulham. The sites were described as well adapted for shops and medium-sized houses. The several plots offered have frontages of 17 ft., with a depth of from 60 ft. to 70 ft. Of the entire number of plots submitted, twelve were sold at prices ranging from 75l. to 80l. each, a corner shop front having a frontage of 23 ft. to Munster-road, with a return frontage of 58 ft. to Bishop's-road, realising 100l. Messrs. Baker & Sons also offered for sale seven plots on another portion of the estate, adjoining Messrs. Gibbs & Flew's steam joinery works, six of the plots having frontages of 20 ft. to Bishop's-road by a depth of from 55 ft. to 70 ft. to Rostrevor-road; and an angular plot, having a frontage of 78 ft. to Bishop's-road by an average depth of about 50 ft. The whole of these plots were sold at prices ranging from 46l. to 65l. each. The total proceeds of the two sales amounted to 1,307l. On Tuesday, Messrs. Debenham, Tewson, & Co. offered for sale, at the Auction Mart, fifty-four plots of freehold building land, on the Southborough Park Estate, situate at Surbiton Hill, Surrey, described as being in a first-class residential neighbourhood, and well adapted for the erection of detached or semi-detached residences, and also including sites for shops. The several sites have frontages of from 60 ft. to 70 ft. each, with depths ranging from 200 ft. to 320 ft., and contain areas varying from about half an acre to an acre each. The first four plots offered, having frontages of 70 ft. to Ditton-road, and a depth of 320 ft., were all sold to one purchaser for 290l. each, being at the rate of about 600l. an acre. For several of the plots next offered from 240l. to 260l. were offered, at which they were withdrawn. A plot having a frontage of 60 ft. to Lovelace-road and a depth of 210 ft., and containing an area of about a quarter of an acre, was sold for 230l., and another plot having a frontage to the same road of 65 ft. was sold for 245l. A corner plot with a long return frontage to Lovelace-road, and containing an area of nearly half an acre, realised 335l.; and two plots having frontages of 51 ft. to Lovelace-road, were sold for 245l. each. The total proceeds of the sale amounted to 2,460l.

Tidal Works on the Seine.—At the meeting on the 5th inst. of the Liverpool Engineering Society Mr. Coard S. Pain, Assoc. Inst. C.E., President, in the chair, a paper by Mr. J. N. Shoolbred, B.A., M.Inst. C.E., entitled "Tidal Works on the Seine, and on other Rivers," was read by the author, who showed that the river Seine is affected by the flow of the tide for about ninety-three miles above Havre, of which the upper fifty-two call for no remark; for the next twenty-five miles down the channel has been confined, where required, within a narrow width, and its navigable bed considerably improved by means of H.W. training walls of rubble stone. The result has been to reclaim 20,000 acres of slob lands behind these walls, which formerly formed part of the bed of the river. These works were begun in 1845 and ended in 1867. The estuary, sixteen miles long, forms the lowest portion of the tidal compartment. Soon after the completion of the river-walls accumulations of sea-borne sand from the coast of Calvados began to be felt in the north-eastern part of the estuary in consequence of the river being no longer available. These accumulations have been gradually extending seawards till their area amounts to about 40,000 acres. The tidal capacity of the estuary has been diminished by one-third. The entrance of the port of Havre is now very seriously threatened, the yearly accretions in its vicinity having amounted for some time past to about eight millions of cube yards. So that the earlier improvement in the navigation of the river Seine threatens to be more than counterbalanced by the deterioration of its estuary.

Polstead, Suffolk.—At a vestry meeting recently held here, it was decided to commence works of restoration to the parish church of St. Mary, Polstead. The church, which is a large one, is one of the oldest Norman churches in the county, and was one of those damaged by the earthquake some two or three years back. The work, which has been placed in the hands of Mr. J. Treadway Hanson, will be commenced at once.

Colonial and Indian Exhibition.—The Reception Committee, recently formed by direction of His Royal Highness the Prince of Wales, Executive President of the Royal Commission, is desirous of offering a fitting and cordial reception to Colonial and Indian visitors of distinction during their visit to England, by facilitating, so far as may be possible, their arrangements for visiting places of special interest in the United Kingdom. To enable the Committee to do this, funds are required; and those who may be desirous of co-operating are invited to subscribe to the object in view. Subscriptions can be sent to the London and Westminster Bank, West End Branch, St. James's-square, S.W.; or to Mr. Arthur Hodgson, C.M.G., General Secretary, at the office of the Reception Committee, "Old London," Exhibition Buildings, South Kensington; or to Mr. H. Trueman Wood, the treasurer, Society of Arts, John-street, Adelphi. Cheques should be crossed "London and Westminster Bank," West End Branch.

Ealing Public Baths.—On Saturday the opening of the new swimming-baths at Ealing took place, Mr. E. M. Nelson, J.P., the chairman of the Board, presiding on the occasion. The baths, which are three in number, are situate on the main Uxbridge-road, and nearly in the centre of the district. They consist of a first-class bath, 90 ft. by 30 ft.; third-class, 75 ft. by 25 ft.; and a ladies' bath, 60 ft. by 24 ft., the latter with a waiting-room overlooking the bath. There is also a club-room, where members of the various clubs in the neighbourhood may hold their meetings. The interior walls of the baths are in plain brick-work relieved with red brick arches. The baths themselves are lined with "Ingham's" white-glazed bricks a special-made brick 1½ in. thick, being used for the bottom. The woodwork of the interior is stained and varnished; the doors of the boxes are only 3 ft. 6 in. high, the upper part being fitted with curtains. The first-class bath has a gallery capable of holding 500 persons. The heating is by steam injected from two 20-h.p. boilers, and the laundry (for baths only) is contiguous to the boiler-house, the whole of the machinery being worked by a small engine connected with the boilers. The whole of the works have been carried out from the designs and under the superintendence of Mr. Charles Jones, C.E., the engineer to the Board, the contractor being Mr. W. H. Waters, of Ealing; and the machinery, which is of the latest description, was all fitted up by Messrs. Bradford. The contract for the baths, including the machinery, was 8,000l.

Artists' General Benevolent Institution.—The seventy-first anniversary dinner of this Institution was held on Saturday last at the Freemasons' Tavern, Great Queen-street, under the presidency of Lord Esher, supported by Sir Frederick Leighton, P.R.A.; Sir J. Gilbert, R.A.; Sir J. D. Linton; Mr. Alma Tadema, R.A.; Mr. W. P. Frith, R.A.; Mr. H. Armistead, R.A.; Mr. H. S. Marks, R.A.; Mr. J. Pettie, R.A.; Mr. A. Waterhouse, R.A.; Mr. J. O. Barlow, R.A.; Mr. E. Burne Jones, A.R.A.; Mr. J. E. Burgess, A.R.A.; Mr. Phil. Morris, A.R.A.; Sir J. E. Millais, R.A. (hon. sec.); Mr. P. C. Hardwick (treasurer), and Mr. D. H. Gordon (secretary). During the evening subscriptions and donations amounting to 2,538l. were announced.

An Old Altar-piece in Selborne Church. The *Field*, in an interesting article entitled "A Pilgrimage to White's Selborne," says:—

"Our first visit, as becomes good pilgrims, is to the grave of Gilbert White. . . . Being Easter-eve, the church was dressed with spring flowers, again simple enough, and in good taste. The good pastor, however, fell short in the condition in which we found our next attraction, which was in a little cupboard-like vestry, the really good picture given to this church nearly a century ago by Gilbert's brother Benjamin, for an altar-piece. Painted in three panels, it represents the offerings of the wise men to the infant Christ, and is said to have been painted by Albert Dürer. This was with questionable taste left standing on a newly-washed floor, its only support being the whitewashed wall behind. In front was the one vestry-chair, requiring but a touch to add to the already too numerous chairs and benches the living care bestowed on it by its long passed-away owners, and to be placed in security from further destruction by insidious damp or more careless injury, through the hurried preparations of those who may have to use the same six-foot square vestry. If no better place can be found, the picture might be thought good enough for the very pretty and well-arranged little museum at Alton."

A New Park for Sheffield.—The Corporation of Sheffield has just acquired the beautiful piece of woodland lying on the south of the town known as the Endcliffe Wood. It is intended to lay this place out for the use of the public and as it is within a mile of the centre of the town, and easily accessible, it will be a boon to the townfolk, Sheffield not being too well off in the matter of public parks and gardens. The Endcliffe Wood occupies the slope and valley near the Botanical Gardens, and is nearly a mile in length. The slope is covered with large trees, chiefly oaks, and the river Porter runs along the valley, and in its course works through old water-wheels used for grinding, one of which will be retained as a picturesque object; in fact it is intended to preserve the rusticity of the place as much as possible. Broad walks will traverse the wood, and rustic bridges will span the stream at various points, while along the boundary will be a carriage and footway, 75 ft. wide, planted with trees on each side. Trenches which have worked the wheels will be converted into lakes for bathing, skating, and waterfowl; and the outfalls and races will be transformed into waterfalls, there being a fall of some 80 ft. or 90 ft. in the course of the stream between one end and the other. The natural beauty of the woodlands is such that when embellished a little, few towns will be able to boast of such a delightful public park as Sheffield. The work of laying out the place has been entrusted to Mr. William Goldring, London.—*Gardeners' Chronicle*.

Cowley St. John, Oxford.—The church of St. Mary and St. John has been further enriched by the opening of a new organ which has been given by Mr. G. Herbert Morrill, of Headington Hill Hall, the cost being defrayed out of second 1,000l. he has generously given towards the completion of the church. The oak case with its elaborate tracery work was designed by the architect of the church, Mr. Martin Mowbray, F.R.I.B.A., of Oxford and Eastbourne, and executed by Mr. Thompson, of Peterborough at the cost of over 200l., while the organ itself was built by Mr. Martin, of Oxford, for 450l. provision being made for the addition of choir-organ later on.

Bath Stone. BEST QUALITY OF ALL KINDS. PICTOR & SONS, Box, WILTS. [ADV.]

Doubling Freestone. THE CHELYNCH STONE. THE BRAMBLEDITCH STONE. HAM HILL STONE. Greater facilities have been provided for working these quarries, and the stone can be supplied in large quantities at short notice. Prices, and every information given, on application to CHARLES TRASK & SONS, Norton-sub-Hamdon, near Ilminster, Somerset. London Agent—Mr. E. WILLIAMS, 16, Oraven-street, Strand, W.O. [ADV.]

Douling Free Stone For prices, &c., address S. J. STAPLE, Quarry Owners, STONE, and Lime Merchant, Stoke - under - Ham (Ground or Lump), Ilminster. [ADV.]

Ham Hill Stone! Ham Hill Stone! For Ham Hill Stone of best quality and workmanship, apply to JOHN HANN & SON, Quarry Owners, Montacute, Ilminster. Establishes 1837, Agents, MATTHEWS & GEARD, Albion Wharf, Regent's Park Basin, N.W. [ADV.]

Asphalts.—The Seyssel and Metallo Lava Asphalte Company (Mr. H. Glenn), Office, 31, Poultry, E.C.—The best and cheapest materials for damp courses, railway arches, warehouse floors, flat roofs, stables, cow-sheds, and milk rooms, granaries, tun-rooms, and terraces. [ADV.]

Asphalts. Seyssel, Patent Metallo Lava, and White Asphalts. M. STODART & CO. Office: No. 90, Cannon-street, E.C. [ADV.]

BANNER VENTILATORS.

The Strongest Exhaust Ventilators for all Buildings, Public Halls, Churches, Billiard-Rooms, &c.

HIGHEST PRIZES at all the most important Exhibitions.

BANNER SYSTEM OF SANITATION AND SANITARY APPLIANCES

WERE AWARDED AT THE

International Health Exhibition, 1884, One Gold Medal, Three Silver Medals, and One Bronze.

For further Particulars and Prices apply to

Competition Designs for Sunderland Municipal Buildings.

IN response to the invitation of the Corporation of Sunderland, issued in February last, and with an endeavour to be in accordance with the numerous conditions in connexion therewith, 4 sheets of drawings were sent in by twenty-three architects. These have been for some days on exhibition in the Art Gallery in the town, well arranged and well lighted for the inspection.

The site chosen is an imposing one. It is at the junction of Fawcett-street (the Regent-street of Sunderland, 70 ft. wide) and Athenium-street, a minor thoroughfare leading to the Central Railway Station of the Northern Railway, which latter is immediately the rear of the proposed buildings. The site in Fawcett-street is 151 ft., and that in Athenium-street about 100 ft. The available area to be covered is 40,720 superficial ft., and the cost not to exceed 27,000l. If the amount were exceeded, the premium was to be forfeited. The abstract showing the accommodation which is to be secured on the site is very clear and concise.

On the first-floor there are to be an artery or reception-room, an ante-room, a council-chamber, mayor's chamber, three committee-rooms, a waiting-room, and the Town Clerk's department is to be here also, consisting of four offices. On the second-floor provision is to be made for the departments of the accountant, medical officer, engineer and surveyors. On the basement, being numerous offices and rooms for disinfectants, &c., provision is made, oddly, for an election and ballot room, and polling booths. On the second floor there are to be rooms for a caretaker, school of art, and a sanitary building.

Most of the competitors seem to have nearly conformed to the conditions. It varies from the other only in the way they have placed the principal rooms. Externally they have all been led to adopt, what servilely, a style of Palladian architecture of a bad, heavy type, that is exemplified in a range of new buildings, shops, and that stand contiguous and in a line with the site in Fawcett-street. None of the competitors have ventured upon any design in the eclectic style. They are all more or less commonplace and impure in style, and none any novelty whatever in them.

One rather unusual feature in this competition is the total absence of any perspective view,—the conditions prohibited it. But granting that the employment of a perspective view to illustrate a design is sometimes much abused, surely the total prohibition of it in a competition is wrong. No architect can tell the possible effect of his design until he has produced it in a perspective view. The result is quite unsatisfactory in this case, and it has led to the employment of a large amount of "prentice work" in preparing the plans, elevations, and sections exhibited in these 155 sheets. There is really not one fine drawing in the whole set.

Two striking points present themselves in connexion with the site for these buildings at starting in preparing a design. One is, where should the council-chamber be best placed to be away from the screeching of the engines and the roar of the steam against the metal roof of the contiguous railway station? The other is, where could it be placed to be clear of the noise of the street? (It must be admitted that the pavement of the streets is wooden and the noise of traffic is thus modified.) None of the competitors seem to have taken these facts into consideration, for the position of the council-chamber should be the key of the whole design. At the quasi "Town Hall" at Newcastle-upon-Tyne the council-chamber is so badly placed that the noises of the street and the railways have to be deadened by double windows, and not a breath of fresh air seems ever to enter it.

How have the competitors managed this and the other points? Let us see. "Nil Desperandum auspice Deo" places the council-chamber in the centre of the Athenium-street frontage, and the mayor's chamber and the art-gallery against the noisy station; and a very grand hall and staircase in the centre, lighted from above. He does not aim at towers or turrets or dormers, or any superfluous effects of the kind, keeping even his chimney-stacks very low. His rusticated basement floor and his pilastered upper floors and balustrated parapets remind one of our old War Office buildings at the Horse Guards.

"Nineteenth Century," the second premiated design, plans to have the council-chamber at the angle of the two streets, catching thereby the noises of both; but by placing the art-gallery reception-room adjoining it he obtains a fine suite. His main frontage in Fawcett-street is entered by a well-arranged pedimented entrance in the centre of it, and he uses a Mansard dome roof to cover and light the central hall. If seen in a perspective, this dome would be so low, according to the elevation, as to be out of sight.

"Stabilitas."—This is the design to which

the adjudicator has given the first premium of 100l. It is shown by four sheets drawn in sepia,—two containing the plans of the four stories, one the two elevations, and one three sections. The council-chamber, 44 ft. by 31 ft., is placed at the angle of the steamy station and Athenium-street, and the mayor's chamber at the corner of Fawcett-street, with an ante-room between them. The art reception gallery is away from these at the opposite end of the site, intercepted by various committee and other rooms. The entrance vestibule is to the centre of the larger frontage, and a grand staircase occupies the centre, lighted from above and by two internal courts. The style of the exterior is Henri Quatre. The basement story is rusticated. The roofs are high-pitched Mansard, and crested with handsome dormers leading out of them, and a lofty central square clock-tower, with a very large clock-face and an octagonal dome-roof surmounting it, occupies the centre of the main street.

One good provision in this design is a kitchen in the top story, provided with a lift to convey the dinners downward on festive occasions. But what the "Sanitary Museum" is to be like, and why it is placed up so high as the second story, is a puzzle.

On the whole, this is decidedly the best design. But provision for deafening the noises from the railway station against the council-chamber should be made, and it would have been better if the arrangement of the seats in the council-chamber and the reporters' and public gallery had been shown.

One of the designs in this collection shows the council-chamber open and ventilated above it, whereas this by "Stabilitas" shows a "cast-room" and "painting-room" over it. Let us hope that he will make the floors sound-proof.

"Time and Tide" is the third premiated design. The author of it has the council-chamber in the same noisy position as that by "Stabilitas"; but he makes a fine room of it by keeping it open and ventilated into the high-crested Mansard roof above it. His façades are much like the Government Offices elevation in Parliament-street. He has no towers or turrets.

"Ad Rem," with his design and alternative design, has some good features and good planning. He places his council-chamber quite in the rear corner close to the station, but away from the noise of the streets. His elevations are very Adam-esque. His oval and festooned attic windows make his elevations look, drawn as they are in black and white, like a leaf taken out of designs by Adam.

"Waiting for the Verdict" has a conscientious set of well-drawn and well-considered

plans and alternative plans. They have not been premiated, probably because there is too much wealth of work in his ornamented façades.

"To be or not to be" has some funny points, notably in making his council-chamber oval shaped in the middle of the dingy rear of the site. He places seats for the mayor and aldermen and council, but gives no desks for the unfortunate aldermen. He has a corridor round one side of the chamber, which he calls a lumber-room for banquet tables and chairs, and places a gallery over it. It is altogether a very ponderous design.

"Speedwell" shows the council-chamber boldly in the centre of the long Fawcett-street site. Had he marked it better as a feature externally this would have been a very promising design. He has a very lofty central ventilating feature in the dome-roofed tower. His design could scarcely be carried out for the limited 27,000*l.* with that costly feature in it.

Going carefully over all the rest of the designs, including those by "Light," "Dum spiro spero," "Forward," "Auspice Deo," "Utility," "N*o* Desperandum," "Plan," "Ars," "Renaissance," "Lux," "Fides," "Hope," one comes necessarily to the conclusion that not one of these designs would show to posterity that the buildings are essentially municipal. At Leeds, at Liverpool, at Birmingham, Chester, Bolton, Bradford, and many cities elsewhere, the ordinary observer cannot mistake the use and intention of their town-hall. Newcastle-on-Tyne has made a great mistake in this respect, from which its citizens will, we are led to believe, on the first opportunity, redeem themselves.

Sunderland will, upon the execution of even the premiated design, only boast of having a fine set of buildings which may be taken for a club-house, hotel, "sets of chambers," anything or everything but a "town-hall" or "municipal building."

AT THE PARIS SALON.

THE interest of the *Salon* for a visitor who is studios either by inclination or "par métier" does not reside in the greater or less number of pictures exhibited, nor in the more or less extraordinary vagaries of what may be called sensation works. What is really interesting is to follow the fluctuations of the French artistic spirit, and the manner in which it is subject to the ascendancy of this or that eminent painter, and imitates his good or bad qualities. Scarcely ten years ago a whole pleiad of young painters were giving all their powers to reviving the vigorous colouring of Delacroix. Now M. Puvis de Chavannes is the master, and the young painters are all on the opposite tack. Every year there is an increasing tendency to imitate and exaggerate his style and technique,—a tendency so marked that it has even received a definite and recognised title. "Puvisme" is the prevalent malady in French art, and seems to supplant in its followers all their natural faculties. One cannot deny that there is a powerful inspiration in the immense painting with which the master is to decorate the Musée at Lyons, his native town. "Le Bois sacré cher aux Arts et aux Muses," exhibited in 1884, has been the suggestion for two new compositions, entitled "Vision antique" and "Inspiration Chrétienne." The first transports us to a Greek landscape, in which various ideal personages are grouped. It is an idyll of Theocritus interpreted in all its charm. Unfortunately the blue of the sea seems to have left a little of its colour on the bodies of the figures reclining on its margin. In the "Inspiration Chrétienne" we are taken into the Middle Ages, at the epoch when ascetic artists decorated with their naive paintings the walls of convents. Monks in dark garments stand out against the white arcade of the cloister, through which a landscape is visible, treated with appropriate severity of line. A third picture, between these two, symbolises the Rhone preparing to join her stream to the Saône. The design of

these two latter figures leaves much to be desired, and their colour is wan and disagreeable; but in this collection there is visible the conception of a great and poetic artist.

The decorative paintings made by MM. Humbert and Lagarde for the Mairie of the Fifteenth Arrondissement are an application of "Puvisme" to scenes of modern life. The first belongs to the time of the bombardment of Paris: an ambulance woman is giving water to a dying soldier, the street is lighted up with the blaze of shells, and dead and dying men and horses make dark blot on the snow-covered ground. As a contrast, M. Lagarde has painted a picture of domestic happiness in the courtyard of a farmhouse. M. Baudouin chooses also a modern scene for the decoration of the Mairie of St. Maur: peasants, artisans, and a landscape background taken from the banks of the Marne. Though with a more rich colouring, this picture also echoes the style of M. Puvis, of whom the author was a pupil.

The *Salon* contains four other large decorative works, executed for the city of Paris. That by M. Chartran, intended for a "salle de mariage," is a hymeneal allegory. It is a great deal better than the cattle-marked scene with which M. Cervex lately decorated the Mairie of La Villette, but it required all M. Chartran's ability to contend against the commonplaces of a subject worn threadbare by repetition. In two other decorative pictures, intended for the Mairie at Passy, M. Emile Levy shows himself as archaic as ever. His "Famille" we do not care for much, but there is a great charm in his composition symbolising "Jeunesse et l'Amour."

It is in Arcadia evidently, in those fabulous regions that only exist in the imaginations of the pupils of the Ecole des Beaux Arts, that M. Comerre has placed the rose-water personages who compose the two subjects intended for the Mairie of the Fourth Arrondissement. The first symbolises rustic love, *sub tegmine fagi*; the second personifies the family, *beat*us* qui procul negotiis*, &c.; but it was hardly worth while to arrive, by the process of public competition, at such very negative results. M. Bouguereau, whose art we do not admire very much, is, nevertheless, always an admirable "virtuoso" in his way. In his picture, entitled "Printemps," a young girl, remarkably beautiful, undergoes the kisses of a crowd of little *amorini*, who are painted with marvellous dexterity. The picture wants the expression of soul, but its execution defies criticism. The same technical qualities and the same coldness of feeling are found in his other work, "l'Amour désarmé." M. Henner adds another to the list of Magdalens in the desert. The subject is certainly not new, but, with its grace and charm and luminous colour, it is far preferable to the "nymphs" of M. Feytaud Perrin and M. Collin, which are its neighbours. We cannot say the same of the "Triomphe de Vénus," of M. Barrias, a painter whose talent seems to have gone astray entirely.

In historical painting, M. Benjamin Constant, who possesses the art of giving light and scintillation to rich stuffs and jewels, exhibits a "Justinien," immovable and as if crystallised among these ornaments. The details hold so large a place, and the figure so small a one in the general effect, that we are almost tempted to class it among paintings of still life. The "Torquemada" of M. Laurens is a vigorous though rather brutal picture, full of serious qualities; the "Mort de Pichegru," by M. Moreau de Tours, a theatrical scene of doubtful interest. As for M. Rochegrosse, who revels in atrocities, after promenading us successively through the massacres of Troy and the horrors of the *massacres*, he has plunged us this time into sacred history. His "Nebuchadnezzar" changed into a beast is a kind of orgy of colour which fatigues without attracting the eye; when will this very gifted young artist learn that epilepsy is not a form of artistic talent?

Are we to class the "Édipe" of M. Gérôme among historical paintings? It shows Napoleon on horseback contemplating the Sphinx, whose enigmatical countenance he seems to scrutinise.

This little work, painted with the highest art, ought, perhaps, rather to be classed as a genre painting.

Among military paintings, numerous enough this year, M. Protain can put to his credit one more good picture. His "Bataillon carré" is a work full of grand and gloomy poetry. On a wide plain and under a starry sky all is death. As far as one can see there are corpses stretched on the ground; lines of dead bodies marking the limits of the last conflict. In the "Combat de la Fère Champenoise," by M. Lehant, a crowd of Cossacks attack from all sides a line of "Gardes Nationaux" in all kinds of heterogeneous costumes, the blouse of the peasant, the capote of the veteran, and the ordinary dress of the citizen who has taken up arms "pour la patrie." M. Leblanc shines in these heroic scenes. Two scenes of the war, by M. Bontigny, are also to be noticed,—*"Les Otages"* and *"La Confrontation."*

Among portraits, M. Besnard seems to have been bent on "astonishing the natives." He has only been half successful in his portrait of a young woman in a lilac-coloured dress beside some yellow flowers, which seem somehow to have shed all their colour down one side of his model. A lamp behind the scenes is apparently the cause of this surprising attack of yellow. Nothing can justify these aberrations of colour, and M. Besnard is making a great mistake in spoiling the fine qualities of his painting by false sensationalism. After this one has to refresh the eye before the two admirable pictures by M. Cabanel representing "Le Fondateur" and "La Fondatrice" of the "ordre des petits sœurs des pauvres"; an old priest,—

"A l'air calme et bon, au regard rechauffant,"

and a "sister" whose pale figure is shadowed by a white head-dress. Here there are tricks, no display of finery, no glistening silks and jewelry; the two portraits are admirable models of artistic truth and sobriety; that of the "religieuse" especially. In another line of subject the portrait by M. Carolus Duran of a young lady in a roseate dress is a charming piece of delicate execution. M. Bonnat, another masterly painter, but too violent in his method, has made a portrait of M. Pasteur, which is a good likeness, but not nearly so pleasing as that by M. Edelfeld. The former is the *savant* formally posing for the gallery, the latter the *savant* working unostentatiously in his laboratory. What makes the charm of a portrait is its presentment of the individual in his everyday habit and manner, and in this way M. Roll has produced an excellent work in the portrait in which he shows us the landscape-painter, M. Damoy in travelling dress and carrying his paint-box, canvasses, and umbrella, amid the crowd at the bustle of a railway station.

There are two portraits of Victor Hugo taken after his death, an incident which might have been foreseen; but these will add nothing either to the glory of the poet or to the reputation of the painters, MM. Glaize and Laugel. Among the great number of portraits we must note a very splendid one of M. Meilhac, by M. Delaunay, that of M. Cain, the sculptor, by his son; that of a brunette, who serves M. Duez as a pretext for a brilliant variation of the gamut of red tones; a portrait of a lady in black by Mr. Sargent; a young girl caressing a greyhound, by M. Mathley; and the portrait of the Duchesse d'Uzès, in Louis XV. costume, by M. Gustave Jaques.

Genre painting takes us into the category of the most numerous, most interesting to the majority of the public, and most difficult to classify, for it touches on the confines of all the other classifications. The "Vieux Paysan" of M. Adan, seated at a cross road on a dull autumn day; the "Enterrement d'une Jeune Fille," by M. Blyan; the "Vieux Coin de Bretagne," picturesquely rendered by M. Emile Breton; the "Jeune Femme" by M. Roll, who stands out brightly from a background of verdure, all these are really landscapes; while on the other hand the two pictures which M. Abbema calls "Tragédie" and "Comédie" are

* Victor Hugo, "Les Rayons et les Ombres."

iously portraits, the chief merit of which consists in the originality of the frames, which consist of great natural palm leaves glued on the wood.

I. Gerrev inclines one to think that his nude study, entitled "La Femme en Masque," is a portrait of one who, more modest than the Duchess of Ferrara in the well-known Titian story, did not sit for the favoured painter except that condition. This fancy, which is inferior execution to preceding works by the same artist, we should class among *genre*. In the same class may be placed the spirited but false painting in which M. Raffaelli has related us into the mysteries of the process of distilling "à lire perdue." Then we have a fine series of scenes which constitute a kind of drama of misery. In one, M. Jean Bénard, better known as a painter of "Society," sees himself by ranging before us a number of wretched women waiting at the *dépot* to be transferred to the St. Lazare prison. Among the types copied from nature with heartless realism, is seen an impassible "religieuse," whose habit has rendered indifferent to such scenes. The picture shows great talent, commuted with a disagreeable hardness of style. M. Lez, who has made the sufferings of the people his artistic speciality, exhibits a painting of a blind and emaciated mendicant, his feet stiff with cold. The "Les Affamés" of M. Miffroy is a collection of people in sordid precipitating themselves with savage avidity on nameless scraps of refuse.

"Still Life" is well represented by M. Gerret in his painting of lobsters and prawns, treated with remarkable technical ability. M. Desseu, whose talent has survived the sufferings of a long illness, sends some admirable groupings of fruits and cheese, executed with finishing realism. M. Vollo's pottery objects are masterly in their way, and M. Desgoffes continues to chase and embellish his armour and precious stones with the grace of a Benedictine. Among flower paintings, the first place must be given to the magnificent dahlia of M. Jennin; while for a vase, Madame Muraton disputes the palm with M. Claude.

Among *genre* pictures properly so-called we mention the "Maquignon d'Esclaves" of M. Langer, only in view of the archaeological value displayed in it. "La Réception à la Galerie Royal," by M. Delort, is a tender and humorous painting; the "Fête Nationale" of M. Dumoulin is the repetition of a picture often seen before, and not nearly so beautiful to the "Vue de la Porte Maillot" so artistically rendered by M. Luidgi Loir, which a municipality will probably purchase.

In a painting under glass, executed with most the delicacy of a water-colour, M. Lez's Flameng takes us to Dieppe in 1798, his belles of the Directory have no occasion to envy the powdered Marquises who were seated under the shadow of the groves of sailles. The "Marché aux Chevaux" in hand, by M. Chelmonski, is a curious ethnological study. M. Connon, a painter generally represented by large, grave, historical pictures, here in colour, has let himself this year run into *genre*. His "Déjeuner d'Amis" is placed in the corner of a studio, among elements very little clothed and painters of an entirely gay temperament; and the Sunday *genre* contemplates with surprise this scene *novus*, which gives them a strange notion of the really laborious artist existence.

Animal painters and landscape-painters can hardly be altogether separated, and M. Barillot, instance, in his "Matinée d'été," and M. son in his "Bœuf à l'Herbage," treat both of this subject with equal success. "A l'illebande" by M. John Lewis Brown, and "en Aller" by M. Penne, are two amusing painting scenes, but it is the military scene titled "Le Boute-selle" that shows the really qualities of M. Brown, who understands the anatomy better than any contemporary such painter, and studies closely and reproduces vividly the costume and manner of past erations.

Le Vallon," by M. Bernier, is a fine and classic Breton landscape; "La Plaine" of M. st, a large and broadly-treated piece of

work. The two little views at Plombières by M. François, the "Nénufars" of M. Hanoteau, and the "Saules" of M. Harpignies merit special mention. M. Lelievre exhibits two fine views on the Loire, and the "Ile aux Oies" of M. Pelouze is a masterly landscape. They are dazzled by the remarkable transparency of the "Lac Suedois" of M. Normann, pauses with pleasure before the green meadows of M. Rapin, wet with the dew of morning; and we salute in passing the last landscape of the late regretted Ségé, a view in the environs of Grandville, of which the painter's death cut short the completion. Among marine paintings we may mention "Les Rochers de Quiberon" by M. Damoye, the beautiful "Plage Normande" by M. Guillemet, two fine views of Dieppe by M. de Elodie Laviollette, the "Port de Bordeaux" by M. Lapostolle, a pathetic shipwreck scene which M. Renouf calls "à la dérive," and the view of the Thames at London by M. Flameng, with the *silhouettes* of shipping profiled against a misty sky.

Want of space obliges us to pass over the water-colours, pastels, and engravings, of which the flood mounts higher every year. It would be wrong, however, not to mention at least the exhibits of M. Fantin-Latour, the fine charcoal drawing by M. Allongé, the curious water-colour by M. J. L. Brown, "Le Paddock des Longchamps," and the remarkable portraits by M. M. Emile Lévy and Edelfeld.

We have now passed rapidly over the contents of the thirty-one rooms reserved for the 3,400 pictures and drawings admitted by the jury, which receives, with judiciously closed eyes, a number of works quite unworthy to figure in the *Salon*. The result is that true talent is drowned amid a sea of mediocrities; that young painters' works are sent up to heights where no one can see them; and that, with the best will in the world, the eye, fatigued in this pandemonium of painting, can hardly take note of the few original works signed by unknown names, for which a future might be predicted.

We may add, in conclusion, that as the Médaille d'Honneur cannot, according to regulations, be given this year either to M. Cahanel or M. Puvis de Chavannes, and there seems to us to be no other painting, even among those of the best names, which ought to receive this honour, it seems probable that this year the highest reward of the *Salon* will go to a sculptor. Of the sculpture we may give some notes separately.

NOTES.

 HIS is the season at which numbers of town dwellers are considering about hiring country houses, while many who live in the country are contemplating a little tour or a little sea-air out of the proceeds of a short "let." It is well to impress on those who are thinking of leaving their own well-drained houses to be very cautious in regard to the sanitary arrangements of country houses. There is no little recklessness shown by persons who take a furnished house for a short period. They think it is summer weather, and so plenty of air is admitted into the house, and therefore sanitary defects are less injurious than in the winter. There is some truth in this, but not enough to justify the running of risks to a family. Other people, again, are content to trust to the mere assertion of the occupier, who very likely scarcely understands what proper sanitary arrangements are. The consequence is that many dangerous and even fatal illnesses are contracted in temporary country homes. The knowledge of sanitary necessities is still very backward in the country as any one will find out who happens to go over a dozen country houses in any house agent's list. Carelessness, want of cash, want of knowledge, all tend to this end, and therefore, however tempting a place may be, it is the veriest folly for any one seeking a healthy home for the summer to overlook sanitary defects because a house is picturesque in itself or placed in a charming spot.

LORD ELGIN'S answer to Lord Hardinge's inquiries last week in the House of Lords as to the new site for the National Portrait Gallery was far from satisfactory. The gist of the answer was that "the Government were obliged to allow the matter to remain in abeyance until the general financial condition of the country exhibited some improvement or the extraordinary demands of the country showed some abatement"; that is to say, that the Government do not at present contemplate building a new National Portrait Gallery, and when they do will probably build one of which the nation will be ashamed. It is clear, therefore, that those who are interested in English art as well as those to whom English history is not a mere collection of dry bones, should put pressure on the powers that be to carry out this undertaking. A Government which has uselessly spent millions in Egypt and contemplates spending many millions in buying out the Irish landlords, can scarcely expect to be allowed to get out of this matter as easily as they at present seem to expect to do.

THE Railway Defence Association, at their meeting at the Cannon-street Hotel, on Tuesday last, discussed the Railway Rates and the Railway Regulations Bills "in the interests, not only of railway shareholders, but of the travelling and business interests of the country." The latter measure, which was brought in by Mr. Channing, and has not attracted so much public attention as the former, has for its object the prevention of accidents, the better protection of railway employes, &c. The Government, in accepting the principle of the measure and allowing it to pass the second reading, referred it to a Select Committee for investigation. The meeting on Tuesday passed resolutions protesting against both Bills as unwarrantably interfering with the property and business of railway shareholders, and the speakers seemed to think that the objects of the Bills were more likely to be attained by the voluntary action of the railway companies themselves than by coercion. The passing of these measures, however, goes to show that this opinion is mainly confined to themselves, and that the country has not much faith in internal railway reform. A point was made in the resolution calling upon Mr. Mundella to recommend that the Railway and Canal Traffic Bill be referred to a Select Committee in the same way as Mr. Channing's measure. In this case, of course, representatives of the railway interests would be allowed to give evidence in support of their objections to the provisions of the measure, thus being enabled to offer a more effective opposition to it than if the Bill went straight to a Committee of the whole House. However, upwards of seventy amendments have been proposed for that stage, and it is evident that the shareholders are going to offer a strong resistance to what was termed by the chairman of the meeting "the scattering of their property."

THE Berlin "Kunstanstellung" just opened (May 23rd) to the public, offers one feature of great interest to archaeologists, the panorama of Pergamon. Not only is the Acropolis itself, with the great altar of Eumenes, the temple of Minerva-Polias, the temple of Augustus, and all the subordinate buildings, to be set forth, but the whole reconstruction is to be thrown up on a realistic background of purple hills, vineyards, woods, and rivers. The general aspect of the Acropolis is familiar enough by now to most people from the reconstruction published in 1882 by F. Thiersch; but the plan then presented has undergone important modifications owing to many recent excavations. It is needless to say that the present panorama will be archaeologically up to date. Never before has such an opportunity for the vivid realisation of ancient life been offered to the public. Germany, somehow, has the happy faculty (would that England shared it!) of making her national art-treasures the pride, not only of museum directors, but of the people at large.

IF any person holding strongly, or, indeed, holding at all,—our advanced English opinions on the subject of coloured decoration should hear that the well-known Italian Church in Hatton-garden has undergone an important restoration and re-decoration at the hands of "eminent" Italian artists, and should be induced thereby to enter that building, we should much like to be present to see his countenance; for it is difficult to imagine anything that would more completely differ from what he would suppose it *should* be. A great part of the flat walls and ceilings is covered with painted *rococo* ornament, skilfully shaded in neutral tones, to produce an appearance of solidity; and the remainder, except the panels, is painted with a diaper pattern of an indescribable yellowish green tint, such as was common in cheap wall-papers not many years since. The clearest windows have what appears to be white linen stretched over them, and on the linen is painted alternately a cross and a sword surrounded by a garland in a halo, the whole enclosed in a rustic frame; the shafts of the columns are painted in imitation of a mouse-coloured marble, and throughout the building a skilful use of yellow and white paint has produced much of the effect of gilding. The panels, as they are confessedly pictures, might perhaps shock our aesthetic friends a little less, though the boy angels *do* rather sprawl, and though the colours are rather crude. The chief subjects are,—over the high altar, the Ascent of Our Lord; in the centre of the nave ceiling, the Assumption of St. Peter; on either side of the nave, the lives of SS. Peter and Paul; and over the altar of St. Joseph, the Death of that Saint. In Germany, as well as in Italy, as every one knows, this kind of decoration is admired and commonly adopted where funds will allow.

AN exhibition of the competitive designs for the International Exhibition to be held in Paris in 1889 was opened on Saturday last, in the reception-rooms on the first floor of the Hôtel de Ville. There are 107 designs shown upon drawings of the extent of more than 4,500 superficial feet, and suggesting all manner of ways of arranging the site, which comprises the Champ de Mars, the Esplanade des Invalides, the Palais de l'Industrie, and the adjacent quays. The most remarkable designs for monumental character are those of M. Eiffel, which include his gigantic iron tower 300 mètres high. The jury for deciding the competition is composed, as is usual on such occasions, principally of political personages, public civil servants and engineers, and includes only six architects, nominated by the Minister of Commerce, among whom, however, we notice the names of MM. Bailly and Ch. Garnier. The jury will find their task no easy one, for if there are few very new or happy ideas among the competitors there are at least fifty or sixty carefully and conscientiously thought-out designs of which from twenty to five-and-twenty might reasonably aspire to one of the all too few and insignificant premiums. Since this was written, we have seen it mentioned in the *Globe* that 89 of the designs have been rejected, 18 being reserved for re-examination in detail.

NEW York and its suburbs appear every year to be growing more and more rapidly. In Brooklyn operations are going on upon a very extensive scale. In the month of March alone, official concessions were obtained for the construction of no fewer than 424 new edifices. Of this number 192 were for villas, sixty-six for houses containing dwellings to accommodate from two to four families each, sixty-five were for shops and stores combined with dwelling-houses, thirty-seven for tenement houses, and the remainder for various kinds of factories and warehouses, including two breweries, two foundries, as well as two churches and one school-house. The estimated cost of the buildings begun in March in Brooklyn is upwards of two and a quarter million dollars, while the total for the last three months exceeds four and a quarter million dollars.

IT is good news to hear (from the monthly *Δελτίον αρχαιολογικόν*, now issued by Dr. Kakhadrias), that the remains of the pediment sculptures of the Temple of Athene Alea at Tegea have been brought to Athens, and are now safely housed in the National Museum. We need scarcely remind our readers that these precious fragments (two heads of youths and one head of a boar) are the only pieces of sculpture we possess of which we can confidently say they are from the hand of Scopas. Many an archaeologist will now be spared the difficult pilgrimage to Tegea. However delightful it may be to the man of leisure to visit ancient remains on the very spot where they were found, we cannot but rejoice that remains such as these are now not only easily accessible, but also safe from the dangers they have hitherto been exposed to from provincial ignorance. Dr. Kakhadrias further reports that the missing half of one of the heads hitherto in the possession of the discoverer had been secured for the Museum. The laudable zeal of the new director has also secured for the National Museum the beautiful female head found some years back at Lerna, and hitherto kept at Argos. The head is life-size, of Parian marble, and from the unworked state of the back (it ends abruptly in a flat surface), evidently belonged, not to a statue in the round, but to a single figure or group in high relief. From its peculiarly soft and pathetic charm, it has been interpreted by some as a head of Demeter, but no attitude remains to give any certainty to this view. Its style is of the third century B.C.

MESSRS. COOPER, of Pallenny-street, have been getting up a novelty in their show-rooms, in the shape of a Greek room, suggested a good deal, apparently, by details occurring in Mr. Alma Tadema's paintings. In particular there is at one end of the room a massive seat on a semicircular plan, resembling a good deal in design the marble seats on which Mr. Tadema's figures are wont to sit; but as this is executed in wood it is somewhat questionable whether it can be regarded as truly Greek in spirit. A Greek would hardly have made a wooden seat on a similar design with a marble one. Other details in the room are well worked out, and the whole effect is very good.

ARCHITECTURE AT THE ROYAL ACADEMY.—V.

1,671. "Carlisle Grammar School," Mr. G. D. Oliver. A large drawing, showing a perspective of the building from a very high point of view, in fact, nearly a "bird's-eye view," and cleverly hung so high as to put such a perspective view in the very worst position. It might, one would think, have occurred to those who are concerned in hanging architectural drawings that to place a drawing of this kind far above the eye is to destroy all chance of its being seen with the effect intended by the author. The building is a plain structure, of domestic Gothic character, with mullioned windows. It is fairly scholastic in character, though it might, after all, be taken for a large private mansion, which should not be the case in a building of this kind. The only marked feature in the design is a square block, which rises above the roofs, over the entrance, and is crowned by a high-hipped roof, with an open-louvered timber story under the eaves. Is this a drying-room? No plan.

1,683. "First Design for the People's Palace at the East End," Mr. E. H. Robson. This design was, we believe, thrown over on account of its costly character. It is a grandiose conception, though we question whether it quite suggests the idea of a people's palace; there is rather a taint of aristocracy about it. The main features are a long ground-story arcade or loggia with a triglyph frieze and Roman Doric half-attached columns running through the impost, the capitals and astragal of which, by the way, are drawn in very exaggerated proportions, as would be seen if they were enlarged. We like to see clean details, on however small a scale, in a Classic building. Over this loggia, which is stopped by pavilions at the ends, is seen the wall of a great circular enclosure, partly occupied by windows, partly by a frieze

representing, apparently, arts and sciences. This is broken by a central pavilion with a dome over it, and a curved pediment beneath in the tympanum of which is a clock face "supported" by two enormous griffins, whose scale dwarfs all the parts beneath them. A little back from the end pavilions, and out flanking them, are two towers, solid wall in the lower stories, with an Ionic order above, and then a circular drum carrying a smaller upper drum with caryatides attached, and ending in a short bulb-roof. This latter is shown with a blank surface; it seems to want the surface breaking up in a decorative manner, to give scale. This and some other parts of the detail we cannot like much, but it is a fine conception as a whole. No plan.

1,689. "New Hatcham School for Girls, New Cross," Mr. Henry Stock. This does look like a school; indeed, could be taken for nothing else. Hung too high to see detail; a red-brick building with three gables over large ranges of windows, and a turret with leaded roof coming in well at one angle. No plan.

1,690. "West Kent College, Brockley," Mr. W. Charles Evans. A large building shown on a small perspective drawing, and cannot be well seen at the height it is hung. It is built round three sides of a central open space, the chapel, which looks a good solid bit of design, occupying part of one side. The walls are prettily regularly pierced with square mullioned windows, and parts of the ground-story treated as open arcades. Apparently a picturesque and suitable building. No plan.

1,691. "New Carmelite Monastery, Kensington," Messrs. Goldie, Child, & Goldie. A very nicely-executed water-colour drawing which looks at first like a row of terraced houses with a cloistered garden (and, after all, who should not terrace-houses have cloistered gardens? How it would add to the happiness of life!), but the treatment of the ground-story with the large long mullioned windows takes the building out of the domestic category. The upper portion hardly seems, however, to harmonise with this ground-story, and wants connexion horizontally also. Otherwise a quiet, suitable, unpretentious building. No plan.

1,692. "King Henry VIII. Grammar School, Coventry," Mr. Edward Burgess. A very pleasant picturesque building, in Late Gothic style, set back from the road, with returning wings; the entrance is marked by a low square battlemented tower. The arrangement of the rather low mullioned windows with flat arched heads to the top lights, carries the eye round the elevation in restless horizontal lines. Long vertical windows come in at the east of the right wing, which seems to be the dining-hall; an octagon stair-turret breaks the re-entering angle. A building which is very picturesque without struggling to be so. No plan. If the author had stuck even a small plan up in the sky, where he has stuck that heraldic armed hand, he would have made a more practical use of that corner of his paper.

1,700. "Infirmary at Champion-hill," Messrs. H. Jarvis & Son. A curious but not unpleasant building, balancing between Elizabethan and Queen Anne; the windows, with their plain sashes and keystones, recall the latter phase of the gables, with their strap ornament in the tympanum, the former. In the centre portion, which apparently retreats a little between wings, the windows are more Elizabethan in character, or even earlier, and terminate in octagons compounded of little pilasters and scrolls, gables, and "knobs," and "spikes." Behind the wings on each side is seen the upper portion of a large square tower, the top stage of which is oversailing on corbels, and made of half-timber work. Now, if the authors had put even a small plan, we might have had some clear notion what these towers were there for, and what part they played in the economy of an infirmary; but, as it is, we can only hazard our guesses. Are there laundries or drying-rooms up there? Or is it a new way of placing isolation wards, with lifts up to them? But this, though a little eccentric, and the drawing rather scratchy, is yet an amusing and interesting bit of building.

1,704. "Competitive Design for the Admiralty and War Offices: View from the Park," Mr. P. J. Marvin. This drawing we publish this week, and we leave our readers, therefore, to form their own judgment; they can see it in our lithograph, whereas one certainly cannot at the Academy, where it is hung very high. It strikes us as a design refined in feeling and

detail, but rather wanting some greater degree of variation and subordination in the treatment of the different stories.

1,711, "Hackford-road Schools, Lambeth," fr. T. J. Bailey. This is a small, very plain drawing of some new or recent Board schools, created in the style which has been adopted for the London Board Schools; the drawing being merely confined to exhibiting the building, without even a figure of a boy playing marbles to relieve its severity. The style of drawing, however, is suited to the peculiar "bonquet" of the architecture, and seems to partake of a prim neatness. The details are so completely in harmony with each other, and the whole so characteristic, that one might find very high expressions of admiration in place, if one could forget that all this, after all, is only a carefully-studied reproduction of the manner of a past generation; a manner supposed, for one reason, to be especially characteristic of London. So it is of the London of one age, not why that particular age for Board schools? However, we prefer to have a recognised Board school style for London than to have them in all styles; and they might possibly have been more original, and less pleasing and suitable.

This completes our remarks on the designs coming under the head of public buildings and institutions, which we have taken separately, leaving domestic and decorative work for further notices.

THE FOLKESTONE EXHIBITION.

THE artistic importance of this Exhibition has been greatly exaggerated by the press generally; one of the results of the system, now pursued in connexion with such undertakings, of inviting representatives of the press to meet on a specified day and go round under the guidance of some one connected with the concern, whose mouthpiece the reporter is fated to become. Our contemporary *Punch* is an exception; he obviously declines to be pumped into, and is sarcastic hints in regard to the pictorial part of the show are much nearer the truth than other accounts we have seen. There are some good pictures there, including among others a very neat and well-known one by Israels; there is also a "Blackberry Gathering" and Linnell's "Hesperus," both fine examples of their authors' work; but many of the good names to be found in the catalogue are represented by works which are not among their best, and there is a great deal of entirely uninteresting work; mediocre paintings by mediocre painters. Among the more interesting ones is Mr. F. Hall's "Deported," and a large painting by the late P. P. Poole, "The Visitation and Surrender of Syon Ferry," which we do not remember to have seen before; and which is an interesting example of Poole's efforts (not very numerous) in historical painting, which, however, is not the field of art in which his special and most characteristic power was displayed. There is also a very fine sea-piece by Mr. H. Moore, which we think we remember in the Grosvenor gallery a year or two ago. The gallery of "Old Masters" is a very poor display of doubtful and second-class works. The making up of the catalogue seems to have been beyond the energies of the committee so far; only a few of the pictures in it have the numbers affixed; a few have descriptive cards attached; the rest must be guessed at, except where signed by the artist.

The building, though certainly not beautiful, is well planned and fairly well lighted for its purpose. The main entrance leads into a large long central hall, on each side of which are doors leading into two suites of galleries, so arranged that the visitor enters by one door, and traverses them to return into the central hall by another door. The hall is decorated rather crudely in strong colours, and with a real deal of bunting depending from the roof, which has a gay effect. At the upper end is an organ and orchestra. Among the culture exhibits here is Mr. Birch's "Godiva," and several other works which will be remembered in recent Royal Academy Exhibitions.

Some cases in the large hall contain some interesting exhibits of early examples of printed and engraved books, including a fine edition of oethias, with engravings by Verard (Paris, after end of the fifteenth century), a copy of the "Player's Edition" of Shakespeare (1623), and some good specimens of bookbinding. In

this hall also is a large stand of Messrs. Donlon's ware; a case of silversmiths' work from Messrs. Hunt & Roskell, mostly modern, but including some interesting examples of old work; and a collection of specimens of Messrs. Diespeker's mosaic; and near this is to be seen the model of Mr. Onslow Ford's fine memorial has-relief, which was in the Lecture-room at the Royal Academy last year, and of which we gave an illustration.

The chief interest of the exhibition, however, lies in the north-east gallery, where there are various loan collections of furniture, armour, ironwork, tapestry, Japanese work of different kinds, &c. In the middle of the room is an ancient specimen of one happily extinct kind of furniture, of which there are probably very few examples preserved, — namely, a pillory, in such preservation that, with the addition of a hasp and padlock to fasten down the top rail, it could still be used for its heinous office. It forms a sinister reminder of the brutality of the forms of punishment once existing among us; though perhaps it was the most suitable kind of treatment for some of those whose beads were locked into it, and possibly some fitting occupants for it might be found even now. From the Goodrich Court collection come some fine tapestries, which line the walls of this room, including a grand piece of Renaissance design, covered with mighty scroll-work, and with a picture of a fountain supported by Cupids in the centre. It is impossible to particularise further than this, as neither descriptions nor numbers were affixed in most cases, and the catalogue merely gives the most general summary.

The Canterbury Museum contributes some bronzes, and a model said to be "the original model" of the Bastille, or for the Bastille, a grim specimen of architectural design, expressive enough in its way. From the Maidstone Museum comes a small but interesting collection of porcelain, old keys (some of them very artistic), and examples of a very curious local pottery manufacture, that of Wrotham, Kent, which is long since extinct. It is a ware decorated with buff powderings and rudely executed escutcheons and other ornaments, on a dark red ground, and is of interest from its marked individuality of style; there are only a very few specimens of it, however. The collection of old iron work lent by Lady Dorothy Nevill includes some most interesting work, a good deal of which was to be seen not long since in London, at the Exhibition of Artistic Wrought-iron Work got up by Mr. A. Newman in Bond-street. Among the furniture scattered about this gallery are some good specimens of eighteenth-century French work, and some older examples of various kinds. Mr. Seymour Lucas sends some swords, helmets, and buff jerkins, some of which we have probably admired in his pictures, and the Baron de Cesson contributes a very fine collection of swords. Mr. G. Treadwell sends some old English jewelry, and (as we find from the catalogue) a "rare and unique key," formerly the property of Mary Queen of Scots; and there are a good many little objects of artistic and archaeological interest which one might comment on more particularly if there were any means, either from the catalogue or from labels, of identifying them. Among the curiosities of this portion of the exhibition there are, among a case of things lent by Mr. Ernest Hart, a great number of what appear to be Japanese metal key-scutcheons (a label was on them, when we looked at them, specifying them as "old china"); these are diverse and curious in design, and form rather a novelty in the way of Japanese collecting. Among the more usual forms of Japanese work in another case are two excellent pieces, a large lacquered paper box, and a double *cloisonné* beaker, part of the "loot" from the Summer Palace at Peking, which turns up in so many places now, of unusual and fine design.

If the objects in this gallery, and the old hooks and armour in the main hall, were collected in one room, they would make a very good and interesting small exhibition of works of art of this miscellaneous class. But the whole building and the whole undertaking, one may say, is far too large for the amount of real interest included in it, and though it may prove a centre of attraction to Folkestone and the neighbourhood, it can hardly be said to be an exhibition worth going far to see, except for those who have seen very little of such exhibitions.

LARGE-SPAN IRON ROOFS: A COMPARISON.

ENGINEERS and architects are much at variance among themselves respecting the merits and disadvantages of single and multiple spans. It is often argued that the cost of painting large spans is an argument against their adoption, and that the cost of erection is greatly in excess of smaller spans. The friends of multiple spans maintain that columns in the centre of a station are not more in the way of passengers than the ordinary lamp-posts, seats, &c., which are usually placed in large stations, but it must not be forgotten that the latter can be easily removed without endangering the structure, if it should at any time be deemed desirable to change the position of the rails and platforms, whereas in a station of two or more spans the central columns might be found to be in the way of an advantageous alteration of the platforms. For instance, the central columns of the Victoria Station of the London, Chatham, and Dover Railway, as at first arranged, stood between the lines of railway, whereas they now very inconveniently come in the centre of the narrowest platform. In the adjoining station of the London, Brighton, and South Coast Railway, the central columns remain, as at first, in the centre of the broad carriage road. In our opinion, a better architectural effect can be produced with a single than a double or multiple span, and certainly better arrangements for ventilation in a railway station can be obtained with the use of a large single span. At Euston Station, where several comparatively small spans are adopted, the roofs were a few years ago raised about 6 ft., as the station was found to be deficient in ventilation. The lifting was effected by the aid of some powerful screw-jacks, which were afterwards employed for lifting the eastern goods shed roof of the Great Northern Railway Co.

The following spans have been adopted at the Euston terminus of the London and North-Western Railway — 62 ft. 6 in. (widest span) over two arrival platforms; 26 ft. 6 in. over the cab-drive next to Seymour-street, arrival side; 34 ft. over cab-drive, arrival side; 26 ft. 6 in. over cab-drive; 40 ft. and another 40 ft. over the east departure; 29 ft. over the local traffic; 39 ft. and 43 ft. 6 in. spans, and 49 ft. 6 in. over the west departure (old London and Birmingham railway station).

The comparative diagram which we publish showing heights and spans of various iron roofs illustrates a width of from 240 ft. to 250 ft. covered in one span at St. Pancras Station (Midland Railway), in two spans at the Victoria Station (London, Chatham, and Dover Railway), in three spans at Paddington Station (Great Western Railway), and in four spans at York Station (North-Eastern Railway). We would refer our readers to the table of examples of fifty iron roofs given on page 37 of *Walmisley's Iron Roofs*, published by Messrs. E. & F. N. Spon, in which the principal dimensions are arranged in a tabular form, and are placed in the order of their span, which varies from 240 ft. to 40 ft. The roof over the New National Agricultural Hall, now in course of erection at Kensington, covers a space between walls of 440 ft. in length by 250 ft. in width, and is surrounded by buildings and open space, bounded by Blyth-lane, the houses on the north side of Hammer-smith-road, and the Addison-road railway station, providing an available area of 6½ acres for the company's purposes, which they propose to extend by the acquisition of a site upon the opposite side of Blyth-lane, recently laid out for proposed markets, but which is now suggested to be reserved for pleasure grounds.

The main roof of this building is 170 ft. clear span, having a gallery floor 40 ft. wide upon the north, west, and south sides, and 26 ft. wide upon the east side. The roof is semicircular, with ribs 7 ft. deep placed 34 ft. apart in eleven bays, and springing from columns described in the *Builder* for April 17. The comparative diagram also shows the size of the semicircular arched roofs of the Crystal Palace, Sydenham, and of the Royal Aquarium, Westminster.

The design of the roof of the National Agricultural Hall at Kensington is by Mr. Am Druce and Mr. A. T. Walmisley, both of Westminster, who have been engaged as joint engineers for this portion of the work. Since the publication of the illustration of the building in our issue of October 3, 1885, we understand that the design for the closed glazed screens at the west and east ends has been altered from

THE NATIONAL AGRICULTURAL HALL, KENSINGTON.—ROOF PRINCIPAL AND STAGING.

the radial construction there shown, to a vertical ridge and furrow form, whereby a better connexion with the screen rib is effected, and the appearance of heavy horizontal members avoided. The screen will present the nearest approach to the idea of a folded curtain that it is possible to produce, in the given situation, with ironwork. The main purlins which run from screen to screen are made to act as continuous girders, and communicate a portion of the wind pressure from one screen to another. The longitudinal inner floor girders under the north and south galleries, which come in line with the inner row of columns, also act as continuous girders, and the stability of the ironwork is independent of the surrounding walls. We may observe also as a peculiarity of the design that, except where required for covers, plates are almost wholly omitted, and the various parts are made up of flat bars and angle irons riveted together. About 1,200 tons of iron will be required, and the cost will be from 26l. to 27l. per square of 100 ft. area.

We illustrate the staging designed by Messrs. Handyside & Co., of Derby and London, for erecting the roof. The stage is 62 ft. on the top platform in width, so that it overhangs 14 ft. longitudinally from the centre of the main ribs, which are 34 ft. apart. Thus, one bay can be completed between two main ribs, and the stage then moved forward to erect the next bay. The stage travels from west to east, working towards the railway. The skeleton iron framework admits of planks being stretched or suspended in any position, so that there will be no necessity to wait for the help of the travelling stage to execute the painting. There are about 10,000 cubic feet of timber in this stage, including the staircase and top platform, an amount which, compared with other travelling stages, shows that no needless expense has been incurred, while the scantlings are amply sufficient for the work required. The travelling stage for the erection of the roof over the King's Cross Station, Great Northern Railway (arrival side) contained 14,000 cubic feet of timber. This stage was designed so that no hindrance was occasioned to the railway traffic passing underneath it, and it was arranged to move a distance of one bay or 20 ft. at a time. In the St. Pancras Station of the Midland Railway more than 50,000 cubic feet of timber were used for the travelling stage, which was divided into three parts, a central and two-side divisions. Two of these travelling stages, moving one after the other in the same direction, were employed, and a smaller separate staging was subsequently erected at the north end for completing the gable. This latter portion was so constructed that trains might pass under it into the station before the completion of the work.

The following is a comparative statement of the dimensions, &c., of the roofs shown on the diagram on p. 774:—

Name of Roof.	Total transverse width.	No. of spans.	Main span.	Clear height above floor or rail level.
	ft. in.		ft. in.	ft. in.
Crystal Palace, Sydenham, Centre transept	104 0	1	104 0	180 0
St. Pancras Station, Midland Railway	240 0	1	240 0	100 0
National Agricultural Hall, Kensington	250 0	1 with side galleries	170 0	99 7 1/2
Royal Agricultural Hall, Islington	230 0	1 with side galleries	125 0	70 0
Victoria Station, L.C. & D.R.	256 4	2 with side galleries	129 0	63 6
Derby Market Hall	111 6	1 with side galleries	89 6	59 6
Paddington Station, G.W.R.	240 6	3 with side galleries	102 0	54 7
Royal Aquarium, Westminster	80 0	1 with side galleries	39 0	49 6
York Station, N.E.R.	334 0	4	81 0	45 0
Liverpool-st., G.E.R.	315 0	4	109 0	62 0
Canon-street, S.E.R.	180 4 1/2	1	180 4 1/2	79 6

Garston.—Mr. Reuben Bennett, of Manchester, has submitted designs and obtained the contract for proposed decorations at Garston Parish Church, near Liverpool.

THE NATIONAL AGRICULTURAL HALL, KENSINGTON.

The ninth Saturday afternoon visit of the Architectural Association was made on Saturday afternoon last to the National Agricultural Hall, Kensington, now in course of erection adjoining the Addison-road station under the superintendence of Mr. James Edmeston, past president of the Architectural Association, Messrs. M. am Endo and A. T. Walmisley being the engineers. The engineers were present, and explained the drawings and construction of the iron roof, and conducted the party over the works, the novel and light construction of the roof being inspected with great interest. Three of the main ribs or principals of the roof are already in position. The roof will be covered partly with zinc and partly with glass, by Messrs. Bellwell, on their patented systems. Messrs. Handyside & Co., of Derby, are the contractors for the ironwork, and Messrs. Lucas & Son, of Kensington, the general contractors, the amount of their contract being 131,573l. Mr. Howard is Messrs. Handyside's representative on the works, Mr. W. F. Siddall being the clerk of works. A novel and ingenious feature of construction adopted by the engineers consists in making the connexions of the columns partake of a ball-and-socket-joint-like arrangement, with the view of giving the columns a certain amount of lateral play, from the expansion and contraction of the roof, without danger of fracture, as mentioned by us in a "Note" in our issue for April 17 last, p. 567. For the purpose of erecting the roof, Messrs. Handyside & Co. have built a gigantic travelling stage, having a platform 62 ft. in width, and containing about 10,000 cubic feet of timber—not 1,000 ft., as was accidentally stated in the "Note" just referred to. We give some diagrams showing this staging. We gave full particulars and dimensions of the hall on the occasion of the laying of the foundation-stone (see *Builder*, July 25, 1885, p. 137), and on October 3 last we gave a view and plan of the hall, as designed by the late Mr. H. E. Coe, the architect, who was succeeded by Mr. Edmeston on his resignation through ill health a short time afterwards. As is elsewhere mentioned, however, the design of the end screens has been altered from the radial arrangement shown in our view of October 3 last.

ARCHITECTURAL ASSOCIATION.

The concluding meeting of this Association for the present session was held on the 21st inst., at 3, Conduit-street, Mr. C. R. Pink (President) in the chair.

The following new members were elected, viz., Messrs. H. S. Berridge, J. D. Michell, Henry Coldwell, J. H. Porteous, and A. F. Cutler.

A vote of thanks was unanimously passed to Mr. Alfred Waterhouse, R.A., for permitting the members to visit the National Liberal Club the other Saturday afternoon.

Studentships and Prizes.

It was announced that the Association Travelling Studentship had been gained by Mr. R. W. Paul, and the second prize of 5l. by Mr. T. E. Key. It was further announced that only one set of drawings had been sent in for the Aldwinckle Travelling Studentship, and the judges did not consider these of sufficient merit to justify them in awarding the Studentship.

The following is the judges' report to the Architectural Association Sketch-book Committee:—

"April 14th, 1886. GENTLEMEN.—Having examined carefully the various sets of drawings included in the last volume of the Sketch-book, we are of opinion that prize 2, of four guineas, for the best set of two transfers should be awarded to Mr. Sydney Vacher, for his drawing of ornamental work and the figures from Schiavoni.

Prize 3, of three guineas, for the best set of three plates, we consider should be given to Mr. G. Oakshott. In awarding this latter prize, we put out of consideration the sketch of the Hôtel de Ville, Orleans; but we consider the three others to be the best for value of subject and finish of drawing combined. We may take occasion to remark that some of the contributors have more or less spoiled their set, when considered in regard to a prize, by sending one or more drawings much inferior to their best work.

We had considerable difficulty in deciding on prize 3, and express our admiration of the work of several of the other sets.—We are, yours faithfully,

H. H. STATHAM.
E. INGRESSE BELL.
ASTON WEBB."

Books.

Mr. R. L. Cox then read a paper on "Books," with special reference to those treating of architecture. At the outset he observed that if he could have been asked to read that paper three hundred years ago, his task would have been considerably lighter than the lapse of time had now caused it to become, for there were in existence at that period only about enough books concerning architecture to suffice for the study of one lifetime. But to-day the number of works connected more or less directly with architecture and its allied sciences had increased to such an enormous extent that the task of dealing with them, even for purposes of classification, was a formidable one. If one came to consider which, from an architect's point of view, was the most important element in the formation of an architectural book—letterpress or engraving,—he thought one would not have much hesitation in declaring in favour of the latter. To architectural students engraving was certainly of greater importance even than printing; one single page of illustration would often convey more meaning than a whole volume of letterpress. The lecturer proceeded to give an interesting sketch of the rise and progress of engraving and printing, pointing out that block books, printed between 1430 and 1450, were often profusely illustrated with figures in architectural borders or settings,—of which one of the earliest, the "Spectaculum Humane Salvationis" had, amongst many other subjects, quite a good representation of a German schloss, with tall angle-towers and pointed extinguisher roofs, the borders to the plates being Gothic in character, with crocket-like foliage in the spandrels; whilst the "Biblia Pauperum" had archaic figure-subjects, bold and heavy outlines, and wide and coarsely-cut lines of shading, the letterpress being confined to short Latin texts in scrolls, and the plates framed with architectural borders of arches carried on shafts with capitals and bases of a Romanesque character. He then went on to say that it was a fact that whilst all the greatest periods of architectural magnificence had their rise and fall long ages before the age of printing, and left their traces,—whether at Thebes or Persepolis, at Athens or Rome, at Ravenna or Caen, at Cologne or Lincoln,—in work of which mankind might well be proud, a marked deterioration in artistic feeling followed rapidly on the universal diffusion of knowledge by the multiplication of precept and example as effected in the publication of works on art; until at length perhaps of lower depth of downright ugliness than was ever achieved in the history of the most art-less of primitive nations was arrived at amongst our highly-civilized selves in the reign of his most sacred Majesty, King George the Fourth, of which menageries examples might be seen in that most amusing volume by A. W. Pugin, published in 1836, and usually known as "Pugin's Contrasts." This fact could only be attributed to the unreasoning pursuit of the arts and literature of an ancient régime, the theories and fancies of which were blindly accepted as living truths and used like fetters to cramp the freedom of natural thought and action. It was the too ardent spirit of hero-worship that made excessive admiration of a bygone art overdo itself; and by forcing that art, admirable though it was at one period of the world's history, upon another and a totally different age, it degraded what was once noble and admirable into a mere empty fashion,—a thing to be slavishly followed because it was *à la mode*, checking in the end all further enterprise, and making men halt for precedents and authorities without whose leading-strings they did not venture to move. It would of course be vain to say that the attention given by Brunelleschi to the neglected remains of Classic architecture in Rome would not have made itself felt through his works over perhaps all Europe itself, the more especially as his visit to that city (about the year 1400) was impelled by the awakened interest in Classic architecture that was being felt in Italy, which would of necessity influence the art of the time; but this was by no means unlikely; that but for this slight aberration, as it were, of the course of architecture would have gone on towards fresh development could the "Great Dictator," as Evelyn called Vitruvius, have remained unknown until (say) the present century, when his study, from an antiquarian point of view, would have been of the highest

possible value, and in this our present more healthy and vigorous state would have been less likely to be productive of harm. Fate willed otherwise, however, and Vitruvius combined all the qualities that were necessary to attract attention at that particular time. First of all, he was a Roman of the true Classic period, and his treatise, in Angustan Latin, was exactly the kind of composition then most in demand. The discovery of his work turned the current of architectural literature, then in its very infancy, into the channel through which it has flowed without interruption down to quite recent times. Having given an account of some of the various editions of Vitruvius, of which there are seventy-six, and quoted some quaint passages from the translation into English by Robert Haydocke, published in 1598, probably the first translation of a writer on Roman architecture published in England, Mr. Cox pointed out that one good result of the spread of Classic literature was seen in the attention that was paid to the careful measurement and delineation of the examples of Classic art, and many magnificent works resulted, of which Sterri's Illustrations of 1784, the plates in which were masterpieces of engraving; Palladio's "Ancient Roman Architecture"; or Wood's "Ruins of Palmyra,"—the latter a book after the style of Stuart's "Athens," and of great practical value,—might be quoted as examples. When at last the Classic monopoly began to wane, and architects began to study in a more generous and cosmopolitan spirit the artistic work of other countries than Classic Italy, they found themselves not only actually deprived of many buildings and remains of artistic and historic value that had been wantonly destroyed by neglect, or removed to make way for something elegant and chaste in the approved style, but they were also totally unable to observe and delineate correctly the therto-despised styles. There were no works in the early days of the Gothic revival the value or execution of which approached that of Classic books that had been common a hundred years before. Such works, for instance, as Nottingham's "Henry VII.'s Chapel," published in 1822, or Caveler's "Specimens," in 1834, could not be compared with some of the Classic works quoted; and although any number of antiquarian works, in which there were illustrations of a pictorial character, the greatest merit in almost any quantity, existed from the days of Dugdale's "Monasticon" downwards, it was not until the one of the Pugins that works on Gothic architecture began to be of any real value to the professional architect. Eastlake had mourned at the publication of such fine works as those of the Pugins, as well as others of a later date, could offer such tempting opportunity to the plagiarist, who, to save himself trouble, could put up a steeps all cut-and-dried ready to hand out of the book; but the pillory of public scorn would be sufficient punishment to prevent the misuse of books in such a way as that, and therefore the author did not see any reason why careful monographs of buildings could not be multiplied, since every day the growth of taste in art rendered it less likely at the use of them would be thus abused. The immediate effect of books in cramping the development of architecture seemed to have arisen from the one-sided twist or bias that happened to be imparted to them at the outset, the result of which was the undervaluing of one particular class or quality of art to the exclusion and almost extinction of the rest,—an evil that would always have a tendency to recur when too strong a feeling of partisanship, or too blind a following of any particular idol or whim of the moment, was allowed to take the place of better judgment, and which could only be prevented by the exercise of a generous and liberal spirit, more able to look out for and acknowledge the good points that were to be discovered in a thing, than to be only on the alert to criticise and condemn what might turn out, after all, to be so bad.

The Chairman, in opening the discussion, complimented Mr. Cox on his paper. It was a result of very wide and extensive reading, and had taken his hearers to many out-of-the-way corners which few of them perhaps would ever otherwise visited. Mr. Cox had spoken only of the untrustworthiness of books of the sixteenth, seventeenth, and eighteenth centuries in regard to Gothic architecture. Books were

one of the chief means by which the student had to gain a knowledge of his profession. The list of books issued by the Institute for the guidance of those students who were seeking to pass the Examination in Architecture was an exceedingly valuable one, if it was regarded as it should be, viz., as a sketch of the student's library of reference. He was afraid that some people thought that it was meant that the student should thoroughly read and study all the books contained in the list as text-books, but that was an absurd idea. So largely, however, had it obtained, that it had been stated that a student in the country had written to Mr. Bateford to send him the whole lot, and was much surprised when he received the estimate. The list would be found most valuable as a list of books for reference, and as a list from which a selection of books which every student should study as text-books might be made. It was necessary that the student should actually possess some, so that he might have them constantly at hand. The list omitted, he thought, some few books which were valuable to the student. With regard to the history of architecture, every one would agree that Ferguson's book was the best in any language. Although it was so valuable, yet the student would possibly, in the first instance, do well to thoroughly study Rosengarten's Handbook; and those smaller ones by Mr. John Slater and Professor T. Roger Smith. Then, with respect to drawing, Burchett's "Perspective," some good book on Sciography, Turu's "Geometrical Drawing," and similar volumes, would be useful; while, in regard to science, Tarr's "Science of Building" was a capital primer in that branch. Mr. S. F. Clarkson proposed a vote of thanks to Mr. Cox, and complimented him on his ability for dealing with such a subject.

Mr. J. A. Gotch, in seconding the vote of thanks, remarked that Mr. Cox had given a good architectural flavour to his paper on "Books." Any product of the early days of printing must be of interest to the architect, and it was curious why the books of that period were so much more interesting, as specimens of typography, than those of the present day. He was inclined to think this was largely owing to their inaccuracies, though such a statement might seem somewhat paradoxical. He believed their charm was greatly owing to the inaccuracies more or less consequent upon hand work. Ancient buildings were also often set out in a most inaccurate manner, and this, perhaps imperceptibly, formed part of their beauty. The Musée Plantin, at Antwerp, contained a series of beautiful designs for title-pages, but to title-pages nowadays no particular interest seemed to be attached. The designs to which he referred were most fanciful and dainty, and it was a pleasure to the members of the Association to feel that they were keeping up this good custom in connexion with the Sketch Book. The findings of hooks, again, were very interesting, some of those published in the sixteenth century being quite a revelation to people who had never before seen them, the amount of fancy expended on the character of the designs being very great indeed.

Mr. John Slater, B.A., said he always had a taste for old hooks, and, like Mr. Gotch, he had often been struck with the curious inaccuracies in those printed from wooden blocks. What astonished one was the courage of the old wood-printers, who never "shied" at anything, the "Nuremberg Chronicle," published in the sixteenth century, beginning with a representation of what one should have thought unrepresentable, viz., Chaos. One also noted in those books the recurrence of the portrait-blocks, the same one doing duty for Moses and Joshua, and even for people who had lived a few years before the book was printed. Again, the relative proportions of virtue and viciousness in the character, were always strictly represented by the amount of clothing. Mr. Cox had said that if Vitruvius had lived several centuries later he would have been able to give his views on some of the Mediæval buildings, but several later writers had not been struck with Gothic work, and even the Frenchman, Quatremère de Quincy, was as much opposed to it as any of those who had been mentioned. Books were invaluable, but they must be consulted and read with a certain amount of care, and with the idea of what they were intended to do. Hand-books must be considered merely as hand-books, and it must not be supposed that the information contained in so small a compass, would free the student from the necessity of

consulting the larger works. He was glad that the Chairman had referred to the list of books put forward by the Institute, because a great deal of misunderstanding had arisen from it. The list might have been made even fuller, but it was intended for use all over the country, and was so compiled as to give an alternative choice of hooks which might be had for purposes of reference. He would like to conclude with the caution that no amount of book knowledge would do away with the necessity for striving to make acquaintance on the spot, or by the inspection of models, with the buildings described.

The vote of thanks was then carried by acclamation, and Mr. Cox made a suitable reply.

Election of Officers for Session 1886-87.
The result of the election of officers for Session 1886-87 was next announced. The complete list is as follows:—

President.—Mr. J. A. Gotch.
Vice-Presidents.—Messrs. J. Slater and E. J. May (Mr. Henry Lovegrove having withdrawn his nomination).

Committee.—Messrs. Cole A. Adams, W. H. Bidlake, F. R. Farrow, Arthur J. Gale, W. J. N. Millard, C. R. Pink, W. A. Pite, L. A. Stokes, S. Vacher, and G. G. Woodward.

Hon. Treasurer.—Mr. J. Douglass Mathews.

Assistant-Treasurer.—Mr. H. W. Pratt.

Librarian.—Mr. W. Burrell.

Hon. Secs.—Messrs. H. D. Appleton and T. E. Pryce.

Solicitor.—Mr. F. Truettitt.

Auditors.—Messrs. M. Fawcett and A. C. Bulmer-Booth.

Registrar.—Mr. T. H. Watson.

Cordial votes of thanks were passed to Mr. C. R. Pink for the manner in which he had discharged his Presidential duties, and to the Hon. Secretaries, Messrs. Appleton and Pryce.

THE SOMERS TOWN GOODS STATION OF THE MIDLAND RAILWAY.

PEOPLE who have passed along the Euston-road of late will have noticed that a structure of large dimensions is in course of erection there. The building in question is the Somers Town Goods Station of the Midland Railway Company, the site of which covers an area of upwards of fourteen acres, occupied until within a few years back by an urban population of more than 4,000 persons. It was in the year 1877 that the Midland Railway Company obtained an Act of Parliament under which they secured powers for the purchase of the site. The clearance of this site and of the site of the St. Pancras Terminus some years previously involved the demolition of several hundred houses and the displacement of thousands of people. It was not until about 1882, or some five years after the company obtained their Act, that the site of the new goods depot was finally cleared. A considerable period elapsed before anything was done with it beyond the ground being enclosed by an unsightly hoarding, and in the meantime the local authorities lost the rates which had been paid on the house and shop property now swept away. Various rumours were from time to time current as to what purposes the railway company intended to apply the land. At one period they were credited with an intention to convert it into a large wholesale vegetable market, to be supplied by the agricultural localities within the districts served by the line; at another time it was rumoured that a considerable portion of the site was about to be utilised as a locomotive and carriage manufactory; whilst at a subsequent period the story prevailed that it was to be laid out as an ornamental garden in connexion with the company's adjoining hotel, a sufficiently improvable application of a property which is understood to have cost the company a sum approaching 1,000,000. All don't was, however, set at rest about two years since, when it became known that an unusually large and costly goods station was about to be erected on the site. The getting-in of the foundations involved some heavy excavations, and near to the bed of the old Fleet river it was found requisite to sink cylinders to a depth of 40 ft. through soft mud, in order to arrive at a sufficiently firm bottom.

The external features of the building are designed to harmonise as far as may be with the adjoining hotel and station, of which it forms a continuation westward. Thus the Euston-

road frontage, which is about 300 ft. in length, extending from the Midland-road, on the west side of the hotel, to Ossulston-street, is upwards of 30 ft. in height, and contains twelve pointed openings, filled in by ornamental iron railing, with two spacious entrances at the east and west angles, closed by ornamental iron gates. The arches of the openings and entrance-gateways are in alternate Leicestershire brick and Mansfield stone, and the elevation is surmounted by a perforated and moulded coping and balustrade, also in Mansfield stone. The return frontages in the Midland-road and Ossulston-street, to the extent of upwards of 50 ft. in length, are of the same architectural character, and the remaining portions of these two frontages, each of which is about a quarter of a mile in length to their northern extremities at Phoenix-street, are faced with a series of pointed arches, those in Ossulston-street being in blank, whilst several of the arches in the Midland-road lead into offices in connexion with the coal and other trades. The area of the land widens considerably from the Euston-road northwards, until at its northern boundary in Phoenix-street it is more than 600 ft. in width. In the Phoenix-street frontage the Gothic character of the several elevations is preserved, the frontages being all faced with Leicestershire red brick; and the whole of the external walls vary from 3 ft. to 4 ft. in thickness. Immediately inside the external walls there is a roadway, 40 ft. in width, running parallel with the Euston-road frontage for its entire length, and also carried to a considerable distance along the east and west frontages. These roadways are bounded by inner walls, enclosing the main area of the station. The structure will comprise two floors, namely, the ground-floor and the floor above it, and as much of the traffic is intended to be marshalled and arranged on the ground-floor, there will be hydraulic lifts by which the railway waggons will be lowered and raised. The upper floor is the chief structural feature in the building. It is constructed chiefly of iron over its entire area of some fourteen acres. This upper floor is being constructed at an elevation of 18 ft. above the ground floor, and as the columns which carry it have to support a dead weight of ballast in addition to heavily-laden goods waggons, they have necessarily been made of exceptionally great strength. There are 400 of these iron columns, weighing 2,000 tons; 4,700 tons of main girders, and 8,300 tons of cross girders. The flange plates required in connexion with these girders are nearly forty miles in length, whilst the floor-plates weigh between 950 and 1,000 tons. Upward of 16,000 tons of iron will, therefore, be used in the construction of this floor. A large block of warehouses is about to be built on the west or Ossulston-street side of the depot; it will be upwards of 400 ft. in length and four stories in height.

The estimated cost of these great works when completed is set down at the sum of 2,500,000l. Mr. J. Underwood, C.E., of the Midland Company, is the engineer, Mr. A. McDonald, C.E., being the superintending engineer. The execution of the works is in the hands of four contractors, Mr. Joseph Firbank, of Newport, Monmouthshire, being the general contractor, whilst the ironwork has been entrusted to three other firms, namely, Messrs. Eastwood, Swingle, & Co., of Derby; Messrs. Andrew Handyside & Co., of Derby; and Mr. John Butler, of Stanningley, near Leeds.

Builders' Clerks' Benevolent Institution.—A special general meeting of the donors and subscribers, convened by advertisement, was held at the offices, 21, New Bridge-street, E.C., on Tuesday last, the 25th inst., Mr. George Haward Trollope, President, in the chair, when the requisite permission was given to purchase another presentation to the Orphan Working School. This presentation, as in the case of the two already bought, will cost 250 guineas, and will entitle the Institution to present a child for a period of twenty-one years. At the close of the business, a vote of thanks was accorded to the chairman for his kindness in presiding on the occasion.

Lying-In Ward, Wandsworth Workhouse.—The Guardians of the Wandsworth and Clapham Union adopted, at their last meeting, plans prepared by their architect, Mr. T. W. Aldwinckle, for new lying-in wards, to be built at the new Workhouse, Garratt-lane, Wandsworth.

Illustrations.

COMPETITIVE DESIGN FOR WAR AND ADMIRALTY OFFICES.

THIS is a perspective view of the design submitted in the first competition by Mr. P. J. Marvin, the original drawing of which is now in the Royal Academy, as noted in another column, in our remarks on the architectural exhibits. The view, as will be seen, represents the building as it would have appeared from St. James's Park.

SCULPTURE AT THE ROYAL ACADEMY.

We give three illustrations this week from this year's sculpture in the Royal Academy; one ideal work, Mr. Lawson's "Summer," and two portrait statues, that of Sir Erasmus Wilson, by Mr. Brock; and that of Mr. Carmichael, of Madras, by Mr. Adams Acton. We have already commented on all of them in our article on "Sculpture at the Royal Academy" (page 739 ante).

We may add that they are all reproduced from photographs forwarded to us by their respective authors for that purpose.

LEGAL AND GENERAL LIFE ASSURANCE OFFICES.

We give a view of this very rich and effective façade, designed by Mr. R. W. Edis, about which we have already spoken in mentioning the original drawing in our notes on "Architecture at the Royal Academy" (see page 737 ante). The offices have been rebuilt on the site

of the old offices of the Society. The contractor was Mr. Boyce, and the materials of the exterior are red bricks, supplied by Mr. Edwards, of Raabon, and yellow terra-cotta dressings supplied by Messrs. Wilcock & Co., of Burmahost.

SKETCHES IN NORMANDY.

The external pulpit at St. Lo, shown in the first of these sketches, is at the north-east angle of the cathedral of Notre Dame there, and is of the fifteenth century.

The church of St. Gilles, Caen, the south-east porch of which is shown in the second sketch, is now used as a store-house. It stands on the heights of St. Gilles, at the top of the Rue des Chanoines, and close to the Abbaye

aux Dames. The effect of the segmental arch, and the wall decoration and parapet above, abutting against the masses of plain wall on either side, is very good and very characteristic of the Mediaeval spirit in building. The abutting masses are as rocks between which a bridge of architectural detail is constructed.

The illustrations are reproduced from original sketches by Mr. Francis D. Bedford, which are very good examples of architectural sketching in pencil, a medium too much neglected by architectural draughtsmen at present.

A SMALL STUDIO.

The studio of which interior and exterior views are given in this number was built for Mr. H. Gibbs, in an ordinary London garden, about 38 ft. wide. It comprises a painting-room, 28 ft. by 18 ft., with a large bay-window shut off by curtains, and a small dressing-room or lavatory, &c., with a porch at the side. The floor is polished, and the painting-room will be paneled in deal and painted. The walls are of stock bricks with red brick dressings. The architect was Mr. T. Edward Pryce.

COMPETITIONS.

Donald Drinking Fountain, Public Park, Dunfermline.—On the 21st inst. the Town Council selected the design submitted by Mr. R. Cameron, of Edinburgh, awarding the 100l. premium accordingly. The style adopted is a phase of the French Renaissance. All the work is to be executed in polished red granite. The pedestal, which is raised on two large steps, is square in plan, having scrolled angle buttresses. On each side of the square is a circular niche with a carved corbel hollowed out to form a basin, the niches themselves terminating in a shelled hood. Beneath the large hasias are recessed dog troughs. Over the niches are relieved pediments, which finish against a scrolled canopy. On the upper part of the canopy is a consisting of shields and other armorial bearings. The structure, which is about 14 ft. high, terminates in a carved cap, surmounted by the burghal coat of arms of Dunfermline. The approximate cost is 750l. There were fifty sets of designs submitted.

New Schools, Horrabridge.—In March last the Whitechurch United District School Board advertised for plans and specifications for new schools to be erected at Horrabridge, South Devon. In response sixteen architects submitted designs, and those prepared by Messrs. Henderson & Son, of Truro, have been selected for adoption by the Board. After the plans, &c., have been submitted to the Educational Department, tenders will be invited, and the works will be proceeded with forthwith.

British Museum Lectures.—The course of lectures recently given by Miss J. E. Harrison at the British Museum, on the "Monuments and Topography of Ancient Athens," will be repeated in the afternoon, to suit the convenience of those who are engaged during the morning hours. The course begins on Wednesday, the 8th of June, at 4:30 p.m. A course on "Vase Paintings" begins on Friday, the 11th of June, at 4:30. Letters in regard to admission can be addressed to the hon. sec., Miss Wilson, 45, Colville-gardens, W. The course is open to both men and women. We may also add that Mr. J. A. P. MacBride is now delivering a course of lectures at the Museum on Sculpture. His third lecture, on "Early Greek Sculpture," will be delivered on Tuesday afternoon next.

Society of Arts Conversations.—One of the two Fridays for which the right of excluding the public has been reserved by the Royal Commission for the Colonial and Indian Exhibition has been allotted to the Society of Arts for their annual conversations, which will be given at the Exhibition on Friday, the 16th of July. Arrangements have been made for the purchase, by members of the Society only, of tickets to the site, on the same system as that which proved so successful last year. Members, who will receive the usual invitation for themselves and a lady, will thus also be enabled to obtain tickets for other members of the family. The price of the ticket has been calculated so as just to cover the actual cost of the entertainment, and to leave sufficient margin to repay the Royal Commission for the loss resulting from closing the Exhibition for the evening.

The Injector-Hydrant.

THE "INJECTOR-HYDRANT" FOR FIRE EXTINGUITION.

In the *Builder* for November 1st, 1884, we gave a detailed account of the work of the London Hydraulic Power Company. Since that time, the Company's system of hydraulic mains, primarily for the supply of power for working lifts, presses, &c., has been greatly extended, and as the mains now traverse some of the most important parts of the City, Westminster, and Southwark, it is proposed to use them for another purpose, viz., that of energising and reinforcing the fire-hydrants fixed on the ordinary water companies' mains, in the manner which will be readily understood by the following particulars and illustration:—

Briefly described, the injector-hydrant, which has been introduced by Sir W. Armstrong & Co., on the suggestion, we believe, of Mr. J. I. Greathead, M. Inst. C.E., consists essentially of the ordinary hydrant D, rising from the water company's main at A, and having its nose-attachment at E, but slightly varied in vertical section so as to permit of the introduction of a pipe of small bore, C, leading from a high-pressure hydraulic main. The termination of this small high-pressure pipe, which is in the form of trumpet-shaped guide-tubes, L, rises upwards for a short distance in the centre of the hydrant, leaving plenty of space all round it for the passage of the water from the water company's main. As a matter of fact, the water from the company's main can be sent through the hydrant without the high-pressure hydraulic pipe being called into requisition, but in that case it will only rise to a height proportionate to the pressure in the water company's main. But when the valve of the small high-pressure pipe is opened, a jet of water at a pressure nine or ten times greater than that issuing from the water company's main is sent upwards in the midst of the low-pressure supply, which it carries or drags with it so as to enable the stream issuing from the nozzle at the end of the hose to reach to a much greater height. The injector-hydrant, in fact, to quote Mr. Greathead's own words, depends for its action upon the "lateral inductive action of fluids," a principle long well known and utilised in various ways, as in Giffard's injector and the last-pipe, for instance. (We may here mention that a full account of Mr. Greathead's proposals for fire extinction with the aid of this hydrant appeared in our contemporary *Iron* some time ago.)

To show the efficacy of the combined jet, some interesting demonstrations were given a few days ago, on a piece of unoccupied

land adjoining the Westminster Town-hall. The water main to which the hydrant was attached formed part of the Chelsea Company's system, and registered a pressure of about 80 lb. to the square inch. This alone was found to throw an inch jet of water, at an angle of about 45 deg., as high as the eaves of the Townhall; but directly the valve of the small branch pipe from the high-pressure hydraulic main was opened the jet of water was carried twice the height, thereby demonstrating the value of the injector-hydrant where high-pressure hydraulic power is available. It was stated that these hydrants have been used with much success in Hull.

It is thus evident that, by a slight modification, the effectiveness of street-hydrants for fire-extinction may be considerably augmented where there happens to be a high-pressure hydraulic main alongside, or in the immediate vicinity of, the water company's main. The matter is one of great importance, for an effective system of hydrants, combined with a constant supply of water, would go far to render a large retinue of fire engines a matter of secondary importance.

CASES UNDER THE METROPOLITAN BUILDING ACTS. NON-DEPOSIT OF PLANS.

At the Guildhall Police Court on Tuesday, before Alderman Sir T. S. Ordwin, Mr. John Mowlem, of the firm of Mowlem & Co., was summoned by Mr. Hugh McLaughlin, District Surveyor for the Western Division of the City, for not having deposited plans of a certain building in course of erection near the Thames Embankment for the City School of Music.

Mr. Blackwell, who was counsel for the complainant, stated that the summons had been taken out under the Metropolitan Management Act, 1873, section 16, for a breach of the by-laws, in failing to send to the Surveyor the plans of the building mentioned.

Mr. Douglas, the Chief Clerk, pointed out that section 20 of the same Act put the complainant out of Court. This twentieth section ran thus:—"Provided always that the provision of part 2 of this Act shall not extend, or apply, to the City of London."

Mr. Blackwell remarked that his contention was that the exception referred to only to dangerous structures.

Mr. Douglas said it referred to the whole of part 2; and section 16 was part of that section.

The Alderman.—It is evident that I have no jurisdiction.

Mr. H. H. Crawford, the City Solicitor, who appeared for the defence, said that Messrs. Mowlem were nominally defendants; but, as a matter of fact,

they were merely contractors under the Corporation. Had the case gone on he was prepared to take technical objections,—one of which was that the complainant was not entitled to take proceedings by reason of six months having elapsed since the plans had been acted upon. This was the second time the City authorities had been called upon to defend themselves against charges made by the District Surveyor, who appeared to be now in his office.

The Alderman dismissed the summons, and awarded one guinea costs.—*Times*.

"WINDOWS."

SIR,—In the admirable paper on this subject, which appeared in the *Builder* of last week (p. 733), the author, while speaking in complimentary terms of Christ Church, Streatham-hill, cites it as an instance of the abuse of stained glass in the windows, which has so darkened the church that gas has sometimes to be used in the day-time.

This church was built in 1840; at that time 4l. per sitting was considered a handsome allowance for cost. To obtain with such slender means some dignity of style, I made the design as simple and massive as I could: there is hardly a moulding about the building. The windows, which are small and numerous, were amply sufficient to light the church, and were not intended to be filled with stained glass; and, trusting that means would be found in time to decorate the interior with mural paintings, I had the shafts of the columns painted dark red, as a sort of protest of my intention, and so left it.

During my long absence in Egypt, the apse was decorated by Owen Jones in a style different from the church; but it has many admirers. I also found on my return that some of the windows had been filled with stained glass, and since then others have been added, till now nearly all the windows are filled with figure subjects in rich full-toned glass. The different donors selected their own artists and designs. Many of them are very good. Had I been consulted, I should have advised the use of lighter tints, which would not have obscured the light so much. The excellent effect of such glass may be seen in a small cloister on the south side of Notre Dame, Paris, the windows designed by Viollet-le-Duc.

My intention that the church should be decorated with mural painting was generously seconded by my friend, Mr. E. Armitage (since made R.A.), who offered to make the designs and execute the work, free of expense, the scaffolding and materials being provided for him. But this project was but coldly received, and, indeed, by some, it was strongly objected to, as being "Puseyite," &c. Figures on glass are harmless, but on walls it was feared they might do mischief.

In conclusion, I beg to say that the loss of light in the church caused by the painted windows must have been foreseen, as the work was done at different stages during a long time.

It has been endured with complacency for the last twenty years, and, indeed, the rich and solemn effect has been much admired. But last year the present churchwardens, in their zeal for more light, have perpetrated the most flagrant act of vandalism by punching various holes in the clearstory roof to admit the light. I protested as strongly as I could against this, but in vain, as I could not controvert their strong position, that it was the cheapest way of doing the business. J. W. WILKINSON.

Soane Museum, May 26, 1886.

THE LATE MR. SANCTON WOOD.

SIR,—Will you permit me to supplement Mr. Robins's interesting account of Mr. Sancton Wood? [See p. 761, ante.]

We were contemporaries in the office of Mr. Sidney Smirke, where he made the sketches of the design for rebuilding the Houses of Parliament which Sir Robert Smirke had prepared by order of Sir Robert Peel's Government; but the House of Commons interfered and decided for an open competition, which stopped our work midway.

His design for the Eastern Counties Terminus was a very different thing from what was executed. John Braithwaite to some extent anticipated the development of traffic and proposed a double station, one for the Cambridge line, and another to Colchester, making a

much more imposing work, but financial difficulties supervened.

Subsequently the first premium of 100l. was awarded to Wood for the station at Ipswich, and he designed several of the stations on the Eastern Union Railway for Mr. Bruff, the Engineer. FREDERICK BARNES.
Ipswich, May 24.

CEMENT.

SIR,—Mr. Bancroft's letter in your issue of the 22nd inst., on tall chimney construction, gives a specification for cement which I think calls for a few remarks, inasmuch as though it was, no doubt, carefully considered when originally drafted, it hardly complies with the present requirements of a cement test.

Taking the items *seriatim* :—

1. Fineness.—Ten per cent. residuo on a No. 50 sieve is, I consider, all that can be demanded of the manufacturer at ordinary market prices, being the limit to which he can economically grind the cement. If a greater degree of fineness is required, an extra price should be paid for it, and it then becomes a question as to whether the cost of the extra grinding is more economical than using a larger proportion of cement.

2. The tensile strength demanded at seven days is a little high, 350 lb. on the square inch, or 700 lb. on the 2½ section, being generally considered enough. I may perhaps be permitted to say that the value of a cement cannot be determined by its tensile strength at only a single date, but that a three days' test should also be carried out, and the increase in strength between these two dates will more exactly determine the ultimate strength which may be expected from it, and this, if time permits, can be confirmed by a twenty-eight days' or even longer test.

3. The Vicat needle in no way determines as to when a cement is set; it is only an elaboration on the rough-and-ready practice of determining the set by the resistance of cement to the pressure of the thumb-nail. The best guide to determine when a cement is set is when a pat ganged with the minimum of water may be placed in water without cracking or alteration of form, but even this is not true in all cases, as some of the quick-setting cements may be put in water directly they are ganged without being in any way detrimentally affected. It is only experience in the use of cement and the testing of it that will enable a correct determination of the time which a cement takes to set being arrived at.

4. The amount of water required for ganging cement cannot be arbitrarily fixed at 9 oz. to 40 oz. of cement; nearly every sample of cement requires a different proportion of water in order that the best results may be obtained from it, some cements requiring as little as 15 per cent. of water, while others will take over 20 per cent. Before the briquettes for testing are gauged the exact amount of water required for the sample should be ascertained by making one or two small experimental pats.

HENRY FAJAJ, M. Inst. C.E.

THE CHURCH OF ST. BARTHOLOMEW-THE-GREAT.

SIR,—I had much pleasure in reading in the *Builder* of May 8th your interesting article on the glorious old church of St. Bartholomew-the-Great, Smithfield; allow me to add a few notes respecting its past history.

"In 1247 a strange scene took place in the choir. Archbishop Boniface, uncle to Eleanor the wife of Henry III., irritated at the want of deference on the part of the sub-prior, rushed upon him, slapped him in the face, tore his cope to fragments, trampled it under foot, and finally, being himself in full armour under his vestments, pressed him against a pillar so violently as almost to kill him. A general scrimmage ensued between the monks and the attendants of the archbishop, and as the inhabitants of Smithfield poured in to the assistance of the former, Boniface was forced to fly to Lambeth, followed by shouts that he was a ruffian and cruel, that he was unlearned and a stranger, and, moreover, that he had a wife!"—*Hare's "Walks in London."*

The destruction of the nave about the middle of the sixteenth century is alluded to, but it is not mentioned *how*. The Protector Somerset having conceived the design of erecting a sumptuous mansion in the Strand, caused the demolition of the magnificent cloisters of St. Paul's, the nave of St. Bartholomew's Priory Church in Smithfield (which had just been completed), five churches, and three bishops' palaces for materials. Somerset House was begun in 1549, John of Padua being the

builder, and was unfinished at the death of Somerset in 1552.

The Parish Register records the baptism of William Hogarth, Nov. 28th, 1697.

Besides the fine canopied tomb of Robertus there is in the south aisle a curious monument to Sir Walter Mildmay, founder of Emmanuel College, Cambridge. He was Under-Chancellor of the Exchequer in the reign of Elizabeth, and died in 1589.

There is a bust near Mildmay's monument of James Rivers (died 1641), which is probably the work of Hubert le Scur. OLD CLIFTONIAN.

MR. R. B. PRESTON ON ST. ANDREWS.

SIR,—My attention has been directed to the *Builder* of the 17th of April, containing a report of "part of a paper recently read before the Liverpool Architectural Society, by Mr. R. B. Preston." As that production is exceedingly inaccurate and misleading, I trust you will allow me to comment on it briefly.

One would have expected that in a paper read before such a society, care would have been taken, at least with the measurements, yet hardly one of those given by Mr. Preston is correct. In speaking of the cathedral, he says,—"The total length inside the walls is 370 ft.; width across transepts, 180 ft.; across nave and aisles, 65 ft." These figures should respectively have been 355 ft., 166 ft., and 61 ft. 6 in. The castle, he says, is at the top of a cliff 80 ft. high; the well in the courtyard is 50 ft. deep, and contains 14 ft. of water. In point of fact, the cliff is about 40 ft. high; the well is barely 33 ft. in depth from the top of the parapet, and it only contains 2 ft. of water. Mr. Preston is surprised that the water is not salt, considering that the well is within a few yards of the sea. But he need not wonder at that, as the bottom is above the level of the sea, though not nearly so much as his measurements imply. Recently, this well was perfectly empty, and various theories were propounded to account for it; but now it may be readily inferred that this traveller's surprise at finding "good fresh water" here was so great that he drank it dry! Some of the towers of the wall enclosing the Priory, he says, "were square, others round or octagonal." Nearly all this wall has been preserved, but the only trace of an octagonal tower which is to be found is in his sketch. Of the cathedral, he says,—"The upper triplet in the east gable was replaced by a large three-light window," whereas the large window was made to serve for two triplets or six smaller windows. He speaks of the east end of St. Leonard's Chapel as the nave; he mistakes the sea-tower at the north-west corner of the castle for the keep, which was at the south-west corner; and he confounds the chapel of the Black Friars Monastery with the chapter-house of the Grey Friars! These are only specimens of the extraordinary mistakes which disgrace his paper, and when such errors are made on points which any one can verify or disprove for himself, the reader may expect to find blunders still worse and more numerous, in what purports to be the *historical* sketch.

His greatest ignorance is revealed when he refers to the results of what he is pleased to term, "the fury of the fanatics under John Knox," and to "the ruthless hands of John Knox and his herd of fanatics." He is reckless enough to aver that, "In St. Andrews alone, besides the cathedral and Augustinian monastery before mentioned, they demolished two churches, the monasteries of the Black and Grey Friars, and three colleges!" This is simply astounding, and is quite enough to take away the breath of any one who has ever been in St. Andrews. The Reformation here was carried out by the magistrates of the City, and such conduct on their part would have been much worse than insane. But the charge is thoroughly false. There is no evidence whatever to show that the cathedral was demolished at the Reformation; while, on the other hand, the proofs are plain and abundant that it fell in more recent times through its own inherent weaknesses and the want of repairs. The churches were certainly stripped of everything that savoured, or seemed to savour, of idolatry at the Reformation; but, with the exception of the Black and Grey Friars, the monasteries, the buildings were otherwise uninjured. Mr. Preston fearlessly goes into details regarding the colleges. Of St. Leonard's he says,—"The college buildings have vanished entirely!" Why, sir, they are almost entire at the present moment. St. Mary's College, he says, "has been almost entirely rebuilt." But any one who cares to glance at the old quadrangle will at once see that the statement is more baseless than a dream. The other college,—St. Salvador's,—was pulled down, but not until Knox had been two centuries and a half in his grave.

I could easily point out a great many more blunders in Mr. Preston's paper, but that would occupy too much of your space to glance at. I need only say to show how utterly untrustworthy his communication is. In the words of Carlyle, "Knox wanted no pulling down of stone edifices; he wanted leprosy and darkness to be thrown out of the lives of men." D. HAY FLEMING.

St. Andrews, May 26, 1886.

SCOTCH NEWS.

Aberdeen.—With the increase of the city the authorities of Aberdeen have found the existing Corporation stables, in West North street,—which are, with the exception of a small addition built six years ago, very old, and of defective construction,—becoming daily more inconveniently situated, and altogether too small to enable them to cope with the city manure traffic and other carting requirements of the street cleansing and other public departments. This defect is now to be remedied, the Town Council having lately accepted estimates amounting to 5,235l. for the erection of new police stables, according to designs prepared by Messrs. W. & J. Smith architects. The new buildings will occupy a rectangular site, about an acre in extent, on the Harbour Reclaimed Ground, recently acquired by way of feu, the annual feu-duty being at the rate of 6d. per square yard. The site lies on the north side of Poynercock-road, along which it extends 300 ft. The stabling occupies the eastmost half of the site, and will give accommodation for a stud of about fifty horses. It is grouped round a central building, which contains on the ground-floor, carpenter's and painter's shops, smithy, boiler and engine house, four large stores, mash-room, and prepared food stores, having a large hay loft and corn store above. There are seven stables, three of them seven stalls each and the others three, four, six, and thirteen stalls respectively. The front of the buildings to Poynercock-road is to be of regularly-coursed and square-sneaked ashlar work of hammer-blocked granite, and the other buildings will be of half-ware rubble bevelled in courses so as to point in straight lines. The width of each stable is 19 ft., and the height 12 ft., and all will be well lighted by large windows. There being no loft over the stables a large straw store is provided in connexion with each. There will be two good loose boxes, and an infirmary containing one stall and a loose box. Fresh air will be admitted to the stables through the head-posts of the traverses, which communicate by a horizontal duct placed under the mangers, with inlets in the external walls. The vitiated air will be carried off through openings in the ceilings connected with Buchan's enrouventilator fitted up on ridge of roofs. Water and gas are to be laid on to each stable, and drinking-troughs provided in the stable-yards. These yards will be causewayed with 4 in. by 6 in. granite setts, with the exception of a gravelled space in the centre of the largest stable-yard, on which lame horses may be exercised. The western half of the ground will be occupied by cart-sheds, the roofs of which are to be covered with galvanised corrugated iron, and supported on cast-iron pillars. A hall for congregational business, &c., meetings in connexion with Oldmachar Cathedral is to be erected in Dunbar-street, Old Aberdeen, at a cost of 950l. The north (gable) elevation towards Dunbar-street is in the Early Gothic style. The hall measures 37 ft. by 62 ft., and will be seated for 400 persons. There will also be two committee-rooms behind the hall. The architects are Messrs. Ellis & Wilson Aberdeen.—The trustees of Holburn Parish Church have ordered from Messrs. Harrison & Harrison, Durham, an organ for the church. The instrument will cost 420l., and will, it is expected, be ready for use in the beginning of August next.

Paisley.—New buildings for the use of the Paisley Liberal Club are approaching completion. The buildings occupy a double site on the east side of Churchhill, forming No. 90, High street. The ground-floor is occupied as shops. The upper floors will be occupied entirely by the club. The principal entrance of the club is from High-street, to which it has an imposing frontage three stories in height. The buildings have been erected from the designs of Mr. James Donald, architect, Paisley, and will cost 11,000l., including price of site, which is 3,000l.

The Superintending Architect, Metropolitan Board of Works.—At the meeting of the Metropolitan Board of Works to be held this Friday, the 28th, the Works and General Purposes Committee will submit a report recommending that a retiring allowance of 1,020l. 10s. 8d. per annum be granted to Mr. William Superintending Architect, from the date at which his resignation takes effect, namely, the 29th of September next.

CHURCH-BUILDING NEWS.

Beeches.—The fine old parish church of Beeches, Suffolk, has just received an embellishment at its east end, which it much needed, in the shape of a handsome reredos. Owing to the height up to the sill of the east window from the floor-line being unusually great, i.e., 10 ft. 6 in., the height of the reredos has not been cramped. The central portion is loftier and more decoratively treated, containing a floriated Latin cross on Calvary steps, above which are seven ornamental panels, with various emblematic carvings suitable to the position. The wings of the reredos have richly-cusped panels. All the cornices contained carving, that in the centre being crested. As the interior of the church has little variety of colour, it would have been out of place to have introduced diversified tints in the reredos, and it has only been attempted to give a little warmth of colour by using Corsehill stone, except to the lower parts of the wings, which are of Forest of Dean stone for contrast. The architect is Mr. B. Edmund Ferrey, F.S.A.; and the work has been executed and fixed by Messrs. White & Sons, of Vauxhall Bridge-road. In style the design is in harmony with that of the church, which is principally fifteenth-century work.

Hebburn-upon-Tyne.—The extensive works connected with the new church of St. John the Evangelist have just been commenced from designs prepared by Mr. Fred. R. Wilson, of Lincoln, Diocesan Surveyor for the Archdeaconry of Lindisfarne. Mr. M. Temple Wilson is the resident architect, and Mr. John Munroe, of Hebburn, is the contractor.

Ipswich.—On the 6th inst. the memorial stone to commemorate the commencement of the restoration of the tower of St. Nicholas Church, Ipswich, was laid by Lord Eichen M.P. For some time past the condition of the structure has given rise to serious apprehensions. A committee having been empowered by the parishioners to undertake the restoration, Mr. E. F. Bishopp, architect and diocesan surveyor, was consulted. A careful external examination of the tower was made, and it was at first believed that it merely required refacing. As soon, however, as the work was commenced, it was found absolutely necessary to pull down the walls from the parapet to the level of the heavy floor, and the contract, which was let to Mr. Geo. Nevard, of Nayland, had to be increased from 450l. to 525l. Designs for the restoration were prepared by Mr. Bishopp, and the work is being carried out under his personal superintendence. The bases as the angle pinnacles, which fortunately remained, with the band of flint panelling below, gave the design for the new parapet. This is really the only new piece of design in the tower, and may be described as being of ashlar and narrow flint panels divided by cusped-headed mullions, and attaining a height of 6 ft. The coping is double sunk, stepped, and battlemented. Niches, with groined and crocketed canopies, are placed centrally in each face, the figures rising from a pedestal with cherubim below. The saints represented are St. Nicholas and St. Michael on the west and east, with St. Peter and St. Paul on the north and south, each group with its characteristic emblem. The pinnacles are crocketed and terminated with copper flags, carried by delicate wrought-iron work. The water escapes through a gargoyle in the east side. The old flag-staff and vane are to be refixed, and the roof is to be entirely renewed in substantial oak timbers covered with lead boarding and lead. The works also include an entirely new face to the tower in knapped iron, tied to the body of the walls by long bands, and replacing the former decayed and dilapidated facings. The masonry, with the exception of the arch to the west door, is to be entirely new, the stone specified being Aubigny and weathered Ancaster. The west window is to be replaced in antique glass, with new slate surrounds to the heavy windows.

Llanddewi Brefi (Cardiganshire).—The dilapidated chancel of this church has been restored and reopened by the Bishop of St. David's, new windows, roof, and floor being added; a new pendente was 500l. The works and a continuation of the restoration commenced in 1873, when the tower and nave were completed. The pinnacles are still demolished and will be the next work to be undertaken. Messrs. J. & D. Evans have carried out the whole work; Mr. Withers being the architect.

Tottington (Norfolk).—Tottington Church was

re-opened on the 4th inst., after restoration. Although of small proportion in comparison with many Norfolk churches, it is one of the most beautiful in its varied detail. Scarcely two windows are of the same design, and the carving on the bench-ends and poppy-heads are all of different tracery, while few screens can be said to equal that dividing the nave from the chancel, which contains some of the most unusual crocketing and carving of natural foliage in the spandrels. The necessity of preserving so much artistic work of the Mediaeval age induced Lord Walsingham to have the work of restoration taken in hand at once, and in May of last year the roof of the nave, which was in a deplorable condition, was taken down, and a new roof of pitch-pine erected upon the lines of the thirteenth-century roof, and covered with corrugated glazed tiles, made upon the Merton estate. The clearstory walls were rebuilt from the nave arcade, and on each side three-light windows, filled with cathedral glass, were inserted. The south porch has been partially restored, and the north and south walls are new. In the taking down of the clearstory windows a richly-carved shield was found in a state of good preservation. The carvings are a series of fleurons-de-lys upon the field, and all round the sides and top, and represent the armorial bearings of a member of the Mortimer family. This shield has been attached to the south aisle wall by wrought-iron brackets. Much still remains to be done to the roof of the south aisle, the porch, and the tower, but want of funds delays further restoration. The works have been executed by Messrs. Cornish & Gaymer, of North Walsham, from plans prepared by, and under the superintendence of, Mr. E. Preston Willins, architect and diocesan surveyor, Norwich.

Warwick.—The external restorations to St. Mary's Church, Warwick, have now been completed, and a new reredos has been erected. The central portion consists of an arcade in three divisions, filled with sculptured subjects in white alabaster, the Nativity being the central group, with the Adoration of the Shepherds and Kings on either side. The framework is of coloured alabaster, enclosed by buttresses and cornice of Derbyshire bird's-eye marble; beyond this, on each side, in continuation of the reredos, is a triple arcading, also of polished alabaster and marble. The work has been executed by Messrs. Thos. Barp, Son, & Hobbs, of London and Manchester, from the design of Mr. W. Butterfield, architect, London.

Wembury.—The restoration of Wembury Church, at the cost of Mr. Cory, of Langdon Court, is progressing so favourably that Tuesday, June 8th, has already been fixed as the re-opening day. Wembury Church is a storm-beaten fifteenth-century edifice standing upon a frowning rock at the mouth of the River Yealm, only a few yards from the seashore. The long-needed work of renovation has taken place from the designs and under the superintendence of Messrs. Hino & Odgers, of Plymouth, and has been carried out, in the workmen, under the foremanship of Mr. W. J. Sherwell. The new massive oak roofs are richly carved on wall plates and on ribs and purlins, whilst all the intersections are stopped by carved bosses. This work is by Mr. Harry Hems, of Exeter. Mr. Hems is also making three carved oak screens. These screens will form a chapel in the south chancel aisle in which will stand the organ. All the oak seating in the body of the church is elaborately carved by Mr. Hems, who is also making the sculptured reredos. The font will be in red Corsehill stone. The pulpit will be octagonal and in oak, upon a granite and polished marble base. Both font and pulpit are Mr. Hems's work.

Canada.—A large block of buildings has just been erected for the Salvation Army in Toronto, Canada, at a cost of 8,000l. It comprises a large hall, and offices, shops, &c., to be used as headquarters. There is also a large basement extending over the entire area, which is to be used for printing and publishing purposes. The roof over the hall has a span of 96 ft., and is supported on walls 4 ft. thick. This is the widest span without intermediate columns of any roof to any public building in Canada. The work has been carried out under the direction of Mr. Herbert Paul, architect, of Toronto, from plans prepared by Mr. E. J. Sherwood, architect, of London.

The Student's Column.

OUR BUILDING STONES.—XII.
THE SELECTION OF STONE.

STONE used in building may be selected by two different methods,—theoretically and practically. Hitherto these methods have to a large extent been applied to the subject, independently of each other, and the result is that each has been regarded as fallacious by the advocates of the other; for the man who works on the theoretical side, in his anxiety to point out the various agencies which may affect the durability of stones, often fails to recognise the fact that facility of working, and other matters of a pecuniary nature, are quite as important to the practical man. On the other hand, the practical man being guided by appearances only, and frequently knowing but very little of the structure and causes of decay of stones, leaves the question of durability to chance. He is sometimes backed up by the knowledge that some of the works apparently produced by the theoretical man have come to the ground. During the course of this inquiry, for instance, we have been met by men who have pointed out the failure in the selection of stones for the construction of the Houses of Parliament, as an example of the fallacy of the theoretical method of selection. They tell us that, after spending a considerable sum of money on a Royal Commission of inquiry into the subject, the stone selected by that Commission was of no use.

As a matter of fact, although the foundations were well looked after, the greater part of the stone of the Houses of Parliament was not selected at all. Professor Kerr, speaking at Carpenters' Hall not long since, said that "Mr. O. H. Smith, a well-known mason of Titchfield-street, was one of the Commissioners and was appointed to examine the stone as it arrived, but, by reason of some difficulty in the matter of his remuneration, he naturally declined to serve. The consequence was that the stones came in without being checked, and the result was that those which were non-crystalline were the stones which had decayed."*

It is noteworthy that wherever competent persons have had charge of the selection of building stones, the latter have almost invariably resisted decay, even in the metropolis. Take the Museum of Practical Geology, for example. The stone used in the front of that building is a magnesian limestone, the same as that used in the Houses of Parliament. It is evident that, as the stone in the former building is even now in a good state of preservation, the selection of stone on a scientific basis is not a matter of mere chance. We will go so far as to express our belief that it would pay to secure the services of a competent man, that is, one who has both theoretical and practical knowledge, for the purpose of selecting stones at the quarry, in all cases where the magnitude of the work allows a sufficient margin of profit for the purpose.

The following are general rules which may be observed in selecting:—

The first thing we would urge as a test of durability is to ascertain the amount of water the stones under consideration absorb. This practically costs nothing, as we have explained, p. 491.

All rocks contain "quarry" water, and, as a rule, they are then most easily worked with the chisel. They are then softer than when on exposure to the atmosphere, that water is, to a certain extent, evaporated, and the rock thus rendered harder. Where a very compact variety is being dealt with, there is not much fear of a great amount of absorption.

The architect or builder, however, has very often to deal with rocks whose qualities are not so superior in point of durability; for he has frequently to be guided by facility of dressing and working, cost of carriage, and various other items of a pecuniary nature. In the desire to do justice to his work, and in the absence of such of the most durable kinds of stone from his locality, he is obliged to select those which present only fair qualities. To fulfil this he cannot be too particular in choosing those the least absorbent of water.

It is highly desirable in selecting stones that visits should be paid as often as possible to the different quarries whence they come. The

* The Builder, ante, p. 491.

manner in which they respectively weather may then be easily ascertained, and the exact horizons of the desired qualities fixed.

Much useful information may be gained by observing the condition of the stones in the various cottages and other buildings in the vicinity of each quarry. It is a remarkable fact that in country villages the local stone built into the labourer's cottage in many instances lasts longer than that in the stately mansion of his employer. It may be that this has resulted from the following circumstances. In the quarry, the material selected for the mansion (which probably required external decoration) has been a freestone, capable of being dressed with facility and of pleasing tint; while the cottage was made of refuse,—odd, hard pieces,—which would not tool well. It often happens that this refuse is, after all, more durable than the freestone, and could with but little extra trouble be utilised for the more exposed parts of the mansion.

Information as to the durability of certain stones may be obtained by observing their condition in old buildings, whether in town or country.

Mere hardness or softness forms no sure index to the comparative power of a rock to resist weathering. A tolerably pure limestone may weather with little or no crust, and yet may be continually losing an appreciable portion of its surface by solution, whilst some igneous rocks may have a thick decomposed crust and yet weather with extreme slowness. In the former case, the substance of the rock being removed in solution, few or no insoluble portions are left to mark the progress of decay, whilst in the igneous rock the removal of but a comparatively small proportion causes the disintegration of the rock, and the remaining soluble parts are found as a crumbling crust.*

Stones are often required to be of certain colours, and are selected accordingly. Now, we have no objection to this, providing that they are of good quality, and the tints are likely to be permanent. Stone can be found which will answer these conditions as far as buildings in the country are concerned, but it is an exceedingly difficult matter to find such for buildings in the metropolis. The colouring of stone in many cases is due to chemicals which the London air soon finds out, and tries its very best to remove. The result is, that in a short time the stones change colour. Besides, the London air soon disfigures the stone by covering it with dirt.

In selecting a stone for its colour, care should be taken to look inside the larger blocks when broken, as the outside colour is so often only superficial, and such blocks should have been exposed to the weather for some time.

In selecting *granites*, the principal things to attend to are the condition of the felspar, the nature of the blotches that so frequently occur, and the easily decomposable accessory and secondary minerals, especially iron oxides. Granites which contain an excess of lime, iron, or soda, are the most liable to decay. Compact medium-grained varieties are generally good stones.

Those containing large crystals of mica are unfit for architectural purposes, and the same may be said of varieties in which soda-felspar and very deep red (iron) felspar predominate.†

Granite is very susceptible of injury by fire, much more so than compact sandstone with a siliceous matrix. This latter is, no doubt, the best natural stone for withstanding fire. Formerly it was exceedingly hard to work with the chisel, and although this difficulty has been much lessened, yet the tendency of siliceous sandstones to have a splintery fracture will always be a great drawback to their general use.

In selecting *sandstones* for building purposes, it is of the first importance to observe what the cementing material is made of, for on it the weathering and facility of working almost entirely depend. Those with a calcareous or ferruginous matrix should be regarded with suspicion. When these are carefully selected, however, they might do well enough for local purposes. Medium and fine grained sandstones, having a siliceo-felspathic matrix, are usually very durable, and not difficult to work.

If the sandstones under selection contain small flint pebbles here and there, as they frequently do, the purpose for which the material is required should be considered. Any mould-

ing for an ornamental structure cannot, of course, be made from such a stone; but if the work is to be plain in character, there is no reason why a rock of this description should not be selected, providing it fulfils the other requirements as to durability, &c.

Sandstones presenting a mottled appearance are almost always of doubtful quality, and so are those having vents, shakes, and spots. This more or less applies also to limestones.

So much care is necessary in selecting *limestones*, that it is difficult to lay down any rules which will apply to the whole. Consequently, the relative remarks previously made during the progress of these articles must be strictly observed. If these rocks are carefully selected they are unquestionably the most durable and most easily worked of all the stones used in building. We have pointed out the principal causes of their decay, and nothing short of a close examination of the structure of each kind is of any practical value. Good limestones are generally rather crystalline in character.

Books.

Domesday Book in Relation to the County of Sussex. Edited for the Sussex Archaeological Society. Lewes: H. Wolff. 1886.

AS feudal tenures disappear the interest in them, from an antiquarian point of view, increases. That wonderful record of the great survey of England made by King William the Conqueror and known as Domesday Book is just 800 years old, and its value has not been impaired by age. In fact, it is only in comparatively modern times that any serious attempt has been made to investigate thoroughly the contents of the record, and to place it within reach of the ordinary student of history.

The Sussex Archaeological Society, which has long held a foremost place among the numerous bodies devoted to the study of English antiquities, has issued to its members a noble volume containing a *fac-simile* of that portion of the survey which relates to the county of Sussex. To this has been added, chiefly through the zeal and industry of the Rev. Chancery Parish and Mr. R. G. Raper, of Chichester, a valuable appendix, containing not merely a translation of the record, but also lists of the tenants, suggestions for identifying the place-names, and a glossary. The *fac-simile* has been executed by H.M. Ordnance Department in photo-zincography, and, were it not for the numerous contractions, might be easily read by any one possessed of a small knowledge of Mediaeval Latin.

As a specimen of the mode in which the Conqueror's officials did their work as surveyors, as well as of the nature of this most interesting record, we give some of the particulars relating to Brighton:—

"Radulfus tenet de Willelmo Bristelmestune, comitis Brietric/ tennit de dono Godwini. T.R.E. et modo se defendebat pro v hidis et dimidia. Terra est iii carucum. In domino est dimidia caruca et xviii villani/ et ix hordarii cum iii carucis et uno seruo. De gablo iiii millia allecium./ T.R.E. valebat viii libras et xii solidos et post C solidos. Modo xii libras."

This is rendered in the following way:—"Ralph holds Bristelmestune of William. Brietric held it by gift of Earl Godwin. In the time of King Edward [i.e. the Confessor] and now it vouched [or was taxed] for 5 hides and a half. There is land for 3 ploughs. In demesne is half a plough and 18 villeins and 9 bordars with 3 ploughs and one serf. Of rent four thousand of herrings. In the time of King Edward it was worth 8*l.* and 12 shillings and afterwards 100 shillings. Now worth 12*l.*"

The change of name from Bristelmestune to Brighton is infinitely less than that of the obscure fisher-village to the most popular watering-place, and the entry clearly disproves the current notion that Brighton derived its appellation from the amount of sunshine it enjoys. What we learn from Domesday is that at the Conquest the lordship of the manor, which had belonged to the great Earl Godwin, and, doubtless, devolved to his son Harold, was bestowed by the Norman invader upon his son-in-law William de Warrenne, who retained a small part of it, namely, one-sixth, in his own hands. This was cultivated in his behalf by eighteen villeins or labourers, attached to the

manor and enjoying some restricted privileges; by nine cottagers, who were in a somewhat better position; and by one serf, who was as much the property of the lord, for life or death, as any beast that grazed the pastures of the manor. No mention is made of any mansion or church. The ecclesiastical duties were probably performed by priests from the far more important town of Lewes, where William de Warrenne built his castle and founded the great Priory of St. Pancras. The rent paid by Brighton to its lord was in the shape of 4,000 herrings, which would find their way to the Baron's larder at Lewes and help to feed his numerous retainers.

Here and there in the record distinct reference is made to a church as attached to a manor, and, as might be expected, we find this to be the case in the account given of Bosham, which, insignificant as it now is, has an early history of no ordinary interest. The church is depicted in the Bayeux tapestry, where Harold and his knights seem to be entering it with a view to imploring divine protection for their voyage across the Channel. Every student of architecture has some knowledge of Bosham Church and its claims to be regarded as embodying the Roman basilica which stood upon its site. Sompting, again, is another place which is mentioned in Domesday as possessing a church, and there can be no doubt that the tower of the existing edifice and some other parts date from pre-Norman times. Under Hovingedene (Ovingdeane) we find mention made of "a little church,—*ecclesiola*,—which Mr. Gordon Hills has described as "an almost perfect Saxon church," and such may have been true also of Falmer, where the same term is used in Domesday, but unfortunately the ruthless hand of the restorer has destroyed every ancient feature in it.

The indications of secular buildings in the record are less frequent and distinct. In general terms we are told that in the Rape of Pevensey William de Warrenne had twelve mansions, seven inhabited and five not; but as the object of the survey was to discover any register sources of revenue, castles and halls were of less importance than mills and salteries and smithies. Sir Henry Ellis estimated the population of Sussex, from the Domesday returns, to be 19,411, of whom only fifteen were tenants-in-chief. Whether the latter have since the present day any lineal representatives we need not discuss, but it is interesting to notice that 800 years have not destroyed some of the Sussex families of lower rank. "The Camo are still to be found near Claverham, and the name of Elphick is still associated with Seveston, where it is clearly pronounced, as written in Domesday, Alfec." The publication of the Great Survey is one which other societies may well take in hand, and the success achieved by the Sussex archaeologists will, we hope, encourage them so to do.

Registration of Titles. Prize Essay by R. L. MORRIS, Barrister-at-Law. London: Printed and Published for the Building Societies Association by Shaw & Sons. 1886.

A LARGE part of this pamphlet is occupied with an historical *résumé* of the questions touching, for example, on the Act of Elizabeth which required sales of land in Lancashire, Cheshire, or the bishopric of Durham to be enrolled, and ending with the Yorkshire Registration Act, 1884. This is a useful little sketch of the present time. More about it need not be said. In the latter part of the pamphlet it is to the system proposed, Mr. Morris advocates registration of titles. He meets the case of settlements of land by making the trustees registered owners. If ever titles do become generally registered in this country, it is clear that the plan will have to be adopted; that, to say, so long as settlements of land are permitted by the law. Whether land should be the subject of settlements is too large a question for discussion in this place. On the whole, this is a clear little publication, and may do something towards the elucidation of a subject which the ordinary reader is apt to avoid.

Compensation for Personal Injuries on Rail Road, and River. By J. T. WESLEY BENNETT, F.R.S.L., F.C.A. London: The Commercial Gazette Office. 1886.

This little hook consists of two parts: advice of those who desire to be compensated for injuries received, and reports of cases tried in the Law

* See Geikie's "Text Book of Geology," pp. 334-5.

† See Page's "Economic Geology," p. 60.

Courts. As in nearly every "accident case" circumstances differ, this collection is of next to no value. As to the advice, a good deal of this is sound enough, in fact, it is so sound as to consist of truisms. The injured man is to be "ready to assent to any fair and reasonable compensation"; when injured he is to call in his usual medical attendant; he is to be careful not to exaggerate his claim; and so forth. All this is very true, but it is what any sensible man, he layman, lawyer, or doctor, would know himself without being told.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

2,590, Door Spring Holder. R. W. Roberts. This relates to a spring-holder for keeping open doors, to be used in place of cabin-hooks for holding doors open. A hollowed plate with a rim and groove is fitted with a spring, whereby a projection is elevated so as to keep the door open, and when the door is required to be shut, the pressure of the foot on a knob releases the catch.

15,856, Slate or Glass Roofing. J. S. & W. Thompson.

The slate, glass, or other material is made in the form of a flat, shallow, trough, and its sides rest on two adjacent rafters, made lighter than usual as they have to carry weight. A covering piece is fitted on the edges of the troughs to cover the interstices. The troughs or tiles are preferably made with cement edges. The cement of one edge almost abuts on that of the other, but not quite, the cement adhering to the slate but not to the rafter. A fresh row of cement is added after the tiles are in place.

7,748, Imitations of Woods and Marbles. T. S. Worthington.

The grain of woods or veins and colour of marbles transferred from a pattern previously prepared as transfer paper, that is, paper coated with a solution of starch and glue, on which the design is printed or painted. For preparing these transfers the process of zincography is used, and a large number of patterns printed off. In the case of oak a transfer is taken from the natural wood and laid down on some or zinc. The paper is moistened and applied to the surface to be grained, and after being left a short time the paper is stripped off, leaving the film in the previously-prepared ground. The film is allowed to dry naturally, and is then varnished.

8,254, Weatherboards, &c. W. B. Shorland. Where the weatherboard consists of a slip of wood sustained in its place by a central spiral spring and two short levers, an improvement is effected by attaching a short rod of metal to one of the levers, the fulcrum, the other end of which rod is suitably formed, and adjusted to press upon the window or door-check or jamb. The door is closed with much less friction than where weatherboards are actuated by levers alone and the fulcrum.

Miscellanea.

Waters of the Bagshot Beds.—A paper was read at the rooms of the Society of Medical Officers of Health, Cranecourt, E.C., on the 21st inst., by Mr. W. Essie, C.E., F.G.S., upon the quality of the waters which are derived from the three main beds of the Bagshot geological series. Whilst admitting that many of the waters were sound in character, the lecturer said there were, nevertheless, various beds of a greenish tint, which interfered with the secretion of pure water, and heinced examples where illness had followed cases in which no filtering provision had been made. The lecturer considered that the acids contained in many of the waters derived from the Bagshot beds ought to be eliminated previously to making use of them as drinking supplies, and he showed that by the use of a peculiar method of filtration the whole of the acids due to decomposed vegetable matter in solution, and always present in peaty waters, could be speedily removed, and that the water yield from the Bagshot beds could be redeemed, as regards their purity, and made equal to any water derived from the purest primitive rocks. He urged the necessity for every one residing upon these tertiary beds to filter the water of their wells, and so assist in rendering the families resident on these strata in the most healthy condition in respect of their water supply.

Depreciation in the Value of Landed Property in Sussex.—A sale which took place at the Auction Mart on Friday, the 21st instant, served to show the decrease which has taken place during the last few years in the value of estates and building land in some parts of Sussex. Messrs. Baker & Sons submitted for sale the freehold property near Horsham known as the Strood Park Estate, comprising the mansion with pleasure grounds, and several farms, the whole of the estate containing an area of about 1,000 acres. The mansion and several farms, containing altogether 829 acres, were first offered, the auctioneer observing that in his judgment the property, at the very least, was worth from 30,000l. to 40,000l., but the highest offer was 23,500l., being less than 30l. an acre, at which it was withdrawn. As evidence of the decreased value of the property, it was stated in the room that not more than six years ago the estate would have realised almost double the sum now offered. A portion of the estate, adapted for building purposes, containing nearly 122 acres, was next submitted, and was sold for 1,800l., being at the rate of a little less than 15l. an acre.

Strong Spring Hinges.—We have received from Messrs. S. Gerish & Co., of Butland-street, Hoxton, a specimen spring hinge made by them under their patent, which embodies an improvement of great practical value. This improvement consists in making the hinge with a screwed rod at the end of the chain, on to which a cylindrical nut with a head pressing against the spring, is twined on to the screwed rod. In this way the strength of the spring hinge can be readily adjusted to any strength required, simply by screwing up or unscrewing the nut. Another advantage consists in the fact that should a new spring be required at any time, the carpenter, after taking the hinge off the door, has only to unscrew the cylindrical nut, remove the old spring, and replace it with a new one. And further, in fitting these hinges to the door the spring can be removed from the hinge, there being no occasion to set the hinge open for fixing, thus avoiding liability to accident.

Concrete Mixing Machines.—We have this week had the opportunity of inspecting, at the works of Messrs. George Waller & Co., Holand-street, Southwark, two "continuous action concrete mixers," one for steam power, and the other for hand power. The larger one has a cylinder 6 ft. long, and is capable of delivering from 100 to 150 cubic yards per day. The smaller one is well adapted for mixing materials for concrete paving, floors, &c., and is fitted with handles and wheels, so that it can be wheeled like a barrow. The cylinders are provided with four deep grooves or channels, into and out of which the materials are continually falling during the rotation of the cylinder, thus ensuring effective mixing. Similar machines, made by the same firm, have been employed with much success on municipal works at Tunbridge Wells, Nottingham, Great Yarmouth, and elsewhere.

The Artists' Benevolent Fund.—The seventy-seventh anniversary dinner of this Fund will take place at Freemasons' Hall, on Friday next, June 4th, the Right Hon. Lord Coleridge in the chair. Since the institution of the society, the sum of £49,175 has been distributed in relieving widows and orphans of artists, whose circumstances rendered such assistance necessary. The committee will be glad to receive donations and subscriptions.

Civil and Mechanical Engineers' Society.—The annual dinner of this society was held at the Holborn Restaurant on the 19th inst. The President, Mr. H. Michell Whitley, occupied the chair, and a large number of members and visitors were present. The usual loyal toasts having been duly honoured, Mr. W. Worby Beaumont proposed "Success to the Civil and Mechanical Engineers' Society," coupled with the health of the President. The President responded, and in the course of his remarks congratulated the members on the close of a successful session, and referred to the importance of the opportunities given by the society for young students being brought into friendly intercourse with members of the profession, who are busily engaged in works of construction, who would give them advice and assistance. Several other toasts followed.

The Sportsman's Exhibition, opened on Monday last at the Royal Aquarium, Westminster, contains a few exhibits of special interest to architects and builders. First of all, we must notice the excellent stable-fittings, comprising two stalls and two loose boxes, exhibited by Messrs. Steven Bros. & Co. The castings are very clean and true. A portion of the bottom sill of partitions is removable with ease in case it is found necessary to insert a new board. The gruel-pot is made with tip-up action instead of plug-fashion. Some good bolts and latches for stables, a variety of harness-room fittings, and a very good adjustable hopper ventilator for stables, are also shown at this stand. Wilkes's Patent Metallic Flooring Company exhibit a stall showing the application of their material to the purpose of stable paving. Messrs. Wrench & Son exhibit poultry-houses and garden furniture; Dr. Jaeger's Sanitary Clothing Company exhibit their all-wool garments for sportsmen and for "all sorts and conditions of men"; and at one of the stands the "Chamberland-Paster" filter is shown. Needless to say that all kinds of requisites for boating, fishing, shooting, hunting, riding, driving, bicycling, and for cricket, lawn-tennis, and other games, are shown in profusion. Some good billiard-tables are shown by Messrs. Burroughes & Watts, and by Messrs. Thurston & Co. The first-named firm exhibit a very simple though ingenious "rest," available for use in any position required, while the last-named firm show their electric marking-board, for billiard-rooms, and the "Cavendish" whist-table, which should be looked at. The Exhibition will remain open until June 5.

The Banner Sanitation Company.—As we announced some time ago, the well-known business of Messrs. Banner Bros. & Co., sanitary engineers, will be carried on in future under this title, and it has been removed from Billiter-square to Wessex House, Northumberland Avenue, where, in a well-lighted and conveniently-arranged show-room, is to be seen a good collection of their own appliances, together with a typical selection of the best sanitary fittings by various manufacturers. One of the novelties exhibited is the "Hygeia" ventilator, which claims to be an improvement upon the water-spray ventilator, inasmuch as the nozzle or spray-diffuser is self-cleaning, and is easily unshipped for examination. Some instructive specimens of bad plumbing work,—done on wrong principles, or rather on no principles at all,—are shown as "frightful examples" of "how not to do it." An automatic slop-sink, which is self-flushing, will meet a want which is felt where servants are too careless or too lazy to flush the sink after use. Banner's airtight manhole cover is now made with its top surface filled in with small blocks of hard wood, under Hawksley's patent, thus ensuring a good foothold. Banner's hollow kerb, for enclosing electric lighting, telegraph, and telephone wires, is another speciality which we should like to see largely used. These, with Messrs. Banner's well-known revolving cowls and fixed final ventilators, and many other sanitary fittings and appliances, go to make up an instructive little exhibition.

The District Surveyorship of Chelsea.—At the meeting of the Metropolitan Board of Works on the 21st inst., Mr. Ewin, Chairman of the Building Act Committee, brought up and moved the adoption of a report with reference to the vacancy in the office of District Surveyor for Chelsea, caused by the death of Mr. Sancton Wood, and recommending that the district be divided into two portions, to be designated North Chelsea and South Chelsea respectively; that the former district do consist of that portion of the parish to the northward of a line drawn along the centre of King's-road and Sloane-square, and the latter of that portion of the parish to the southward of such line; that the usual course be taken for filling the vacancies in the offices of District Surveyor for such districts, and that the Board do proceed to the election on Friday, June 4.—Mr. Mossop moved, as an amendment, that the motion be referred back to the committee, to be thought that Chelsea should have the benefit of a man of thoroughly practical experience in similar duties who had been under the Board in other districts. He thought that there were officers under the Board who ought to be promoted. He did not think that a fair division had been made in the district, one having a large ground for new buildings, and the other very little. After considerable discussion, the amendment was put and lost by twenty-five to twenty. The recommendation of the committee was then agreed to.

The Medical Profession and the Church of St. Bartholomew-the-Great.—Those who have received their education at the great School of St. Bartholomew will probably be familiar with this ancient and interesting edifice, founded by Rahere (who was also founder of the hospital in the year 1123, and which has endured nobly until now. The *Builder* of May 5th contains an excellent description of the church, and the proposed restoration of this magnificent relic of the architecture of the period; and a letter which appeared in the same journal on May 15th shows very cogently that the project has a singular claim upon the sympathy of the medical profession. The lawyers of the Temple possess their fine memorial church of the past; Lincoln's Inn is also similarly endowed. Why should not medicine be represented in its specially appropriate church of St. Bartholomew-the-Great? Its restoration would probably be costly, and funds would be needed, but the medical world of to-day will have reason to be proud if they render aid to this work of respect to their pious friend and benefactor of times gone by, Rahere.—*Lance*

Colonial and Indian Exhibition.—The arrangements of the Conference Committee, which the Duke of Manchester is chairman, are now fairly complete, and meetings are announced for dates previous to Whit Sunday. The meetings are open to all visitors to the Exhibition. Among the subjects to be discussed are, "South Africa as a Field for the Emigration of the Industrial Classes," 4.0 p.m., Thursday, June 3, by Mr. Arnold White. "The System of Land Transfer adopted by the Colonies," 3.0 p.m., Friday, June 4, by J. D. Wood. "The Mineral Resources of India," 3.0 p.m., Saturday, June 5, by Prof. Valentine Ball. "Indian Carpets," 4.0 p.m., Thursday, June 10, by Mr. Vincent Robinson. "The Industries of New Zealand," 8.30 p.m., Saturday, by Mr. F. W. Pennefather. "Emigration to the Colonies," 3.0 p.m., Friday, June 11, Mr. F. Young.

The Sunday Society.—The eleventh public annual meeting of the members and supporters of this Society was held in Prince's Hall Piccadilly, on Saturday last, when Sir H. E. Roscoe, M.P., F.R.S., delivered his Presidential address, and it was resolved:—That the Committee of the Sunday Society be authorized to send a memorial to His Royal Highness the Prince of Wales, K.G., requesting that the interests of the community, the Colonial and Indian Exhibition may be open on a few Sundays, by free tickets, either to the public generally, or in some restricted way, by means of tickets distributed through the Sunday Society, the London Trades Council, the Working Men's Club and Institute Union, and other agencies.

Rolls Girders.—Messrs. Gardner, Anderson, & Clark send us a new sheet of sections of rolled girders, accompanied by a useful and convenient "pocket-card" of sizes and strengths of this class of girders.

TENDERS.

BECKENHAM (Kent).—For new vestries and parish-room to St. Paul's Church, Beckenham, Kent. Mr. Sydney F. Bartlett, architect, Beckenham:—
Wall & Hook, Brinscombe, Gloucester (accepted).....£475 0 0

CHISLEHURST.—For the construction of roads and sewers, Sundridge Park, Chislehurst, for the Trustees of the will of the late Sir Edward Scott, bart. Mr. W. H. Gibbs, West Kensington, engineer. Quantities supplied:—
Nowell & Robson.....£10,175 0 0
J. Mowlem & Co.....9,700 0 0
W. Webster.....8,560 0 0
B. Cooke & Co.....7,800 0 0
H. R. Treherne & Co.....7,265 0 0
E. Peill & Sons.....6,580 0 0
T. Lansbury (accepted).....6,400 0 0

CROYDON.—For alterations and repairs to premises, Queen's-road, Croydon. Mr. R. Ridge, Croydon, surveyor:—
Shepherd.....£202 0 0
Bryan.....151 0 0
Gondler & Glasscock.....177 0 0
W. G. Wyatt & Co.....175 0 0

FRINTON (Essex).—For the erection of portion of hotel, Frinton, Essex. Mr. E. C. Homer, architect, Mansion House-chambers. Quantities by Mr. W. Birds-eye:—
Dable.....£3,298 0 0
Nightingale.....3,187 0 0
Kilby & Gayford.....3,100 0 0
Dixon & Co.....2,579 0 0
Hook.....2,249 0 0
Gillingham (accepted).....2,247 0 0

FULHAM.—For road and sewer works on the Sand's End Estate, for Messrs. East & Sons:—
Marshall, Brighton.....£3,300 0 0
Oliver, Harlesden.....2,940 0 0
Osenton, Erith.....2,653 0 0
Wilson, Walthamstow.....2,439 18 0

Marshland and its Churches.

SITUATED in the north-western corner of Norfolk, between the rivers Ouse and Nene, Marshland, as its name implies, was at one time a great swamp, forming, in fact, a considerable

part of the Wash, impassable at low tide, and one great expanse of water when the tide was full; in breadth about seven miles, and extending from Lynn southward as far as the Por or Pa dyke; westward including Wisbech and the neighbouring villages in Cambridgeshire.

The traveller in this district will probably at first be struck with the extreme flatness of the country (for it is a dead level), and also with its apparent baldness; but it improves on acquaintance, and it must be remembered that this is one of the richest grain districts in England, whilst the pasture for cattle is unrivalled, owing in great measure to the numerous ditches and dykes which intersect the land in every direction. The county is purely agricultural; and it is this which makes it so surprising that such splendid churches are to be found in almost every village,—often several within sight of each other. That much good work exists in King's Lynn is easily accounted for from the fact of its having been at one time,—as it is even now in a less degree,—a seaport of considerable importance, and its inhabitants a very wealthy class. Many traces of its former splendour are still in existence, and a short walk through the town will reveal much of interest. The streets wind about in most confusing fashion, and seem, as in so many old towns, to have been laid out without plan or reason. Curious courts and alleys, leading off from the main thoroughfares, excite curiosity, met sometimes by disappointment, but more often rewarded by the discovery of some quaintly picturesque brick gable, or perhaps of some old courtyard surrounded by a building which was at one time the abode of some wealthy merchant of two centuries back, but which is now divided into several small tenements, each with its own proprietor, who still takes a certain pride in his surroundings, and who will be only too happy to open his doors,—especially if assisted by that silver key which no traveller can long do without: it may be, wondering a little what there can be of special interest in his room, but nothing worth to do all in his power to oblige, saying, in a peculiar sing-song common to the Norfolk lower classes, and raising his voice at the end

of the sentence,—“Coomo in, sur, coomo in; they do saay as thaat boarding, sur, agin they wall be woonderful oold”; directing our attention, at the same time, to some Jacobean oak panelling which has survived the changes from which the building has suffered. In response, however, to a feeler thrown out as to purchase, we are met by the answer, which clearly shows that the same thing has already been attempted by others,—“Noa, no-a, sur; I loikes the room woonderful well, and I beant agooin to part.” With a sigh,—for the panelling is very good and in beautiful preservation,—and, after further examination, we take our departure, not without some feeling of relief that, at all events, even if we are not to be the fortunate possessors, nobody else is likely yet awhile to obtain it. One such courtyard as that above mentioned goes by the name of “Hampton Court,” and from the roof of the arched entrance hangs suspended a cannon-hall, which the inhabitants tell us was pitched into the middle of the building during the siege by Cromwell, when the town stood out for King Charles.

First and foremost as objects of interest in Lynn are the two great churches, St. Margaret's, and its wonderful chapel-of-ease, St. Nicholas. St. Margaret's is the more important of the two, being the mother church. It is said to have been built by Herbert de Losinga, Bishop of Norwich (1091-1119). Portions of his buildings still remain in the west front, and are good specimens of Norman work. The nave was destroyed in 1741, owing to the falling of the spire of one of the western towers, but it was rebuilt in the style (?) of the period. The Early English bases of the former nave-piers have recently been brought to light, and show a central column with four clustered and detached shafts. The choir is Early English, and very beautiful, the caps being richly carved with foliage, each one varying in design. In this church is the famous “peacock” brass (1374), now removed to a safe position in the south-west tower. This commemorates Robert Brauncle and his two wives. They lie under canopies with eight mourners, in male and female costume, at the sides; at their feet a peacock feast is portrayed. King Edward III. is seated with his courtiers at table, and a peacock is being brought in; on one side a knight is reaching forward for the dish, with one leg thrown across the table in his haste. Another very similar brass, to the memory of Adam de Walsoken, lies by its side, with the date 1349. Both brasses are the same size, 10 ft. long by 5 ft. wide, and they probably came from Flanders, as they bear all the characteristics of Flemish work. Haimes says:—“The principal lines are broader and more deeply cut, and wrought with a flat chisel-shaped

tool instead of the ordinary engraving burin.” The organ-case should be noticed as very fine, resembling in many points that in King's College Chapel, Cambridge. The Late Jacobean screen is worthy of notice; also the beautiful stall-work; this latter is of the most costly description, and very perfect, temp. Edward III. On one of the subellies is a head of Edward the Black Prince, together with his device of feathers, besides many other coats-of-arms of worthies who have long since ceased to exist, and whose names in many cases are forgotten.

St. Nicholas, the chapel-of-ease to St. Margaret's, is a fine church, 200 ft. long, originally built in 1160. The tower alone remains of the old building, which was replaced by the present structure during the years 1374-1419. Unfortunately, the church has been robbed more than once; few of the bench ends, which were very fine, remain, and the old glass has almost entirely disappeared. There is a curious inscription on a tablet, with date 1600, which runs as follows:—

“A good steward is liberal and giveth to the pore;
The wicked one as owner keepeth still his store;
Distrusting God's providence hath made his heart hard;
He doth not part from a penny in hope of reward.”

Another slab in the pavement, with date 1789, in memory of Thomas Hollingworth, a bookseller, states that he was “a man of strictest integrity in his dealings, and much esteemed by gentlemen of taste for the neatness and elegance of his hinding.”

Leaving Lynn, and crossing the Ouse by the new bridge, we find ourselves in Marshland proper,—a district rich in churches. To the left the spire of Tilney All Saints; the grand tower of Terrington St. Clements on our right; a little further, the two churches of Walpole,—all these promise us good material for our sketch-book. Making our way to Tilney All Saints Church, we find a building containing work of every period, from early Norman to Perpendicular and Jacobean, with even some nineteenth-century additions. This is the more noteworthy because of the comparative sameness of the majority of those in the neighbourhood; with but few exceptions these are late Perpendicular, with occasionally small portions of a former structure remaining. This is the case at Walpole St. Peter's, which possesses a Decorated tower and nave clear-story; how this latter feature has come about it is difficult to determine, for to all appearance the piers and arches which carry it are of a much later date,—but how or when it was done has not yet been settled, and it still remains an interesting but unsolved problem. Another noteworthy feature in this church is the way in which the altar is raised to a considerable height, to permit the construction of

a passage underneath. The total length of the old building equalled that of the nave as at present. The accommodation proving too small for the requirements of the parish, the church was remodelled, and a new chancel built at the east end of the existing one. A public right of way, however, cut across the proposed site, and apparently prevented this change from being effected; but the difficulty was met in the way indicated, and the height to which the altar is necessarily raised has an imposing effect. The roof of the passage underneath is richly groined, and has a profusion of elaborately-carved bosses at the intersection of the ribs. A similar expedient has been resorted to at St. Michael's, Norwich, but in this case it is not so conspicuous, as the church stands some way back from the main street.

The civility and kindness of the Norfolk folk are proverbial; this is specially noticeable in the way in which the architectural student or visitor is treated by the clergy of the churches he visits. At Walpole, the rector, besides offering the usual courtesies, takes the greatest interest in explaining the peculiarities of his church, when he can find an appreciative listener, and draws attention to many little points and details which the casual observer might fail to perceive. Of course some curious characters are to be met with. On one occasion a ladder was necessary to enable us to take some dimensions. On applying to the parson for help we were informed that one could be obtained opposite for the asking, and he gravely added, "I can assure you that that man (referring to the builder who owned the ladder) is a most excellent workman, although he is a Dissenter." At another time we were given permission to sketch, provided that beer-bottles and cheese-parings were not left on the founders' tombs. *Experientia docet*. Evidently, some one of the fraternity had been feasting at one and the same time both his inner and his outer man, and had left traces behind which were not altogether pleasing to the authorities that were. Our promise having been given, friendly relations were once more restored, to such an extent, indeed, that before parting, more than one empty bottle remained, not upon the founders' tombs, but on the rectory sideboard.

Making our way to Terrington St. Clements, we find a church well worthy of notice, containing an elaborate porch on the south side and a fine tower on the west. This latter is detached from the rest of the structure, having been built at a different date. It is thought by some to have been erected as a refuge from the floods which, in former times, so often devastated the country. The tower is built of stone brought down the river Nene from the Barnack quarries in Northamptonshire. This stone is of a blue grey colour, and is little affected by time or weather, the strings and moulded work being as sharp and clean now as when they left the hands of the mason. Almost all the neighbouring churches are partly built of the same stone, the only other material available being flint, and this latter is generally used for the body of the walling. The tower walls of Terrington, at the ground-floor level, are 7 ft. thick, fully bearing out the idea of having been built to resist the floods. It is related that in the year 1607 one of these floods occurred, and the Jury for the Hundred reported that, "in their distress the people of the town fled to the church for refuge, some to haystacks, some to the baulks in the houses, till they were near famished; poor women leaving their children swimming in their beds till good people, adventuring their lives, went up to the breast in the water to fetch them out at the windows. Whereof Mr. Browne, the minister, did fetch divers to his church upon his back. And had it not pleased God to move the hearts of the mayor and aldermen of King's Lynn with compassion, who sent beer and victuals thither by boat, many had perished; which boats came the direct way over the soil from Lynn to Terrington."

The danger of such a flood occurring again has been practically prevented by the great scheme known as the Nene outfall. A stream

some 200 ft. wide and 24 ft. deep, embanked on either side, was formed in 1830 by Messrs. Rennie & Telford. This, by a direct route, takes the drainage of the whole of the North Level,—a district containing 48,000 acres,—and has converted a barren swamp into rich pastures and cornfields. "We may mention, as a remarkable effect of the opening of the new outfall, that in a few hours the lowering of the waters was felt throughout the whole of the fen level. The sluggish and stagnant drains, cuts, and leams in distant places began actually to flow, and the sensation created was such that at Thorney, near Peterborough, some fifteen miles from the sea, the intelligence penetrated even to the congregation at church,—for it was Sunday morning,—that the waters were running, when immediately the whole flocked out, parson and all, to see the great sight, and acknowledge the blessings of science.*"

Perhaps the most remarkable of the Marshland churches is that at Walsoken, about one mile out of Wisbech on the Lynn road, and of which we give measured drawings in the present number. The west doorway of the church is a good specimen of Early English work, having a deeply-recessed and richly-moulded circular arch, carried by three slender detached shafts with carved caps,—these latter having been restored. The church is of large size, and presents internally a somewhat confused mixture; the arches which separate the nave from the aisles are semicircular, and have a heavy Norman zigzag moulding on the soffit; the columns which carry these arches are alternately circular and octagonal, and these octagonal piers are again varied by being placed the one with a plain face parallel to the axis of the church, the next one anglewise. This arrangement gives not a little variety to the arcade, an effect which is increased by the curious treatment of the chancel arch,—this is an unusual and not altogether pleasing feature. The arch is Norman, and is covered with several hold round chevron mouldings, as well as a lozenge ornament; it is pointed, and almost equilateral, while the shafts which carry the caps from which the arch springs are divided up every 2 ft. by large projecting annulets, which produce an effect of broken surface quite out of keeping with the severity of the rest of the work of the same period. The caps to the nave piers are carved, and are all different in design, but not specially noteworthy, except the responds at the east end, and these are good examples of the transition from Norman to Early English,—small knob-like leaves break out from the plain face of the cap, and these lead up to the chancel arcade, where the genuine Early English foliage appears. Over these arches a Perpendicular clearstory of three-light windows has been added, entirely obliterating in the nave all traces of the windows which formerly existed. In the chancel, however, the windows remain, notwithstanding later additions; the stone arches and jambs showing through the plastering clearly indicating the original design. A flat hammer-beam roof has also been added, and this will repay a careful examination, as it is in a good state of preservation, the greater part of the original colour decoration being very perfect. Taken as a whole or in detail the building is worth study, and a visitor to the neighbourhood should on no account miss seeing it, as the time occupied, even at some inconvenience, will have been most profitably spent.

The last church we can notice is that at West Walton, which is about one mile beyond Walsoken, and is of almost equal interest. The churchyard is entered under a detached Early English tower, which stands at a considerable distance from the main building, and is probably a trifle earlier in date; unfortunately the whole place is in a dilapidated and almost ruinous condition, besides having been sadly mutilated in past times; the clearstory is blocked up by the great fifteenth-century aisle roofs. The west wall has had two enormous buttresses added, in order to keep it from falling, and is painfully out of the perpendicular even now,—in fact,

everything points to neglect and decay. Why a restoration is not attempted it is difficult to say. Possibly the expense would be too great, for the work is so elaborate and costly, that a very considerable sum would be needed. The nave arches are carried on central stone piers, with four banded and clustered Purbeck marble shafts, the caps being carved with free Early English foliage, similar, both in design and execution, to that in the nave of Lincoln Minster. Strange to say, the carving has been but little injured, though in many cases the marble shafts have disappeared, and those that remained were in many cases broken and otherwise defaced. This richness of work is not confined to any particular part, but is apparent in the whole of the older parts of the building,—these include the nave and chancel, south porch, and a considerable portion of the aisle walling. This church is easy of access, being but a short distance from Wisbech, and not more than a few miles from Lynn; but it is a great surprise coming upon it unawares, even in a country such as Marshland, where there are continual surprises. It is in a district which has not been much studied, or even much sketched, but is one which deserves to be better known than it is, and which will well reward a visit.

RELICS OF OLD LONDON.*

THE PHOTOGRAPHS FOR 1886.

WE use no trite form of words in saying that we receive this collection of views with a not unmixed pleasure for they constitute the final issue of the Society's publications. Mr. Alfred Marks, the honorary secretary, should be warmly congratulated upon the progress and conduct of the enterprise. We are sure that his brother subscribers will cordially acknowledge him to have been the leading spirit in their undertaking, and that to his exertions, as to the skill of the Messrs. Dixon, the Society's photographers, its successful accomplishment,—despite many inherent difficulties of time and space,—is entirely due. That the work was not begun too soon is manifest from the circumstance that since 1875,—when the series was opened with six views of the Oxford Arms Inn, Warwick-lane,—many of the illustrated subjects have already ceased to be, including, for instance, one of the two fine old shop-fronts in Soho, Oxford Market, Sion College, Temple Bar, the Oxford Arms itself, together with various antiquated tenements in Leather-hall-street, Fore-street, Gray's Inn-lane, and Aldgate.

It has been urged against these photographs that they give us very good presentations of advertisement placards, drawn blinds, and closed shutters. Criticism of this kind is a little considered as it is easy and illiberal. The "posters" and "boards" will show a future age how we disfigure our streets. Most of the outdoor views were necessarily taken when the city was in the condition that so forcibly struck Wordsworth as he crossed over Old Westminster Bridge. That these were done in the early morning is obvious enough from the direction and length of the shadows, the unextinguished gas jets, the time as shown on certain dials, and the absence of wayfarers. Devotees of the picturesque must not look here for such attributes as are conspicuous in the cognate etchings, say, of Mr. Ernest George. But we do get an otherwise unattainable fidelity of outline and detail, lacking only the brilliancy and colour of the image that is cast by the camera lucida. The later issues are singularly good in their treatment of a difficult matter, the photographing of dark interiors witness the Charterhouse and Temple groups. The exterior views are not free, of course, from what we may term the congenital defect of photographic pictures when applied to close perspective. The foregrounds stand out so disproportionately vast as contrasted with the middle and remoter distances. The camera rigidly fixes those nearer objects which the

* Smiles, "Engineers."

* Photographs published by the Society for Photographing Relics of Old London. Alfred Marks, hon. secretary. Nos. 119-120. Issued, 1886.

eye does not take in except by its rapid,—albeit, unconscious,—movement. Moreover, no artistic skill has yet been able to transfer on to the flat sheet that indescribable effect of dimmed atmosphere and softened tones which by inductive experience the human vision associates with relative distance.

To the pictures under review, Clerkenwell and Westminster contribute eight subjects. Thus we have, on the one hand, St. John's Gate, the chimney-piece of Hicks's Hall, and the Court Room of the New River Company; on the other hand, Emmanuel (Anne, Lady Dacre's) Hospital, Queen Anne's statue in Queen-square, and three doorways in Queen-square, Grosvenor-road, and Delahay-street. This last "is from No. 17, Delahay-street, given by Mr. Hare,—I fear without sufficient authority,—as that of Judge Jefferies's house ("Walks in London," ii., 296)." Mr. Hare, even at his best, is no very trustworthy guide. As it happens, this particular doorway is reinstated *in situ*, as Mr. Marks reminds us.* But Jefferies's house, or rather what remains thereof, should be looked for at Chapel-place, Nos. 7 and 9, in the street, where the stone house with a circular tanking tower (circa 1870), occupies the site of Duke-street Chapel. The rest of Chapel-place is indubitably the house pre-figured as Judge Jefferies's in Shepherd's earlier drawing, of which we have a print. In his description of the Tennis Court, James-street, Haymarket, Mr. Marks speaks of it and of its timber-fronted neighbour, "The Barn," as though they are relics, probably, of Piccadilly Hall. Certainly Clarendon's quoted description gives us an idea that the Gaming-house grounds were of considerable extent. Yet there seems to be some confusion here with the Gaming-house,—vulgarily known by the style of "Shaver's Hall," built by Lord Pembroke's valet,—which stood at the north-eastern corner of the Haymarket, just where, until the widening of Coventry-street, was Wishart's snuff and tobacco shop, a noted Jacobite rendezvous in its day. The Barn, by the way, was about thirty-five years ago, Busher's coach factory, at which time the tablet, with date 1673, was affixed on the front wall of the house between the factory and the Tennis Court. It is now against the Tennis Court wall. Singularly enough, in Newcourt's map, engraved by Wm. Faithorne (1658), the Way to Piccadilly Hall is indicated (corresponding with the present Piccadilly), but whilst that hall is not marked by name the building at the corner of Coventry-street and Haymarket is designated as the Gaming-house. Piccadilly Hall, we gather, lay on the northern side of Coventry-street, at the angle with Great Windmill-street, in St. Martin's-in-the-Fields parish, and on the ground which is now covered by Scott's supper-rooms. Timbs (1855) says the house was demolished about 1683, and adds that "a tennis court in the rear remained to our time, upon the site of the Argyll Rooms (the Trocadero), Great Windmill-street." The Tennis Court shown in the view, we believe, built for King Charles II. It is that mentioned by Pepps (Jan. 4, 1663-4, and Sept. 2, 1667), wherein the King's play was strolled in such terms as are but fit in the case of a sovereign; though in no unmeasured phrase, almost worthy of Juvenal, Pepps in his instance marks his opinion of courtly vocation. Pity it is that the sums of money which were sunk in skating-rinks were not pent upon the revival of this right royal amuse. We are glad to see a picture of an old and little known friend,—the Bear in Lower Thames-street. He, of course, has nothing to do with the Royal Menagerie; but, with his collar and chain, he reminds us of his congener, the Tower Bear, who, similarly secured, was allowed to disport himself and fish in the Thames. Perhaps the most interesting, though scarcely the most striking, photograph is that of London Stone. We are at one with Mr. Marks in his conjectures upon the origin and purport of that relic. Jack Cade, or "Mortimer," clearly went through no idle ceremony when he struck its stone with his sword, proclaiming himself

at last "lord of this city." Were it, indeed, a milliarium, as Camden thought, we should have had, doubtless, some tradition of its situation by the Roman forum near to where is now the Mansion House. Its venerable antiquity opens many questions which we cannot discuss here. On the score of age and its supreme significance as a mute but incontestable witness to contracts and the like, its history should be read along with that of the whet-mound stone at St. Michael's le Querne, or ad Bladum, in Chepe. This latter is specified in a conveyance, A.D. 889, of the parcel of land whereon it stood by King Ælfred to Werewit, bishop of Worcester, relatively to the corn-market at that spot.

NOTES.

THE second report of the Committee on the Ventilation of the House of Commons, just published, dealing chiefly with the causes of smells in the House, shows conclusively that the system of drainage, planned at a time previous to much of the modern sanitary gospel, requires a radical reform. The main sewer under the House is obviously far too large, and its invert at the junction with the public sewer is below the lowest level of the sewage in the latter, so that there must be always a standing pool at the lower end of it. The Committee propose to construct within the present large brick drain a smaller one, of a better section, about 3 ft. 8 in. high, by 2 ft. 4 in. wide in the clear, constructed of white glazed fire-bricks, in Portland cement; the remaining space in the existing sewer to be filled up with concrete. They propose that this new sewer should discharge into a vertical stand-pipe, whence the sewage should be pumped by Shone's pneumatic ejectors into the outside portion of the existing sewer, and run thence into the low-level main sewer, so as to cut the latter off from all connexion with the Houses of Parliament drainage system. They propose effectual means for ventilating the new drain by a fresh-air down-take pipe at the lower end, and a foul-air up-take pipe from its upper end into the shaft over the furnace in the Victoria Tower. This will be effectual. The Committee take the opportunity of making an attack on the state of the large low-level sewer adjoining, which the Chairman of the Board of Works, in answer to a question addressed to him in the House, said that his Board did not think it necessary to ventilate; "an opinion to which the Committee venture to think his Board will not long be able to adhere." The Committee, without echoing the groundless complaints that have been made about the ventilating system of the House (which, provided it has pure air to deal with, is really a very efficient one), point out quite rightly that where an extraction system is used there is a pull of air into the apartment, which facilitates the ingress of contaminated air escaping from pipes or waterclosets; and they recommend the substitution of propulsion, which we have repeatedly said is the true system to employ for large public buildings. There are propulsion fans and engines now in the basement of the House, for use when the state of the weather vitiates the action of the extraction system; so it is only necessary to substitute this for the extraction system. The report generally is a most sensible and practical document, which, we hope, will receive the attention it deserves.

ON the 31st ult. a banquet was given at the Hôtel Continental at Paris, by one hundred members of the Société Centrale des Architectes, to M. Charles Garnier, in honour of the decree of the presentation to him this year of the Royal Gold Medal of the Institute of British Architects. M. Achille Hermant, Vice-president of the Société Centrale, occupied the chair, the President, M. Bailly, being prevented by illness from attending. The chairman gave the history of the Royal Gold Medal, and proposed the health of M. Garnier, who, in replying, expressed in warm terms his sense of the kindness of his professional brethren on both sides of the

Channel. The delegates of the Society of Architects of Bordeaux congratulated M. Garnier also in the name of the provincial architects of France. M. Paul Sédille, after reading letters from Mr. W. H. White, Mr. R. P. Pullan, and Mr. Aitchison, regretting their inability to be present on the occasion, proposed the toast of "Nos confrères Anglais" and the Royal Institute of British Architects.

THE Town Council of Bath have been occupied in considering the question of the proposed extension of the modern baths and its probable effect in destroying or obliterating part of the valuable and interesting remains of the ancient Roman bath. The report of the Baths and Pump-room Committee took the line that ancient remains should not be permitted to interfere with works of modern and public utility,—a line of reasoning which, in itself and in a general way, we should not be disposed to dispute; but, as we have already observed, the Roman remains at Bath are of very exceptional interest and value, and every effort ought to be made to avoid injuring or hiding them from view. As far as we can gather from the various very contradictory statements dropped at the meeting (as reported in the *Bath Journal*), it would appear that in the mind of the City Surveyor and his supporters utilitarian considerations have gained rather too much the upper hand. Alderman Murch, in a moderate and sensible speech, urged the importance of the ancient remains, and suggested that the basement of the proposed addition should be sacrificed, and that there should be fewer new baths. How far this would meet the case we cannot, of course, tell without knowing what is the actual demand for more bath accommodation. Alderman Gilhis proposed an amendment that the report be referred back for fuller consideration, and that another architect should be called in to consult with the Surveyor (Mr. Davis) "as to the best mode of effecting the extension of the modern baths without any interference with the ancient remains." This would have been the best course to take, and we regret to observe that this amendment was lost by one vote (21 against 22). As the vote was such a near thing, we hope the matter will not be considered altogether settled. From the comments and correspondence in the local papers the result seems to be regarded in Bath with anything but satisfaction.

THE rule that before an award of an arbitrator can be taken up, his fees must be paid, frequently is very unjust towards the successful party. This has just been illustrated by the case of Westwood & Co. v. The Government of the Cape Colony. A lengthy arbitration between these parties as to certain work done by the former was held before Sir James Brunlees. Messrs. Westwood took up the award and paid the arbitrator's fees, amounting to 1,200*l.* odd. The award was in their favour, and the Government were ordered to pay the cost of the reference. On taxation 800*l.* odd of Sir James Brunlees's fees were disallowed, the consequence being, of course, that Messrs. Westwood will have to pay this sum out of their own pockets. The decision of the Taxing Master was upheld by the Court. No doubt the Taxing Master acted perfectly correctly in reducing Sir J. Brunlees's fees to the ten guineas per day which would have been allowed a Queen's Counsel, but the matter shows how hardly the rule we have mentioned presses on a successful party if it happens that he does not receive all the costs from the other side on taxation. It is one of the extravagances of an arbitration that private individuals are paid for services for which the time of a judge can be had for nothing. But in those cases where an arbitration is actually necessary it seems to us that the proper rule would be for the arbitrator to fix his charges beforehand, and at the end of each day's hearing each party should pay half the fee for the day. If either side refused to pay the fee, it should be the duty of the arbitrator to continue the reference without him, and if on the next hearing the party was still of the same mind, judgment

* Nos. 13 and 17, adjoining one to the other, seem to have placed Nos. 13, 15, and 17.

should be given against him, as in an action by default. The case to which we have alluded shows that, under the operation of the present rule, a successful party may be actually out of pocket as regards costs.

LAST year the Postmaster-General obtained the authority of Parliament by a special Act to acquire land in Birmingham for the purpose of erecting thereon additions to the present head office. With extraordinary want of foresight,—perhaps, if it were a private individual of whom we were speaking, we should simply say with great carelessness,—the Department did not make sure that such additions would prove adequate for the wants of that great city. So a new Bill is now before the House of Commons. It is naively remarked in the preamble, after various recitals from the preliminary “whereas,” “but since the passing of the said Act [last year] it has been found that even if the said head post-office were so enlarged as aforesaid, it would in a very short time prove inadequate for the requirements of the public service”; therefore the Postmaster-General drops the Act of 1885, and wants powers to take other land for a new head office. But what can we think of the business capacities of a Department which in one year actually get an Act to enable them to add to existing buildings, and then, before the year is out, find that they must have new buildings? It is fortunate that the inadequacy of the additions to the present post-office at Birmingham has been discovered before they were erected; if this had not happened the country would have been put to a double expense, simply from a want of proper prudence in regard to the ascertaining of the required amount of space.

THE Post-Office Sites Bill, 1886, as the Bill above referred to is called, consists of fourteen clauses, most of them of a general nature, which would seem to be applicable to the purchase of sites in any place. Thus there is a power given to divert streets; it is to be enacted that the Postmaster-General shall not acquire ten or more houses occupied either wholly or partially by persons belonging to the labouring classes until the Local Government Board have sanctioned a scheme for providing new dwellings for such persons. It would be more satisfactory if a general Act were passed giving certain powers and rights to the Postmaster-General, and placing him under certain obligations when he has to purchase sites for post-offices. It seems to be altogether absurd to pass a Bill of this kind every time a site is required. It adds to the labour of Parliament, and it might be done once for all, so that all the world would know what was the law in case the Postmaster-General at any time desired to purchase a site for a post-office.

IN the last issue of the *Mittheilungen des Deutschen Archäologischen Instituts* (x. 3), Dr. Dörpfeld propounds an interesting, though rather startling theory. It has been universally accepted that the older Temple of Athens, on the Acropolis, which was destroyed by the Persians, occupied the site of the present Parthenon. The old temple was the work of the Peisistratidae, and it is supposed that Themistocles employed a good deal of the unfinished structure as building material for the repair of the fortifications of the north Acropolis wall. Fragments of pillars of marble and of an architrave of porous stone have been found built into this wall. The difference of material has inclined Dr. Dörpfeld to suspect that they did not belong to one and the same temple. His theory is that the architrave remains of porous stone belong to the old temple of the Peisistratidae, and that this was built, not where the present Parthenon is, but between the Parthenon and the Erechtheum, on a plateau 45 metres by 22 metres, where the remains of walls are still clearly to be seen. The whole of this temple was, he thinks, built of porous stone; it was of peripteral form, and he sees in its plan close resemblance to the old temple of Dionysos at Eleusis. Part of

the present Erechtheum is built on its site. The remains of marble pillars, he thinks, belong to a later temple, begun by Cimon, and this temple, he thinks, occupied the site of the present Parthenon. It was left unfinished on the banishment of Cimon, and eventually superseded by the final Parthenon of Pheidias. The theory, like some others of the enthusiastic German architect, seems to rest on rather slight grounds.

THE same number of the *Mittheilungen* also contains a paper by Dr. Köhler and Dr. Dörpfeld conjointly on the Choragic monument of Nikias. The Choragic monuments of Lysicrates and of Thrasyllos are well known, but though the remains of the monument of Nikias have been accessible since the excavation of the Beulé Gate, they have not till now been reconstructed into an intelligible whole; in fact, Beulé, their discoverer, thought the architrave with the victor's inscription, the triglyphs, and the cornice, all belonged to separate buildings. On Plate VII. of the *Mittheilungen* Dr. Dörpfeld reconstructs for us the front view of the building, which has special interest because it offers a third and wholly different type of Choragic monument. The Lysicrates monument, it will be remembered, was a circular building of the Corinthian order; the monument of Thrasyllos was a small Doric portico, forming the entrance to a natural cave; the monument of Nikias is in the form of a small Doric temple, with six columns in front supporting architrave and low pediment. Dr. Dörpfeld notes that the remains have further interest in connexion with the question of polychromy; the main portion of the building was of white marble, the triglyphs of the much cheaper “poros.” The triglyphs only bear traces of painting. Dr. Dörpfeld thinks that the triglyphs only were covered with a thick and opaque coating of paint,—hence the use of the cheaper material. For the special interest of the inscription on the architrave we refer our readers to Dr. Köhler's disquisition.

IN regard to the competition for the new facade of Milan Cathedral, of which we have already spoken, it is to be feared that the composition of the Jury will not inspire any greater degree of confidence than is usually felt in tribunals of this description. The competition is styled “international,” but foreign nations will be very imperfectly represented by the three architects to be chosen by the Milanese Academy of Fine Arts. The plan of allowing the competitors to elect four members of the Committee is a novel one, but it is very doubtful whether it will be found practicable; and, if practicable, it must almost of necessity result in an advantage to Italians. The preparation of a design for the preliminary competition need not involve a large expenditure of time or money, and perhaps some English architects may think it worth while to send in designs. The superintendence of the model is another matter, and would probably be a long and difficult task, and would involve a lengthy stay in Milan. The Italian architect selected by the Academy of Fine Arts at Milan to serve on the Committee is the Cavaliere Giacomo Franco, Professor of Architecture at the Academy of Fine Arts at Venice.

THE *Berliner Philologische Wochenschrift* (May 29) reports a paper read by Dr. Petersen at the last meeting of the Archaeological Society at Berlin. Dr. Petersen took part in both the expeditions recently made by Count Lanckoronski to Southern Asia Minor. He showed a number of plans and photographs which are to form part of the official report of the expedition shortly to be published. Special attention was drawn to the fortifications of Adalia. Seven plates are to be devoted to the detailed publication of the arch of Hadrian in that town, it being remarkably well preserved. On the site of the Greek colony of Sidé a richly-decorated fountain has been discovered, and the foundation of one of the gates of the town; the directions of the principal streets can be

clearly made out, and a great number of colonnades opening in the streets are still traceable. A plan has been made of the ancient harbour, close to which the remains of an exedra-shaped building have been found. Eleven plates will be devoted to reproducing the famous theatre of Aspendos. At Aspendos and Sytheion only have inscriptions in Pamphylia dialect been found. Time was spent in Southern Asia Minor was a field of exploration peculiarly English: witness our Lycian sculptures in the British Museum. But our mantle has now certainly fallen on Vienna.

ON the 27th ult. the last meeting for the season of the Société Centrale des Architectes took place at Paris, when a paper was read by M. Napoli, Chief Engineer of the Laboratory of Physics and Chemistry in connexion with the “Chemin de Fer de l'Est,” on “The Application of Electricity to Buildings.” He went through the subjects of electrical transmission of force, telephonic communication, electric lighting for dwellings, application of electricity to lifts and to automatic fire-alarms, to the great interest of an audience of architects, among whom were present M. Garnier and M. Questel.

SINCE the publication in our last of Mr. Wild's letter about Christchurch, Brixton-hill, we have been to see what the churchwardens have done. They must, indeed, be penitents, to have been obliged to cut a number of square holes in the aisle roofs, letting in the midday sun upon the heads of the congregation in the manner of a greenhouse. The effect upon that architecture is no less disastrous, the solemn tall columns being now seen in shade against these violent lights. The removal of St. Anne's Asylum has set at liberty a great deal of space formerly occupied by the steep gallery for the children, and it would seem an easy matter to re-arrange the organ so as to obtain room for increased light in the west wall; for the stained glass in the side windows, although evidently much darker than was intended by the architect, is very good of its kind, and must, no doubt, be left. As to the apse windows, one feels a delicacy in criticising what may have been memorial gifts to the church, but modern stained glass has been so much improved since they were executed that the substitution of paler glass to increase the light would be a welcome change.

OUR attention has been called to a trade circular which is being sent round by the “Providence Iron Works Company, Limited,” to architects and engineers, giving information as to their improved riveted girders, and concluding with this clause, to which special attention is called by a “Nota”:

“A commission of 2 per cent. will be allowed architects and engineers specifying our girders and brand. They are respectfully requested to send us as soon as possible, a copy of any specification to that effect.”

From the open and business-like manner in which this is done the only conclusion one can come to is that it is the result of sheer ignorance on the part of the Company issuing the circular. Do they know that every architect of respectability would regard that as an impertinence, and that those who entered into such an arrangement would be acting dishonourably towards their clients? Once more let us repeat what we have said before, that an architect has no business to consider any interests but those of his client in selecting the materials for use in a building, and a firm in doing a most improper thing in sending round such a notice to the profession. We charitably conclude that the “Providence Iron Works Company” are not aware that there is any impropriety in the matter, from the open way in which the offer is made, as offers of commissions of that kind are usually made *sub rosa* in diplomatic letters marked “private.” Architects who value the dignity of their profession ought to decline to do any business with firms sending such circulars until the obnoxious paragraph is removed; but we hope the company in question will have the good sense to cancel it themselves.

ARCHITECTURE AT THE ROYAL ACADEMY.—VI.

THE first exhibit among domestic architecture, in the order of hanging, is

1,548, "A Country House in Hampshire," by Messrs. Wyatt & Spiers; what agents call a "hijon house," as appears from the plan, which the authors are to be commended for appending. The drawings consist of a small view of the drawing-room, with the bay-window stretching all across one side and giving a wide view of the prospect, and a perspective of the exterior, which latter is hardly architecture in the usual sense of the word; there is nothing that can well be called "design" in it, but it is entirely unobjectionable.

1,550, "A Mentone Villa," Mr. S. J. Newman. Another hijon house; a two-storied villa, in what may be called rural Italian style, with a plan appended, showing two sitting-rooms facing down the hill, and a "garden-room" on the ground floor of the short tower at the other end; and a small open loggia between that and the porch.

1,553, "Old Falcon Inn, Chester," Messrs. Grayson & Ould. A "restoration" of a charming piece of half-timber work, shown in a neat perspective drawing. There is nothing to indicate how much is new and how much original.

1,555, "The Firs," Mr. C. Foster Hayward. A very nice water-colour drawing of a brick country-house of Queen Anne proclivities, with some good points about it. The doorway, set on diagonally at the angle, would probably seem to join the house rather awkwardly from some points of view. The bay-window and the gable flanked by chimneys on the left group well; the other front is rather fragmentary, and seems to want the details pulling together. No plan.

1,558, "Front in Terra-cotta, 17, Oxford-street," Messrs. Batterbury & Huxley. A pen elevation of a front partaking of Francis I. style, with Renaissance foliage decorations.

1,564, "House to be built near Guildford," Mr. W. S. Weatherly. A pleasant-looking country-house, shown in a pen drawing; lower story brick, with stone dressings, upper story half-timber,—that is to say, we presume, the usual pretence of timber and plaster on a background of brick wall; the treatment of the entrance, with its carved panels over, is quietly picturesque, so also the projecting wings on the left, with the arcade connecting them. A plan is appended, showing that the sitting-rooms are pleasantly varied on plan, but the drawing-room would be rather deficient in light, considering that all the windows except that of the recessed bay are under verandahs.

1,566, "Dining-room, No. 3, Stanhope-place, Hyde Park," Mr. W. Flockhart. A pen drawing of a room, with plain panelled wainscot and decorated frieze over, rather sketchily shown. The general style of the drawing is effective in execution, but we may suggest that a tablecloth hanging over the edge of a table does not make a sharp black line at the angle, an incident in the drawing which jars on the eye.

1,568, "House at Ingatestone," Mr. G. Sherrin. A "rustic" house. The frequently-repeated scheme of wall below and black and white work above, rather overdone by now. No plan.

1,579, "Beauvale, Sunningdale," Mr. G. Vigers. An old English style of country-house, well carried out; brick below, plaster on first floor, and tiling between the main cornice and the higher roofs. A double-storied bay-window forms a feature, but there is no plan to show how it works in.

1,580, "The Briary, Coves," Mr. Aston Webb. Is this an addition to an existing house? It looks rather like it, the left-hand part being the addition. In the right-hand portion the gables are cut off awkwardly from the main wall by the heavy cornice below, and seem to rise again out of the slope of the roof. The additions (?) at the left are in the same general style, but avoid this defect. A plan is appended. The house is of the practical order, and does not suggest "the briary"; it is too prim and proper for the title.

1,585, "Houses in Hans-place," Mr. C. W. Stephens. Heavy, and not picturesque. Would perhaps look better in a coloured drawing, showing the brick tones, &c., than in this rather weak pen drawing. No plan.

1,591, "Three Cups Hotel, Colchester," Messrs

E. P. Anson & Son. A rather heavy "country inn" design, with mullioned windows, semicircular projecting bays on cornels, gables with strap ornaments, and panels with sunflowers growing in them, as they grow in some recent city buildings. If, as we presume, this is the accepted design (there was a competition), there were some better ones, architecturally, submitted. It might look better in another drawing, this one being in a heavy style devoid of artistic touch. No plan is given, so we cannot judge what may be the practical merits of the building for its purpose.

1,592, "Saighton Grange, Cheshire, before Restoration," Mr. E. Hodgkinson. A very good sepia drawing of a delightful massive Late Gothic gatehouse, with later additions tacked on to it. The author knows how to handle the hrnsh.

1,593, "Additions to the Park, Ledbury," Messrs. R. Coad and J. M. Maclaren. Nothing to show whether any of this is old or whether it is all addition. If the latter, there is too much affectation of antique style about it; if it were old one would say, what a nice old house; but, as new work, it is rather a masquerade, like some other modern housework. No plan is given, and we are left entirely in the dark as to what is the nature of the additions or how they combine with the old building.

1,594, "Design submitted for the Three Cups Hotel, Colchester," Mr. R. A. Briggs; hung high; a better drawing than the selected one for the same building, but not one of those which we remembered as superior to it in design.

1,596, "Study for an Italian Villa," Mr. R. Phené Spiers; a coloured elevation, savouring of the air of the Ecole des Beaux Arts,—correct, finished, cold. The author landishly appends a plan, but the drawing is hung too high to see either that or the detail of the front.

1,597, "Holcombe Wood, Kent, Garden View," Mr. John Belcher. An eccentric sketch in coloured chalk on grey paper, apparently by Mr. A. B. Pite, showing the walls and the tiled roofs their natural red in the midst of a landscape of a ghastly grey. The house has picturesque points, especially the octagonal turret at the re-entering angle, with its chequer work upper story. No plan.

1,598, "Wrea Head, near Scarborough," Mr. E. Burgess. A cold, feelingless Gothic house shown in a neatly-finished, hard, uninteresting drawing, hung much better than it could rightly claim to be. The only good point in the design is the large mullioned hall and staircase window filling up the whole wall surface between two projections. The author has given a plan, which appears a good one.

1,602, "New Houses, Cadogan-square," Mr. J. J. Stevenson. Like many other houses in the same neighbourhood (many by the same hand). There have been better ones from Mr. Stevenson than these, or they look better in the carefully-executed water-colours he has generally sent; these, drawn in pen and ink, appear to us hard, wiry, and almost as uninteresting as domestic architecture by an architect could be made.

1,607, "Knighton Spinmies, Leicester," Messrs. Goddard and Paget. A beautifully-executed water-colour drawing, showing a picturesque house, brick, tile, half timber, many gables, and cottage and stable buildings beyond, in the midst of a sunlit flower-garden with thick clipped hedges dividing one lawn from another. The object of the drawing seems to have been to show an English house as Tennyson pictured it in the "Palace of Art,"—

"A haunt of ancient Peace."

There is nothing especially to remark on in the architecture of the house. It is picturesque, and lends itself admirably to the kind of effect depicted in the drawing. No plan is given. The drawing is certainly one of the pleasantest to look at among the domestic architectural drawings.

1,608, "Design for a Town House," Mr. Gerald Horsley. This very original design was published in our pages. It is somewhat beyond the scale of what is usually spoken of as a town "house"; it is rather a mansion. The cornice is prodigious in projection, and on too large a scale altogether for the order under it; but there is a great deal of boldness in the design. No plan.

1,611, "Kensington Court," Mr. J. J. Stevenson. A pen drawing of a hloek of houses

surrounding three sides of a quadrangle, similar in general character to those in Cadogan-square, before mentioned, but with more variety and picturesqueness of detail. The interposition of a house of positively Gothic detail and feeling among the "Queen Anneries" is happily thought of as a bit of variety in the picture. No plan.

1,613, "Houses: Pont-street," Mr. C. W. Stephens. A pen drawing of brick houses, hung too high to be well seen; heavy, but solid looking; the projecting bays finishing with deep cornice and frieze. No plan.

1,617, "Chambers and Shops, Mont-street," Messrs. Ernest George & Peto. This very picturesque street-front we have already illustrated. The shop-windows are treated with bold arches, with adequate piers between; the shops are continuous in design, but the upper stories are pleasantly varied, the projecting bays in one portion being square, with mullioned windows, the others three-sided, with smaller windows. The pierced halonies and the open tracery finish to the square bays are picturesque points of detail. The whole form a building containing so much real character that it was quite unnecessary to give the design a factitious interest by a drawing studiously treated so as to give an old and weathered look to the buildings. This is affectation. A great deal of the best architecture in the world is unfortunately old, and more or less dilapidated; but it was once new, and there is nothing sinful or inartistic in a new building that there should be an effort to make it look old.

LETTER FROM PARIS.

DEATH has been sadly busy among the ranks of the painters. Scarcely has Paul Baudry departed, than Isahy, Edouard Frère, and Karl Danhigny have followed. The two last have occupied an honourable place in art, but Isahy was incontestably a master of more than fifty years' renown, who had the good fortune to see himself placed, from his first appearance, among the great ornaments of his country.

Eugène Louis Gabriel Isahy was born at Paris in 1804. His teacher was his father, the celebrated miniature-painter, and his earliest pictures, "Un Ouragan devant Dieppe," and "La Plage de Honfleurs," both exhibited in 1827, as well as the "Port de Dunkerque" (Salon of 1831), and "Combat du Texel" (Salon of 1837), placed him in the first rank of painters. Among other admired works are "L'Arrivée de la Reine Victoria au Tréport" (1846), "Le Départ de la Reine d'Angleterre," "L'Embarquement de Bayette" (1851), "L'Alchimiste," &c. Isahy, who, during the Siege and the Commune had found a generous hospitality in London, occupied his last fifteen years in producing admirable water-colours; and it is only since the last year that he abandoned his pencil. In this painter, young almost to the last in his art, France loses one of the last and most brilliant representatives of the older French school of this century.

Edouard Frère, who died at the age of sixty-seven, had studied in the atelier of Paul Delaroche. He executed an immense number of genre pictures, popularised by engravings, and his work was as well known in England as in France. He had the gift of rendering the movement and expression of life in his figures, while attending at the same time very carefully to the execution of accessories.

Karl Danhigny died at the early age of forty. He was the son of the celebrated landscape painter, whose general manner he continued, though with a rather heavy touch, but with the same artistic conscientiousness. His picture, "La Vallée de la Scie," gained him a "Première Médaille," and the present Salon possesses one of his last and one of his best works, "Lever de Lune au Soleil couchant."

About the same time last year we mentioned the death of De Nittis, the clever and agreeable painter of Parisian fashionable society. His principal works have now been collected by the care of M. Bernheim, and the re-inspection of them confirms the impression they formerly produced.

Parliament is actively busied about the question of the Metropolitan railway, on which we have touched several times. The formation of the system of lines is getting into a practical stage, but it is of importance that its route should be laid out so as not to spoil the appear-

ance of the city or injure any of the buildings of historical interest. In regard to this view of the subject, the Society of "Amis des Monuments Parisiens" is disturbed by the projects of the municipal engineers, and M. Charles Garnier has been appointed the interpreter, to the "Ministre des Travaux Publics," of these artistic pre-occupations. It is hoped that the Government will take the application of the eminent architect into serious consideration, and that, while satisfying public requirements, and that, while respecting the picturesque and archaeological claims of Old Paris.

The preliminary work has been commenced for the transformation of the old Halle aux Blés into the Bourse du Commerce, according to the design submitted to the Municipal Council by the architect, M. Blondel. According to this design three lofty central entrances flanked by columns, surmounted by a pediment crowned by allegorical sculpture, will give access to the edifice. All round the main cornice are to be statues representing the chief cities of France. The existing cupola is retained, but filled with glass in the upper portion; the lower part will be occupied by a decorative ceiling by an eminent artist; and lastly, in the three principal avenues facing the three entrances will be groups of sculpture, for which M. Blondel hopes to secure the co-operation of such eminent sculptors as MM. Chapu, Moret, Millet, or Falguère. We may add that the design leaves absolutely unaltered the curious fountain in the centre, the work of Jean Bullant.

We may announce also the speedy demolition of the Quadriga group which surmounts the Arc de l'Étoile, which has long disgraced this fine monument, besides threatening danger from its dilapidated condition.

The environs of Paris will soon boast of a new Hôtel de Ville, at Suresnes, the design for which has been chosen in a public competition recently decided. Three premiums have been decreed by the jury: the first to M. Bresson, who is commissioned to carry out the building; the second to M. Ronyer; and the third to M. Loviot.

A great competition has been open, for some days past, at the Hôtel de Ville, for the buildings for the Exhibition of 1889. We must say at once that the programme, rather hastily drawn up in the Ministère du Commerce, leaves much to be desired in the way of perspicuity. However, in spite of obscurity of instructions and shortness of time, 107 architects have responded, and the designs were on public view up to the 31st of May. Ninety were thrown out on the preliminary examination, and at the final one three designs were selected as equal in merit, and obtained the three first premiums, each of 4,000 francs. The authors of these are M. Dutert, Eiffel (in collaboration with M. Sanvestre), and Formigé.

Among other conditions, the official programme imposes on architects the obligation to show on plan, section, and elevation, an iron tower 300 mètres in height. This gigantic construction, the utility of which is very questionable, was not calculated to stimulate the artistic spirit of the competitors, who have struggled bravely to produce an artistic and well-balanced ensemble with this "tower of Damocles" hanging over their heads.

M. Dutert plants his tower on the Champ de Mars, isolated from the main exhibition building, in the midst of a great park, over which are scattered exotic architectural constructions half hidden among trees.

M. Eiffel, the initiator and first proposer of this abnormal tower, places it at the entry of the Champ de Mars. His design is a triumph of metallic construction; vast, commodious, exceedingly practical, but as ugly as an iron railway station; with immense iron galleries, in horse-shoe form, furnished with an aerial railway to take spectators all round the exhibition.

M. Formigé, whose design is much more decorative, leaves the famous tower nearly out of consideration, merely showing it formally, so as to satisfy his competitive conscience. Though a little heavy, his principal façade has a grand monumental aspect, with the central pavilion united to two angle pavilions by long lines of arched galleries decorated with frescoes. Each pavilion is surmounted by a cupola, adorned with statues and winged genii.

Three premiums of 2,000 francs each have also been awarded to MM. Cassien-Bernard, Nachon, M. Raulin, and M. Depertthes. In th

design of the first-named, the buildings on the Champ de Mars are not very remarkable, but the tower, planted boldly on the Seine as an immense bridge, serves as the entry to the Esplanade des Invalides transformed into a park, with the axis occupied by a vast avenue of foreign-looking constructions. Very remarkable also is the design of M. Raulin, who places along the banks of the Seine, from the Invalides to the Champ de Mars, a length of about two kilomètres, a line of various edifices, Egyptian houses, Turkish mosques, Chinese pagodas, Indian temples, whose minarets, domes, and colonnades would give to that part of Paris the illusory appearance of a city of the far East, reflecting, like Benares, its palaces in the waters of the sacred stream.

We give our preference, nevertheless, to the design of M. Albert Ballu, which has only obtained, however, a third premium of 1,000 fr., along with those of MM. Pierron, Hocheau, Vaudoyer, and Fonquiau. M. Ballu's tower, which rises above a gigantic portico ornamented with allegorical statues, is crowned with a sphere on which hovers the genius of France. The ensemble of the Champ de Mars buildings is less successful, but the interior of the Palais des Beaux Arts, which he proposes to erect on the Esplanade des Invalides, is remarkable for its architectural taste and elegance. M. Fouquiau has evidently aimed at reproducing the constructions built by him at Amsterdam for the International Exhibition of 1883. If the special character of that exhibition, and the colonial connexions of the Dutch Government, might have justified that pseudo-Asiatic luxuriance, this does not apply to Paris, and the design, commonplace enough otherwise, only recalls what we have seen in former exhibition buildings.

MM. Simil, Claris and Morel, Walwein and Proust, Gaston Hénard, Blondel, and François Ronx, have each obtained honourable mention, but there is nothing in their designs out of the common way or meriting special description.

It remains to be seen what the Government will do. Will it adopt one of the three first premiated projects, or combine ideas or parts from all of them as may seem to best suit the requirements of the situation? Or has the Government only wished to give the architects the platonic satisfaction of having the competition which they asked for? We shall soon know, for to secure the subvention of the City authorities it is a condition that the work should be commenced in September next, so that a prompt decision is imperative.

As to the tower of 300 mètres, although, according to M. Berger's lecture at the Société Centrale, it ought to mark "the apogee of the age of metallurgy, to which will soon succeed the age of electricity," we earnestly hope it will be abandoned. It is entering on an enormous and useless expense to end in a sham. Besides, it will be absolutely injurious to the picturesqueness of Paris, as it will destroy entirely the scale of the panorama as now seen from the rising grounds surrounding the city; this tremendous tower will dwarf the effect of the whole.

Contrary to all expectation, the sculptors have not secured the "Médaille d'honneur" of the Salon, after all; only seventeen votes went to avenue for poor Schonenwerk the neglect in which he lived, and of which he, in fact, died; and in architecture, M. Ballu obtained only seven votes; while among the painters, after two votings, M. Jules Lefevre received 183 votes from among 367 voters, as against 79 given for M. Benjamin Constant and 38 for M. Hnhert. Without questioning the great talent of the recipient of the medal, but no regret, for M. Lefevre is a favourite in the artistic world, which feels a satisfaction in seeing this crowning of a long career of fine work.

School of Art Wood-Carving.—The students at this school (which, it will be remembered, is carried on at the City and Guilds of London Institute, Exhibition-road, South Kensington) have just finished a handsome carved mantel and over-mantel for H.R.H. the Rajah of Kooch Behar, from designs supplied by Mr. John Hungerford Pollen, M.A. The mantel-piece is executed in teak wood, and the whole is effectively carved, and may be seen at the School on application to the Manager for permission.

FURTHER NOTES ON THE EDINBURGH EXHIBITION.*

ENTRANCE is obtained to the Exhibition grounds at the north-east angle under a large archway of cast-iron. The archway is a very solid-looking affair, at least 50 ft. high, having a frieze decorated with wreaths in relief and a dentilled cornice, upon which is a trophy of flags (cast iron) and vases at each end; the spandrels have shields in relief and the uprights have moulded angles and laurel foliage in relief on the surface. The whole of this portion of the structure might reasonably have been constructed in stone, and then it would not have elicited admiration, but in cast iron it is simply detestable. The gates attached are fair specimens of their class, such as are usually found in price catalogues. The castings are sent by the Grahamstown Iron Company, Falkirk.

To the right of this entrance there is a model block of workmen's dwellings, designed by Mr. Cowans. They are only two stories high, but other stories might be added without affecting the internal arrangement. It has been the endeavour of the architect to show what can be done in this direction by the utilisation of cheap but durable material. The walls are constructed of the granite and Whinstone blocks: used for street paving, hacked by refuse stones: from freestone quarries, and the dressings are formed of portions of freestone cut off when lintels, &c., are being dressed for superior structures. The entrance is ample, and the stair is in easy flights and well lighted, as are all rooms and passages. The sanitary appliances and internal fittings, which are excellent, are contributed by a number of tradesmen.

In connexion with this subject the Executive Committee intend to invite competitive designs for workmen's dwellings, which are to be exhibited in Mr. Gowans's block. A diploma is to be awarded to the author of the most approved design as regards plan, cost, and external effect.

Against the external east wall of the Exhibition Buildings, Mr. William Langlands, Myrton Quarry, near Dundee, exhibits a plat, steps, and flagstone of a fine, hard, durable, blue freestone, suitable for monumental purposes as well as for stairs, &c. The plat is 9 ft. square, and the steps (two) 19 ft. long each. One is shown with a plain machine-edge, and the other with a bottle and fillet, also machine-wrought. The edge of the plat and the pavement show the difference between the machine and finely-wrought handwork.

In Court 2, No. 25, Mr. Marcus Bain, the lessee of Ballochmyle Quarries, Ayrshire, shows an octagonal memorial cross, as a sample of the stone which constitutes one of the chief commodities of the Land of Burns. It is possessed of admirable qualities, and is of a deep red colour. Now that the desire is spreading for the introduction of coloured material in the exterior as well as the interior of buildings, this stone will be found well adapted for the purpose. Builders give it a good name as regards ease of working, and it seems to possess the elements of durability. The percentage of soluble matter is 1.8, and the pressure tests are stated to be high. It is extensively used in the West of Scotland, and is exported to Ireland, London, and the United States. Amongst buildings constructed of it may be mentioned the offices of the Glasgow Citizen, the Burns Monument and Museum at Kilmarnock, and the station and hotel recently opened at Ayr by the Glasgow and South-Western Railway Company.

In a separate pavilion Messrs. P. & R. Fleming & Co., of Glasgow, have a large display of agricultural implements and fittings. The place of honour is given to a model of a farm-steading on the estate of Roseneath, Dumhartonsire, erected to the order of His Grace the Duke of Argyll. The whole steading is covered in by a series of semicircular corrugated iron roofs. If Mr. Ruskin should visit the lovely Garloch scenery the sight of this erection may drive him frantic. In good truth, it is with extreme regret we observe that in many parts of the Highlands the thatched or slated roofs are being superseded by corrugated iron ones, which no length of time appears to mellow into harmony with the surroundings.

An adjoining pavilion is devoted to the display of Willsons' roofing. Willsons' paper is stated to be water-proof, rot-proof, and to be a warmer covering than slate, and it is certified to have

* See pp. 671, 703, ante.

"weathered the 2-35 in. rainfall and gale of September 3rd and 4th, 1884." It is formed of various thicknesses, and in different tints of green and brown. The sample shown on the pavilion roof is neutral green in colour, and soft and pleasing in effect. If this material should prove equally serviceable as galvanised iron there can be little hesitation in giving it the preference, for besides its inoffensiveness as regards appearance it is easy of application and cheap, the prices being 1s. and 1s. 2d. per yard, 2 ft. 3 in. wide. It possesses also the quality of lightness, one ton covering 13,500 square feet, whereas one ton of galvanised iron covers 2,170 square feet only.

Red tiles are, to a considerable extent, superseding slates, and they are finding favour in Scotland as elsewhere, although not to the same extent as farther south. Scottish manufacturers are turning their attention in this direction, and we find admirable specimens of Roman, flat, and ridge tiles, finials, facing bricks, &c., produced by Messrs. W. R. & J. Carmichael, of Alloa. Court 6, No. 854.

A small model roof in Court 6, No. 831, has specimens of flat tiles, hip tiles, and ridge tiles, by H. J. and C. Major, of Bridgwater. The flat tiles have a roll moulding from ridge to eaves, which gives them a character somewhat different from those generally in use.

In Court 2, No. 7, Messrs. Smart & Co., of Cliffe-on-Thames, and Torphichen-place, Edinburgh, have a "Granolithic Trophy." It is 20 ft. long and 18 ft. high. At each corner are fluted columns with Corinthian capitals, 16 ft. high, standing upon richly ornamented bases. Between these there is a dado, consisting of dies and balusters with female figures supporting an entablature. Within this there is a massive mantelpiece, 6 ft. wide and 8 ft. high. There are also stair-steps and window mullions dressed in different manners. They also show the materials from which Portland cement is manufactured and the granite as specially prepared for mixture therewith. The cement is passed through a sieve containing 2,500 meshes to the square inch, and stands a strain of 500 lb. on the square inch at seven days.

From Macdonald & Co., Aberdeen; D. H. & J. Newall, Dalkeith; and the Ben Cruachan Granite Company, have polished and incised crosses and tombstones in red, grey, and blue granite; and different monumental sculptors show examples of their designs in this material. Amongst these we note Mr. J. H. Kerr, Dalrymple, Edinburgh; "Mural Monument executed in the Italian style, with marble figure emblematical of Faith," &c.; Thomas McEwen, Lothian-road, Edinburgh; "Life-sized Statue of Hope, in Sicilian marble, on Peterhead granite pedestal, with Ratho whinstone under base," marble monument inlaid with lead, &c., Nos. 1-6, Court 2. Mr. J. A. Kennedy, Pitt-street, Edinburgh, sends a mantelpiece in Kene's cement, mirror frame in plaster above; very neat, but a misappropriation of the materials.

There is abundance of cast-iron productions of this description, including mantels and over-mantels, in imitation of oak and other woods, from the Mashet Ironworks, Dalkeith, Court 17, No. 982, but there is very little wrought-iron work. In Court 6, No. 825, are a pair of wrought-iron entrance-gates, by Hill & Smith, Brierly Hill Ironworks, Staffordshire, which do not appear to us remarkable either in the way of design or spirited treatment; and in Pavilion No. 2216, there are railings, &c., from Cockburn & Co., of Gowanbank Ironworks, Falkland, commonplace in design.

The slates produced in Scottish quarries are generally thick and heavy, but durable. Those exhibited by the Aberfoyle Slate Quarries, Limited, Class 1, No. 6, upon a small model, are of this description, and are of a quality to withstand the severe gales which visit the northern coast-line. The rock is also shown in different stages of its manufacture and of several classes. It does not appear to be readily obtained in slabs of extra size, and is more suitable for use than ornamental purposes.

Anderson & Sons, Marshall-street, Edinburgh, Class 1, No. 30, show rough and finished roofing slates from Craiglea Quarries, of excellent quality. This slate is suitable for ornamental purposes and mantel-pieces, finished with a very high polish, which brings out the colour admirably. The enamelled table, with landscape, is not so much to our taste. Slate may indeed be enamelled so as to resemble marble in a manner highly deceptive; but it is liable to be chipped, and, when the enamelled colour is light, the

dark material beneath painfully betrays itself. We have seen enamelled slate applied to exterior decoration, but in the course of a year or two it loses lustre, and becomes dull.

Pavement flags are to some extent now superseded by cement for footpaths, but they have one advantage over that material, they can be lifted and relaid. The best Scottish quarries are situated in Forfarshire and Caithness-shire. Of the latter we have specimens from Castlehill quarries, near Thurso, Court 2, No. 29, and from Forns Caithness Pavement Company, Limited, Court 2, No. 41. Slabs can be procured of any size required that can readily be carried by ship or rail, special vessels being constructed for exportation. The material is remarkable for the wear and tear it will sustain, and for its non-porosity. For water-tanks, heartstones, and fireproof flooring it is most useful. Currie & Co., Leith, Court 2, No. 27, exhibit fine specimens of Arbroath and Caithness pavement. Galloway & Co. show the same material, Court 2, No. 39, along with stone steps, bottles, &c., from the Gagie Quarries, near Dundee, and Arbroath steps, wrought by machinery, are exhibited in the grounds by Walters & Jackson, of Edinburgh.

THE SURVEYORS' INSTITUTION.

The annual general meeting of this Institution was held in the Lecture Hall, 12, Great George-street, at three o'clock on Monday afternoon last, the retiring President (Mr. E. F. Anson) occupying the chair. The ballot for the election of the new Council having been declared open, the annual report on the affairs of the Institution was read to the meeting. We append a few passages:—

"During the past year 55 new Members have been elected, viz., 3 Honorary Members, 25 Fellows, 22 Professional Associates, and 5 Associates,—making, with 34 new Students who passed the Preliminary Examination in January last, an addition of 89 new names to the roll. Against this, however, has to be placed a large deduction representing losses by death, retirement from the profession, or on account of inability to maintain the payment of subscriptions, leaving a net increase of 19 of all classes. There has been a slight increase in the income proper during the year, due in part to additional subscriptions, and in part to a slight increase in the amount of fees received for hire of arbitration rooms. On the capital side of the account a further sum of 2,000*l.* has been invested in New 2½ per Cents.

The Institution investments stood at Christmas 1885 as follows, viz.:—2,541*l.* 9*s.* 6*d.* Consols, on Revenue Account; 6,500*l.* 10*s.* 10*d.* New 2½ per Cents, on Capital Account; 5,397*l.* 11*s.* 2*d.* Reduced 3 per Cents, on Library Account; and 228*l.*, North British Railway Preference Stock, on account of the Crawter Bequest.

A sum of 1,000*l.* has been added to the investments in New 2½ per Cents during the present year.

The unabated interest in the proceedings of the ordinary general meetings is attested by the volume of 'Transactions' (the eighteenth of the series) now approaching completion. The Council have endeavoured, as far as possible, to consult the tastes and interests of the various classes of members in the order in which the papers have been taken, and this has necessitated the holding over of several excellent papers until next session. The welfare of the Institution is very largely dependent upon the character of the papers read and of the discussions that take place at the fortnightly meetings. The collection and dissemination of information was one of the principal purposes for which the Institution was established, and it may be claimed for the 'Transactions' that they have admirably served this purpose.

It appeared, however, to the Council that something further might be done in the same direction, without trenching in any way on the proper province of the 'Transactions,' by means of an occasional publication comprising short items of professional information of the nature and under the title of 'Professional Notes.' The two numbers of the new publication already in the hands of the members will enable them to form an opinion as to the nature of the experiment. Whether it will be justified by success will depend upon the support it receives from the members. The plan of the 'Professional Notes' is wide enough to embrace every kind of contribution, and, as members come to recognise their practical utility, the number of original contributions and items of interest communicated will, it is hoped, be largely multiplied.

The Examinations continue to attract an increasing number of Candidates, notwithstanding that proof is now required of previous practical experience in a surveyor's office. About the usual proportion have satisfied the Examiners, but the Council will lose no better knowledge in some of the more important subjects on future occasions.

The Council have carefully watched various measures recently introduced into the House of Commons affecting the interests with which surveyors are identified. It is impossible to regard some of these proposals as serious projects of legislation, or to look upon others as framed with a due sense of the consequences likely to result from their finding their way into the Statute-Book."

The report having been adopted and the ballot having been closed, the following was declared by the scrutineers to be the result of the voting:—

President.—Mr. William James Beadel, M.P. Vice-Presidents.—Messrs. E. P. Squirey, R. C. Driver, F. Vigers, and C. J. Shoppee.

Members of Council.—Messrs. T. Chatfield Clarke, D. Watney, J. Martin, W. Fowler, H. J. Castle, R. L. Cobb, A. M. Dunlop, C. Oakley, R. Vigers, T. M. Rickman, and R. G. Clutton (Members); Mr. E. Smyth (Professional Associate); and Mr. J. Wolfe Barry and Sir Richard E. Webster, Q.C., M.P. (Associates).

In the evening upwards of 100 members dined together in the Venetian Room of the Holborn Restaurant, the chair being occupied by the new President (Mr. W. J. Beadel, M.P.), supported by Mr. John Clutton (the senior past-President of the Institution), Sir Richard E. Webster, Q.C., M.P. (the newly-elected Associate of Council), Mr. T. Huskinson, Mr. W. Sturge, Mr. E. Ryde, Mr. T. Smith Woolley (past Presidents), and a large attendance of the Council.

ARCHITECTURAL SOCIETIES.

Birmingham Architectural Association.—On Saturday afternoon last this Association made an excursion to Fenny Compton and Burton Bassett Churches, Warwickshire, under the guidance of Mr. Jethro A. Cossins. On arriving at the station the party walked to Burton Bassett Church, which is picturesquely situated on the sloping ground, and contains good examples of Norman, Early English, Decorated, and Perpendicular work. A halt was here made for an hour to allow members an opportunity of taking away in their sketch-books, and with the aid of photographic apparatus, the many interesting details of the chancel. A walk over the hills brought the party back again to Fenny Compton, where a due inspection was made of the old village houses, chancel, and churchyard; notes were taken of all interesting details, and after sketching for another hour the party returned to Birmingham.

Edinburgh Architectural Association.—On Saturday last the members of this Association travelled to Carnock and Stirling on their annual excursion. Carnock House, over which the party were shown, is a most interesting and little-known specimen of Scottish architecture of the sixteenth century, exhibiting both the solid building and the picturesque grouping characteristic of that period. In the early part of the seventeenth century the windows of the south front were enlarged and dormer windows introduced into the roof, while of the same date there are some beautifully panelled and decorated ceilings in the dining-room and drawing-room. The party afterwards drove by Bannockburn and St. Ninian's to Stirling, where they were conducted over the Castle by Mr. David MacGibbon. The Sallyport, the old Parliament Hall, the chapel, the Douglas Garden, and the Palace were each visited in turn. The next place visited was Argyle's lodging, plans of which were exhibited by Mr. MacGibbon, who pointed out the portion built by the Earl of Stirling, as distinguished from the somewhat later portions added by Argyle. A feature not common in Scottish buildings of this period consists in a wooden staircase rising from the hall to the first floor, although this feature was common enough in English manions of the same period. The east and west churches were examined under the guidance of Mr. Washington Browne, who read a short paper on their history. Time did not permit of the party visiting Camhann-kenneth Abhay, so, after dining in the Golden Lion Hotel, they returned to Edinburgh.

Manchester Society of Architects.—The Manchester Society of Architects offers the following prizes, to be competed for by such draughtsmen as may be eligible, and by students serving their apprenticeship in the office of architects in Manchester, or in the office of any member of the Society, viz.: a first prize of five guineas, given by the Society, and a second prize of three guineas, given by

Capitals from the Wall Arcade, "Angel Choir," Lincoln.

the President, Mr. Redmayne, for the best portfolio of Architectural Sketches, including figured sketches. Mr. James P. Holden's prize, of the value of five guineas, for the best set of not less than four sheets of drawings of a good example or examples of Classic architecture, made from the actual building or buildings, with a short description of each subject. Further particulars, and conditions, may be obtained of the Honorary Secretary of the Society.

CAPITALS, LINCOLN CATHEDRAL.

These drawings of four of the beautiful Early English capitals in the choir of Lincoln Cathedral are reproduced from sketches by Mr. W. H. Bidlake, made on his tour last year as "Pugin Student" of the Institute of Architects.

EXAMPLES OF JAPANESE WORK.

We are enabled to illustrate a few of the objects in Mr. Ernest Hart's collection of Japanese art which was on view last month in the rooms of the Society of Arts. One great advantage this collection possesses over many others is that it is arranged in something like chronological order, with date and name of the artist or school attached, and the student

desirous of specific information stands some chance of having his desire satisfied. Too many collections of Japanese curios are simply a miscellaneous gathering of good and bad examples, ancient and modern reproductions made expressly for the English market, with little or no information about any of the objects. In fact, Japanese works too often are treated merely as curiosities, and it is only here and there that we find a collector who has gone to the trouble of classifying his collection. One great obstacle that has stood in the way of many collectors is the difficulty of reading Japanese characters, but Mr. Hart has been fortunate in securing the help of a Japanese expert, whose aid has been invaluable. Skilful workmanship is in part at least hereditary, and we find in Japan "schools" of work, or, in other words, families who have for generations devoted themselves to the production of one kind of work. Knowledge and skill are thus accumulative, and by this means a general proficiency is reached, whereas, with the individual system, we only get great excellence in specially-gifted persons, the general level of excellence being proportionately low, as in our own case. But the Japanese are breaking with all their old traditions and customs, and in the space of a few years have thrown their ancient civilisation to the winds, and in its place have taken a rather cheap "Brunnagem" thing, and this means an end to their own beautiful

characteristic work. When they at first broke with the past the Japanese shipped their work over to Europe without a moment's hesitation, where they found a ready sale for "curios," as they were generically termed, and in those times collectors had a good opportunity of buying the best, cheaply; but the Japanese themselves have taken to collecting their old choice work, and it is now no longer possible to buy good work at a low price. The Japanese have taken to manufacturing sham old work for the European market, and collectors had best be wary and on their guard, for, like the "Heathen Chinese," the Japanese are a match for most Western people in "business." Of the objects illustrated here, fig. 1 is a bronze carp. This fish, which often occurs in Japanese work, is held by the Japs as typical of endurance. Fig. 2 is a bronze figure of religious character. Fig. 3 is a beaten war-mask of hard iron of ancient manufacture, and is consequently a most difficult class of work to produce. It is made so that the nose and mouth parts can be detached so that the warrior could feed. Fig. 4 is a fine specimen of old bronze casting; cheap reproductions of this are often seen. Fig. 5 is a serpent in the act of attacking a frog. The original is a very fine piece of casting. Figs. 6 to 11 are knife-handles. The subjects of the decoration are sometimes religious, sometimes humorous, and at other times mere quaint conceits.

Decorative Panel: Conventional Treatment of Mistletoe. By Mr. F. T. Piggott.

DECORATIVE PANEL.

This panel represents a conventionalised treatment of mistletoe, the design of Mr. F. T. Piggott. It was exhibited some time since in the architectural room of the Royal Academy, when we noticed it as a very good example of decorative design founded on foliage forms. The original is in colour, with the stems of the leaves gilt.

Illustrations.

WINDOW IN THE BUTCHERS' HALL.

FIVE windows, by Messrs. Lavers & Westlake, — four representing the monarchs who have granted charters to the Butchers' Company, and one the arms of that corporation, — have been placed in their hall in Bartholomew-close. The monarchs represented are James I., Charles I., George II., and her present Majesty, — this latter window forming the subject of our illustration. These windows are the gifts of Messrs. Venables, Hart, Baker, and Kilby. The window is designed by Mr. Westlake.

STATUE OF BERLIOZ.

This statue is intended to be erected in the Square Vintimille at Paris, a few yards from the house where Berlioz died.

It is the work of Alfred Lenoir, grandson of the celebrated architect and antiquary. The statue is rather more than life-size, and has been cast in bronze at the foundry of MM. Thiébaud. The head, which is both very expressive and a remarkable likeness, has been cast,

with the hand, on the *cire perdue* system, while the remainder has been cast in the ordinary manner.

The statue, commissioned by a subscription committee presided over by Vicomte Delahorde, is to be erected on a stone pedestal of very simple character, designed by M. Boitte, architect, brother-in-law of the sculptor.

SHOPS AND OFFICES, NEW BROAD-STREET, CITY.

This block of buildings occupies a commanding position in New Broad-street, in close proximity to the termini of the Great Eastern and North London Railways, and opposite the Bishopsgate Station of the Metropolitan Railway.

The façades are constructed of Portland stone, with polished granite work on the ground story, and have a frontage to New Broad-street of about 220 ft.

The accommodation comprises six shops (some of which are sub-divided), with extensive basements.

The upper floors are arranged for offices, which will be divided to suit tenants, and, with very few exceptions, every office will overlook New Broad-street.

The entrance to the offices is planned to be quite distinct and apart from the shops, and comprises a boldly-treated arched opening, relieved with polished granite, conducting to a lobby and vestibule.

There are two stone staircases communicating with corridors on each floor, the walls being lined with tiles, and the floors laid with mosaic.

The whole of the works have been carried out for the Broad-street Syndicate, under the

superintendence of the architect, Mr. F. Adams Smith.

The contractors are Messrs. Wm. Brass & Son, and Mr. Thomas Bennett has acted as clerk of works.

ALL SAINTS' CHURCH, WALSOKEH.

THE three pages of measured drawings of this fine church are reduced from larger drawings by Mr. A. G. Adams, who was awarded a Medal of Merit for the originals last year by the Royal Institute of British Architects. Some notes on the church will be found in our first article this week.

ANGLESEY HOUSE, CARSHALTON.

THIS house, now in course of erection for Mr. J. Gibbs, is situated on Bandon Hill, with good views of the surrounding country. There is nothing very special about the construction. The walls are faced with local stock bricks, with Ham Hill stone dressings. The roof is constructed on the plan suggested by Mr. Ralph Nevill at the Institute last session, the rafters being lathed and battened, and covered with silicate breeze concrete, 1½ in. thick and the slates, which are Eureka slate nailed to the concrete. It was found necessary to introduce the slating battens, as the slates were found to drop slightly without them when the nails touched a small grain of breeze in the concrete; but with the batten the point of the nail just catches and holds the slate in position till the concrete is quite set. It makes an excellent roof, and is especially good for circular work. The work has been carried out by the builder, Mr. E. J. Burnand, of Wallington, Surrey, from the designs of Mr. Herbert D. Appleton.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

The tenth ordinary meeting of the present session was held on Monday last, Mr. Edward Fanson, F.G.S. (President), in the chair.

The New President.

The President.—As this is the first time I have been able to preside at one of our ordinary meetings, since you did me the honour to elect me as your President, I take this, the first opportunity which has occurred, to offer to you, gentlemen, my warmest thanks for having placed me in this very distinguished position. And you will better be able to understand how very highly I appreciate this honour, when I tell you that I felt very uncertain whether you would concur in conferring it upon me, because I feared you might think the large amount of attention and time I have bestowed on that branch of our profession which appertains to surveying might have so far estranged my mind and thoughts from the study and consideration of the more noble art of architecture that you might have hardly felt I was the right man to represent you as President of the representative body of architects. Therefore, I do feel grateful and especially proud of being the President of the Royal Institute of British Architects; for my ambition,—my sole ambition,—throughout life has been to be an architect. From the time, since about 1830,—when I was admitted a student in the Antique School of the Royal Academy, through an exceptionally long and very arduous professional career, the study of our art has never been laid aside, and all my leisure time has been devoted to it. And as a proof, I may venture to remind you that in 1837 I was the first to call attention at one of our weekly meetings to the restoration of the Temple of Victory Apteros at Athens, to exhibit measured drawings of the same, and a perspective in the Royal Academy; that I have notably been the means of calling your attention to, and making generally known, the then almost, if not entirely, unknown remarkable Medieval works in the Island of Cyprus; that I have also called more full attention to the architectural monuments in the Kremlin of Moscow and Central Russia; as also to the remarkable Cathedral of Trondhjem in the north of Norway, than had before been done; thereby convincing,—I trust you will feel,—that although I have largely profited as a surveyor, I have never ceased to be a student in that school to which I was admitted more than half a century ago. Again, gentlemen, I thank you very sincerely for the distinguished honour you have conferred on me. (The President's remarks were received with applause.)

Miscellaneous Communications.

Mr. William H. White (Secretary) announced the death, on the 22nd of May, of Mr. Richard Kyke Penson, Fellow, one of the elder members of the Institute.

The Secretary also announced that a dinner was being held that evening at the Hôtel Continental, Paris, by the French architects, in honour of M. Charles Garnier. The dinner, in the words of the communication he had received, was pour "fêter la grande médaille de Reine d'Angleterre."

Professor Kerr.—Perhaps you will allow me to say a word with regard to the decease of Mr. Penson, who was a singularly accomplished and amiable character. Very few members of our profession would suppose that a man bailing from a remote town in Wales could have been accomplished as Mr. Penson undoubtedly was. He was a gentleman in every possible sense of the term, being a country-gentleman may say, by birth, certainly by education, and manners most clearly so. I am sorry to hear of his decease, and I am sure you, gentlemen, will bear with me in paying this slight comment to his memory.

Mr. John Hühn.—I have been asked by Signor Boni, who was lately elected an honorary and Corresponding Member of the Institute, to thank the members for the honour they have done him, and at the same time to present some pamphlets which he has lately written on subjects connected with the history of Venice and its buildings, with a small piece of a pile which formed one of the foundations of the Arsenal. I may be allowed to say that Signor Boni is a man of exceptional ability and

of considerable erudition, and that not only has he a knowledge of the dead languages, but also a remarkable acquaintance with several living languages, speaking also very good English. He apologises for the length of time that has elapsed since receiving the notice of his election, but explains that he has been away. He sends only so many of his works as are in print, and promises that several others, which will probably be reprinted, shall be at the service of the Institute. He also says he has lately found two contracts for the building of the Ca'd'Oro at Venice, which he considers will be two of the most interesting documents illustrating the history of building in that city.

Mr. George Aitchison, A.R.A.—As I have had the honour of knowing Signor Boni for a good many years, I can endorse all that Mr. Hebb has said about him. I think we have been extremely fortunate in enrolling a man who is so devoted to his profession, who has so enlarged a knowledge of antiquities, and who takes such an immense interest in the particular features of the historical portion of the architecture of Venice. I may add that Signor Boni is one of the descendants of the builders of the Ducal Palace.

On the motion of the President, a cordial vote of thanks was passed to Signor Boni for the works he had sent.

Japanese Architecture.

A paper, entitled "Further Notes on Japanese Architecture," by Mr. Josiah Conder, was then read by his brother, Mr. Roger T. Conder. The following is an abstract of the paper:—

The author, after referring to his previous paper on the same subject,—communicated in March, 1878,*—alluded to the curious mixture, in the buildings of the Kiobu Shintō style (as shown by illustrations of the temple of Miyo-Jin, Kanda-Tokio), of the simplicity of the early Sinitic faith with the ostentatious display of the ordinary Buddhist temples. The oldest existing Buddhist temples differ but little in style from the most recent structures. Historical records assert that the early wooden Buddhist temples of Japan were erected under the direction of Chinese priests, leaving us to suppose that their work was gradually modified to suit the tastes of the Japanese. The planning of the Japanese temples is remarkable for the importance given to their approaches and landscape surroundings, and for the isolated arrangement of the group of accessory buildings, as exemplified in the plan shown of the mausoleum of Iye-yasu, at Nikko. The author then proceeded to describe generally the construction and details of ornamentation of an ordinary temple, considering such a building as a model of Japanese architectural art. These buildings vary greatly in size. The temple at To-dai-ji, at Nara,—a two-storied building, containing a statue of Buddha, 53 ft. in height,—measures 290 ft. long by 170 ft. wide, by 156 ft. high; that at Miyo-Jin, Kanda-Tokio, measures 66 ft. by 27 ft., by 40 ft. high to the ridge. The standard of measurement employed by the Japanese builders is the "ken," which is divided into twenty-two minutes, each minute being divided into twenty-two seconds. The "ken" in common use is understood to be six Japanese feet, or "shaku," the "shaku" being 11.93 English inches. The mats with which the floors are covered are always one "ken" long, one half "ken" wide. The "ken" is taken as the standard of measurement of the detached pillars, and of the pillars and parts of the wall enclosures. The wall-posts are framed into a large horizontal sill, the wall space above being subdivided by horizontal timbers, halved on both sides. Diagonal bracing or strutting is nowhere to be found. Detached pillars are square or circular, the circular ones being often reeded, and the square ones monied on the edges; and the lower ends rest upon flat stones or bronze moulded bases; the tops receive a square block of wood, generally consisting of a square and hollow. The principal facade is filled in one, two, or three compartments, with hinged doors, which are generally left open, and through these openings the light for the interior is principally obtained, windows, as we understand the term, being rare. An elaborate cornice of wooden bracketing crowns the walls, forming one of the principal ornaments of Japanese buildings. A very important feature of the facade is the portico covering the main entrance steps, covered by gable roofs of

various forms, having a considerable projection, and being often richly ornamented. The forms of roof used to cover the main building are various, but the general appearance of the ends is usually half hip and half gable. Heavy ribs of tile cresting, with large terminals, are carried along the ridge, hip, and along the slope of the gable, set some little distance back. The result of the treatment is very picturesque, and has the advantage of looking equally well from any point of view. A slight tilt is given to the corners of the roof, so that the eaves curl slightly upwards towards the ends. The interior arrangement of wall columns, horizontal beams, and cornice bracketing corresponds with that on the outside, the top beam of the bracketing supporting a panelled ceiling. The wood employed in these temple buildings is usually the native elm, called "keyaki," which is often left quite plain, without colour or paint of any sort. The ends of the timbers are protected by brass caps, and ornaments of the same material are added to the points where beams and pillars intersect, and to cover joints of timbers. Colour decoration, applied to the exterior of the building, has several grades or degrees of richness. The ruder kind of decoration consists of a coating of red (oxide of iron) or black (Indian ink), mixed with animal size. The common red is a raw, harsh colour inclining to orange, but the real vermilion red, made of vermilion mixed with size, or with lacquer, to be seen at Nikko and elsewhere,—is a deep, rich colour, slightly crimson in tint. For portions very much exposed to the weather, black lacquer is used. The application of colour decoration to exteriors commences generally with the lintels or ties, near the top of the posts or pillars. From this height, the different beams and brackets, together with the flat spaces and raised carvings between, are diapered, arabesqued, and variously picked out in bright colouring and gilding. Such a treatment imparts a light elegance to the otherwise ponderous eaves of the Japanese buildings; and the deep sun shadows, beneath the massive projections, assist in subduing and harmonising the bold contrasts of colour employed. The interiors of the principal sanctuaries are also in most cases elaborately coloured, the columns and posts in such a way as shall not be detrimental to their appearance of vertical strength, the horizontal beams in light colours, or in deep colours relieved by an abundance of white and gilding. The recessed spaces between beams and lintels, and between the cornice bracketing, are filled in with elaborate carvings, which are pierced if in internal divisions. The ribs of the coffered ceilings are generally lacquered black with gold lines on their edges, the enclosed panels being filled in with richly-coloured decorations. It is this decorative perfection, this application of the arts of painting and carving to the constructive arts, which imparts the great charm to Japanese structures, a charm of endless variety amidst perfect harmony. As the foster-mother of fine art, the Japanese style of building can lay special claim to rank as an important architectural style. The author then referred to the various accessory temple buildings, to the bishops' palaces, and the monasteries. The accessory buildings are usually the gateways, the font sheds used to cover the holy water basin, the belfries, the drum towers, the store-houses, and the pagodas; the latter, usually of five stories, contain shrines or wooden images in their lower stages, the upper serving no purpose but that of a belvedere; they average 150 ft. high, and are the only Japanese buildings which have sufficient height to assert themselves from any distance.

Mr. G. A. Andsley, in opening the discussion, expressed the pleasure he had experienced in listening to Mr. Conder's most interesting paper. The great glory of Japanese architecture was its marvellous system of carving. Prior to the sixteenth century he believed that little carving was applied to the temples or private buildings of Japan, but at the close of that century was born the famous Japanese left-handed sculptor who was practically the founder of the modern school of Buddhist architecture. Previously to that time there was little carving to the outside of the temples; but this carpenter,—for such he really was,—endowed with great genius and skill, apparently struck out the idea of employing carving for the beautification of the temples, and of applying it wholesale as a system of

* See *Builder* for that year, pp. 238, 263, 398.

decoration. The photographs showed how marvellously skilful this carving was, and the only blunder he had been known to make was in a temple at Nikko, where two elephants were to be found carved with their legs jointed the wrong way. Probably he never saw an elephant. From the time of this great carver, till the decay of Buddhist architecture, Japan seemed to have poured forth one endless mass of carvings, marvellous not only for their dexterous manipulation, but also for their beauty of design and appreciation of the works of nature. Flowers, birds, fish, waves, and waterfalls, were all treated in a manner which was perfectly decorative, and seemed to have grown into their place rather than to have been carved. It was a system of decoration which obtained nowhere else, it was special to Japan, and it raised Japanese architecture to the dignity of being one of the great architectures of the world. The Japanese had never indulged in stone architecture, except for the basements of their buildings, on account of the frequency of earthquakes. Mr. Andsley concluded by moving a vote of thanks to the writer of the paper.

Professor T. Roger Smith, in seconding the vote of thanks, remarked that he had the pleasure both of relationship and of intimate friendship with Mr. Conder. The paper was a very good illustration of the way in which a man who found himself in a foreign country, with objects of interest before him, might serve a great many of his countrymen at home. Mr. Conder's business in Japan was not to study the native architecture, but to teach the young Japanese something of the architecture of Europe, and to practise in styles very different to those they saw before them in the drawings on the screen. Mr. Conder appeared, however, to have taken the opportunity of minutely studying the buildings of the native architects, and the record of his work would be sufficient to show any of the members who might visit Japan what they should look for, and should render the works of Japanese architects much more intelligible. The architecture of Japan struck him as showing an extremely complete style. Mr. Conder had put before them the whole anatomy of the temples and their decorations, and had afforded a glimpse of a complete style entirely different from anything they had to deal with. As was pointed out by Mr. Andsley, the architecture of Japan was essentially a timber architecture, but its decorative side had been carried much further than we in Western Europe had ventured. A great deal might therefore be learned from the success of Japanese architecture in the way of decoration. He could not but hope that a careful study of Japanese art in many ways might stimulate us, not to put these decorations into our own buildings, for that would not be learning the lesson of consistency, but to increase the amount of colour decoration and carving, so as to make our interiors far more splendid and rich than they hitherto had been.

Mr. R. Phené Spiers remarked that he had been asked to look through his collection, by Mr. Conder, to see if he could supply any further illustrations of architectural subjects. He had, therefore, looked out a few books, and it was interesting to note that one of the greatest artists of Japan had not considered it beneath his dignity to include in two of his works a number of drawings of architectural models. In the course of inquiry he found that in the ninth century there existed a celebrated man, called Hidano-Takumi, who laid down laws which had regulated Japanese architecture to the present day. Those laws were not laid down in writing, as were those of Vitruvius, but were handed down by tradition; and, although there were no works which represented the ideas of that celebrated man, still, temples which had been built from the instructions he gave, had, when in a bad state and ready to fall down, been re-built in exactly the same form and with the same decoration and details. It would appear that in the sixteenth century these temples were further enriched by carving and painting, but that would not alter their main form; and from the apparent regularity of disposition, and the scheme of setting out the number of feet between the different posts,—all this must have been laid down by some great man at an early period, and the tradition might have descended to later times. One of the characteristic features of Japanese architecture

was the use of timbers which, through some freak of nature, were not straight. These, in England, would, generally speaking, be rejected, but the Japanese delighted to make use of an irregularity of nature. Consequently, in some of the buildings these twisted timbers were to be found turned to good account, and rendered most picturesque features. This Hidano-Takumi was also said to have invented a method to prevent lofty pagodas being overturned by earthquakes. He is said to have found that if from the top of a lofty pagoda a huge hulk of timber was suspended, its oscillation would keep the pagoda from being blown down. He understood, however, that Mr. Conder had never found the timber left free.

Mr. Aitchison, A.R.A., said that photographs and drawings of Japanese buildings showed that the work was often very beautiful, and a rather fine effect was produced by the number of successive roofs put on the pagodas. With regard to Japanese ornament, over one-half of the modern ornamentation of domestic articles was now founded on the Japanese principle, and it also afforded infinite means of study in regard to colour. He hoped that Mr. Conder, or some coadjutor, would be able to transmit to the Institute the drawings of some of these old temples, the interiors of which were said to be some of the most splendid specimens of colouring the world had ever seen. The Japanese Government might be induced to have diagrams made of some of their finest temples, which were said to be virtually going to decay, or her Majesty's Government might be memorialised to send out artists to make some kind of delineation of them, so that those triumphs of colouring might not be lost to England and the world.

The vote of thanks was then carried by acclamation.

Mr. Roger T. Conder, in returning thanks on behalf of his brother, referred to the question which had been raised as to the pagodas. He also read a letter on the subject addressed to his brother by a Japanese professor of architecture, who had examined a great many of these structures, and who stated that the assertion as to the central swinging post could not be invariably true; that there might be some examples of it; but that he had never been fortunate enough to meet with one; and that he believed it was never intended that the post should swing.

The proceedings then terminated.

THE ROYAL STAND, EPSOM.

THE first new additional building has been erected at the west end of the old Grand Stand, and consists of a large saloon, 50 ft. by 36 ft., with arched ceiling, the cornice and frieze being carried by pilasters with carved Corinthian capitals, the total height of the room being 22 ft. At one side of the saloon there is a wide refreshment-bar; a portion of this room is partitioned off for the use of the Telegraph department, and a pneumatic tube is placed here, in connexion with the instrument-room, so that the general public using the Grand Stand can send their messages without going outside the building. The room is lighted by large windows at one side, in addition to a ceiling-light. Between the saloon and the course, lavatories and other conveniences have been erected for the use of the general public using the Grand Stand, thus adding greatly to the comfort of visitors. Running past the Grand Stand and the saloon, a wide passage has been made leading to the lawn, with a new staircase at the north-west corner of the Grand Stand. This staircase facilitates the gaining of the second balcony, which will mitigate the crush at the other entrance. Beyond the saloon, which may be considered as an integral part of the Grand Stand, is the vestibule and entrance to the Royal and Club Stand. The entrance-hall is 32 ft. by 24 ft., the approach to it from the vestibule at the entrance being cut off by an arched screen, constructed of huff terra-cotta; the two arched openings on either side are filled with stained glass. The walls of the entrance-hall are tiled, with a brown majolica dado, black tile skirting and capping. This is continued round the screen to form the base of arcade. Above, the walls are covered with cream-coloured tiling. The hall is partly lighted by two ceiling-lights, filled with stained glass, the design and colouring of which are Indian in style, the ceiling being panelled, with moulded cornice and

enriched frieze. From the entrance-hall a stone staircase runs up through the building, giving access to the balconies and standings. The staircase is lighted and ventilated by windows on the landings, and by a lofty lantern-light, rising to a height of 70 ft. from the ground, and surmounted by an iron grille, in the centre of which a lofty flag-post is erected. The dining-hall, a fine and spacious apartment, 50 ft. by 40 ft., and 18 ft. high, is to the right of the entrance-hall. The walls are relieved by fluted pilasters having Ionic caps carrying the frieze and enriched cornice, moulded panels being formed between the pilasters, with a dado carried round the room; the ceiling is panelled, with moulded ribs. Two refreshment buffets, with mahogany and walnut fronts and marble tops, are placed at the end of the room, and a doorway leads to the kitchen and large store-rooms. At the back, a dinner-lift runs from the basement, and communicates with the Jockey Club luncheon-room and the Prince of Wales's rooms.

The rooms for the use of their Royal Highnesses, the Prince and Princess of Wales consist of sitting-room, 30 ft. by 16 ft. and 11 ft. high, lighted by three windows, overlooking the course. The ceiling is enriched by a raised-geometrical pattern in plaster, and a decorative frieze and cornice surround the room; the dado is formed of Lincolnshire-Walton, with moulded capping. The mantel-piece is of wood, with carved over-mantel and tiled hearth. The lights to windows are filled with stained glass, designed in the Renaissance style. A private staircase, for the exclusive use of H.R.H. the Prince of Wales, leads to the Jockey Club room. The luncheon-room is 24 ft. by 16 ft., and adjoins the sitting-room; the decoration is similar in all respects, except that the general treatment is varied. A servery is placed at the back of the luncheon-room, and communicates therewith. The Princess's retiring-room is entered from the sitting-room. The walls are tiled, with a majolica dado, dark border and skirting, and French grey tiling above.

Adjoining the Club Stand, still to the west, come what may be called the rooms devoted to the actual business of racing, being the jockeys', press, telegraph, and weighing rooms, and the room for the clerk of the course. The press-room is a very comfortable apartment, 16 ft. by 30 ft., with a flight of stairs leading immediately from the room to the reporters' balcony. At the back of this balcony, which is about 35 ft. long, are the lavatories, cloak-room and other conveniences set apart for the use of the press. Another great improvement upon the ordinary location of the telegraph will be a short passage leading from this balcony and communicating directly with the large instrument-room behind. This room is 36 ft. by 35 ft. and 18 ft. high, with an open-timbered roof which is stained and varnished. Accommodation is provided for 100 telegraphic operators. On the ground-floor there are two telegraph rooms, one for the use of the Grand Stand public, the other for the use of the general public. The new Club Stand is a very commodious structure. Although it is not so high as its larger neighbour, the Grand Stand, it has the same length of frontage. The first balcony is partly reserved for the use of the members of the Jockey Club, and partly for those of the members of the New Club, which will be limited to about 700 members. Over this, again, is the second or royal balcony.

The whole of the work has been carried out by Messrs. Colls & Sons, builders, London, from the designs and under the superintendence of Mr. J. Hatchard Smith, architect, Moorgate Station Buildings. The stained glass is by Mr. E. A. Oldaker; the enriched ceilings are made of Messrs. Jackson's fibrous plaster; Messrs. T. Shaw & Co. supplied the ironwork; the terracotta screen is by Messrs. Doulton; Lascaille's concrete has been used throughout for landings, pavings, &c. The buildings are enclosed by a flint wall with large stone gate-piers; the gates are of wrought iron with a shield. Mr. French has acted as clerk of the works. The building has cost about 11,000*l.*, and the work has been completed in six months, notwithstanding the severity of the winter.

British Museum.—Mr. John A. P. MacBrick delivered his third lecture (subject, "Early Greek Sculpture") on Tuesday last. The next, on Pheidias, will be given on Tuesday next, at half-past two precisely.

THE CONSTRUCTIVE TREATMENT OF CONCRETE.*

THE first use of the word "concrete" probably (as Mr. Geo. Godwin supposes) dates somewhere between the years from 1815 to 1820, and has been derived from the Latin word "concretere," to "grow together." As that idea is involved when we use the word "concrete," the writer of this paper proposes to use the expression "extraction of concrete," when "building up concrete" is meant; because to speak of the construction of concrete, i.e., the putting together of a thing that grows together, seems rather absurd, and, therefore, the extraction or building-up of concrete would be a happier term.

Not a few works have been written upon concrete; but the three principal that are likely to be of use to those interested in this paper are "The Nature and Properties of Concrete," an essay by Mr. Geo. Godwin, published in the Transactions of the Institute of British Architects for 1835, vol. i., p. 1; "Concrete as a Building Material," a paper read by Mr. Alexander Payne before the Institute of British Architects on the 10th of April, 1876, which, together with its discussion by many eminent practical men, was continued on the 15th and 20th of May of the same year, and will be found in the "Transactions" of that Institute; and, lastly, a small book by Mr. Henry Fajia, entitled "Portland Cement for Users," published in Weale's Series of Technical Works.

Allowing that it is entirely within the province of the chemist to say whether lime or cements are the more suitable for certain classes of work under other than ordinary conditions, as, for example, marine work, in speaking of which M. Poirel (in his "Mémoire sur les Travaux à la Mer, comprenant l'Histoire des Ouvrages exécutés au Port d'Alger, et l'Exposé complet et détaillé d'un Système de Fondation à la Mer au Moyen de Blocs de Béton") says that "he believes that none of the Roman cements are capable of resisting the destructive action of the salts contained in the sea water, and he has no doubt but that all the English harbour works executed in Portland cement are doomed to more or less speedy destruction. For the last fifteen or twenty years the use of the Roman *pozzuolana* has been abandoned in France, and the concrete employed for marine works has been made with lime from Thiel, a village in the department of Eure, fifteen miles from Louviers. It was used exclusively at Algiers, London, Marseilles, and the harbour of Saida. The future will show whether these blocks will resist the action of sea water as well as those of the Roman *pozzuolana* is an ingredient." M. Poirel regards this as the only material capable of forming a perfect concrete for marine works. It is certain that for the ordinary purposes of walling and such-like, 1st, the setting or hardening of lime concrete is not uniform throughout the mass; 2nd, owing to its low tenacity, its surface (and, therefore, the arries) is liable to injury; 3rd, expansion takes place in the concrete during the slaking of the lime, and in some cases local expansion, or, what is technically known as "blowing," takes place in the mass; 4th, lime-concrete is not impervious to moisture, as is Portland cement concrete; and lastly, it requires a longer time than cement concrete to thoroughly harden, and without a proper admixture of and will never become hard. Some of these points have been noticed in the "Professional Papers" of the Royal Engineers.

Referring to the tenacity of lime concrete, I will quote from Mr. Fajia's book, "Portland Cement for Users," in which, at p. 50, he says that:

"The erroneous impression regarding the cost of a cement mortar or concrete, as compared with one of lime, another point which has hitherto in many cases precluded it from being used; but inasmuch as a concrete or mortar can be made with a very much smaller proportion of cement than of lime, and yet be of greater strength, it becomes a simple matter of calculation which is the cheaper and will still satisfy the requirements of the work."

If an ordinary lime concrete is required to be, say, 12 in. thick to support a given weight, and the proportion of lime to the aggregate be as one to four, an equally strong mortar would be secured by adding a cement concrete 6 in. thick and with a proportion of cement to the aggregate of not more than one to seven or eight, so that it would be as saving, not only in the amount of cement used against the quantity of lime, but there would also be the saving due to the less amount of labour necessary to produce the smaller amount of concrete. That good cements and mortars may be produced with a very small

portion of cement, and at a very low cost, is shown by what Mr. Bernays has done at Ghent. The proportion he used for the dock walls was one of Portland cement to twelve of river shingle, and he explains that the concrete thus made was cheaper and stronger than the lime concrete, which it was originally intended to use. Mr. Bernays also calculates the cost of a cubic yard of cement concrete, based on ordinary London prices, at

		Yard onhe.	
		s.	d.
12 parts shingle to 1 of Portland cement	...	7	2
" " " "	...	8	24
" " " "	...	10	3

The cost of a grey lime mortar, as given by Mr. Coulson, the proportion being one of lime and two of sand, is 11s 3d shillings per yard cube and its tensile strength at six months 36/85 lb. per square inch.

Comparing it with the three following Portland cement mortars:—

Cement.	Sand.	Tensile strength.	Cost per yard cube.
No. 1 6	103.79 11.96
" 2 8	63.80 9.93
" 3 10	50.16 8.83

It seems that cement may be used in the small proportion of one to ten of sand and still be stronger than a lime mortar of the proportion of one to two."

Put in another way, the Portland cement concrete, ganged 1 to 10, is 30 per cent. stronger and 25 per cent. cheaper (for the same bulk) than lime concrete ganged 1 to 2.

"That cement is, therefore, a more economical material for use than lime there can be no doubt, but that it is advisable to use it as mortar with such a very large proportion of sand is somewhat doubtful. It would be found to be so very gritty and unmanageable that a small proportion of loam would have to be added to render it soft and workable. This would of necessity reduce its strength, and it would, perhaps, be desirable to be satisfied in procuring a greater strength without reducing the cost, as compared with lime mortar."

A concrete is composed of two parts, a matrix and an aggregate, and Portland cement concrete has a matrix of Portland cement, whilst for aggregate almost any material may be used, with a few exceptions.

Portland cement concrete (if made with non-porous aggregates, such as gravel, slag, &c.) is impervious to moisture, and yet, at the same time (if not hydraulically compressed), will take up a sufficient quantity of moisture from the air to prevent condensation upon the surface of such walls as may be built of it. It not only resists the disintegrating influences of the atmosphere, but becomes even harder with the lapse of time. When the material is newly cast it can be cut and carved with great facility. By using different aggregates this material may be made so hard that a nail cannot be driven into it, or sufficiently soft to become a fixing for joinery. It may be made in several different colours, and can be finished off to nearly a polished surface, or can be left quite rough. It will further take an exact impression of the mould in which it sets, because with a "true" Portland cement there is neither expansion nor contraction in setting. Being a bad heat-conductor, it is an excellent material with which to erect dwellings much exposed to extremes of heat and cold. Being also non-porous (when a non-porous aggregate is used) no moisture can get into the walls of a dwelling, and no damp-course is therefore required. Farther than this, if there be sufficient gravel upon the site of the building to be erected, it can be used (provided all clayey matter be washed out) as the aggregate; or even if clay be found upon the site, it may be used as the aggregate, provided it be well burned; but this latter would not form a non-porous aggregate. In seaside localities the (salt) shingle from the beach may be used, and sound and dry walls will be obtained. The use of concrete as a material for building will be found to meet all the defects set forth by practical people, as it may be made fire-proof, vermin (large and small) -proof, and nail-proof, which last property will be found to be very beneficial in the commonest class of dwellings, usually occupied by those of our race that have the hump of destruction largely developed. These, then, are the properties of Portland cement concrete.

With regard to the erection of walls in concrete, we have three divisions of our subject.—Firstly, the casing system; secondly, the block system; and thirdly, the slab system.

The Casing System.—This system, no doubt, was that employed by the Romans and in most of the structures of antiquity; for in the walls of the fortress of Ciudad Rodrigo we see the marks of the boards that retained the semi-fluid concrete of which they were formed. This system of building walls is the commonest in use. Two sheetings of planks and boards are formed, and being placed in a vertical position, and with their surfaces parallel to each other, at a distance equal to the thickness of

the wall, they are made to contain the semi-liquid concrete, which sets and forms a solid mass between the casings. The casings are not erected of a height equal to that of the wall, but the work is done in lifts, the casings being shifted upwards from the bottom of the work as soon as it has become sufficiently hard to allow them to be removed. The system commonly adopted, however, provides no scaffolding, but a modification of it was made by Mr. Tall, who called it his "bracket scaffolding." In this system the casings were kept parallel by means of tie-pieces passing across the wall, and having shoulders to them, and on the outside of these casings brackets were fixed, to do the same duty as putlogs do in ordinary scaffolding, viz., to support the scaffold. Thus the scaffold was supported by the wall as it progressed. Mr. Drake's casing system consists of an iron apparatus formed of sheet-metals, riveted together in sections and sliding upward between iron uprights that have been fixed "plumb" beforehand. Bolt-holes are left in the work as it proceeds, and by this means brackets are affixed to it for the purpose of supporting a scaffold at the required heights.

A derrick, with block and fall, is used to hoist the concrete in buckets. Henley's system is a wood-casing system, the casings being supported by uprights. The casings are, however, pivoted to the uprights, so that by merely reversing each section it may be made to travel upward as the work proceeds. It is not for me to pass judgment on any particular form of the casing system, but I will mention a few of the disadvantages under which the system itself lies. There are difficulties experienced in the introduction of separate courses of moulded work, and also in introducing any kind of heavy ornament upon the face of the work. A good and durable face that will not burn off, and of a good and even colour over the whole work, can seldom, if ever, be attained. Again, the treatment of the face is difficult, owing to the awkward position in which the work is placed for the operation of the workmen; and lastly, it entails an enormous waste of material in cutting the casings to suit the work. I will take the average contractor's price for doing the plain work. It is this:—

External Face of Wall.		Yard super-
		s.
Use and waste of casings, &c., at 2d. per ft. super.	1 6
Render and float ½ in. thick with one part of cement to two parts sand, and joint in imitation of stone	2 0

Internal Face of Wall.		Yard super-
		s.
Use and waste of casings, &c.	1 6
Render internal face of walls with a thin coat sufficient to fill the interstices in one part Portland cement and two parts sand	1 0

This gives us 3s. for two faces of one yard each. As I am now only dealing with the methods of treating the surface, it is unnecessary for me to take the cost of the filling, as that will cost much about the same wherever it is deposited, and as I wish more to compare the slab system with the casing system, I shall omit comparing it with the block system, which everybody knows is the most expensive of the three.

The Block System.—The block system has been spoken of by several eminent men as no concrete system at all; for they say it is merely a system of using building stones, no matter how those stones have been formed. It works under the disadvantage of having to deal with cumbersome masses of material that could just as well have been used in less bulk; it gives us a wall having all the defects of a stone one, particularly the through joints, which very often allow driving rains and winds to pass along them; and lastly, it takes no account of the monolithic principle which is found to be so beneficial in foundations, and which, applied to the walls, is merely an extension of the foundations upwards. The ordinary block constructions are formed in the same way as those of stone, with the exception perhaps that better joggle-joints and dowel-holes can be formed at a less cost than in stone. For this reason (viz., the less cost for working) also, blocks of special form can be made more cheaply in concrete than they can in stone, and Mr. Beamish, of Queenstown, has made prisms of H, or rather I, section, which are made to tooth into each other, and to form submarine structures. It can be seen that in this system the vertical joints of the blocks are kept together, and the structure can accommodate itself to an uneven foundation. Another form of block is

* From a paper by Mr. F. West, read before the Institute of Inventors on the 17th ult.

that of Mr. Woodhouse, of Bridgwater. Many advantages are claimed for this block, but the chief seems to be that dry walls are ensured by the air-passages formed in the centre of the wall. In speaking of concrete, to urge such an advantage as this is absurd; because, whether the inside of the wall be hollow or solid, no water can pass through the material on account of its impermeability; but if it be intended to show the advantage of the form for a block to be made in any material, it is a good point.* The greatest advance, however, in the block system is the skeleton-block system; and as these blocks are rather of a doubtful classification, I prefer, for the sake of convenience, to put them under the heading of slabs. I therefore now refer to

The Slab System.—Hitherto the great difficulty in constructing walls of concrete slabs has been to prevent the slabs from being forced outwards, or from toppling over by the pressure of the plastic filling-in material from the time of its deposition between the slabs until it has become sufficiently hard to form with the slabs a solid wall. Several devices have been used to obviate this difficulty:—(1) Temporary ties or gauges connecting the slabs forming the two faces of the wall have been used, and these have been removed as soon as the plastic filling-in material has become hard. (2) Permanent ties or cramps, which, as their name implies, have been allowed to remain in the wall, and to be entirely buried in the plastic filling-in material. These permanent transverse ties have been of two kinds: those which were affixed as soon as the slabs were placed in position, and those which were made to form part of the slab during the period of its manufacture, as, for instance, slabs (really skeleton-blocks) of Z or H horizontal section. (3) Slabs of L section (these might also be called skeleton-blocks), vertical or horizontal, and some with a kind of buttress projecting from the back of the slab into the wall, have also been used, as well as slabs having a wide base, and when these have been bedded, or a thin layer of plastic concrete has been deposited between that on the inner and that on the outer face of the wall, and this layer of concrete has become hard, a transverse-tie had thus been formed. Or these same slabs have been used, and a temporary tie has been placed across their upper edges during the time that the filling behind them has been in a plastic state; or else these same slabs have been shored up from the outside of the wall. (4) A casing has been formed by means of the slabs entirely of concrete, those slabs forming the faces of the wall in the unfilled courses being keyed to the slabs below that form the faces of the wall to the filled courses. In this system, therefore, any kind of transverse-tie to be used during the process of construction, or rather of extrusion, is entirely dispensed with, and the courses of slabs above depend solely upon the courses of slabs below them for their stability and rigidity up to the time that the filling-in material has been deposited and become hard behind them.

As the objects of all slab construction are:—(1) To retain and to mould the plastic concrete used in forming the wall; (2) to key or fix the slabs to the mass which they themselves have moulded; and (3) to form a facing to the wall,—it is seen that all the devices mentioned above are not of permanent utility, but are only temporarily required. For when the three objects have been attained there is no need of any transverse tie whatever beyond that which naturally obtains in a concrete wall. I will now illustrate these principles by some examples. The first I mentioned was slabs with temporary ties or gauges. These were generally placed across the upper edges of the slabs forming the inner and outer faces of the wall, and extended down the faces of the slabs to the next course. They could not be relied upon for building a wall plumb, as their angles might have been easily knocked out of square. The second was slabs with permanent ties or cramps. These were buried in the mass of

* Messrs. Parr & Strong are the inventors of a cellular system, as it is called. The blocks are really hexagonal tubes of terra-cotta and other material, containing a filling of concrete. The hexagonal teeth in each other to form the bond, and the open ends of the pipes, which show the concrete filling, form the faces of the wall. This is very effective, but a similar face to the wall may be obtained by using the slab system of West and at probably a quarter the cost. A wall outside Messrs. Oakley's, in Westminster Bridge-road, is built of Messrs. Parr & Strong's tubes. (Illustrated in *Builder*, vol. xxvi., p. 334.)—F. W.

concrete filling, and remained there permanently, because they were placed in such a position that they could not be extracted after the setting of the concrete. Iron ties seem to have been first used, and these were hooked into eyes cast into the slabs, or else into holes formed in them. In Sidebotham's system metal ties are used, but he also uses a transverse tie of I horizontal section, formed of concrete, and each end of this tie fits into grooves in the back of the slab. Drake has a system somewhat similar in principle, but with a little alteration in the form of the ties, and, instead of a square edge to the slabs, has a tongue-and-groove joint. Lish's slabs (or rather skeleton blocks) may be of Z L T or H (Greek character) form; but his Z form, the only one shown in his specification, is not a happy one, as special slabs must be made for every thickness of wall. The form of the slab forbids its transport, and the awkwardness of moulding forbids its manufacture. It is the same, more or less, with all skeleton blocks. Before mentioning those under the next heading I will call attention to the slab or skeleton block of Lee and Beale. This is of L horizontal section, but as its return end extends right across the wall it must be classed with the permanent transverse ties. It has, no doubt, several good points, as, for instance, the saving of one transverse tie, and also the ensuring of accuracy in building a wall; but, if the cost of producing the slab be gone into, it is too expensive to compete with other systems. Under the third heading I class Lockwood's slab. This is a slab of L vertical section, the foot of the L extending for a short distance into the wall. Only one course at a time can be built up with this slab. It is no doubt a very simple form of slab, almost too simple, because no tie between it and the filling is obtained over a large part of its area, but it obeys the proper principle of slab construction, inasmuch as it can be used for any thickness of wall. It must, of course, be bedded upon each course, and a tie might have to be used here and there across its upper edges.* Potter's is on somewhat similar principles, except that he does not get such a large bed surface, but he improves the key-hold of the slab by forming dovetailed projections, which extend down the slab at each end. These projections are further buttressed inwards, and therefore project farther into the heart of the slab at the lower edge of the slab than they do at the upper. Temporary ties are used with these slabs, and if necessary permanent transverse ties can be formed by simply depositing a thin layer of concrete between those on the inner and those on the outer faces of the wall and allowing it to become hard. In another system of Mr. Drake's the slabs have all been held together by a framework, which is shored up from the outside of the wall, and this has been removed when the slabs have become keyed to the wall. This latter, however, is really a casing system, but without the advantages possessed by that under heading 4; for in this of Drake we have expensive metal tie-rods and bars in addition to the slabs, and also the additional cost of fitting up the slabs to form a casing.

[The lecturer, in conclusion, described his own system of concrete construction, which was described and illustrated in the *Builder* for June 20, 1885.]

Liverpool Exhibition.—Messrs. Maw & Co ask us to mention that they have on view here a collection of specimens of their best work, including examples of "Anglo-Persian" tiles, which are reproductions of ancient examples found in Oriental mosques and palaces, both as regards design and execution, and "relief-enamel" tiles executed in raised enamels on terra-cotta grounds of various shades and colours; these are intended to meet a demand for fireplace tiles not uniformly glazed or enamelled. The same firm also exhibit examples of "Benthall-ware," in which designs, modelled in relief, in red terra-cotta, are enriched by the partial application of colour in enamels; and sgraffito tiles, which are entirely hand-work, and are used in fireplace and wall decoration where cost is not such a consideration as the production of an artistic result.

* This slab of Lockwood is exactly similar to Taylor's brick which he used for concrete walling, with the exception, of course, that this brick was made of burned clay and of the size of a brick. (Illustrated in *Builder*, vol. xxvi., p. 658.)—F. W.

CASE UNDER THE METROPOLITAN BUILDING ACTS.

NOTICE AS TO SHOP FRONT.

In the case of the District Surveyor of St. Giles's, r. Peck, heard at the Bow-street Police Court before Mr. Vaughan, the defendant had taken out an old shop-front at No. 96, Oxford-street, and had put in a new one without giving notice to the District Surveyor. The District Surveyor had requested the builder to give notice of alterations done to a shop-front, in fixing new sashes and stall-board, also altering the position of the entrance-door; the cornice and plaster remaining as before.

Defendant contended that the work was only a necessary repair, and as such not requiring notice to be given.

The Magistrate decided that the work done was more than could be considered as a necessary repair, being a new shop-front, and that, to the extent of such alteration, it was subject to the regulation of the Act. A penalty of 20s. and 12s. costs was imposed.

"LIGHTS."

SIR,—Can any of your readers refer me to some reliable authority in dealing with such a case as the following?

A certain property consists of a public-house and a mews in the same ownership, but forming separate holdings. The mews is held on a lease, and a portion of the boundary between the two holdings consists of an imaginary line drawn between two fixed points and running parallel to one side of the public-house main building and about 10 ft. therefrom. The tenant of the public-house has received permission from the owner to extend his premises on that particular side by building up to the boundary line. There are several "lights" on the side referred to, and the question is whether the lights can be retained in the extension without the permission of my client, the lessee of the mews. SURVEYOR.

** If these lights have not been enjoyed without obstruction for twenty years the lessee of the mews can clearly obstruct them, that is assuming also that the lights in the addition are in fact the same as the former lights, though somewhat advanced.

DUSTBINS.

SIR,—May I ask a little space in your influential paper to say a few words on a little (?) grievance that exists in this parish (Fulham)? On Sunday I inspected some houses in the locality of "Hurlingham," and was horrified to see the dustbins of a row of houses quite underneath the kitchen windows,—so near that the servant would only have to lift up the window and empty the ashes and refuse into it. Surely this is indeed an evil, and the result of such a nuisance on the health of the incoming tenants must be lamentable, especially to the poor servant who has to breathe this foul atmosphere. Who is answerable for this?

A WOULD-BE TENANT.

THE NEW GOODS DEPOT FOR THE MIDLAND RAILWAY.

SIR,—In your account of the St. Pancras Goods Station [p. 777, ante] you state that the ironwork was entrusted to three firms, giving the names, but, as we were the makers of the whole of the wrought-iron screens and gates, and have more in hand, and our name is omitted, we shall be much obliged if you will supply the omission next week.

THOMAS FUTTER & SONS,
South Molton-street.

Sanitary Institute of Great Britain.

The annual general meeting was held at the Parkes Museum of Hygiene, on Thursday, May 27th, Captain Douglas Galton, R.E., C.B., F.R.S., in the chair. Report was made by the Council on the work accomplished during the past year, attention being especially called to the examinations for local surveyors and inspectors of nuisances. Sixty-four candidates presented themselves for examination during the year, and the Council are glad to see that local authorities are beginning to appreciate the importance of appointing properly qualified men to fill these offices. It was reported that the Council had accepted an invitation to hold its next congress and exhibition in the City of York. An address of much interest with regard to sanitary science was given by the chairman, and the officers for the ensuing year were elected, the President being His Grace the Duke of Northumberland; Trustees, Sir J. Lubbock, bart., Dr. B. W. Richardson, F.R.S., and Mr. Thomas Salt.

The Student's Column.

OUR BUILDING STONES.—XIII.

THE SELECTION OF STONE (continued).

WE have frequently alluded to the action of the atmosphere in destroying stone in large cities and in the country, and pointed out both the principal causes and effects in connexion therewith. We have now to consider other destructive and preservative agents which affect certain districts only.

We will first consider rain. The amount of rainfall in some districts is much greater than in others. Now, we have seen that the action of rain and its impurities are the principal causes of the decay of stone, and it will, therefore, be quite evident that the rainy districts require more durable stones than those in which the annual rainfall is less. To reduce this to its minimum, we might now that in rainless countries no care whatever need be exercised in selecting stone, as far as durability is concerned, for in those countries very soft and bad stones will last for a considerable length of time. We will, however, confine our attention to this country.

In winter time the land on our western coasts is colder than the adjacent sea. Thus, when the warm and damp air of the Atlantic arrives on our shores it is chilled on contact with the colder surface of the ground, and rain is the result.

Moreover, the land being mountainous on that side of our country, the damp air is forced to ascend into the colder regions of the atmosphere. Thus another mode of condensation comes into play, helping to increase the humidity of the climate.

Being thus deprived of its moisture, the air, as it travels towards our eastern shores, is comparatively dry. Consequently the annual rainfall of our western coasts is considerably higher than that of the eastern.

The annual rainfall at sea-level ranges from 60 or 80 in. on the west coasts of Ireland and Scotland, to about 20 in. on the east coast of England. In some localities, however, the fall is much greater, amounting to 154 in. on the average of six years, at Seatwaite, in Borrowdale, at the height of 422 ft. above the sea.*

But even as far as our western coasts are concerned, local circumstances so much influence the amount of rainfall of a district, that it is necessary, in estimating the rate of decay of building stones in a certain town, to ascertain the annual fall. Matters of this nature must be continually borne in mind when selecting stone. If, for instance, a stone be selected from the observed rate of disintegration in the quarry, and this quarry be situated in a district where the average annual rainfall is 25 in., it will be seen that if the stone be carried away from that district and built in one having an average of 50 in., other things being equal, the stone will decay there at rather more than double the observed rate at the quarry.

By attracting rain, as woods and thick forests, more particularly on elevated ground, are believed to do, the stones of mansions and other structures in their vicinity are also liable to decay more quickly than they might otherwise do.

The stone in edifices built in a position altogether sheltered from the sun soon rots, unless it is of very good quality, because after rain, there being no sun to quickly dry out the moisture, the acids and other destructive impurities in the rain have more time to act on the stone. On the other hand, those parts of a building exposed to the sun's rays stand a better chance of being preserved.

The direction of the prevailing winds in a district should be taken into account, for the side of a building exposed to their action is affected by the moisture, &c., they bring. Wind, nevertheless, is also a preserving agent (see note, p. 525).

It is evident from the foregoing that not only the position of an edifice with reference to the physical features of the surrounding country, but the position of a stone in a building may very much influence its durability. The effect of the deleterious agents referred to may to a great extent be counteracted. The best stones should be placed in the more exposed parts of the building. Interior decora-

tions may be constructed with freestones of moderate quality only, as they are not so liable to decay. Steps and other portions which are subjected to much wear and tear must be made of strong compact stones. Siliceous sandstone and granite are probably the best materials for these purposes.

The foundations of a building should be made with good, compact stone. Professor W. R. Johnson, speaking of the stone used in constructing the foundations of the extension of the United States Capitol, said that the foundations of the Capitol were intended to be enhanced in such a manner that frost will never reach them, and that since the water falling on the building will be mostly carried away by pipes and drains, and the shielding of the surface by pavements or flaggings, the foundation walls will be kept comparatively dry.* The inference is that under these conditions the progress of decomposition of the stone will be retarded.

In building walls, stone having a laminated structure should be placed with the planes of those lamina in a horizontal position. Considerable experience is required to find the bedding-planes, as they are called, in some stones, and if the structure of the stone is such that they cannot be otherwise distinguished, the mason usually knows them from the direction of the grain. But it is not necessary to be so careful in observing the bedding-planes in rocks that are not distinctly laminated.

If the bedding-planes of a clearly-laminated stone are placed in an upright position, parallel to the face of the wall, the layers peel off, one after another, under the action of the weather. If, however, these planes be placed at right angles to the exterior face of the wall, this peeling action cannot take place; but little furrows may be formed, as some of the laminae are more susceptible to weathering than others.

"In arches, laminated stones should be placed with the natural bed as nearly as possible at right angles to the thrust upon the stone,—that is, with the "grain" or lamina parallel to the centre lines of the arch stones, and perpendicular to the face of the arch.

In cornices with undercut mouldings the natural bed is placed vertically and at right angles to the face; for if placed horizontally, layers of the overhanging portion would be liable to drop off. There are in elaborate work other exceptions to the general rule.†

There are sandstones fit for large edifices, the appearance of which might be considerably improved in the tooling and dressing. Thus Dr. Page remarks that, whilst polishing will bring out the beauty of one variety, vertical dressing may be more suitable for a second, and parallel broaching, or pearling may mask the grain or spottings of a third.

We may observe, however, that these ornamental lines often help the decay of stones, by affording ledges for rainwater to rest on, especially if the broaching lines are built in a horizontal position.

As the majority of stratified rocks have a tendency to weather more rapidly along their planes of stratification than anywhere else, it will be seen that when sandstones have a flaggy or fissile structure they are not desirable for building purposes. When exposed edgewise to the action of frost, however, they often split up into capital paving stones.

There are certain rocks known as Stonesfield "slate," Collyweston "slate," &c. These are not metamorphic slates produced by heat and pressure, like the Welsh and Scotch rocks of the same name, but are, in fact, merely fissile limestones, which, by the aid of frost, are capable of being split up into slabs of sufficient thickness for roofing purposes.

Electrical Transmission of Power.—The Cannon Foundry at Douvres has two 20-ton cranes for the handling of very large ordnance. Each of these is worked by a special electrical motor, with current furnished by a single generator. The power is transmitted a distance of 120 metres, and is about 13 h.p. out of 25 h.p. The working has always been effected without accident. In the same establishment there has also been employed, since 1873, two gramme dynamos, one as a generator, the other as receiver for the testing of metals by means of a traction machine.

* See Dobson's "Fundamentals of Masonry and Stone-cutting" (1878), Appendix, p. 121.

Books.

Builder's Work and the Building Trades. By Col. H. C. SEDDON, R.E., Superintending Engineer H.M. Dockyard, Portsmouth, &c. With illustrations. London: Rivingtons, 1886.

THE facilities now afforded to students of both the engineering and the architectural professions for gaining information are enormously in advance of those which existed a few years ago. The numerous works which have been published, treating in detail the various operations connected with building from a practical point of view, and the admirable illustrations which add so largely to the value of these works, will enable a student to gain a very clear idea of what he has to learn, while the various technical schools and institutions which are springing up all over the country afford ample opportunities for supplementing the knowledge gained from books with a practical acquaintance with the subjects treated of. It must always be remembered that no amount of mere book-learning in the various branches of building construction can dispense with that practical familiarity which can only be gained from a close study of works in progress, but if a student has learned the reason why one method of doing a thing is right and another wrong, he will be able much better to appreciate the right way when he sees it.

In the work by Col. Seddon, under notice, it is stated in the preface that the details of construction are treated from the point of view of those who are actually engaged in the execution of builders' work, and it is precisely this fact which renders the work of great value to the architectural student, as he will find numerous small details noticed upon which he would in vain seek information elsewhere. The different building trades are separately treated, mainly from the point of view of the War Department contracts. The various operations and processes are carefully described, and the method of arriving at the value of finished work is explained. Excavators' work is discussed much more fully than is done in the majority of books, and useful details of carting, wheeling, &c., are given. As an instance of minute detail, we notice that attention is called to the fact that, as in laying concrete the joints are always weak parts, any joints in one layer should be covered by the succeeding one. This is a little matter too often neglected.

The subject of bond in brickwork is treated very fully, and the principles upon which bond really depends are elucidated, illustrations being given not only of what to do, but also of what to avoid, and sundry methods in which brickwork may be scamped are particularised. There is also an admirable illustration showing the different ways of jointing and pointing brickwork, and the abomination of tuck-pointing is clearly demonstrated.

Masons' work is described in considerable detail, and the various modes of dressing stones are explained and illustrated. In the remarks upon bedding stones it is stated that "in projecting undercut mouldings and weathered copings the natural beds should be placed parallel to the side joints." Now surely this is rather too general a statement. No doubt, if one member of a cornice be deeply undercut it is not desirable to lay the course which comprises the member on its natural bed, but this is the only course which we should treat in this way, and we should certainly prefer to lay the stones of a weathered coping on their natural bed. The necessity of proportioning the hedging area of individual stones to their face area, and the danger likely to result from what are called flush joints, are clearly pointed out.

Some excellent information is given as to the various kinds of fir timber brought to the London market, and the shippers' and quality marks upon the baulks are illustrated and explained very clearly. This information must be of great value to architects, who, as a rule, have a very limited acquaintance with the brands on timber.

The different kinds of joints used in carpenters' work are fully described and well illustrated, and the absolute necessity of properly forming the joints connecting together the various parts of any framework is clearly pointed out. A capital illustration is given of what we do not remember noticing in other works of this kind, viz., the method

* See Scott's "Elementary Meteorology" (1893), 137.

of securing a tenon by fox-tail wedging, and the different kinds of iron straps, bolts, &c., are described. We are also glad that the author calls attention to what we have always considered the very effective and simple method of roof-construction (on Philibert de l'Orme's principle) adopted in the Exhibition buildings at South Kensington. There is one little point in connexion with joiners' work on which we certainly cannot agree with the author. He says that in all cases of moulded panels, the moulding should be planted on, i.e., made on separate pieces of stuff, and not worked on the stiles and rails. We quite admit that the latter method requires more care, and is more expensive, but all the best and strongest Mediaeval joinery was constructed in this way, and we should have thought there could not be two opinions as to its superiority to the modern process of planting on.

The other building trades are all carefully treated, the plasterers' work being very fully described, and a large amount of valuable information as to the pigments and other materials used by painters is given. The use of Griffith's white in place of white lead in recent Government works is alluded to, and it will be matter for general congratulation if this excellent invention proves to stand the test of time.

The most valuable information is often found in the appendices to a work of this kind, and this is certainly the case here. In Appendix I. we have the tabulated results of a number of experiments upon the strength of concrete slabs. This is the very information which has been most urgently wanted, and if further experiments should confirm those here given we shall have to modify the generally received opinion that the admixture of sand with ballast or broken bricks increases the strength of cement concrete, as the reverse seems to be the case. A full specification for concrete floors and roofs is added. Useful tables for the strength and deflection of timber are also appended.

It might have been supposed that the three volumes on "Building Construction," published by Messrs. Rivingtons, had exhausted this subject, but, admirable as these volumes are, there are yet omissions in them, and many of these are admirably filled up in the work under notice, and we can, therefore, cordially recommend Col. Seddon's book as a supplement to the larger work.

Ground Rents and Building Leases. By C. H. SARGANT, Barrister-at-Law. London: Swan, Sonnenschein, & Co. 1886.

This is a small volume of 160 pages, which very clearly explains the nature and attributes of the subject with which the writer deals, and weighs the arguments for and against leasehold enfranchisement and the rating of ground-rents. It is the best of the passing works on this subject which has yet come under our notice, and is the one which will best give a reader a clear view of this matter. Mr. Sargent points out in regard to the taxation of ground-rents that the present system is, in the first place, most convenient in regard to payment and collection; and in the second, even if ground-rents were taxed, it would not in reality benefit the occupier. It is obvious that the landlord, if he has to pay some part of the taxation now borne by the tenant, will increase by this amount the rent in the future; for, if a tenant will pay, say 100l. rent and 25l. taxes, he will be willing to pay 105l. in rent and 20l. in taxes. It is extremely probable, in our opinion, that the Legislature will make this change, even though it produces no substantial benefit to the occupier, simply on the ground that there is an apparent injustice in the present custom, although there is none, in fact, and because it will prevent the idea that the occupier is touched by an increase in local taxation, and not the landlord. However, we are not now discussing this subject, but pointing out that Mr. Sargent's work should be read by any one who desires to become master of it.

Les Céramiques de la Grèce Propre: Vases Peints et Terres Cuites. Par ALBERT DUMONT et JULES CHAPLAIN. Première Partie (3^e fascicule). Paris: Firmin Didot. 1885.

This third instalment of M. Dumont's great projected work on the Ceramics of Greece proper has a very melancholy interest. It has tarried long, owing to the death (in August,

1884) of the illustrious author. He left behind him, it seems, ample material for this third issue, and a detailed plan for its arrangement, the completion of which has been undertaken by M. Pottier, his pupil and friend. From internal evidence we should say M. Pottier has added little of his own. The volume takes up the thread of the historical narrative just at the point where the Geometric style begins to blend with the Oriental style, as seen in the Rhodian vases; then come the earlier and later Corinthian styles, with the predominance strongly marked of Oriental manner. It is enough to read these two chapters to see that all the old hemieses are perpetuated. Much that is valuable is gathered together, but there is no digest. M. Dumont's intellect was of the order that accumulates, but does not focus, information. We are also strongly conscious that the whole point of view is distinctly *arriéré*. It is quite right, in speaking of Corinthian vases, to point to the analogy of the Chest of Cypselus, but it is superfluous to give us a detailed description of the technique and contents of this monument, which every archaeologist knows by heart, and to point to analogies which are the commonplace of vase specialists, such as the Amphiaros vase. All this is well enough for the populariser, but quite unworthy of the scientific archaeologist. "Backwardness," the sin with which our German critics charge us, is, however, almost the invariable and indeed the inevitable concomitant of books planned on a large and sumptuous scale,—they tarry while time goes on. The best part of the book is undoubtedly the plates. They are published by anticipation, and have nothing whatever to do with the text. We are delighted to see a charming reproduction of a vase from Copenhagen, little known and of great beauty. It is the top of a pyxis, and the drawing is in the most exquisite manner. The design represents a "Judgment of Paris," but after a unique fashion. Instead of modestly walking to the "Judgment" the goddesses come in their chariots. Hera is drawn along in sober human fashion by four goodly horses, but Athene has yoked to her chariot two fine, bearded snakes, and Aphrodite's steeds are none other than two charming love-gods. We may note also an exquisite vase with red figures from Boeotia, which represents in quite novel fashion the Slaying of Busiris by Herakles; also a beautiful red-figured pyxis, with delicate designs, representing scenes of a Greek lady's toilet.

Ornament und Form des Attischen Grabstelen. Von ALFRED BRUECKNER. Straasburg: Struchner. 1886.

TREATISES on the subject, meaning, and sculptured decoration of Attic grave-stones, already number legion, but, up to the publication of the present book, so far as we are aware, no systematic attempt has been made to catalogue and classify them on the basis of architectural form and ornamentation. It is manifest that this should be an important factor in any attempt to determine their chronology. For his material, Herr Brueckner has had access to the largest collection of photographs of grave reliefs at present in existence, that made by the Vienna Academy with a view to its projected Corpus of Attic tombstones. For this Corpus, it will be remembered that the grave reliefs, even of the British Museum (whose re-entombment Mr. Newton has recently so pathetically deplored) were for a while disinterred, so that Herr Brueckner's monograph will have special interest for English readers. We recommend the book for careful study, but we may note briefly that he divides all the stelæ into two main classes, the stèle proper or simple slab, and its later development the naiskos or small shrine; that passing from form to decoration, he treats decoration under three heads, taking each in its historical development: vegetable motives, such as the palmette, the rosette; figure motives, the siren, the sphinx, lion, &c.; and the architectonic motives, pediment, ante, &c. The text is illustrated by two maps.

The National Agricultural Hall.—A party of members of the Civil and Mechanical Engineers' Society on Saturday last visited the roof now being erected over the central portion of this building, and which was described and illustrated in our last number. The party were shown over the works by Mr. am Ende and Mr. A. T. Walmisley, the engineers.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

7,552, Window-sash Fastenings. J. Sharp. This invention relates to a safety, self-closing locking fastening for window-sashes, sly-heights, &c., and consists of an apparatus worked by means of a cord, chain, or lever. A locking bolt is fixed on the top sash, which slides into a catch when the window is shut. To open the window an arrangement of pulleys is so placed that on pulling a cord to raise the sash the bolt is pulled out of its catch and the window unfastened, enabling the sash to be raised.

7,021, Roofs. J. B. Spence. The object of this invention is to provide a temporary transparent covering for recreation-grounds or pleasure-gardens in winter, so as to form a winter garden, without the necessity for taking down the covering in the summer. One half of the space forming the pleasure-ground is covered with a permanent roof. For the other half of the ground a movable roof, which may be slid over or under the permanent roof, is provided. The temporary roof is constructed of steel girders of lattice or such like form, and the sides rest on a track which is supported on suitably constructed masonry. In these tracks the roof slides and is moved backwards or forwards by suitable power as required.

8,662, Closet Pans and Seats. J. B. Weller. In the upper part of the closet-pan, either solid therewith or connected thereto, is formed a nozzle, or branch, opening into the interior of the closet-pan above the water-line, on the outer end of which is attached a ventilating pipe, carried in any convenient way to the outer air, and fitted with a ventilating cowl. On the top edge of the pan rings of indiarubber are arranged to form an air-tight packing.

1,693, Window-fittings for Curtains. J. & H. A. K. Davis.

For affixing short curtains, instead of the ordinary nail or hook, a strip of brass carrying a tongue or blade spring is employed by the inventor. The cord suspending the blind is passed over the tongue, which grips it, and keeps it perfectly taut under the weight of the curtain suspended therefrom.

11,351, Ornamenting Glass and Vitreous Surfaces. John Slater.

Platinum sponge is ground with flux and turpentine, and then the glass coated with this is suspended in an electric bath and various metals deposited thereon in patterns. The copper, which is easiest in depositing, may be engraved or lacquered, and various patterns may be in this way fixed upon tiles, china, glass, or any vitreous surfaces.

NEW APPLICATIONS FOR PATENTS.

May 21.—6,817, J. Partington, Metal Doors and Frames for Buildings.—6,825, C. Priestland, Improvements in Knobs.—6,827, T. Robinson, Horizontal Saw-Frames.—6,831, P. Davies, Stench-Traps.—6,836, G. Nunn, Protection of Walls, Gates, &c.—6,850, G. Redfern, Preventing Condensation in Water Pipes.—6,855, J. Aebury, Traps for Sinks, Drains, Water-closets, &c.

May 22.—6,900, W. Sanday, Combined Lathe, Circular Saw, &c.—6,912, G. Butt, Wood Mouldings.—6,926, A. Clark, Sawing Machines.

May 24.—6,943, E. Wright, Ventilator.—6,945, J. Lamb, Flushing Tanks.—6,970, J. Pettor, Heating Stoves or Firegrates.

May 25.—6,991, L. Nelke, Incidence Windows or Vault Lights.—7,009, R. Strangman, Reflectors.—7,011, T. Morris, Household Signals or Bell Indicator.

May 26.—7,060, C. & F. Smith, Door-Checks.—7,067, W. Smeaton, sen., Flushing Water-closets, Lavatories, Urinals, &c.—7,068, W. Smeaton, sen., Flushing Water-closets, Urinals, Lavatories, &c., and Preventing Waste of Water.—7,069, W. Smeaton, sen., Flushing Water-closets, Urinals, Lavatories, &c., and Preventing Waste of Water.—7,078, S. Wilmot, Galvanised Iron Roofing.—7,079, H. Bridgen, Sash Fasteners.

May 27.—7,100, J. Rollason, Wedge for Securing Doors and Windows.—7,114, R. Stofert & T. Dykes, Girders.—7,146, W. Doehring, Watchman Detector and Alarm Apparatus.

PROVISIONAL SPECIFICATIONS ACCEPTED.

5,212, F. Nutter, Wooden Fencing.—4,055, E. Wharington, Sanitary Pan.—4,567, G. Rayner and H. Hughes, Retaining Doors, Windows, or Shutters, in Open or Closed Position.—4,901, T. Whitaker, Hinges for Folding Doors.—4,977, G. Spink, Mould and Accessories for Making Bricks.—5,031, R. Weaver, Water Closet Apparatus, &c.—5,045, T. Burns, Felted Wire Netting, a Waterproof Material for Covering Buildings, &c.—5,235, W. Jenkins, Treble Ladder.—5,321, M. Hussey, Roofing Tiles, &c.—5,975, A. Boulton, Manufacture of Cement.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to opposition for two months.

8,205, P. Davies, Apparatus for Burning Lead.—9,261, R. Boyle, Stoves, Furnaces, Firegrates, &c., for Heating and Ventilating Rooms.—9,418, J. Carter, Window Sashes to Fold Horizontally Inwards.—4,618, J. Anderson, Carriers for Dovetailing Machines.—5,445, H. Bureon, Chimney Cows for Extracting Smoke.

MEETINGS.

SATURDAY, JUNE 5.

Colonial and Indian Exhibition.—Conference of the Geologists' Association. Paper by Professor Valentine Ball, F.R.S., on "The Mineral Resources of India," 3 p.m.

St. Paul's Ecclesiastical Society.—Visit to Ongar, Greensted, &c. Paper by Major Heales, F.S.A. Train from Liverpool-street to Ongar at 3.30 p.m.

Association of Municipal and Sanitary Engineers and Surveyors.—Eastern Counties' District Meeting at Great Yarmouth, Town-hall, 1 p.m.

MONDAY, JUNE 7.

Society of Engineers.—Mr. R. P. Spice on "Some Modern Improvements in the Manufacture of Coal Gas," 7.30 p.m.

Clerks of Works' Association.—Paper by Mr. F. A. Hocking, 8 p.m.

TUESDAY, JUNE 8.

British Museum.—Mr. J. A. P. MacBride on "The Sculpture of Phidias and his School," 2.30 p.m.

Colonial and Indian Exhibition.—Conference of the National Association for Promoting State-directed Colonisation, 2 p.m.

THURSDAY, JUNE 10.

Society for the Encouragement of the Fine Arts.—Conversations in the Galleries of the Institute of Painters in Water Colours, 8 p.m.

Society of Antiquaries.—8.30 p.m.

Colonial and Indian Exhibition.—Mr. F. W. Pennefather on "The Industries of New Zealand," 8.30 p.m.

FRIDAY, JUNE 11.

University College.—Professor C. T. Newton, C.B., on "Greek Myths Illustrated by Fictile Vases and other Monuments,"—III., 4 p.m.

Colonial and Indian Exhibition.—Conference of the Royal Colonial Institute. Paper by Mr. F. Young on "Emigration to the Colonies," 3 p.m.

Miscellaneous.

"Silchester in 1886."—Under this title, Mr. Joseph Stevens, of Reading, contributed to the Reading Observer of the 15th ult. an interesting account of the present condition of the Roman remains at Silchester. He says:—"Any one who feels an interest in the antiquities of the country, and who has from time to time inspected the Roman vestigia at Silchester, will be painfully reminded of the changes which have taken place in the features of the exposed foundations since they were laid bare by the late Mr. Joyce in 1864-5. These observations are directed to the persistent, although not always uniform or noiseless, workings of Nature, which have certainly operated more largely in sapping the foundations of this ancient 'City of the Dead' during the twenty years of their exposure to the light, than had been effected in the 1,400 years of their entombment underneath the soil. Man has also done something as a wasting agent, inasmuch as the tiles and tessellations, which have been loosened by frost and scattered about by rain and wind, have gradually disappeared in the pockets probably of visitors. It appears evident that unless some measures be adopted for the protection of the foundations, their destruction at no distant date will be as thoroughly worked out as if accomplished by the agencies of the pick and spade."

Association of Municipal and Sanitary Engineers and Surveyors.—An Eastern Counties District Meeting is to be held at Great Yarmouth this Saturday, June 5. Members will assemble at 1 p.m. in the Town Hall (kindly offered for the occasion by the Mayor), and after the transaction of the usual routine business, they will visit the following works, in course of construction:—1. The sea-water works for sewer flushing and street watering; 2. The concrete footways. On returning to the Town Hall, the following papers will be read and discussed:—(1) "Great Yarmouth," and some of the Works of its Sanitary Authority," by Mr. J. W. Cockhill, Borough Surveyor, Great Yarmouth. (2) "The Sewerage, Surface Drainage, Sewage Disposal, and House Drainage of the Great and Little Bowden Local Board District," by E. G. Mawbey, Borough Surveyor, King's Lynn.

The Bricklayers at Turin have been lately agitating for an increase of pay and a re-adjustment of the hours of labour. After considerable discussion the men have agreed, as a temporary settlement of the question, to work ten hours a day—namely, from 6 a.m. to 11.30 a.m., and from 2 p.m. to 7 p.m., at the rate of 45 centimes (14d.) an hour.

A New Building Estate at Wandsworth.

For some months past the Down Lodge estate at Wandsworth, the property of Dr. Watney, has been in progress of conversion for building purposes. The estate, which occupies an area of upwards of 60 acres, is situated in the valley of the river Wandle, bounded on the east side by Garratt-lane, and on the west by Merton-road, and stretching northwards from a point near the Royal Paper Mills to within a short distance of High-street, Wandsworth. The works now going forward embrace the construction of several new roads intersecting the estate, and include the erection of no fewer than five bridges across the river Wandle and its tributaries. Two of these bridges are in connexion with a new road through the estate between Garratt-lane and Merton-road, running parallel, on the east side, with the new aqueduct which forms a portion of the storm-water sewer between Clapham, Brixton, and Putney, just completed for the Metropolitan Board of Works. Two other bridges form a portion of a second road across the estate, approached from South-street close to its junction with High-street, about the centre of Wandsworth Old Town. Altogether there will be four main approaches to the estate, two on the east side, in Garratt-lane and South-street, one at the north side at the junction of High-street with Merton-road, and a fourth approach in Merton-road on the west side, near the old mansion known as Down Lodge, which is about to be removed. A park and recreation ground, about 20 acres in extent, forms a special feature in the undertaking. A considerable portion of it has already been laid out and completed, and in addition to numerous winding walks, mounds, and plantations, includes a lake. The large area of the estate will admit of the erection of several hundreds of houses. Mr. Milner, C.E., has furnished the plans for laying out the estate, and has also designed the several girder bridges. Mr. Mackenzie is the general contractor, the park and recreation ground being formed under the superintendence of Mr. Martin, landscape gardener. Mr. Hutton is clerk of the works and general superintendent.

Recent Exploration.—The Director of the Geological Survey of Ireland, Professor Hull, F.R.S., delivered the annual address of the Victoria (Philosophical) Institute on Friday, on which occasion the Institute's new President, Professor Stokes, President of the Royal Society, took the chair. Professor Hull sketched the course taken by the scientific expedition of which he had charge (which, to a considerable extent, took the route ascribed to the Israelites), the physical features of the country, evidences of old sea margins 200 ft. above the present sea margins, showing that at one time an arm of the Mediterranean had occupied the valley of the Nile as far as the First Cataract, at which time Africa was an island (an opinion also arrived at by another of the Institute's members, Sir W. Dawson), that, at the time of the Exodus, the Red Sea ran up into the Bitter Lakes, and must have formed a barrier to the traveller's progress at that time. He then alluded to the great changes of elevation in the land eastward of these lakes, mentioning that the waters of the Jordan valley once stood 1,292 ft. above their present height, and that the waters of the Dead Sea, which he found 1,050 ft. deep, were once on a level with the present Mediterranean sea margin, or 1,202 ft. above their present height. The great physical changes which had taken place in geological time were evidenced by the fact that whilst the rocks in Western Palestine were generally limestone, those of the mountains of Sinai were amongst the most ancient in the world.

The Iron, Hardware, and Metal Trades' Pension Society.—The forty-third annual festival dinner of this charity was held on the 27th ult., in the Hall of the Ironmongers' Company, Fenchurch-street, Mr. Wm. G. Ainslie, M.P., presiding. During the evening, subscriptions and donations to the amount of £37, 19s. 6d. were announced by the Secretary, Mr. T. Hodges Papworth.

Bryant, Powis, & Bryant (Limited).—At the first annual meeting of this company, well known in the timber trade, the report (which was unanimously adopted, on the motion of the Chairman, Mr. Wilberforce Bryant) stated that the company had earned 22 per cent. on its capital during the year, and recommended the division of 15 per cent. to the shareholders.

COMPETITIONS, CONTRACTS, & PUBLIC APPOINTMENTS.

Epitome of Advertisements in this Number.

COMPETITIONS.

Table with 5 columns: Nature of Work, By whom required, Premium, Designs to be delivered, Page. Includes Hospital, Mertyhr Tyddl.

CONTRACTS.

Table with 5 columns: Nature of Work, By whom required, Architect, Surveyor, or Engineer, Tenders to be delivered, Page. Includes Taking down Buildings and Clearing Site, Making-up Roads, etc.

PUBLIC APPOINTMENTS.

Table with 5 columns: Nature of Appointment, By whom Advertised, Salary, Applications to be in, Page. Includes Surveyor and Inspector of Nuisances.

LONDON.—For new Infants' School, Chickland street, Tower Hamlets Division, for the School Board for London. Mr. J. Bailey, architect. Quantities by Mr. Earl, Outer Temple, W.C.

LONDON.—For new cell accommodation at Bow-road Police Station, for the Commissioners and Receiver for the Metropolitan Police District. Mr. John Butler, surveyor for Metropolitan Police.

LONDON.—For Artisans' Dwellings, in Cleveland street, Mortimer-street, W. Mr. E. C. Robins, architect, Berners-street.

LONDON.—For alterations and additions at the Metropolitan, Farringdon-road, E.C., for Messrs. G. Warman & Co. Mr. W. T. Farthing, architect.

BETHNAL-GREEN.—For alterations to premises known as the Flying Horse, Usk-street, Bethnal-green. Mr. Fred. C. Hees, architect.

FULHAM.—For St. Peter's Vicarage House, for the Rev. R. Cordwell, Mr. J. E. K. Cuts, architect.

CARDIFF.—For hotel and two dwelling-houses, Splott-lane, Cardiff. Messrs. W. G. Habersham & Fawcner, architects.

GRIMSBY.—For the erection of the Prince of Wales Theatre, for Mr. H. J. Curry, Freeman-street, Grimsby.

CHATHAM.—For re-erecting, new gallery front, windows, decorations, &c., at the Ebenezer Congregational Church, Mr. George E. Bond, architect, Rochester.

GRIMSBY.—For the erection of house, for Mr. A. Bester, Grimsby. Mr. E. W. Farebrother, architect.

CLEETHORPES (Lincolnshire).—For the erection of new stabling, for Mr. Joseph Chapman, Mr. E. W. Farebrother, architect.

HACKNEY.—For additions to 44, Pembury-road, Hackney Downs, for Mr. J. Edell, Messrs. R. & W. Stone, architects, Great Winchester-street, E.C.

COBHAM.—For the erection of a pair of villa residences, at Cobham, Surrey, for Mr. Chas. Woodbury, Mr. H. A. Whitbury, architect, Woking.

ISLINGTON.—For additions and alterations to premises, 219, Upper-street, Islington, for Mr. D. R. Roberts, Mr. J. Kingwell Cole, architect, Messrs. Bateman & Co., surveyors, Mount-street, Grosvenor-square, W.

FULHAM.—For new hot-water supply apparatus, at the Western Hospital, Savaroad, Fulham, for the Managers of the Metropolitan Asylum District, Messrs. A. & C. Harston, architects. Quantities not supplied.

KENNINGTON.—For the erection of male staff quarters at the Infirmary, Marlow-road, Kennington, for the Guardians of Kennington, Messrs. A. & C. Harston, architects, Lodenal-street. Quantities supplied.

FULHAM.—For alterations and additions to the fever and other work, at the Western Hospital, Savaroad, Fulham, for the Managers of the Metropolitan Asylum District, Messrs. A. & C. Harston, architects, Lodenal-street. Quantities not supplied.

LONDON.—For taking down and rebuilding 11, Harley-street, Cavendish-square, for Mr. W. Morrant Baker, Messrs. Alexander Payne & F. M. Elgood, architects. Quantities by Mr. E. J. Cain, Buckingham-street.

LONDON.—For constructing new road, paving, kerbing, and drainage, Madron-road, S.E., for the Trustees of Mrs. Beckhouse, Mr. W. C. Reed, surveyor, Adelaide-place.

LONDON.—For paving a portion of Bett-street for the Vestry of St. George-in-the-East. Mr. G. Wilson, surveyor.

LONDON.—For alterations to 44 and 49, Lombard-street, E.C., for Messrs. Fielding Bros. Messrs. T. & W. Stone, architects, Great Winchester-street, E.C.

LONDON.—For the erection of warehouses in Farringdon-street and Bear-alley, E.C., for Messrs. Harriell & Sons, Messrs. Theodore E. Green & Son, architects, Finsbury-pavement, E.C.

LONDON.—For taking down and rebuilding 11, Harley-street, Cavendish-square, for Mr. W. Morrant Baker, Messrs. Alexander Payne & F. M. Elgood, architects. Quantities by Mr. E. J. Cain, Buckingham-street.

LONDON.—For alterations to 69, Pall-mall, Mr. C. R. Baker, architect.

LONDON.—For alterations, repairs, and decorations, Hyde Park-gate, W., for Mr. C. E. Lewis, M.P. Mr. T. Pearson, architect. Quantities supplied:—
 Bateman & Heywood, Oxford-street... £1,244 0 0
 Sendall & Son, Brighton... 1,210 19 6
 W. & H. Castle, Southwark-street... 1,174 0 0
 [Architect's estimate, 1884]
 * Accepted.

REDHILL (Surrey).—For stables at the Hawthorns, for Mr. E. F. Hubback. Mr. F. Edwards, architect, John-street, Adelphi:—
 Patrick & Sons, Lambeth... £1,473 0 0
 Gerrard, Lambeth... 1,289 0 0
 C. Ansell, Lambeth... 1,288 0 0

SPITALFIELDS.—For the erection of the superstructure of a block of model dwellings, in Flower and Dean-street, Spitalfields, for the Four Per Cent. Industrial Dwellings Company, Limited, Messrs. N. S. Joseph & Smith, architects, Mr. S. B. Wilson, surveyor:—
 E. Conder... £23,936 0 0
 Killby & Gayford... 25,785 0 0
 Outwaite & Son... 25,560 0 0
 Scriveners & Son... 24,984 0 0
 G. S. Williams & Son... 24,970 0 0
 W. Shepherd... 24,837 0 0
 Ashby bro... 24,570 0 0
 J. T. Chappell... 24,393 0 0
 Collis & Son... 24,270 0 0
 Patrick & Son... 24,079 0 0
 Patman & Rotheringham... 24,873 0 0
 M. Gantry... 22,970 0 0
 Brass & Son... 22,335 0 0
 Ashby & Horner... 22,240 0 0

SUTTON (Surrey).—For stabling to North Chaeon House, for Mr. J. Proctor. Mr. Herbert D. Appleton, architect, Wool Exchange:—
 H. Hillman... £146 0 0
 E. J. Burnand... 638 0 0
 G. Hards... 448 0 0

TOTTERIDGE (Herts).—For the erection of an orphanage, Mr. G. Hall, architect, Hammersmith. Quantities by Mr. Wm. Henry Strudwick:—
 Joseph Brown & Son, Margate... £7,990 0 0
 * Accepted.

VENTNOR (I.W.).—For the erection of residence, stables, &c., at St. Lawrence, I.W., for Captain C. B. Eisher, Mr. Theodore B. Sanders, architect. Quantities by the architect:—
 J. Newbain, Ventnor... £9,150 0 0
 J. Bell, West Cowes... 5,293 0 0
 Jolliffe & Son, Bonchurch... 5,151 0 0
 Ingram & Son, Ventnor (accepted)... 5,094 0 0

WALWORTH.—For pulling down and rebuilding the Prince Alfred public-house, Walworth-road, for Mr. J. Dyke, Messrs. J. & J. S. Edmeston, architects, Old Broad-street. Quantities supplied:—
 Frost... £2,830 0 0
 Hayworth... 2,405 0 0
 Lunden... 2,380 0 0
 Huthwaite... 2,389 0 0
 Stuel Bro... 2,328 0 0
 Marsland... 2,325 0 0
 Holloway... 2,296 0 0
 Smith & Sons... 2,256 0 0
 Jackson & Todd... 2,213 0 0
 Kynoch & Co... 2,240 0 0
 Baels... 2,223 0 0
 Crocker... 2,070 0 0

WALWORTH.—For alterations, &c., at the King's Arms, Walworth-road, Messrs. G. Warren & Co. Mr. W. T. Farthing, architect:—
 W. Jockelyn... £2,100 0 0
 Canning & Mullins... 1,897 0 0
 R. W. Edgley... 1,877 0 0
 H. Pickersgill & Co... 1,820 0 0
 J. Beale... 1,798 0 0
 Spencer & Co... 1,795 0 0
 W. Scriveners & Co... 1,716 0 0
 Leslie & Knight... 1,700 0 0
 Ben. Cook (accepted)... 1,557 0 0

WALWORTH.—For additional room at 18, and repairs externally and painting at 57, and nine private houses adjoining, in Villa-street, for Mr. W. Lywood, Mr. Edward Cross, architect and surveyor, Bermondsey-square. No quantities:—
 T. Laphorne & Co., Lambeth... £184 0 0
 J. Appleby, Lambeth... 144 19 0
 A. White & Co., Rotherhithe... 129 0 0
 P. Lidston, Deptford (accepted)... 107 0 0
 J. F. Scipio, Peckham... 99 12 0

WATFORD (Herts).—For erecting new house in the Bushay Hall-road, for Mr. G. Ellingham (all bricks found by employer). Mr. C. P. Ayres, architect, Watford:—
 T. Turner... £896 0 0
 C. Brightman... 845 0 0
 Clifford & Gomb... 825 0 0
 W. B. Neal... 825 0 0
 Andrews & Sons... 823 0 0
 G. & J. Waterman... 789 0 0
 A. W. Chadwick (accepted)... 760 0 0
 [All of Watford.]

WATFORD (Herts).—For additions to the West Herts Liberal Club, Mr. C. P. Ayres, architect:—
 G. & J. Waterman... £721 0 0
 Judge & Earnes... 704 10 0
 Andrews & Sons... 698 10 0
 C. Brightman... 633 0 0
 A. W. Chadwick... 618 0 0
 T. Bennett... 602 0 0
 [All of Watford.]

WATFORD (Herts).—For alterations and additions to Ashwellthorpe, Clarendon-road, for Mr. F. Kayvet, Mr. C. P. Ayres, architect:—
 A. W. Chadwick, Watford... £771 0 0

WESTMINSTER.—For rebuilding the Two Brewers public-house, James-street, Buckingham-gate, for Mr. Samuel Raven. Quantities by Mr. Frank Thomson, Mr. H. I. Newton, architect, Queen Anne's-gate:—
 Heath... £2,800 0 0
 Cook... 2,790 0 0
 Haylock... 2,712 0 0
 Spencer & Co... 2,584 0 0
 Lambie... 2,657 0 0
 Chappell & Co... 2,614 0 0
 Walker... 2,538 0 0
 Goddard... 2,300 0 0
 Bond Bro... 2,275 0 0
 Barman & Sons, Kensington Park... 2,275 0 0
 * Accepted.

WINDHIELD.—For repairs and exterior painting at the Hatchley Wintry Workhouse. Mr. W. H. Turner, architect:—
 J. A. Sims, Basingstoke... £285 0 0
 Liming Bro., Farnham... 270 0 0
 H. Merton, Havley-cow (accepted)... 193 0 0
 [Architect's estimate, 1885.]

SPECIAL NOTICE.—Lists of Tenders frequently reach us too late for insertion. They should be delivered at our office, 46, Catherine-street, W.C., not later than Four p.m. on THURSDAYS.

Building Stones at the Colonial and Indian Exhibition.

THE authorities of the Colonial and Indian Exhibition appear to have paid considerable attention to the representation of building stones, in their respective departments, almost with-

out exception. Some of these exhibits are intended to induce us to purchase some of our stones,—especially those of an ornamental nature,—from the colonies, whilst others are merely to show the kinds of stone used locally.

The stones from the Indian Empire are arranged under the walls of the Economic Court. The Archaean rocks are of vast extent in India, granitoid gneiss being the prevailing type, and this, together with granite, has been employed on a grand scale in the temples of Southern India. Nos. 7, 8, 9, and 32 are examples. No. 8 is a grey granite, of a rather coarse texture, the felspar being large, and is the principal building stone at Hyderabad, in the Deccan. Crystalline limestones in India, as elsewhere, are amongst the most beautiful ornamental stones. No. 25 is the white "Makrana Marble" so extensively used in the Great Mogul monuments of Delhi and Agra, from the Makrana quarries in Jodhpur, Rajputana. This is the material also employed in the construction of the famous Taj Mahal at Agra. No. 26 is a dolomite polished as white marble.

The Deccan traps, which are a series of lavas and tuffs of the Cretaceous period, appear to furnish some of the best building stones in the Bombay district, nine kinds being exhibited. No. 12, "Sewri blue trap or basalt," Bombay Island, is stated to be the best class of building stone in Bombay. Nos. 13 and 14, traps from the Coorla quarries, Salsette, twelve miles north of Bombay, are much used in that city for coping, sases, columns, arches, large steps, &c.

The sandstones from the Goodwana formation are generally too porous and friable to form sound building materials. No. 17, "Hem-nagar sandstone," Guzerat, and No. 18, "Seoni stone," from Hoshangabad, Central Provinces, are in good repute, now largely used in Bombay for fine and plain carved and moulded work. The former is grey, with light violet tints, and the latter of a light brown colour. The upper Vindhyan sandstones afford everywhere building stones of the best description, with many shades of texture and colour, from

nearly pure white to bright red. They have been very extensively used by the natives wherever within reach, for temples and palatial edifices, and by the British for railway viaducts. No. 20 is the "Chunar stone," Mirzapore district, North-West Provinces. It is of a grey colour, and much used in Calcutta, though terra-cotta mouldings are often substituted for it in architectural ornamentation. Nos. 35 and 36, "Agra stone," and "Agra red," are very fine salmon-coloured sandstones, and form the main material in the great buildings of Agra and Delhi.

In Sind, tertiary rocks afford numerous fine building stones, especially the nummulitic limestones, but there are no examples of them exhibited. The "Porehunder stone," No. 24, is principally made of foraminiferal remains, and is of recent origin. It is said to be an admirable building material, working like the finest oolite or Bath stone, and is extensively used in Bombay.

Three kinds of slate are exhibited. No. 1, Kangra slate, from the quarries of that name in the flanks of the Dhauladhar range, north of the Kangra valley. It is as fine and even as could be desired, but is more siliceous and crystalline than our Welsh roofing slate.

Considerable care has been taken to show, by means of maps, the extent of the various formations, and the fact of the whole having been under the supervision of Mr. H. B. Medlicott, M.A., Director of the Geological Survey of India, is a sufficient guarantee for the completeness of the work.

Amongst the few building stones from Ceylon, we may mention a gneiss from Mahára, used in making the Colombo breakwater; red granite from Veyangoda, and Cahook (or Laterite) from Colombo, extensively used for building in lieu of brick. A specimen of stone carving in a block of granite is exhibited by the Stone Guild of Hong Kong; and in the section allotted to Canada a large collection of rocks and minerals is shown, which apparently are not yet quite arranged.

The Geological Survey of the Dominion Government have sent several things, amongst which we notice a fine series of small cubes of sandstones, limestones, marbles, dolomites, granites, and porphyries. These represent the chief building stones of the colony. The sandstones and limestones are of various shades of colour and texture. Some of the granites are bluish (like Ruhislaw); others are red, the felspar containing much iron. The lighter-coloured granites have sometimes a rough resemblance to that called "graphic" in this country. These specimens are placed above a large slab of "New Rockland" (near Quebec) slate, about 10 ft. by 4 ft. A fine piece of ornamentally-worked marble from

Arnprior, Ont., is exhibited by Messrs. Hurd & Roberts, of Hamilton, Ont. The calcite in this limestone is of a light bluish colour, and presents a curious granular appearance. Thick dark streaks run here and there through the stone, which is beautifully polished. Three other marbles are from Barrie, Ont. All are more or less white, with oblique streaks of a light blue and dark slate colour running down them. Another marble from Hull, Quebec, has a laminated structure of a slaty-brown colour; others have white and black streaks. A conglomeratic-looking marble, with large vivid vermillion and dark-brown patches, attracts considerable attention.

There are two specimens of New Brunswick granite. One is similar to our light blue Aberdeen, but slightly yellow; the other has large crystals, the predominating felspar (orthoclase) being red. A granite from Gananoque, Ontario, is of a brilliant red colour; whilst another from Stanstead, Quebec, is white, with black mica, the felspar having a granular appearance. A cross on a pedestal is made of Halifax granite. It is of a whitish yellow colour, with very large crystals. Flags, serpentines, and many ornamental stones are also exhibited. It would be better, perhaps, if the stones were more grouped together.

The building stones from Queensland are well represented by about sixty large blocks, slabs, and cubes. Sandstones appear prominently, and amongst them we may notice two specimens of a brown colour, from Stanwell Rockhampton. This stone is said to get very hard on exposure, and stand the weather well, the angles remaining sharp for a considerable length of time. It has been used for many public buildings in Rockhampton.

There are five blocks of sandstone from three quarries near Helidon. These show the kind of materials which have been certified by the Colonial Architect to be used in the construction of the Brisbane Public Offices. The white varieties from No. 1 quarry will be used in the upper stories; the brown rather dark kind from No. 2 quarry, in the basement; and the bluish from No. 3 quarry (which takes a high polish) for the inner embellishments. Some specimens of sandstone are shown from Moggill Ferry. The rocks from these quarries have been examined by the Hon. A. C. Gregory, in selecting stone for the construction of the South Brisbane Dry Dock, and the result of his investigations will be published in the descriptive catalogue of the department. The white and brown sandstones from Grantham, Toowoomba, are said to be exceedingly good freestones, and have been used in the Government House, the Houses of Parliament, and the Town Hall in Brisbane. Several limestones and some beautifully-

polished marbles, together with samples of granites, syenitic granites, and syenites, are also exhibited, but do not call for any special comment. We may, however, notice two specimens of porphyry from O'Connell Town, Brisbane. It is a compact rock of a light reddish-brown colour, consisting of felspar base, with a few quartz crystals scattered about. The Roman Catholic Cathedral is built of this porphyry, as well as the basement of the New Government Printing Offices, and various other public and private buildings in Brisbane.

We cannot close the remarks on the exhibit of stones from this colony without expressing our gratification not only as regards the manner in which the stones have been arranged, but the amount of useful and practical information which will be given to the public in the catalogue. The Hon. A. C. Gregory's private notebook has furnished the latter with the amount of absorption of water, specific gravity, weight per cubic foot, &c., of many of the stones represented.

From New South Wales there is only a small collection of stones. Light-yellow freestones from Pyrmont show us the material with which the principal edifices in Sydney are built, and o'her blue and white varieties come from West Maitland and Manly. A broad, tall obelisk-shaped object has some beautifully-polished slabs of marble from Marulan, Cow Flat, and near Tamworth, let in a wooden frame, covered with cloth. That from near Tamworth is a red enorinital marble, and in structure is precisely similar to our Derhysire marble of the same name, being almost wholly made up of the stalks of fossil crinoids.

The group of stones from the colony of Victoria is arranged just outside the court. The most prominent object is a tall obelisk of "Stanwell" or "Grampian stone," from the Grampian Quarries, Victoria. It is a light-yellow colour, and is now being used for the Parliament Houses, Melbourne. Several blocks of sandstone, limestone, marble, and a few slates are shown. A beautifully-polished fountain is made of coarse grey Harcourt (Mount Alexander) granite, and there is a small block of rather coarse red granite, in which the orthoclase felspar is conspicuous.

Building stones from South Australia are well represented by about forty-five specimens, mostly cubes, arranged in tiers. We may notice the Finnis freestone of a light yellow colour, which is reported by some of the leading architects and others to be the best freestone yet discovered in the colony.

The main public buildings in Adelaide are constructed of Teatree Gully freestone. Three samples of this are exhibited: one is a light yellow colour; the others, white. One of the latter is moulded to show its effect. "Red Dolomite" from Mount Gambier, and several marbles, some blocks of which are moulded, are exhibited. The Willunga stone has been extensively used for paving, but the Mintaro flag-stone has now taken its place, not being quite so laminated. Of the granite, that from West Island, near Port Victor, has been used in the basement of the new Parliament buildings. It is of a greyish colour, and very coarse, having large felspar crystals.

In the department of Western Australia there is a fine, almost white, granite pedestal, cut in the neighbourhood of York Green Mount; together with a block of light brown coarse sandstone.

There are also six small 6-in. cubes in a case representing the stone obtained from Kellm-scott, Freemantle, and Champion Bay. Surrounding these is a small limestone ornament, moulded to show facility of working.

The majority of the stones from New Zealand, in the West Annex, are exhibited by the Public Works Department, Wellington. Some of them are very similar in appearance to our oolitic freestones; and one cube is almost wholly made of fossil shells, in such a manner that we might imagine it to be a block of Portland. The object calling for special attention, however, is a finely carved and moulded white limestone column exhibited by the Totara Freestone Co., Oamaru, Otago. It stands on a rough block apparently of the same kind of stone, and shows at once the skill of the mason, and the

homogeneous character of a freestone of first-rate quality. It has, unfortunately, been chipped here and there at the corners (in transit probably), but this is only noticeable on a close inspection, as it has since been mended. Other freestones are of light green, slate, and salmon colours, and there is a cube of crystalline white marble having a fine polish. Two blocks of "Timaru blue stone," and one block of dressed "Raglan," are examples of stones much used. The igneous rocks are represented by a block of fine white granite, with large felspars; white mica and little black micaceous-looking specks are found all over the stone. A little iron, as shown by brown markings, is also present. One block, probably a lava, is of a dirty slate colour and full of small holes: it might do very well for rough work when stone of better appearance is not at hand.

There are several blocks of building stone from the Cape of Good Hope in the Queen's Gate Annex. Unlike those of some of the other departments they are not arranged in a group, but are scattered about here and there. Some blocks, too, stand by themselves with nothing printed on them to show where or for what purposes they are used. The exhibit would be much more useful if this were attended to.

We may notice a large cube of granite from Paarl, exhibited by the Table Bay Harbour Board. It is of a light grey colour, rather coarse, the crystals not being well defined, very much resembling some of the white Irish granites when dressed; but polishing reveals a slight light-brown tinge of a peculiar nature. It has been used in the construction of the Graving Dock, Cape Town.

There is a white freestone from Grahamstown, one from Maraisburg, Cradock district; two specimens of marble from Troe Troe, Clanwilliam division, and sandstone from Mossel Bay. The marble has a white ground with small irregular light-blue veins running over it, and, being finely crystalline, takes a good polish.

The stones sent from Natal appear to be still under arrangement. A noticeable object in the collection is a moulded column and pedestal executed in a fine grained sandstone of a light greenish colour. The stone appears to be easily worked and the angles are sharp. Several freestones of a grey colour come from Umginto, Weenen, Pietermaritzburg, and Greytown. In such a climate as that of Natal they are, no doubt, very durable. There are specimens of crystalline limestone (marble) streaked with blue veins, and some beautiful white marbles. The latter are exhibited by Messrs. Marcus Moxham & Co., of Swansea. The Natal Commission show, amongst other things, a sample of building stone from Mount Moriah, Victoria, and four blocks of unpolished granite from Inchinga. A specimen of granite, partly polished, has large white felspar crystals, being very coarse.

The small but important dependency of Malta has sent a very large series of building stones, the majority of which are arranged in a stack outside the door facing the south-east basin. They form one of its prominent exhibits and include marbles, sandstones, and granites. The façade outside the main entrance to the Court was made in Malta under M. Galizia, Superintendent of Public Works, from an original design, based upon German Renaissance met with at Heidelberg, sent out to Malta and there executed, and sent back to this country in numbered blocks, so that it was re-erected here in a very short space of time. We can strongly recommend those interested to pay a visit to the Maltese Court to see the beautiful and elaborate carvings in stone, which are not equalled by those of any other department in the exhibition.

We are not altogether surprised that ornamental stone-work is so well represented, because it is, in fact, one of the chief specialities of the island, and the official catalogue, p. 461, invites us to purchase some of our stone carving from Malta, or to get it done there; but this can hardly be convenient or practicable.

From Cyprus we have several crystalline marbles and some sandstones, from quarries

near Larnaca, Nicosia, and Limassol. In conformity with the general care taken in the arrangement, which characterises the exhibits from this island, we find that the building stones each have the weight per cubic foot given on neat labels, with the name of the quarry; an example which might with advantage be copied in some of the other sections of the exhibition.

NEW THEORY ON THE SCULPTURED "THANATOS" DRUM OF THE EPHEBUS COLUMN IN THE BRITISH MUSEUM.

THE *Buletino della Commissione Archaeologia Comunale di Roma*, published by the Accademia dei Lincei, enters this year on a new series. The first issue is marked by a paper from Dr. Benndorf, which, offering as it does a new interpretation of the famous "Thanatos" drum in the Ephesus room of the British Museum, cannot fail to be of interest to English readers. The drum in question, it will be remembered (of which we published an illustration at the time of its discovery), has upon it five figures in good preservation,* and to one of

these, the figure of a youth with wings and a sword in his scabbard, the current interpretation,—that of Dr. Robert,—is due. He sees in the group a representation of the return of Alcestis to the upper world. Heracles has fought with Thanatos and wrested from him his prize. Thanatos, the youth with wings and sword, softened in face and gesture, motions to the woman next him, Alcestis, to depart. Hermes, with face upturned, already looks away from the lower world. Persephone, to the right, stands in front of the seated Pluto, from whom she has just obtained consent for the release of Alcestis. When we say at the outset that instead of this scene of the conquest over death, solemn and yet triumphant, Dr. Benndorf asks us to read a tale whose import is light and cheerful, the "Judgment of Paris," we feel that to the uninitiated the faith of the archaeologist must seem, indeed, a reed shaken by the wind.

Dr. Benndorf shall, however, make good his own case. He was brought, as so often happens, to reconsider the Thanatos interpretation by certain reflections arising from the study of quite another monument. This monument was the figure of a youth, a photograph of which he publishes in the *Buletino*, tav. I. and II., side by side with the so-called "Thanatos." This statue was found in 1876 at Rome, in the spot where formerly the Rospi-gliosi Gardens were, now destroyed by the Via Nazionale; it is life-sized, of Pentelic marble, and bears evident traces of having been painted, specially about the eyebrows, pupils of the eye, and hair. It has fortunately escaped restoration, and it can be clearly made out that it was worked in several pieces, afterwards put together. It now stands in the beautiful octagon room of the Conservatori Museum on

* We give a small sketch of it here again, as a memorandum of the arrangement of the figures here referred to.

the Capitoline Hill. Placed side by side with the "Thanatos," the resemblance between the two is obvious; there is the same melancholy inclination of the head, approximately the same pose of body, the same belt across the body and right shoulder. Further, Dr. Benndorf thinks it certain, from the holes at the back of the Capitoline figure, that it was originally winged like the Thanatos. The execution of the figure points to the days of Greco-Roman work, but Dr. Benndorf thinks the conception is of good Greek times. Accepting the analogy of the two figures, the statue in the round would certainly not be a copy of a decorative work in relief; the work in relief is of prior date to the statue in the round; if, therefore, any connexion is to be established between them they are not, either of them, a copy of the other, but rather both must have borrowed their motive from a third great original. The question is what was this original?

Unless there is a strong reason to the contrary, we should naturally interpret a youthful male figure with wings as Eros. How, then, has the Thanatos interpretation come about for the Ephesus figure? Obviously in order to account for the apparently strange conjunction of the wings and sword; what had the gentle Eros to do with so warlike a weapon? Why does he lay aside his accustomed bow and arrows? We must add that Dr. Rohert, the author of the Thanatos theory, had his mind full of this conception of the winged and sword-bearing Thanatos, he had long devoted himself to the interpretation of that peculiar series of white Attic lekythoi, on which is represented the laying of the dead man in the grave, by the four-winged figures, Death and Sleep. He had, therefore, naturally, a predisposition to see this figure of Thanatos wherever possible. Given Thanatos, he set himself to find a fitting myth where Thanatos should be the principal figure; hence the Alcestis interpretation. If we can take away the necessity of the Thanatos interpretation (based entirely on the attributes, not on the character of the figure), the Alcestis theory falls away with it.

As we have noted, but for the attribute of the sword, the figure, soft and youthful, tinged with reflective melancholy as it is, would naturally be regarded as Eros. Is this attribute of the sword really incongruous? A moment's consideration will show that, on the contrary, it is absolutely appropriate and expressive. We are too apt, Dr. Benndorf points out, to regard Eros from the Roman point of view, to think of him as the mischievous schoolboy with how and arrows, always in mischief, but never a serious divinity. But this is not the conception of Sophocles or Plato, or even of Euripides, nor is it the conception embodied in plastic art until Alexandrian days. For Sophocles (Trach., 441), Eros is the strong hozer (*μικρὸν*) with whom a man does ill to contend. He is the warrior unconquered in battle (*ἀνικτὸν μάχῃ*); he comes not to bring peace, but a sword; and for Amacreon is the smith who smites with ponderous blow. These passages alone would amply justify the attribute of the sword; but, turning to the far more apposite evidence of the traditions of art itself, we remember that Alcibiades bore on his shield the device of Eros armed with a thunderbolt. On vase-paintings he appears wielding a goad, which he compels Zeus himself to love; often he carries a lance, and on one archaic vase he flies through the air hearing both shield and spear. Such is the Eros of the fifth and fourth centuries B.C.—robust, virile,—a warrior, hearty, indeed, but also terrible, never frivolous; a warrior who might wield on occasion any weapon from the arsenal of Zeus. So far we are with Dr. Benndorf entirely. We believe that he has satisfactorily disposed of Thanatos, and the winged deity bearing the sword will henceforward be acknowledged as Eros.

Having established Eros, Dr. Benndorf has now to cast about for a myth which shall give prominence to Eros and shall admit Hermes; or about the explanation of the youth carrying the caduceus there is, of course, not the shadow of a doubt. Dr. Benndorf, at the suggestion, he says, of Dr. E. Petersen, proposes the myth of the Judgment of Paris. In justice to

him we must say that he regards this theory as a mere conjecture (*simpliciter congettura*). The seated figure he proposes as Zeus, the standing female figure next as Hera; then follows Hermes, looking upward; then Aphrodite; then Eros; the rest of the column not preserved must, on this hypothesis, have been filled up by the figures of Athene and Paris. We cannot say we feel any inward conviction of the truth of this hypothesis; though there is no objection to the presence of Zeus. The judgment took place by his decree, and he is present on red-figured vase-paintings contemporary with the drum. It is noticeable also that the Hermes of these vase-paintings, e.g., the famous vase at Berlin, has just the upward gaze of the Ephesus Hermes; but in the vase-painting there is a reason,—Paris is seated on a rock above Hermes. The principal point that we feel to be unsatisfactory is the scattered arrangement of the figures; naturally on a column they would be arranged in a frieze-like procession,—Paris, Hermes, the three goddesses,—whereas in the Ephesus drum we have Zeus and Hera, then Hermes, then Aphrodite, Eros, Paris, and Athene. This objection is not, however, fatal, but the theory wants confirmation.

Dr. Benndorf has more to say on the Eros figure. He believes that the Capitoline and the Eros figures are both copies of one and the same great original, the Thespian Eros of Praxiteles. As the details of this argument are largely philological, we do not reproduce them here. The Thespian Eros was the one own love for Phryne. Eros is represented there as himself love-smitten as well as smiting. This which certainly appears in both the figures in question, the type which represents Eros plunged in melancholy, gazing intently (*ἀντι-ἐκτενῶς*), lost in thought. It was a conception thoroughly in the manner of Praxiteles, and this intent, wrapt, love-smitten gaze we undoubtedly see in the Ephesus figure. Taken as Eros it helps us to a conception of his idea of the love-god, whether or not we take the figure for an actual copy of his Thespian Eros.

NOTES.

SINCE more we have before us that pathetically amusing document, the Annual Report of the Society for the Protection of Ancient Buildings, recounting the few successes of the Society and the numerous snubs they have received, their own queer ideas on the relation of modern buildings to ancient remains, and the equally queer ones, in another direction, of some of their antagonistic correspondents. In the present Report the absurdities are, perhaps, pretty evenly divided on the two sides; at all events, more evenly than usual. The letter from some one concerned in the matter of Saltfleetby Church, Lincolnshire (no clue is given as to whether the writer is architectural or clerical, probably the latter), in which the Society are assured that the most reverential attention has been paid to the conservation of the ancient church, by pulling it down with the view of using the whole of the materials in the new church, is unquestionably very pretty reading for archaeologists of a cynical turn of mind. The society have scored a quite unexpected success in obtaining the consent of the Benchers of Lincoln's Inn to retain the old gateway into Chancery-lane,—a success the more marked as the work is known to have been in the hands of a certain too notorious legal architectural cobbler, who would probably have delighted to pull down the gateway if only to cause annoyance to the Society. Archaeological sentiment seems, however, to have penetrated the legal minds of the Benchers to this extent, and the gateway remains. Its value is exaggerated by the Society, but seeing how unlikely it was under present circumstances that anything tolerable would have been put in its place, its retention may be considered a clear gain. The fine design for the re-building of the east end of St. Bartholomew's Church, of course, is

stamped with obloquy by the Society, who would prefer, we gather, to leave the bare wall and the iron columns, which we presume they would consider as interesting examples of the taste of a former generation. The hest thing in the Report is, perhaps, to be found in the letter about Puncknoll Church, Dorsetshire, where the Society, after taking upon themselves to explain to the Rector that, as his church will seat one-fifth of the population of the parish, it is impossible he can reasonably want it enlarged, add, "the addition of an organ-chamber and a vestry would go still further to spoil the church as a Medieval building." So that, according to the views of the Society, a church in regular use for modern worship is not to have an organ or a new vestry, because the rest of the church is old. Is it any wonder that some architects refuse to give any attention or reply to the views of such silly and impracticable doctrinaires? The tone of what may be called polite impertinence which pervades the correspondence of the Society is enough in itself to put up the back of any man of spirit and possessed of a healthy contempt for humbug.

THE rejection by a Select Committee of the House of Commons of a part of the Salford Corporation Bill forms another incident in the history of the Manchester Ship Canal. The Salford Corporation desired to contribute 250,000*l.* towards the capital required for the construction of the canal, and the matter occupied the attention of the Select Committee for two days, resulting in a refusal to grant the powers sought for. This is a victory for the railway companies, who have, of course, persistently opposed the whole scheme as calculated to endanger their interests. They are large ratepayers to the Salford Corporation, and naturally objected to being compelled to contribute towards a competitive concern. This is another hitch in the progress of the scheme, the preliminaries of which are proving very costly, and it is to be hoped that when carried out it will justify the expectations which have been formed respecting it. The railway companies evidently regard it as a dangerous rival, and it seems probable that were the existing waterways of the country less under the direct and indirect control of the railways they would be of more advantage to the trading community than they are now.

AMONG the Bills which a General Election would put an end to for the present session is that for the better prevention of fires within the metropolis, which was set down for the second reading on June 25th. It is probable that, though it may be temporarily shelved, it will sooner or later become law. It must be confessed that its title is not altogether appropriate, for it does not seem necessarily to be a measure which will prevent fires. Stated in half a dozen words, it is a Bill to authorise inquiries into fires when damage to the extent of 500*l.* has been done, and the origin of the fire is unknown, or when the Chief Officer of the Fire Brigade shall report that the circumstances of a fire are proper to be investigated. The inquiry is to be held by a Commissioner to be appointed for the purposes of each particular inquiry. As most fires in the metropolis are caused by some trifling and common piece of carelessness, the results of inquiries are scarcely likely to lessen the number of fires, unless it be by a constant recommendation of certain structural arrangements of buildings. On the other hand, it is certainly advisable that these accidents should be carefully investigated, just as much as railway accidents or explosions in mines.

REFERENCES have once or twice been made in our columns to the Sanitary Registration of Buildings Bill, which was read a first time in the House of Commons on the 2nd inst. The Bill, which is backed by Dr. Farquharson, Sir H. E. Roscoe, Sir Guyer Hunter, and Dr. Cameron, was originally drafted by Mr. Mark H. Judge, and was brought in at the instance of the Sanitary Assurance Association, who, while desiring that legislation should take place with the

view "of affording some guarantee that every dwelling-house shall be reasonably fit for habitation," do not, we are pleased to note, desire the establishment of a central authority for the stereotyping of even the best system of sanitation, but they wish, as they say in a petition which they have presented to the House of Commons in favour of the Bill, "to see a law enacted which shall empower the Local Authorities to demand the certificate of some competent person or corporation that the sanitary arrangements of any building are satisfactory before it shall be lawful for such building to be occupied."

A REPORT has recently been made to the Town Council of Antwerp which contains matter of interest in regard to the questions of water-supply and sanitation. The long-continued drought of the summer of last year, and the sudden increase in the consumption of water caused by the Exhibition at Antwerp, prevented the water-purifying apparatus used in that city from completely destroying the marshy taste and smell which characterise the water of the Nethe. The fear of cholera, then raging in Spain, caused additional anxiety, and a Commission of five chemists was appointed to examine into the matter. The report in question was made by this body, and after dealing with matters of local interest, it discusses the process of purification and its theory, the general arrangement of the waterworks, the cause of the marshy taste and smell, and finally the result of the examination of the water with reference to microbes and bacteria. The conclusions arrived at were,—that the water was never unwholesome, in spite of the unpleasant taste and smell, and that all doubts about the efficacy of the purification of water by means of iron applied through the instrumentality of revolving purifiers must fall before the researches of the English scientific men who have investigated the subject, and before the labours of the Commission itself, which confirmed their conclusions to the fullest extent. Particulars of the investigations on this subject referred to will be found in the Minutes of the Proceedings of the Institution of Civil Engineers, vol. lxxii., p. 24, and vol. lxxxii., pp. 279 and 285.

A CORRESPONDENT writes:—"Some of your readers may be interested to hear that at an auction held the other day in Old Bond-street several well-authenticated relics of ancient Carthage, collected by Count D'Hérison, from recent excavations, were exposed for sale. Among these were two mosaics, in excellent preservation, each about 3 square feet in size. The one represents a nude youth sitting beside a woman dressed in a peplos and wearing a crown of rushes; the other a youth, also nude, on whose shoulders is an eagle. They were discovered near Tunis, in a garden at Danar-el-Sciati, situated in the midst of the ruins of ancient Carthage. The subjects of the two mosaics have been arbitrarily entitled 'Peace' and 'War,' but they are probably mythological rather than allegorical representations. The first might possibly be intended for Paris and Helen, the second for the Abduction of Ganymede. They are evidently Greek and not Roman in character, while the superior excellence of their design shows them to have belonged to an earlier and more artistic age than the mosaics discovered at Pompeii. These mosaics seem to point to Carthage as the originator of mosaic art. Ancient Greece has left no traces of it, while its development in Italy is much later. Carthage, with her wonderful variety of coloured marbles and the world-famed skill of her craftsmen,* may well have originated the idea. Whether she possessed indigenous artists of any merit is a question, but her skilled craftsmen may have worked from Greek designs, or even made copies in tesserae of Greek paintings. Roman mosaics have also been discovered on the site of Carthage, but

these are evidently later than the Carthaginian, not only because they are less deeply imbedded in the soil,* but also because they are inferior in design and execution, and not even so well cemented. The two above-mentioned specimens, besides some superb pieces of Carthaginian pavement, were purchased for Mr. Edwin Long, R.A."

ALL lovers of the picturesque will regret to hear that the scene of the market at Siena is shortly to be transferred from the Piazza del Campo to the open field behind the Palazzo Pubblico, in the centre of which a common-place open erection, consisting of a roof of red tiles, supported by a series of red brick piers, has just been completed. This is the more to be regretted, when it is known that the chief reason for the change is not sanitary, or for extra convenience of buyers or sellers, but because, forsooth, of the untidy appearance it gives to the historic piazza. It is true that one of the most romantic sights in Italy is this piazza at night, when there is a full moon, the Palazzo Pubblico and the Mangia tower casting their great sprawling shadows even upon the houses opposite. Then the feeling of desolation and want of life is the great charm; but in broad daylight one will sadly miss the busy crowds of *contadine*, with their enormous-brimmed straw hats, seated at their rawning-covered stalls, bargaining *altissima voce* with the matrons of Siena. This so-called improvement was initiated by the same member of the municipality who advocated the removal of the Early Renaissance chapel at the foot of the Mangia tower, in order to restore the symmetry of the Palazzo Pubblico. Fortunately, he did not carry the day in this suggestion, and now,—rest his soul,—he is removed from the affairs of Siena to another sphere, where it is to be hoped his Vandalisms may be forgiven him.

ANOTHER, and perhaps more famous market-place of Italy, has also suffered, viz., the Mercato Vecchio at Florence, the scene of many an exciting gossip in Medieval times, and once overlooked by the workshops of many world-renowned artificers, in particular the honest independent curt old smith, Niccolò Grasso, or Caparra as he was usually called, who executed, among many other well-known works, the spirited *bracciolotti* at the angles of the Strozzi Palace. This piazza is now enclosed with a tall hoarding, behind which the myrmidons of the Florentine Hengler display their feats of horsemanship to the gaping public. Of yore it was certainly a very untidy and dirty quarter; but it was "picturesque dirt." Now, however, even that cannot be said for it,—even the delightful view of Giotto's Campanile and Brunelleschi's dome has been cut off by this hoarding. Surely the Florentines could find some open space on the outskirts of the town more appropriate for the site of a circus than a historical piazza in its very centre.

OF all things in the world to get into Chancery the last one would expect would be the ancient boat of Brigg. However there it is, and the dispute will probably give rise to some interesting legal question as to its ownership. Meanwhile it seems clear that it should become the property of the nation and be shown, without charge, to any one, and not, as at present, be the means of putting shillings into the pockets of some one. The proper resting-place would be somewhere near where it was found, for it is a mistake to carry off local relics to the British Museum or to London, instead of adding to their interest by the local characteristics with which they are connected.

WHATEVER may be the advantages, or disadvantages, of a building "boom," there can be no doubt that archeologists should feel indebted to it for much valuable information, and for the discovery of many archaic treasures. There are few cities which

cannot show examples of this kind at some time or other, Rome being the latest, and, perhaps, the most fertile of any. On various occasions we have chronicled the finding of many specimens of statuary or mosaic pavement, not the least important of these being the bronze figures dug up during the excavations for the new Opera House in the Via Nazionale. Mr. Newton considers that one of these, which represents a boxer waiting his turn to be called into action, is of the school of Lysippos, and of a date between 300 and 200 B.C. Some day or other, when there is more money to spare in the coffers of the Roman municipality than there is now, a noble museum will be added to the interesting sights of Rome, filled with the discoveries of the last few years, but which are now, for want of room, stowed away under the care of Professor Lanciani.

EVEN in these poverty-stricken days it appears that money can be found for *bric-a-brac*, especially if the articles on sale can be proved to be of undoubted parentage and pedigree. At a sale the other day at the Hôtel Drouot in Paris, some astonishing prices were realised. Amongst them were a couple of vases of Urbino faience, which went for 67,000 francs; while a cup of the same date (at the commencement of the sixteenth century), with decorations attributed to Andrea, was sold for 11,000 francs. Amongst other "unconsidered trifles" were an ovoid glass with painting in *grisaille* by Pierre Raymond, which went for 10,000 francs; a glass of Venetian blue for 13,000 francs; and a small copper with plaques of enamel for 8,600 francs.

THE *Allgemeine Zeitung* quotes a letter from M. Maspero reporting his progress in the great work of excavating the buried sphinx of Gizeh. The workmen have got down as far as the paws of the creature; on her right hand are a number of Greek inscriptions (*προσκυφήματα*) of imperial date. It seems that the paws were hewn out of a kernel of living stone, and built round with stone work; the surface of the stonework was painted red with articulations in yellow. The excavators have now got down below the level formerly reached by Mariette and Caviglia, and they are now at work in layers of sand, which have lain undisturbed since the first centuries of our era. This sand has become exceedingly hard, and, in fact, has coagulated into a material more like stone. The face of the sphinx has always been exposed to about 15 metres, but we are glad to learn from M. Maspero that on laying bare the lower part the expression of the Sphinx has greatly gained in "serenity and cheerfulness." She has borne her long imprisonment well. M. Maspero still needs an additional 10,000 fr. completely to free this captive of the ages.

THE last number of the "*Notizie degli Scavi di Antichità*" reports the discovery of a mosaic of considerable importance at Chiusi. Some workmen came unexpectedly on the pavement in digging a watercourse at the foot of a hill near Monte Venere, on the property of Cav. Giovanni Paolozzi. The mosaic is in all 6 by 4 metres in size. The centre part represents a double hunting scene; in the top row are three stags pursued by one hunter armed with a spear, below is a boar pursued by two hunters armed respectively with axe and lance. The centre design is excellently preserved,—perfect, in fact, but for a few scratches made by the pickaxes of the workmen at the moment of discovery. It has been carefully taken up by the owner and removed to his private museum. The rest of the pavement is left *in situ*. It is the first piece of mosaic that has been found in the neighbourhood of Chiusi.

AT Messrs. Boussod & Valadon's rooms in New Bond-street there is, in addition to the collection of Dutch paintings we mentioned the other day, a collection of oil and water-colour drawings by Miss E. M. Osborn, illustrating the scenery of the Norfolk Broads. These show much artistic power and feeling,

* Homer calls them *πολυδαίδαλοι*.

* Roman remains at Carthage are found at depths of 3 ft. below the surface of the ground, Carthaginian at never less than 10 ft. (Davis).

and have a special interest from the peculiar character of the scenery. In "Belaugh Marshes" (4) we have a sunset over a network of watercourses which twist like a red ribbon through the landscape. We see the flat-bottomed Norfolk craft, built for navigating shallows, threading their way through the winding canals, coming down before the wind "On the Bure, Yarmouth" (21), or pursuing the apparently hopeless task of working to windward along a narrow channel which turns this way and that at every fifty yards, as in the "Breezy Morning, Belaugh" (11). A morning effect under the title "Gossamer" (7), with the swans coming along mid-stream in procession through the mist, is a peculiar and charming effect very well represented. There are twenty-two small oil paintings and about twice the number of water-colours, containing much that is worth looking at.

THE *Pall Mall Gazette* of Monday published an ill-tempered but amusing reply from Mr. Ruskin to some innocent evangelicals who asked him to subscribe to pay off the debt on Duke-street Chapel, Richmond. Why, he asked, did they build churches they could not pay for? Why not preach behind the hedges rather than run into debt? "and of all manner of churches thus idiotically built, iron churches are the damnablest to me." In the latter sentiment we are disposed inwardly to concur, though we do not wish to emulate Mr. Ruskin's peculiar and rather pronounced phraseology.

UNDER the heading "Naval and Military Intelligence," a communication appeared in the *Times* of the 9th which it is impossible for any who feel concerned in the efficiency of our marine artillery to read without a very disagreeable kind of interest. It is there stated that on the previous day "the harbette ship *Impetuous* made a protracted and thoroughly satisfactory trial of her multifarious armaments and gun-mountings at Portsmouth." In the course of this "thoroughly satisfactory" trial it appears that at the first fire from the harbette gun at its extreme angle of (horizontal) training, the flash set on fire some of the ropes in the vicinity. In succeeding rounds "Several misfires occurred either from defective tubes or the results of insufficient handling, and the last round was considerably retarded by the giving out of the spindle by which the breech-piece is pushed into the breech." In succeeding trials of other guns "only a few misfires occurred," but on the starboard guns being fired with 50 degrees of training "the blast carried away several clutches and forced open one of the ports." This, we learn, is "not insignificant," as it shows that the blast "would probably prevent the 6-in. guns nearest the midship harbettes from being worked in action." If this is a "thoroughly satisfactory" trial, what is an unsatisfactory one like? Or was it a misprint, and should it have read "thoroughly unsatisfactory"?

WOOD CARVING, POTTERY, AND GLASS EXHIBITED IN INDIAN COURTS.

COLONIAL AND INDIAN EXHIBITION.

No nation in the world can surpass the inhabitants of India in skill and band-cunning, and that patient industry which the savage exhibits in the carving of his canoe-paddles and war-clubs, though with the Hindoos (using this name in a general sense) this quality has been refined and directed to the best results by centuries of practice, and nowhere is this marvellous band-cunning exhibited to greater advantage than in their wood-carving. The instinct of nearly all Oriental races is to decorate a surface by breaking it up, so to speak, with a more or less intricate pattern, often in slight relief, and by this means great richness of effect is obtained. The Hindoos have great fertility of resource in designing these diapers, witness some of the screens, which have hardly two panels alike, though the difference is only noticeable on close inspection, which will further reveal the fact that there

is a marked character and likeness running through all their work, the same motifs being introduced, with very slight variation, again and again. In giving a few illustrations of the Indian wood-carving we have endeavoured to select typical, interesting, and various specimens of their work,—specimens that may be taken as representative of what is best in Indian work.

Figs. 1, 2, and 3 are from the central pro-

we have often before noticed, we find well-known Classical motifs introduced again and again, and handled in a way characteristic of the workers. We give the palm to the Burmese for wood-carving, both for design and workmanship. There is a sideboard back exhibited, composed of interlacing scrolls, which might have been wrought by Grinling Gibbons himself. The Burmese are fond of grotesque heads, half animal, half human,

Fig. 2.

Fig. 3.

Fig. 4.

Fig. 5.

Fig. 6.

vines. Figs. 2 and 3 are thoroughly characteristic in design and workmanship, the carving being in slight relief, having the appearance almost of having been laid on in the form of a fret. Fig. 1 is more elaborately carved, and is very rich and flowing in design, and withal simple, so that it is effective at a distance.

The remaining illustrations are from Burmah. The scroll-work in figs. 4, 5, and 6 is very finely carved in much higher relief than is usual with Indian work, and the design, too, is much more flowing and "Classical." In fact, in all Indian work, as

and several instances of these may be seen on the screens in front of their exhibit.

Pottery.

There is a good deal of painted pottery exhibited, and some of it is very excellent. The Hindoos, like the Chinese, possess the art of producing the best effect with one or two colours, blues being the favourite. The bulk of the pottery is decorated in a deep blue, with turquoise introduced into the background to give relief to the patterns. Sometimes a low-toned purple is sparingly introduced, but in the majority of cases only the two blues are used.

In selecting our illustrations we have been guided by two considerations,—beauty of shape and skillfulness of decoration. Most of the Indian shapes are graceful and effective, and admirably adapted for decoration, a most important consideration in painted pottery, and one not sufficiently studied by Europeans. Simple shapes are the most effective, and most of the shapes here figured are simple. The Indians are apparently more restricted than the Chinese in the matter of shapes, and the same form will be seen again and again in different sizes and with slight modifications. Figs. A to I, in the pages of sketches in this number, are from Mooltan, Punjab, and are entirely of native manufacture. The decoration will be found to consist of about three motifs, which occur in all their pottery. The decoration on figs. A and D is one type, that on E and the neck of B another type, and that on F and J another type. The beauty of this pottery is mainly due to the glaze, which gives a charming softness to the colours, and is in itself brilliant and soft without being "shiny." De Morgan in his files has perhaps approached nearer this kind of glaze than any other pottery painter in this country.

Fig. G is decorated with raised and incised ornament glazed with a soft yellow glaze. There is also a case of rather rude-looking pottery glazed with soft colour glazes, but they were not of sufficient merit to warrant us giving sketches of them.

Fig. I is part of a large vase, and shows clearly the type of ornament commonly used in this Punjab pottery. The outline is a deep purplish blue, and the background pale turquoise.

Figs. J and K are from Bombay. The decoration is in black on a peacock-blue ground, and the effect is very rich and unique. That in black on a green ground is not as satisfactory. The Bombay pottery is produced under the direction of the school of art, and some critics think that the work is in consequence less characteristic than that of Mooltan, for instance. There is a slight hardness in some pieces, we must admit.

Figs. L to S are from Jeypore. The decoration on Fig. O is very Persian in character. That on Fig. P is very daring, and is not ineffective.

The last three figs., T, U, and V, are from Rampore native state. Some of their pottery (figs. T and U) has a dark rich green ground with the decoration in white slip coloured turquoise. The effect is very striking. There is also some red terra-cotta pottery, decorated in slip, and coloured blue and turquoise, which has something fresh about it. All the pottery we have figured is painted under the glaze. Looking at Indian pottery generally, it will be noticed that the Hindoos prefer to space out the surface, and decorate the different spaces, to adopting the Japanese method of letting the decoration cover the surface without occupying the space to be decorated. Their decoration may be termed geometrical in character, there scarcely being a single piece painted in the free manner of the Japanese. The effect of their pottery is bold and effective, owing to its simplicity, and will well repay the attention of English designers and craftsmen.

Glass.

The only town exhibiting any notable glass is Patna, and we give sketches of five pieces to give an idea of the class of glass it is. The glass itself is both transparent and opaque, and varies from white to turquoise, blue, green, grey, yellow, and mauve. Some of it is fluted, but the bulk of it is plain. Two or three specimens are decorated with ornament in gold. Hindoo glass is of much less merit than the pottery, if this Patna glass may be taken as representative; and evidently glass is little used by the natives, who prefer pottery and metal work.

The Institution of Civil Engineers.—At the first meeting of the present Council of the Institution, Mr. H. L. Antrorns was re-appointed treasurer, Dr. William Pole, F.R.S., honorary secretary, and Mr. James Forrest the secretary. From a new edition of the list of members, corrected to the 3rd inst., it appears that there are now 1,553 Members, 2,187 Associate-Members, 499 Associates, 20 Honorary Members, and 910 Students, together 5,174, against 4,884 at the same date last year.

ARCHITECTURE AT THE ROYAL ACADEMY.—VII.

CONTINUING the subject of domestic architecture, we notice next No. 1,619, "Arundel and Fitzalan Houses, Arundel-street, W.C.," Mr. John Dunn. These are the group of chamber residences facing the Thames Embankment, which form a block of buildings in a very tame late Gothic style; they look better in reality, however, than in this weak and spotty drawing. No plan.

1,620, "St. Bride's Vicarage, Fleet-street," Mr. Basil Champneys. A pen elevation of the house of which we published a view in the *Builder* of May 22, with plans, which are not appended here. It is a successful reproduction of the London house of the eighteenth century, and is in keeping with its surroundings, but certainly looks tame enough in this line elevation. It is a pity the plans were not added, because they show very good practical dealing with an awkward and restricted site.

1,621, "House at Bickley, Kent," Mr. Ernest Newton. A very homelike house in cottage style, simple and unaffected, shown in a good pen drawing, and with the distinguishing merit of having a plan appended.

1,624, "Mourne Park, County Down," Mr. John Birch. What is called an "imposing pile," shown in a large and effective pen drawing, a square tower with angle turret in the rear standing holdly in the centre of the group of building. As far as one can see, it does not look interesting in detail, and seems to have no central idea in its design; a number of parts put together. No plan.

1,626, "Abheystead, Wyresdale, Lancashire," Messrs. Douglas and Fortham. A pleasantly-designed domestic Gothic house, with a good deal of character; long, low, diversified in the outline of the plan, which is not given plan-wise, however, but can only be judged of from the perspective. Behind the domestic-looking façade (under part of which runs the carriage-drive beneath a segmental arch), is apparently a square "keep," with a castellated turret at the angle. This, if modern, is an anachronism, though it certainly serves to contrast very well with the character of the front buildings. A plan might have shown us its justification, real or supposed.

1,629, "New House at Scarborough," Mr. E. J. May. Looks like a sketch of an old tumble-down house, selected from the point of view of the picturesque. If the size of the windows is correctly represented, the "new" house must be decidedly deficient in light and air.

1,634, "Saltskog, near Stockholm, Sweden," Mr. Howard Ince. Apparently a timber house, after the (constructive) manner of the country, with a certain amount of English feeling imported into it. The balconied recess under the gable is a good feature. Sketches of the hall and of the staircase-window are added. The design is picturesquely grouped, and there is more variety of incident in it than is usually found in a house of that size. No plan.

1,637, "Houses at Barnes Common," Mr. Herbert Read. Hung high; apparently picturesque, but rather too manifestly intending to be so. No plan.

1,640, "New Studios, South Kensington," Mr. W. Flockhart. There is no doubt a great deal of character in this front, particularly in the treatment of the windows, which, in the first floor, are mullioned five-lights, with a decorative panel formed over three of the lights, above the line of the window-head. The "character" in the twisty-twirly gables is overdone; the projecting curls look as if they would be certain to chip off some day. No plan. The drawing (pen and ink) is a bold and effective one.

1,645, "Rebuilding of 125-123, Mount-street, Grosvenor-square," Mr. W. H. Powell. Skied, and difficult to see. Apparently a rather "broad" treatment of the mass of building in a dark-and-light-stripes manner (what profane persons used to call the "streaky-hacou style"), but the heavy façade has little but plate-glass to stand upon in the ground story. No plan.

1,649, "Residence, Shrewsbury," Mr. T. M. Lockwood. A brick and half-timber house, got up with great propriety, but without a touch of originality anywhere. Drawing mannered and hard, and makes us wonder, like some others, why it was placed on the line. Another view of apparently the same house is shown in No. 1,653, which appears more interesting, but is hung too high to be seen well. No plan.

1,650, "Croft Stables, Stanstead, Essex. Back View," Mr. W. D. Caros. The front view is shown in No. 1,657. Very good drawings, especially 1,657, which would have been much more worth placing on the line than some that enjoy that honour. Buildings picturesque decidedly; how far in detail suited to their practical requirements we cannot, of course, judge very well from picturesque drawings. The author is to be commended for appending a plan, in which he shows the barns-room in the right place, adjoining, but not opening into, the stable. Whether it is advisable to have so close a communication between the coachman's parlour and the stable may well be questioned, and the small staircase and partition wall from it, jutting into the stable, makes the way to number four stall rather awkward steering for the horse. From the scale it appears that the stable-door for the horses is only three feet wide,—much too narrow. Very few of the "picturesque" architects really know how to build stables.

1,652, "Beeston Lodge, Cheshire," Messrs. E. Salomons and John Ely. This house, of which we published a view and plan some time ago, is shown in perspective in one of the best water-colour drawings in the room; a trifle heavy, perhaps, but very thoroughly worked out. The house is red brick with stone dressings, and stone mullioned windows below, with black-and-white work above; this upper portion over-arching slightly. The roofs are red tiled. The whole is exceedingly effective and rich, and the most of this has been made in the drawing. The design has, however, the defect of a certain want of refinement in detail, and a somewhat too obvious effort at effectiveness; the authors do not seem to have quite the pure gospel, so to speak. Still, it is a country house out of the common way, and evidently carried out with great care, and the plans, of which ground and first-floor are appended, are very good. Though on somewhat irregular lines, they are nevertheless convenient, and the rooms well-arranged in regard to each other, and the rooms and corridors are full of little unexpected points, embayments, flirtation corners, &c., which add so much to the interest of an interior, we do not mean specially in the view of flirtation, but for general interest and variety. A whist-gallery is placed at one end of the billiard-room, raised a few steps; this may have been the wish of the owners; we should not think the most favourable position for playing anything worth calling whist, with the click of the billiard-halls and the calling of the score going on below, not to speak of the temptation to look away from the little green cloth to see what is the progress on the large one. The morning-room would be rather deficient in light, unless it gets a full level eastern sun, which there is nothing to show (*N.B. Points of the compass should be shown on plans*, especially those of dwelling-houses). But on the whole this is a noteworthy house. We might, for all we know, have been able to say the same of No. 1,607, which is a still better water-colour drawing, occupying a similar central position on another wall, had the authors of that also allowed us the chance by showing a plan; but they gave us nothing but a picture. A dwelling-house, of all other buildings, without a plan is only half, say only a quarter, illustrated; it may be a pretty house, but whether it is a good or a bad one no one can say.

1,670, "Wortley Vicarage, Yorkshire," Mr. Basil Champneys. A house with mullioned windows and Elizabethan curved and recurved gables, presenting no special features. The pen perspective is very spotty in effect, and produces the impression of the grounds being neglected and the place deserted. No plan.

1,673, "Houses in Cadogan-square," Messrs. Ernest George & Peto. A picturesque brown-tinted drawing (published in the *Builder*, of May 15) showing houses decorated with flat scroll ornaments in brickwork, and rusticated pilasters standing on corbels, and with no meaning or architectural function of any kind; but this is the fashion now, and the authors cater for it better than most of their contemporaries, though they can do much better than this. No plan.

1,674, "Proposed Restoration of Glenbucket Castle, Aherdeenshire," Mr. R. T. Blomfield. A sketch should have been given showing the present condition of the castle; it is impossible otherwise to form a judgment about it as a restoration. The drawing shows corbelled out angle turrets, square and circular, after the

ancient Scotch manner, and an effective arrangement of windows under the eaves of the roof, not, we think, in the ancient Scottish manner, but effective nevertheless. No plan is given; in fact, as a restoration of an ancient dwelling-house for modern use it is impossible to judge of it at all. It is a view of a modern-antique castle, and that is all.

1,675, "Wedderburn House, Hampstead," Mr. Horace Field. There is nothing objectionable in this; but what, in the name of goodness, are the claims of either drawing or design to be hung on the line? Who has been responsible for the hanging?

1,676, "Proposed House, Beckenham-place Park, Beckenham," Mr. John Ladds. A rather attractive domestic Gothic house, but with no particular principle of design manifest in it. The author is to be credited with the unusual merit of having appended plans; and perhaps it is rather unkind in the same breath to find fault with them; but while the drawing-room, library, and billiard-room form a connected suite, the dining-room seems unnecessarily thrust away from them; and, in spite of its contiguity to the kitchen regions, there is no way for the diner (as far as we can see) from the kitchen to the dining-room except through the out-of-door in the passage, and in full view of the main hall and staircase. A serving-door may be intended, but is not shown. The two inner angle faces of the main hall also are rather shams, to produce an octagon which does not arise naturally out of the planning of the building.

1,679, "Stowell Park, Gloucestershire. North and South Elevations, Restorations, and Additions;" Mr. John Belcher. Neatly-drawn elevations of an old house, with portions in section, the meaning and object of which are, in the absence of a plan, absolutely unintelligible.

1,880 and 1,683, by Mr. Basil Champneys, are small pen sketches of various houses at Sunningdale, of no very special character, but quiet and domestic looking, which is probably what was aimed at. Wonderful to relate, plans are appended to all of them, in a sketchy but sufficient manner,—a fact which leaves us too surprised and impressed to make any further notes this week.

THE ANNUAL REPORT OF THE METROPOLITAN BOARD OF WORKS.

The Annual Report of the Metropolitan Board of Works, for the year ending December 31, 1885, has just been issued, and it forms a record of a vast amount of heterogeneous work which has been done, and on the whole done well, by the Board,—which, whatever the anomalies and defects of its constitution, is nevertheless the only body exercising municipal authority (however limited to certain functions) over the metropolis as a whole.

With regard to sewerage and drainage, the Board has been engaged since the year 1879 in constructing in various parts of London additional large sewers by way of supplementing and relieving some of the sewers of the main sewer system, which in times of heavy rain were found to be inadequate to carry off with sufficient rapidity the enormous quantity of water which found its way into them. At such times the sewers were apt to overflow, greatly to the inconvenience of the inhabitants of some of the low-lying districts, and the new relief sewers have been constructed in order that the storm water may be more rapidly carried off, so as to prevent the occasional floodings. The new main sewer from Roehampton-lane, Putney, to the Clapham-road, with branches running into it at various points, is still in course of construction. The contract price for these works, commenced in 1882, is 151,995*l*. The new sewers for the relief of the Ranelagh and King's Scholars' Pond sewers, commenced in 1883, are virtually completed, the price for which the work was undertaken being 96,300*l*. To relieve Holloway and its neighbourhood from flooding, it was deemed necessary to make a new sewer, 17,700 ft. in length, commencing in the Holloway-road. A tender to execute these works for the sum of 78,509*l*. was accepted by the Board in November, 1884, and a total length of about 10,000 ft. has been completed. A new sewer at Eltham, which has cost 23,500*l*., one at Lee, costing 5,836*l*., and two at Hammersmith, costing together 8,353*l*., have also been completed; and the Queen's-road, Dalston,

sewer, passing along Great Cambridge-street to the Middle Level Sewer in Bethnal Green-road, was commenced in February, 1885, the contract sum being 19,850*l*.

With regard to the sewage and the river Thames, the Report details the various steps which have been taken by the Board consequent on the report of the Royal Commission on Metropolitan Sewage Discharge, but this portion of the report is now "ancient history;" as the subject has been prominently before the Board on two recent occasions, when we published full accounts of the Board's proposals.*

Having chronicled the steps taken by the Board to carry out the provisions of "The Metropolis Management (Thames River Prevention of Floods) Amendment Act," which empower the Board to require the wharfs, walls, and banks of the river Thames within the metropolis to be so raised as to prevent the overflow of the river, the Report goes on to refer to the metropolitan street and other improvements already carried out or in progress. At the date of the report the Board was still engaged in acquiring the property required for the formation of the new street from Tottenham Court-road to Charing Cross, authorised by the Street Improvements Act, 1877, and during the year claims to the amount of 130,038*l*. in respect of the property so acquired had been settled.

With regard to the operations of the Board under the Artisans' and Labourers' Dwellings Improvement Acts, the Board reports that only one official representation had been received by it during the year. The blocks of buildings already erected in the metropolis upon ground acquired and cleared by the Board under the powers of the Acts are 221 in number, and the number of persons housed in them is 21,678.

The Act of Parliament which empowered the Board to acquire and maintain for the free use of the public most of the bridges over the Thames within the metropolitan limits was passed in the year 1877, and the Report details the operations of the Board under the Act during the past year, and refers to the proposed establishment by the Board of ferries or other means of cross-river communication below London Bridge.

The parks, commons, and open spaces now under the Board's control have a total area of 1,834 acres, the largest items being Blackheath, 267 acres; Hampstead Heath, 240 acres; Clapham Common, 220 acres; and Wormwood Scrubs, 193 acres.

Having given a *résumé* of Bills in Parliament promoted or opposed by the Board, the Report gives an account of the present position of the Metropolitan Fire Brigade, the total strength of the force being, at the date of the Report, 589 officers and men. There are 55 fire-engine stations, 23 street stations, 127 fire-escape stations, 26 land steam fire-engines, 87 6 in. manual engines, 37 small manual engines, 3 self-propelling steam fire-floats for river service, 4 steam tugs, 4 steam fire-engines on barges, 144 fire-escapes, 5 long fire-ladders, and 4 vans to carry the same, and 131 horses. The fires of 1885, compared with those of 1884, show a decrease of 19, but, compared with the average of the last few years, an increase of 41. The Board call attention to the fact that the expenditure upon the Fire Brigade in the year 1884 was found to be in excess of the income by 10,854*l*. 17*s*. 7*d*., and they point to the necessity of increasing the limit of that portion of the consolidated rate applicable to fire-brigade working expenditure from one half-penny in the pound on the gross annual value of property to one penny in the pound on the net or rateable value. They also ask for increased contributions from the insurance offices.

With regard to the water supply of the metropolis, the Report chronicles the gradual extension of the constant-supply system and the fixing of fire-drainants.

The Board's powers and action with regard to gas-tosting; tramways; telephone and telegraph wires; the prevention of the spread of cattle diseases; the inspection and registration of dairies, cowsheds, and milk-stores; the control of slaughter-houses and offensive businesses; the storage and transit of explosive substances and petroleum; and the supervision of "baby-farms" under the "Infant Life Protection Act, 1872," are all set forth in the Report, and their mere enumeration is enough to show

how many really extraneous duties,—duties never contemplated when the Board was instituted,—have been thrust by Parliament upon the Board in the absence of any nearer approach to a metropolitan municipality.

When we turn to the financial transactions of the Board, we find that its revenue is equal to that of many a kingdom. The Board's expenditure during the year 1885, including 1,486,552*l*. advanced on loan to other local authorities, 1,197,892*l*. invested in Treasury Bills, and 225,533*l*. applied to the reduction of debt, has amounted to 5,549,181*l*., of which 1,644,280*l*. has been defrayed out of money raised by the issue of Metropolitan Consolidated Stock.

The Report details at length its procedure in the supervision of streets and buildings under the Metropolis Management and Building Acts, and the appendices include the reports of the Engineer and Superintending Architect on the work done in their departments during the year. From the report of the Superintending Architect we learn that the total number of building operations (for the year 1884) was 26,363, including alterations, the amount of fees received by the District Surveyors in respect of the same being 46,792*l*. 11*s*. 6*d*. It seems that the difference in the value of the several districts is considerable. The gross fees received in thirty-nine districts during 1884 varied from 22*l*. to 592*l*. In two of the districts the receipts did not amount to 100*l*. each; in four districts the receipts were less than 300*l*. each; in nine less than 400*l*. each; in eleven less than 500*l*. each; and in thirteen less than 600*l*. each. In thirty-one districts the receipts ranged from 60*l*. to 2,377*l*.

COMPETITIONS.

The University College of Wales, Aberystwyth. We are informed that the Council of the College have awarded the premiums offered for the best three designs for new buildings at Aberystwyth in the following order: First prize of 100*l*. to Mr. Frederick Boreham, F.R.I.B.A., Fishery-pavement, E.G.; second prize of 50*l*. to Messrs. Seward and Thomas, St. John's Chambers, Cardiff; and the third prize of 25*l*. to Mr. H. G. Williams, of Liverpool. The council, before adopting any of the plans referred to, have asked Mr. J. P. Seddon to prepare designs showing how the old building may be adapted to meet the requirements laid down when the specifications for a new college were considered. The ultimate decision as to whether the remains of the old college, of which a considerable portion escaped injury during the late fire, will be utilised, or an entirely new college be built, will depend mainly on financial considerations.

Harrogate Bath Hospital.—The Governors of the Bath Hospital and Convalescent Home at Harrogate, having decided on erecting a new building, recently instituted a limited competition, and appointed Mr. Waterhouse, R.A., assessor. They invited seven architects to send in designs, and Mr. Waterhouse decided in favour of that submitted by Messrs. Thomas Worthington and J. G. Elgodd, of Manchester, who have received instructions from the committee to prepare the necessary working drawings, &c., for its erection. The outlay contemplated is about 17,000*l*.

A New Building Estate in Surrey.—In the neighbourhood of Woking, and within easy distances of the St. George's Hills and the rivers Wey and Thames, another large estate, about 60 acres, has been laid out for building purposes. The estate is the joint property of Mr. Alderman Norton, of Poole, and Mr. Alfred Gale, and is situated in the centre of a beautifully-wooded surrounding country, principally consisting of fir-groves and heaths. The roads have been laid out. The other works have been executed from the designs and under the superintendence of Mr. H. Humphrey Rumble, C.E., and building operations have been already commenced.

Metropolitan Board of Works.—We understand that among the numerous candidates likely to offer themselves for the post of Superintending Architect to the Metropolitan Board of Works is Mr. Gordon Smith, the present architect to the Local Government Board.

* See *Builder*, pp. 457, 806, ante.

ELECTION OF TWO DISTRICT SURVEYORS.

At the meeting of the Metropolitan Board of Works, on the 4th inst., the Board proceeded to the election of two District Surveyors for Chelsea, the old district having been, by resolution of the Board, divided into two (North Chelsea and South Chelsea), after the death of Mr. Sancton Wood. There were thirty-two candidates for the two appointments, viz., Messrs. T. Batterbury, H. H. Bridgman, H. Cheston, S. Flint Clarkson, P. Cowper, F. E. Eales, J. S. Edmeston, G. Edwards, R. F. C. Francis, W. Grellier, F. W. Hamilton, J. Hamilton, J. Hamilton-Gordon, W. J. Hardcastle, A. Harland, E. Haslehurst, A. Heyes, G. Inskipp, G. Jackson, G. A. Lean, H. Lovegrove, T. E. Mundy, R. C. Murray, W. Hilton Nash, H. A. Pelly, C. G. Saunders, M. L. Saunders, W. Smallpeice, L. Solomon, W. L. Spiers, W. H. Stevens, and H. W. Stock.

The preliminary voting to reduce the number of candidates to six was, for each appointment, taken by show of hands, as has been usual; but Mr. Williams, no doubt in view of certain circumstances referred to by us on the occasion of the last election,* moved as an amendment on the usual procedure that the subsequent voting on the reduced number of candidates be taken by ballot. This was negative on being put to a show of hands, but a division being demanded, the amendment was carried by 28 to 23. After a long discussion as to the way in which the vote should be taken, it was resolved, on the motion of Mr. Lindsay,—

"That after having taken a show of hands for the first six candidates, each member write the name of the candidate he wishes to record his vote for on a piece of paper, and tender the same to the Clerk, and that one or more ballots be taken until the candidates are reduced to one candidate with a majority of the votes, and that the candidate be elected to the office, the same course to be taken in electing both officers."

North Chelsea.

The following were the six candidates selected in the preliminary voting, viz., Messrs. T. Batterbury, 30 votes; S. Flint Clarkson, 40; J. S. Edmeston, 29; W. J. Hardcastle, 38; T. E. Mundy, 33; and M. L. Saunders, 32. The following shows the result of the subsequent voting, the balloting papers being deposited by the members of the Board in a mahogany box (marked "Tenders") which was taken round by an officer, the papers being counted and the name of the candidate on each called out by the Clerk:—

	First Ballot.	Second Ballot.	Final Ballot.
Batterbury	4	23	25
Clarkson	19	23	25
Edmeston	5	7	9
Hardcastle	7	6	7
Mundy	6	5†	—
Saunders	5	5†	—

Mr. Clarkson, having thus received a majority of the votes cast, was declared to be duly elected, and he briefly thanked the Board.

South Chelsea.

The six candidates selected by show of hands for this appointment were Messrs. J. S. Edmeston, 25 votes; W. J. Hardcastle, 26; H. Lovegrove, 21; T. E. Mundy, 27; M. L. Saunders, 24; and W. L. Spiers, 16.

The balloting gave the following results:—

	First Ballot.	Second Ballot.	Final Ballot.
Edmeston	9	10	10
Hardcastle	8	8	7
Lovegrove	1	—	—
Mundy	11	15	23
Saunders	5	3†	—
Spiers	6	3†	—

Mr. Mundy, having received a majority of votes, was declared to be elected, and he also thanked the Board.

The innovation in the method of election, however necessary it may be, caused some delay and confusion, and it is therefore satisfactory to know that at the meeting of the Board to be held this Friday, June 11, Mr. Fowler will move, "That it be referred to the Works and General Purposes Committee to consider and report as to the future mode of conducting the elections of District Surveyors."

* Builder, pp. 162, 168, and.
 † Both these candidates were, by resolution of the Board, struck out together.
 ‡ Struck out together by resolution.

GROUND FLOOR PLAN

Scale of 1" = 20 Feet

"Hatton House," Westgate-on-Sea.—Plan.

Illustrations.

CHURCH OF THE SACRED HEART, LIVERPOOL.

THIS church, designed by Messrs. Goldie, Child, & Goldie, of Kensington-square, was commenced in the spring of last year, and is now rapidly approaching completion. It stands on very high ground, and is consequently much exposed to wind and weather; hence the plan adopted for the atrium and principal entrance, which had to face the front and back below it.

The confessionals and priests' corridor were specially planned to meet special requirements, and to afford easy and direct communication between the presbytery (already built), the sacristies, and committee-room.

The chancel might have been deeper with additional effect, but expense and "utility" were special instructions to the architects. A substantial working and inexpensive church with tracery was the ideal, and this it professes to be, and yet nothing is scamped.

The walling is of Yorkshire rock-faced stone, with dressings of selected Ranecon stone of the neighbourhood, and beautifully built. All the arch stones, dressings, and mouldings of the interior are in stone comparatively simple, but carefully worked out and executed.

The contract price is a very low one, and great credit is due to Mr. Fogarty, the contractor, for the thorough manner in which he is carrying out his agreement, under the practical superintendence of Mr. Hinsley, the clerk of the works.

NEW BOARD SCHOOLS FOR LONDON.

THE Hackford-road Schools, Brixton, of which we give an illustration, are being erected by the School Board for London from the designs of the Board's architect, Mr. T. J. Bailey. They are planned to accommodate 1,000 children, with power of extension to 1,400, and the amount of the contract is 10,249l. The builder is Mr. Henry Hart. The drawing from which the illustration is taken is in the Architectural Room at the Royal Academy.

The Berner-street Schools, Whitechapel, are also being erected by the School Board for London from the designs of the Board's architect, and are planned to accommodate 1,200 children; the amount of the contract is 13,300l. The builders are Messrs. Atherton & Latta.

ADDITIONS TO "THE PARK," LEDBURY.

"The Park," Ledbury, is a manorial house of seventeenth-century date, and stands at the outskirts of the village, at the corner of the main street and the road which leads to Tewkesbury. The original building is shaped on plan, and like other buildings of the village of which it is the most important, it is built of brick (rough cast on face) and timber,

the portion facing the main street having five overhanging gables, which have a striking effect as seen from the market place. About thirty or forty years ago a wing was added towards the lawn, so that the house now forms three sides of a square. The present alterations are being carried out in the courtyard, with the addition of a new wing in continuation of the old portion which faces the side street. The style of the old house, which is the prevailing style of the more interesting parts of the village, is being observed in the new work, all that is shown in the present view being new. The architects are Messrs. Richard Coad & J. M. MacLaren.

"HATTON HOUSE," WESTGATE-ON-SEA.

The above house, of which we give a view in this week's issue, is now in course of erection and rapidly drawing to a finish at the above-named sea-side place, and is carried out from the designs and under the superintendence of the architect, Mr. John Thomas Wimperis.

It is built with hollow walls faced with red bricks with stone dressings.

The dining-room, entrance-hall, &c., are fitted with old oak wainscoting with pilasters, doors, over-doors, mantels, &c., and recessed side for fireplace.

The ceiling is in ornamental fibrous plaster with large ribs and panels.

The library is fitted with walnut panelling, doors, and chimney-piece, with panelled ceiling, and the drawing-room with pine dados, and carton pierre chimney-piece and ornamental fibrous plaster ceiling, with handsome over-doors and dressings.

The staircase is in old oak with close string, carved and enriched balustrades and newels, and enriched soffits.

There are parquet floors to all the principal rooms and inner hall, and mosaic floors to all the passages and lobbies.

The stables are shown in the drawing and are just finished and provided with all the best and most approved fittings.

These latter buildings are executed in red brick, flint work, and timber.

Messrs. Wm. Corbett & Co., of Westgate and London, are the builders. The carving is done by Mr. Anstey, and the ornamental ceilings by Messrs. G. Jackson & Sons.

TOMB OF BISHOP WM. DE LA MARCHIA. "A.A." TRAVELLING STUDENTSHIP DRAWINGS.

This tomb is situated in the centre of the south transept of Wells Cathedral, and is composed of Donlingstone. Considerable remains of colour still exist. All the foliage was gilded on a red ground. The diapered spaces are alternately red and green; the figures at the back are treated in red and green also. For further notes on colour, see details.

Wm. de la Marchia died in 1302. The beautiful octagonal chapter-house, with its approaches, is said to have been built during

TOMB OF BISHOP WILLIAM DE LA MARCHIA, WELLS CATHEDRAL, DRAWN BY MR. R. W. PAUL.

AWARDED A.A. TRAVELLING STUDENTSHIP, 1886

F. Bell, Photo-Litho & Engraver, 25, Finsbury St., Holborn, London, E.C.

the time of this bishop, who had it not been for his misappropriation of Church funds to pay the soldiers of Edward I., would in all probability have been canonised. He was treasurer of England, 1290-1295. Many miracles are said to have been done at his shrine.

Amongst the many interesting details is the central boss in the vaulting, the roses being coloured green, and the leaves gilded with red edges. Most of the other carving was gilded on a red ground. The figure-work is an especial feature, the effigy itself being one of the finest in the cathedral, while the angels at the back, and those at the pillow, are very delicately executed. The grotesque heads placed along the plinth of the tomb are quite unique in their treatment. The female head in the western-most bay is a good example of the head-dress of the period. Westward of the tomb, a row of heads, painted in fresco, and evidently part of the same idea, are placed in the hollow of the embattled cornice which finishes the curtain wall of the steps leading to the ambulatory at the back.

R. W. PAUL.

SOCIETY FOR THE PROTECTION OF ANCIENT BUILDINGS.

The ninth annual meeting of this Society was held in the Hall of the Society of Arts on Tuesday afternoon, the Hon. Richard C. Grosvenor in the chair. There were about fifty persons present, including a number of ladies.

The annual report, which was taken as read, stated that the Society continued its work steadily, the efforts which it made not being affected either by success or failure. During the past year, the Committee's efforts had been rewarded by success in two important instances, viz., the York churches and the Charterhouse,—clear proof that public opinion was changing, and that the world was beginning to value ancient buildings more highly. Much damage, however, was still being done yearly by the "restorer," and valuable buildings were destroyed, both in this country and abroad, owing to the great and unfortunate movement which was started years ago. Even when that movement was first set on foot, it was interesting to note that there were some who realised the harm which was being done, though they were themselves under the influence of the movement, and spoke of commendable. In support of their views, the Committee quoted from the *Builder* of 1855, p. 459, an extract from a paper by Mr. Truefitt, read at a meeting of the Worcester Architectural Society, who, in speaking of the line to be followed in restoring an old building, said:—

"Never pull down any work and rebuild it in another style, but always prop up and patch an old building in all its lines of form; never pull down elegant spirelets at the angles or cathedral buttresses because they are not of the date of the original building, but restore them; never remove such quaint original buttresses as those lying ones at the east end of the choir structure near a hundred miles from the Faithful City, merely because they were not there when the building was first erected; for if such mutilations were fully carried out, nearly all our churches would be eventually pulled down with the exception of the original portions, namely, Norman doorways and broken fonts. Our buildings should be restored just as we found them; if there were a Norman nave and a Decorated chancel, restore each, but do not try to make them alike; a building should be mended just as we patch an antique chair, or rivet an old china bowl."

The report gave other extracts, including one from the *Gentleman's Magazine* for 1826 (vol. 96, part 2, p. 109), protesting against the work which was then being done to the Hall of Gray's Inn, a building of the time of Queen Mary, such work consisting in covering the dark red brickwork with combs. The "restorers" of Gray's Inn Hall, no doubt, believed that they were improving the building and making it more Gothic; but so beloved the "restorers" of ancient buildings at the present time. The only difference was that now the imitation of the Mediæval work was so much closer that it required a man with a better knowledge of the genuine Mediæval work to detect the imitations of the well-practised "restorer." And no doubt in another sixty years' time men will be scoffing at the works of to-day as the world scoffed at the restoration work of sixty years ago. But the "restorer" of to-day was the more to blame because he had had time enough to see what a hopeless task he had undertaken, and time to learn that the greater his power of close imitation the greater was the damage done to the history of art. The efforts of the Society were, however, surely telling, and during the last two or three years architects of

note had taken to putting the date upon their imitative work, while others were making sincere efforts to render their work as little imitative as possible. The report, after enumerating several of the home cases with which the Committee had dealt during the past year, referred with satisfaction to the labours of the Société des Amis des Monuments Parisiens; and, in conclusion, suggested the formation of a society for the preservation of ancient buildings in India,—a society in which Englishmen and natives of all races and denominations might combine for the protection and preservation of monuments in which all, but especially the natives of the country were so deeply interested.

The Chairman, in moving the adoption of the report, said that since the establishment of the Society nine years ago its necessity had become manifest more and more, and it had done good work, but he should like to see it go a step further in the future. He suggested that it might be possible to raise a fund from which the Society could directly contribute money towards the needful repairs of churches with the view of keeping those buildings out of the hands of the "restorer."

Mr. William Morris, in seconding the motion, said that the Society had scored one great success in the matter of the Charterhouse, although Mr. Beresford-Hope, who posed as a great defender of ancient institutions, was in favour of the scheme of destruction which was proposed,—a scheme which, indeed, deserved to be classed as an audacious attempt at robbery from the public. With regard to the chairman's suggestion of a special fund, no doubt it would be useful, but unfortunately the Society had had some difficulty in obtaining the necessary funds for carrying on their ordinary work. If the Government would put a thumping tax, say 75 per cent., on the cost of all restorations, and hand the proceeds to the Society to be spent in the preservation of threatened or neglected buildings, it would be a most beneficial piece of legislation for the country. If only a hundredth part of the sum which had been spent on "restorations" had been spent on the preservation of the buildings operated upon, there would have been no need for the existence of the Society.

The motion having been carried,

Mr. J. T. Micklethwaite, F.S.A., read a paper entitled "A Charchman's Plea on behalf of the Old Churches." He urged that although the Society had now obtained a hearing, it had still a great work to do. It had to make the guardians of old buildings understand their true value, and how easily they could be harmed. That was a hard task, but not a hopeless one, for encouragement might be drawn from the history of the very evil against which they were fighting, which was expressed in the one word "restoration."

Fifty years ago churches, especially in towns, were sometimes subjected to very barbarous "improvements," but most of them suffered only from neglect. That neglect was only one manifestation of a general decadence in all church matters. At length a body of men arose who set themselves earnestly to work to bring about an awakening and reform. They were the first who in any way felt the real value of the old churches and seriously set to work to study them. If the men who formed the Cambridge Camden and such like societies had not been, the destruction of churches would have taken another form than that of "restoration," but we should not have learned the value of the remnant that remained. There could then have been no "Society for the Protection of Ancient Buildings," though it was to be doubted whether the need of it would have been less. The fundamental error of the old teachers was in holding that it was possible and proper to bring back an old church to its original condition. However old a church might be, each generation in using it had altered and improved it according to its wants and its ideas of what was right. It might be that every part of it had been built and rebuilt several times over, and that the building we now saw was five times the size of that from which it could be shown to have grown; but the changes had been made in such a fashion that the identity had never been lost, and the church was still the old church to us, as it had been to each one of the, it might be, more than thirty generations who had preceded us. Some of the adherents of the

* Does Mr. Morris seriously imagine that the interests of the Society will be promoted by such nonsense as this?—Ed.

society had said, in their indignation at the brutality of the restorers, that we ought not to touch an old building at all, save to protect it from further injury than it had already received, but should keep it with all its history exactly as it had come down to us. It was, perhaps, well for the first advocates of preservation to call attention to their teaching by stating it in its harest and most extreme form, but a hearing having been obtained, it was, he thought, wisest to present the doctrine now in a form which would not provoke men to reject it as impracticable. "Restoration," as the word was now commonly used, included a right and proper treatment of a church as well as an improper one. The great revival of church life in our time had created wants which did not exist fifty years ago, and changes made to meet those wants honestly and without affectation were genuine additions to the history of the buildings. The harm had come of men trying to make believe that their nineteenth-century works were not done by themselves, but were part of some imagined original design. He contended that works done to meet the real wants of churchmen of the present day were, if good in themselves, very proper additions to such works should take care that he did so clearly show itself to be of its real date. Not that it should intrude itself as a thing out of harmony with its surroundings. The men of the fifteenth century could make their own additions to the churches of the thirteenth century without producing discord, and some of the men of the nineteenth century could do the same thing, or they were not fit to touch the work. Some might say that reverence required that a church should be kept decent and in proper order. That was specious, but if used to defend "restoration," it was really heging the question. Age was not indecent, and that which had upon it the dignity of centuries was far more fitting to an old church than the same thing patched, polished, and straightened up into newness. The Society wanted to make men distinguish between useful and needful repairs and needless and mischievous renovation. Repairs were right and proper when they were done for the structural good of the buildings; and so were alterations when done in the right way and to meet real modern wants. But renovation done for no other end than to gratify the vulgar taste for smartness was always wrong. If we would save the remnant of our churches from destruction, that was the lesson which we must teach to their guardians. It was not sought to stop them from improving their churches as their convenience or devotion required, but to show them a better way to do it. Let them write the history of their own time as freely and fearlessly as they would, but not in palimpsest.

On the motion of the Rev. Newton Mant, M.A., of Sledmere (who indulged in some extravagant remarks as to architects generally and diocesan surveyors in particular), seconded by the Rev. T. W. Norwood, F.G.S., of Nantwich, the thanks of the meeting were tendered to Mr. Micklethwaite for his paper; and a vote of thanks to the Chairman, moved by the Mr. John Hoib and seconded by Mr. Philip Webb, brought the proceedings to a close.

ARTISTS' BENEVOLENT FUND.

ANNUAL DINNER.

THE seventy-seventh anniversary festival of the Artists' Benevolent Fund was held at the Freemasons' Tavern on the 4th inst., the Right Hon. Lord Coleridge, Lord Chief Justice of England, in the chair.

In proposing the health of "The Queen," the Chairman referred to her Majesty's sympathy with artists, as evinced by the fact that she had this year, as usual, sent her contribution of 100 guineas to the Artists' Benevolent Fund, making a total gift of nearly 5,000l.

The Chairman, in proposing the toast of the evening, "Prosperity to the Artists' Benevolent Fund," remarked that it had been said that the world knew nothing of its greatest men. The point of that expression was that some men were checked and hindered, some out of short, some diverted perhaps, now and then, by a high sense of duty, from a career which they would have done honour to, and compelled to trudge along the road of every-day life, to die at last, as Dr. Oliver Wendell Holmes had said, "with all their music in them." That was especially true

of the artist. Some were tempted into the path of art by a feeling which they mistook for genius; perhaps by the sympathy which they thought was power, or by a multitude of other considerations, and after a few years of struggle they found themselves face to face with starvation, or something very nearly approaching it. There were others of real genius who were too poor to rise, and who, after a struggle of more or less gallantry, fell into a base captivity, and spent their lives in enriching some vulgar tradesman, or else became the real foundation of some fraudulent reputation. It was true of art as of other callings, that not all artists were among the unworldly. Any one who was at all acquainted with art knew that that supreme and magnificent genius, Rubens, was possessed of a high-minded and shrewd and tradesmanlike mode of disposing of his pictures. Sir Joshua Reynolds left a considerable fortune behind him; and Turner made something like 150,000*l.* before Mr. Ruskin wrote a line about him. But it was to assist those who were not like Rubens or Sir Joshua Reynolds that that society existed, and the Chairman concluded by an appeal on its behalf, coupling with the toast the name of the President of the Fund, Mr. Beresford-Hope, M.P.

Mr. Beresford-Hope responded, and proposed "The Chairman," who again briefly addressed the Company.

Mr. George Codwin, F.R.S., in proposing "The Royal Academy," expressed regret that the members of the Academy were apparently for the most part so very little disposed to help this, the senior Artists' Benevolent Fund. The impression seemed to prevail in some quarters that it was a mere benefit society, but that was a complete mistake. The society consisted of two parts. First, there was the Artists' Annuity Fund, a sort of benefit or insurance society, most admirably managed, but which was entirely self-supporting, and neither asked for nor received help from the public; and secondly, there was the Artists' Benevolent Fund, a charitable society, to which, in fact, the members of the Annuity Fund contributed, and to whose funds they asked the public to contribute in aid of the widows and orphans of artists. Referring to the Academy, Mr. Godwin said that, notwithstanding much that had been said against it, it still remained the great centre towards which all artistic effort was directed, and it was, he was glad to say, doing more now for the furtherance of art than it had ever done. With the toast he coupled the name of Mr. C. B. Birch, A.R.A.

Mr. Birch briefly responded, and other toasts followed. During the evening subscriptions to the amount of 400*l.* were announced, including a donation (the forty-seventh annual) of 105*l.* from her Majesty the Queen.

The musical part of the entertainment was given by some members of the Savago Club.

[In reference to Mr. Godwin's remarks as to the want of knowledge of the objects of the Fund, we quote the following from the Address of the Committee:—

"The 'Artists' Fund' was established in the year 1810, and received in 1827, from his Majesty King George the Fourth, its patron, a Royal Charter of Incorporation. It now enjoys the most gracious patronage and support of her Majesty the Queen.

The Artists' Annuity Fund is raised and wholly supported by the contributions of its members for their own relief in sickness or old age; it neither asks for nor receives any support from the public. All artists in Painting, Sculpture, Architecture, and Engraving are eligible to become members.

The Artists' Benevolent Fund is purely charitable, and has for its object exclusively the relief of the widows and orphans of members of the Annuity Fund left in need; it is supported by the donations and subscriptions of the patrons of the fine arts and artists, and annual subscriptions of the members of the Annuity Fund. The annual sums payable to the most needy of the widows and to the orphans are respectively supplemented by donations and from the interest on benefactions of Miss E. L. Eyre and the late Edward Absalom, Esq. The claims of all widows and orphans who become entitled to its benefits are admitted at once, and without limit to number."

We may add that during the past year 55 widows and 18 orphans received annuities, amounting in the whole to 1,137*l.*]

Wandsworth Workhouse.—The Guardians of the Poor of the Wandsworth and Clapham Union at their last meeting instructed their architect, Mr. T. W. Aldwinckle, to prepare plans for alterations and additions to the old Workhouse, St. John's-hill, New Wandsworth, with a view to its occupation as an extension of the present infirmary.

ASSOCIATION OF MUNICIPAL AND SANITARY ENGINEERS AND SURVEYORS.

A DISTRICT meeting of this Association was held at Great Yarmouth on Saturday last, on which occasion the following papers were read and discussed.

Mr. J. W. Cockrill, Borough Surveyor, read a paper on "Great Yarmouth, and some of the recent Works of its Sanitary Authority." He said that the population of the town at the commencement of this century was 16,573; at the census of 1881 it was 46,153, and now is very near 50,000. The death-rate as given by the Registrar-General last year was 17.85. The acreage is about 3,400, of which 500 acres is Corporation waste, and available for building land. The roads and streets are upwards of 110 miles in length, exclusive of the "Rows," of which there are about eight miles. The "Rows" form a peculiar feature of the town, and accommodate a population of upwards of 13,000.

There are upwards of fifty miles of sewers in the borough. The river Yare, which divides the borough into two equal parts as far as area is concerned, forms the main sewer, and, in Mr. Cockrill's opinion, makes a most efficient one. A strong tidal current exists, with plenty of back-water, by which the sewage is swept out to sea, only returning to the beach at a point beyond the Corporation district. In 1851 and 1852 complaints were repeatedly made about the stench given off by the surface ventilators to the sewers, and in October, 1852, Mr. Cockrill was instructed to investigate and report upon the condition of the sewers in the town district, and the necessary work to put them into efficient working order. To carry out these instructions he opened 144 sewers, upwards of twenty-three miles in length, at points not more than 100 yards apart. The defects discovered in the sewers were, in a large number of cases, entirely attributable to the utter disregard with which private and even Corporation connexions had been made with them. A large number of brick sewers existed within the area bounded by the town wall; these were several centuries old, the bricks were thoroughly rotten and rat-eaten, and many of them so repaired, altered, and cut about, that there were not 10 yards in one length in which the sewer remained of its original section. In two cases the sewers had been cut off from the outlets through which they had originally drained, and were connected with another sewer at their upper ends, thus involving a deposit of 15 in. or 18 in. of sewage in about 100 yards in each case. It was not to be wondered at that about twelve months previously to the discovery being made, three deaths from diphtheria had taken place in one house draining into one of these sewers. Mr. Cockrill advised the Sanitary Authority to take up and relay all the pipe sewers in which any defects had been discovered, re-making private connexions with the same with proper junctions, and to take up all the old brick sewers and replace them with glazed pipe sewers. He also advised that full means of flushing on some automatic system should be adopted wherever possible, and that a movable flushing-tank be constructed of 3,000 gallons capacity; that the sewers should be thoroughly ventilated by pipes, with a sufficient number of surface gratings to provide fresh air; and that the sewers should be divided into lengths by light galvanised iron flaps to prevent the uprush of sewer air from the low levels into the upper reaches of the sewers. His estimate for this work was 8,000*l.* He also advised that connexions should be only made by Corporation men, and that only with proper junctions for both brick and pipe sewers, and he invented (although he afterwards found out that a similar block was in use at Leeds), a special junction block for pipe sewers. He had found that in making connexions, if he insisted on taking out a pipe and inserting a junction, that it was next to impossible to get the sewer laid correctly again, and he claimed for this block that a connexion with ordinary care could be made quite equal to that made with the junction-pipe in one piece. The report referred to was in the main adopted, and after more than two years' trial the work done gives thorough satisfaction; and the estimates were not exceeded, and for the sum of 8,000*l.* about six miles of new pipe sewer were laid and seven miles of pipe sewers relaid, involving about one-third new materials; about 3,000 house and other connexions were re-made;

40 cast-iron ventilating pipes, 6 in. by 9 in. and 6 in. by 6 in. were erected against houses, three wrought-iron shafts to stand alone and two brick shafts (four brick shafts had been previously erected) and six flushing-tanks of 3,000 gallons capacity, with automatic syphons, were put at the heads of sewers where they would do most work. The cost of water to supply these flushing-tanks, and the large movable tank, led to discussion as to whether it would not be advisable for the Authority to provide their own supply for sewer flushing and street watering. Of course, opposition was raised to this; scientific evidence was obtained to prove that sea water would be both injurious to roads and health, but under Mr. Cockrill's advice the opinion of Mr. H. P. Bonhous, of Portsmouth, was obtained on this subject, and at the inquiry held before the Inspector of the Local Government Board, he completely (or at least to the satisfaction of the inspector) demonstrated that all the evil charges made against sea-water when used for such purposes were untrue, and that much good might be expected both on roads and in sewers by its use. Mr. Cockrill said he had had previous experience in road-watering with it, found that it was much more efficient in laying dust, and that roads in the summer time were less liable to break up than where fresh water was used, but he advised that one section of the town should be watered for a whole season; this was done, a large expense was saved in quantity of water used, and also gravel which it had been necessary on previous occasions to use for patching. The Council had, during the year previously to this matter being brought on, used about 10,000,000 gallons of the company's water to flush sewers and water the roads in the district which he proposed should be served with sea water; these 10,000,000 gallons had cost 552*l.* 0*s.* 6*d.*, while the average cost of the water for seven years, in which little or no flushing had been done, came to 404*l.* 6*s.* 7*d.*, and he estimated that to supply the flushing necessary to keep the sewers clean would involve an outlay of at least 700*l.* per annum, and for this they would receive about 14,000,000 gallons only. The scheme he prepared involved fixing an "Otto" gas engine of 8-horse power (making the third he has now fixed for this Council, the previous ones working admirably), with pump, the erection of a tower, and cast-iron tank to hold 22,000 gallons, six miles of distributing cast-iron pipes of 8 in., 7 in., 6 in., 5 in., 4 in., and 3 in. internal diameter, with forty valves for flushing, and forty hydrants for street watering; six flushing-tanks of 2,000 to 3,000 gallons capacity were also included (making twelve now at work), and, much to his surprise, his estimate only came out at 4,500*l.*, and Messrs. H. F. Snow & Co., of London, are now at work upon the scheme, which is within a month of completion, the contract price being 3,987*l.*, while works not included in this contract, may, perhaps, amount to about 200*l.*

These figures give a clear gain to the Corporation, as may be seen below:—

Interest and repayment of loan on 4,500 <i>l.</i> per annum	2270
Working expenses, depreciation and small additions, per annum	140
Total annual cost	410

For this sum the plant erected will raise in 120 days, of ten hours each, 30,000,000 gallons, of which about 5,000,000 gallons will go on to the streets, while the remaining 25,000,000 gallons will go into the sewers, and more can be raised at less than 1*½*d. per 1,000 gallons, as less water is used for street watering; a considerable saving will also be made in horse hire; this is estimated at about 80*l.* per annum.

In the borough there are nearly fifteen miles of footway laid with concrete, in a similar manner to that now being put down, and described below. Some of this has had heavy traffic for fifteen years, and now shows no sign of wear, and will, no doubt, under fair treatment, last at least half a century longer, and, in Mr. Cockrill's opinion, is the cheapest and most durable footway which can possibly be formed.

The works now in progress have been undertaken by Messrs. M. C. Duffy & Son, of London and Yarmouth, and include about 17,000 yards super. of footway, 2½ in. thick, at 1*s.* 9*d.* per yard super.; rather more than three miles of kerbing, at 1*s.* per yard run, and a large quantity of granite crossings.

Mr. Cockrill gave the following as a few of the rules which experience had taught him

should be observed. Concrete must not be laid in frosty weather, and he had none laid from the middle of October to the end of March. It is also better to avoid extreme heat, as the sun takes the moisture out of the upper face before the cement has time to set. What concrete work he had done in hot weather is always well watered. If this is not sufficient it should be kept covered with mats. It is also advisable that the ground should be well wetted before it is laid. The expansion in hot weather is counteracted by the insertion of wood splines, placed from 5 ft. to 6 ft. apart. These are of the full depth of the concrete, and if at any time a piece of pavement is found to be lifting with the heat, at night, as soon as the temperature begins to lower, if a spline is taken out in every 100 ft. of the footway it will resume its proper position.

An objection to concrete paving, as laid en masse, is the difficulty of laying drains and water and gas pipes through the same, without cutting it up. The water and gas companies at Yarmouth find it possible to get under paths 7 ft., 8 ft., and 9 ft. wide, without breaking them up.

The paving now being laid is 2½ in. thick, the lower 1½ in. thick composed of four parts beach shingle, screened through a ½-in. sieve, to one part Portland cement. The top 1-in. thickness is composed of two parts beach shingle, screened through a sieve of 4-in. mesh, and one part Portland cement. The kerf is 6 in. by 3 in., and mixed in the same proportions as the paving. In practice he found that however carefully concrete is laid, or however good the proportions, it will not stand vehicular traffic, and that is the reason for the large number of granite crossings included in the present contract.

In selecting the materials forming the base of the concrete, he had found that no other class of materials wears as well as beach shingle. The Sanitary Authority has had under discussion the desirability of erecting public slaughter-houses.

Mr. E. G. Mawbey, Borough Surveyor, King's Lynn, read a paper on "The Sewerage, Surface-drainage, Sewage-disposal, and House-drainage of the Market Harbrough Great and Little Bowdeu Local Board District."

During the day the members visited and inspected the concrete pavements of Yarmouth, and the sea-water sewer-flushing and street-watering arrangements.

THE CHEMICAL TREATMENT OF SEWAGE.

On Tuesday evening, at a meeting of the Society of Chemical Industry (London section), held at Burlington House, Dr. C. Meynot Tidy, F.C.S., &c., delivered a lecture on the above subject to a large audience of the members, Mr. Howard, the president of the London section, being in the chair.

Dr. Tidy said the subject was very vast, and it would be very interesting, to follow the history of the subject through all its numerous phases and changes. He had tried to follow it conscientiously through all the Blue Books, and he hoped not many people would follow his example. It seemed to him that Blue Book No. 2 was always doing its best to undo all that was done by Blue Book No. 1, the two vieing with each other to bewilder the reader with facts and figures. Royal Commission followed Royal Commission, the members of which seemed mostly to be badly chosen. They were entrusted with inquiries into the subject of the pollution of rivers and of the diseases resulting from their pollution, although no medical man was placed on the Commission. He did not think there was much hope of any brighter future. He thought the outlook seemed better a few months ago, but some very dark clouds had gathered later. It was, in fact, a problem of a very complex nature they were called upon to solve when asked to advise upon sewage schemes. The researches of Lawes and Way in this country, and of Wolf and Lehman abroad, had given them some valuable conclusions. Taking the population per 1,000, they would find the liquid and moist excreta amount to 2,640 lb., the dry excreta to 141 lb., while the amount per head of other dry matters would be 2½ ounces, with a large volume of water. To get results of that kind was an important matter. An important branch of the subject was the nature of the refuse,

obtained from the washings of the streets. It was found after heavy showers that the solid matter discharged into the gutters from a roadway of granite amounted to 800 grains per gallon, of which 280 were in solution and 520 in suspension. With wood pavement it was 50 grains per gallon, 40 in solution and 10 in suspension. Of course, it was to be expected that the quantities would vary with the traffic and the class of roads; but, in order to get results of any value, it was necessary to get samples every half-hour throughout the twenty-four. Factory refuse it was impossible to calculate, because the circumstances varied from day to day and from hour to hour. Samples of sewage that might be sent for analysis could not be trusted. It was even necessary in taking samples of river-water to get a series of samples at various places right across the stream.

The difference would be found to be great in the same stream, between samples taken at the edge, where the sediment collects and putrefies, and in the middle, where the air has free access. The calculations made as to the value of sewage were generally ridiculous and illusory. They were told to take the value of the excreta at six or seven shillings per head of population, and on that basis calculations made years ago, when London had only 3,000,000 inhabitants, had given the sum of from 1,000,000l. to 4,000,000l. as the value of the sewage lost. Of course, theoretically they ought to follow the teachings of science, and apply the sewage to the land, but when it came to be tested practically, it was always found that the question of making a profit out of it had to be given up. There were two things they could not do. 1. They could not produce a sludge as valuable as Peruvian guano; and (2) they could not produce an effluent as pure as drinking-water. In the present effluent there was always left a disagreeable odour. The only way in which the effluent could be properly purified was by running it over land. In concluding his paper Dr. Tidy strongly condemned the views of those who advocated the system of water-carriage for the disposal of the sewage, and called upon the members of the Society to remember that it was their duty to apply their science to the daily wants of daily life, and thus endeavour to meet the common needs of humanity.

A discussion followed in which Dr. Dupré, Mr. Bischoff, Mr. Cresswell, and other gentlemen took part.

Mr. Cresswell regretted that the lecturer had not given them the advantage of his own views respecting an alleged recent discovery, which, if true, would deserve to be recognised as one of the greatest discoveries of modern times. He referred to the employment of permanganate of soda proposed by the Metropolitan Board of Works.

Upon this point Dr. Tidy said he had not touched, not because his opinions were not formed, but for reasons already stated. He might say that the three eminent chemists who had sent in the report referred to by Mr. Cresswell had all given evidence that nothing further was required to be done in the treatment of sewage than had been done by the Board, and that the Board, which believed it had conferred a great benefit on the community in turning the sewage into the Thames, was quite content in making choice of those eminent chemists to support it.

The proceedings closed with a vote of thanks to Dr. Tidy.

TILBURY DOCKS ARBITRATION.

On Monday last, Lord Coleridge and Lords Justices Lindley and Lopes delivered judgment in the matter of a question arising out of the arbitration between Messrs. Kirk & Randall, the contractors, and the East and West India Dock Company, concerning the contract for the construction of the large docks recently opened at Tilbury.

The question before the court was whether it was within the jurisdiction of the arbitrator to receive evidence upon and entertain certain of the claims preferred against the Company by the contractors, more especially those involving a consideration of the nature of the soil in which the excavations had to be made. The arbitrator himself, Sir Frederick Bramwell, had ruled that the claims before him were properly within his jurisdiction, but the Company appealed to the Court of Queen's Bench to direct him to the contrary. This the court declined to do, and the Court of Appeal has now unanimously supported them.

Judgment was therefore given in favour of the contractors, with costs.

ASSOCIATION OF PUBLIC SANITARY INSPECTORS.

ANNUAL DINNER.

THE third annual dinner of this Association was held in the Venetian Saloon of the Holborn Restaurant on Saturday evening last, Mr. Edwin Chadwick, C.B., President of the Association, in the chair.

The usual loyal and patriotic toasts having been given, Surgeon-General Sir Guyer Hunter, M.P., responding on behalf of "The Army and Navy,"

Dr. Alfred Carpenter proposed the toast of the evening, "Prosperity to the Association," and urged that sanitary inspectors should be granted something like "fixity of tenure" of their offices, and be paid out of the Consolidated Fund. They should not continue to be placed, as they were at present, at the mercy of members of sanitary authorities who were interested in dilapidated and insanitary property, but their tenure of office should be assimilated to that of Poor Law officers. The Association was a very useful and valuable one, not only to the members individually, but to the nation at large, for the members sought, by periodical meetings for the interchange of views, to protect the nation, and not merely their own localities, from epidemics and other results of insanitary conditions. (The toast, with which was coupled the name of Mr. Chadwick, was very heartily received.)

Mr. Chadwick, in responding to the toast, gave an interesting address on "Sanitation versus Militarism." At the outset he referred to the deplorable cost in life and money of the delay of sanitary legislation incurred by political pre-occupations. Whilst we were under further delay of legislation, it might be advisable that we should consider our normal standards of sanitation, for the future application of their principles. We must strengthen our principles by considering and revising our results. These were all sound. Take, for example, our prisons, once the chief seats of pestilence, now by sanitation, with the means of water carriage, and cleanliness in every case, the seats of the highest health. So with our district half-time pauper schools, in which the "children's diseases" were almost banished, where typhus, by which they were once so dreadfully ravaged, was now unknown, and in one year (Anserley), with some 900 children, there had not been a case of measles for the last two years. In those institutions, those who entered without developed diseases upon them showed a death rate, although they were children of the lowest type, less than one third of the death rate amongst the children of the general population, to whom the principles might be eventually applied. In extension of facts bearing on these results, urban districts should be examined and studied as normals where the separate system of drainage had been duly applied, where by correct sanitation foul smells were cleared from the houses and from the streets, and from the fields, where fresh and undecomposed sewage was duly applied with a five-fold production, and where the death rates had been reduced by one-third, and in some instances by one-half, what they previously were. Such normal examples should be kept in view and studied, though for the present they were shut out by the prevalence of sinister interests in regard to expense, or by pre-occupation with inferior political questions. These results might well be studied in contrast with those in which by the contraventions of sanitary principle the population of the Metropolis had been depressed, as declared by Lord Bramwell, through works that were now declared to be a disgrace to the Metropolis and civilisation, and were demonstrated as such in the condition of the seat of legislation itself, on which there was much to be said in exemplification of legislative disunity. To the normal results we might add the normals of the preventive service, which showed how sanitation had half emptied military hospitals which curative science, unaided by sanitary science, kept full, with augmentation of force and economy by the reduction of the army death-rates by two-thirds of what they formerly were. Our immediate means of economy by sanitation were now, however, straitened by the general distress which restricts immediate outlays of which the economical results were as yet little known in Parliament. Let us look at Italy. Two millions of money were voted for the relief of Naples, by sanitation, from the dire visitation of the cholera. But there was a deficit in the treasury, and the Government had not the money to give. The deficit was due to the enormous expenses of militarism, — to hoisted armaments, and to a fleet of big war-ships, some of which ships must have cost, as ours had done, a million of money each. It might be of use to give an estimate of the civil life and force that might be gained to a country by the application of a million of money, — the cost of one big ship, — if the sum were spent on sanitation. His only son had, he was happy to state, to meet a Royal Engineer become a special sanitary engineer, and had been doing sanitary work in several colonies for the Colonial Office. His recent work had been at Malta, and he presented it for this occasion as an example. The complete works of constant water supply of the water carriage from the houses, and of the application of foul water to agricultural production by irrigation, will cost about 80,000l. for

the whole of the population, about 100,000. He could confidently aver that the result of that expenditure, with well-qualified sanitary inspection, would effect a reduction of the death-rate by ten in a thousand,—as the like works under the separate system had done at home, would make Malta a real health-resort, and would also make it a great garden, with a fivefold production in an inferior climate. The expenditure on one big ship—the million of money,—would serve for the sanitation of a territory and population of some twelve or thirteen Malts, would save yearly a hundred lives, and more than two thousand cases of sickness, and all the expenses of lost labour to the adult population. Germany had paid the foremost attention to the application of sanitary principles to her army, and since the Franco-German war had gained by it as much life and force as was then lost by the sword. It was to be hoped that the like attention might be given by her to her heavily dethroned civil population. For ourselves, sanitation had gained for the Indian, as well as the home army, a great extent of the relief we proposed for it. In the Indian army we had obtained a reduction from the old death-rate of six to nine to thirteen per thousand. During the last decade, when the reduction had been got down to twenty in a thousand, a gain of forty thousand of force, first to last, had been achieved, and a gain of six millions of money. We had yet to advance there and to hold more firmly our dominion by the sanitary improvement of the civil population. In our Colonies, where, in the ignorance of sanitation, settlements had been made on undrained and malarious sites, with undrained houses and towns, there had been a great excess of preventable disease. Sanitation defences against these, it might be shown, were of primary importance, and would give more strength of life and force than those military defences, so very gratuitously, as he conceived, imagined to be immediately necessary. In conclusion, he said, let us keep our attention on our established sanitary normals and our extending normals; with confidence it would give us a greater future than the world had ever imagined, much less seen. Towards that great future the labours of the sanitary inspectors, modest as they were, would contribute their certain and useful quota, if they went on and on, trusting ever in industry, truth, and increasing knowledge.

Other toasts followed, including "The Executive of the Association" (proposed by Lord Fortescue and coupled with the names of Mr. G. B. Jerram, Chairman of Council, and Mr. H. S. Legg, Hon. Secretary, who responded).

WEATHER STAINS ON WALLS.

STR,—I should be glad if any of your readers can tell me what process is the best for taking weather stains from the face of a brick building covered by about 1 in. thickness of cement. Is there any process for dressing the face after cleaning by the application of any solution of silicate or similar substance which would not only have the effect of protecting the cement from absorption of the rain, but of rendering the face less liable to be disfigured in future by weather stains? What are the prices for cleaning and after-treatment respectively? A. F.

Duration of Kauri Forests.—Estimating says Professor Kirk, in his "Report on the Native Forests and the Timber Trade of New Zealand," the total extent of available Kauri forest at 200,000 acres (an area greatly in excess of that stated by the best authority, Mr. S. P. Smith), and placing the average yield at the high rate of 15,000 superficial feet per acre for all classes, the present demand will exhaust the supply in twenty-six years, making no allowance for the natural increase of local requirements. If, however, the demand expands in the same ratio that it has shown during the last ten years, the consumption in 1895 will be upwards of 240,000,000 superficial feet per annum, and the Kauri will be practically worked out within fifteen years from the present date. Under these circumstances the best interests of Auckland and the colony at large demand the strict conservation of all available Kauri forest. The progress and welfare of the northern district have been largely due to her magnificent forest resources, and their conservation will prove an important factor in the permanence of her prosperity. The utilisation of ordinary timbers should be encouraged, and it should be an axiom with the settlers not to use Kauri when red and white pine can be made to answer the purpose. Any steps tending to postpone the period of exhaustion will be of the greatest benefit to Auckland, as a longer period would be allowed for the growth of timber to take the place of Kauri within the restricted limits in which replacement is possible. Should this warning be heeded, a large displacement of labour will result, and the prosperity of the north greatly retarded.

The Student's Column.

OUR BUILDING STONES.—XIV. ARTIFICIAL METHODS OF RENDERING STONE DURABLE.

BETWEEN the natural and the artificial stone there is a transitional series, viz., those natural stones treated artificially in order to strengthen and cause them to resist the action of weathering as much as possible.

The principal cause of the invention of these processes arose from the rapid decay of the stone of which the Houses of Parliament are built.

Now, there are many solutions which the chemist tells us may be used to saturate stone with, in order to assist in its preservation, but the majority of them are so costly,—either in the methods of application or the chemicals themselves,—that comparatively few have been tried, and, with one or two exceptions, they may be regarded from a commercial point of view as failures. It is not the slightest use to invent solutions which involve anything but the commonest and most easy methods of application, such as may be carried out with a brush or something of that sort. The principal drawback to materials only superficially introduced into the stone, however, is that a crust forms, and although they preserve it from attack for some little time, eventually this crust scales off or becomes ineffective. The solutions applied in many cases alter the colour of the stone.

Silicate of lime seems to have secured to itself a good name for preserving stone. It has long been acknowledged as one of the substances best adapted to resist both the influence of the atmosphere and the action of sea-water.

The affinity of silica for lime is so great that if a piece of clay, very gently calcined, or a little gelatinous silica be placed in a solution of lime water, the whole of the lime is quickly abstracted from the solution and enters into solid combination with the silica, forming an insoluble silicate of lime.

It was the knowledge of this fact that caused Mr. Ransome, of Ipswich, to invent a process which is one of the most admirable of scientific contrivances, and we are sorry that the invention has not been more successful in this country. In this process the surface of the stone has to be made thoroughly clean and dry and restored in places where necessary. The stone is then saturated as far as practicable with a solution of silicate of soda or potash, and afterwards applying a solution of chloride of calcium, which, coming in contact with the silicate, produces an insoluble silicate of lime, aggregating and cementing firmly together the several particles of which the stone is composed.

The silicate is diluted with soft water and made thin enough for the stone to absorb it freely. The less water used the better. The solution is applied with a brush, and it will at first be found to enter the stone very slowly. The brushing having been repeated several times it will eventually be found that a shining surface is produced. This shows that the stone has absorbed as much as it is then able; and the brushing should stop immediately the first indication of it is apparent. If, by accident, a little more of the solution than is actually necessary is applied, the excess must be removed.

After the silicate has become perfectly dry, the solution of chloride of calcium is brushed on lightly, but without making it froth.

It is stated that in some cases, in order to complete the preservation as much as possible, the stone should be washed after the first application with soft water and the operation repeated. "In the second dressing the prepared chloride of calcium may be tinted so as to produce a colour harmonising with the natural colour of the stone."

The trade circular also gives us the following cautions:—

- "1. The stone must be clean and dry.
- "2. The silicate should be applied till the stone is fully charged, but no excess must upon any account be allowed to remain upon the face.
- "3. The calcium must not be applied until after the silicate is dry; a clear day or so should intervene when convenient.
- "4. Special care must be taken not to allow either of the solutions to be splashed upon the

windows or upon painted work, as they cannot afterwards be removed therefrom.

"5. Upon no account use any brush or jet for the calcium; that has previously been used for the silicate, or vice versa."

The success of the operation as a check to further disintegration depends in some measure upon the condition of the stone itself and the state of the atmosphere just before and at the time the process is applied.

In Kuhlmann's process a solution of silicate of potash or silicate of soda is applied to the surface of the stone. The surface is hardened by the decomposition of the silicate of potash.

If a limestone be operated upon, carbonate of potash, silico-carbonate of lime and silica will be deposited, besides which the carbonic acid in the air will combine with some of the potash, causing an efflorescence on the surface which will eventually disappear.*

It will be obvious, however, that the result of the process must depend on the purity of the limestone under treatment.

M. Kuhlmann has also introduced several chemicals to be applied to the stone which have the effect of producing certain colours in order that this process shall not disfigure it more than is absolutely necessary: these colours harmonising with that of the materials to which they are applied.

Secretmey's Process.—This is also a solution which was patented for the preservation of stone.

It appears to consist in the application of two coats of specially prepared silicate, with a third coat of asphaltum.

The silicate solution, however, is said to be the only essential part of the process, the asphaltum being merely applied to protect the silicate from moisture.

No doubt a solution of silicate of lime, even in the hands of less experimental operators, will be found very efficacious in arresting further decay if the application be made in time; but there are cases when decomposition and disintegration of the stone have already made such progress that it would be both a waste of time and money to apply any of these processes to stay the evil.

Other means have been employed, by filling the pores of the stone with solution of baryta, followed by solutions of ferro-silicic acid or super-phosphate of lime.

Soluble oxalate of alumina has been used on limestones.

The principle of each of these processes is the same. It is stated that they differ from those just described, in that they cause an insoluble substance to enter into the structure of the stone without at the same time giving rise to the formation of any soluble salt, likely to cause efflorescence,—this latter being disadvantageous.

When appearance is not important, ordinary paint may be used, but, as every one knows, the atmosphere, even under favourable conditions in London (where these processes are more particularly required) destroys the paint in a few years.

Mr. Davis invented a process in which he used a solution of *linseed oil and sulphur*. The solution seems to penetrate the surface to the extent of a quarter of an inch, and to harden it to a remarkable extent. The percentage of sulphur held in solution by the oil itself is small, and the weight of the sulphurised oil used in proportion to the weight of the stone treated with, is likewise small, so that the percentage of sulphur, even close to the surface of the stone, is extremely minute.†

Paraffin has also been used to protect the surface of stone, and we are informed that it has been so employed on the other side of the Atlantic with considerable success. Amongst other things the Cleopatra's Needle, which adorns the Central Park, New York, and which has suffered severe disintegration, has been coated with paraffin. It has given a slightly darker colour to the stone, but is said to have been effective in stopping its decay.

Paraffin dissolved in naphtha, together with a number of other mixtures, have been made use of from time to time, but we are very doubtful whether any of these processes afford permanent protection to building stones.

It would be much better if the stone were properly selected in the first instance, and then these supplementary expenses would be considerably minimised.

* Gillmore, on "Limes, Cements, and Mortars."
† See Dobson's "Rudiments of Masonry," &c., p. 141.

We have previously pointed out that in the ordinary course of decay, many natural stones have a hard layer, formed by chemical action, on their exterior. This crust has a tendency to preserve the stone underneath; and although buildings certainly, for a time, look better for being washed down, yet we do not think this method advisable when they are constructed with this particular kind of stone for this crust is often removed in the cleaning, and the stone becomes more exposed, besides having to reform (if it can) another crust, resulting in a considerable loss of substance. This remark is only meant to apply to buildings which have been erected a considerable length of time.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

3,458, Joining Edges of Squares or Panes of Glass. J. Plenty.

The object is to unite or join together the edges of separate pieces or panes of glass by means of a cement composed of an insoluble silicate of lime, which unites with and forms part of the substance of the glass, gets harder and stronger with age, and is not acted upon or destroyed by the action of the weather. It is applicable to all kinds of glazing. The edges of the glass are covered with a thin layer of a paste composed of about three parts silicate of sodium, with one part dry powdered air-slaked quicklime, and one part carbonate of lime. Chemical action takes place, the soda combines with the glass, forming a hard insoluble silicate of lime, and uniting with the silicate of soda. The joint is not seen a few pieces of it, and it is claimed that this will allow of large lighting spaces with no apparent break. The system can also be applied to roof-glazing or to stained glass.

5,533, Door Knobs. R. R. Harrison.

This is a combination of a method of fastening the knob to its spindle, and also to an attached rose (fast rose) for fastening the knob to the door. A square spindle has holes or depressions for a neck screw, by which the knob is fastened to the spindle. The attached rose is connected to the door by screws as usual, but the neck of the knob has a screw turned upon it, so that in addition to the small screw of the spindle the knob is kept in place by a loose ring on the neck, which, when screwed into place firmly, fastens the knob.

15,512, Screw-drivers, Gimlets, &c. T. Dussieux.

This invention relates to improvements in these tools, each being made in one piece with its handle. The essential feature is in simplicity and cheapness of production. The blades and handles are made by cutting lengths from wire of steel or other suitable metal, bending part thereof to the required shape to form the handle, and leaving a length below for the blade, the bottom of which is hammered, ground, or shaped as required.

British Museum.—Mr. John A. P. MacBride on "Later Greek Sculptors." 2.30 p.m.
WEDNESDAY, JUNE 16.
Royal Meteorological Society.—Four papers to be read. 7 p.m.
Builders' Foremen and Clerks of Works' Institution.—Ordinary meeting. 8.30 p.
SATURDAY, JUNE 19.
Architectural Association.—Vacation Visit (see advt.).

Richmond Hill.—We are glad to learn that the Duke of Buccleuch's property at Richmond Hill has been purchased by the local authorities, who, with a public spirit not always manifested on such occasions, have thus saved from destruction one of the most beautiful pieces of sylvan landscape near London. The purchase money is stated to be 30,000.

Miscellaneous.

Birmingham Architectural Association. At the ordinary meeting held at Queen's College on Tuesday evening, June 1st, the following gentlemen were elected to serve as the officers and committee of this Association for session 1886-87:—President, F. B. Osborn, F.R.I.B.A.; Vice-President, John Cotton; Ordinary Members of Committee, H. Beck, H. H. McConnaill, A.R.I.B.A., Franklin Cross, A. V. Ingall, W. H. Kendrick, T. W. F. Newton, F. B. Peacock; Hon. Treasurer, A. Reading, A.R.I.B.A.; Hon. Librarian, A. Hale; Hon. Secretary, Victor Scruton.

Sanitary Institute of Great Britain.—At an examination held by this Institute on June 3rd and 4th, sixty candidates presented themselves,—ten as Local Surveyors and fifty as Inspectors of Nuisances. Questions were set to be answered in writing on the 3rd, and the candidates were examined *visu voce* on the 4th. As a result, the Institute's certificate of competency to discharge the duties of Local Surveyor has been awarded to Messrs. Edwin T. Beard, J. G. Morley, W. H. Parry, F. H. Tulloch, and T. W. Wits. The Institute's certificate of competency to discharge the duties of Inspector of Nuisances has been awarded to Messrs. C. G. Bateman, J. V. Brooke, T. B. Warren, W. F. Wheeler, J. H. Leverton, C. F. Newman, E. Clayton, W. J. Treadwell, M. Hampson, G. Bartlett, W. J. G. Wreford, G. Darley, T. Salter, A. E. Black, J. E. Smith, A. J. Munro, T. H. Freeman, J. E. Evans, J. W. Hildreth, G. Taylor, A. M. Thompson, W. Garland, W. W. Cooper, L. W. Mellows, S. Crane, T. Ashdown, F. P. Burscough, H. Brownings, J. E. Massey, J. Cooper, W. Jones, J. J. Sargent, R. Chamberlain, W. Green, A. Gunn, J. Radcliffe, T. Anderson, W. J. Press, J. Wilkinson, A. R. Bull, G. Phinister, C. Cox, J. Haworth, and H. C. Bascombe.

Society of Engineers.—At a meeting of the Society of Engineers, held on Monday evening, at the Town-hall, Westminster, Mr. Perry F. Narey, President, in the chair, a paper was read on "Some Modern Improvements in the Manufacture of Coal Gas," by Mr. R. P. Spico, C.E., past-president. The author gave a résumé of the history of the various steps in the progress of coal-gas manufacture since the adoption of clay retorts. Referring to the objections raised to these on their first introduction, he showed how these objections had been disproved by experience. He then noticed the exhauster in its two forms,—by air-pump and steam-jets—and explained the advantages of both. The question of charging and drawing retorts by machinery instead of by hand was fully considered. Some of the difficulties that arose in practice were afterwards discussed, such as those caused by dips and anti-dips, choked ascension-pipes, and those occasioned by naphthaline, with the various remedies proposed. The paper then dealt with the advantages of purification in closed vessels, as now carried on by means of carbonising coal with a small percentage of slaked lime mixed with it before charging the retorts; the result being the entire abolition of the nuisance arising from the frequent opening and cleansing of purifiers on the old method, which is no longer necessary.

Trade Mem.—Messrs. W. H. Lindsay & Co., of the Paddington Ironworks, announce that they have been appointed by Messrs. Dorman, Long, & Co., of Middlesbrough, sole agents for the sale of their English steel and iron rolled joists, &c. We are informed that all Messrs. Dorman, Long, & Co.'s joists are branded with their name in full, and are guaranteed to stand a test of from 22 to 24 tons tensile strain. The prices, we are informed, are only very slightly in excess of those of Belgian joists. We are glad to see English ironmasters competing with those of Belgium in rolling joists of deep section.—The Coal-brookdale Company have just removed their London show-room from Holborn Viaduct to the Victoria Embankment, corner of New Bridge-street, Bricklayers, and opposite Queen Victoria-street.

Tottenhall.—A window in Tottenhall Church, Wolverhampton, has recently been filled with stained glass from the studio of Messrs. Warrington & Co., of Fitzroy-square. The window is of two-lights, and illustrates subjects of two of the Acts of Mercy, beneath architectural canopies.

British Archaeological Association.—The closing meeting of the session was held on Wednesday, June 2nd, Mr. W. H. Cope in the chair. Mr. J. T. Irvine exhibited sketches of some early Norman sculptures in Castor Church, Northants, and pointed out their resemblance in style to others on the font of the neighbouring church of Wansford. Mr. R. Mann described a remarkable carved stone found at Bath, having figures on three of its sides. Mr. Loftus Brock, F.S.A., reported the existence of a Saxon font at Triug, Bucks, now lying overturned in the porch. It is covered with interlaced work. A paper was then read by Mr. Algernon Brent on some early seals, which were exhibited at the same time. One of these was of Richard de Redvers, Earl of Devon, who died 1184. A second paper was then read by Mr. G. B. Wright, F.S.A., on a Roman building at Reims. It is only partially executed, and was inspected by the members of the Leland Club during the recent visit to France. There are six or more columns in a row,—their bases and about one half of their shafts being perfect, *in situ*; the remains of a hypocaust, and a great many walls, indicating that the building has been one of magnitude. The position is close to the Great Roman Archway in a public garden. The excavations are suspended for the present, until the Town Council has given sanction for the further works of clearance. The Rev. Scott Surtees pointed out some points of resemblance of the construction to those of the Roman Camp on the Saalberg. The concluding paper was by Mr. E. Walford on the painted glass still existing at Vane House, Hampstead, formerly the residence of Bishop Butler. There is a similar series of roundels at Oriel College, Oxford, believed by Cardinal Newman to have been brought from Hampstead.

Steel Rails for Foundations.—Steel rails are now frequently used in the foundations of large buildings, and Chicago is, we believe, the city where they were first employed. The Montank Block and the Central Building, now being erected on the old Rookery site, are among the structures partially supported by steel rails. Such a foundation is specially required in that city on account of the nature of the soil. In New York and elsewhere, where there is a solid rock bottom, there is usually no need of such a device, but even New York builders who have seen the use rails are put to are on the point of trying the experiment. The rails are laid close together imbedded in cement, which in time becomes almost as hard as the steel itself, and there is no danger of weakening the steel by rusting when it is so protected from air and moisture. Such a foundation enables the builder to make the stone piers above lighter, and thus save a good deal of room in the basement. And on the basis of recent prices, steel rails are cheaper than stone. This is an enlargement upon a system of wire concrete introduced into construction in this country some ten or twelve years since, in which a network of steel or iron wire was woven into the concrete.—Iron.

Prices Current of Materials. (Table with columns: Material, £, s., d., £, s., d.)

Table with columns: Material, £, s., d., £, s., d. Includes items like Greenheart, Teak, Birch, Elm, Pine, Lath, Deals, Waincot, Riga, St. Petersburg, White Sea, Canada Pine, Spruce, New Brunswick, Batten, Flooring Boards, Cedar, Honduras, Australian.

Architectural Backgrounds.

The admirably-written, but now certainly not much read, *Essay on the Picturesque*, by Sir Uvedale Price, one of the most interesting chapters is that which he devotes, with much intelligence and great acuteness of observation, to architecture and building; disavowing at the same time any technical knowledge of architecture, and illustrating his views on the subject more from the works of great landscape painters than by examples of known buildings, though not without, too, some considerable references to the latter. This treatise, written a good deal as a sequel to Burke's "Essay on the Sublime and Beautiful,"—and forming with that work and Alison's "Essay on Taste," what may be considered the old English classics in this walk,—enters largely into the subject of landscape gardening, and in the chapter referred to particularly in its relation to buildings, and that in a manner very interesting and suggestive.

While treating thus fully, however, of the landscape surroundings of buildings, the author does not seem quite to recognise the fact that these must resolve themselves into what is more strictly *background* on one side at least of every building having a principal front, a character applying to nearly all buildings not absolutely "monumental," as the term is architecturally used, and to some even of these. To this not much noticed topic of background in architecture, a little space may perhaps be not unkindly devoted in these columns. Landscape and buildings may be considered as mutually accessory to each, accordingly as one or the other may be for the time the chief object of attention; and as from the architect's stand-point his art claims that place, the relation which his work is to bear to the natural features of its site, and especially to those with which it must combine when seen in its most important aspect, becomes a matter of serious moment, and a very important element in the motive of his design; and it is, without doubt, frequently from deficient appreciation of this truth that buildings fail to produce the effect which the general merits of their design would seem calculated to secure. This is not the place to dwell on the many varying and often conflicting reasons which must be weighed by an architect in his choice of style and disposition of parts in designing a building, and some of which may, in many cases, overrule considera-

tions arising chiefly from the character of a site; and there are, of course, instances in which a building may be so circumstanced as in itself, from mere mass or extent, to outweigh any influence attaching to a perhaps tame and unmarked site; cases in which it becomes, in fact, the office of the architect to dictate and not at all to follow local character; and when this happens, the taste and judgment of a designer are shown in what may be held more strictly *pure* architectural design, as distinguished from what (horrowing a term from mathematics) we may describe as *mixed* design,—influenced, that is, in a great degree, by local rather than directly architectural considerations.

We must, for the purposes of our subject, suppose that the several questions involved in the best treatment of a design are pretty equally balanced, and consider how, under such circumstances, this special point of "background" should weigh in the scale.

To begin with,—of course it is only in buildings in which external appearance is felt to be of importance that this influence can be at all materially recognised; but, at the same time, it may be said that, however practical or commonplace the purpose of a building may be, any architect claiming to be at all a master of his art will find means of making it interesting in external character. The reference to the effect of buildings represented in the landscapes of the great masters, so frequently made use of, as mentioned above, by Sir Uvedale Price, is very consonant with sound reason, as these, for the most part, represented existing structures, built most probably of local materials, and thus, as Wordsworth was at pains to teach the Lake people, having one great element of the picturesque, in their harmony of tone with the natural objects around them. It is no gain, in an artistic sense, that "advanced civilisation," as the phrase goes, has so furnished the means of easy communication and of ready carriage of materials, that the products of all places are almost as available for use in all others as in their own; these facilities for the use of exotic materials have led, in but too many cases, to the neglect of those, more fitting but perhaps less "taking," of local origin, ignoring the unquestionable fact that the vegetable clothing of a country or district has such a relation to its geological features and products that where the former constituted the background the latter will not fail to harmonise with it when forming the substance of buildings relieved against it. As a first point, then, to be regarded by an architect in aiming at harmony between his building and its background we would name the use, as far as possible, of local materials in its construction, used, too, in such manner and form as shall

least disguise the qualities of colour or texture which give them a marked character. It would be difficult to exaggerate the gain in respect of picturesque effect which might be secured by a recurrence to this natural and primitive practice in places where it has been forsaken. No stronger case of the kind could, perhaps, be quoted than that of the Lake district just referred to.

A hideous practice had grown up in the last century, and was continued in the early part of the present one, of coating all new buildings with a surface of rough cast, highly coloured in most cases with what in the broad dialect of the country was known as "boort cambre," a copious infusion of which was held essential to afford the hot, foxy, yellow-fawn colour which had become dear to the tutored (?) native mind. The picturesque old farm-buildings of an earlier date, among which may be found many to arrest and charm the eye of an artist, showed no such vicious treatment, but grew, as it were, from the soil, in the strong, broad, rugged random walling of native ragstone.

Settling at Rydal in the second decade of the century, Wordsworth found the natural beauty of the country deformed and blotted over by these great yellow blotches of building, and, by precept and example, set himself to work a reformation, in the course of years bringing about so complete a change that, except in cases where additions had to be made to buildings already so coated, the face of yellow roughcast became the rare exception, and the hold, wholesome rubble work in dark grey stone the almost universal rule. The gain to both buildings and landscape is immense, and, with the rich body of foliage so common in that country, it has become quite possible for a new building to be felt as an addition to the beauty of the scene instead of, as at one time, a sure blot in it. To take another example. There were, in this country, until the last half score of years or so, few combinations of landscape and buildings so interesting and picturesque as that presented by Arundel, its castle, church, and accessory buildings, in form varied but not too broken, the square masses of building alternating with the rounded and undulating shapes of the foliage, and the whole resolving into a graduated decline from the higher level towards that of the sea. In colour the combination was no less happy; the grey of the masonry, the green of the trees, and the quiet mild red of the tiles met in harmonious contrast (there are accordant and discordant contrasts), and made a picture which artists delighted to dwell on. In an evil day (architecturally speaking) the Duke of Norfolk resolved to build a great church close

to his castle, and, under a no less evil star, his architects decided to build it of yellow oolitic stone. Farewell, henceforth, to the landscape charm of Arundel! A large raw mass of Bath-brick coloured masonry took precedence of all else in the view, drowned all the delicate contrasts of tint erewhile so interesting and attractive, and caused the artist who had once delighted to get a note of Arundel under one or another of its many phases of effect, to close his sketch-book and turn away with a sigh,—haply with a groan. A rather undignified, but not inapt, comparison was made, in our hearing, of this result, to that of putting a new cream-cheese into a howl of lobster-salad; and, in truth, the jar was not less on the sense of fitness. An architect, if an artist, should be so much alive to the effect which his building is to have on its site, as to give it deep consideration as he works it out on paper; and had such forethought guided the designers in this instance, one charming picture of Old England would not have been irretrievably destroyed. Centuries, but not less, may tone down this raw product to quiet combination with what existed there before it. Netley Abbey, as was once noticed in these pages, has gained an exquisite grey in its long contest with time, and it is built of an oolitic stone; but no one now living, or for generations to come, can again realise what Arundel was to the lover of the true picturesque, before it was defaced by an unhappy invasion of crude Bath stonework.

Our limits forbid our dwelling much at large on the several points of our subject. Let us speak next on form in relation to background. One general truth may be stated in this respect,—that where the natural forms are bold or much varied a building will tell best which is designed with decided sobriety and simplicity of form and detail, avoiding anything like an aim at *competing* with the power of its background. On the other hand, where the natural features are tame and subdued, boldness of design will have its best opportunity for effect. In the case of buildings having a character of defence, such as the castles and fortified houses of the feudal period, more of an air of rivalry with natural boldness of site may be admissible; but even in these a *tempered* spirit of contrast will be found more really powerful in effect than any pronounced character of emulation. The fact is that so powerful is any impression, even of a quiet kind, produced by natural objects that it is always safer to build in subjection than, so to speak, in opposition to them, and where their character is *decidedly* powerful, all attempt in the way of competition will be a failure. A recollection from the Lake country again occurs to us in illustration. The simple, unobtrusive character of the old and often diminutive churches of that district strikes most tourists who have an eye for artistic effect, and they are felt to combine and harmonise with the bold scenery in a way in which more ambitious buildings would quite fail to do, and even in the case of the larger churches, such, for instance as Crosthwaite Church, the ancient parish church of Keswick, its considerable scale appears subdued and unpretentious among its mountain surroundings from its broad horizontal character, square spireless tower, and absence of vertical prominences or features of marked detail; and its character is felt to be in consonance with its site. When a new church was to be built for Ambleside, the very eminent architect justly selected to deal with that beautiful position did not, unfortunately we think, look at the problem of fitly occupying it from the point of view which seems to have been that of the old church-builders, but to have thought that the hold massive natural features of the site must be met by a design in some sort competing with them. The result is that a church of strongly-marked character, and very interesting in many points of its treatment, does not enhance the power of the landscape; but failing, as was to be expected, in the aim, apparently, to assert its *own* scale and importance by a large massive tower and spire (very far larger than would be supposed by any one not actually testing their scale), it is at once

dwarfed by the background of cliff, hill, and mountain, and serves also to dwarf them, since its large scale is unappreciable in such association. Had a church of *flatter* treatment been designed, with a low square tower or simple bell-turret, both it and the landscape would have gained in effect. In designing buildings for town sites, where existing structures will back their new neighbour, too little thought is often bestowed on the very grave consideration of what effect will be produced by their combination; and we frequently see a multiplied aggregation of similar, but disconnected, forms where a departure from the existing type might have produced a happy and picturesque contrast instead of as in too many cases, a new building being felt as an intrusion and an eyesore.

Suppose the Radcliffe Library at Oxford had been treated with another spire, like St. Mary's, or another tower like Magdalen, what an immeasurable loss to that most picturesque city would have resulted. Yet in the present *fashion*, as we must term it, of dealing with such structures, it is a hundred to one but some such course would have been pursued, and this is but one instance among many which might be appropriately cited.

It was not, surely, without thought that Wren placed on Ludgate-hill the short spire which emphasises the mass of his majestic cupola beyond, as we know it was not without thought that he, with his well-trained eye for effect, decided on the character to be given to his two western towers of St. Paul's.

If architects before settling the designs of their town buildings would more frequently, with the useful modern aid of photography, try how the forms they contemplate using would group in harmony or contrast (or *both*) with what must be their background, there would be less frequent occasions for lamentation over *new* good work put out of place, or over *old* good work put out of countenance.

The subject of "Architectural Background" seems to include those cases in which existing architectural masses form the principal features of distance or middle-distance in views of interest, and may, for ages perhaps, have given the leading character to the landscape for miles around; and any material alteration of such through dealings with them, in way of repair or restoration, would be felt as a serious injury to the scenery of a whole district. There are those of us who can well remember how, during the third decade of this century, when Windsor Castle was under the hands of the architect later known as Sir Jeffrey Wyattville, much solicitude was felt lest the noble structure which from its elevated site was a feature in the background of the landscape for leagues in different directions, should be damaged in its character and charm by the changes and additions made in it. Whatever other criticism may be passed on the work then done, it must be admitted that nobility of outline and mass was preserved, and the castle still forms one of the finest of distant objects from many points. One of the most striking instances of its scenic value in a distance may be found, in clear weather, on the open country road between Headley and Ashted, near Epsom, where at a distance of some twenty-one miles it rises against the sky with a dignity which would have led to its record in the sketch-book of the present writer had not the exigencies of a time-table interfered; the foreground also being (some fourteen years since) picturesque and full of character. Not so, we fear, can the handling of St. Alban's Abbey be characterised in relation to its landscape. The long low-roofed nave, with its many clearstory lights, had a character and value in the neighbouring scenery which could not, without damage, be taken from it, and the needless (as we think) raising of the roof (as if, forsooth, there were some inherent vice in one of a low pitch) has made a change, sensibly taking away the particular feeling and landscape value of the church in its old form. Another instance of unfortunate alteration in a long-recognised and characteristic architectural feature is found in Chester Cathedral. It is true that much dilapidation and defacement had taken place in this building, and restoration to anything like

its original external detail meant extended and heavy labour. The particular character, however, of the central tower was so marked and peculiar, and had for generations so presided over the city with an air of grave solemnity, that it was surely worth while in any restoration of that leading feature to preserve to the utmost that dignified, if rather sombre, air of old-time stillness. The octagonal angle turrets, cut down probably on account of their decayed state, had been given a pointed dome shape, and covered with lead a little above the battlement level, and with the square breadth of the massive red stone tower aided in giving an impression of size and power probably a good deal beyond what belonged to the absolute scale. Had the turrets been a little raised only, and finished in a form something like those of King's College Chapel at Cambridge, a sufficient restoration would have been made, and the old solemn character little interfered with; but the shafts being carried up high above the parapet, and finished with projecting embattled caps with large gurgoyles, and tall pinnacles being placed on the small buttress projections on the tower faces, the repose of the whole has disappeared; the tower seems much lower, in its main mass, as compared with the cathedral, and the structure generally much smaller in scale. Other restorations by the same practised hand give cause for no such regrets; as, for instance, Exeter and Worcester cathedrals, and in these comments a result is pointed out not perhaps easily foreseen, but which, perhaps, some careful trials in perspective upon views or photographs of the tower, in combination with the buildings which it backed, might have prevented.

Speed is so much the prevalent passion of the day that in architecture, no more than in other callings, can due preparation by thorough study be easily secured; but it is no less the fact that, without this, both in respect of a design in itself, and in its relations to its backings and surroundings, no results can be secured which shall escape the evil repute of interfering for the worse with the landscapes they invade, but which, with due and full care and study of the points we would impress, they might have enhanced and beautified.

NOTES.

BY the defeat of Mr. Gladstone's measure for the Government of Ireland and the consequent withdrawal of all Bills of a contentious character, another chapter in the history of railway legislation is closed. Mr. Gladstone, in referring to the Railway and Canal Traffic Bill, remarked that it was of a magnitude which rendered it impossible to proceed with it compatibly with the intention of winding up as rapidly as possible the business of the Parliament. Consequently, this measure, which promised to go a long way towards settling one of the most vexed commercial questions of the day, falls to the ground. This cannot but be regarded as unfortunate, as it will be a great disappointment to many, and the railway directors themselves, while they may perhaps experience a sense of relief at the disappearance of a measure which they regarded with so much alarm, must recognise the fact that such relief is only temporary, and that matters are left in an unsettled and unsatisfactory condition. At the same time, the attention which has been drawn to the subject has led to a better knowledge of the various points in the controversy, and some of the companies have proved themselves willing to meet to a certain extent the demands of their customers, and to redress admitted grievances. The Bill has been freely criticised, certain clauses failing to commend themselves to either party, and statesmen may find plenty of material with which to build up a satisfactory measure in the future. It is certainly a matter of regret that such a determined attempt to deal with this matter should have met such a fate, but the time and trouble which have been bestowed upon it may yet bear fruit.

WHAT is called, rather unadvisedly, the "Westminster Abbey Restoration Bill" was read a second time and passed for consideration in Committee on Wednesday. The object of the Bill is to give authority to the Ecclesiastical Commissioners to make grants out of funds under their control for the restoration of Westminster Abbey, the Dean and Chapter having no sufficient funds available. As these funds are really required not necessarily or primarily for restoration in the commonly understood sense of the word, but for carrying out the extensive repairs which have now become necessary for the very stability and preservation of the fabric, it would be better that the Bill should be so worded, and that such an expression as "restoration," which begs a very large question and may lead to endless disputes as to the application of the fund, should be avoided. Mr. Caveudish Bentinck availed himself of the opportunity to read the House a lecture on architecture, and on the misdeeds of Deans and architects, in the course of which he condescendingly spoke of the late Dean Stanley as "a very worthy man," and insinuated that the powers vested in the Dean and Chapter were so great that if they chose "they might pull down the magnificent western towers." Now the western towers are not in the least magnificent. They are a very bad attempt at a sort of bastard Gothic-Classic, by an architect (whether Wren or not is disputed) who had obviously no feeling for or knowledge of Gothic detail. We have no wish to see them interfered with, but to talk of them as "magnificent" is ridiculous.

MR. JOHN FIELD'S analysis of the accounts of the Metropolitan and Suburban Gas undertakings, for 1885, the seventeenth annual number, continues to be such an excellent abstract that it could be wished that it included a longer list of the provincial undertakings. Of these nineteen only are given, nine of them being in the hands of Corporations and ten in those of companies. The field thus surveyed is, however, large enough to give great value to the results tabulated. They are of a very satisfactory nature. During the last five years the capital employed for producing equal quantities of gas, the working expenses on the same, and the selling price of gas, have all been reduced in each of the former groups of undertakings. The produce of gas per ton of coal carbonised has slightly increased, but the cost of coal per 1,000 cubic feet of gas sold has diminished in a higher ratio. The net proceeds of residuals per 1,000 cubic feet of gas sold has, however, diminished, and, measured as a percentage on the cost of coal, has fallen 13 or 14 per cent. since 1881. Thus there has been reduction of price of material, of price of labour, and of net profit. M. Field has not tabulated the relation of net profit to capital, so as to be compared from year to year.

THE magnitude of the gas industry of the United Kingdom is best illustrated by two House of Commons returns dated May 27, 1884; the first relating to all authorised gas undertakings belonging to local authorities, and the second to all others. In England and Wales there are 112 of the former, representing a capital of 15,000,000*l.*, on which a net profit of 459,739*l.* was distributed in the year 1883. The gas undertakings in the hands of companies, including the metropolitan companies, now condensed into three, number 350. The total share capital paid up at the end of 1883 was 27,906,128*l.*; and 4,885,906*l.* had been horrowed. The sums earned, expended, and divided, are not stated in this return. The total capital invested in gas shares and loans in the United Kingdom is 51,988,881*l.*, of which 17,874,951*l.* is in the return of the local authorities. By the outlay of that capital for works, nearly 77 thousand millions of cubic feet of gas were extracted from 7,700,000 tons of coal, and distributed to 2,019,846 consumers, besides providing for 375,536 public lamps, in the year 1883.

MR. E. REICHARDT, of Jena, has lately published some experiments and observations with regard to the use of lead pipes for water distribution. He examined the leaden pipes which had been in use for upwards of 300 years for the supply of water to the town of Andernach, and found them to be coated internally with a layer, about half of a millimetre thick, of phosphate and chloride of lead, with a little free oxide of lead. Very small quantities of lime and magnesia were present in this coating, and the metal of the pipes, after being in use for this long period, was perfectly good in quality. Further experiments were made with a piece of common lead piping, which was capable of containing about 1 litre of water, and which was tested alternately with spring water, distilled water, and water impregnated with carbonic acid. Each kind of water was allowed to remain in the pipe for periods varying in length up to several weeks. Both distilled water and water containing carbonic acid speedily gave indications of reaction on lead; but spring water, even after many weeks, had no action on the lead. In these experiments the pipe was completely filled so as to exclude the air; but when the pipe was alternately emptied and filled, so as to give opportunities for the oxidation of the lead, the metal readily became soluble in water. The conclusion Mr. Reichardt arrives at is that lead pipes which are not always full should not be used for pumps and water distribution.

SOME investigations have recently been made at the chemical laboratory of the Berlin Polytechnic on the destructive action of cements on lead. A piece of pipe which had served for about six years as the supply-pipe to a fountain basin was examined. It had been embedded in cement and was much corroded, the effect being most marked at the end nearest the basin. There was a coating of a chocolate-coloured layer of oxide of lead, of the hardness of glass. A portion of this was pounded in an agate mortar, and dried at 110 centigrade. It was found to contain 99.05 parts of oxide of lead, the residue consisting of carbonic acid with traces of lime and silica. Dry Portland and Roman cements have been found by Mr. Otto Peschke, of Berlin, to have no action on lead, but the presence of water effects corrosion. Mr. Peschke invites the attention of engineers, architects, and chemists to this action, which it is difficult to explain, and which may be due to certain phenomena in connexion with the induration of cement-mortar, which are at present extremely obscure.

THE greater part of the interior of the Duomo of Orvieto is still divided off for the workmen employed on the restoration which is being carried on by Signor Franci, the Presidente delle Opere, in conjunction with Signor Zampi, both under the supervision and control of a Committee of the Belle Arti. The roof of the south aisle is complete, as is also the nave roof, with the exception of another truss and the connecting rafters between it and the west wall of the church; when this is done the north aisle roof is to be treated in a similar way. The walls of the north and south aisles are being ruthlessly stripped of all the Renaissance additions to the church, but great care is being taken to preserve whatever remains may exist of the thirteenth-century frescoes. It is also suggested to remove the greater portion of the thin slabs of alabaster, now used in several cases instead of glass in the window openings; preserving it, however, in most of the lower portions of the windows where it exists, in order to keep a record of the system. We hardly think the mixture of alabaster and glass in one opening would give a very happy result, but nothing is settled as yet as to how the two materials will be connected together.

WITH the number just issued (Jahrgang xliii., viertes heft), the *Archaeologische Zeitung* ends its long and honourable career. This particular number has one paper which

should interest readers. Dr. Furtwängler boldly attacks the genuineness of the well-known antique head in the British Museum, usually called the "Hera of Gigenti." Dr. Furtwängler says that in looking at casts of the head he had all along been troubled with a sense of insecurity as to its date and style. When he was over last year in England he took occasion to examine the original. He plainly states his conviction that the head is a forgery. The head is of fine Italian marble, of bluish-grey colour, a good deal corroded. It first saw light at Naples, passed into the hands of Sig. Castellani, at Rome, hence to our museum. With it Dr. Furtwängler thinks must stand or fall three other heads, of which he gives sketches, one still in the possession of the Castellani family, another in the Berlin Museum, and that belonging to the private collection of Count Warsburg, in Vienna. The arguments of Dr. Furtwängler rest on an elaborate analysis of style which it would be unprofitable to retail except in the presence of the original. It will be interesting to see what answer the guardians of the "Hera of Gigenti" will make to this attack. For our own part, we still incline to believe the head to be genuine.

WE regret to learn that the sub-committee for the Paris Exhibition of 1889 have agreed to sanction the proposal, which has been referred to more than once in our Paris letters, to erect an iron tower, 900 ft. high, as one of the attractions of the Exhibition. We think they have made a mistake. It is a foolish and costly piece of clap-trap, which will only please the mob.

A CORRESPONDENT sends us a cutting from the advertisement columns of a provincial paper containing a most edifying and touching effort on the part of a local architect to raise himself into fame and practice. The advertiser gives his name and residence in large type, with the affix "architect and surveyor," followed by a categorical statement of the work he is prepared to carry out:—"Architectural and constructional details and specifications of every class of building. Building operations superintended during progress Perspectives. Dilapidations. Plans put on deeds," &c., &c. But the cream of the advertisement is in a sentence added at the end:—"N.B. Stated by Professor —, of the — Phrenological Institution, to possess those natural abilities essential for an architect or engineer." This is actually copied *verbatim* (except the omission of the bumpologist's "name and college") from a published advertisement!

Technical Instruction in Building and Engineering.—The City and Guilds of London Institute for the Advancement of Technical Education have issued the prospectus of their summer course of lectures and laboratory instruction for technical teachers and others. During the month of July the following among other courses will be held in the Institute's New Buildings in Exhibition-road:—"On Iron Girder Bridge Designing, with Experiments on some Materials used in Construction," by Professor W. C. Unwin, B.Sc., M.I.C.E. This course will extend over two weeks, from ten till five daily, Saturdays excepted, commencing on Monday, July 5th. "On Plumbing."—A course of four lectures, by Mr. W. R. Maguire, of Dublin, on Tuesday, June 29th, Wednesday, June 30th, Thursday, July 1st, and Friday, July 2nd, at 7.30 p.m. each day. (Fee for the course, 5*s.*) "On Brickwork and Masonry."—A course of four lectures will be given by Mr. John Slater, F.R.I.B.A., Examiner for the Institute in Brickwork and Masonry, on Monday, July 12th, Tuesday, July 13th, Thursday, July 15th, Friday, July 16th, at 7.30 p.m. each day. (Fee for the course, 5*s.*) "On Building Materials."—A course of four lectures will be given by Mr. W. G. Dent, F.C.S., on Monday, July 26th, Tuesday, July 27th, Thursday, July 29th, and Friday, July 30th, at 7.30 p.m. each day. (Fee for the course, 5*s.*) Further particulars and syllabus of each course may be obtained at the Central Institution, Exhibition-road, S.W., or at Gresham College, London, E.C.

ARCHITECTURE AT THE ROYAL ACADEMY.—VIII.

1,685, "Porch in Terra Cotta, East Sheen," Mr. T. E. Colcott. This pretty corner of domestic architecture we have already illustrated. It consists simply of a porch with an elliptical arch, and a window adjoining, the decorations consisting of pilasters and a frieze enriched with ornamental detail of an Elizabethan cast. A plan is added. The drawing is an exceptionally good specimen of pen drawing.

1,686, "No. 70, Ennismore Gardens," Mr. Basil Champneys. A neatly-drawn pen elevation of a house in the manner which is analogous in England to that of Francis I. in France, though later chronologically; Classical wall columns and entablatures, one over another, forming frames for mullioned windows. The front is in three divisions, crowned with three ogee-curved gables, with decanter-stopper finials, which (let us once more observe) are not a bit the better or more artistic detail because there are numerous precedents for them. The design is less flat in effect than appears on the drawing, the first-floor windows on each side and the centre second floor one being projected as bays, apparently on elliptical lines, and treated with a good deal of boldness, the wall space under the windows being dished out in domble curve (like the front of a theatre gallery), and carried by corbels decorated with foliage and masks. The ornament is well distributed so as to emphasise the salient points of the design, and give a general richness of effect with plenty of undisturbed wall-space to balance the windows and decoration. The whole of the details can be got out of books, it is true; but they are treated and combined exceedingly well. No plan.

1,688, "The Black Bull Tavern, High-street, Lewisham," Mr. Horace T. Bonner. Hung too high to be well seen; a house with two gables and bays diversifying a flat front wall; architecturally adequate to the occasion. No plan.

1,693, "Alterations and Additions, Woodlands Park, Stoke d'Aheron, Surrey," Mr. Rowland Plumbe. Nothing to show what portions are additions and what are old. In such cases a small plan, with old work scored and new work in black, would enable one to understand what has been done. As it is, one can only say that it is a pretty house of Domestic Gothic character, with a good deal of picturesque incident about it; but how much of this is the present architect's we cannot tell. We may observe that the pilasters and gables at the angles of the porch do not harmonise with anything else in the building.

1,694, "Proposed House, Beckenham Park Place, Beckenham," Mr. John Ladds. Another "proposed house," a better one than No. 1,676, in that it shows much more breadth of treatment, but a very poor drawing,—the semi-circular bay is, in fact, all out of drawing. Plans are added.

1,695, "Part of a New House, Cromer," Mr. E. J. May. We presume Mr. May is so particular in saying a "new" house in this as in another case, from a sub-consciousness that otherwise it would certainly be taken for an old one. This is an excellent specimen of artistic pen drawing, by a draughtsman who has a style of his own, and a picturesque piece of building, with a heavily-timbered gable and a castellated octagonal bay sticking out of one side of it. The object seems to be to persuade the spectator that the house has been added to at different times by different owners. A house that has really been through those phases is often very interesting on that account, but we do not feel the same interest in these made-up effects.

1,697, "Lanhydrock House, Cornwall, as restored," Mr. R. Cond. A view of a large Gothic house, extending round three sides of a parallelogram, taken with a very high point of sight, and therefore, of course, placed by the inspired hangers at the top of the room, so that we can see it from the worst point of view. It is, to all appearance, a charming old house, but, as it is impossible to tell what in it is ancient and what is modern, no more can be said about it here.

1,702, "Mansion, Grosvenor-square," Mr. J. T. Wimperis. A cold but very well finished pen drawing, showing a Classic front with a ground story slightly projected and carrying three-sided bays above, running through two stories; a central porch with semicircular

pannelled arch projects from the centre of the ground story; a soffit, with a projecting semi-circular balcony, is carried across from one bay to another at the second-floor line level. A well-marked cornice runs across the whole, with a central dormer and "fronton" (to borrow the French word) over it. The building is of a style and handling which does not evoke our sympathies much, but it is palatial and dignified. The columns carrying the soffit between the bay windows are surely too attenuated.

1701, "Lincoln College, Oxford, Addition to Rector's Lodgings," Mr. H. Wilkinson Moore. A pleasant bit of quiet domestic architecture, and the door and windows on each side, under a label, group very nicely.

1705, "Private Residence, Montreal, Canada," Messrs. Taylor & Gordon. A small water-colour drawing hung rather too high to be well seen; apparently a large red brick house on a basement (battered and rising a few feet above the ground) of grey granite. The salient feature is a large circular angle turret rising from corbels on the first-floor level. There is no very marked style about it. No plan.

1706, "Portion of new Wing to Mansion at Fetcham, Leatherhead," Messrs. Romaine-Walker & Tanner. An interior (from the seats round the wall apparently a billiard-room with the billiard-table omitted), a vainscoted room with a frieze of decorative paper over, and a fireplace nook, with small leaded windows. The main light is from vertical leaded windows in the ceiling lantern. A pleasant-looking room and a good drawing.

1707, "Bosham Hill, Sussex," Messrs. Ernest George & Peto. This is the sheet of drawings we published in the *Builder* for May 15 last, showing a staircase, a fire-side, and part of a gallery. The drawings, tinted in brown, are among the most admirable and artistic in the exhibition; and the staircase, with its moulded and enriched angle posts, and its stairs formed out of solid slabs of oak, moulded in front and on the soffit, and its carved open-work panels, is a piece of work at once rich and solid in effect. The only point we object to is the sham jointing or rustication of the lower part of the posts, which is certainly contrary to good taste as a treatment of wood-work. The fireplace, with its sloped-out chimney-breast and grotesquely-carved corbel, is delightful, though it might be said that there is too much of the look of modern antique about the whole.

1708, "Design for a Country House," Mr. C. D. Fitzroy. Apparently a student's design, and creditable as such, but not what we should have expected to find on the Academy walls.

1710, "Park Lodge and Entrance Gates, near Kingston," Mr. F. W. Lacey. A good specimen of the lodge type of house: brick below and half timber above; the first-floor joists brought boldly out on one front, with moulded ends, the upper portion over-sailing considerably. A careful pen drawing. No plan.

1716, "Staircase, Gosford House," Mr. W. Young. A large and good, though not particularly effective, pen drawing of a grand staircase, hall, and gallery, on the Italian model. The staircase has a flight on each side, joining over an arch at the further end of the hall. The pilasters and arcade of the gallery are carefully drawn. The whole is dignified, but has little originality (we presume it is a modern staircase, not a drawing of an old one). The coved ceiling seems weak in comparison with the sub-structure.

1720, "Cottage Residence at Winchfield," Mr. T. E. Colcott. The low windows in the upper story, with low-pitched gables over them, and irregularly spaced, have a pleasant and picturesque look. The verandah supports might have been made a little less ugly; the figures introduced ditto. A plan is added.

1726, "Lodge" to the house shown in No. 1,693 (see above), Mr. Rowland Plumbe. A good little water-colour drawing showing a lodge treated with the usual materials at present in vogue for lodges; brick, with timber and plaster above; in this case a band of wall tiles is introduced between them. The changes have been rung very often on this style of work now; this example is characterised by more careful and considerably-worked-out design, less effort to appear abnormally picturesque, than in a good many other examples.

1731, "New Premises in Edgware-road," Messrs. Eales & Son, hung high; a street front presenting no very special feature for comment.

1735, "House at Otford, Kent," Messrs. Roger Smith & Gale. Two very nicely-drawn and coloured elevations of a good-sized red brick house with stone dressings and mullioned windows; an angle tower with an ogee-pointed lead roof forms a feature in it; and on the long front some timber and plaster work is introduced in the upper portion. The wall spaces between the windows look a little bare; they seem to want some filling-up here and there. A plan is appended, but without the names of the rooms; the turret forms an angle nook to what is obviously the drawing-room. The house seems conveniently and compactly planned, and the offices spacious and well shut off from the rest.

1736, "Hothorough Court, Snodland, Kent," Mr. Hubert Bensted. A very good water-colour drawing of a solid, well-built, dignified, but rather prosaic-looking house; the shape of the windows is ugly, and cannon-hall finials are scattered over the copings and gables with too lavish a hand. No plan is given; it is what we should expect to find a good house; the exterior has no nonsense about it; but it leaves the regret that on so good a basis a little more decorative and really architectural effect had not been realised. The tower is the only bit where there is an attempt at a little picturesque effect, and that, to say truth, not very successfully. The plain and simple stables and out-buildings group well in the drawing, but the whole seems rather an opportunity lost.

1739, "House at West Wickham, Kent," Mr. A. R. Stenning. Hung high. A pen drawing of a house meant to be picturesque; but too much all gables and chimneys repeating each other. No plan.

1743, "House at Combe, near Shaftesbury," Mr. E. Towry Wbyte. A small pen drawing of an inner quadrangle, quiet and domestic, but with nothing for special comment. No plan.

1744, "House about to be erected facing Rotton-row," Mr. G. Truefit. An odd little meagre pen sketch, apparently made in a hurry, showing a house in which the windows are arranged and grouped with much originality, but no detail can be made out. It is a pity the author did not take the trouble to make a more adequate drawing of it. No plan.

1745, "Stable, Weirleigh, Kent," Mr. John Belcher. A little water-colour drawing of a charmingly original bit of building. The coach-house is apparently contained between two lumps of unadorned brick wall, across the top of which is supported a timber upper structure which sails far away from its base, so that it has to have extra support from a line of posts and a bressumer, on a separate brick foundation. The stable is behind. The author should have added a plan, but he may be complimented on having produced a little building which would certainly make one take out one's sketch-book on coming across it.

1746, "A Warehouse Facade," Mr. W. Stirling. We presume not an executed one, although the label of "Smith & Co." is affixed to the building. A peculiar and original coloured elevation, with a great deal of merit and originality in it; a mixture of Gothic effect with quasi-Classical details. The gable on the right over the warehouse doors would be much better without the spiky finials on each side of it; they spoil the solidity of the whole.

1748, "Studios, Weirleigh, Kent," Mr. John Belcher. Another small water-colour drawing of a picturesque building with timber and plaster upper story; pretty, but we prefer the stables; we feel quite grateful for those stables.

The Chapter-House of St. Paul's.—The enlargement and reconstruction to a great extent of the Chapter-House of St. Paul's Cathedral, which has been in progress during the last few months, is now almost completed. The works consist of an additional story, whilst the interior has been structurally re-arranged. Several of the interior walls have been removed, and new reception and other apartments have been constructed. The works have been carried out with the view of providing a residence for the Archdeacon of London, who intends taking up his permanent residence in the Chapter-House. The ecclesiastical business of the Dean and Chapter will continue to be carried on there as heretofore. The works have been carried out under the superintendence of Mr. F. C. Penrose, architect to the Dean and Chapter, and by their own workmen.

THE CONGRESS OF FRENCH ARCHITECTS.

THE fourteenth Congress of French Architects was held last week, according to the programme previously published in our columns. The annually increasing number of the attendances at these meetings is a proof of the interest with which they are regarded among the members of the profession in France.

Owing to indisposition, the venerable president, M. Bailly, was obliged this year to give up the chair to M. Achille Hermant, the vice-president, who on the 7th opened the Congress in the Hémicycle des Beaux Arts, the first meeting being, as usual, devoted to the nomination of special committees. M. Moyaux then undertook the delicate task of reading a critical paper on the architectural exhibits at the *Salon*, about which we have already spoken at some length. The paper was distinguished by great critical insight and originality of view.

The same day the Congress paid a visit to the new synagogue in the Rue de la Victoire. Of the four synagogues in Paris* this is the richest and most important, being probably (except that at Berlin) one of the largest in Europe. It is designed by M. Aldrophe. The general style of the building may be said to be Romano-Byzantine. The effect of the really fine exterior is very much lost owing to the narrowness of the street in which it stands. The front shows two stages of arcades surmounted by a circular tympanum overhead, pierced with a great rose-window. On the ground level a large porch leads to a columned vestibule, from whence we enter the interior,† of a severe and grandiose character, which was made to look more striking on the occasion of the visit of the Congress by the additional effect produced by rich hangings, lighted lanterns, the accompaniment of organ-music, &c., the visit being almost like a religious celebration, while a learned Rabbi discoursed to the meeting on the relation of the architectural design to the ritual. Since the Mosaic law, as we all know, forbids all representation of men or animals in sculpture, the architect had to evolve from his fancy sufficient decorative incidents to give interest to his work. Thus, in the vestibule the principal feasts of the year are inscribed in Hebrew on escutcheons interwoven with myrtle and olive foliage. In the nave, whose five bays are separated by columns, the arcades of the tribunes are richly ornamented, and rest on brackets of acanthus leaves, and on the frieze are the Commandments inscribed in Hebrew. The highest decorative effect has been concentrated on the arch separating the nave from the entrance to the sanctuary. In front of this is the "théba," the tribune of white marble where the officiating priest stands. It is raised five steps above the floor of the temple. Behind it is a splendid silver chandelier presented by Baron Alphonse de Rothschild. On each side a stair of twelve steps leads to the entrance to the Tabernacle. Columns of marble, with carved capitals of fruits, separate the hemicycle into five bays, with windows, in which are represented the emblems and banners of the tribes of Israel. Over these are circular windows, with central designs emblematical of the five books of Moses. In the upper frieze are inscribed in Hebrew the names of the five principal prophets, whose names appear also, but in French, among the painted decorations of the cupola. Ten steps of white marble lead to the door of the "Holy of Holies" the oak door of which is carved and gilded, and over it is a circular panel with a pediment over it, containing the ten commandments cut on white marble. In the tympanum is a plaque, also in white marble, on which the name of the Eternal is engraved in Hebrew letters, surrounded with rays of gold. The building contains also a small temple where daily prayers are said, and the Consistory chamber. The stained glass is by MM. Oudinot, Lefevre, and Lussan; the organ-case, a remarkable piece of work, is made by M. Merklin; and the lighting apparatus, in bronze and wrought iron, by M. Lacarrière, from designs by the architect. The total cost of the synagogue was 3,200,000 francs.

On the 8th, in spite of torrents of rain, the Congress visited at St. Denis the *ateliers* of M. Guilbert Martin, the able mosaic worker

who received last year the medal founded by M. Paul Sédille for art industries. This manufactory, once at Sèvres, and after that at Crenelle, was transferred to St. Denis in 1867. It has been nearly eighty years in existence, and is the only establishment which has given itself, since its origin, to the production of glass mosaic and enamel. After having seen the melting furnaces and other franchises of the work, the members of the Congress examined the finished product in the garden, where examples of mosaic are laid out with very good effect in the midst of the interposing spaces of green.

Not to reduce our sketch of the Congress to the level of a tourists' guide, we merely observe here that the Cathedral of St. Denis was the object of the second extra-mural excursion; and concerning St. Denis, and its date and history, and how it was restored by Viollet-le-Duc, it is unnecessary to say more here, except to comment on the startling anachronism presented by the window in which Louis Philippe and his family are represented in costumes of the nineteenth century, presenting a strange contrast with the other windows and the general style of the cathedral. Viollet-le-Duc, however, though a great archaeologist, critic, and restorer, did not shine equally in the matter of original design, and while the great church stands magnificently among the mill chimneys and industrial buildings on the Plain of St. Denis, like a defiance sent by the past ages to the modern ones, the parish church, built by Viollet-le-Duc, between 1864 and 1867, makes a very poor show opposite to it. The style does not wait grace, and the interior details are charming, but the general architectural design has no breadth of treatment, and the clock-tower, heavy as it is, seems crushed beneath the neighbouring cathedral. This formidable neighbourhood also weighs heavily on the new Mairie of Saint Denis, which the party afterwards visited. This municipal building, only just finished, is the work of M. Paul Laysnaud, who has chosen the style of the French Renaissance, and has availed himself well of the sources of effect offered by the style of that fine epoch. The building, which has cost nearly a million francs, is to receive shortly some pictorial decoration, to be executed by M. Delahaye.

The second day's proceedings terminated by a paper from M. Eugene Guillaume, the eminent sculptor, who had taken for his subject "L'Unité de l'Art." After him M. Charles Lucas read a report on the "Congrès des Sociétés Savantes," and the meeting adjourned to meet the next morning to inspect the mosaics of the new Escalier Daru, at the Louvre, executed by M. Guilbert Martin from the designs of M. Lenepveu. The work is far from completion, but from the scaffolding the members were able to appreciate the grand style of the figures personifying Germany, Italy, Flanders, and France. Above there is a frieze of winged geni, and medallion portraits of illustrious masters of various schools. Before quitting the Louvre, M. Edmond Guillaume, the architect for the new works, wished to show his professional brethren the new treatment of the Salle des États. The very rich decoration of this room has been executed under the direction of M. Paulin, a young artist who probably has a great future, to whom, however, we would recommend some modification in the exuberance of the details which encumber the frieze and infuse the general effect.

The incessant rain nearly put an end to the visit to the building-yard of the new Sorbonne, which was transformed into a morass. M. Nenot escorted a courageous minority of the party over the works, but as we shall be able to give a descriptive plan and elevation of the building next week, we pass over further notice of it now. The less enterprising majority repaired to the Pantheon, the next visit on the list, but, dealing here with a monument even better known than Saint Denis, we need not follow the Congress into the immense nave, at present melancholy and bare in its aspect, or into the vaults where the crowns and garlands offered up to Victor Hugo are accumulated. We will only observe that of all the decorative paintings going on or completed there, those of M. Puvion de Chavannes seem by their tone, at once quiet and harmonious, to harmonise best with the decoration of a stone interior. The paintings by M. Bonnat, opposite to them, appear coarse and violent by comparison; those of MM. Cabanel

and Maillat are only misall illuminations magnified to an exaggerated scale; and the triptych by M. Laurens cuts a great hole in the wall instead of harmonising with the total effect. These irritating contrasts form an emphatic condemnation of the system of parceling out the decoration of a building, and form a curious satire on the "Unity of Art," the subject of M. Guillaume's paper aforesaid.

At two o'clock came the paper by M. Heuzey, the eminent Egyptologist, on Chaldean architecture under the king-architect Gondea, 3,000 years B.C. This dissertation came as a kind of sequel to the interesting details given last year by M. Ledrain, the joint curator of the Assyrian Museum, and M. Ronchard, on that chapter of the art of a remote past so long hurried in obscurity, and in which the labours of M. de Sazzev, French Consul at Bassorah, have thrown considerable light.

This year the ancient capital of Champsagne was the object of the archaeological excursion of the Congress, who, on the 10th, in spite of a deluge of rain, successfully visited the principal monuments of Troyes, under the guardianship of M. Schmersheim, diocesan architect of the Département de l'Aube. Among these were the Church of the Madeleine, the roof-loft of which was made by Jean de Gualde in 1503; St. Rémy; the cathedral, so well known as a splendid example of architecture from the thirteenth to the fifteenth centuries, and rich in works of art of all kinds; St. Urbain, a *chef d'œuvre* of the thirteenth century, commenced by Pope Urban, and left unfinished; the Hôtel de Marizy, one of the historic monuments of France; and the Hôtel de Ville, built in 1630. We can only give a brief note of the proceedings of Friday, the 11th, entirely devoted to the work of special committees and to technical papers. There was an interesting paper by M. Bousard, on the sanitary conditions of rural buildings, and an interesting and learned one in which M. Gosset, architect, of Reims, gave us, by the help of numerous drawings, a complete history of religious buildings in their successive transformations from the early Basilica form to their modern form, of which the Church of the Sacré Cœur at Montmartre formed the latest and most complete type. The closing day of the Congress was commenced by a visit to the Catacombs, those vast subterranean excavations which extend under the right bank of the river, and which enclose the spoils of the ancient cemeteries of Paris. This excursion, made by candlelight, between a double row of human remains diversified by funeral inscriptions, was not a very exhilarating recreation, and after two hours tramping on the dust of past generations, we were not sorry to see the light of day again. It is the Service of "Ingénieurs des Mines" of Paris, and not that of the architects, which has the responsibility of looking after the catacombs and guarding against the failures of the ground which have been too frequent of late. The Congress was taken there, accordingly, rather from curiosity than professional interest.

The last meeting in the Hémicycle des Beaux Arts attracted a numerous audience. By the side of M. Kaempfen, the Directeur des Beaux Arts, who presided in the name of the Ministre de l'Instruction Publique, were placed Mr. l'Anson, the delegate of the Instituto of British Architects, Mr. Pullan, representing the Archaeological Institute of Great Britain, and MM. Hermant, Charles Garnier, Questel, Sédille, and Paul Wallon. After a few words from M. Kaempfen, M. Paul Sédille spoke at some length on the series of works which had placed the late M. Théodore Ballu in the highest rank of contemporary architects; the completion of Stc. Clotilde, the rebuilding of the Tour St. Jacques la Boncherie, the construction of the Tour St. Germain l'Auxerrois, of the churches of La Trinité, St. Ambroise, St. Joseph, and that of Argenteuil, and lastly of the Hôtel de Ville, constituting certainly a sufficiently considerable body of work to transmit the name of the architect on the honour to posterity, without any necessity for the inexplicable silence of the speaker in regard to Ballu's colleague in the last-mentioned work. As we recently observed, when the Hôtel de Ville was put up for competition, Ballu obtained the prize in conjunction with M. Depertthes, whose name M. Sédille never once mentioned. Why this ostracism of the name of a colleague who is recognised by every one, whose name is in all the official papers, and who is still actually directing the completion of the building? It was more than forgetfulness,

* Called respectively the Synagogue de la Rue de la Victoire, that of Tourzelles, that of Notre Dame de Nazareth, and that of the Rue de Buffault (the Portuguese synagogue).

† Of the interior: we will give a view next week.

it was a want of common justice which took the audience by surprise. But where M. Égédie was warmly applauded was when, after having referred to the incontestable superiority of the English architects in all matters which concerned the design and construction of the private house,* the "home," he sarcastically referred to the "decennial outrage" of scraping and washing to which the houses in Paris were subjected at stated intervals. What would now remain, he asked, of the interesting examples of Middle Age or Renaissance works, or even of the splendid Hôtels of the seventeenth century, if these barbarous regulations of the "Voirie" department had been in existence and been insisted on in former times? It was necessary, he said, in the interests of art and of history, to demand a prompt revision of the Act of March 26, 1852, which pitilessly prescribed these measures for the pretended preservation of property.

Following on this came the distribution of the honours decreed by the Société Centrale des Architectes. M. Echernier, architect of Lyons, and M. Gaillard, architect, of Paris, obtained the "grandes médailles d'argent" for domestic architecture. The medal of jurisprudence, also a silver one, was adjudged to M. Cuadet, the architect of the new Hôtel des Postes, and that for archaeology to M. Charles Lucas.

The schools at Athens and Rome have obtained two bronze medals, one going to M. Maurice Holleaux for excavations of the Temple of Apollo in Bœotia, the other to M. Victor Blavet, whose restoration of the sacred enclosure of Demeter at Eleusis we have already mentioned.

M. Rey (pupil of MM. Train and André), and M. Léon Margot (pupil of M. Guadet), then each received a silver medal founded in connexion with the Ecole des Beaux Arts. Similar rewards were shared by the Ecole des Arts Décoratifs, the Ecoles Privées d'Architecture, and the Ecoles d'Apprentissage. M. Désiré Hayon, the *doyen* of French ornamentists, who was the zealous collaborator of Viollet-le-Duc in the restoration of the Château Pierrefond and of the Église Notre Dame, obtained this year the medal given for Art-Industries, and the remainder of the meeting was devoted to the honours decreed to "vétérans du travail," who, in the midst of loud applause, came forward in turn to receive the reward of their unostentatious labours of a lifetime. The list was a long one, and the enumeration of this band of devoted working men, who have been untempted by demagogues and leaders of strikes to leave their work, would be the best practical answer to the falsely humanitarian theories which excite "le peuple" to revenge for imaginary injuries. In seizing the occasion for an energetic protest against a dangerous utopianism, M. Paul Wallon achieved a legitimate success.

In the evening, according to custom, a dinner brought all the members of the Congress together for the last time at the Hôtel Continental, and brought to a close a session which has pleasantly united for a few days those whose multiplied labours and special circumstances usually keep them at a distance from one another.

SCULPTURE AT THE PARIS SALON.

The sculpture at the Salon is, as a whole, much more interesting this year than last, and it may be said that the sculptors bring, in the main, more serious thought and effort to their art than the painters. It may be that the latter, producing their work with less difficulty and at less cost, address themselves more to the question of saleable work, of *genre* of a light and graceful type, and neglect the pursuit of the ideal to confine themselves to the more popular and remunerative types of realistic art; for painters have suffered as much as other artists under the industrial crisis, and a large easel picture is as difficult to dispose of just now as a work in bronze or marble. The general result is in favour of the sculptors, for while private purchasers hesitate at the cost of an important picture, the Municipalities, the State, and the bodies of public subscribers continue to give good commissions to sculptors for the decoration of public buildings and for the

* We hope the wise-ones who write leaders in English papers abusing the whole architectural profession will take note of this.

continually increasing number of statues in honour of eminent men.

We may first notice the fine marble group commissioned by the Comte de Paris from M. Mercié for the funeral chapel of the Château de Dreux.* The sculptor had a difficult task. Popular caricature has dealt so hardly with Louis Philippe that no ordinary talent was necessary to idealise in any way the somewhat bourgeois personality of the last reigning sovereign of the House of Bourbon. The king, standing and draped in his mantle, leans one hand on the shoulder of his queen, who kneels in prayer. The whole aspect of the group is very dignified, and the figure of the queen treated with much feeling, and the thin and almost transparent hands are beautifully modelled. The lace and other accessories are sufficiently rendered, without that over-wrought realism which annoys one in much modern Italian sculpture, and the whole goes to confirm the author of the celebrated "Gloria victis" in his position of a master among modern sculptors. Of this work we give an illustration in the present number.

The monument which M. Dalon has designed to the memory of Victor Hugo is another remarkable work, of a very different type. Under an arch, flanked by columns supporting an entablature, the figure of the poet reposes on a funeral couch draped with a cloth covered with crowns and palms. A group of allegorical figures, including a Pegasus, surmounts this triumphal arch, the tympanum of which is decorated with garlands. Two other groups flank the composition; on the right, Eviradnus, from the "Légende des Siècles"; on the left, Quasimodo rescuing Esmeralda. The rays of a setting sun form an aureole round the head of the poet, and the background beneath the arch is occupied by a relief personifying his principal works,— "Les Châtiments," "La Légende des Siècles," "Les Rayons et les Ombrages," "Les Orientales," &c. Though executed on a reduced scale, the model has been finished with great care, and has a fine decorative effect.

In comparison with this masterly work, the "Apotheosis of Victor Hugo" by M. Lucien Faliez is a disagreeable contrast,—a pretentious and unreal work, produced in response to official command, and not worthy of the occasion. It may be observed, however, that the sculptors generally have shown more reticence in regard to the great event of the year than might have been expected, and that "La Mort de Victor Hugo" has not been so overdone as we feared it would.

The Duc d'Anmale continues to enrich his wonderful palace at Chantilly with works by our leading sculptors. It is for him that M. Paul Dubois has produced his equestrian statue of the Constable de Montmorency, of which he exhibits a model two-thirds the intended scale; of this we give an illustration. It is for Chantilly also that the decorative statue by M. Chapu is intended; a young girl kneeling and plucking flowers; the figure is very beautiful, and the lines of the draperies recall Classic art; but it was a singular and not a happy idea to have covered the figure with a shiny composition, giving it a gray earthy aspect, and bringing out all the spots on the marble.

It is with sad recollections that we notice here two statues by Schenewerk. The first is a seated figure of Lulli, intended for the Opera House. The second, entitled "Un Prisonnier dangereux," is a pleasant bit of mannerism, treated with the charm which characterises the works of this unfortunate artist, whose career came to so sad and premature an end.

We note a statue of "General Chanzy," by M. Croizy, very superior to that exhibited last year by M. Crank, and there is an "Edmund About" by the latter, which, unfortunately, has no resemblance at all to the man of whom it is supposed to be a portrait. The exhibit of M. Longepied is a reproduction in marble of the admirable group entitled "Immortalité," which, four years ago, brought its author the "Prix du Salon." The marble version is even finer than the original model, and counts among the finest works which have figured at the Salon for some time back. Of this also we give an illustration.

We may mention also with praise the "Judith," a group in marble by M. Lanson, the kneeling statue of Cardinal Regnier, commissioned from M. Louis-Noël for the Cathedral of

* This was written before the recent unhappy and ill-advised action of the French Government in reference to the Comte de Paris and his family.

Cambray; the figure executed by M. Godemsky for the tomb of Madame Tamberlik, the Japanese figure in marble by M. Aizelin, intended for the Museum of Natural History; and a model of a candelabrum by M. Hugues, symbolising Asia, and which is to ornament a room of the Hôtel de Ville.

For the Hôtel de Ville also M. Blanchard has executed a fine statue representing "Science," and the municipal administration has commissioned also several other important works in the exhibition, especially the "Etienné Dolet going to Execution," by M. Cuilhert. Though selected in a competition, we have but a poor opinion of this large statue, which may perhaps look better when cast.

In sculpture of the *genre* class we find also a whole series of works belonging to the Municipality; in the first place, the "Jeune Faune," by M. Charpentier, a very clever and pretty marble figure; then another group, "Daphnis and Chloé," by M. Guilhert; an elegant figure by M. Hercule, entitled "Primevère"; further on, "Le Gué," by M. Lefevre, who exhibits also a good bust of M. Michelin, the Deputy of the Seine; "Le Sauvé" of M. Rolard, and a very well modelled marble group which M. Lange Regliemio calls "Vieille Histoire," and which represents a young peasant girl seated at the feet of her mother, who is spinning.

Mme. Marie Cazin, the wife of the painter, has for some years occupied an honourable position as a sculptor of *genre*. She exhibits this year a twin bust of two little girls, and a fragment of bas-relief perhaps rather loose in execution, but of real merit.

M. Alvert Lefevre takes us into ultra realism. The peasant woman cutting bread for her children is a figure direct from life, and, in spite of the nature of the subject, has nothing trivial or commonplace about it. The "Mars and Venus" of MM. Zacharie Astruc, in spite of the talent of the artist, is not a success; a nude woman, of very full contours, is seated on the knees of a warrior cased in complete armour, whose helmet she is opening. The juxtaposition in this way of the nude and the clothed figure suggests something akin to indecorum, and the proper title of the work should be "Rhaude et Soudard." The "Souviens-toi" of M. Allouar is a paraphrase of the line "Grandiaque effossis ossa sepulchris,"—a labourer points out to his son the bones and remains of armour which the ploughshare has turned up from the soil.

We will pause a moment before the exhibit of M. Falguière: two Bacchantes, with contorted bodies and dishevelled hair, are fighting furiously. How can an artist who has reached the height of his reputation descend to such a sorry kind of artistic joke? It cannot be excused on the ground of "furia Française," for not far off is the group of M. Boncher, of three racers, as full of spirit as you please, but quite free from the coarseness of design and execution which characterises this work of M. Falguière's. A fine animal group by M. Caïn is to be noted,—a lioness dragging a wild boar to her den; and another noteworthy work is the "Alleluia d'Amour," by M. Destreez, an unpretentious but careful and well-studied bit of sculptor's work. As to the "Égalitaire" of M. Captier, which thrusts itself violently on one's attention, it is a personification of "Anarchy," brutal and repelling in style and feeling, which would be more in place at Decazeville than in the Palais d'Industrie.

Among the long series of busts, as numerous as usual, we may mention as a work of the first rank that of Dr. Deschamps, by M. Barrias, a fine marble portrait, full of expression and splendidly modelled. He has substituted for the traditional pedestal a pile of books, negligently posed on some manuscripts. The bust which M. Alvert Lefevre has made of M. Louis Ulbach is also a remarkable example; and M. Carrier-Belleuse has given great truth to the head of the historian Henri Martin. M. Crank has been more successful with M. Sarcely than with Edmund About; the bust of the eminent critic is a striking likeness, and the same praise may be given to that of M. Coquelin, jun., by M. Falguière, a work which helps to make us forget the unfortunate "harpies" above referred to. We may mention also the bust of the tragedian Mauhant, that of the caricaturist Stop, by M. Moreau-Vauthier, and the head of an old countrywoman in a bonnet, which M. Baffier exhibits under the title of "La Mère Baffier."

Among medallists M. Chaplain continues to take the lead. Among his works may be noticed the medal commemorating of the Hôtel de Ville, and the two medallion portraits of Górrna and Baudry. We may single out for mention also a pretty medal in antique style, in very low relief, by M. Peter, which he entitles "L'Age Honneur," and a fine frame of medals by M. Roty.

We have necessarily omitted mention of many works, but it may be confidently said that even among those works which leave something to be desired in regard to taste, choice of subject, &c., we find evidence not only of serious study but of strongly-marked character and individuality. The sculptors constitute the chief artistic honour of France at present.

A POINT IN THE REPORT ON THE VENTILATION OF THE HOUSES OF PARLIAMENT.

In the above-named Report, on which we have already commented, the Committee attribute much of the evil which has of late assumed intolerable proportions to "the absence of proper ventilation in the Low-Level Sewer," and "venture to think his Board will not long be able to adhere" to a statement by the Chairman of the Metropolitan Board of Works to the effect that it was not necessary to ventilate the Low-Level Sewer.* But at the same time that they express this opinion they cite a fact which in itself is hardly reconcilable with it, viz., that "a very strong smell of sewage of an intermittent character, both inside and outside the building, occurred, especially at the time of high water." This, they add, "conclusively proves that the pent-up gases are forced out of the Metropolitan Sewer into those connected therewith." We need not entertain much doubt of the fact that sewer gas formed in the 84 miles of this Main Sewer does, from time to time, force its way into the Westminster Palace, and other buildings. So far, no doubt, the Committee do us injustice. The point to which we demur is that such effect is due to the rise of the tide.

What is called the Low-Level Sewer has, in point of fact, so constructed as to be cut off from any direct connexion with the river, and thus from any effect of rising and falling tide. It is not only an artificial cutoff, but one which has been before now pointed out in the columns of the *Builder* to have been laid at a level which there is much reason to regret. The drainage of 144 square miles of the western suburbs of London, collected in what is called the Western Sewer, is pumped up at what is called on Sir J. W. Bazalgette's plan (Proceedings of the Institution of Civil Engineers, vol. xiv., plate 14), the Chelsea Lift, to a height of 17 ft. 6 in. Starting at this artificial level, the sewer falls at between 2 ft. and 3 ft. per mile to Abbey Mills; where its contents are pumped up, for another 36 ft., into the Northern Outfall Sewer.

In consequence, in the vicinity of the Houses of Parliament the surface of the liquid in the Low-Level Sewer, supposing it to run half full, is intermediate between high and low water mark; or about 6 ft. 6 in. above the latter. The variation in depth of flow during the day, in dry weather, is stated by the Committee at a foot. But in heavy storms the water rises up the shafts and sewers connected with this sewer to 13 ft. above Ordnance datum. This, no doubt, is a serious evil for Westminster. But it has no connexion whatever with the height of the tide.

At the same time the statement of the Committee, that the offensive smell which has recently become so intolerable as actually to put a stop to the business of the House of Commons on the 27th ultimo, was most perceptible at high water, is to be received with due consideration. On the day in question high water at London Bridge occurred, according to the tables at 8.51 p.m., so that the action of the House supports the view of the Committee. The only point is that, so far as this aggravation of the malaria was due to the tide, it rose from other sources than the contents of the Low-Level Sewer, which is carefully disconnected from the tide.

If there really is this connexion between the state of the tide and the smells in the House,

it is important to consider how such connexion can take place. Those who were familiar with Westminster, underground as well as above ground, before (and, for that matter, during) the construction of the Thames Embankment, will have little difficulty in tracing this evil to its source. Before the construction of the Main Drainage Works so much of Westminster as lies below the 10 ft. contour line was in a highly unsanitary condition. In houses of some importance,—we can cite Chapel-place, Spring-gardens, and many other spots,—the occupants of the basement stories were but too well aware of the time of high water. They needed no calendar. The nose gave the information. The drains of these houses so closely skimmed the level of high water,—then not so high as it is now,—that no outflow took place at the top of the tide, even if the sewage did not filter into the cellars and kitchens. On the other hand, as the drains were originally laid so as to get as much fall as the ebb of the river would allow, at low water, especially at spring tides, they became, to some extent, cleared out. The effect was bad, but not so intolerable as a penning-up of sewage, with no escape.

But with the construction of an intercepting drain, which when half full is 6 ft. or 7 ft. above the old level of automatic drainage at low water, the case is very different. Much, no doubt, may have been done by way of fitting the street and house drains to the new outlet. But the question is: how much was *not* done? How much of the original drainage construction, even if not used at present, has been left undisturbed, and unfiled up? And where, over any such neglect has occurred,—and it would not be difficult to point out glaring examples,—a fertile nucleus of disease and nuisance must have been left festering under foot.

It must be remembered that much of this low-lying district, recovered, within the last 500 years, from the sands and marshes of the Thames, is pervious and water-logged. The experience attained in getting in the foundations of the quay wall attests this. A solid wall, built on and founded in the solid clay, would no doubt cut off such a sponge from the river. But if the committee are correct as to the fact of tidal influence, evidently no such complete diaphragm has been everywhere made. Any subterranean connexion, through pervious soil, between the river and the subsoil water, would allow the water to ebb and rise as it did in the old days before the construction of quay wall or intercepting sewer. The detection of tidal action by increased activity in foul smell is thus highly instructive. The palace of Westminster may have, as the committee say, sewer gas poured into it from the metropolitan system; and this is especially likely to occur after rain. But if bad smells are propelled by the rising tide they must arise from that subterraneous system of sewers and drains which ought to have been thoroughly rooted out when the level of their discharge was raised.

On this view, which we think few persons familiar with Westminster can hesitate to accept, the expedients recommended by the committee cannot be expected to command more than a partial success. Let us suppose that the forcing of 84,000 gallons per day of not very foul sewage into the Low-Level Sewer can be so conducted as to avoid any back flow of gas; that process can have no effect on the tidal vomit. From which source the greater part of the evil arises it is highly desirable to ascertain. The Committee have not ascertained it, because they have failed to recognise that there may be two sources; at all events, they are evidently not aware that the tide cannot affect the Low-Level Sewer itself.

Lynton.—Mr. S. J. Smith, C.E., Local Government Board Inspector, held an inquiry at the Local Board Office at Lynton, on the 26th ult., respecting the application of the Local Board for a loan for carrying out drainage works, erecting a sea wall and slipway, and forming an esplanade, and constructing a swimming bath at Lynton and Lynmouth. Mr. T. V. H. Davison, C.E., of Windsor, the engineer for the works, attended the inquiry and explained the drawings to the inspector, who approved of the plans, &c. At a meeting of the Local Board on the same day, Mr. Davison was instructed to obtain tenders for the works forthwith so that they may be commenced as early as possible.

NEW HEAD-QUARTERS FOR THE LONDON SCOTTISH VOLUNTEERS.

The finishing touches are now being put to the new head-quarters for those physical "stalwarts" who compose the London Scottish Volunteer Rifle Corps. The building, which is situate in James-street, Victoria-street, Westminster, consists of a large hall for drill and gymnastic exercises, surrounded by two galleries, and well-lighted by a double range of clearstory windows on each side and by the glazed screens which form the end gables of the roof. Over each end of the hall are a number of rooms,—at one end being the committee-room, officers' room, and commanding officer's room, and at the other end the canteen, reading-room, &c. In order to get as large an area of unobstructed space as possible for the floor of the great hall, the galleries and the partition-walls and floor-riders of the rooms referred to are very ingeniously suspended from main girders carried at a higher level. The hall is 120 ft. long in the clear by 62 ft. wide, the ends at the back end of the hall being canted off. The hall is laid with Mr. Roger L. Lowe's admirable wood-block flooring, the construction of the floor itself being of iron and concrete, there being a large basement below it. The whole of the ironwork in this floor, and in the roof and galleries, has been supplied and fixed by Messrs. Matthew T. Shaw & Co., from the architect's designs. The roof-principals are light but not wiry in appearance, and they are so designed as to dispense with tie-rods. They are painted a dark chocolate colour, gilding being sparingly introduced. The roof is boarded. The effect of the ironwork of the roof is very pleasing, and the same may be said of the gallery fronts. The height of the hall from floor to top of roof will be 62 ft. A dado of "teapot-brown" and sage-green, made of glazed bricks of those colours supplied by Messrs. Wilcock & Co., of Burmantofts, runs all round the hall, the large fireplaces (one on each side of the hall) being also in the same material. The effect of the fireplaces and dado is extremely good. The walls above arc of stock bricks relieved with red. The lower gallery will be used by spectators of the gymnastic and other exercises which will take place in the hall, and contains a number of lockers arranged along the wall so as to serve as seats when the lids are shut down. The upper gallery will also be available for spectators, but contains a large number of dressing compartments (across the ends of which curtains can be drawn), each containing four lockers. These compartments and lockers are intended for the use of members who need to change their dress. The committee and officers' rooms are at the Brewer's-parquet end of the hall, and are provided with parquet floors, Indian matting, dadoes, &c. There is also a commodious and pleasant reading-room on the second floor of the James-street end of the building, and a non-commissioned officers' room; both these rooms can be thrown together for concerts or dramatic entertainments for small audiences. On the first floor at this end of the building is the canteen, having a drinking-bar at one end and a grill at the other. The greater part of this room will be furnished with tables and chairs for the use of members requiring refreshment. All these rooms have parquet floors and matting dados, this part of the work, and the upholstery and furniture, being by Messrs. Shoolbred. The basement contains a lock-up armoury for 1,000 stand of arms, with armourer's room, and store-rooms for seats, tables, &c., required for use on the occasion of meetings or entertainments in the large hall. There is also a large kitchen, the fittings of which are by Mr. Boulting, of Unicorn-street, Middlesex Hospital. From the kitchen there is a lift to the canteen. The lavatories have been supplied by Messrs. Steven Bros. & Co. The urinals are on the continuous trough system, with automatic flushing arrangements. These and the whole of the plumbing work are being done by the North British Plumbing Company. There are four staircases, all executed in breeze concrete. The iron balusters to the stairs and the gearing for opening the ranges of clearstory windows before referred to are by Mr. Shrivell, of Castle-street, Long Acre. The white glazed bricks extensively used in the basement are by Messrs. Wilcock, of Burmantofts. The sun-burners and other gas fittings are by Messrs. Strode & Co., of Omsa

* The Board have, in fact, already, on the proposal of their Chairman, relegated the consideration of the subject to a committee.

burgh-street. Hayward's prismatic pavement lights have been largely used, and are specially introduced into the flight of seven steps, 12 ft. wide, at the "march-out" doorway in Brewer's-row. The principal elevation is towards James-street. It is mainly of stock bricks relieved with red brick and terra-cotta, and with Douling stone doorway, the pediment of which contains the Scottish arms and national emblems. The total cost of the building will be from 13,000l. to 14,000l. It has been erected from the plans and under the supervision of Mr. John Macvicar Anderson, architect, Mr. Thomas Gamage being the clerk of works. The general contractors were Messrs. Lawrance & Son, of Wharf-road, City-road, whose foreman was Mr. Williams. The building will be formally opened in a few days, and the members of the corps are to be congratulated on having obtained such admirable quarters.

DUST-BINS.

NEXT to the disposal of sewage, the removal of household refuse should certainly occupy a prominent place in the science of house building. In those proverbially "good old times" when cesspools were universally employed in default of better sanitary arrangements, little, if any, attention was bestowed on the subject now alluded to. A cursory glance at any old house now standing intact will reveal this fact. In such places the repositories for dust and garbage are to be found in all their old-fashioned primitiveness. Small and confined in themselves, they are furthermore hidden away in some dark, obscure, and awkward corner, invariably at the back of the house. The heterogeneous matters brought from the house were piled up in the interior of the wood or brick cavity month after month, until the whole germinated and became one huge bed of festering disease. In due course the mass settled down, some portions dissolving and being absorbed by the soil, through the medium of which the poison-laden fluids percolated into the foundations of the adjoining premises with disastrous effects. Local boards and vestries were then in a chrysalis stage,—their development was a matter of after years,—consequently it devolved almost entirely on the enterprise of private individuals to accomplish the periodical clearing of these domestic Augean stables. The unpleasant business was naturally performed as infrequently as possible, for the simple reason that in order to reach the street the putrefying mass had to be conveyed through the interior of the house. What disease and sickness these hotheds of living germs must have created it is, of course, impossible to guess. But it is safe to assert that some ill results must have resulted from this flagrant abuse of the rudiments of sanitary science.

Everything has materially improved since then, and the situation and construction of dust-bins now receive more attention. In a large number of modern houses the dust-bins are placed in front and in close proximity to the roadway, so that the operations of emptying and removing the contents can be effected with ease and rapidity and without causing inconvenience to the occupants. It is ridiculous, however, to place a receptacle for dust immediately in front of a basement window. Unfortunately this situation is too often selected. Leaving alone the subject of "appearance" and the fumes arising at all times and especially during the summer months, the constant passage of servants to and fro for the purpose of filling, and of men to empty the bin, cannot be anything but disturbing and annoying. Moreover, a window cannot be opened for ventilation without the danger of stray particles being wafted into the room. In every way it is an error of judgment to place a dust-bin in too prominent a position. It is true these receptacles should be situated so as to be easily "get-at-able," but, at the same time, all offensive conspicuousness should be carefully avoided. What should be the proper form of a dust-bin circumstances and experience must alone dictate. A brick structure with a small door in front is, perhaps, the most ordinary arrangement. This style of bin is, however, both difficult to fill and empty, and, in consequence of this difficulty, it is natural to conclude that the last-named operation is rarely, if ever, performed with thorough completeness. This drawback has led to the adoption by some of

a bin with a wooden or iron front capable of being removed bodily. The interior is by this means laid bare, and the consequent result is apparent. Still, this method possesses a drawback. The refuse has to be shovelled into baskets to be conveyed away, and this process is a work of time and a work full of unpleasantness. To avoid all this, and make the cleaning-out easy and speedy of achievement, has led some people to abolish the fixed bin altogether, and to substitute a portable box, basket, or, better still, galvanised iron cylinder, all of which can be conveyed away and thoroughly cleaned in one operation, without fear of any residue remaining, to decompose and contaminate soil and atmosphere.

There is much to commend this method, and the builder should take kindly to it, for its general adoption would save him a good deal of the time and trouble now expended on brickwork arrangements which, at their best, are far from perfect.

But it must be added that the offensiveness of dustbins, whatever their form, is largely the fault of their users, who should remember that a dustbin is not a fit receptacle for fish-bones, cabbage-leaves, potato-parings, tea-leaves, and other house refuse, which can generally, with a little management, be dried at the back of, and burned in, the kitchen fire. The good housewife and the tidy domestic may be known by the state of the dustbins under their control.

The Cavendish Memorial Fountain at Bolton Abbey, erected as a memorial of the late Lord Frederick Cavendish, was publicly inaugurated on the 11th inst. The work has been carried out from designs by Messrs. T. Worthington & J. G. Elgood, architects, Manchester, by Messrs. Stephenson & Co., Manchester, for whom the carving has been executed by Messrs. Earp & Hobbs, London and Manchester. A view and description of the fountain appeared in the *Builder* for Oct. 2nd last.

CHIMNEYPIECE FROM ROMSEY.

This chimney-piece has been brought from Mottisfont Abbey, near Romsey, and stood in the dining-room there. The whole is of oak, parts being carefully carved, but the general effect is rather spoiled by the distorted perspective of the side panels, which are traditionally said to represent part of the Priory. Colour has been extensively used, the columns having been painted to imitate marble, and the ground of some of the panels retains traces of red and blue. The whole is about 10 ft. high and 8 ft. broad. It is now in the possession of Mr. Blount, of 47, Southamption-street, Camberwell, by whose kind permission the sketch was made.

OBITUARY.

Mr. T. G. Andrews.—The death is announced of Mr. T. G. Andrews, architect, Bradford, after a short illness. He was the son of the late Mr. Andrews, who for many years carried on the business of an architect in conjunction with the late Mr. Delaney. That firm had charge of a large number of important building operations from the time when Bradford began to develop into a town of importance, and subsequently their professional connexion was carried on by Messrs. Andrews, Son, & Pepper in the Old Bank Buildings, of which they were the architects. After the death of Mr. Andrews, sen., the business was continued for some years by Mr. T. G. Andrews and Mr. Pepper, and latterly by this former gentleman. The extensive premises of Messrs. S. C. Lister & Co., at Manningham, the Fever Hospital, and the Mechanics' Institute were among the principal works designed and superintended by his firm. The illness which caused his death followed upon a fall which he sustained while walking towards his home in Horton-lans on the evening of the 4th inst.

Mr. James Hall, C.E., Borough Surveyor of Stockton, died early on Monday last, after a very short illness.

Mr. Llewellyn Jewitt, F.S.A., died on the 5th inst. at his residence, Duffield, Derbyshire, in his seventieth year. He was born at Kimherworth, near Rotherham, and was the youngest son of Arthur Jewitt, the topographical writer. In 1838 he settled in London, where he remained for a few years, and during that time was mainly engaged in illustrating many leading works of the day. At this period, too, he published his "Handbook of British Coins," which has since passed through several editions. Subsequently, at Oxford, Mr. Jewitt greatly assisted by his pencil in the admirable labours of his brother, Mr. Orlando Jewitt, the eminent architectural engraver, in Parker's "Glossary of Architecture," and in many other works. At a later period, he was appointed chief librarian of the Plymouth Public Library. In 1853, Mr. Jewitt removed with his family to Derby, where he continued to reside till 1867, when he took up his residence at Winstler Hall. In 1880, Mr. Jewitt removed to "The Hollies," Duffield, the home of his early years. He was for a long time hon. curator and hon. secretary of the Town and County Museum, and also took an active part in amalgamating with it the Derby Philosophical Society (founded by the celebrated Dr. Darwin) and the Town and County Library, for which, with princely munificence, the late Mr. Bass erected a commodious building. Mr. Jewitt was well known as the projector and editor, for more than a quarter of a century, of the *Reliquary*, an illustrated antiquarian magazine, besides being a writer upon kindred subjects for the *Art Journal* and many other periodicals. In this month's *Antiquary* there appears an interesting article from his pen on "Some Derby Streets and their Historical Associations." He was recently awarded, on the nomination of the Prime Minister, one of the Queen's Civil List pensions for distinguished literary services—a deserved reward, which, unfortunately, he has not lived very long to enjoy. Mr. Jewitt was buried at Winstler on June 9th, exactly three months after the interment there of his wife.

A NEW NAIL.

This patented nail, which we are told is the invention of a lady, is intended to obviate the leaving of nail-holes and the necessity for putting up. The *modus operandi* is as follows: suppose the case of flooring boards,—the nail is driven into the joint first in the direction shown by the arrow, by hammering on the head A; the corresponding portion

belonging to the other half of this twin nail at B, is cut wedge-shaped, and bites into the wood. The point C is thus left projecting, and the flooring-board is hammered on to it, instead of the nail being hammered into the board in the usual manner; the same system applying, of course, to any other case in which two pieces of wood have to be connected by nailing.

The idea is very ingenious, but we should want to see it tested in practice before ordering a large job to be nailed up in this way. Except in the case of decidedly soft wood we should expect to find a good many of the nails turning in hammering the wood on to them, as there cannot be the same power of directing the course of the nail, and the direction of the blow on it, as when each nail is hammered down separately.

International Hydrological and Climatological Congress at Biarritz.—Arrangements are being made by the officers of several French societies for holding an international congress for discussing papers upon climatology, mineral and thermal springs, and allied subjects. A letter has been received from the Foreign Office transmitting copies of documents, and stating that the French Government is anxious that members of scientific societies in this country should assist. The co-operation of the Royal Meteorological Society has also been specially asked by the President of the Congress, Dr. Durand Fardel. The sittings at Biarritz will occupy the first week in October, and be followed by a three weeks' tour to the principal watering-places of Southern France.

Illustrations.

ARTISANS' DWELLINGS, VICTORIA SQUARE, LIVERPOOL.

THESE dwellings, which were opened in the autumn of last year, have been erected by the Corporation of Liverpool from designs by the City Engineer (Mr. Clement Dunscombe, M.A., M. Inst. C.E.), and under his superintendence.

The designs, as well as others for dwellings suitable for the poorer classes, capable of being let at rents of 1s. and 1s. 3d. per room per week, were exhibited at the International Health Exhibition in London two years ago; the Corporation of Liverpool was awarded a diploma of honour for the exhibit, and Mr. Dunscombe was awarded a gold medal for the designs.

The buildings occupy part of a site formerly known as Nash Grove, situated in Scotland Ward, in the parish of Liverpool. The area was cleared under the Artisans and Labourers' Dwellings Act, 1875. It comprised 22,487 superficial yards, of which 3,717 superficial yards were occupied by public streets, and the remainder by low-class, unhealthy dwellings and buildings and yards in use for trade purposes. The population displaced by the carrying out of this scheme was 1,310, of which population 1,100 were of the working classes, and the number of people living on this area, under the worst sanitary conditions, was at the rate of 282 per acre.

After the site was cleared and filled up to a proper level it was laid out for the erection thereon of artisans' and labourers' dwellings, and offered by auction, but no bids could be obtained for it, and, as private enterprise could not be induced to take the matter up, the Corporation were therefore reluctantly compelled to erect these dwellings on a portion of the site. Again, in November, 1884, the remaining area unbuilt upon was offered by auction, and, although an extremely low reserve price was fixed so as to admit of buildings being erected upon it to pay a moderate rate of interest, this further effort on behalf of the Corporation was likewise unsuccessful.

Site.—The site upon which the dwellings have been erected is bounded on every side by streets, and contains 9,195 superficial yards, of which 3,924 superficial yards are occupied by dwellings, and 5,271 superficial yards in approaches, and in a quadrangular open space suitably laid out. Tramways, affording cheap means of communication with all parts of the City, pass along two of the streets.

The entire area occupied by buildings, after being excavated to the requisite depths, was covered with a layer of Portland cement concrete, averaging 9 in. in thickness, the concrete foundations for the walls being carried to a greater depth, and for a width of from 3 ft. to 5 ft., to receive the various footings to the brick walls.

Above the ground level a damp-proof course of asphalt is laid over all the walls throughout.

The quadrangle is laid out with wide footwalks, and a 15-ft. carriageway round the buildings. The central portion of the quadrangle is enclosed by a low wall and iron railing, provided with entrance gates in convenient positions. On the inside of this enclosure a border for shrubs has been reserved. The remainder is laid out as a playground, and finished in Portland cement concrete.

The footways are likewise laid with 6 in. Portland cement concrete, and the carriageways are formed with a similar foundation, the surface being finished in compressed natural asphalt.

All the streets surrounding the dwellings have a 6 in. Portland cement concrete foundation, and are paved with syenite setts, the joints being filled with pitch shingle, and grouted with a mixture of pitch and creosote oil, the footwalks being finished in compressed asphalt. The site is, therefore, practically impervious.

The buildings are five floors in height, and divided by party-walls into thirteen separate dwellings, each of 75 ft. frontage, and 36 ft. in depth, outside measurements. They are arranged so as to admit of a free circulation of air around them.

There are five entrances to the quadrangle, provided with ornamental wrought-iron gates, approached from the surrounding streets.

Two of the blocks have shops on the ground-floor, with spacious basements, lavatory, and w.c. connected with the shops by staircases. These blocks have only four floors of tenements above them. All the other blocks are entirely devoted to dwellings, and have no basements.

Each dwelling has a separate entrance from the quadrangle and common staircase, giving access to the corridors and tenements right and left on each floor.

There are in the thirteen dwellings 271 tenements and a superintendent's house, made up as follows:—

	No. of rooms.
69 Three-roomed tenements.....	258
164 Two-roomed tenements.....	328
21 One-roomed tenements.....	21
Superintendent's house.....	4
Total No. of rooms.....	611

The three-roomed tenements are arranged as a living-room, 13 ft. by 12 ft. 4 in.; one large bedroom, 15 ft. 3 in. by 9 ft. 7 in., capable of being divided into two bedrooms by a movable screen, with separate entrances to each half; one bedroom, 13 ft. by 8 ft. 6 in.

The two-roomed tenements are arranged as a living-room, 13 ft. by 12 ft. 4 in., and one bedroom, 15 ft. 3 in. by 9 ft. 7 in., capable of division as above described.

The one-roomed tenements are arranged as a living-room and bedroom combined, 12 ft. by 12 ft.

All the rooms are 9 ft. in height.

The twelve shops have a frontage of 12 ft. 6 in. each, and a depth of 32 ft., and an average height of 11 ft., with basements, 9 ft. in height, under the entire area of the shops.

Water Closets.—Entering from a lobby out of the corridors, and adjacent to the sculleries, water-closets, slightly projecting beyond the main line of buildings, are provided, two on each floor, for the joint use of the four tenements. These water-closets are thoroughly disconnected from the tenements; they have constant through ventilation and pivot-hung windows, and are fitted with Bristol glazed flush-out closets of the best construction, and water-wash preventing cisterns.

Staircases, Lobbies, and Floors.—There are thirteen staircases, one to each dwelling. The stairs and landings are of stone. The landings to the stairs are open to the quadrangle front for their entire height, and project from the main building, forming a balcony protected by a wrought-iron railing. The stairs and corridors are amply lighted by the windows of the sculleries and by these openings, thus affording through ventilation from front to back of each dwelling.

The floors of laundries, sculleries, corridors, and water-closets are of Portland cement concrete; the floors to living-rooms and bedrooms are boarded, but are specially constructed to prevent, as far as possible, the spread of fire.

A granolithic washable dado, finished terra-cotta colour, is formed for a height of 4 ft. round the staircases and corridors, above which the walls are plastered and coloured in a suitable tint. The walls of the laundries and water-closets are fair pointed and lime whitened.

Receptacles for Dust, Ashes, and other Refuse. The dust and ashes only on each floor are disposed of through a ventilated shoot formed in the angle of the lobby leading to w.c. This shoot terminates in a receptacle placed in position on the ground-floor, and there are two connexions in this shoot in the corridors on each floor. Provision is made for all other refuse being deposited in special orderly-hins external to the building, and placed in the railing of the enclosure in the quadrangle.

Laundry.—In addition to the above accommodation, each tenant will have the sole use, for a fixed day, or portions of days, of a spacious laundry placed centrally on each floor, with two entrances from the corridors, and intended for the use of the four tenements on that floor. The laundry is lighted by a large bay window, which is divided into several pivot-hung sashes all opening for ventilation. By the proposed arrangements each tenant will have for the day, or portions of days, the privacy that would attach to a laundry within his own tenement, without any of the disadvantages arising from conducting washing operations therein. It is fitted up with double wash-troughs and a copper, water being laid on to each. A galvanised iron hood is placed over each copper and connected with the flue, so that the steam may be speedily carried away.

Sculleries.—On each side of the laundry on every floor immediately leading from the corridor is provided a double sink of Bristol glazed ware with hardwood drainers, with water laid on to each, being one sink for the use of each tenant. An additional water-tap is placed in the corridors on each floor near the sculleries.

The interior of the tenements is made as attractive and cheerful as possible. The walls of all the rooms are plastered and finished in distemper. Around the living-rooms there is a dado of a dark tint, surmounted by a neat stencilled border, above which the walls are finished in a lighter colour.

Special care has been exercised in selecting serviceable and pleasing tints for the finishing colours of the woodwork and distempers. The fittings to each tenement comprise a series of useful articles, thus dispensing to the fullest extent with movable furniture.

A special combination dresser, larder, coal-bunker, and closet are provided in each living-room. The larder is fitted with slate shelves, meat-hooks, hangers, &c., and is ventilated by openings into the corridor filled in with terra-cotta ventilators, covered on the inside with perforated zinc. There are also attached cup rails, small and large cupboards, drawers, &c., and underneath a coal-bunker with sliding doors in the living-room, and fitted with a small door in the corridor, through which the coals can be delivered.

Hat and coat rails are fixed in all the rooms, and in the bedrooms shelving and hanging closets, and in the divisible bedrooms, which are provided with two entrances, one of which forms a convertible closet when not required as an entrance.

The sashes of all the windows throughout open for their entire area. They are divided into three parts, the lower sashes being double-hung, and the upper sash pivot hung. The lower portion of each window is divided into small squares, and is glazed with cathedral tinted glass, giving both a cheerful appearance, and at the same time acting as a window blind. The windows of all the living rooms and bedrooms are fitted with Venetian blinds, stained and varnished.

Adequate provision has been made for the admission of fresh air through the ventilators in external walls and corridors, and the extraction of foul air is provided for through flues in the chimney breast fitted with mica flap ventilators.

Each living-room has a specially designed cast-iron combination mantel and over-mantel and a cooking range fitted with oven, plate-rack, and other useful accessories. All parts liable to heavy wear are made in wrought-iron, such as the fire bars and fall-down bars of fire-grate and draw-out fret, &c. At the back of the fire-grate a hot-air chamber has been constructed which is supplied with cold fresh-air through perforated terra cotta air bricks fixed in the external walls and thence through a cavity formed in the wall leading to the air-chamber. The air when warmed passes through pipes leading to the living-rooms and bedrooms, the supply being regulated by cast-iron hit-and-miss ventilators placed in the walls of these rooms.

The whole of the door furniture and fittings and general ironmongery is specially designed and made of malleable iron, the cost being less than the commoner furniture generally used.

The outer door of each tenement is furnished with a malleable iron knocker, representing "The Liver" (which forms part of the Corporation crest), a door-handle forming a knocker capable of being used by children, and an enamelled iron number. The keys to all locks throughout each dwelling vary.

Elevation of Buildings, &c.—The buildings have been erected in Liverpool grey common bricks, with splayed red pressed brick arches and window jambs, moulded labels over windows and panels under same, cornices and bands, and red pressed bricks used sparingly in a few other places. Red terra-cotta has been used in the main entrance doorways and dormers. Wrought-iron balconies are introduced in connexion with the main staircase of each dwelling in the quadrangle front. The roof is covered with Welsh slates from a selected quarry, and there are Yorkshire stone sills to all windows projecting 1 ft. from the face of the wall for plants in pots or window-boxes, each being fitted with neat wrought-iron guard-rails.

The buildings have practically double elevations, requiring careful treatment. The wall-

surface has been broken by slight projections surmounted by dormers. The extra cost incurred by this mode of treating the elevations, by the introduction of terra-cotta and the materials already described, over elevations of the plainest character, is inappreciable in so extensive a block of dwellings.

Sewerage and Drainage.—The sewers in the streets surrounding the dwellings are 3 ft. by 1 ft. 10 in., brick sewers. They are of recent construction, and thoroughly ventilated at frequent intervals by means of open grids. They receive all the waste and soil pipes from the buildings, with the exception of the block fronting Cazneau-street.

The drains in the quadrangle consist of glazed earthenware socket-pipes, caulked and jointed in Portland cement, 6 in., 9 in., and 12 in. in diameter respectively. One of these takes the waste and soil pipes from the closets of the shops above referred to, and eventually discharges into the main sewer. The others only receive the water from the roofs, and the surface water of the quadrangle. The former drain is ventilated by a special 6 in. ventilating shaft fixed to the building, discharging well above the roof-line, and is furnished at its highest point with an automatic flush-tank of 300 gallons capacity, constructed in brickwork.

The remaining drains in the quadrangle are also ventilated. The whole of the waste-pipes from the buildings are disconnected from the drains, and discharge into ventilated 4 in. by 4 in. cast-iron pipes attached to the buildings, and they are caulked and jointed in red lead. These pipes again discharge over the water line of a trapped gully at the foot of same, fixed in the footpath within the building line, and covered with a grating acting as an air inlet.

The closets discharge into an external 6 in. socketed and lead-jointed cast-iron soil-pipe, with special junction cast on, of sufficient length to reach inside the wall of the building to receive the outlet from the closet, the joint being made within the wall-line. These soil-pipes continue above the roof-line to fall diameter, and terminate with a cowl on top, and are supplied with fresh-air inlets. Both the syphon and improved flush-out closet are of Bristol glazed ware, the former having an air-tight inspection cover.

The waste-pipes from the sculleries, sinks, wash-troughs, &c., are formed entirely of Bristol glazed pipes, 1½ in. in diameter, thus dispensing with lead piping. They are fitted underneath with a syphon of the same material, furnished with an air-tight inspection inlet, with the requisite piping, and discharging external to the buildings, as already described.

The public drains are flushed at frequent intervals, and all the private drains within the city are flushed twice annually, free of cost, by the Corporation, and oftener, on payment of a small fee by the owners of the property. These regulations will equally apply to this block of buildings.

Water Supply.—A constant-service supply is laid on to every floor of the dwellings, to sinks and laundries, and in corridors. The taps in the corridors are provided with half-coupling on nose for hose-pipe, rendering them capable of being used in case of fire on any floor. Fire hydrants are also fixed around the quadrangle, and two double drinking-fountains are provided. All water for domestic use is drawn direct from the mains. A 500-gallon slate storage-cistern fixed in the roof of each dwelling supplies the 6-gallon flush regulating cisterns fixed over each water-closet. All taps used are screw-down bib taps.

The whole of the fittings are of the best description, stamped and approved by the Water Department of the Corporation of Liverpool.

Gas Supply.—Gas is laid on to the buildings through an independent 3-in. cast-iron main laid around the quadrangle. The outlet from the street main leads into the meter-house in the basement of the superintendent's house, in which are fixed two 200-light meters discharging into the 3-in. main.

The gas supply is under the control of the superintendent in his general office by means of a wheel attached to a valve on the main.

Pressure gauges are also fixed in his office to facilitate the adjustment of supply, and a ½-in. by-pass is fixed on the valve to prevent the total extinction of the lights.

Branches to each of the thirteen blocks are laid from the main with a stop-cock fixed on same on

the outside of the building inclosed in a suitable iron box. The corridors and sculleries are provided with glazed lanterns of suitable design affixed to the walls, and in each of the living rooms and laundries an ornamental iron pendant with ball joint is fixed. Over the entrance door to each dwelling a bracket lamp of ornamental design has been fixed, also lamps to main entrance in Cazneau-street.

The fittings throughout are of the best description of their class, and every precaution is taken to avoid the waste of gas and ensure its economical consumption. To each of the burners in the corridors, sculleries, and laundries a special cock is fixed capable only of being opened or shut by a key in the possession of the superintendent, also separate main cocks to the supply-pipes laid to each of the tenements and fixed in the corridors. These are also under his control.

Governors are fixed to all the lights limiting the consumption to 3 cubic feet per hour of 20-candle gas, with the exception of the outside lamps, which are rated at 4 cubic feet per hour.

Cost of Dwellings, and Estimated Returns.—The total estimated cost of the dwellings, including the market value of the site, viz., 9,195 yards of land—is 70,000. It is estimated that at least the following moderate rents will be readily obtained, viz.:

Three-room tenements, 6s. per week.
Two-room tenements, 4s. 6d. per week.
One-room tenements, 2s. 3d. per week.

These rents are exclusive of the charge for gas if used in the living-room, but inclusive of all rates and taxes, which will be paid by the Corporation. These rents are well within the means of those of the artisan class who require to reside near their work, and for whom these dwellings have been erected. They compare favourably with the average rents generally paid for the inferior accommodation now provided in cottage houses in Liverpool.

On this basis, and a moderate estimated rental for the shops, after allowing ample margin for all leakages, such as rates, taxes, insurance, superintendent's salary, empties, and repairs, the buildings only should yield a net return of 4½ per cent. on their estimated cost of 55,000, and still leave a balance of rental which, if capitalised on a 3½ per cent. basis, will represent the full market value of the site for this purpose.

In judging the financial result of this scheme it has to be borne in mind that the object of the Corporation was not to cover this site to its full capacity with dwellings, but to erect buildings of the best class for their purpose and of the highest sanitary standard, thus affording an example to be followed in the future by private enterprise, while, at the same time, providing a large unbuild-upon space in this densely-populated district.

The unbuild-upon open space attached to these dwellings over and above that required by the Liverpool Building Act is 2,845 square yards.

The value of this land, as well as the cost incurred in laying it, out is included in the total cost upon which the above percentage returns have been calculated.

Messrs. Hughes & Stirling, of Liverpool, were the contractors for the buildings.

The Corporation supplied the ranges, grates, and ironmongery to be fixed by the contractors. They have also executed certain other works in connexion with the buildings, viz., the external gas supply and the granolithic dado, by contract, and the external drainage, laying out, and paving of the site and the paving of the abutting streets and other minor works by Corporation workmen.

Mr. John G. Garthwaite acted as chief architectural assistant both in connexion with the preparation of the contract and the detail drawings, and during the execution of the works. Mr. Augustus F. Scott acted as clerk of works.

SCULPTURE AT THE PARIS SALON.

For some particulars regarding the three works in sculpture which form the subjects of part of our illustrations this week, see the article "Sculpture at the Paris Salon" (p. 878 in the present number).

British Museum.—Mr. J. A. P. MacBride's next lecture on "The Succeeding Greek Sculptors after Pheidias," is fixed for the 22nd inst., at 2:30 p.m. precisely.

THE CREMATORIUM AT MILAN

THE CREMATORIUM AT MILAN.

THE practice of burning the dead does not appear to be making much progress in this country, although a crematorium has been for some time established at Woking Cemetery; on the Continent the formalities and difficulties attending cremation are less onerous, and the practice is gaining in popularity both in France, where it has only recently been legalised, and in Italy, where this method of burning the dead has been carried out since 1880. Several of the Italian cities have crematoriums. Perhaps the best example is the one at Milan, which was

carefully designed for the purpose. It is a single-storied building, constructed of white marble, and situated at the extreme end of the Campo Santo or cemetery of Milan. The general arrangement is shown in the accompanying illustrations. The funeral service takes place in the entrance-hall, marked A, the body usually lying on a bier; a closed coffin is only required when the death occurred from a contagious disease. After the rites of the church are finished, the corpse is removed to the mortuary, G, where the attendants place it on an iron shell, which is supported by a carriage

on small wheels, and this also is held by a framework, with other rubber-covered wheels running on two iron rails, which are laid parallel to the cremators, F.F. The apparatus is thus noiselessly brought in front of one of these previously-heated chambers, the shell on its carriage is quickly run into the cremator, where it is left supported when the carriage is withdrawn. An air-tight door is now closed, the gas fully turned on, and in from forty to fifty minutes, the ashes are all that remain of the corpse, and these are collected in the iron shell, which is removed in a similar manner. The mourners can either witness the operation through a sight-hole, or may wait in the room

marked C. The cremator generally employed is that marked F, which is heated by gas specially made in a Siemens producer fixed below. The old plan, for which F is fitted, was to heat with wood, in which case two hours were required to reduce the body to ashes; after considerable trial with both systems, the gas plan is always adopted, and is said to be far preferable. The ashes are placed in a terra-cotta box or cineraria constructed to fit one of the niches shown at a, b, c in figs. E E, a marble tablet with name closing the openings; these are of similar size, larger tablets being used when it is desired to place several boxes together.

The expense at Milan is very small, the fee for cremation being 50 francs, and the charge for the cineraria and niche is 40 francs in perpetuity. The poor are cremated free of charge, their ashes being placed in plain boxes in the vaults under E.

The cremation takes place on an average four days a week, but on some days several funerals occur, in which case the cost of the operation to the society who carry it out is very trifling, the greatest expense with the gas system being the heating of the furnaces, which should, if possible, be not allowed to cool. An inscription in front of the building states that it is dedicated to Paolo Gorni, who was the first to introduce cremation into Italy, and whose remains were thus disposed of in 1863. The Campo-Santo is well worth a visit, as it contains many handsome and artistic monuments, both of old and recent date, and the general arrangements of the cemetery are exceedingly well planned.

AMERICAN CEMENT TESTS.

In the construction of the extensive main drainage works which have recently been carried out at Boston, Massachusetts, a large quantity of cement was used, about 180,000 barrels being required in all. In order to find what was best suited for the purpose, a large number of tests of natural and artificial cements were made, which are quoted in the Proceedings of the Institution of Civil Engineers. The briquettes for testing tensile strength were of the usual shape used in this country; the breaking section at first was 1 in. square, but in the later tests it was increased to 2½ square inches. For ascertaining the weight per cubic foot, a box which would contain one-tenth of a cubic foot was placed 3 ft. below a coarse sieve, with which it was connected by means of an iron tube. The cement was shaken through and struck off level. The weights were found to vary considerably; for instance, Rosendale cement weighed from 49 lb. to 56 lb. per cubic foot, while an American Portland cement weighed 55 lb. The more coarsely ground the cement the greater was its weight, but no direct ratio could be discovered between weight and strength, although, as a general rule, heavy cement, if thoroughly burned and finely ground, was preferred to lighter kinds. Colour also was found to be of little use for indicating quality, except in the case of some Portland cement, in which a yellowish hue denoted lack of sufficient burning.

Great importance was attached to fineness, standard sieves varying from No. 50 to No. 120 being used in testing. The former was found to be too coarse, and the latter was adopted as a standard, but was considered quite as fine as would be practically useful. The difference in price between two cements, in one of which 70 per cent. and in the other 85 per cent. passed the sieve, was 88 cents. (3s. 8d.) per barrel; but it was found to be cheaper to use the dearer and finer of the two. Tests were made with neat cement and cement and sand, the latter being found preferable. The strength of neat cement briquettes did not always indicate a capacity of the cement to bind with sand. The usual proportions used were one of cement to three of rather coarse sea-sand. The proportion of water used in making the briquettes varied with different brands, and was so arranged that the mortar was somewhat stiffer than that commonly used by masons. The mortar was rammed into the mould, and the time of setting was determined by noting the time elapsed before the cement would bear a wire 1-12th in. diameter loaded with a ½ lb. weight, or a 1-24th in. diameter wire loaded with a pound weight. If it would bear the latter test the setting of the cement was assumed to be complete. No direct relation was estab-

lished between initial energy and subsequent strength. To make a satisfactory trial, not less than a month was required. In one case briquettes showed a strength of 267 lb. in one month and fell to pieces in six months. In one series of tests extending over two years it was found that when ten or more parts of sand were mixed with one part of Portland cement, the strength at the end of the second year was less than at six months. Salt water was found to retard the setting, but it had no important effect upon strength. Although the differences in strength due to the amount of water are considerable at first, they diminish greatly with age,—from 20 to 25 per cent. of water gave the best results for Portland cement. Finely ground cements were found to be weaker than coarsely-ground when tested neat, but with an admixture of sand the positions were reversed. German cements were found to be more finely ground than English. Ten per cent. of loam in sand reduced the breaking load by about one half when tested at one month, but at six months and one year little difference was found. For stopping leaky joints a mixture of clay with cement mortar was used, and tests made showed that clay in moderate quantities does not weaken cement mortar, and such mortars were found not to suffer from exposure to the weather during a period of two years and a half. Another mixture used for the same purpose was composed of melted tallow mixed with Portland cement and sand in equal parts. The tensile strength of this compound after one week was 40 lb. per square inch, but it did not increase in a year.

Tests of transverse stress were made with concrete beams 10 in. square and about 6 ft. long, which were broken after being buried in the earth for six months. They were found to have a rather low modulus, and it was considered desirable to give concrete ample time to harden when transverse stress is to be opposed.

Tests were made to show the resistance of cement mortars to abrasion. Blocks were moulded 1½ in. square, and were allowed to harden eight months. They were then pressed against a grindstone with a pressure of 20 lb. The largest quantity of sand that the cement would bind without allowing the grains to be pulled out when grinding gave a mortar that opposed the greatest resistance. Cement, both neat and mixed with sand, was filled into lamp-glasses, in which they were allowed to set, and afterwards were immersed in water. In three days all the glasses began to crack. An attempt was made to measure the expansion, the result being that 10-in. cubes expanded linearly 0.001 as a maximum. A mortar of one of Portland cement and two of sand was allowed to harden for a week, when it was pulverised and again made into briquettes. After two years the strength was 93 lb. per square inch. Silenitic cement was not found to have superiority over

Durrans's Patent Scour Trap.

the ordinary kinds sufficient to compensate for increased cost.

The paper from which these brief quotations are made contains many other details of considerable importance, and those of our readers who are interested in these matters would do well to refer to the original communication, which was contributed to the American Society of Civil Engineers by Mr. E. C. Clarke, and is to be found in the twenty-fourth volume (1885) of the Transactions.

DURRANS'S PATENT SCOUR TRAP.

This trap, of which we give a section, is the invention of an architect, Mr. Thomas Durrans, A.R.I.B.A., and it is being introduced by the House Sanitation Company, Upper Baker-street. The special advantages in this new trap over existing devices are thus summarised by its manufacturers:—

1. Freedom of access to and perfect command for cleaning purposes of the trap and waste-pipe leading from same.
2. A good scouring wash-out is effected in the usual action of the trap, thereby avoiding settlement of deposit therein and preventing corrosion.
3. It is a readily accessible and perfect trap, and it will be seen that on removal of swirl dip every facility of access is obtained to the waste-pipe leading from the trap (which no other trap offers) for the removal of deposit which so often occurs in the pipe.
4. The momentum of the water is checked by the scouring arrangement in the dip, thereby avoiding all possibility of syphoning, which is so often the cause of untrapping in other traps.
5. The dip seal is not too readily separated by the domestic or user, which facility in existing traps is the frequent cause of the introduction of sewer gas, and consequently of ill health to houses.
6. The obstructive screw cap which collects deposit is avoided, and better access provided to all parts of the trap and waste-pipe from the top of the sink, instead of, as now, to the trap only in an awkward position underneath the sink, and usually requiring skilled labour to cleanse the same.

We briefly referred to this trap in our notice of the recent Building Trades' Exhibition. We may add that only one metal joint is required to fix it, and that the outlet connexion can be adjusted to any angle.

The Sites of the Clerkenwell Prisons.

At the meeting of the Metropolitan Board of Works, on the 11th inst., Mr. Selway reported, with reference to the suggested erection of artisans' dwellings on the sites of Coldbath-fields and Clerkenwell prisons, that the Works and General Purposes Committee had informed the Secretary of State that the committee did not think it expedient to enter into negotiations for purchasing the sites for the erection of artisans' dwellings, and were of opinion that the ground would be of more service as open spaces.

ARBITRATION CASE: INGESTRE HALL AND STABLES, STAFFORDSHIRE.

BIRCH v. EARL OF SHREWSBURY AND TALBOT.

This matter in arbitration has recently been brought to a close. The case as stated for the plaintiff was that, having been appointed architect for the restoration of Ingestre Hall, and for the new stables at Ingestre, he made certain arrangements with the defendant as to remuneration, and had conducted the works up to an advanced stage of completion, when he was summarily dismissed without any cause being assigned. Under these circumstances he considered himself entitled to send in his account in the usual manner, and in accordance with the customs of the profession; and that, notwithstanding his having in the first instance agreed to forego remuneration for certain services, under the altered circumstances this was now fairly chargeable, owing to the course adopted by the defendant, no charge of professional neglect or misconduct having been alleged against the plaintiff.

The defence was that the plaintiff was not entitled to these charges, nor to any percentage beyond 5 per cent. on the sum actually expended up to the date when his services were dispensed with; that he was not entitled to 2½ per cent. on the cost of works which had not been actually executed and under his supervision; and that the sum paid into court was sufficient.

Evidence for the plaintiff as to the fairness of his (the plaintiff's) charges and the customs of the profession was given by Mr. Charles Barry and Mr. W. Young. Representatives of Messrs. Maples, of Tottenham-court-road, and Messrs. Jennings, sanitary engineers, of Lambeth, were then called by the defence to prove having prepared designs and executed works independent of the plaintiff's supervision, and subsequently to the termination of his services.

At this stage the proceedings were closed by the defendant offering to augment the sum already paid into Court to a satisfactory amount, and to pay all costs of the action. This was agreed to by the plaintiff, and the arbitrator, Mr. F. A. Bosanquet, Q.C., was requested to make his award agreeably therewith.

Mr. Charles, Q.C., and Mr. F. Radcliffe were counsel for the plaintiff, the solicitors being Messrs. Radcliffe, Cator, & Martineau. Mr. Witt was counsel for the defendant, and Messrs. Woodward, Macleod, & Blyth, solicitors.

BISHOP DE MARCHIA'S TOMB.

SIR.—From the notes accompanying the very beautiful drawings of the tomb of Bishop Wm. de Marchia in Wells Cathedral, which appeared in the *Builder* of last week, it seems that Mr. R. W. Paul is not aware of the existence of documentary evidence existing in the hands of the Chapter, proving that, though the death of the bishop was in 1302, the monument was only erected during the time of the great dean, John de Godesley (his son from 1305 to Feb. 4, 1332); and further, that its execution probably was a little before 1326, immediately after which time the dean seems to have pulled down the older chapter-house, having its site, and built up, or rebuilt, that now existing, it being from this circumstance that the stone floor yet exists of the first, and presents that wonderful collection of full-sized Medieval drawings now seen on the pavement stones, a discovery made by Mr. J. O. Scott,—the same the largest collection existing in England of such things, certainly deserves more consideration than it has yet received.

JAS. THOS. IRVINE.

PROVINCIAL NEWS.

Carlisle.—The Border Counties New Home for Incapables, Carlisle, was formally opened on the 10th inst. in the presence of a large company. The Lord Bishop of Carlisle conducted the dedication service, after which Lady Vane declared the building open. The building was designed by Mr. Geo. Dale Oliver, architect, of Carlisle, whose plans were selected in competition, and carried out under his superintendence.

Chester-le-Street (County Durham).—A large extension of the Chester-le-Street Co-operative Store has just been opened, having been erected at a cost of about 4,000. The contractors are Messrs. Joseph Barnett & Son, of Birtley; and the architects are Messrs. Septimus Oswald & Son, of Newcastle-on-Tyne, whose designs were selected in public competition. The work just finished is only a portion of the entire building scheme contemplated, and further works will be commenced forthwith.

Tunbridge Wells.—Mr. Elphicke is preparing drawings for the erection of a brick church mission-room, to seat 300 people, at High Brooms, Tunbridge Wells. The High Brooms Brick and Tile Co. have kindly given a site, besides a handsome donation, for this purpose.

CHURCH-BUILDING NEWS.

Aylesbury.—It is proposed to add a tower, baptistery, and porch, to insert a new west window, and to reseat Walton Church, Aylesbury. Mr. Brett A. Elphicke is preparing plans for the above additions and alterations.

Blackburn.—A new church, built throughout of stone, has been recently erected in Blackburn, from the designs of Mr. W. S. Varley, of that town, and will be opened very shortly. The order for the choir-stalls, altar-table, pulpit, and rails was entrusted to the firm of Messrs. Jones & Willis, and carried out by them under the superintendence of the architect.

Cheadle.—A carved oak pulpit, in the Early Decorated style, has been erected in Cheadle Church, which is shortly to be opened. It has been made by Messrs. Jones & Willis, and was carried out under the superintendence of the architects, Messrs. Lewis & Son, of Newcastle, Staffordshire.

London.—Considerable alteration and enrichment has been made to the chancel of Christ Church, Lancaster Gate, lately. The old stone steps have been removed, and polished green granite substituted for them. The Communion-table has been raised, and the step under same enriched with a representation of the passion-flower in ceramic mosaic. All the remaining space inside the altar-rail, which is of polished brass, is laid with Godwin's encaustic tiles, of a rich design. It is also intended to relay the remainder of the chancel with tiles, and to add marble steps at the entrance from the nave. Lady Brabazon has kindly offered to give a new pulpit in polished alabaster and marble of very rich design, and which is now being prepared; and another member of the congregation has also promised to defray the cost of a baptistery at the west end of the church, and within which will be placed an inlaid marble and alabaster font. The whole work has been designed and executed by Messrs. J. Underwood & Sons, to whom the pulpit and baptistery have also been entrusted.

Paignton (Devonshire).—The church accommodation of Paignton being somewhat limited, steps have just been taken to provide a new church in that district. Having obtained a grant from the Ecclesiastical Commissioners towards the endowment, in addition to the gift of the site, the committee invited a limited number of architects to send in designs, and unanimously decided in favour of the one submitted under the *nom de plume* "Red Rock." This proved to be the joint work of Mr. Edward Gabriel and Mr. W. G. Coudrey, who have now been instructed to prepare the working drawings for same. The style of the church is Early English, and the well-known red sandstone of Devonshire is to be used both for the exterior and interior, with Bath stone dressings. The plan consists of a nave 30 ft. wide, with narrow aisles to be used only as passages, north and south transepts, chancel 24 ft. wide, with apsidal end, organ-chamber, and vestry. A narthex is provided at the west end, which gives access both to the nave and aisles. The tower, which is at the south-west angle of the building, serves as a baptistery, and is finished with a lofty spire, 180 ft. high. Accommodation is provided in the nave and transepts for 550 persons.

Streatham.—The memorial stones of the Eardley Memorial Church were laid on the 3rd inst. The church, which is to be erected in memory of the late vicar of Emmanuel Church, Streatham-common, the Rev. Stenton Eardley, will be built of red brick, with stone facings. The site is at the south end of Ellison-road. The cost of the building will be about 8,000. Mr. Ernest George is the architect, and Mr. Nightingale is the builder.

STAINED GLASS.

Bangor.—Through the munificence of Mrs. Symes, of Bangor, a large Munich window has lately been erected in the south transept of Bangor Cathedral, to the memory of the late Dean Edwards. There are two two-light windows, with a circle above each, a large rose above all uniting the whole into one grand window. The Rev. Owen Evans, M.A., Professor of Welsh at St. David's College, Lampeter, and Minor Canon of Bangor, has worked out the idea of representing Christ as the Centre and Interpreter of all things. This is illustrated by subjects from the lives of Moses

and Elijah in the Old Testament, and from St. Matthew and St. Paul in the New. In the large rose above is a figure of Christ enthroned in glory, while in the small circles are adoring angels. The artists to whom the carrying out of this elaborate scheme has been entrusted are Messrs. Mayer & Co., of Munich and London.

Dalston.—A large east window has lately been erected in St. Philip's Church, Dalston. The subject, which is carried through the three lights composing the window, represents the Ascension of Our Lord. The work has been carried out by Mr. R. Morris, of Kennington-road, from the designs and cartoons of Mr. O. J. von Holtrop, of Forest-road, Dalston.

Knobury.—The three-light east window of Knobury Church, Ludlow, has lately been filled with Munich stained glass. The centre compartment contains the Crucifixion; the left-hand light a Jewish priest sacrificing a lamb as a burnt offering; and the right-hand light a Christian priest offering the Holy Eucharist, the whole being intended to convey the idea of the connexion of the sacrifices of the Old and New Testaments by the sacrifice of Our Saviour on the cross, the quatrefoil above containing a slain lamb. The work has been designed and executed by Messrs. Mayer & Co.

The Student's Column.

OUR BUILDING STONES.—XV.

ARTIFICIAL STONES.

ARCHITECTS and builders have had to give considerable attention of late years to the question as to whether it is better to construct edifices with natural or artificial stones. Some of the kinds of stone artificially made are unquestionably more durable than the ordinary natural stones used in building, and if they can be produced at a reasonable cost they should on that account be utilised where practicable.

One of the principal of these is

Terra Cotta.

As its name implies, this material is "burned earth." In the strictest sense of the term, bricks and pottery should be included under the same heading, but *terra cotta* is generally understood to mean that kind of burned earth which has been carefully prepared, the clay being of better quality, besides being more skilfully manipulated and fired than ordinary pottery ware.

Terra cotta is made in the following manner. The clay is first thoroughly mixed by passing through what are called "pugging-mills." Finely-ground burned clay, in certain proportions, is also mixed with it to prevent it from warping and twisting in the after stages of manufacture. The mass should be as perfectly homogeneous as it is possible to make it, and, in particular cases, after undergoing a process which expels any air that may be present, it is pressed carefully into moulds, precaution being again taken to prevent any accumulation of air in the corners and crevices of the moulds. The reason why these points are so carefully attended to is because the heat of the kiln would cause the air to expand, and the work in consequence would be cracked. In pressing the material into moulds, it is necessary to keep it the same thickness throughout, as when the burning causes the clay to contract, any variation in thickness would distort it. The moulded clay is afterwards dried very gradually and with extreme care. If the operation is carried on too quickly, or if any draughts of cold air are admitted, the stone becomes warped and useless. The final burning is, perhaps, the most important part of the process, as the quality of the *terra cotta* is greatly dependent upon it. Its ordinary colours, when well burned, are red, blue, and buff. They may be considerably modified by the amount of heat used; and if other colours are desired, foreign matter must be added. If the clay used contains much oxide of iron, lime, magnesia, or other impurities, it will not burn well. White clay is sometimes used with only enough iron mixed to colour it.

Terra cotta is very durable; but it is not from the fact that monuments of high antiquity made of this material in Eastern countries have been handed down to us in such an excellent state of preservation, that we should judge of its durability when utilising it in this country; for

the climate of those countries is often quite different from that of our own, and the monuments under consideration have, in many instances, not been exposed to the action of the weather. We know the durability of terra cotta, because it has been tried in this country for many years, and the rate of its decay has been shown to be almost *nil*. Thus it has an immense advantage over those other artificial stones but recently introduced into the market, for we know next to nothing, from experience, of the durability of the latter.

Like almost everything else, however, there are both good and bad kinds of terra cotta. Those of bad quality have usually resulted from defective burning; and when that is the case it disintegrates very shortly after being built up.

It is very difficult to produce blocks of burned clay which shall have a greater thickness than 1 in., so the ordinary method of making the blocks for building is to construct a shell of terra cotta 1 in. thick strengthened with cross-webs, which also help to preserve its shape in the burning. The spaces are then filled up with concrete, according to whether it is required to be extra strong or not.

This concrete is mixed rather weak to prevent it swelling and thus bursting the sides of the block.

The better kinds of terra cotta are capable of taking a great thrusting stress, but, of course, the actual weight required to crush it depends on the thickness of the walls of the blocks experimented upon, and whether they are filled with concrete or hollow. The kind of concrete used must also be taken into account.

A block of terra cotta about 1 ft. cube, which had no cross-webs or concrete in it, splintered at the edges at 40 tons and broke at 100 tons. Its resistance when solid is said to bear a compression nearly one-third greater than ordinary Portland stone.

Terra cotta when used hollow is very light, not weighing more than 60 lb. to 70 lb. per cubic foot. This is a source of economy, as much saving is effected in carriage and labour.

It is a good material for resisting the action of fire. Mr. James Doulton, speaking on this subject at Carpenters' Hall a short time ago, said that heat has merely the effect of burning off the dirt from terra cotta, making it look fresh. This was exemplified by the fire at his own premises not long since. After the fire, which, though of short duration, was terrifically fierce, on examination the sills of windows and copings of walls, which were of stone, were found to be destroyed, but the dressings of the windows, which were of terra cotta, were perfectly sound, the great heat merely brightening them up, and making them look like new.*

One of the disadvantages of using terra cotta for building walls is that the unequal shrinkage causes the blocks occasionally to be twisted; thus the long lines of the building become uneven. To set such uneven blocks right, they are often chiselled. This should not be too frequently resorted to, as it takes off the outer surface of the material,—the part, in fact, that is the chief cause of the preservation of it from the attacks of the atmosphere. This outer surface is formed in the burning.

An inferior kind of terra cotta is made by coating a rough indifferent clay with one of a much more expensive nature, but unless these two bodies have been most carefully prepared, they are sure in course of time to destroy one another; that is, the inequality in their shrinkage will cause air cracks in the fine outer skin, which will inevitably retain moisture, and cause the surface layer to drop off in scales after the winter frosts.

Terra cotta is largely used in architectural ornamentation, and especially where the designs have to be repeated several times.

Buildings exist with terra-cotta mouldings and ornaments which were erected between the thirteenth and fourteenth centuries. The use of the material appears to have been discontinued shortly afterwards, and it was not until the latter end of last century that it again came into use.

Slag.

Where ordinary stone is not easily obtainable, slag proves to be a most useful substitute. It has not been used in this country to any great extent, but in places where it has been employed the results have been perfectly satisfactory.

* See the *Builder*, p. 539, ante.

All kinds of slag are not suitable for manufacturing into building stones; those which contain too much lime fall to pieces on exposure. In general, it may be said that slag should contain from 38 to 44 per cent. of silica, and that the furnace whence it is obtained should be working continuously.

According to experiments made at the Conservatoire des Arts et Métiers in Paris, slag when made while the furnace was running on white iron, never became fissured under a pressure of less than 242 kilogrammes the square centimètre, and was crushed at a pressure of 886 kilogrammes as a minimum.

Basalt Stone.

The lava known as basalt has been experimented with, on rather an extensive scale, to discover whether it cannot be utilised for mouldings and the like.

The rock is melted in a furnace, after which it is received into moulds of the required shape. It needs to be cooled very slowly, or it turns into a glassy substance. The tendency of basalt to assume a columnar structure when under treatment is rather a drawback, according to some French authorities, but we are of opinion that by mixing different substances with it the difficulty could be overcome.

VARIORUM.

FROM Messrs. Crosby Lockwood & Co., Stationers' Hall-court, we have received No. 255 of "Weale's Rudimentary Series," viz., "Locomotive Engine Driving," by Michael Reynolds. We are not surprised to find that this excellent manual, which is dedicated to "the engineers and firemen of locomotive engines throughout the United Kingdom," and which has on previous occasions been favourably noticed by us, has reached its seventh edition. Messrs. Crosby Lockwood & Co. also send us No. 256 of the same series, which is by the same author, its subject being "Stationary Engine Driving." This work, which is in its third edition, revised and enlarged, fully maintains its claim to be "a practical manual for engineers in charge of stationary engines." If its precepts were known to and practised by people who own or who are placed in charge of steam-engines and boilers, there would be a marked diminution in the number of breakdowns and explosions, and we should not hear of such strange things as have been sworn to in the case of the recent catastrophe at Limehouse. The author is an advocate for the adoption of a system of examination and certificates for engineers, and pending the adoption of such a system, he has certainly done his part in contributing to their technical education and capability.—"The Twenty-sixth Annual Report of the Amalgamated Society of Carpenters and Joiners" (Manchester: Co-operative Printing Society) covers a period of twelve months, from December, 1884 to December, 1885. It includes the financial reports of the branches, income and expenditure at the general office, the number of members, addresses, and nights of meeting of branches, and a mass of other information of interest. It appears from the "General Secretary's Remarks," which serve as a preface to the volume, and which are brought down to the end of March of the current year, that owing to the prevailing depression of trade, 180 members per 1,000 were unemployed on the 31st of January last. Mr. Murchie, however, does not think that there is any serious falling-off in the general volume of the building trade. The net income of the Society for the year was 63,121. 10s. 7d., and the net expenditure 75,663l. 9s. 3d. Unemployed benefit, the largest item in the Society's expenditure, cost 34,909l. 18s. 10d., or 1l. 7s. 0½d. per member, as against 18s. 9½d. per member in 1884. In sick benefit the Society expended 16,719l. 9s. 8½d., or 12s. 11½d. per member, as against 11s. 11½d. in the previous year. The report, which consists of nearly 400 pages, appears to have been carefully compiled.—"A Discourse on the Principles of Domestic Fireplace Construction," by T. Pridgin Teale, M.A., F.C.S. (London: J. & A. Churchill), is a publication, in pamphlet form, with illustrations, of Mr. Teale's lecture at the Royal Institution on February 5th last, which was reported in our columns at the time.—"The Insurance Year Book, 1886" (London: Simpkin, Marshall, & Co.), gives such information as to the position of the many offices mentioned as to justify its claim to be

"a guide for persons effecting insurances."—"Loss of Life and Property by Lightning, at Home and Abroad," by W. McGregor, Member of the Society of Telegraph Engineers and Electricians (Bedford: W. J. Robinson, Silverstreet), is avowedly a plea for inaugurating a new and responsible "Society for the Protection of Life and Property from Lightning." It is proposed to collect and to collate information as to disasters caused by lightning, and to endeavour to educate public opinion to the pitch of demanding municipal or other inspection and control of lightning conductors. The Society is to be cosmopolitan in its scope, and the proposal for its formation is based on the conviction of the author that so-called "accidents" by lightning have no right to be included in the chapter of accidents at all. The pamphlet is a suggestive one, and will well repay perusal.—"Mathieson's Highest and Lowest Prices and Dividends Paid for the Past Six Years, 1880-85" (London: Effingham Wilson, Royal Exchange) is a compilation which will be found very useful for reference.—"The Camera, a Monthly Magazine for those who practise Photography" (London: Wyman & Sons), is a new aspirant for favour. It is edited by Mr. T. C. Heworth, and contains interesting articles by Mr. R. A. Proctor, Mr. J. S. Hodson, Mr. T. H. Joyce, Dr. G. Lindsay Johnson, and the Editor.—The last volume issued of the "Transactions of the National Association for the Promotion of Social Science" (London: Longmans, Green, & Co.) is wholly occupied with a report of the "Conference on Temperance Legislation," held in London in February last. Both parties to the controversy,—the followers of Sir Wilfrid Lawson and the representatives of the beer, wine, and spirit trades,—seem to have left off where they began: neither succeeded in convincing the other, which is just what might have been expected.—"The English Illustrated Magazine, for June (London: Macmillan & Co.), contains an interesting paper, by Mr. Joseph Hutton, on "Yarmouth and the Broads," and there is a well-illustrated paper on "Umbria," by Katharine S. Macquoid, the illustrations being by Mr. Thomas Macquoid.—Messrs. Cassell & Co., of La Belle Sauvage-yard, send us a parcel of their popular magazines for June. *The Quiver* contains a sensible article, by Lord Brabazon, on "The Welfare of Young Men," *Little Folks*, a magazine ever popular with the children, completes a volume of its new and enlarged series. In *Cassell's Family Magazine* the first article takes the shape of "An Interview with the Rev. S. A. Barnett," of "St. Jude's, Whitechapel, who discourses to "our special correspondent" of "The Dwellings of the London Poor." Mr. Barnett's views are pretty well known to our readers. He considers that the good management and administration of tenement houses are much more important and infinitely more likely to produce the wished-for results than new legislation; and that Sir Richard Cross's Act, properly worked, is amply sufficient to meet all needs. He sums up the two essentials of amelioration as consisting in improved local administration and the development of the sense of duty on the part of the landlords. "The Practical Dictionary of Mechanics," another serial work published by Messrs. Cassell, has now reached its 114th part, and brings us down to the word "Siphon." It is very fully illustrated, and copious references are given.—"The Religious Tract Society (London: 50, Paternoster-row) send a number of their well-known magazines. *The Leisure Hour* continues "The Story of the English Shires," by the Rev. Professor Creighton, of Cambridge, Cumberland being dealt with in the June number; this is a very readable chapter. "Life in the Backwoods of Wisconsin" gives some account of the "Innumbers' camps" of that state. In the *Sunday at Home*, Mr. Henry Harper continues "An Artist's Jottings in the Holy Land," the illustrations clearly exhibiting the rugged and barren nature of some parts of that country. The same Society issue the *Boy's Own Paper* and the *Girl's Own Paper*. In the former, the illustrated papers on "Our Great Public Schools" are continued, Westminster and Eton being treated of in the current number, in which Captain W. de W. Abney, F.R.S., contributes illustrated articles on "Photography for Boys." In the *Girl's Own Paper* Mr. H. W. Brewer concludes his papers on "Architecture," and Mr. Richard Taylor commences a series on "Wood Engraving as an Employment for Girls."—Several trade-books and catalogues lately received deserve

mention. Messrs. Hamilton & Co., of Greek-street, Soho, have sent us an illustrated catalogue and price list of their well-known "Semper Idem" painting-brushes, graining tools, &c. From Messrs. J. Arthur Young & Co., of Victoria Chambers, Westminster, we have received a useful illustrated catalogue of iron constructions, fittings, and utensils requisite in "the field, the farm, the garden, and the stable." Messrs. A. Ransome & Co., of Stanley Works, Chelsea, send us their price list of patented and improved woodworking machines; and Messrs. W. E. Smith & Co., of Cremorne Works, Chelsea, send us some illustrated sheets also referring to machinery for working in wood. Mr. Thomas Fletcher, of Warrington, sends us a very useful illustrated catalogue of gas-heating apparatus, which he claims to be unique in illustrating all the purposes for which gas is applied as a fuel; but he does not appear to include gas engines, in which, perhaps, he would say that the gas is used as a "motive-power" and not as a "fuel." Messrs. Merryweather & Sons, of Long Acre, send us a very complete catalogue of fire engines and other apparatus used in connection with the extinction of fires and the preservation of life and property. It contains a great deal of useful information with reference to the powers of Town Councils and other authorities in regard to the protection of their respective localities from fire, as well as rules and suggestions for the formation and working of fire brigades. Messrs. Charles Williams & Co., of Ferry Iron-works, Chubb Town, have issued a new and useful sheet of sections of iron joists and girders, with dimensions, weights, and loads figured. It will be found handy hung on the office wall.—Mr. Roger L. Lowe, of Farnworth, Bolton, has issued a new catalogue illustrating the applications of his excellent system of wood-block flooring. It is well worth the notice of architects.—"Fosnic's History of the Iron Trade" (London: E. & F. N. Spon), is a very useful coloured and figured diagram, compiled and designed by Mr. R. R. Mabson, F.R.S., showing the production of iron in the United Kingdom since the year 1830, with the weight of iron and steel exported, and the prices of typical descriptions of iron during the same period.—"The Colonies and India" (London: C. Mitchell & Co., Red Lion-court, Fleet-street) is a reprint (published at Is.) of the very useful "Colonial Supplement" issued with Mitchell's "Newspaper Press Directory" for the current year. It contains fifty-two large and closely-printed pages of statistical and other information of special interest just now, with regard to India and our colonies, their commerce, industries, &c.—Messrs. Jarrold & Sons, of Norwich, have issued a cheap illustrated "Guide to Norwich," which may be found useful by visitors. The same firm also send us cheap illustrated guides to "Great Yarmouth" and "The Rivers and Broads of Norfolk and Suffolk." These guides are very creditably got up, and cost only a few pence.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

6,813, Improvements in Cement. C. Kingsford.
This is an apparatus designed to utilise more economically and advantageously the waste heat from coke ovens by providing an apparatus which comprises within itself means for making coke in combination with means for utilising the heat generated in the manufacture of coke for generating steam and for drying purposes. The most important application or use of the improved apparatus, however, is the drying of "slurry," i.e., a mixture of chalk and clay mud, used in the manufacture of cement, and this is greatly hastened by the arrangement for drawing off the heat and constructing the apparatus with drawers or trays placed above the boiler.
8,257, Improvements in Metal Roofing. C. Holden.
The flange at the top of the roll cap and the stop end at the bottom of the roll cap are connected by means of grooved and welded seams. Modifications of existing methods are also made by attaching a holding-down clip to the roll cap by means of a slot and welt, which does away with the use of solder, and, at the same time, allows for free expansion and contraction. The flange is attached to the roll cap by means of a double fold, one fold being made on the roll cap and one on the flange. The fold on the roll cap is formed by turning up an edge three-eighths of an inch at the end of the roll cap and again three-sixteenths of an inch. The flange has an edge three-eighths of an inch turned out of

the internal part and turned up again three-sixteenths of an inch, thus forming a fold on the flange, the flange then being placed on the roll cap, and, by means of a grooved tool, securely fixed together. The stop end is stamped out somewhat similarly, and the clip, which is a piece of metal 1 1/2 in. by 2 1/2 in., is passed through the slot in the roll cap and fastened down in such a manner as to prevent it moving.

8,400, Improved Ventilated Water-closet Basin. F. W. Holloway.

One or more additional arms or apertures are provided above the level of the surface of the water forming the trap and above the level of the valve. The enlargement of the supply arm or pipe provides also for ventilation in the basin itself, which it is claimed is always kept pure, the ventilation being entirely distinct from any ventilation of the soil-pipes or traps or any contrivance attached to or connected with any part other than the basin itself.

2,639, Imitation of Inlaid Wood. J. Ritzdorf (Bonn).

The surface of the wood to be treated is smoothed and then impregnated with a solution of (approximately) one-third boiled linseed oil and two-thirds turpentine mixed with benzine. A stencil plate is then used, and a solution of ozokerite and benzine is brushed over. After this is done the design is brushed over with a mordant or stain dissolved in water, which only affects that portion of the design not stencilled. It is rubbed over with glass paper and then retouched, after which it is again painted over with a light white or yellow solution, and when this has become dry it is rubbed over with glass paper and lightly ground over, then rubbed over with wax or merely polished. In this way work may be produced to represent inlaid or marquetry executed in several kinds of wood. It may also be shaded or burned with a burning instrument.

NEW APPLICATIONS FOR LETTERS PATENT.

June 4—7,501, E. Bailey and C. Mackey, Attaching Door and Other Knobs to Spindles.—7,513, P. Gay, Apparatus for Cutting, Dressing, and Polishing Marble, Stone, &c.—7,519, E. Salendro, Apparatus for Cutting, Dressing, or Polishing Stone, Marble, &c.—7,541, M. Brophy and J. Archer, Transparent Material for Roofing, &c.
June 5—7,568, J. Hookham, Locks and Latches.—7,572, J. McConnell, Soldering.—7,597, J. & J. Crombie, Concrete Pavement, Floors, &c.
June 7—7,630, J. Betteley, Sliding Window Sashes to Retain same in any Position.—7,635, A. Clark, Ventilators.—7,647, H. Dietrich, Tiles.
June 8—7,670, G. Mason, Fastenings for Window Sashes.—7,674 and 7,675, H. Mathey, Manufacture of Cement.—7,676, H. Mathey, Colouring Cement.—7,683, J. Fawcett, Weather Bar for Doors and Windows.—7,684, L. Wall, Connecting Knobs to Spindles.—7,708, H. Lake, Draining of Houses, &c.—7,712, H. Deane, Window Fastener.
June 9—7,726, J. Horrocks, Trapping and Ventilating Water-closets and Drains.—7,745, H. Poole, Compositions for Artificial Stone, Cement, &c.—7,754, F. Parkes, Urinals.—7,769, G. Smith, Compiling for Gas Pipes.
June 10—7,793, W. Beames, Water-closet Apparatus or Fittings.—7,797, C. Elliott, Glazing.

PROVISIONAL SPECIFICATIONS ACCEPTED.

4,378, J. Barnes, Siphon Cistern.—5,197, F. Powell, Heating Apparatus for Buildings.—5,820, J. Warwick, Manufacture of White Lead.—6,898, H. Turner, Gas Kitchen-ranges.—5,916, S. Bott and C. Hornor, Door Knobs or Handles, and Attaching same to Spindles.—6,336, W. Chambers, Screw-driver.—3,109, J. and O. Cunningham, Jointing Gas or Water Pipes.—4,779, J. Bolding, Water Waste Preventer.—5,324, G. Oulton, Siphon Cisterns for Flushing.—5,351, B. Bradshaw, Carrying-off Table for Brick and Tile Machines.—5,515, A. White, Roads, Pavements, and Paving Blocks.—5,787, S. Stott, Fireproof Buildings.—6,033, R. Owen, Lock or Latch and Catch.—6,103, E. Flint.—W. Knowles, Hinges.—6,162, H. Hennes, Self-acting Fastener for Double Doors.—7,133, N. Greening, Apparatus for Screening and Carrying Lime.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to opposition for two months.
8,022, R. Leo, Electrical Communications between Dots, Knobs, Letter-boxes, and Bells.—9,731, W. Westlake, Brickmaking Machinery.—9,738, W. Gordon, Chimney Cows, &c.—12,470, T. Murphy, Whitewash or Distemper Brush.—12,656, A. Martyn, Forming Letters or Designs upon Glass.—15,773, C. McWhirter, Steam Ventilating Apparatus.—1,902, E. Penfold, Opening and Closing Gates.—2,707, E. Stanley, Bandlethers and Pendants.—2,255, L. Nash, Water Meters.—7,302, W. Parnall, Shop Counters.—8,772, E. Webb, Latching Door Knobs to Spindles.—9,972, J. Royle, Suspended Gas Lights.—10,021, W. Lake, Revolving Shutters.—73, C. Watkins, Graining Tools.—3,783, J. Egan and J. Adams, Pipe Joint.—5,749, J. Howorth, Ventilators.—6,307, W. Hulse, Spirit Levels.—6,360, H. Haddon, Burglar Alarms.

RECENT SALES OF PROPERTY.

ESTATE EXCHANGE REPORT.

JUNE 7.	
City, Tarnhill-street—Ground-rent of 60l. a year, reversion in 98 years	£1,200
By G. A. WILKINSON.	
Fairy House	
Harrow, Weddington—The freehold residence, 830	
Stepney, Mile-end—161, Edinnet-street, 27 years, ground-rent 2l. 10s.	165
Kennington—9 to 14 and 19a, James-street, freehold 1 to 5, Anne's-place, freehold	1,830
By FELLES & SON.	
City—10 and 12, Hearn-street, freehold	500
Commercial-road, E.—13, 14, and 15, Station-place, and 44 and 44, Dean-street, freehold	630
By THOMAS WAKEFIELD.	
Drixton, Hinton-road—A plot of freehold land	420
By E. E. CHURCH & CO.	
London-lane—No. 291, freehold	610
By BOWLES & HARRING.	
Edmonton—A plot of land, 2a, 2r. 0p., freehold ...	80
By FULLER, MOON, & FULLER.	
North Cheam—The Elms, with grounds, freehold...	600
JUNE 8.	
By FRISBY & MOORE.	
Hackney—95 and 97, Wall-street, copyhold	600
4 and 5, Jerusalem-square, freehold	460
239, Dalston-lane, freehold	450
By W. T. GRAY.	
Hackney—155 and 157, Bentham-road, 68 years, ground-rent 8l.	520
By J. S. GOSMEY.	
Kennington-road—Nos. 98 and 100, term 32 years, ground-rent 15l.	800
By C. & H. WEAVER.	
Wandsworth—54, Alma-road, freehold	800
Lambeth—168, Upper Kennington-lane, 89 years, ground-rent 11l. 10s., with the goodwill of the business	660
By J. DRYBELL.	
Camden-road—12, Hilldrop-road, 75 years, ground-rent 9l.	695
By DEBENHAM, TAYSON, & CO.	
Hants, Alresford—Three freehold enclosures of land, 13a, 2r. 37p.	960
Two enclosures, containing 29a, G. 12p.	660
By EDWIN SMITH & CO.	
Lambeth—17, 18, 19, and 30, Rowett-street, 66 years, ground-rent 14l.	740
By EDWIN SMITH & CO.	
Hamstead Heath—Ground-rent of 6l. reversion in 30 years	265
Peckham—Ground-rent of 60l. 1s. 4d. reversion in 48 years	1,850
Ground-rent of 70l. 10s., reversion in 44 years ...	1,720
Ground-rent of 48l., reversion in 44 years	810
Newington Butts—69 to 77 odd, Edward-street, 67 years, ground-rent 30l.	1,420
15 and 17, Albert-street, 66 years, ground-rent 12l. 5s. 6d.	1,375
Clapham-road—2 to 9, Love-lane, freehold	1,875
By H. RUTLEY.	
Hamstead-road—27, Edward-street, 38 years, ground-rent 8l. 8s.	655
Enston-road—57, Judd-street, 29 years, ground-rent 31l. 10s.	330
Brunswick-square—28 and 34, Compton-street, 21 years, ground-rent 40l.	645
Islington—7 and 9, Northampton-street, 32 years, ground-rent 8l.	500
St. John's Wood—6, New-street, 41 years, ground-rent 8l.	350
By ROBERTS, CHAPMAN, & PHILLIPS.	
Chelsea—71, 73, and 75, Burnaby-street, 93 years, ground-rent 25l.	1,480
By F. JOLLY & CO.	
Bow—12, Wellington-road, 49 years, ground-rent 8l.	410
Mile-end—24, Bancroft-road, 71 years, ground-rent 5l. 5s.	565
By H. G. KINGDOM.	
Spalding, Bourne-road—Freehold house and foundry	610
JUNE 9.	
By W. HALL.	
Islington—32, Northampton-street, 31 years, ground-rent 3l. 5s.	265
By C. R. CROSS.	
Edgware—The White Lion Inn, freehold	1,810
Sherriss—13, Chapel-street, freehold	200
By C. D. FIELD & SONS.	
East Ham, Gladding-road—Three plots of freehold land	285
Bermondsey—135, Alcock-road, 43 years, ground-rent 4l. 7s.	300
By A. SPAIN & SON.	
Gravesend—83, Parrott-street, freehold	510
By LEARD & DAVIS.	
Hoxton—Improved rentals of 62l. 8s. term 33 years	460
By FULLER, HOESBY, SONS, & CASSELL.	
Headley—Hants—The Barford Flock Mills, copyhold	1,000
Two copyhold cottages	150
A plot of land, 2a, 1r. 23p., copyhold	90
By BAXTER, PATYB, & LEPPERS.	
Knockholt, Kent—Scott's Lodge, 2r. 14p., freehold	870
Three enclosures of land, 20a, 1r. 3p., freehold...	1,040
By W. A. BALEMORE.	
Pimlico—4 to 10 even, Cornwall-street, 47 years, ground-rent 31l.	2,470
By JONES & SON.	
Poplar—2, Paristerrace, 62 years, ground-rent 2l. 10s.	170
25, Oriental-street, 74 years, ground-rent 4s. 4d.	380
Bow—13, Coburn-street, 31 years, ground-rent 18l.	500
By DEBENHAM, TAYSON, & CO.	
Harpden—A Plot of land, 3r. 17p., freehold	431.10s.
Three enclosures of land, 21a, 3r. 11p., freehold	623
JUNE 10.	
By MESSRS. LADY.	
Chelsea—16, Upper Cheyne-row, and stabling, &c., freehold	3,000

Sidem—Two freehold houses and building land, 40s. 1r. 12p.	20,920
By A. WALTON.	
Hornsey—45, Shaftesbury-road, 89 years, ground-rent 7l. 7s.	450
Holloway—13 and 15, Victoria-road, and the reversion to three freehold houses in 48 years	625
New North-road—51, Rushton-street, 49 years, ground-rent 4l. 15s.	335
Canonbury—210, St. Paul's-road, 66 years, ground-rent, 5l. 6s.	305
By B. BROWN.	
Clacton-on-sea, Ellis-road—Four houses, 97 years, ground-rent 20s. 8s.	1,200
Walthamstow—1, 2, and 3, Adelaide-villas, freehold	770
Hoxton—17, Forston-street, 17 years, ground-rent 4l. 10s.	175
By M. MILLS.	
Kenilworth—139 and 141, Carlton-road, 71 years, ground-rent 12l. 12s.	550
By E. SIMSON.	
Walworth—64 to 70 even, South-street, 65 years, ground-rent 17l. 10s.	1,175
51 and 53, Invill-road, 68 years, ground-rent 10l. 8s and 87, Thurlow-street, 66 years, ground-rent 11l.	650
8 to 16 even, Thurlow-street, 49 years, ground-rent 25s.	575
8, 9, and 10, Shaftesbury-road, 24 years, ground-rent 6l.	1,270
29 to 38 even, Kingston-street, 73 years, ground-rent 35s.	410
Old Kent-road—16 and 18, Kinglake-street, 21 years, ground-rent 6l.	2,220
Southwark—47 and 50a, Trinity-square, 9 years, ground-rent 12l. 10s.	260
Brixton-road—No. 335, term 64 years, ground-rent 17s.	1,330
Brixton-hill—52 and 64, Endymion-road, 93 years, ground-rent 22s.	870
Walworth—62 to 68 even, Invill-road, 65 years, ground-rent 24s.	1,015
3 to 21 odd, Portland-street, 15 years, ground-rent 50s.	870

By ROBINSON & FISHER.	
Lancing—The Stork's Nest, and 4s. 1r. 10p., freehold	2,610
Freehold building estate, 36s. 2r. 35p.	4,365
Two plots of freehold land, 4s. 1r. 35p.	600
Hampstead—102, Adelaide-road, 69 years, ground-rent 15s.	400

MEETINGS.

SATURDAY, JUNE 19.
Architectural Association.—Visit to Waltham Abbey and Cross. Train from Liverpool-street Station at 2:40 p.m.
 MONDAY, JUNE 21.
Royal Institute of British Architects.—Ordinary Meeting. Presentation of Royal Gold Medal and other Medals and Prizes. 8 p.m.
Dundee Institute of Architecture.—Business Meeting. 7 p.m.
 TUESDAY, JUNE 22.
British Museum.—Mr. John A. P. MacBride on "The Works of Greek Sculptors Subsequent to Phedias," 2:30 p.m.
Statistical Society.—Sir Francis Dillon Bell, Agent-General for New Zealand, will read a paper by the Hon. Sir Robert Stout, K.C.M.G., Premier of the Colony, entitled "Notes on the Progress of New Zealand for twenty years, 1864-1884," 7:45 p.m.
 THURSDAY, JUNE 24.
Society for the Encouragement of the Fine Arts.—Mr. T. H. Maguire on "The Importance of the Fine Arts to Humanity," 8 p.m.
Society of Antiquaries.—8:30 p.m.
 FRIDAY, JUNE 25.
Junior Engineering Society.—General Meeting. 7:15 p.m.

Miscellaneous.

Home Arts and Industries Association.
 The annual exhibition of this Association will be opened by H.R.H. the Princess Louise on the 22nd of June. This year it will be held at the East End, and the large iron room at St. Andrew's, Bethnal-green, has been lent for the purpose. The exhibition will include specimens of wood carving, metal work, and of other hand arts taught in the classes of the Association. H.R.H. the Princess of Wales has kindly promised to visit the exhibition.
Clocks.—A large church clock has just been erected at Southey, Norfolk, by Messrs. John Smith & Sons, Midland Clock Works, Derby. It strikes the hours, and shows time on two dials, each 4 ft. across. All the wheels are of hard hammered brass, and the pendulum-bob weighs 1 cwt. A large clock has also been fixed at the parish church of Mendlesham, Suffolk, by the same makers. It strikes the hours and half-hours, and has one 5-ft. dial.

Insanitary Venice.—With rather more than her proper share of the unhealthily conditions that seem inseparable from Mediterranean seaports, Venice has refrained from sanitary reform until three years of epidemic disease, with its consequent scaring off of visitors and of the advantages they bring, has aroused her to a sense of duty. Instead of reassuring proclamations by prefects or protests of injured hotel-keepers, it is edifying to read such a letter as that which Signor C. Castellani addresses to the Italian Government through the columns of the *Fenicia*. "We must frankly confront the fact," he says in effect, "that Venice invites epidemic disease, and that Italy must interpose to save her most picturesque city from ruin. We must subject to the most vigilant surveillance the water-supply, the drainage, the canals, the dwellings of the poor, the food-markets, the hospital service, the subsoil, the lagoons, the streets, the whole ensemble of Venetian life. Cleanliness, public and private, must be the order of the day, and until it is practically observed our economic kitchens and free dormitories do little more than parley with the enemy instead of expelling it. Money, however, is wanted, and the Italian nation must do for Venice what she has done on so grand a scale for Naples and other cities. The Government which obtained from Parliament so many millions for Neapolitan rehabilitation, could it not spare a few for Venice, which has hitherto asked nothing? What Italian city has stronger claims on the national benevolence than the "pearl of the Adriatic"? Like her sisters of the seaboard, in fact, Venice is now the scene of something like an explosion of cholera, and having ignored the admonitions given her to stamp out the malady during its early insidious stage, she is making tardy amends for past remissness by an impassioned appeal for help from without.—*Lancet*.

The Hardening of Plaster.—Some time since* attention was called in these columns to a communication on this subject made to the French Academy of Sciences by M. Julhe, who advocated the use of hardened plaster for flooring. The *Cheniker Zeitung* has since quoted a statement of Herr Denstedt, who claims priority in the idea thus demonstrated, and refers to a French patent obtained by him in October, 1884. Baryta water is the agent he mentions, but he remarks that this process has the defect that, when drying takes place, all the baryta is brought to the surface with the evaporating water, being changed into carbonate by the carbonic acid in the air; a thin insoluble layer being formed. On the other hand, a heated solution of baryta, completely saturated, gives very satisfactory results, if the substances used are first heated to 140°-175° F., in order to prevent baryta crystals being developed. By external air-pressure the solution is pressed down to a certain depth, and when cold, baryta crystals are formed inside the mass. These remain, however, inside, and are changed into insoluble combinations by the carbonic acid of the air, or by the substances added to the plaster. For producing a greater degree of hardness, free silicic acid is added to the plaster, or such metallic salts (sulphates) as react with baryta, forming insoluble barium salts and insoluble hydro-oxides. In place of silicic acid, it is possible to use glaze sand (made by the pulverisation of burned quartz). The sulphates which are most suitable are those of zinc, cadmium, magnesium, copper, aluminium, chromium, cobalt, and nickel. Some of them produce colourings which can be preserved uniform if the baryta is replaced by lime. The plaster is stirred with milk of lime, and after drying, the objects formed are saturated with the sulphates in question.

Slaitwaite.—The Providence Baptist Chapel, after being rebuilt, has been reopened. The whole of the work has been carried out from designs prepared by and under the superintendence of Mr. J. Berry, architect, of Huddersfield. The excavators', masons', and slaters' work has been executed by Messrs. E. England & Sons, Slaitwaite; carpenters' and joiners' work by Mr. James Christie, Huddersfield; plumbers' and glaziers' work by Mr. F. Goodall, Slaitwaite; plasterers' and painters' work by Mr. R. W. Sutcliffe. The hot-water engineer was Mr. R. Rendle, Shipley, Leeds. The organ has been built by Messrs. P. Conacher & Co., Huddersfield. The chapel will accommodate 490, and has cost 1,600.

The Widening of the Charing Cross Railway Bridge and Station.—The works at the widening of the South-Eastern Company's bridge across the Thames at Charing Cross are so far advanced that the Middlesex side of the river has now been reached, the works having been commenced on the Surrey side. The girders of the bridge will rest on iron cylinders, having a total depth of 96 ft., and descending 32 ft. below the bed of the river. When completed, the bridge will be widened to the extent of 48 ft., admitting of the laying down of four additional lines of rails. Messrs. J. Cochrane & Sons, of Westminster, are the contractors. The widening of the bridge has necessitated the removal of the Charing Cross Swimming-bath, which was moored immediately to the west of the bridge. The undertaking includes the enlargement of the Charing Cross Station by widening it to a considerable extent on the west side. This involves the removal of the recently-erected Avenue Theatre, together with the demolition of a large number of houses on the east side of Craven-street, and we are informed that this portion of the work will shortly be commenced.

The Volumes of Cements.—Dr. Böhme publishes some particulars respecting the constancy of volumes of cements, which appear in the "Transactions of the Institution of Civil Engineers." For determining the constancy of volume the standard Prussian test is as follows:—Pure cement is mixed with water to a stiff cement, and formed into a thin cake on glass or metal plates. After setting, cake and plate are placed under water. If after one or more days the cake shows crumpling, or cracks at the edge, the "flying" of the cement is indicated. Another test is known as the "baking proof." The cement is mixed with water to a syrrupy consistency, and is poured on a gypsum plate covered with damp filter-paper. In about ten minutes the cake is placed on a heated iron plate, and baked for an hour. If the cake remains sharp-edged and free from cracks, the cement is constant in volume. A third test proceeds on the hypothesis that the quick hardening of cement in boiling water proceeds just as in water of mean temperature. The cakes formed on glass plates are hardened twenty-three hours in air, and then placed in boiling water. The least tendency to flying of the cement is shown in from ten to sixty minutes.

The Printing Machine Managers' Super-annuation Fund.—The annual excursion to Hastings and St. Leonards in aid of the funds of the above charity will take place on Saturday, July 3. The committee say that they are again enabled, through the kindness of the Brighton Railway Company, to provide accommodation on a most liberal scale. The excursion will be from Saturday to Monday, one, two, or three days, at the option of the ticket-holder, starting from either London Bridge or Victoria Stations, and the fare, there and back, is 6s. for three days, or 5s. for one day. The fund was established thirteen years ago to provide a small allowance to printing machine managers who, from age or blindness, become incapacitated from following their trade. We trust that the excursion will be well patronised by the public, and that it will result in substantial help to the finances of the charity. Printing machine-managers are a hard-working body of men, to whom every newspaper reader is indebted. Further particulars concerning the charity may be had of Mr. D. De Leahy, secretary, 134, Salisbury-square, E.C.

Metropolitan Board of Works.—At the meeting of this Board on the 11th inst., a letter was read from the St. Saviour's District Board of Works stating that Mr. T. F. Rider had been appointed their representative at the Metropolitan Board. Mr. Rider is a builder, and a member of the well-known firm of Rider & Sons, Union-street, Southwark.

New Dwellings for Artisans at Hoxton. The Prince of Wales has consented to open Bleyton's Industrial Dwellings, Chatham-avenue, Nile-street, Hoxton, on Monday, July 5. These dwellings are the work of the trustees of the joint charities of St. Giles, Cripplegate, and St. Luke, Middlesex.

Fire.—The Directors of Wilkes's Metallic Flooring and Eureka Concrete Company, Limited, announce that the fire which occurred at their works, West Kensington, on the 8th inst., will in no way interfere with the conduct of their business.

* See *Builder*, vol. xlix., p. 365 (Sept. 12, 1885).

Ecclesiastical Art Exhibition at Wakefield.—The annual exhibition of Ecclesiastical Art will take place as usual during the Church Congress, which is to be held this year in the diocese of Ripon, at Wakefield, and from the historic wealth of the diocese it is expected that the loan collection will be more than usually interesting. The exhibition will be held in the spacious Drill Hall, which is within easy reach of the Congress Hall. Many of the leading church furnishers, embroiderers, silversmiths, and glass-painters will be represented, and educational works and appliances will also be included in the exhibition. It is hoped that the clergy of the diocese and others possessing interesting objects, suitable for the loan collection, will assist in making the exhibit of ecclesiastical art a representation capable of sustaining the high repute the diocese enjoys in the estimation of antiquaries and archaeologists. The loans will embrace goldsmiths' and silversmiths' work, ancient and modern, and ecclesiastical metal-work in general, embroidery, needlework, tapestry, wood and ivory carving, ecclesiastical furniture, paintings, drawings, architectural designs for churches and schools, photographs, books and MSS., and other objects of archaeological interest belonging to the churches of the diocese.

The Associates Sketching Club, Leeds and Yorkshire Architectural Society.—A monthly meeting of the members of this club was held at the Rooms, Albion-street, last week, when the drawings produced during the previous month were exhibited. Some of the best are Mr. F. W. Bedford's "Lees Hall," a fine pencil sketch nicely shaded; and a coloured drawing by Mr. H. P. Buckley of the wood lectern from St. John's Church; Mr. A. E. Dixon exhibited a measured drawing of the old Norman porch at Adel; and other interesting exhibits were—Drawings of Italian carved wood panels, by Mr. J. S. Preston; Calverley Church porch, Mr. G. Rhodes; north aisle of the choir, Selby Abbey Church, Mr. J. W. Twist; and Kildal Hall, Scholes, Mr. Alf. Whitehead. There was a large attendance of members.

PRICES CURRENT OF MATERIALS.

Art in the Colonial Exhibition.

WE shall disarm those critics who may feel inclined to criticise this critique on the art-work of the Colonies by saying that we do not judge the Colonial exhibits by their art-work.

They are the producers of the raw material and the raisers of produce, and that part of the exhibit speaks for itself and makes the inhabitants the mother country justly proud of her children. But as the Colonies elect to exhibit the work that comes under the domain of art, using that word in its widest sense, it is only just that we should examine these works, and in forming an opinion on them we must use the same standard of criticism as we expect employed in our own work; for to give the Colonies "points" to bring them level with us, and so compensate them for the disadvantage they naturally labour under, would give a wholly valueless result, for no criticism is worth anything that is not comparative.

Looking at their exhibits generally, it must strike the most casual observer that our Colonies have done very little to win the sympathies of the spectator by that most powerful of the senses,—sight; and this is brought the more prominently before one by the contrast exhibited between the Colonial and Indian Courts, which latter are beautiful to the eye, and arrest the attention by their general effect, before the observer has the opportunity of making himself acquainted with the exhibits in detail. Arches made to look like gold, to show the amount of that metal raised in a certain colony, are, as exemplified in the Colonial Courts, not lovely objects,—far from it,—and yet here was a capital opportunity of exhibiting whatever taste was in the Colony, for the badness of these trophies artistically cannot be excused on the ground of their usefulness, as is the case with many other objects they exhibit. Their cases of stuffed birds, too, are not seen to the best advantage, owing to had grouping, and the public is no longer content with the taxidermy of twenty years ago, since it has had put before it those splendid cases in the New Natural History Museum. But we will leave the sphere of generalities and look at the "Colonies" in detail.

Although we are not specially concerned here with their pictorial work, we can just take a glance at the Colonial pictures, for this exhibit will detain no one very long. We hardly expected to see such a display of poor, amateurish, uneducated work as is shown. Apart

from an unskilful technique, or a technique that has that fatal facility of the "pot-boiler," the colouring is crude, and the scheme of it disagreeable, and it is hard to distinguish many of the landscapes from bad oleographs. These remarks apply not only to the works exhibited in the main building, but also to those in the gallery of the Albert Hall, where the best pictures are to be seen. The pictures, in fact, exhibit an almost entire absence of anything like Academic training. There is only one name we remember as an exception among dozens in the Australian Courts, that of Mr. P. F. Paterson, whose Colonial landscapes and river scenes show that he has had a fair European training, for his work insensibly reminds us of work we are familiar with here. Canada of all our Colonies exhibits the best pictorial work, and the men who stand out prominently have evidently had a Parisian training, and for that matter, seeing how the Americans patronise the French *atelier*s, some of the Canadian artists may have drifted from America.

There are some English people who imagine that Colonial scenery does not paint well, because the paintings one sees of it are all so inferior, but from a few good pictures in the Colonial Courts it is evident that their artists have plenty of scope, though some of the subjects they elect to paint, especially in New Zealand, strike one as more curious and geologically interesting than beautiful.

India, though not included in our estimate of other work, we may remark, *en passant*, shows pictures by two men, Mr. Horace Van Huth and Mr. John Griffiths, that are worthy of high praise. The water-colour studies by the former of Indian life, on grey paper, remind one somewhat of the work of our own Lewis. Mr. Griffiths's oil pictures of Hindoo life are really fine, and they show what splendid material an artist who has a strong feeling for colour and the requisite amount of manipulative skill has in this wonderful country.* The pictures, mostly portraits, by native artists, exhibit all that painstaking realism which seems to be the one thing aimed at by native artists, but they are wanting in all those qualities that make a painting a picture. The school of art work exhibited in the Canadian and New Zealand Courts is poor, there being hardly a creditable piece of work in the whole of it.

Leaving pictures, and coming to photographs by a natural transition, we leave failure behind and have undeniable success. Photography seems to have found a congenial home in all our Colonies, and European photographers cannot show better work, especially in land-

* The two clever water-colours in this year's Academy attest this.

scape and out-door work, than even the younger of our colonies. It was natural this should be so, for having nothing but the camera to record matters of interest, they naturally sought to perfect their method, so as to make it yield the best results, and they have brought to bear upon the subject the same mechanical skill which is so strikingly exhibited in their agricultural and domestic machines. We in this country worked, on the contrary, from painting into photography, and the latter has not yet elbowed the former out of the field. We must take exception to those composite photographs exhibited by a Montreal firm, produced by sticking a number of separate photographs together, and painting in a background. This is not the sphere for photography but the province of the painter, and "The Skating Club at Montreal," with its hundreds of figures, and "The Tobogganing" picture, skilful as they are in one sense, are not pleasant possessions, we should imagine. We note a slight hardness and stiffness about some of the Colonial portrait photographs, which it is the aim of the best photographers here to avoid, and which it must be granted they do, but we say again that their out-door work is worthy the highest praise. Their climate, doubtless, helps them here.

We will next take a survey of the furniture exhibited, and in this department we are afraid we can find little for praise. Two Melbourne firms have fitted up rooms, and though, doubtless, the furniture is well made, the design of it would be considered here unworthy a second-rate house. There is a want of restraint and repose about all the Colonial furniture. They apparently do not understand the beauty of simplicity. The general lines are often faulty or had, and to this they add meaningless and uninteresting ornament, which is as bad as gilding a painted lily. The furniture is heavy and massive, and yet lacks dignity. Grace and refinement apparently are qualities they do not deem essential in furniture. Their furniture, compared with the best of ours made now, leaves the Colonial makers a generation distant, and it is a pity that the best firms pay so little attention to the important,—all-important,—matter of design. The inlaid furniture exhibited in the New Zealand Court is had.

But the worst features of Colonial furniture are to be seen in the pianoforte and harmonium cases in the Canadian Court. These instruments, with the souls of musicians (the tone of the harmoniums and organs struck us as particularly sweet and mellow) have the bodies of a very low type of animal indeed, and that is a pity, for such a defect could be easily remedied by getting designs for cases made out of the country. The spirit of the Colonists seems rather to be,—We do everything for ourselves

by ourselves. In some departments the Colonists are *facile principes*: there is, then, little merit in doing for yourself what can be done so much better by another. A harmonium with such a case as one we noticed, brown and shiny with varnish, and elaborately decorated with laid-on carving, common in character, could not be tolerated in a decently-furnished room.

It is evident that our Colonies have main practical requisites at hand for good furniture, viz., a countless variety of good woods and skilful and ingenious workmen. Graft on to this stock good design, and the result cannot but be satisfactory.

Scarcely any native-made china or pottery is exhibited, and what little there is, is of an ordinary description. A few ladies show what they can do in painted china.

Two Canadian firms exhibit some painted glass, both domestic and religious. A buffalo hunt, the subject of one panel, shows how impossible it is to overstep the limit the art imposes upon one without leading to the most disastrous results. If the Colonial work in stained glass is to be gauged by the examples exhibited (though not worse than some of our own firms produce), we trust that they are not filling their public buildings with it.

The Colonies come out strongly in silversmith's work, that is as far as quantity is concerned. Our own work in this department of industry is not of very high excellence, for the best sculptors find it too unremunerative to model and design for high-class metal work, and it needs a sculptor of very great excellence to produce work worthy to be compared to the best work of the fifteenth and sixteenth centuries, when silversmiths' work had a Cellini and a Holbein to design for it. Most silversmiths' work seems too pretentious, too ornate, too overlaid with cheap decoration to be good. The Queen Anne work which commands such high prices now is simple compared even to the work we produce, and simplicity is sadly absent in the Colonial silver-work. Tree ferns and palm trees in silver are about the highest flights the Colonials are capable of, and they occasionally introduce a figure or two (natives usually), and sometimes an ostrich or emu, whose eggs seem to be the nucleus of a good deal of the work exhibited. We must confess that among all the silver work exhibited not one single article arrested our attention by reason of its intrinsic worth, while much of it was, on the other hand, repellent. There are too many examples of misdirected energy, "of the industry without art," which Ruskin tells us is "brutality."

Colonials should take this opportunity of studying the Indian silver work. There is much they might learn from it.

There is a small collection of gold ornaments from the Gold Coast, which, rude as they are, have much more that is pleasant about them than the same class of British or Colonial work; for there is character and individuality in them, and a simplicity that is quite refreshing after silver tree ferns and palms. Our own jewellers might take an idea from it, for some of the brightly-coloured heetles' wings mounted in gold are quite as beautiful as gems.

Material prosperity, we have long since discovered, does not go hand in hand with culture and refinement. Good art can only be produced by a people who are keenly appreciative of the best, and it seems a pity that we English-speaking people should always have to wait until we have grown rich and luxurious, wait until material prosperity is at its zenith, before we think of making those things that environ us worthy of us as thinking beings with souls as well as bodies; for, during the interregnum, there is a mass of bad work produced which unfortunately long survives the occasion that gave it birth.

"A New Nail."—In regard to the new form of nail, which we noticed and gave a sketch of last week, we have received inquiries from one or two building firms as to where it is made or is to be had,—a matter on which we received no information.

THE NEW SORBONNE, PARIS.

HE old Sorbonne at Paris, which, we may remind our readers, was the ancient cradle of theological instruction, and whose dicta had once all the authority of an oracle, was founded in 1250 by Robert de Sorbon, Canon of Paris, whose name has thus been perpetuated in the building. At first it was only a humble college for sixteen students. But St. Louis took the modest establishment under his royal protection, and among the chairs of theology so numerous at that time, that of the Sorbonne was soon the most celebrated. Its great extension dates from 1629, the time at which he who was surnamed "the Great Cardinal" became its principal. At a later date the French Revolution caused the absorption by the State of the property of this rich university, with which a royal decree of May 16, 1821, endowed the municipality of Paris, with the charge to preserve in perpetuity this chief centre of the faculties of literature, science, and theology. Thus it happens that the Sorbonne is now a municipal building attached to the State service. The expenses of reconstruction and management are divided between the State and the municipality.

The style of the ancient edifice is not without grandeur, but now that there is an inclination, and a reasonable one, to give a more agreeable and inviting aspect to the exterior treatment of university buildings, the old walls of the Sorbonne appear, in the light of modern taste, very severe and gloomy in expression.

The buildings surround a great rectangular court, at one of the extremities of which rises the celebrated church which contains the marble tomb erected in 1694, by Girardon, over the burial-place of Richelieu, from the designs of Lebrun. Though deprived of much of its once rich decoration, the nave nevertheless preserves considerable vestiges of its ancient splendour, especially the paintings by Philippe de Champagne. The dome of the church is one of the best works of Lemercier, to whom is also attributed the old church "De la Visitation," now become a Calvinistic temple.

But we will not deal further with what was and what is no more, as we are concerned just now in speaking of what will be, and describing the disposition of the new buildings, the first stone of which was laid on the 3rd of August, 1885, and which is now in a tolerably advanced stage.

When the State and the Municipality decided to rebuild at their common cost the Sorbonne, which had become long since notoriously insufficient for its uses, the work was the subject of a very interesting competition in which twenty-eight architects took part, and in which M. Paul Nenot was the successful competitor. M. Nenot, a pupil of MM. Questel and Pascal, obtained the Grand Prix de Rome in 1877; and during his residence in Italy he also obtained the premium in the competition for the monument to Victor Emmanuel.* The fact of his being a foreigner did not permit the Italian Government to entrust him with the execution of the work, of which we spoke in our account of last year's Salon.

The Sorbonne comprises, as we have said, the Académie de Paris, the Faculties of Letters, Sciences, and Theology, the University Library, and the Victor Cousin Library. These different departments, though related to one another, were, according to the programme, to be arranged so as to be independent; so the architect had to take into consideration the various needs of each of these departments, and to foresee and provide for their possible future growth and extension without mutual interference. One result of these conditions is that the project has been amplified since the competition, and that instead of the space of 19,776 square metres given for the competition, the actual buildings are to cover a space of 23,000 metres, bounded on the east by the Rue St. Jacques, on the west by the Rues Sorbonne and Victor Cousin, on the south by

the Rue Cujas, and on the north by the Rue des Ecoles, facing which is the principal façade, of which we give in this number the elevation, copied from a photograph of the original drawing, which has been kindly furnished to us for the purpose by M. Nenot.

In the centre of the façade five large arches give access to the ground-floor main vestibule. Above are five windows divided by engaged columns, each supporting an allegorical statue. The wings, as will be seen, are crowned by circular pediments enclosing bas-reliefs, which symbolise Literature and Science. On each side of this main block is a wing of five stories treated in a very simple manner, and the architectural design of this portion is returned along the side façades, which extend to a length of 230 metres.

Internally, a great staircase of twenty-five steps leads to a second vestibule communicating by long corridors with the various departments. This vestibule will be, in some sort, a grand antechamber to the amphitheatre of the Academy, which will contain 3,000 persons. This apartment, intended for university ceremonies, and especially for annual distributions of prizes, will have six tribunes in two stages, and a semicircular parterre. Above this, on the principal floor, will be the "Salle du Conseil Académique," and above that again the "Salle des Archives."

If from the main vestibule we turn to the left towards the Rue St. Jacques, we find the "Amphithéâtres de l'Enseignement libre," the Salles des Compositions, and the examination rooms, to which access is gained direct by the entrances situated in the buildings at the return angle of that street. The buildings situated to the right of the main vestibule are similarly arranged. The offices of the Académie de Paris will be in this quarter, towards the Rue de la Sorbonne. The apartments of the Rector and the Secretary of the Académie, situated on the upper story, will have their own entrances in the angle pavilion.

The Amphithéâtre de l'Académie has a staircase giving access at once to the public tribunes, which will contain 1,100 persons, and to the Salle du Conseil Académique. This large room, with the two committee-rooms and the dining-room adjoining, will form, on the occasion of official receptions, a suite of richly-decorated rooms, in which more than 3,000 persons can be easily entertained.

The literary department and the library of the Sorbonne will have their access direct from the Rue de la Sorbonne. The library will occupy the place of the church, which will thus find itself secularised while still preserving its character as a historic monument. The scientific department, extending along the Rue St. Jacques, will have its distinct entrances from that street and from the Place de Sorbonne.

Independently of the Victor Cousin Library, the University Library has to be in direct communication with the "Ecole des Hautes Etudes" which, in the new plan, occupies a considerable place. It must also be conveniently reached from the studies and lecture-rooms of the Faculty of Literature, of which it is the indispensable complement. This latter department, besides examination-rooms, will include lecture-rooms and five public amphitheatres of seat-room varying from 200 to 1,000. Six amphitheatres are included in the department of the Faculty of Science, and the Faculty of Theology requires two. There are therefore in all no less than twenty amphitheatres in the building, capable of containing about 9,000 persons, without counting the examination-rooms, which are also open to the public.

The building will cost about twenty-two millions of francs, of which the Municipality pays eleven millions. The buildings are being carried on with great rapidity, and as soon as each department of the public service has taken possession of M. Nenot's building, the other portions of the old Sorbonne will be successively attacked in order to substitute the new buildings, so as to cause no serious or general interruption to the regular work of the schools.

* His design was illustrated in the *Builder* of July 1st, 1882.

The artistic decoration which it is intended to add to the new building claims a word. MM. Chartran, Benjamin Constant, and Flameng are, it appears, designated by the *Ministre de l'Instruction Publique* to execute the pictorial decoration of the reception-rooms and the Amphithéâtre de l'Académie. On its side, the Municipal Council has been called on to approve of a list of sculptors presented by M. Nenot, and who have been chosen from among the best representatives of the modern French school. Among the number are MM. Chapu, Mercier, Barrias, Dalou, Falguère, Luchet, Lanson, Crank, Marqueste, Hiolle, Albert Lefevre, &c. The sculptural decoration will comprehend, in the first instance, the two large pediments in the main façade, of which we have already spoken. Then there will be eight statues in the attic, over the columns, which will symbolise respectively, Physics, Chemistry, Natural History, Mathematics, Geography, History, Archaeology, and Philosophy. Internally, the main vestibule will be ornamented with two statues in stone personifying the Faculty of Letters and that of Sciences. Six other seated statues, placed in the large amphitheatre, will represent six eminent Frenchmen from among the ranks of science and literature. One other statue, on the great staircase, will personify the University of France; while in the vestibule of the Rector's department will stand the statue of "La Sorbonne" itself, executed in marble.

The foregoing rapid sketch will sufficiently indicate the practical and architectural importance of the building which is destined to change materially the physiognomy of the ancient "quartier des écoles." Some details may be open to criticism. In the principal façade, the mass of the first-floor story rather crushes the ground-floor design; a mistake in regard to balance of proportion which may be also charged against the new Opera House, and which the eighteenth-century architects have carefully avoided in the grand buildings of the Place de la Concorde. This does not, however, seriously detract from the merit of the selected design for the Sorbonne. The nineteenth century has no architectural style properly so called, and the majority of its monuments in France are borrowed from Renaissance or Neo-Greek. Without the pretension to be entirely original, M. Nenot has at least not reproduced in a servile manner any too common type; he has put the mark of his own originality on his work. Let us wait till the great mass of building forming the new Sorbonne has acquired the patine of age, and it will probably be regarded with respect as a building giving evidence of a masterly architectural talent in its plan and design.

NOTES.

THE memorial stone of the new Tower Bridge was laid on Monday afternoon by the Prince of Wales with due ceremony, and thus was formally commenced the work of bridging the Thames below London Bridge, a work which has long been needed, considering the increasing populations and myriad factories which line the river for miles below London Bridge. After long and wearisome discussions and inquiries, and not without some rivalry between the Corporation and the Metropolitan Board of Works as to which body should carry out the work, the Corporation a year or two ago obtained an Act empowering them to build a bridge across the Thames just eastward of the Tower. After much consideration of the needs of the wharfingers and owners having frontages between the site of the new bridge and London Bridge, a compromise has been arrived at by the decision of the Corporation to construct an opening bridge, on the bascule principle, so as to allow of the passage of shipping at certain times. The bridge, which will cost 750,000, is the joint design of Mr. Horace Jones, the City Architect, and Mr. J. Wolfe Barry, M.Inst.C.E. We will give some further particulars of the structure, with illustrations, in our next number, but must here congratulate Mr. Horace Jones, not only on his share in the

work, but on the narrow escape from injury which he experienced when making arrangements for the ceremony, as mentioned in the papers of Tuesday.

AT a special meeting of the Hellenic Society, to be held in the Rooms of the Society of Antiquaries, at Burlington House, on Friday next, at 4.30 p.m., the remains at Tiryns will form the subject of a discussion which is likely to excite a good deal of interest, as it will really be an exposition of the very opposite views of Mr. Penrose on one side, and Drs. Schliemann and Dörpfeld on the other. The two eminent German archaeologists are coming over to support their views. Mr. Penrose will open the discussion. It is very desirable that the questions which have been raised as to Dr. Schliemann's walls at Tiryns should be brought to some definite issue.

THE discoveries made early in February on the north side of the Acropolis caused naturally a great stir in the archaeological world, but hitherto, though we have had abundant writing on the subject, no illustrations have been publicly accessible. We are glad to find that the widespread desire for fuller details has prompted Dr. Kabbadias, General Director of the Antiquities at Athens, to publish the discoveries in full. He has embarked in an undertaking on a very large scale, and which should be of the greatest value both to artists and archaeologists, i.e., the publication of a work called "The Museums of Athens." The work is to consist of a number of heliotype plates by the well-known photographers the brothers Rhomaides; the descriptive text is to be entirely by Dr. Kabbadias, and is to be in modern Greek, French, German, and English; it is to appear in a succession of volumes, each volume is to have six numbers, and each number is to contain eight heliotypes. The subscriber binds himself only to take one complete volume. The first number contains an instalment of the recent discoveries. Though these recent discoveries and the sensation created by them have been the prime motive to the publication of the work, it will contain also every other piece of sculpture of importance to be found in the Athenian Museums. We hope that, as the volumes can be had separately, the published sculptures will be carefully classified under such heads as votive reliefs, sepulchral monuments. The work is to be published by Karl Wilberg, Athens. We hope shortly to notice the first issue.

THE present age seems to become more and more prolific in big undertakings, and in proportion as the opportunities for carrying them out at home are exhausted, engineers have to seek them in every quarter of the known world. Three fresh ones have been either commenced or proposed within the last few weeks, the fields of labour being respectively Switzerland, Greece, and the Canadian Confederation. The Swiss scheme is that of an Italian engineer, Signor Agudio, of Milan, for making a way through the Simplon, which he declares he can do by a tunnel of only 6,050 metres, the whole of the traction being done by hydraulic power. He considers that by this means from 3,000 to 4,000 tons of goods could be safely transported, without any breaking up or transshipment of trains, while the cost of the entire line would be only 28 millions of francs. The second undertaking is of a rather more practical nature, and consists of the drainage of Lake Copais, near Thebes, in Boeotia, by which an area of 100 square miles will be added to the territory of Greece. Of almost more importance than the acquired land will be the doing away of one of the greatest hot-beds of fever and malaria that is to be found in the whole country, while the rivers which at present feed the lake are to be employed for irrigation purposes. Greece will be more benefited by such works as these than by any amount of wars. The most ambitious of the proposals is one to connect Prince Edward's Island with the Canadian mainland by a submarine railway

tunnel, and thus allow the ice-bound inhabitants of the island to come out into the world for a bit during winter. The distance is but six miles and a half, and the bed of the Northumberland Straits, which is the scene of the operations, shows no great engineering difficulty, the depth of the water being 36 ft. on the Prince Edward's side, 10 ft. 6 in. on the New Brunswick side, and 80 ft. in the middle. The actual tunnel, which is 13 ft. in diameter, is to be made of chilled white cast iron (non-corrosive in sea-water), with the sections bolted together with inside flanges. The cost of the whole is estimated at a million sterling, a pretty handsome sum for the accommodation of the 125,000 persons who inhabit the island. The scheme has, however, been well considered, and will be brought before the Canadian Parliament very shortly. Indeed, by the articles of federation, Canada is bound to do everything that lies within the range of possibility to keep up an open communication with her island clients.

AT the meeting of the Gloucestershire Archaeological Society held on Thursday, the 17th inst., the Rev. G. Butterworth, M.A., Vicar of Deerhurst, Tewkesbury, read a paper on the newly-discovered Saxon Chapel which has been described in the last volume of the *Builder* (pp. 712, 819). The conclusion to which the author arrives is that the building is probably a chantry chapel erected by the powerful Earl Oddo in A.D. 1056, and also that it is not unlikely that its erection marks the donation of the Manor of Deerhurst to Westminster Abbey, or, if Leland's statement is to be accepted (which is doubtful), to Pershore Abbey. It is to be hoped that the Society will publish Mr. Butterworth's paper, as it will form a valuable pendant to an exhaustive essay which it is about to print on Deerhurst Parish Church, written some years ago by Mr. J. C. Buckler, which exists among the MSS. at the British Museum, and has never yet been published. The newly-discovered chapel has been already repaired to some considerable extent. In the nave all the modern windows have been filled up with masonry, and the original north entrance has been opened and repaired. The proportions of this entrance are curious, the opening being 8 ft. high, but only 2 ft. 8 in. in width. As the upper portion of the chancel walls is lost, the room which rests on the lower parts of these walls will remain.

THE Berlin Antiquarium has recently received an odd, and so far as we are aware, unique addition, in the shape of a bronze votive frog. There is no doubt about the creature's sacred purport, for on his back is inscribed in large and fairly well preserved letters, his dedication, "Ἄμων Σωνίου Βόδασου, Ἄμων, the Son of Sonios, to the Loud Cryer." This inscription has its special epigraphic value, because the letters are Corinthian of about the first half of the fifth century B.C. Corinthian inscriptions of this date are rare. The question naturally arises what god can be addressed as Ἄ Βόδασου, the Loud Cryer, and why does he receive this tribute of a votive frog? Dr. Fränkel, of the Berlin Museum, thinks the Loud Cryer is undoubtedly Apollo, the clear utterer of omens. There was a famous frog in ancient times, own brother to the Berlin one, consecrated by Cypselos of Corinth to the Delphic Apollo: even in Plutarch's days its connexion with the god was matter of dispute. We need not revive the "Sun frog" who, Mr. Andrew Lang somewhat confidently hopes, has "sunk for ever beneath the western waves." Rather we should be inclined to think that the frog was associated with Apollo for the same cause as the raven, because he was the typical croaker. His tongue, we know, was possessed of magic power; if torn out and laid on the heart of a sleeping woman it compelled her to answer truly to every question. Or was the frog a Totem animal, as perhaps the sacred Smithsonian mouse? We leave these matters to those they concern,—the mythologists. Anyhow we are sure that the epithet Βόδασου

was meant as complimentary. To be *βοήθη* *ἀγαθός*, good at a shout, was for the oracle good a very desirable qualification.

WE are glad to find that the Trustees of the British Museum have provided a convenient lecture-room near the gallery now occupied by the remains of the Tomb of Mausolus at Halicarnassus, discovered by the late Keeper of the Greek and Roman Antiquities in the British Museum, Prof. C. T. Newton. This lecture-room, although not yet finished, was used for the first time on Tuesday last, when Mr. J. A. P. MacBride delivered the fifth of his present course of lectures on sculpture. The lecturer dealt with the works of the Greek sculptors subsequent to Pheidias, principally speaking of those of Polykleitos, Lysippos, and Praxiteles. He referred to the great industry of one or two of these sculptors,—an industry which he said he could not but regard as in some degree fabulous or legendary. It was recorded of Lysippos alone that he produced 1,500 works, many of them groups, and nearly all containing figures not less than life-size. If so great a number of works was justly attributable to him, he must, the lecturer thought, have had a large number of assistants. Referring to the Hermes of Praxiteles, he said that although it was a very fine work, marvellously executed, the surfaces were too lumpy or knotty,—there was too ostentatious a display of anatomical knowledge on the part of the sculptor, and too much adiposity in the figure, while the child held in its arms, the infant Dionysos, was a mere doll. It was a curious point, Mr. MacBride said, that in the whole range of Greek sculpture, as it was known to us, there was scarcely one satisfactory representation of babyhood. The Venus of Milo, he thought, could not, when compared with the Hermes just referred to, be regarded as the work of Praxiteles, as some believe; it was altogether different. As an old artist, he had little hesitation in saying that the Venus of Milo was better than the best work of the ablest disciple of Pheidias, viz., Praxiteles, and was not unworthy of Pheidias himself. The lecturer criticised the Venus de Medici as having too small a head, and he commended Mr. Murray for exhibiting it without the arms, which had been very badly restored. The first part of the lecture was given in the new lecture-room, and the lecturer afterwards conducted his audience to the galleries, and recapitulated, in front of the various statues or casts referred to, the points which he wished to emphasise. Mr. MacBride is clear and painstaking as a lecturer, and enlists the close attention of his hearers. His concluding lecture of the present series will take place on Tuesday next.

WE certainly live in an age of constant and rapid change in matters of taste; the change is, of course, not always in the right direction, but, on the whole, a very real and substantial improvement is evident. This reflection is perhaps not very fresh, but it occurs again after a visit to Messrs. Collinson & Lock's new show-rooms in Oxford-street. When we reflect upon the age of ornolu, or upon the heavy Gothic style which succeeded it, when a stop-chamber was the symbol of artistic salvation, or even when we remember the cut brackets and rows of plump little balusters, that but yesterday, as it might be, were hailed as high art, our hearts are filled with gratitude for the delicate cinque-cento ornament and the light and luxuriously-comfortable furniture which our decorators and upholsterers, following the lead of our architects, now give us. Messrs. Collinson & Lock, without pretending to make it a speciality, seem to be particularly successful with this cinque-cento ornament. We saw nothing of the kind in their rooms that was not both well drawn and in good taste, whether in carving or in marqueterie or in their fibrous plaster. They also show a good deal of "fitted furniture," good both in design and execution, and which we hope may help to persuade the public to adopt it more generally. There is nothing like fitted furniture for increasing accommodation in small rooms, and

for preventing those unhealthy and untidy accumulations of dust which cannot be prevented from occurring on the tops of, and below and behind, heavy pieces of movable furniture.

A VOLUME of "Picturesque Sketches in Italy," by Mr. Daniel Brade, F.R.I.B.A., is to be published shortly by Mr. Batsford. It will contain 28 drawings, about half of them in illustration of Rome, and most of the rest of Venice. The specimen plate forwarded to us,—a view of St. Peter's,—photo-lithographed from a pen drawing, would have been better if the author had been more reticent of lines and shading; the effect is rather scrambling and obscured. That St. Peter's does not show its scale is perhaps the fault of St. Peter's.

IN last week's number of the *Church Times* occurs a critique on the Liverpool Cathedral designs, amusingly indicative of the attitude of the clerical mind towards church architecture. The result of the critic's reasoning is, of course, a foregone conclusion. Messrs. Bodley & Garner's design is the best one, because theirs is the closest imitation of English Mediaeval architecture. That is the argument, divested of verbiage. Mr. Emerson (whose name the critic cannot spell rightly) is, of course, dismissed with scorn for having suggested new ideas in a cathedral. However, the design, we are told, "has found favour with the critics of the building trade," which is apparently the *Church Times* view of the architectural journals.

WE learn that President Cleveland has accepted the honorary presidency of the American Exhibition to be held in London in 1887. To this news is added the curious announcement that the President "will perform the opening ceremony by telegraph from the White House." This is certainly a novelty in the application of the telegraph, and perhaps a hint of what the perfecting of telegraph and telephone may bring the world to in time. There will be no occasion to change one's geographical situation to take part officially in any ceremony. But it will be rather dull. Men like to see each other's faces after all.

ARCHITECTURE AT THE ROYAL ACADEMY.

CONCLUDING NOTICE.

TURNING to the more decorative portion of the drawings in the Architectural Room, we may take first those which come under the head of wall decoration, leaving stained glass and purely decorative work to be considered afterwards.

1,556, "Additions to Milton Hall, Cumberland," Mr. C. F. Ferguson. A small elevation of what looks like a bit of old wainscoting, or else it is coloured so as to give that idea, with a red marble fireplace inserted in the centre portion, and a delicate gilt wall-paper above. There is what is apparently a modelled plaster panel above the fireplace portion of the wainscot; what are the precise "additions" there is nothing to show.

1,565, "Design for Morning-room," Mr. Christopher Gill. A Renaissance design, with dark wood pilasters and broken cornice enclosing the fireplace and mantel, similar wood dado, and cabinet and door, the dark ground lined with lighter material in inlay, wall in panels of flowered paper with a gold ground, enclosed by a darkwood architrave. The frieze is apparently plaster, modelled in relief, of a low drab tone, connecting the gold of the walls with the white plaster cornice above. Harmonious, but rather suggesting a dining-room than morning-room: somewhat too strong and decided in effect for a morning-room.

1,581, "Design for a Frieze in Glass Mosaic," Mr. Jas. Ward. Nondescript birds (we have no objection to their being nondescript,—rather like them the better for it) with dark blue necks and light blue bodies, perched on coils of artificial branches, and divided, each pair, by a six-pointed star panel with lighter ground, containing a conventional flower with three open hosioms. Elegant in

design and rich and well-balanced in colour; a very pretty piece of work.

1,590, "Proposed Decoration of Ball-room, S. Chesterfield-gardens," Mr. Henry G. Liley. Very well executed drawing, but rather commonplace both in design and colour. Apparently a natural wood tint in the woodwork, which forms pilasters against the wall, the enriched caps of which are carried along as a string, leaving a kind of attic with consoles and panels over. The wall a light blue with a white foliage diaper. A cheerful-looking room it would make, which is one object in a hall-room, but it belongs only to the A B C order of design.

1,599, "Design for a Hall and Staircase," Mr. Lewis P. Grace. Perhaps this should hardly be classed with decorative design. It is really a coloured perspective of an interior, with nicely-designed and proportioned woodwork, and a large coved cornice divided by timber ribs into panels of dark blue, on which are devised gilded scrolls and tendrils and leaves, which are much too large, and reduce the scale of the whole. The treatment of this cove spoils the interior. The Turkey carpet on the floor is a silent rebuke to it.

1,666, "A Lady's Sanctum and Private Reception Room," Mr. W. F. Rawlady. Plan, elevations, and ceiling. A charmingly-planned little room with two recesses, screened off by columns, containing sofas and divans. The room is completely wainscoted, with heavy carved columns at intervals, rising from the surface line; the wood rather dark in tone, with a painted frieze of figures in which gold and rich browns predominate. The effect is somewhat sombre, but rich and reposeful, and to be noted as a variation from the conventional idea of a lady's boudoir, which is currently imagined to be a place of mere prettiness and light airy tints. The ceiling, panelled, with gold in the panels, is rather heavy, but not out of keeping with the room, perhaps. It would take a woman of a certain dignity of presence to properly occupy such a room, to be in harmony with the surroundings. If it is an executed work for a client, perhaps this has been considered.

1,721, "The Drawing-room at 29, Chesham-place," Mr. G. Aitchison, A.R.A. A symphony in blue-green and gold, with an architectural *cadre* of white touched with gold, round the alcove in the centre. The upper part of the alcove is gilt, plain gilt; below, a blue-green wall, with a white-flowered frieze, and a dado of a darker and more decidedly blue tone. The adjoining walls are a more delicate shade of the green, over which gilt sprigs wander. The darker colours of the dado are repeated in the cornice. So far, this is a delicate scheme, interesting because fugitive and somewhat evasive in regard to colour, tempting the eye to pause and consider; but why this violent intrusion of mahogany polished doors (are they not?) with plate-glass panels in them? They do not seem to belong to it; they have no right there; or were they perhaps rather there already in possession, and had to be made ashamed by the delicacy of their surroundings? Anyway, it is an odd combination. The ceiling above (1,722) is pretty, divided into three panels by white soffits, illustrated with flower-sprigs and gilt lines, the panels having foliage and small figures on a gold ground, with a darker strip to separate the gold and white. It goes well with the wall-design; but then—good heavens! those doors again.

1,728 and 1,732, "Decoration of Ceiling and Auditorium, Theatre Royal, Lyceum," Messrs. Campbell & Smith. Theatre decoration seems always to upset the *morale* of the decorator. Something licentious seems to be expected in such a case. The design in this case is a good reproduction of a certain type of Italian Renaissance ornament; panels with pictures spotted about, and the interspaces filled in with Cupids and ribbons and thin festoons wound about. We do not call this really design. The general effect is "festive," which is probably what was wanted.

1,740, "Decoration of a Room," Mr. Henry G. Liley. A symphony in browns, drabs, and blue. Very neat drawing; no thought or fancy either in colour or design.

Among stained glass and other decorative design we find,—

No. 1,554, "Design for Memorial Window, Hyde Church, Kent"; Messrs. Heaton, Butler, & Bayne. A small drawing showing good figure-drawing and colour, but not giving the character of stained glass; the left-hand com-

partment in particular is a regular picture, with a long vista of perspective, and distant figures. 1,563 and 1,573, "Windows on North and South Sides of St. Botolph's Church, Aldersgate"; Messrs. Ward & Hughes. Low segmental arched windows, representing scenes from New Testament history and parable, in what may be called decorative paintings, sufficiently on one plane, with decorative borders enclosing them. No lead lines are shown, except in the borders; so that we are left to suppose that they may be enamel painting on glass, and not stained-glass proper. The style of design better suits this idea. The groups have a good deal of spirit and expression, and are perhaps the right sort of thing for a church where they may appeal to the uneducated eye; from our point of view, they are rather too pictorial for windows; they would do better as wall-paintings.

1,584, "Design for Window over Font, St. Vedast, Foster-lane," Messrs. Heaton, Butler, & Bayne. A design, with a frame of Renaissance architecture to suit the style of the church, and a group within it of Christ inviting little children, in the well-known sentence. The general effect of the design is decorative, as that of a stained-glass window should be; but there seems an odd sort of effort to steer halfway between realism and conventionalism, in the half naturalistic treatment of the tree and the grass and flowers; and then there is the distant background and coast-line. This is only doing badly what a painting could do much better. If people would only find out what stained glass is really fitted to do best, and stick to it, they would be more likely to produce work worth general admiration; but too many stained-glass designers seem to have an immortal wish to make the best of both worlds; they know they must conventionalise to some extent in such a material, and then they compound with the popular mind by getting in as much realism as they can manage.

1,614, "St. Nicholas, Cole Abbey," Mr. G. H. Birch. A decorative scheme for part of the church, with dark red columns and apparently stained windows between, with a generally rich effect, but hang too high to make out anything of the details.

1,633, "Design for an Eight-light Stained Window, illustrating the Creation and the Deluge," Mr. W. F. Dixon. One could have formed a better idea of the decorative effect if the tracery had been drawn out and coloured, instead of being left blank spaces. The drawing is, in the lower part, a series of small figure pictures in water-colour, of considerable merit, and promising a good general colour effect. In the upper or tracery portion of the window the small lights are occupied with emblematic figures, rays of light, &c. The author seems to have borrowed from Mr. Burne Jones the notion of angel figures holding circles with emblems of the days of Creation.

1,681, "Design for an Advertisement Placard of the Guardian Fire and Life Assurance Company," Mr. E. J. Poynter. A richly-coloured Ionic Greek shrine, with a blue-robed figure of Minerva standing in the centre, is surrounded by imitation columns (gilded) and a wood architecture, of the type and proportions derived from ancient vase painting. The lettering is given in irregular writing, according to antique custom, part of it appearing as cut on the marble pedestal of the Minerva, and part as executed in mosaic on the side pedestals. This kind of imitation of materials and processes does not seem to us a correct principle in decorative design. The effect of the whole is gay and brilliant, but not very harmonious.

1,717, "Sketch Design for Domestic Window in Grisaille and Colour," Mr. Lewis F. Day. Now this is a real stained-glass design. Side panels filled with conventional figures running into foliage, all treated in the broad manner suitable to the material; low tones are used here; the centre panel is "a note in red," apparently representing demons dancing. Without caring particularly for demons, we commend the design to notice as a piece of pure stained-glass effect. We may say the same of No. 1,718, by the same hand, a sketch design for a clearstory window in mosaic. This is a capital bit of purely decorative design—a centre with scroll foliage in two tones of blue, with greens intermixed; a lighter-toned border of more severely conventional type enclosing it. These are real windows, not paintings applied to window decoration.

1,719, "Design for Stained Glass Window,"

Mr. J. G. Bromilow. A small one-light window of the Flight into Egypt, very good in tone, and more decidedly stained glass in style than a good many others. It is hardly necessary, however, to emphasise the fact that glass is led in by carrying the lead lines so defiantly across and in opposition to the architectural lines of the canopy.

1,723, "Design for a Window," Mr. H. W. Lonsdale. This, again, is a piece of real stained-glass design; no realism of any kind. White-robed figures are intertwined among scrolls, apparently in the "Adoration of the Lamb." The central shrine with the Lamb is much too naïve for our taste; but the general effect is unquestionably good.

1,724, "Pomona: Design for Stained Glass," Mr. G. Parly. A Classical stained-glass window is not very common, and in this the figure is a pretty one, and some of the border-work very pretty and gem-like, but the perspective of the architectural entablature mars the effect. Stained glass should look flat; it is ridiculous to put in a perspective entablature which must obviously be out of the window at one side or the other.

1,725, "Design for Memorial Window to Lady F. Chaplin," Mr. Ion Pace. A little one-light drawing, with a portrait figure, and a small scene underneath, which looks like the stoning of Stephen, though it is difficult to see the connexion of that with the object of the window. A good stained-glass style, perhaps rather over-emphatic in colour.

1,727, "Design for Aisle Window in St. James' Church, Yarmouth (Isle of Wight)," Mr. Charles Hardgrave. Excellent as a piece of stained-glass effect. A two-light (wide) window, with central figures of David in one light and Isaiah in the other, with jewelled backgrounds; the rest of the window filled in with architectural canopy-work and angels, with small pictorial subjects underneath. The mild old man who does duty for the fiery Isaiah is intellectually ridiculous, but then one does not expect stained-glass artists to rise to the intellectual conception of a character; if they rise to the proper style of putting a figure on stained-glass at all, that is wherefore to be thankful. Stained-glass figures are usually dummies, and these are no exceptions, but the decorative effect of the whole is very good.

1,733, "Design for Large Screen in Wrought and Chiselled Iron: subject, 'Peace,'" Mr. John J. Shaw. A fine bold piece of Renaissance design, apparently partially inspired by the work of the author's namesake, the Shaw of the Hampton Court ironwork; figures, interspersed with hold acanthus foliage. We wish the designer, however, had kept purely to this conventional type of foliage, instead of mixing apples and festoons and other haulies with it.

1,734, "Design for Stained Glass, Upper Standon Church, Beds," Messrs. Shrigley & Hunt: very pretty, and true stained-glass work. Faith, Hope, and Charity, in a three-light window; no absurdities of background or landscape, the figures in fine, freely-treated draperies, with darker drapery backgrounds, over which angels with wings crossing fill up the space. We do not quite like the marked horizontal line formed by the top of the draperies behind the figures; but in general it is a good and artistic window.

1,737, "A Toilet Set; Hand Mirror, Trinket Tray, and Casket," Mr. W. G. B. Lewis. The casket is the best part of the work, the open tracery panels very well designed; the grilidons or lions which form the feet are too light and flimsy in character for the style of the rest. The trinket-basket stands on a hillock of realistic rockwork, which we dislike exceedingly.

1,741, "Design for East Window of St. Edmund's Church, Lombard-street," Mr. C. Hardgrave. Rather strong in colour, but showing a true perception of what stained-glass is for; the design being a crowd of angelic figures and rays of light, &c., entirely ideal and conventional. The subject appears to be the adoration of the saints and elders, from the book of Revelations. We do not like the smoke from the censers; it looks like so many halloons in process of inflation. But in the main the window is a fine bold idea, in the right direction.

1,741, "Design for a Reredos," Mr. P. H. Newman. In the centre, St. Michael as a celestial housemaid, sweeping up Satan; on each side angels kneeling to see that she does her work properly; and behind, cherubs' heads on a counterpane. A remarkable little work.

1,747, "Design for Five-Light Window," Mr.

E. T. Taylor. Illustrating the passage, "Verily I say unto you, inasmuch as ye did it unto one of the least of these," &c. A very good subject for a window, recalling Flaxman's series entitled "Acts of Mercy." The groups of figures are well designed, and the whole character of the window decorative and suited to stained glass, as far as design is concerned; but the colouring seems rather dull and muddy, and this effect is, perhaps, increased by the employment of gold for the dividing mullions. In execution the window might look clear enough in colour, but the drawing does not convey the idea of stained glass.

Among drawings which are illustrative only, and which we have omitted to notice, may be named, "Old Church of St. Nicholas, Boulogne-sur-Mer" (1,589), a good, clear water-colour drawing, a little dull in tone, by Mr. R. J. Cornwall Jones; "Farnese Palace" (1,618), by Mr. E. P. Anson, a drawing of one of the interior courtyards; "San Michele, Pavia" (1,678), a view of the east end, by Mr. E. G. Hardy, and (1,715), the north and south transepts, by the same hand. The collection also includes Mr. G. H. Birch's original water-colour elevation for "Old London," an interesting record of a work which has excited much public admiration, and which was, we believe, prepared on very short notice by a *tour de force* in the hurrying of midnight oil.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

The concluding ordinary meeting of this Institute for the present session was held on Monday evening, Mr. Edward P. Anson, F.G.S., President, in the chair. There was a very large attendance including Sir Frederick Loughton, P.R.A., Mr. Charles Garnier (Recipient of the Royal Gold Medal), M. Paul Sédille (Vice-President of the Société Centrale des Architectes, Paris), and Mr. Richard M. Hunt, of the United States (Hon. and Corresponding Member).

Obituary.

Mr. William H. White (Secretary) announced the decease of Mr. Edward Hughes, of Huddersfield, FELLOW.

Books: The Late Mr. Fergusson.

Mr. White.—I have also to announce a long list of donations from members of various societies, and from others, and I have to formally inform the Institute of the bequest made by the late Mr. James Fergusson. The terms of the will are as follow:—"I bequeath to the Royal Institute of British Architects such works as they may select from among the architectural books in my library, not being duplicates of those already possessed by them." (The books, 140 in number, were exhibited on a table.)

Mr. Hansard (chairman of the Library Committee) drew attention to the fact that this bequest had been made under somewhat peculiar circumstances. Mr. Papworth and he, with the assistance of the Librarian, had gone through every book in Mr. Fergusson's library, choosing those which the Institute did not possess.

Mr. Charles Barry, F.S.A., wished to know whether it was the intention of the Council, and specially of the Library Committee, to record the name of the donor upon these valuable gifts? It was most desirable that this should be done, not only as a recognition of the value of the gift itself, but as an encouragement to those who were able, like Mr. Fergusson, to be more or less generous to the Library.

Mr. Hansard replied that a special book-plate would be designed and planted in each book. The Council had also decided to have a new book-case to contain these and other works which the Library might receive.

The President.—We can hardly exist as a useful institution without occasional donations of this sort. We have recorded this evening the gift of a singularly valuable addition, and I presume it will be your pleasure that we pass a vote of thanks to the executors of the late Mr. Fergusson, and the other donors of the works which the Secretary has announced.

The vote was passed by acclamation. Mr. J. Maevicar Anderson.—Sir, it will be gratifying to the meeting, I am sure, to be informed of the appreciation with which the late Mr. Fergusson's memory is held in other

lands besides our own. I therefore crave your permission to read a letter we have received from the American Institute of Architects:—

"At an adjourned meeting of the Board of Trustees of the American Institute of Architects, held at its office in the Welles Building, 18, Broadway, New York, on the 21st of May, 1886, the following report was received and unanimously adopted.

(Signed) A. J. BLOOR,
Trustee and Secretary, *pro tem.*

'To the Board of Trustees of the American Institute of Architects.

Gentlemen,—Your committee nominated to prepare resolutions expressive of the loss sustained by the profession and the Institute in the death of their late Honorary Member, James Fergusson, the eminent and learned historian of architecture, would respectfully submit the following:—

The Board of Trustees of the American Institute of Architects in recording the decease of a late honorary member of the Institute, Mr. James Fergusson, F.R.S., M.R.A.S., F.R.I.B.A., &c., &c., desire to express their high estimate of his eminently valuable and productive labours in the field of historical architectural criticism, and of his profound and extended researches into the origin and development of architectural styles. His grand work on East Indian architecture stands unique, and will always be a mine of wealth for future investigators. His "History of Architecture," developed from his previously issued Handbook, forms the highest authority on the subject for English-speaking architectural students and connoisseurs, while these and his many other architectural writings, published during an active career of authorship of forty years, all attest the depth of his scholarship and his earnest devotion to the cause of good architecture—a devotion which those who were fortunate enough to bring into contact with the man found to be as sincere as it was enthusiastic. Much of the modern catholic and sympathetic appreciation of the benefits peculiar to each style, owing to his teaching, and the influence of his work is felt in all directions by the present generation of architects.

A most notable fact in connection with Mr. Fergusson's long and highly honourable career is that he was an educated to architecture, either as a practitioner or an amateur, but to mercantile pursuits, and that he voluntarily gave up fine prospects in this direction for the sake of devoting himself to the disinterested study of architecture, and to the literary elaboration of the history of its form. The profession, while deeply mourning his loss, should feel grateful that he was yet spared to an advanced age, while retaining in its behalf, and in that of the cultured public, the full vigour and active use of his faculties to the end.

Resolved that the above be forwarded to the American Architect, and also to the Royal Institute of British Architects in London, for such publication as the latter may think proper.

(Signed)
A. J. Bloor, } Committee,
P. L. Le Brun, }

Welles Building, 18, Broadway, New York,
May 21st, 1886."

Distinguished Visitors.

Mr. Anderson continued,—Sir, it is our custom at these meetings to introduce formally to you, as President of the Institute, any members who attend for the first time since their election. We are honoured to-night by the presence of a distinguished *confère* from France, who, in the course of this evening's proceedings, will receive at our hands such honours as it is our happiness to ask him to accept. And we have amongst us a gentleman who happily unites in his own person the land of his education, *La belle France*, with the land of his achievements, America: I refer to Mr. Richard M. Hunt. Mr. Hunt's works are well known to most of you. He entered the Ecole des Beaux-Arts in Paris as a student, and on his return he was offered the position of one of the Government Architects. This he declined, and he has since prosecuted a very extensive practice in the United States. It would ill become me to refer in his presence to his many large and notable works; I will only express the gratification it is to us, and I think it must be to himself, to have bestowed upon him the rank of an Hon. Corresponding member of the Royal Institute of British Architects.

Mr. Hunt (who met with a very cordial reception on his admission by the President) said:—Mr. Chairman and gentlemen, I have to thank you for the honour you have done me. All such honours, I know, are accompanied with corresponding obligations, and it will be my sincere endeavour and duty to perform them so that I may carry out the trust to your satisfaction. I did not expect to be called upon this evening, and was rather taken aback as I came into the room; but, at the same time, if you will allow me, I would express my sincere thanks for the universal kindness that has been shown by all my fellow colleagues and brother architects both in England and on the Continent. I must also express the sincere thanks of the whole confraternity in the United States for the expressions of regret and sympathy that have been made by this Institute on learning of the death of Mr. Richardson, which has been an immense loss to our country.

Mr. G. J. Martin (Government Architect of Bengal) was also admitted by the President.

Mr. R. Phené Spiers then read the following letter he had received from Mr. Henry Irving with regard to the late Mr. Richardson:—

"Lyceum Theatre.
Dear Sir,—It was with very deep regret that I heard of the death of poor Richardson. My acquaintance with him was necessarily limited, as our only opportunities of meeting were during my brief stay in Boston, but from the moment we met I am glad to say that we fell as friends. I hear no most pleasant remembrance so afternoon which I spent with him in his delightful house at Brookline. I was much struck with his great energy and goodness of purpose. A few such men in a generation mould the artistic destinies of a country, and it seemed to me that he grasped in the hollow of his strong hand two series of facts widely distant,—those concerning the needs, and those concerning the possibilities, of a marvellously growing land. He has built monuments of his power in his church at Boston, in Back Bay, which struck me with renewed admiration every time I saw it; in those beautiful arches of the State House at Albany; in his building at Cambridge; and in those colossal works for Pittsburg, on the Allegheny, for which he was engaged when I visited him. But more even than these things was his work for the nation in the school which he was founding, by gathering round his own studio the young men of bright promise, whom I saw, and whose ability was being moulded to his endeavour by his enthusiasm. I most sincerely hope that this work will not lapse by his untimely death, but that it will be continued,—for, to my mind, its prosperity would be a national good. Need I say that my deepest sympathy is with Mrs. Richardson and their family in their affliction, as is that of each and all of their friends?—Believe me, dear sir, yours very faithfully,
HENRY IRVING.
R. Phené Spiers, Esq."

Presentation of the Royal Gold Medal to
M. Chas. Garnier, of Paris.

The President then said,—

Gentlemen,—We are met together this evening to perform an agreeable duty, the most important part of which is to present the Royal Gold Medal for Architecture, the gift of Her Most Gracious Majesty the Queen, to the chosen recipient for the year, M. Charles Garnier, whom we have the great satisfaction of seeing amongst us (applause).

Most, if not all, of the gentlemen I have now the honour to address are acquainted with the Opera House of Paris. Still it may not, on this occasion, be uninteresting to recall that grand work to our minds. None of our theatres at all approach it in magnitude or magnificence, for it has a

Superficial area of (37,317	Mètres.	Cube
English feet)	11,337 ...	—
And cubical contents of ...	—	428,660

Whilst the comparative area and cubical contents of the Opera Houses of Vienna, St. Petersburg, and Berlin are as follow:—

	Mètres.	Cube
	Mètres.	Mètres.
Opera House of Vienna ...	8,567 ...	222,777
" St. Petersburg ...	4,500 ...	114,288
" Berlin	1,891 ...	35,000

The number of seats the French Opera House contains is 2,156; the width of the façade is 70 mètres (230 English feet); the greatest width of building, 124 mètres (408 ft.); its height above the ground level equals 56 mètres (184 ft.); and from the foundation to the summit it attains the great height of 81 mètres 60 centimètres (266 ft.). I might give further particulars, such as the size of the magnificent staircase, of the *anté-foyer* and the *foyer*; of the splendour of decoration in marble and mosaics, in painting, in sculpture, in bronze; but my object is simply to call your attention to the real importance of this truly magnificent work, which, since its completion, has been accepted as the model for all similar monuments erected in Europe. There are others which, no doubt, vie with and even surpass it in costliness of material, such as the St. Isaac's Church at St. Petersburg, the Medici Chapel at Florence, but there are none which in my recollection combine so much artistic work with such costliness of material.

No less than fifteen eminent painters, fifty-six eminent sculptors, besides nineteen sculptors of ornament, were engaged on the external and internal decorations.

The construction of this great work occupied thirteen years, which, considering that the Bourse of Paris, a very much smaller building, occupied nineteen years, is but a short period for such a work. M. Garnier gave his entire and unremitting attention to it, and aided by several zealous assistants, produced the prodigious number of more than 30,000 drawings (applause).

Gentlemen, it is M. Garnier's rare fortune to have been the architect of one of the grandest and most original buildings of our time, under circumstances which (having reference to the

very rare occasions when our Government subsidises or undertakes works of public utility, but when all that with us emanates from private enterprise) do not occur in England. It has also been his good fortune to live and practise in a country,—in that great city which is aptly called the modern Athens, where art in all its branches is keenly appreciated by the public, and, moreover, is substantially acknowledged by the State,—where the national appreciation of operatic performances is evinced by the noble theatre which the liberality of his fellow countrymen has enabled him to erect.

There is also a reason for emphasising our welcome of M. Garnier. He comes to us in a high representative character, and perhaps on this account, gentlemen, I may be permitted to express your pleasure as well as my own at seeing here this evening Sir Frederick Leighton, P.R.A., our illustrious chief of the arts in this country. M. Garnier is not only a great architect, but this year, in France, he is the chief of the arts of painting, sculpture, architecture, engraving, and musical composition,—the President of one of the five academies which compose the Institut National de France. He represents and illustrates, in a practical as well as a moral capacity, an academic system older and more extended than our own, and he has profited by a method of education peculiar to the French people and eminently national,—a method, to say the least, which is more careful in its character and aims than is our own. A pupil in the atelier of Hippolyte Lebas, who was an Hon. Corr. Member of our body in 1835, M. Garnier was received as a student of the Ecole des Beaux-Arts in 1842, and he obtained, at the early age of twenty-three, the *Grand Prix de Rome* for Architecture. Thereby he earned the right to be received for four or even five years at the Académie de France at Rome, as the Government student. During that period he was enabled to visit the principal cities of Italy, and to make a prolonged stay in Greece. His studies of ancient buildings and of their remains were duly sent to Paris and approved. In 1852 his admirable restoration, consisting of fourteen drawings, of the Temple of Jupiter Panhellenius at Egina, was finished, and it has since been published, at the cost of the French Government, in the great work entitled "Restaurations des Monuments Antiques par les Architectes Pensionnaires de l'Académie de France à Rome depuis 1788 jusqu'à nos Jours," and still in progress. Though he returned a short time afterwards to France, it was not until 1861, at the age of thirty-six, that he commenced the labours of his more mature professional life. Elected in 1874 one of the eight architect-academics pertaining to the Académie des Beaux-Arts, he has been just called to the presidency, it being this year the turn of the Section d'Architecture to preside over those of Painting, Sculpture, Engraving, and Musical Composition.

M. Garnier, Sir, having reference to your past career, to the fact that you obtained in your early years the "Grand Prix" for Architecture, that you have since distinguished yourself in Greece, Rome, and other parts of Italy, and that the great work of the Opera House at Paris was the honourable result of a double competition with other distinguished architects practising in your artistic city, and that you moreover fill the position of President of the Académie des Beaux-Arts: this Institute, having these facts before it, came to the conclusion that we could not more appropriately show our appreciation of your distinguished career, and of the great work you have carried out, than by recommending our Sovereign to confer this Medal upon you; and I am sure it must be gratifying to you to know that, in this honour, your name will be henceforth associated with the names of those of your countrymen who have been recipients of the Medal: with Jacques Ignace Hittorf, in 1855; Jean Baptiste Lesnart, in 1861; Eugène Emmanuel Viollet-le-Duc, in 1864; Charles Texier, in 1867; Joseph Louis Duc, in 1876; and the Marquis de Vogüé, in 1879,—all but the last-named being now deceased.

Sir, it remains for me to say, in placing this medal in your hand, that it affords us the greatest pleasure to welcome you here on so interesting an occasion as the present, and I esteem it a great privilege that, in virtue of my official position as President, I am permitted to present to you this medal, which, on the recommendation of this Institute, our most gracious

Sovereign, of her royal bounty, allows us annually to offer to some distinguished architect or man of science, of any country, who by his labours has tended to promote or facilitate the knowledge of architecture or the various branches of science connected therewith (applause).

And now, gentlemen, for myself, if I may still trespass a little longer on your attention, I will add that I have, from my youthful days, been a warm admirer of modern French architecture, particularly that of Paris, of which I have naturally seen most, and my study and appreciation of which has, I think, sensibly and beneficially influenced many of my own works. I have, moreover, very personal reasons which invest France with a sentimental interest for me; the best part of my early education was received at the Collège Henri IV. at Paris, and I have enjoyed, in that interesting land, the recreation of my middle life, visiting its provincial cities, studying its grand cathedrals and municipal buildings of the Middle Ages. It affords me, therefore, exceptional pleasure to welcome our *confères* here this evening, not only on account of his honorable and dignified position as a distinguished artist, but also as a citizen of a country the genius of whose architects we admire, and with whom we sincerely wish to live on terms of brotherly friendship and mutual esteem, reciprocally communicating the particulars of our labours, and the results of our studies.

Before I sit down I ought to tell you that in the course of the day I have received a telegram from M. Bailly, President of the Société Centrale des Architectes, in Paris. Unfortunately, Thales does not bring it with me, but it was to this effect,—that M. Bailly regretted extremely that he was himself unable to be present on this very interesting occasion, but that representing him, M. Paul Scéville, whom we have the pleasure of seeing, and who is Vice-President of the Société Centrale, would be here this evening amongst us. M. Bailly also said that all the members of the Société Centrale most heartily congratulated their *confères*, M. Garnier, on having been made the recipient of so honourable a distinction as that of the Gold Medal for architecture conferred by the Queen of England; and they wished him all joy and happiness in receiving that medal.

The President, having invested M. Garnier with the Gold Medal, amidst loud cheers,

Monsieur Charles Garnier, our oriser, to thank the Institute for its award, was greeted with renewed applause, said:—Monsieur le Président, Messieurs, et chers Collègues,—Mes émotions sont bien trop grandes pour me permettre de répondre dignement au discours si élogieux de notre honorable Président. Les paroles sympathiques que le Président a prononcées et la bienveillance qui m'a été témoignée par tous mes *confères* me mettent presque dans l'impossibilité d'exprimer dans des termes assez dignes toute la sympathie qui a été éveillée dans mon esprit et toute la valeur que j'attache à la médaille d'or de sa Majesté la Reine dont ils m'ont honoré. Ainsi, si je ne dis pas toute la gratitude que je sens, c'est seulement parce qu'il y a des choses qui sont bien plus faciles à sentir au fond du cœur que d'exprimer par des paroles. Cependant, chers collègues, je vous prie de croire que ma gratitude est, comme j'espère, à la hauteur et de votre bienveillance et de la valeur de la grande médaille d'or que le Président vient de me décerner. Cette médaille se rattache au nom de la Reine Victoria ainsi qu'à l'Institut Royal des Architectes Britanniques, est un honneur, au dessus de tout autre, le plus admirable et le plus enviable des distinctions. Personne ne conteste sa valeur, personne ne peut se méprendre sur sa signification. Pour ma part, je festine et je dois l'estimer, au dessus de tous les compléments qui m'ont été accordés. Elle n'est pas seulement un simple expression de bienveillance, mais elle vient d'un corps indépendant, qui n'a pas de parti pris et qui cherche celui qui a le plus de mérite, et qui paraît le plus digne. Les architectes ne sont pas comme les hommes politiques. Ils n'ont ni des portefeuilles à conserver ni des électeurs à considérer,—ils n'ont à écouter que leur conscience, et lorsqu'ils ont fait choix d'un de leur collègues pour un honneur, celui-ci a le droit d'être fier du choix. Laissez-moi, donc, mes chers collègues, être fier d'avoir été désigné par vous,—laissez-moi croire que votre décision a atteint le but que vous vous proposiez. Mais ce n'est pas moi seulement que votre résolution ataigne, elle s'étend plus haut et plus loin. Vous avez voulu choisir encore un architecte Français,—

sans doute pour honorer la France ainsi bien que son architecture,—mais sans considérer les exigences politiques et sans agir autrement que dans les intérêts de l'art, que vous avez voulu soutenir de votre grande autorité. C'est ainsi que votre résolution a été comprise par l'Institut de France et par la Société Centrale des Architectes et qu'il est considéré dans mon pays extrêmement important de gagner ce prix. Voici pourquoi votre médaille d'or est tant respectée, tant désirée. Il me semble que l'appréciation que votre médaille commande à l'étranger doit vous être agréable, et doit donner à elle-même valeur toute particulière. N'est-ce pas la grandeur de l'âme du donateur qui donne une valeur supérieure à ce qu'il offre? Je ne saurais donner jamais une trop grande place dans mon estime à la distinction que vous m'avez conférée, car le plus il me paraît précieux le plus il marque mon respect pour le corps qui me l'a décerné. Cependant ce sont les faits même qui parlent. Les applaudissements qui ont été accordés en France à votre décision sont bien certainement l'expression de la gratitude des architectes de la France faite aux architectes Anglais. C'est dans une fraternité cordiale (applause), et lorsque je vous offre l'expression de ma gratitude je remplis également une mission de la part de mes compatriotes.

Mais il y a deux autres raisons, celles-ci spéciales, qui me font apprécier d'une manière particulière l'honneur que vous m'avez accordé. Il y a bien long-temps lorsque je fus de retour de Rome, après mon séjour comme étudiant du Villa Medici, et, comme il arrivait souvent à ce temps-là, je revint pauvre, sans ouvrage et presque sans espoir d'en avoir bientôt. J'étais par conséquent dans l'embarras. En attendant, sa Majesté la Reine Victoria est venue rendre visite à Paris. Un grand bal fut donné en son honneur à l'Hôtel de Ville, et le Prêfet visitait tous les salons. Vouant offrir à sa Majesté un souvenir de cette soirée, M. le Prêfet désirait faire un grand album contenant des vues de tous les salons, les galeries, et les salles du bâtiment. Je fus recommandé, et puisque alors je n'avais pas trop mal les aquarelles j'ai reçu la commission de faire deux de ces vues. Vous pouvez vous figurer combien j'étais enchanté de cette honne chance qui me rapportait le premier argent que j'avais gagné depuis mon retour. Je n'ai jamais oublié cette circonstance. Je considérais (sans l'autorité de sa Majesté, bien entendu) la Reine de votre pays comme mon premier client, ou du moins la cause de ma première clientèle. Il me paraît alors que c'est, en quelque sorte, à sa Majesté que je dois le succès que j'ai pu obtenir depuis dans notre profession.

Plus tard, en 1867 j'ai reçu inopinément une lettre, signée par feu Mr. le Professeur Donaldson, conçue en ces termes:—« Les membres de l'Institut Royal des Architectes Britanniques se sont honorés en vous nommant membre correspondant, » &c. Cette manière de conférer l'honneur me paraissait bien courtoise, et la formule me semblait bien digne d'être retenue en mémoire. Je fis non moins charmé que surpris que l'on ait pu penser à moi dans un pays étranger. Depuis ce temps-là j'ai été nommé membre de beaucoup d'autres académies, mais, sans vouloir mépriser la valeur de ces nouveaux titres, c'est toujours le premier honneur,—celui que votre Institut m'a conféré, qui m'est resté le plus cher et le plus précieux. Ainsi, le premier argent que je gagnais et mes premiers honneurs viennent de vous. On dirait quelque chose que vous vous êtes chargés de moi, et que, une fois la voie ouverte, vous vouliez me conduire jusqu'au bout. À tout ceci je dois ajouter la réception cordiale d'aujourd'hui, où vous m'avez traité pas seulement comme un *confère*, mais comme un ami. Ceci me va droit au cœur (applause).

Je ne sais pas si ma carrière d'architecte devait terminer ou s'il me serait donné de me livrer encore une fois à mon art, mais si, après les bâtiments que j'ai construits, j'avais à construire un autre, il me semble que je serais d'autant plus encouragé de faire de mon mieux, que j'aurais à me montrer encore plus digne de l'honneur que vous m'avez accordé, et à agrandir mes idées, afin que la médaille d'or de sa Majesté la Reine Victoria ne perde rien de l'estimation et rattachante, en tombant dans des mains défallantes.

Mes chers *confères*, je vous prie de pardonner ce discours, un peu long peut-être, pour vous qui l'ont entendu, mais trop court pour me laisser exprimer toutes mes reconnaissances.

Monsieur Garnier resumed his seat amidst loud and continued applause.

Sir Frederick Leighton, F.R.A., then rose, and said,—I fear, Mr. Chairman, it may seem presumptuous, or even almost impertinent in an individual to whom, in your excellent address, you alluded incidentally, but in too indulgent terms, to rise to speak, however briefly, on the occasion of a ceremony, of which I am only one of very many spectators, and on the subject of the award of a medal, in determining which I had neither part nor share. But I have been given to understand, sir, that it was your wish, and your wish here is my command, and I do it. Well, sir, I stand here in the position of one who owes a double allegiance; I owe allegiance, first, to you as the respected President of a society of which I am a member; I owe allegiance also to the famous architect, on whom all eyes are turned this evening, and who, as you have been reminded, is at this time President of that section of the Institute of France of which it is my great pride to be an Associate. And, indeed, I rejoice to have this opportunity of expressing my loyal respect to one who will fill a position so conspicuous. Well, then, sir, since you have permitted me to express an opinion on the subject before you to-night, I will venture to say that this Institute has done well in recommending her Majesty the Queen to confer this special distinction upon the highly-gifted architect of the Grand Opera House of Paris. It is not for me here to rehearse his many claims to this distinction, in respect of his works, for this has been done, and exhaustively done, by your President. He has himself, with native grace and eloquence, expressed his sense of the honour which has been conferred on him by his comrades beyond the sea, and you, I venture to say, have added a worthy name to the long and distinguished muster-roll of this Institute (applause). But there is in this award more, I think, than a tribute of respect to a considerable personality, and this, sir, you foreshadowed in the closing passages of your address; and it was also referred to in the eloquent words of M. Garnier himself. For, it seems to me, you have wished to express that deep debt under which all the world of art is laid by the genius of the great people to which M. Garnier belongs (applause). That debt is, I think, patent over the whole field of art, but nowhere, perhaps, more specially manifest than in the field of architecture. If you consider the inexhaustible profusion, the endless variety, with which the builder's art has adorned the sunny broadths of that favoured land, whether you turn to their civil architecture or to their ecclesiastical architecture; whether you consider that phase of art which, in the South and in the West of France reveals to us a Latin severity and sobriety linked with a Celtic fire; or whether, further in the North, you observe that anperb evolution of the French spirit which during three centuries lighted up Medieval Europe; whether you consider the ornate stateliness and elegance of the *châteaux* of the Loire, or the regal splendour of the buildings of the *Grande Siècle*, you will feel how vast is the fund of wealth which has been poured into the common treasury of this singularly brilliant people (applause). Gentleman, I am able to say that no one in this room can join with a deeper conviction of this, and with more grateful impulse, in the honour which you have paid to French art, in the person of one of its foremost representatives. In conclusion, Sir F. Leighton turned to M. Garnier, and addressed him as follows:—Et vous, cher collègue, et très honoré Président, souffrez que je joigne mes félicitations personnelles et bien chateleuses aux paroles officielles que vient de prononcer le Président, au sujet d'un honneur qui rejallit sur ceux qui le décernent aussi bien que sur vous qui le recevez (loud applause).

Provincial Visitors.

Mr. Macviver Anderson.—It is somewhat galling to have to come down from these agreeable proceedings to the everyday humdrum of ordinary business, but we have a certain amount of work to get through to-night, and I must ask your attention to it. Before proceeding to the ballot, I should like the meeting to know that the individual members present at this meeting are of a highly representative character. It is our wish, and we are endeavour-

ing now, so far as we possibly can, to unite the members of our profession throughout the country by a system of federation. We have a scheme in contemplation, which will be duly submitted to you; but my object now is simply to intimate that we have the honour and pleasure of receiving here to-night the following gentlemen, as representatives of several professional societies:—Mr. Thomas Worthington, as representing the Manchester Society of Architects; Mr. G. Washington Browne, as representing the Edinburgh Architectural Association; Mr. James Sellars, as representing the Glasgow Institute of Architects; Mr. G. G. Hoskins, as representing the Northern Architectural Association; Mr. G. E. Grayson, as representing the Liverpool Architectural Society; Mr. J. Wreghitt Connon, as representing the Leeds and Yorkshire Architectural Society; Mr. J. B. Everard, as representing the Leicester and Leicestershire Society of Architects; Mr. A. Nelson Bromley, representing the Nottingham Architectural Association; Mr. F. B. Osborn, representing the Birmingham Architectural Association; and Mr. J. A. Gotch, President of the Architectural Association of London. These gentlemen have not yet attained to the distinguished eminence of M. Garnier, but they are all men who are distinguished in their own neighbourhoods and spheres, and it is with very great pleasure we welcome them here to-night.

Election of New Members.

On the motion of Mr. Charles Barry, seconded by Mr. Penrose, M.A., the following gentlemen were elected Hon. and Corresponding Members of the Institute, viz., Herr Julius Carl Raschdorf, architect, Professor of Architecture at the Royal Technical High School of Berlin; and M. Paul Sédille, Architect, Vice-President of the Société Centrale des Architectes, Paris.

M. Paul Sédille, who was applauded on rising, then addressed the meeting in French. He said:—

Je regrette vivement, Messieurs, de ne pas pouvoir exprimer en Anglais ce que je sens de ce moment-ci. Heureusement, beaucoup d'entre vos membres comprennent le Français et ainsi je puis peut-être me permettre de vous parler Français comme aux Français. Je ne sais pas, Messieurs, si, appelé comme de snis, à représenter la Société Centrale des Architectes, cette société n'aura pas pu être représenté auprès de l'Institut Royal par un membre plus digne que moi, mais je snis certain qu'elle n'aura jamais de représentant animé d'un plus grand désir de voir avancer mon art dans l'Angleterre. (Applause.)

Six Fellows, twenty-two Associates, and three Honorary Associates were also declared to be duly elected.

Other Medals and Prizes.

The President then presented the various prizes to the students and others who had won them.

The Tithe Prize of 30l. and a certificate was awarded to Mr. Benjamin Priestley Sibers. The subject was a School of Medicine and Surgery, and there were six competitors. In the same competition Mr. Alexander Nisbet Paterson, M.A., of Glasgow, was awarded a Medal of Merit; and Mr. Everard William Leeson, of Oldham, a Certificate of Honour.

The Grissell Gold Medal and Ten Guineas, a prize which has not been awarded for three years, was gained by Mr. Alfred Arthur Cox, Associate, the subject being the central hall of a market of iron construction.

For **The Soane Medallion** (with 50l. to be afterwards paid under the usual conditions) there were sixteen competitors. The medallion was won by Mr. Arthur Needham Wilson, of Snarebrook, Essex. The President, in presenting this prize, said that the drawings were very meritorious and picturesque, but Sir John Soane could never have dreamed that his Medallion would have produced a style so decidedly different from what he himself practised. Still, had he been alive he would doubtless have greatly rejoiced to see what strides had taken place in the knowledge of Medieval architecture since his time. [In the same competition a Medal of Merit and ten guineas were awarded to Mr. John Henry Curry, Associate, of Sutton, Surrey; a Medal of Merit to Mr. William Henry Bidlake, M.A. (Pugin Student, 1885); and a Certificate of Honour to Mr. Robert Weir Schultz.]

The **Institute Medal** and Ten Guineas, for measured drawings, elicited seven sets of drawings from the same number of competitors. Awarded to Mr. Edmund Harold Sedding.

The Institute Medal and Five Guineas were won by Mr. Arnold Bidlake Mitchell (Soane Medallist, 1885); a Medal of Merit being awarded to Mr. Eustace Lauriston Conder, of Parliament-street; and a Certificate of Honour to Mr. Sidney Howard Barsley, of Bromley, Kent.

The Institute Medal and Twenty-five Guineas for the best Essay on "Pediments and Gables," were awarded to Mr. Paul Waterhouse, a Medal of Merit being given to Mr. William Thomas Oldrieve, of Edinburgh (Holder of the Godwin Barsary, 1886). Ten essays altogether were sent in, three of them being specially good.

The President then declared the session adjourned until the first Monday of November, and the proceedings terminated.

Illustrations.

"THE PEOPLE'S PALACE" FOR EAST LONDON.

WE give a view and plan of this important building, the foundation-stone of which is to be laid by the Prince of Wales on Monday next. The site consists of about five acres, and has been bought for 22,000l. from the Drapers' Company. The design for the building has been prepared by Mr. E. R. Robson, F.S.A., F.R.I.B.A., and when erected, the "Palace" will form a notable addition to the buildings of the East End and, indeed, of London at large. It may be mentioned, *en passant*, that the design exhibited by Mr. Robson amongst the architectural drawings in the present Academy exhibition, and of which we spoke a few weeks ago (see p. 772, *ante*), is not the one that is intended to be carried out; it was given up as too costly. The main outline of the building about to be commenced, and which will stand some 50 ft. back from the Mile End-road, partakes, as will be seen by our illustration, somewhat of an Oriental character, though the details are Renaissance in feeling. The building externally will be of stock brick with red edgings, Portland stone of the best description being used for columns, arches, pediments, &c. The chief features towards the main thoroughfare will be the semicircular portico; the two minarets, capped with gilded cupolas; and the dome. The latter will cover a large rotunda, which will constitute the entrance-hall of the Palace. Arrangements will be made for heating this covered space in the winter, and it is intended to serve as a playground for children in the day time throughout the year, while in the evening it is to serve as a sort of common-room in which those who choose may sit and chat and smoke their pipes. Opening from the rear of this large circular vestibule will be "The Queen's Hall," which will be about the size of St. James's Hall, Piccadilly. This will be the central feature of the scheme, and the "foundation-stone" about to be laid will form part of one of its walls. This hall will be used for several purposes, such as concerts, band performances, and assemblies; it will also be used as a large club-room, in which people may meet for talk and refreshment. Beyond "The Queen's Hall" will be a library and reading-room, while to the right of it will be a series of workshops and lecture-rooms, constituting a technical school for instruction in various handicrafts, somewhat on the principle of those established by Mr. Quintin Hogg at the old Polytechnic Institution, but with the additional advantages afforded by the fact that at "The People's Palace" the lecture-rooms and workshops will be specially planned and constructed to serve their purpose, and will be provided with the most suitable fittings, appliances, and plant. To the left of "The Queen's Hall" will be the cookery schools, a restaurant, and a hall somewhat smaller than Prince's Hall, Piccadilly; this smaller hall, it is suggested, may serve, among other purposes, for an art school. The inner end of the great hall ("The Queen's Hall") is to open into a large winter garden, — a great space which is to be covered in with glass, and adorned with flower-beds and sub-tropical trees and plants, arrangements being made for keeping it at the necessary temperature. On the left of the main building, and detached

from it, will be warm and cold swimming-baths, and well-appointed gymnasiums for men and women. The plan also provides commodious rooms for cycling and cricket clubs, &c., trade associations, and small social gatherings of various kinds. Meanwhile, of the five acres of ground purchased by the Beaumont Trustees, enough (3½ acres) will remain uncovered to permit of some 5,000 persons disporting themselves at the same time. The amount required to carry out the scheme (including the cost of site) is 100,000l., of which £75,000 has now been subscribed or promised. The Drapers' Company has given 20,000l. We shall watch with much interest the development of the scheme, in furtherance of which Sir Edmund Currie, Lord Rosebery, Mr. Brownlow, and the East and West India Docks Company have rendered valuable aid.

It should be observed that the plan here given, though representing in the main what will be carried out, is still to be regarded as "under revision," and is not the final and completed form.

THE NEW SORBONNE, PARIS.

WE give an elevation of the principal façade, forming one end of this great block of building, concerning which further particulars will be found in a separate article.

We regret that the elevation has been sent to us from Paris without any scale, a deficiency which, of course, we are unable to supply.

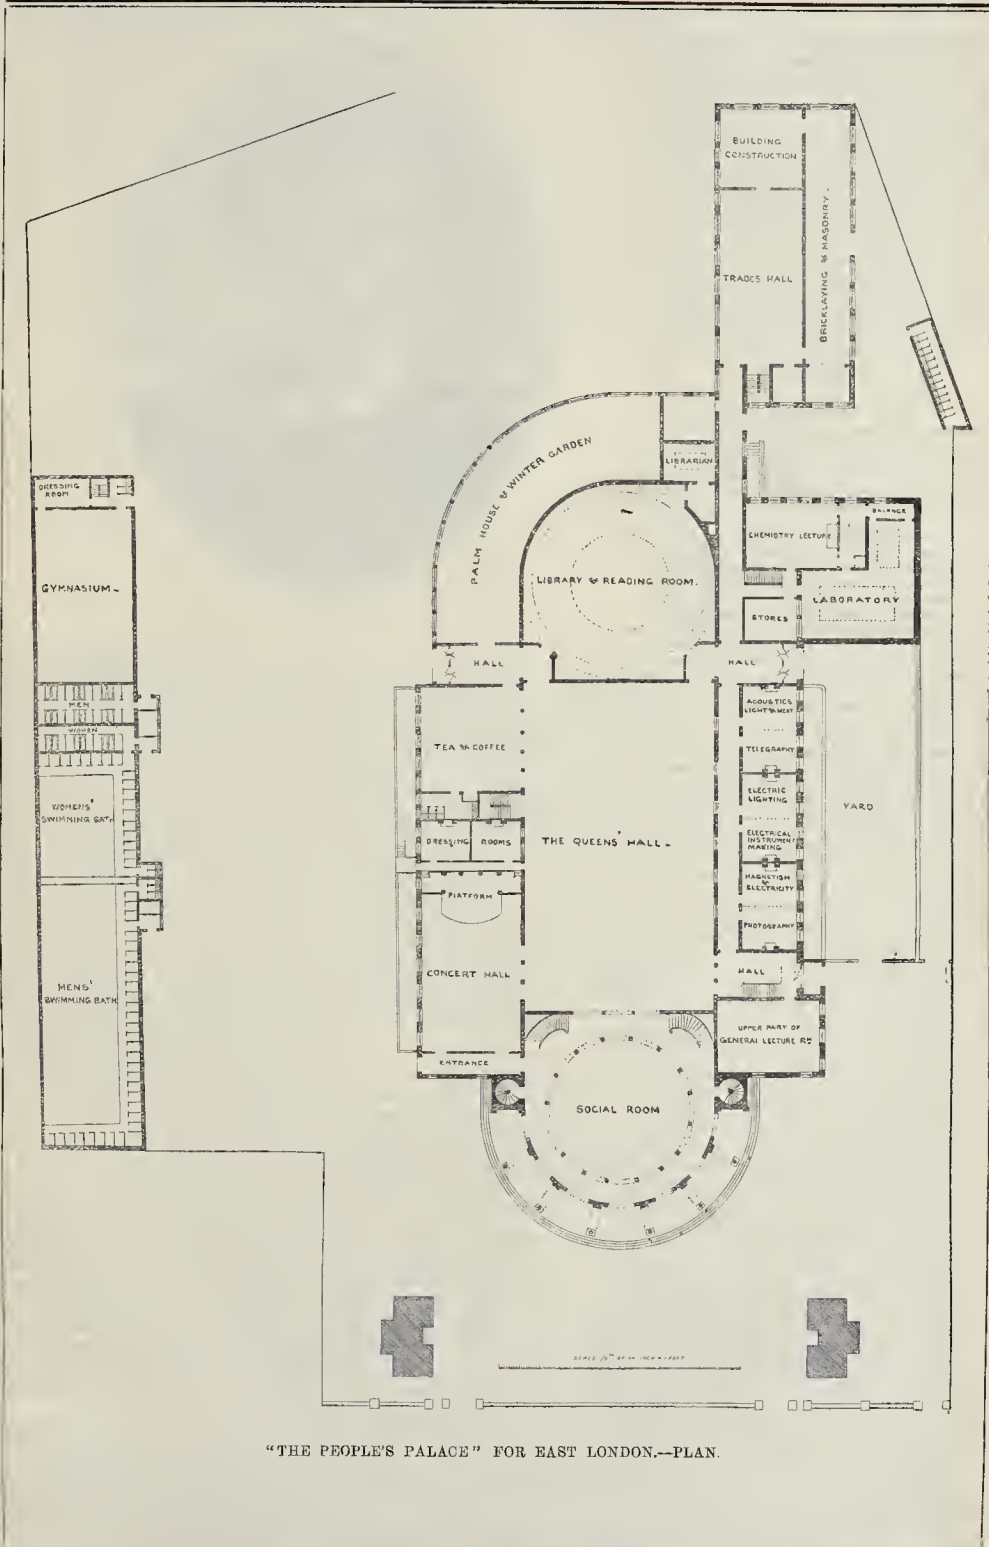

THE RATH-HAUS, LIMBURG-ON-THE-LAHN, AND THE THREE CROWNS INN, WURZBURG.

THE two sketches which we publish are examples of the picturesque style of German domestic architecture which came into use at the close of the sixteenth century, and which forms the link between the old Gothic style and the more "correct" revised Classical. This kind of architecture has suffered more than any other by modern "improvements" and in a few years scarcely an example of it will have escaped; this is to be greatly regretted, because it not only delights the artist with its quaintness and picturesque quality, but really offers valuable hints to the architect; the little how-window, for instance, of the Three Crowns Inn, though exceedingly plain, has a remarkably original appearance; the treatment of the corbel which supports it is very uncommon; it is as plain as it could possibly be, and yet has a remarkably good effect, and would be a very pleasing feature to introduce in a country house. The house next to the Three Crowns is a baker's shop, and shows an arrangement which, we think, is peculiar to this part of Germany. The stall is an erection which very much resembles a stone altar, over which projects a kind of wooden canopy, or hood, covered with slate; the resemblance to an altar is all the more remarkable on grand festival days, when these stone stalls are covered with a white cloth, and adorned with a pair of candles and a crucifix. One never enters the shop to purchase the bread, but it is exposed for sale upon the slab; we have no doubt that this custom is one of very considerable antiquity, but is now being given up, as are all the links which bind the Germany of the present to that of the "Middle Ages." The little church shown in the same view is called the Hofspital Kirche. It is a poor example of the very latest Gothic, with a Corinthian portico added in later times; it contains nothing remarkable except a curious piece of sculpture in wood, representing the patron saints of Franconia, executed by Tilman Riemenschneider about the year 1500.

The Rath-haus at Limburg is a very quaint and irregular structure, the earliest portion of which dates from about the middle of the sixteenth century, and it is not the least picturesque of the old buildings in that curious town. H. W. B.

SYNAGOGUE, RUE DE LA VICTOIRE, PARIS.

THIS is an interior view of the large Synagogue, designed by M. Aldrophe, which was visited the week before last by the Congress of French Architects, and which was described at some length in our article on the Congress last week (See p. 877, *ante*).

"THE PEOPLE'S PALACE" FOR EAST LONDON.—PLAN.

SUNDERLAND MUNICIPAL BUILDINGS.

We give this week an elevation and section of the design by Mr. Brightwen Binyon, which received the first premium in the recent competition, together with plans of two of the floors to a small scale.

The Town Council have appointed Mr. Binyon architect for the building, and commissioned him to proceed with it. The variations from the design as first drawn will be very slight, which is not always the case in competitions.

Some remarks on this and others of the competing designs appeared in an article in the *Builder* of May 29th.

We may observe that the return elevation of the shorter side of the building (which is at the angle of two streets) is so nearly the same design returned, only somewhat shortened, that we have thought it better to give the one elevation on a pretty large scale than to give the front and side on a smaller scale.

THE ANTIQUITIES OF PARIS.

THE second annual report of the Society of Friends of Parisian Monuments,* in addition to a summary of the work of the Society during the past year, contains several interesting notes contributed by various members on Parisian antiquities, and is further enriched by some remarkably good engravings. M. Charles Sellier contributes an essay on the Hôtel Salé, otherwise called the Hôtel de Juigné, recently used as the Central School of Arts and Manufactures, of which we gave a short account last year (vol. xlviii., p. 161). This fine old mansion, which is situate in Rue Thorigny, is offered to be let or sold, and it is impossible to predict what may be its ultimate fate. It contains a very handsome staircase, which is illustrated in the report by a plan and elevation. The house occupies a portion of the farm of the Hospital St. Gervais, which belonged to the Convent of St. Anastasia, who sold it in 1656 to Auhert de Fontenay, a rich farmer of Constaun, who built the present mansion. As Fontenay's large fortune was chiefly derived from a duty on salt, the populace nicknamed his mansion the Hôtel Salé, a name which it retains to this day. Fontenay sold the mansion to Jean le Camus, secretary to the king, who was Governor of Auvergne, and occupied the post of civil lieutenant of the Châtelet from 1670 till his death in 1710. After his death the mansion in the Rue Thorigny remained in his family, it being marked in Turgot's plan of 1739 under the name of the family, and the Royal Almanack for 1746 mentions it as the residence of M. Nicolas le Camus, first president of the Court of Assistants.

The hôtel was for some years the residence of the Venetian ambassador, and afterwards of Marshal de Villeroi, the tutor of Louis XV.; in 1763 it is called, on Deharme's plan, Hôtel Chameville, and eventually, having passed into the hands of the Juigné family, it became the residence of one of the members of this family, who became Archbishop of Paris in 1781, about the same time that another member acquired the mansion formerly belonging to the Duc de Mazarin on the Quai Malaquais.

Monsieur Leclerc de Juigné, who was a member of the States General, had his carriage riddled with stones by the populace, because he had advised the king to resist the Revolution by force. He was compelled to emigrate, and the Hôtel Salé became the property of the nation. During the Convention the house was used as a temporary store for books which had been saved from the libraries in the neighbourhood, and was finally sold to a private person for four million francs (160,000*l.*), paid chiefly in assignats. It is now the property of M. Ronssille, the nephew of the last purchaser, who let it during the Restoration for university purposes. In 1829 the Central School of Arts, &c., was established and remained here until its removal to the new buildings in the Quartier des Arts et Métiers. The Hôtel would be admirably suited for a museum, a school, or a library, and it is to be hoped that some means may be found for adapting it to one of these purposes.

Attention is drawn to another interesting mansion, the Hôtel de Rassus, Rue Visconti, which is threatened by the proposed continua-

* Bulletin de la Société des Amis des Monuments Parisiens. Année 1885, Numéro 2.

M. Charles Garnier.

tion of Rue de Rennes. It was here that Racine and Adrienne Lecouvreur died, and Mdlles. Clairon and Champmeslé lived. It is believed that Racine wrote his tragedy of "Athalie" in a part of the building now occupied by M. Mario Proth, and Voltaire carried to the portico the dead body of Adrienne Lecouvreur.

The Report gives a list of mansions worthy of note with a view to their classification and preservation. Among them may be named the Hôtel la Vienville, Rue Saint Paul No. 2, brick and stone front, painted beams,—rooms next the Quai des Célestins, have ornamented ceilings; Rue des Lions-Saint-Paul, No. 13, has-relief on staircase, painted ceiling in boudoir; Hôtel Lambert, the Saint Louis, paintings by Lebrun, Lesueur, &c.; Hôtel de Pimodan or de Lauzun, the Saint-Louis, handsome rooms; Hôtel Scipion-Sardini, Rue du Fer-à-Moulin, internal court, terra-cotta bas-relief; Hôtel Colbert, late Rue des Rats, remarkable seventeenth-century work; Rue Saint-André des Arts, Renaissance fronts; Hôtel Fieubet (École Massillon), Quai des Célestins.

M. CHARLES GARNIER, THE INSTITUTE ROYAL GOLD MEDALLIST, 1886.

JEAN LOUIS CHARLES GARNIER, of whom we give a portrait,* and on whom the Royal Gold Medal of the Institute of British Architects was conferred on Monday last amid much enthusiasm, was born on the 6th of November, 1825, and is, therefore, 60 years old, though his appearance conveys the idea of his being a much younger man.

In spite of his decidedly southern-looking physique, the eminent architect is a Parisian *pur sang*. He showed, when very young, remarkable artistic talent, and entered, in 1842, the École des Beaux-Arts, where he studied successively in the ateliers of Lével and Hippolyte Lébaut. In 1848 his design for a "Conservatoire des Arts et Métiers" gained him the Prix de Rome, and the young architect turned to account his sojourn of some years at Rome to send successively his very remarkable studies on the Forum of Trajan, the Temple of Vesta, the Temple of Jupiter Serapis at Pozzuolano, and the polychromatic restoration of the Temple of Jupiter Panhellenus.

M. Garnier passed almost the whole of the year 1853 in the kingdom of Naples and Sicily, in the preparation of a work on the restoration of

the Angevine tombs and monuments there. This work, commissioned by the Duc de Luynes, has, unfortunately, never been published. In 1857 he obtained a "Médaille de Troisième Classe" at the *Salon*, and, after some years passed in unostentatious work in the service of the Municipal Administration, during which he took part in the restoration of the Tour St. Jacques la Boucherie, he appeared as a competitor, in 1861, in the competition for the rebuilding of the Opera House.

The design of M. Garnier was unanimously adopted by the jury, and its author became at once a celebrity. Thanks to the encouragement given by the Imperial Government, and the liberal sums placed at his disposal, he was able to secure the assistance of the most illustrious artists, and to employ the richest materials in which to realise his creation.

After having, at the *Salon* of 1863, obtained a "Médaille de Première Classe," he received the following year the Cross of the Legion of Honour. In 1861 he had already been named Honorary and Corresponding Member of the Royal Institute of British Architects, and sixteen other foreign academies count him among their members. In 1874 he was elected Member of the Académie des Beaux-Arts, as successor to M. Victor Baltard.

In 1875 took place the inauguration of the new Opera House, on January 5th, on which occasion its architect was promoted to be an officer of the Legion of Honour.

Since that day, which was the crowning of the work to which he had devoted his whole care and thoughts for fourteen years, the eminent architect has directed the construction of the Nice Theatre and edited the monograph of the Opera House. He is now occupying much of his leisure time in defending, at the head of the "Société des Amis des Monuments Parisiens," the remains of old Paris against the attacks of official demolishers, and in giving his active assistance to the different artistic undertakings of the State and the Municipality of Paris. Since the funeral of Victor Hugo, he has been commissioned by the Government to build the catafalque of the great poet, under the Arc de l'Étoile.

It may be added that M. Garnier is not only an artist of great ability, but a learned and clever writer, with a style full of humour, and his facile and original pen has been often engaged in critical reviews. His "Étude sur la Construction théâtrale," published in 1871, is a didactic work of the first order, and as such has obtained a legitimate success in the world of art, both in his own and in other countries.

ATION.

THE PHOTOGRAPH BY A. C. DE MARTINS LANE, CARBON ST., LONDON, E.C.

INTERIOR OF SYNAGOGUE, RUE DE LA VICTOIRE, PARIS.—M. ALDROPHE, ARCHITECT.

North Street Postern, York.

Old Ouse Bridge, York. Taken down in 1809.

Hayman, Hogarth's friend, and Van Nost, the sculptor, Reynolds merely added a fresh artistic tradition to the house in St. Martin's-lane, where he first made his London reputation, and the studio at the back of which had been tenanted by Ronbillac, the sculptor. J. T. Smith, the antiquary,—"Rainy Day" Smith,—who remembered all the artistic life of the last century has, in his amusing "Life of Nollekens," related many of the facts associated with this classic little corner, where, he tells us, Ronbillac executed his statue of Handel. Upon Ronbillac leaving this studio "it was fitted up as a drawing academy, supported by a subscription raised by numerous artists, Mr. Michael Moser being unanimously chosen as their keeper." This is Moser the sculptor, and, it will be remembered, in after years one of the foundation members of the Royal Academy. From an article written by Hogarth about 1760, and published in Ireland's "Hogarth," we learn the share he took in the formation of this drawing-school:—

"Sir James [Thornhill] dying, I became possessed, in 1734, of his neglected apparatus, and, thinking that an academy, if conducted on moderate principles, would be useful, I proposed that a number of artists should enter into a subscription for the hire of a place large enough to admit of thirty or forty persons (drawing after the naked figure). This proposition having been agreed to, a room was taken in St. Martin's-lane (Peter's-court). I sent to the Society the furniture that had belonged to Sir James's academy; and attributing the failure of the pretious academies to the leading members having assumed a superiority which their fellow-students could not brook, I proposed that every member should contribute an equal sum towards the support of the establishment, and have an equal right to vote on every question relative to its affairs. By these regulations the Academy has now existed nearly thirty years, and is, for every useful purpose, equal to that in France or any other country."

Till the foundation by the regularly constituted Royal Academy of its free schools, the little "Academy" in St. Martin's-lane prospered amidst all the bickerings in which the artists indulged in the middle of the last century respecting the formation of an adequate "Academy of the Fine Arts." How the Dilettanti Society generously offered to take upon themselves the organisation of such a body, even purchasing a site in Cavendish-square and supplying the Portland stone; how they were thrown over; how Newton,—in later years the first Secretary of the Royal Academy, but in 1753 Keeper of the "Academy of Painting, Sculpture, &c.," St. Martin's-lane," endeavoured to evolve his conception of an academy; how the Duke of Richmond's private gallery of casts was generously thrown open; how the then newly-formed Society of Arts came to the rescue and opened in 1760 at their new home the first genuine exhibition of English pictures; how further squabbles led to the split which produced the Spring-gardens exhibition,—its catalogue illustrated by Hogarth's caustic pencil; how the Society of Artists enlisted the services of Dr. Johnson; how the St. Martin's-lane Academy after thirty years of active services in Peter's-court at length moved to Pall Mall (where over the door, at least, the school was dubbed the "Royal Academy"); how the Incorporated Society of Artists continued their painful quarrels; how eventually, thanks to Sir William Chambers, who had been tutor of architecture to Prince George, the interest of royalty was extended to the young body of artists who were soon to form the legitimate Royal Academy; how Reynolds was elected their first President, and George III. in 1768 signed the famous "Instrument" which defines the constitution and government of the authorities now at Burlington House; how the newly-formed Academy founded its schools at their first home in Pall Mall, where Sir Joshua delivered the earliest of his famous discourses; how the Academicians were eventually moved into Somerset House, where the bead of Michelangelo over the old entrance still keeps alive the memory of the artists' sojourn in the land of red tape and circumlocution; how the Academy moved to Trafalgar-square, and eventually to their familiar home in Piccadilly; all this, which would demand much space to relate, can be found, by those interested in a little pleasant research, in the pages of Sandby's "History of the Royal Academy," where a small woodcut of "the Old Academy in Peter's-court, St. Martin's-lane," will soon remain all that will serve to recall a spot intimately connected with the story of the arts in England.*

* Though in the present changes Peter's-court (which opens out of St. Martin's-lane) will not itself disappear, the Mission House at its furthest end has already been demolished, all that remains being the doorway, which is now boarded up.

In that story St. Martin's-lane has played no small share. From the outset of its existence in the seventeenth century as an acknowledged thoroughfare, it would seem to have been the residence of more than one personage eminent in art. Konolm Digby, the intimate friend of Vanduyck; Daniel Mytens, the brilliant court painter; and that charmingly English and genuinely artistic poet, Sir John Sackling, are all known to have resided in St. Martin's-lane. To the names of Ronbillac, Sir James Thornhill, Van Nost, Hayman, and Reynolds, artistic residents in the lane, must be added that of Fuseli, while Slaughter's Coffee House, till it disappeared within the memory of many still among us, may be said to have been the Caffè Greco of London, the general meeting-ground of the London artists of the last and the beginning of the present century. Well, indeed, might "Rainy Day" Smith,—who in his "Life of Nollekens" has left a short sketch of St. Martin's-lane,—remark, "St. Martin's-lane affords so rich a mine for anecdote, that I never pass through it without receiving a ray of recollection from almost every window." As next-door neighbour to "Slaughter," lived John Beard the singer, one of the privileged and historic few belonging to the "boards," who may be said, if not to have entered, at least to have skirted the charmed circle of "society" by his marriage with Lady Harriet Powis, daughter of the Earl of Waldegrave. In Beard's parlour (when it passed to his son-in-law, Rich, of Covent Garden Theatre fame) would gather in the congenial atmosphere of tobacco and its "allied comforts," Ronbillac, J. T. Smith's father, Rich and Quin and Woodward the comedians, and George Lambert the scene-painter, and founder of that Sublime Society of Beef Steaks, which has since his day earned for itself a world-wide reputation.

Architecturally, too, St. Martin's-lane commends itself, for here lived Payne, who, among other works, designed Salisbury-street, in the Strand, and the original Lyceum Theatre; the intimate of Gwynn, the architect, one of the foundation-members of the Royal Academy, in which their friend in common, Sam. Wale, was the first lecturer on perspective. Friendships between artists a century ago were, we see, as abiding as in the days which have seen the rise of Melbury-road, for Payne, so Smith tells us, "built two small houses at the end of his garden, purposely to accommodate Gwynn and Wale; the entrances were in Little-court, Castle-street, and are still standing." The recent demolition will, however, at length remove all traces of Little-court, which, with the whole eastern side of Castle-street, will soon have been carted away, with many an unsavoury memory which in modern days has been associated with a thoroughfare little over a century ago the residence of that most sedate and respectable of artists, Benjamin West, P.R.A., and the scarcely less courtly engraver Sir Robert Strange, who here, according to Cunningham, engraved the portrait of Charles I. after Vanduyck, so familiar to all print collectors. With the disappearance of the eastern side of Castle-street will pass away, too, all trace of those gardens where, a century back, vines were able to grow which could produce from one tree a pipe of wine, as Smith tells us was the boast of Powel in St. Martin's-lane, the then keeper of "one of the oldest, colour-shops in London," still, doubtless, remembered by not a few readers; a house immortalised by Hogarth, who has introduced one of its well-planned rooms into the scene of the interior of the quack doctor's, in the series of "The Rake's Progress."

If it be difficult for the Londoner to realise the existence of Powel's vine, few would believe that on the space opposite St. Martin's Church,—where the demolisher's pick is now hard at work,—could, within comparatively recent times, have stood a pair of elaborately carved stocks, which Smith assures us were, within his memory, "standing opposite to the centre of the portico of the church." * Looking over old maps, it is indeed easy to realise that not so very long since, Gibbs's fine Church of St. Martin truly stood "in the fields," when existed in full bloom the Hop Gardens on the eastern side of the lane, the site of which is still marked by a court bearing their name,

* The existence of this old-world relic can be believed when it is remembered that within the sound of "Big Ben" there can still be seen, almost at the gate of Waltham Abbey—that far too-little-visited memento of our Norman history—a pair of stocks, belonging, if we mistake not, to the seventeenth century.

within hut a few steps of May's Buildings, and the quaintly designed red brick façade of the house which Mr. May built about the year 1793, before the reputation was established of his neighbour Chippendale, the upholsterer, who published at his house, No. 60, in St. Martin's-lane, that interesting book of models of furniture, of which a grateful generation made ample use, till fashion flung it aside, to be once more,—within but a few years,—taken up again, and yet another time set aside for the monstrosities of a so-called "art decoration," more calculated than all the picks and shovels of the contractors to rouse from their quiet slumbers the shades of the many artists who have made their home in St. Martin's-lane.

THE ROYAL HOLLOWAY COLLEGE FOR WOMEN, MOUNT LEE, EGHAM.

On Saturday last a large number of gentlemen, with a few ladies, were invited by Mr. Geo. Martin-Holloway to a private view of this large and costly building, which is to be opened by Her Majesty the Queen on Wednesday next. The building, as our readers know, was founded by the late Mr. Thomas Holloway, and it is intended to meet the demands for that higher education which modern requirements claim for women, and at the same time to conform to the usages of home life. It is stated in the foundation deed that "The college is founded by the advice and counsel of the founder's dear wife."

The first step taken in furtherance of the project was a conference in 1875, at which were present, among others, the late Professor Fawcett, M.P., Sir James Kay-Shuttleworth, bart., Mr. Samuel Morley, M.P., Mr. David Chadwick, M.P., Dr. Hague, of New York, and Mr. F. Pennington, M.P. Being thoroughly convinced of the importance of the educational question, and foreseeing a great need which must arise with the advance of public opinion, Mr. Holloway at once resolved to take upon himself the whole burden of building and endowing a college on such an unprecedentedly large scale that it would practically form the nucleus of a university for women.

In order to acquire full information, extensive foreign inquiries were personally made by Mr. Holloway and his brother-in-law, Mr. Martin-Holloway, who was associated with him in the scheme from the first.

A suitable site of 95 acres was selected at Mount Lee, Egham, and was conveyed by Mr. Holloway on the 8th May, 1876, in trust to Mr. Henry Driver-Holloway, Mr. George Martin-Holloway, and Mr. David Chadwick. Plans were settled (Mr. W. H. Crossland, F.R.I.B.A., being architect) and a first contract for the original building was entered into with Mr. John Thompson for 257,000*l.*

The first brick was laid by Mr. Martin-Holloway on the 12th September, 1879. The building under the original contract was finished well within the stipulated time of four years, and as a proof of the business capacity exhibited throughout may be mentioned the fact, almost without parallel in a building of such magnitude, that not a shilling was claimed or paid for extras. Other extensive works were subsequently undertaken, which, with the requisite fittings, furniture, pictures, &c., have brought the total outlay up to about 600,000*l.*, exclusive of endowment.

The style of the college is the French Renaissance, in red brick with Portland stone dressings. The whole building forms an immense double quadrangle, and probably covers more ground than any other college in the world.

As to the arrangement of the buildings, the two long blocks are devoted to accommodation for students and professors and class-rooms, the corner pavilions containing class and teachers' rooms. Each student will have a study and a bedroom.

In the three connecting blocks are arranged the chapel, with organ by Mr. Walker (the chapel decorations being the work of Messrs. Clayton & Bell), the recreation-hall, the commodious dining-hall and kitchen, the latter being intended for the purpose of a school of cookery; the spacious museums and libraries, with beautifully-designed ceiling ornamentations, and handsome oak fittings; pianoforte practising and music rooms, gymnasium, racquet-court, lecture theatre, and other rooms, &c.

The notable pictures in the Recreation Hall

A SKETCH IN BIDSTON VILLAGE. CHESHIRE. by F. U. Holme

were collected by Mr. Martin-Holloway at a cost of upwards of 30,000L, and include such celebrated works as Millais's "Princes in the Tower" and "Princess Elizabeth in Prison at St. James's"; Landseer's "Man proposes, God disposes"; Friih's "Railway Station"; Long's "Babylonian Marriage Market" and "The Suppliants"; Luke Fildes's "Applicants for Admission to a Casual Ward," &c.

The College contains in all nearly 1,000 rooms, and provision is made for 250 students and for an ample staff.

On the four façades of the building there is a great deal of sculpture, and in the quadrangles, in the four pediments, some figures, designed and partly completed by Signor Puocigas, who also entirely designed and modelled the chapel ceiling.

The fittings and furniture are most substantial and comfortable.

A subway leads from the engineering and other detached buildings to the inside stores.

There are all modern and sanitary appliances, and complete systems of electric and gas-lighting and steam-heating. The electric lighting has been carried out by Messrs. B. Verly & Son. Mr. R. B. Stirat, of London and Newcastle, has carried out the engineering works connected with the heating, cooking, &c.

The curriculum is left to the discretion of the governing body. Applicants for admission must have attained the age of seventeen, and those who have neither matriculated nor passed senior local examinations are required to pass an entrance examination.

It was the founder's desire that power should be ultimately sought to enable the College to confer degrees.

The College is to be conducted as an orderly Christian household, where the students shall be made to feel, in the words of the Founder, "their individual responsibility and their duty to God."

We will say more about this remarkable building on a future occasion.

Chester-le-Street (Durham).—Extensive alterations are about to be carried out at "The Hermitage," near Chester-le-Street, for Mr. Lindsay Wood, from designs by Mr. H. T. Garton, architect, of Durham, under whose superintendence the work will be carried out.

A SKETCH IN BIDSTON VILLAGE, CHESHIRE.

This sketch shows part of a very characteristic bit of English village architecture, and has some additional value as it is feared that in the course of building extension and the new laying out of the neighbourhood it may henceforward be altered out of all recognition. The village is just below Bidston Hill, a picturesque hill two or three miles from Birkenhead, from which a fine view of the Mersey and Liverpool is obtained in one direction, and in the other direction a view over the flat plain which divides the estuaries of the Mersey and the Dee. Much of the land in the neighbourhood of Bidston has for long existed as picturesque open common, covered with furze and heath, and only dotted with a house here and there; but the extension of Birkenhead suburbs and the laying out of new roads and building land are fast altering all this.

Mr. Holme's sketch represents very faithfully the character of the village, with its substantial old stone houses.

ARCHITECTURAL ASSOCIATION.

VISIT TO WALTHAM ABBEY AND CROSS.

THE Architectural Association made its first summer vacation visit this year on Saturday last, to Waltham Abbey, under the guidance of Mr. Reeve, who gave a brief description of the foundation of the Abbey, and discussed the question of the claim of Harold to the foundation of the existing church, referring to the well-known controversy between Mr. Parker and Mr. Freeman in the *Gentleman's Magazine*. Mr. Reeve, who acted as clerk of the works to Mr. Barges when he restored the church in 1860, made careful measured drawings of the nave arcade, and he arrived at the conclusion that the two first bays of the arcade from the east end were built in the reign of Henry I., the remainder of the arcade belonging to Harold's church. Mr. Reeve explained the various features in the work which led him to this conclusion, the principal points being connected with the second pier from the east on the south side, which was rebuilt by Mr. Barges. After examining the beautiful Lady Chapel, the new stained-glass window recently inserted in the tower from the designs of Mr. Barges repre-

senting the four periods in the day, the ruins of the abbot's house, and the gateway to the abbey, the members passed on to Waltham Cross and saw the drawings prepared by Mr. Pouting for the restoration of the Cross, and the interesting collection of drawings and documents relating to the Cross which were shown and described by Mr. Tydeman, the hon. secretary for the restoration fund.

NOBLE'S PATENT EXPANDING MANDREL.

EVERYTHING which gives convenience in the workshop is of practical service to the mechanic, and as the lathe is the machine-tool most commonly in use, any invention which adds to its efficiency deserves attention. We have been asked to inspect some expanding mandrels exhibited by the Britannia Company, of Colchester, at their London show-room in Fenchurch-street, and the visit has impressed us with a high opinion of the practical value of these appliances. The ordinary method of the shops in fitting a pulley or bush, or other like object on a mandrel to be turned is to turn down any odd piece of metal slightly conically to fit the central bore or interior hole of the object to a tight fit; and then to hammer and drive it in with the risk of splitting the boss or object into which it is driven. Much work is spoiled in this rude way. The term, expanding mandrel, sufficiently expresses at once the nature of the new invention. It is intended for any class of lathe-work, and consists of a central shaft, E, tapped with a left-handed screw for nearly its entire length; the remainder being cut with a right-handed screw, D, of smaller dimensions, for the purpose of fitting on the carrier. A cone, A, works over the left-handed screw. In its surface are cut three equidistant grooves, F, into which are placed three corresponding wedges or slides, which are dovetailed into the grooves, and are thus held in position. The bases of these wedges abut against the carrier-collar, B, so that when the mandrel is inserted in the bore or hollow of the bush or pulley, or other article to be turned, the screwing-up of the carrier tightens the wedges by driving them forward within the hollow, and so the object is firmly held. The mandrels are made of various dimensions,

Noble's Expanding Mandrel.

according to the size of work required to be done. Each set is of course of its respective minimum size, but extra wedges to fit are also supplied to suit the same mandrel for dealing with increased sizes of work. The merits which the makers claim for these mandrels are that any article can be fitted on in a moment without fixing in a vice or hammering; that the slides expand automatically with the action of the lathe, the lever of the carrier being brought into contact with a pin on the face-plate of the lathe, and consequently the deeper the cut of the tool the tighter the mandrel holds, as the driver correspondingly tightens up; and that the mandrels always expand parallel to centres, thus assuring true work. They further claim economy of time to the extent that in a few weeks the cost of the new mandrels will be repaid. We do not consider these claims in any way exaggerated, but regard these mandrels as very useful adjuncts to the lathe, and as supplying a want in that branch of their application in which most waste of time and material now in the common practice ordinarily occurs.

A BUILDER'S CLAIM: ST. PATRICK'S CATHEDRAL, DUBLIN.

FILE V. DEAN WEST.

THIS case came before Lord Chief Baron and a special jury of the city of Dublin a few days ago. It was an action in which (according to the *Irish Times*) the plaintiff, who is a builder and contractor, sought to recover 4,700*l.*, balance due for sundry works and repairs executed at St. Patrick's Cathedral. It will be remembered that in September, 1883, one of the flying hutchesses of the cathedral fell, and in consequence it became necessary to do a much larger amount of work than at the time had been contemplated by the Cathedral Board. The plaintiff carried out the necessary works under the direction of Mr. J. F. Fuller, Architect to the Board, and the work was afterwards measured by Messrs. Patterson & Kempster, building surveyors. A question then arose as to the amount which the Cathedral Board should pay the contractor. The defendants lodged in court 1,000*l.* in settlement of the plaintiff's demand, and they disputed the rest of the account, their defence as to which involved a very large amount of evidence.

Lord Ardilaun and Sir Edward Cecil Guinness, Bart., D.L., were sued as two of the former members of the Board, and they filed separate defences denying their liability.

When the case was called, Mr. Holmes, one of the counsel for the Cathedral Board, stated to the Lord Chief Baron that a conference had taken place between counsel for all parties concerned, and the terms of a settlement had practically been arrived at, and these terms would be considered at a meeting of the Cathedral Board at two o'clock. He would therefore ask his lordship to allow the case to stand till half-past two o'clock.

The Solicitor-General and the other counsel concerned agreed to this course.

The Chief Baron allowed the case to stand till the hour mentioned.

Later in the day counsel attended and stated that in the morning they would ask his lordship to make a consent in the case a rule of court.

The Chief Baron.—Very well. It is stated that by the consent the defendants agreed to pay plaintiff another 1,000*l.* in addition to that lodged in court, and 450*l.* costs.

WESTMINSTER ABBEY.

SIR,—An Act has just been passed empowering the Ecclesiastical Commissioners to advance the necessary funds for restoring the exterior of the Abbey. We may, therefore, reasonably expect that the work will now be pushed on with vigour, but seeing that this is somewhere about the tenth more or less important restoration of this great national edifice, it would be satisfactory to the public to know whether the best possible security has been taken that it shall be the last. It is not a very creditable spectacle that the country should be required to keep restoring restorations. Can it not be avoided in future?

As, I believe, the words "restorations and improvements" were, on the motion of Mr. Cavendish-Bentinck, struck out of the Bill, and only the words "substantial repairs" retained, the intended work will be of such a comparatively simple nature that it would perhaps be only reasonable to leave it, without comment, in the hands of the Abbey architect, for whose genius all who know his beautiful works must have the greatest admiration. But though simple from an architectural point of view, it will be a very important practical work, and Mr. Pearson is not, I believe, responsible for the selection of the stone, for it was in use at the Abbey when he received his commission.

The decay of improper stone has led to these repeated restorations,—ten or a dozen of which are historically recorded,—and as there is some doubt about the matter it may very properly be asked, What guarantee is there that the stone in use for this present restoration,—already commenced,—is of such a nature as to put an end to the lamentable failures for the future? I venture to say there is none. Chemical tests, as we know too well, are dangerously mis-leading. The absence of any injurious effect of time upon the stone of the buildings of manufacturing towns is the only safe monitor, and such buildings are sufficiently numerous.

Chilmark stone,—the stone in use at the Abbey,—is a very beautiful material, and if it were about to be used on Salisbury Plain instead of at Westminster, it would be unnecessary to question its suitability for the purpose. But it is a limestone, and costly experience has proved that all limestones, whether oolites or dolomites, are destroyed sooner or later by the noxious gases which contaminate the air of Westminster. As well may we expect water to mix with oil as carbonate of lime to remain unchanged in the presence of muriatic acid, carbonated hydrogen, ammonia and the dozen other destructive gases and fuliginous compounds of our atmosphere. If it had hitherto been so accommodating, British tax-payers would not now be compelled to spend 2,500*l.* a year upon the external repairs of an adjacent national edifice, and which amount a late First Commissioner of Works has stated would be required as a permanent expenditure. Lambeth Palace has been restored twice in living memory. Only recently the mason's scaffold was removed from the Treasury Buildings. At Buckingham Palace the lives of the sentries were in danger from falling stones, immediately after the east front was completed. Now, as the material used for these buildings (and for many more) was derived from some well-known limestone quarry, and has so lamentably failed, common sense and actual experience,—to say nothing of chemical science,—seem, I think, to demand that stone of a different nature should be used for the "substantial repairs" of the Abbey.

There is no difficulty in the matter, except it be that of overcoming a pernicious local custom. There is no excuse; and for in these days railways, and shipping, and quarries yielding the most durable stone abound. In the northern towns, if a limestone is used at all, it is only to throw it into a

furnace for the reduction of ores, and for other useful economic work, but never for a building of any importance. Their atmosphere is much the same as that of London.

The additional cost, at the outset, of proper stone for the restoration of the Abbey would be trifling in comparison with that of the repeated repairs rendered necessary by the injudicious use of a material quite unsuited to the local circumstances. URBANUS.

PROVINCIAL NEWS.

Handsworth.—The new Drill-hall for the 1st V. B. South Staffordshire Regiment of Volunteers, just opened at Soho-road, Handsworth, has been designed by Messrs. Osborn & Reading, architects, of Birmingham, the size being 102 ft. by 75 ft. The front block of accessory buildings comprise orderly-room, armoury, clothes store; meeting or lecture room, 43 ft. by 20 ft.; and sergeant-instructor's house, gateway, &c. Messrs. Barnsley & Sons are the builders.

Repton (Derbyshire).—An important addition to the school buildings was opened on Thursday, the 17th, by Mr. Justice Denman (an old Reptonian). The new buildings occupy the site of the old Priory Church nave, and have been so arranged as not to disturb any of the remains *in situ*. The old wrought stone found during the excavations has been built up by Mr. G. W. Haswell, the clerk of works, as a wall on the north side. The new buildings are from designs of Mr. A. W. Blomfield, M.A., and are of the Perpendicular period, harmonising with the adjoining priory house. The west gable is flanked by embattled turrets, and the south side is broken up by four large arches leading to the cloisters, off which run the class-rooms, lavatories, &c. The main staircase and entrance to hall above are at the east end, over the class-rooms, &c. One large hall has been built (101 ft. by 40 ft.) in memory of the late Dr. Pears, head master. It is a room of grand proportions, and is roofed with an open hammer-beam roof, springing off stone corbels, and the room is lined round with oak panelling, 7 ft. high, and at the west end is an orchestra capable of holding a full band and chorus; on it is built a three-manual organ (with oak case specially designed by Mr. Blomfield), with Brindley's patent pneumatic action, by Messrs. Brindley & Foster, of Sheffield. The buildings have been built throughout with Coxheath (Derbyshire) stone. The pavements and staircases being built with Stuart's granolithic stone. The heating and ventilation had special attention paid to them, and these important matters have been admirably carried out by Mr. R. Crittall, Manchester-square. The whole of the buildings have been carried out by Messrs. Walker & Slater, of Derby, under the direct superintendence of Mr. Geo. W. Haswell, of Chester.

Swanage, Dorset.—A marine drive, of great beauty, is being made round Durlstone Head, at the expense of Mr. George Burt, of Westminster. It commands views of the rock-bound coast (including Tilly Whym), which is very fine here, consisting of Portland stone cliffs, against which the green seas wash, it being several fathoms deep close under the cliff without any shore whatever. The works, which are intended for the public use, consist of a drive encircling the headland, and working spirally up to the summit, where a pavilion is to be erected. A large circle is formed of large stones, which are placed in such a position as to denote the points of the compass, and serve for seats. The whole will, when complete, form an admirable pleasure park for the inhabitants of the town.

Church at Cae-Gurwen, Carmarthen-shire.—A new church, built by Mr. C. Edwards, of Leominster, from the plans and under the superintendence of Mr. E. H. Lingen-Barker, has just been opened at this place. It consists of a nave 50 ft. by 24 ft., with a well-developed chancel, commodious vestry, and south porch. The walls are of local stone, and the wood-work is principally of pitch-pine. The floors are laid with Webb's Worcester tiles, and the church is warmed by Porritt's heating apparatus. The cost has been 638*l.*, which, for 200 persons, is only 3*l.* 4*s.* per head.

The Student's Column.

OUR BUILDING STONES.—XVI.

ARTIFICIAL STONES (continued).

Ransome's Artificial Stone.

STONE bearing this title has been before the public for many years. It is made of clean sand artificially dried, mixed into a paste with silicate of soda, to which a small quantity of ground-up or powdered stone is added. The whole is thoroughly mixed together in a mill, being subsequently pressed into moulds and turned out as blocks when dry. A cold solution of chloride of calcium is then poured over them, after which they are placed in a hot solution of the same chemical. In order that the pores of the material shall become thoroughly filled, in particular cases the chemical is introduced under pressure. A cross combination, or double decomposition ensues; chloride of sodium is washed out, and silicate of lime is formed within the stone. When this process is completed, and the material has dried, the excess of chloride of sodium which has formed on its exterior is wiped off. It would be difficult to imagine an artificial method of producing stone, the result of which more closely resembles the one which in nature produces a sandstone with a calcareo-siliceous matrix. For the artificial stone now under consideration is nothing more nor less than a sandstone with a matrix of silicate of lime, with a little powdered foreign matter in it.

We have repeatedly observed that natural sandstones of this description are amongst the most durable stones, and we should expect to find that this artificial product, which is so similar to them, is almost as durable. The principal matters, perhaps, upon which the actual durability of Ransome's stone to a great extent depends, are the purity of the chemicals used, and the nature and amount of foreign powdered matter added to the sand in mixing, at the commencement of the process.

The material has been formed in moulds, in imitation of decorative carving; a use of it which cannot be too strongly deprecated, and which is fatal to true artistic feeling and workmanship. We do not, however, see the slightest objection to the use of this homogeneous stone for walls and dressings of buildings in districts where it can be used as economically as natural stone, other things being equal. Moreover, like the average limestones and sandstones, it can be worked with the chisel whenever necessary. In this respect it has an advantage over some other artificial stones, where the removal of the outer layer of the material is a source of decay.

Many experiments on Ransome's stone are recorded in Gwilt's "Encyclopædia," p. 485.

It is generally admitted that it absorbs about 64 per cent of water, although as high as 12 per cent, has been recorded (see Wray "On Stone"). It weighs between 110 lb. and 120 lb. per cubic foot, whilst its resistance to crushing, per inch, is about 2 tons.

Mr. Ransome has made several improvements on his original stone, and in 1870 he invented a superior variety, called

Apenite.

This material can be made on the works where it is intended to be used. It consists in mixing Farnham stone, or soluble silica, with silicate of soda or of potash, together with lime, sand, alumina, or other convenient materials in proper proportions. The alkaline silicate is then decomposed, the silica combining with the lime to form an insoluble silicate of lime, and also forming, with some of the materials, a silicate of alumina, whilst the caustic alkali, set free by the decomposition, seizes upon the soluble silica of the Farnham stone, and forms a fresh silicate, which in turn is decomposed by more lime.

The stone is said to absorb from about 54 to 12 per cent. of its weight in water, and weighs from 130 lb. to 140 lb. per cubic foot.

It is used for balustrades, steps, landings, &c.

Victoria Stone.

Many forms of Portland cement are employed in building operations. It would be out of place here to describe any of the ordinary kinds of that cement, as well as those which do not rank as building stones, and although Victoria stone is principally formed of it, an

important part of the process of the manufacture of the stone is a decided departure from the ordinary methods of making that cement.

The stone is made somewhat in the following manner.—Granite, obtained from Groby Quarries, near Leicester, is pulverised and subsequently washed. This washing frees it from any soft or foreign substance which might prove detrimental to the uniform character required in the stone. It is then mixed with the best Portland cement. If desired to make slabs for pavements, it is then moulded in frames, which are lined with metal, so that both sides of the slab are equally level, and the edges being true, enable the different slabs to be evenly joined together, thus causing the pavement to present a symmetrical appearance. The next stage of the process is to take the slabs of cemented material out of the moulds about a week after, and immerse them in baths of silicate of soda, where, according to the trade circular, they are allowed to remain about eight or ten days.

The silica is obtained from under the chalk deposits of Farnham in Surrey, and prepared in a solution.

The lengthened immersion causes the slabs to become impregnated with silica, and produces a chemical change. The silicate combines with the lime in the cement, the mass being made hard by the silicate of lime so formed.

How far the silicate renders the stone impervious to water, appears from experiment to be uncertain. We will not inquire into the causes of this variability in structure, and, indeed, no result of practical value would be obtained by it, for, as the stone only absorbs from 2 to 7.6 per cent. of its weight in water in twenty-four hours, it will be seen that if we take the highest of these figures as the ordinary absorption power, even then it would be tolerably compact, and, in this respect, compare favourably with many of the natural stones used for the same purpose.

Wray says that the thinner flags are less compact and more absorptive than the thicker ones.

When the stone is taken out of the silica tanks it is exposed to the air for rather more than a month before being utilised.

The process of manufacture of the material when not made into slabs is nearly the same, allowances being made under certain conditions.

The quality of the Victoria stone was not so uniform when it was first made, because too much reliance was placed upon the immersion in silicate of soda. It was thought that this chemical would render durable almost anything it bound together in the shape of concrete, but it was found necessary to use only the better quality of cement, and also to wash the crushed granite, which was not previously done.

The crushing-weight of the stone is stated to be 6,440 lb. per cubic inch, and its weight from 140 lb. to 160 lb. per cubic foot. An average of ten brigades of Victoria stone showed that it was capable of bearing a tensile strain of about 794 lb. per square inch.

It is used principally for paving, but in a lesser degree also for window and door sills, balustrades, landings, tanks, sinks, &c. The clock tower and chimney-stacks of Messrs. Peek, Frean, & Co's factory, Bermondsey; and at Fresh Wharf, London Bridge, are examples of the stone when built up.

Sorel Stone is made of calcined magnesite, mixed with sand or powdered marble, and wetted with a liquor containing a considerable amount of magnesium chloride. The whole is then forced into moulds of different materials. In three or four days it becomes hard enough to handle. Its crushing-weight is very high.

Patent Petrammite and Rust's Vitrified Marble are other examples of stone artificially made.

Mortomley.—On Whit Sunday the new Roman Catholic Church and Schools erected by the Duke of Norfolk at Mortomley, near Chapelton, were formally opened. The foundation-stone was laid on the 26th July, 1885. The buildings, which occupy a site near Mortomley Hall, consist of church, school, Presbytery, and house, provision being made for future extensions. The church, which is dedicated to "Our Lady, Refuge of Sinners," has cost upwards of 1,000*l.* Mr. Edward H. Lloyd, of London, was the architect.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

5,445, Chimney Cows. H. G. Burson.

The improvements are effected by the arrangement of the parts which form the chimney cow. Special apertures and air-pressure or deflecting plates for increasing draught are so arranged that the mouth always faces the wind as it revolves upon its spindles. As the air blows upon a deflecting plate, it causes a greater pressure as it reaches the centre of the shaft, and creates a partial vacuum assisted by the inlets discharging the smoke through the mouth of the cow, rendering a down-draught impossible.

4,618, Dovetailing Machines. John Anderson.

This is an improvement on a former invention for use in machines having vertical cutters, dove-tailing wood joinery, boxes, drawers, &c. It is capable of being used for any required size of dove-tails by simply changing the cutters, as there are no teeth to obstruct the variation as is the case, with carriers hitherto in use.

3,418, Window-Sashes. J. Carter.

The window, when shut, has an ordinary appearance, without cords, weights, or boxes. At the lower part of the stiles of sash is a bracket of brass or iron, with a screw passing through it into the window-frame. This forms the fulcrum on which the sash revolves, and they can be completely reversed, and opened and let down for cleaning, painting, or repairing. The upper sash has a latch on the top rail latching into the window-frame, and the lower sash shuts close against the top sash and against the woodwork.

8,006, Manufacture of Plaster. R. Stone.

First the raw materials,—chalk, limestone, and analogous materials,—are immersed in tanks, or otherwise, and soaked with vitriol as they are taken from the quarries. They are then loaded into furnaces or kilns, mixed with fuel, such as coke, coals, &c., suitable for producing a very high temperature, which has the effect of reducing the materials so as to prevent contraction. In order to assist in raising the heat, and producing such temperature, a reservoir is filled with compressed air, and a continual supply is forced amongst the materials until thoroughly exhausted. Special mixtures are specified, and also special grinding-machines and crushing-rolls, with annular grooved or corrugated surfaces for grinding and disintegrating the material.

NEW APPLICATIONS FOR LETTERS PATENT.

June 11.—7,827, J. Shaw, Cooking Ranges.—7,863, P. Hoppe, Raising or Hoisting.—7,866, J. Banks, Door Bolts and Staples.

June 12.—7,871, J. Peaco, Window-Sash Fastener.—7,873, S. Harrison, Notched Blocks for Building Walls Downwards.—7,880, J. Armstrong, Water Waste-preventing and Regulating Cistern.—7,882, C. Coutts, Corrugated Water Supply Pipes.—7,921, G. Walker, Laying Wood Flooring.—7,924, J. Carpenter, Cleaning Floors, &c.

RECENT SALES OF PROPERTY.

ESTATE EXCHANGE REPORT.

Table listing real estate sales with columns for location, terms, and price. Includes entries for Kingsland, Kennington, Clapham, Putney, Islington, Stoke Newington, East Dulwich, Kennington, Peckham, Wandsworth, Clapham Park, Forest Gate, South Norwood, East Dulwich, Liverpool, Chelsea, and College-street.

MEETINGS.

Table of meetings including St. Paul's Ecclesiastical Society, British Museum, Statistical Society, Society of Arts, Dundee Institute of Architecture, Royal Archaeological Institute, Society for the Encouragement of the Fine Arts, and Architectural Association.

Miscellanea.

A New Laundry at Aberdeen.—The formal opening of the Bon-Accord Steam Laundry took place on the 9th inst. The new buildings, which are situated at Craighshaw, in the parish of Nigg, on the rising ground on the south side of the Dee, opposite the Duthie Park, are of granite; and the river front being of fair-picked ashlar work, the triple-roofed structure presents a prominent and pleasing aspect as viewed from the park or the riverside esplanade at present in course of construction on the north bank. The designs were furnished by Mr. Duncan McMillan, architect, Aberdeen, while the whole of the machinery has been supplied by Messrs. Thomas & Taylor, of Stockport. The Ironing and Calendering Room contains a patent steam mangle (with reversible motion), two calendering machines, starch-boiler, starch-washer, rinsing-machine, and tables for ironing and folding on. At the north end is an airing-chamber, with a patent iron-stove, which is stoked in the usual way, but from which the irons can be taken without entering the chamber. Of this, to the east, are the drying-closets, with coils of galvanised steam pipes around and under the sliding frames, which run on grooves in the floor. Above the drying-closets is the Curtain Room, for drying and stretching window-curtains, fitted up with the latest improvements. South of these is the Public Wash-house, furnished with four eccentric-motion washing-machines, and hlaeing, wringing, and rinsing machines. There is also a hydro-extractor, the frame of which is of cast-iron, and the perforated cage of copper and brass: it works up to 1,000 revolutions a minute. Opening from the public wash-house is a private wash-house for ladies' underclothing, &c., similarly provided with smaller machines, all the washers having cold-water spray apparatus attached. The water used is taken from the Craighshaw Burn. It is stored in a trapezoid-shaped reservoir, from which it is conducted to a sunk well under the engine-house (on the east side of the building), from which it is lifted by a double-action steam-pump as wanted. There are two Galloway boilers (27 ft. by 7 ft. 6 in. each), and in the boiler-house is a patent heater. The engine is a horizontal one of 12 h.p., and at the top of the building near the centre is a patent filter, hot-water tank, and cold-water tank. The Receiving and Issuing Rooms are fitted up in the usual way.

The Wesleyan Chapel, Studley-road, Clapham-road, has been recently redecorated and altered, and was opened last week with special services. The window openings have been entirely reconstructed and filled in with traceried frames, with coloured ornamental lead glazing, with new moulded strings and labels to the windows outside. The interior of the chapel has been reconstructed and entirely coloured in the Renaissance style, with quiet tints of green, Pompeian red, and gold. The lighting arrangements have been entirely altered, and a new sunburner fixed in the ceiling, with specially-designed brass gas fittings under galleries. The school and class-rooms have also been altered and redecorated. The interior decoration has been carried out by Messrs. Heaton, Butler, & Bayne, of Garrick-street; the gas arrangements and ventilation by Messrs. Z. D. Berry & Sons; the coloured lead glazing by Mr. Odell; the builder was Mr. F. Higge, and the whole of the works have been carried out from the designs and under the superintendence of Mr. Sidney R. J. Smith, and Mr. Arthur Catt, architects, of Furnival's-Inn.

Colonial and Indian Exhibition.—Arrangements have been made for the examination in the Indian Court of certain commercial products, which are believed to be insufficiently known or to be suitable for new purposes. Among the substances which will be examined are fibres, silk and silk substitutes, drugs, tobacco, gums and resins, minerals, oils, oil-seeds and perfumery, dyes, mordants and pigments, timbers, tanning materials and leather, and food-stuffs. Any visitors to the Exhibition, who are interested in the subject, will be permitted to attend these examinations of products, which will take place in the Commercial-room attached to the Economic Court, where all further information may be obtained. Should the results of this examination render such a course desirable, conferences of a formal character will probably be held at a later date.

The Metropolitan Sewage Sludge.—At the meeting of the Metropolitan Board of Works this Friday, the 25th of June, the Works and General Purposes Committee will present a report stating that the Committee have considered the designs, specifications, and tenders for a vessel capable of conveying 1,000 tons of sewage sludge out to sea, and are of opinion that the design sent in by the Barrow Ship-building Company (Limited) is, with certain modifications which they have agreed to make best suited for the Board's requirements, and recommending that one vessel be ordered from the Company in accordance with such design, and that the Solicitor be instructed to prepare the necessary contract. And further recommending that Mr. J. Casey be informed that the Board are not prepared to adopt his suggestion to throw open to the public the designs which they have received for sludge-vessels, and that all the designs which are not accepted will be returned.

PRICES CURRENT OF MATERIALS.

Table of material prices including Timber (Greenheart, Sequoia, Ash, Birch, Elm, Fir, Oak, Pine, Lath, Deal, White Pine, Canadian Pine, Spruce, Hemlock, Fir, Cedar, Honduras, Mahogany, St. Domingo, Mexican, Hoopwood, Maple, Rose, Box, Satin, Porto Rico, Walnut), Metals (Iron, Bar, Sheets, Nails), Copper (British, India, Australia, Chili, Yellow Metal), Lead (Pig, English), Silesian, Tin (Banca, Billiton, Straits, Australian, English ingots), Zinc (English sheet), Oils (Lined, Coconut, Ceylon, Copra, Palm, Rapeseed), and Turpentine (American, Swedish).

CONTRACTS AND PUBLIC APPOINTMENTS.

Epitome of Advertisements in this Number.

CONTRACTS.
