# PECULIAR PHONETIC SYMBOLS

## USED IN THE WRITING OR TRANSLITERATION OF THE DIFFERENT LANGUAGES.

ā, ē, etc.: long vowels; in the Scandinavian languages the accent (*á*, *é*, etc.) is used to denote length.

ą: a nasalized *a*; so used in the transliteration of the Iranian languages.

å: labialized guttural *a* in Swedish.

æ: open *a* of Eng. *hat*, used chiefly in O. Eng.

aí: used in Gothic to denote *e* (open), in distinction from *ái*, the true diphthong.

aú: used in Gothic to denote *o* (open), in distinction from *áu*, the true diphthong.

bh: in Sanskrit a voiced labial aspirate (cf. *ch*).

ƀ: voiced bilabial (or labio-dental?) spirant, used in discussions of Teutonic dialects.

ç: voiceless palatal sibilant, similar to Eng. *sh*, used especially in transliteration of Sanskrit.

č: frequently used, e. g. in Slavonic languages, to denote the sound of Eng. *ch* in *cheek*.

c: voiceless palatal explosive, commonly used in transliteration of Sanskrit and the Iranian languages.

ch: as used in the transliteration of Sanskrit, a voiceless palatal aspirate, an aspirate being an explosive with excess of breath; as used in German grammar, the symbol for a voiceless palatal or guttural spirant.

dh: voiced dental aspirate (cf. *ch*) in Sanskrit.

ḍ: voiced cerebral explosive, so used in transliteration of Sanskrit.

ḍh: voiced cerebral aspirate (cf. *ch*) in Sanskrit.

đ: voiced dental (interdental) spirant, equivalent to Eng. *th* in *then*; so used in the Teutonic and Iranian languages and in phonetic writing.

ë: a short open *e*, used in Teutonic grammar, particularly in writing O. H. G.

ə: the short indefinite or "obscure" vowel of Eng. *gardener*; used in the reconstruction of Indo-Eur. forms, and in transliterating the Iranian languages.

gh: in Sanskrit a voiced guttural aspirate (cf. *ch*).

*g*: voiced velar (back-guttural) explosive, used most frequently in Indo-Eur. reconstructions.

ȝ: voiced guttural (or palatal) spirant, equivalent to Mod. Greek $\gamma$, and used in transliteration of Iranian languages and O. Eng.

ḥ: a voiceless breathing, the Sanskrit *visarga*.

ƕ: a labialized *h*, similar to *wh* in Eng. *what*; used in transliteration of Gothic and the Iranian languages.

ḫ: voiceless guttural (or palatal) spirant, equivalent to German *ch*, and used in transliteration of the Iranian languages.

i̯: the semi-vowel *y*, or consonant form of *i*; used in phonetic writing and reconstructions of Indo-Eur. forms.

j: in the transliteration of Sanskrit and the Iranian languages a voiced palatal explosive; in the Teutonic languages a semi-vowel (= *y*), for which in Indo-Eur. reconstructions *i* is generally used.

jh: in Sanskrit a voiced palatal aspirate (cf. *ch*).

kh: in Sanskrit a voiceless guttural aspirate (cf. *ch*).

ł: the guttural ("thick" or "deep") of the Slavonic and some of the Scandinavian languages.

ḷ: vowel *l*; used in transliterating Sanskrit, in reconstructing Indo-Eur. forms, and in other phonetic writing.

n̥: nasal vowel; used in reconstruction of Indo-Eur. forms and in phonetic writing.

ṇ: in Sanskrit the cerebral nasal.

ṅ: in Sanskrit the guttural nasal (see following).

ŋ: the guttural nasal, equivalent to Eng. *n* in *longer*; used in transliteration of Iranian languages.

ñ: palatal nasal, similar to *gn* in Fr. *regner*; used in transliterating Sanskrit and in phonetic writing.

ö: palatalized *o*; used in German and in phonetic writing.

ǫ: short open *o* in Scandinavian.

ø: short palatalized *o* (ö) in Scandinavian.

*ph*: in Sanskrit, voiceless labial aspirate (cf. *ch*).

ꝗ: voiceless velar (back-guttural) explosive; used in reconstructions of Indo-Eur. forms and in other phonetic writing.

ṛ: vowel *r*; used in transliterating Sanskrit, in reconstructions of Indo-Eur. forms, and in other phonetic writing.

š: voiceless cerebral sibilant, equivalent to Eng. *sh*; used in transliterating the Iranian languages and in phonetic writing.

ṣ: voiceless cerebral spirant; used in transliterating Sanskrit.

th: in Sanskrit a voiceless dental aspirate (cf. *ch*).

ṭh: in Sanskrit a voiceless cerebral aspirate (cf. *ch*).

ṭ: in Sanskrit a voiceless cerebral explosive.

ţ: a form of dental spirant used in transliterating the Iranian languages (represented in Justi's transliteration by ṭ).

þ: voiceless dental (interdental) spirant, equivalent to Eng. *th* in *thin*; used in Teutonic dialects and in phonetic writing.

u̯: consonant form of *u*; used in phonetic writing.

ž: voiced cerebral sibilant, equivalent to *s* in Eng. *pleasure*, and to *j* in Fr. *jardin*; used in Iranian, Slavonic, and in phonetic writing.

ʒ: a symbol frequently used in the writing of O. H. G. to indicate a voiced dental sibilant (Eng. *z*), in distinction from *z* as sign of the affricata (*ts*).

# EXPLANATION OF THE SIGNS AND ABBREVIATIONS USED IN THE ETYMOLOGIES.

>, yielding by descent, i. e. under the operation of phonetic law.
<, descended from.
=, borrowed without change from.
:, cognate with.
+, a sign joining the constituent elements of a compound.
*, a sign appended to a word the existence of which is *inferred.*

# KEY TO THE PRONUNCIATION.

aa...... as *a* in *father*, and in the second syllable of *armada*.
ă̆a...... same, but less prolonged, as in the initial syllable of *armada*, *Arditi*, etc.
a....... as final *a* in *armada*, *peninsula*, etc.
ă....... as *a* in *fat*, and *i* in French *fin*.
ay or ā.. as *ay* in *nay*, or as *a* in *fate*.
ă̆y or *ā̆*.. same, but less prolonged.
ã....... as *a* in *welfare*.
aw...... as *a* in *fall*, *all*.
ee...... as in *meet*, or as *i* in *machine*.
ĕe...... same, but less prolonged, as final *i* in *Arditi*.
e....... as in *men*, *pet*.
*e*....... obscure *e*, as in *Bigelow*, and final *e* in *Heine*.
ė....... as in *her*, and *eu* in French *-eur*.
i....... as in *it*, *sin*.
ī....... as in *five*, *swine*.
ī̆....... same, but less prolonged.
ō....... as in *mole*, *sober*.
ō̆....... same, but less prolonged, as in *sobriety*.
o....... as in *on*, *not*, *pot*.
oo...... as in *fool*, or as *u* in *rule*.
ŏo...... as in *book*, or as *u* in *put*, *pull*.
oi...... as in *noise*, and *oy* in *boy*, or as *eu* in German *Beust*.
ow...... as in *now*, and as *au* in German *haus*.

ö....... as in *Göthe*, and as *eu* in French *neuf*, *Chintreuil*.
ŭ....... as in *but*, *hub*.
*ŭ*....... obscure *o*, as final *o* in *Compton*.
ü....... as in German *süd*, and as *u* in French *Buzançais*, *vu*.
y or *l*.... see *l* or y.
yu....... as *u* in *mule*.
yŭ....... same, but less prolonged, as in *singular*.
ch....... as in German *ich*.
g....... as in *get*, *give* (never as in gist, congest).
hw...... as *wh* in *which*.
*k*h...... as *ch* in German *nacht*, *g* in German *tag*, *ch* in Scotch *loch*, and *j* in Spanish *Badajos*, etc.
ṅ....... nasal *n*, as in French *fin*, *Bourbon*, and nasal *m*, as in French *nom*, Portuguese *Sam*.
ñ or n-y.. Spanish *ñ*, as in *cañon*, *piñon*, French and Italian *gn*, etc., as in *Boulogne*.
*l* or y.... French *l*, liquid or mouillé, as (-i)ll- in French *Baudrillart*, and (-*i*)*l* in *Chintreuil*.
th....... as in *thin*.
*th*....... as in *though*, *them*, *mother*.
*v*....... as *w* in German *zwei*, and *b* in Spanish *Cordoba*.
sh....... as in *shine*.
zh....... as *s* in pleasure, and *j* in French *jour*.

All other letters are used with their ordinary English values.

## NOTE.

The values of most of the signs used in the above Key are plainly shown by the examples given. But those of ö, ü, ch, *k*h, ñ, and *v*, which have no equivalents in English, can not be sufficiently indicated without a brief explanation, which is here given.

ö. The sound represented by this symbol is approximately that of -u- in *hurt* or -e- in *her*, but is materially different from either. It is properly pronounced with the tongue in the position it has when ā is uttered and with the lips in the position assumed in uttering ō.

ü. This vowel is produced with the lips rounded as in uttering oo and with the tongue in the position required in uttering ee, into which sound it is most naturally corrupted.

ch and *k*h. These are both rough breathings or spirants made with considerable force, ch being made between the flat of the tongue and the hard palate, and *k*h between the tongue and the soft palate. ch approaches in sound to English sh, but is less sibilant and is made further back in the mouth; *k*h is a guttural and has a hawking sound.

*l* or y. These are both used to represent the sound of French l mouillé, in (-i)ll- and (-i)l, which resembles English -y- in *lawyer*. Final *l*, that is, (-i)l, may be approximated by starting to pronounce lawyer and stopping abruptly with the -y-.

ñ or n-y. The consonants represented by ñ (Spanish ñ, French and Italian gn, etc.) are practically equivalent to English -ni- or -ny- in bunion, bunyon, onion, etc., and, except when final, are represented by n-y. Final ñ, as French -gn(e), may be produced by omitting the sound of -on in the pronunciation of *onion*.

***v***. This may be pronounced by attempting to utter English v with the use of the lips alone.

See Preface (vol. i., p. xli.) and the article Pronunciation of Foreign Names.

# THE
# UNIVERSAL CYCLOPÆDIA.

**Sodom** [from Heb. *Sᵉdhōm*, liter., burning, conflagration; Gr. Σόδομα]: a city memorable in the earliest records of the Hebrews for its connection with Abraham and Lot, and its miraculous destruction by a storm of brimstone and fire (Gen. xix. 24, 25). The exact situation of Sodom and its allied cities, Gomorrah, Admah, Zeboim, and Bela or Zoar, in the vale of Siddim, has long been discussed, the usual conclusion having been that the "cities of the plain" occupied the present basin of the southern bay of the Dead Sea, which was formerly supposed to have been formed at the time of the destruction of those cities. Geological examinations have shown, however, that the supposition is erroneous. The sea only underwent enlargement at that time. The shallowness of the southern end is an argument for locating the cities there. The catastrophe was not volcanic, but in consequence of the ignition by lightning of the asphalt with which the land is full, which would, of course, burn up the cities. The land sank when the asphalt had been burnt out, and then the Dead Sea overflowed the sunken ground. An earthquake may have been a contributing cause. On the southwest coast of the Dead Sea is Jebel 'Usdom (hill of Sodom), a mass of mineral salt. At the south end is a tall, isolated needle of rock, resembling a woman carrying a child. This is called Lot's wife. Josephus (*Jewish War*, iv., 8, 4) says that traces of the lost five cities could be seen under the waters of the sea, and travelers have repeated the idle tale. The catastrophe itself, outside of the Bible and Josephus, is mentioned by Strabo (*Geography*, xvi., 2) and Tacitus (*History*, v., 5). Some locate the cities at the northern end of the sea, and employ a similar argument from the presence of asphalt there; and another argument is the supposed necessity of locating Zoar at the northern end, in order to justify the language of Gen. xiii. 8–12. SAMUEL MACAULEY JACKSON.

**Sodom, Sea of**: See DEAD SEA.

**Soest**, sōst, or **Sohst**: town; Westphalia, Prussia; junction of the Berlin-Düsseldorf railway. In the Middle Ages it was one of the most flourishing cities of the Hanseatic League. It is still a handsome town surrounded by substantial walls. One of the old gates, the Osthofenthor, has been restored. The town has several important schools, a fine cathedral of the fifteenth century, and does a large trade in grain and cattle. Pop. (1895) 15,407.

**Soetbeer**, ADOLPH, Ph. D., LL. D.: political economist; b. in Hamburg, Germany, Nov. 23, 1814; educated in Hamburg, Göttingen, and Berlin; syndic of the chamber of commerce at Hamburg 1840–72; became professor in Göttingen University in 1872. He was an authority on coinage. His principal published works are *Edelmetall-Produktion und Wertverhältniss zwischen Gold und Silber seit der Entdeckung Amerikas* (Gotha, 1879) and *Literaturnachweis über Geld und Münzwesen insbesondere über den Währungsstreit, 1871–91* (Berlin, 1892). D. Oct. 23, 1892.

**Sofa'la**: a Portuguese settlement on the southeastern coast of Africa, in lat. 20° 11′ S.; also an ill-defined flat coastal area from the mouth of the Zambesi to Delagoa Bay, comprising several Portuguese settlements (see map of Africa, ref. 8–G). The city of Sofala consists of a few mud huts, situated in an unhealthful salt-swamp, but the surrounding territory is very fertile. The low coast-land swarms with wild animals. Pop. about 1,300. M. W. H.

**Sof'tas** [from Turk. *softa*, from Pers. *sōkhtah*, liter., one who burns or is zealous]: persons attached to the service of the mosques. At Constantinople the term is specially applied to the whole body of the theological students who receive instruction in the colleges (medressehs) connected with the larger mosques. From them are recruited all ranks of the Mussulman clergy. Without ordination, but according to personal aptitude or length of study, each one is appointed to his special religious functions. At various times this body of students have taken a prominent part in political affairs. Thus prior to the Russo-Turkish war (1877) they caused the deposition of an incapable grand vizier and of an obnoxious sheik-ul-Islam. Their number at the capital is probably not much below 10,000. E. A. GROSVENOR.

**Sogdia'na** (in Gr. Σογδιανή): formerly a territory of Central Asia, separated N. from Scythia by the Jaxartes, S. from Bactria by the Oxus; nearly the same regions as the present Turkestan, the city of Bokhara still bearing the name of *Sogd*. It was conquered by the Persians under Cyrus, and fell after the death of Alexander the Great to Syria; it was subsequently conquered by the Turkomans.

**Sohn**, zōn, KARL FERDINAND: painter; b. in Berlin, Germany, Dec. 10, 1805; studied painting under Schadow, whom he accompanied in 1826 to Düsseldorf, in 1830 to Italy; was appointed professor in the Academy of Düsseldorf in 1838. D. in Cologne, Nov. 25, 1867. Among his most celebrated pictures are *Rinaldo and Armida* (1827); *Diana and Actæon* (1833); *The Judgment of Paris* and *Romeo and Juliet* (1836); *Tasso and the Two Leonoras* (1838).

**Sohrāb**: See RUSTAM.

**Sohst**: See SOEST.

**Soils**: See AGRICULTURAL CHEMISTRY.

**Soissons**, swaa'sōn' (anc. *Noviodunum* and *Augusta Suessionum*): fortified town; in the department of Aisne, France; on the Aisne, 65 miles by rail N. E. of Paris (see map of France, ref. 3–F). It has manufactures of cloth and hardware, and an important trade in grain. Soissons has been many times captured in war, the last time in 1870 by the Germans. Pop. (1896) 12,373.

**Sojourner Truth**: lecturer; b. in slavery in Ulster co., N. Y., about 1775; discarded the name Isabella given by her master for that of Sojourner, claiming that the Lord had bestowed it in a vision, adding the appellation Truth because that was the substance of the message she felt impelled to deliver to men; was held in bondage even after the abolition of slavery in the State, but escaped. Although illiterate, her force of character, shrewd wit, and impressive voice made her an effective speaker, and she traveled widely in the northern parts of the U. S., advocating general emancipation, women's rights, temperance, and political reforms. D. at Battle Creek, Mich., Nov. 26, 1883. See *Narrative of Sojourner Truth* (1884).

**Sokoto'**: the largest of the HAUSA STATES (*q. v.*) in the Sudan, Africa; E. of the Niger river and S. of the Sahara Desert: separated from Lake Chad by the sultanate of Bornu. It is also known as one of the Fulbe states, because the conquering Fulbe long ago imposed their rule and the faith of Mohammed upon this and other vast regions in the Sudan. It is one of the most densely populated parts of Africa. Trade and manufactures are well developed, particularly the fabrication of leather goods, cotton cloths, and weapons, but the chief industries are agriculture and cattle-raising. To Sokoto proper belong many tributary states and districts, the largest of which is Adamawa, S. of the Benue river, besides Yakubu, Saria, Kano, Muri, Katsena, and Samfara, all of which pay annual tribute to the sultan. Here the slave-trade flourishes. A small standing army, chiefly cavalry, is maintained. The capital, Sokoto, has only about 30,000 people, and is less important in population and trade than several other towns, notably KANO (*q. v.*). C. C. ADAMS.

**Solana'ceæ**: See NIGHTSHADE FAMILY.

**Solan-goose**: See GANNET.

**So'lanine** [from Lat. *sola'num*, nightshade]: a natural organic alkaloid found in the black nightshade, potato, bittersweet, and other species of *Solanum*. The alkaloids obtained from these different sources are probably not exactly the same. Solanine is a solid crystalline substance, readily soluble in alcohol. It is very poisonous, producing paralysis of the lower extremities before death, as has been seen in cattle poisoned by eating the green shoots of potatoes, which contain solanine largely. Revised by IRA REMSEN.

**Solano**: See SIMOOM.

**Sola'num** [Lat., nightshade]: a genus of herbs and shrubs of the family *Solanaceæ*, most or all of which contain the poisonous principle solanine. The U. S. has several native species, mostly southern. There are a great many tropical species, some of them of great use in local therapeutics, though none is extensively employed in the medical practice of civilized lands except perhaps the *Solanum dulcamara*, or bittersweet. Several afford edible fruits, that of the egg-plant (*S. melongena*) being the most important. See NIGHTSHADE FAMILY. Revised by CHARLES E. BESSEY.

**Solar Cycle**: See CYCLE.

**Sola'rio**, ANDREA, da (called also *Andrea Milanese*): painter; b. at Solario, near Milan, Italy, about 1460. His method of painting indicates that he was influenced by Leonardo da Vinci, but nothing positive is known as to his teaching in art. He spent the years 1490–93 in Venice with a brother, Cristoforo, surnamed Il Gobbo (the hunchback), who was an architect and sculptor. In 1495 he had completed for S. Pietro at Murano an important altarpiece of a Holy Family with St. Jerome, now at the Brera at Milan. In 1507 he was decorating with frescoes for Charles d'Amboise the chapel of Château Gaillon in Normandy. Morelli supposes that Solario visited Flanders during the two years of his stay in Normandy, as his pictures have characteristics resembling those of the Flemish school. Andrea Solario died some time after 1515 while painting for the Certosa of Pavia an *Assumption of the Virgin*, now in the sacristy there. His best-known works are an *Ecce Homo* and a *Repose in Egypt* in the Poldi-Pezzoli Gallery at Milan, dated 1515; a *Vierge au Coussin vert*; a bust-portrait of Charles d'Amboise; a *Crucifixion* dated 1503; a *Head of John Baptist in a Charger* at the Louvre; and two portraits in the National Gallery of the London, both on panel. This painter is sometimes confounded with another Andrea di Milano, called Salai or Salaino, a pupil of Leonardo. W. J. S.

**Solar Parallax** [*solar* is from Lat. *sola'ris*, belonging or pertaining to the sun, deriv. of *sol*, sun]: the difference of the directions in which the sun is seen from the surface and center of the earth. (See PARALLAX.) The problem of determining the solar parallax is identical with that of measuring the distance of the sun, and has justly been called one of the noblest in astronomy. Attempts to estimate the distance of the sun were made even by the ancient astronomers Aristarchus and Ptolemy, but they were necessarily futile, since no observations they were able to make would measure so small a quantity as the parallax of the sun. Still they thought they measured the distance, and found it to be 1,210 radii of the earth. It is remarkable that even had the sun been as near as this, its apparent size would show its real diameter to be more than five times that of the earth. As soon as accurate observations were made with the telescope, it was found that the sun had no such parallax as it would have were its distance only 1,200 radii of the earth. At the time of Newton all that was known of the solar parallax was that it must be immeasurable with the instruments then at command.

To understand the modern solution of the problem, we must see how it presented itself to astronomers after the laws of the celestial motions were established. Imagine the sun with its retinue of eight large planets, the earth being one. As the earth revolves around the sun, astronomers see other planets in various directions, and can thus determine the annual parallax of each. In this way the ratios between the different orbits admit of very exact observation, and yet more exact determination by Kepler's third law. Thus there is no difficulty in making a map of the solar system in which all the orbits shall be laid down on the same scale. Without any knowledge of the actual distance of the sun, it can be said that if the distance of the earth be represented by unity, then that of Venus will be represented by 0·72333, that of Mars by 1·52369, that of Jupiter by 5·2028, etc. It follows from this that if any one of these distances can be determined, or even the distance of Venus or Mars from the earth at any moment, all the other distances will follow, including that of the earth from the sun, just as the knowledge of a single distance on a map will give the scale of the map. It will also be readily understood that the nearer a planet comes to the earth the greater will be its parallax, and the more easily will its distance be determined. Moreover, observations on the position of a planet can be made with much more accuracy than on the sun. Thus French astronomers of the seventeenth century saw that if the apparent position of the planet Mars among the stars could be carefully observed from two distant points of the earth's surface, its parallax, and thus its distance, and the distance of the sun, could be determined. An expedition was sent for this purpose to the colony of Cayenne in South America, to make observations of the position of Mars during the opposition of 1672. Corresponding observations were made at the Paris Observatory. By a comparison of all the observations, Cassini computed the parallax of the sun to be 9·5″. The error of this result is only about one-twelfth of its entire amount, so that this may justly be regarded as the first actual determination of the solar parallax. The corresponding distance of the sun would be 21,600 radii of the earth, or about 85,000,000 miles.

In 1849 Capt. James M. Gillis, of the U. S. navy, who was afterward superintendent of the Naval Observatory, made an expedition to Chili, for the purpose of observing the parallaxes of both Venus and Mars; but the two oppositions of Mars which occurred while he was there were not favorable, the planet being too far from the earth, and in addition to this the corresponding number of observations were not made in the northern hemisphere. No satisfactory result could therefore be reached.

Attempts to determine the parallax of Mars were not made between 1672 and 1849, because it was supposed that a much more accurate parallax could be determined by observations on transits of Venus. It occurred to Halley, the English astronomer, as far back as 1677, that the time required by the planet Venus to cross the disk of the sun in transit would be different at different parts of the earth, owing to the effect of the parallax of the planet. It was necessary, however, to wait nearly a hundred years for an opportunity of making such an observation, as no transit of Venus occurred from Halley's time until 1761. Then a transit occurred, and another in 1769. Expeditions to the southern hemisphere were sent out by various European nations, and these transits were observed wherever astronomers could see them. The results, however, were found to be much less accordant than had been anticipated, and the uncertainty of the observations thus shown was so perplexing that more than half a century elapsed before the results were definitively worked up. The German astronomer Encke, from an exhaustive discussion of all the observations, reached the conclusion that the sun's parallax was 8·5776″, a result now known to be too small by about 0·20″.

It is now found that the most accurate measures of the parallax can probably be made on the small planets between Mars and Jupiter. It is true that these bodies do not come so near the earth as either Venus or Mars, and the quantity to be measured is never so large as in the case of these planets; but this defect is more than compensated by the extreme accuracy with which the measures can be made. Dr. David Gill, astronomer at the Cape of Good Hope, has brought this method into use with great success.

Modern science has shown that there are other methods of determining the sun's distance and the dimensions of the solar system besides that of actually measuring the parallaxes of the planets. One of these consists in determining the velocity of light. The phenomena of aberration show that there is a certain ratio between the velocity of light and the velocity of the earth in its orbit. This ratio is such that the velocity of light is a little more than 10,000 times that of the earth around the sun, and from this it follows that light takes about 498 seconds to pass from the sun to the earth. It follows that if it can be determined how many miles per second light travels, the distance of the sun can be at once obtained by multiplying this number by 498. This determination has actually been made with a high degree of precision. (See LIGHT.) Unfortunately, the constant of aberration has not yet been determined with corresponding exactness, owing to the inherent difficulties in the way of measuring so small a quantity, and especially owing to the fact that measures made six months apart have to be compared to determine it.

Yet a third method of determining the sun's distance is founded on the theory of gravitation. The action of the sun in changing the motion of the moon around the earth will be slightly different, according to its distance. The difference is such that an inequality of about two minutes in the motion of the moon arises from this cause; but this inequality is very difficult to determine from observation, because the measures have to be made near the first and last quarters of the moon. Owing to the different ways in which the light of the sun falls on the moon these measures are not strictly comparable with each other, and thus arises an uncertainty which has not yet been completely eliminated.

How numerous the attempts are to determine the distance of the sun in these various ways will be seen from the following *résumé*, which gives a synopsis of some of the principal independent results so far worked out.

In 1824 Encke published his celebrated works on the transits of Venus in 1761 and 1769, in which he concluded that the sun's parallax was 8·5776″.

In 1854 Hansen found from the sun's action on the moon that Encke's parallax was too small. He did not reach a definite conclusion as to the exact amount of the increase until 1863, when he computed the parallax to be 8·916″.

In 1858 Le Verrier, from observations of the sun, found that the parallax was 8·95″.

In 1862 observations of Mars were made at several of the leading observatories in both hemispheres. From a computation of some of these, Stone found a parallax of 8·943″, and from those made at Pulkowa and the Cape of Good Hope Winnecke derived 8·964″. The close agreement of these results with those of Hansen and Le Verrier led to a general belief among astronomers that the true value of the parallax was between 8·9″ and 9·0″.

In 1867 Newcomb discussed all the observations of Mars made in 1862, and combined with the result a revision of the methods of Hansen and Le Verrier. His conclusion was that in the then state of astronomy the most likely value of the parallax was 8·848″. This result was so much smaller than others that it was received with distrust, but it was nevertheless adopted in the national ephemerides of the U. S., Germany, and Great Britain. In 1877, however, Gill, of England, made his well-known expedition to Ascension island, for heliometer measures on Mars, from which he concluded that Newcomb's result was much too large, and that the true value was 8·78″. About the same time Sir George Airy announced that the British observations of the transit of Venus in 1874 gave the surprisingly small result of 8·76″; but Capt. Tupman, from a more complete discussion, afterward raised the result to 8·813″.

In 1884 Newcomb, from observations of the velocity of light, combined with Nyren's determination of the constant of aberration, reached the result 8·794″.

In 1890, he rediscussed the transits of Venus in 1761 and 1769, and found for the parallax 8·79″.

In 1891 Harkness, from a general adjustment of astronomical constants, in which the parallax from the American photographs of the transits of Venus was included, concluded that the most probable value of the parallax, from all available data, was 8·809″.

Toward the end of 1891 Auwers, from the German heliometer measures of the transits of Venus of 1874 and 1882, found 8·87″.

Recent careful examinations of the data on which these results depend reduce their discordance, and lead to the conclusion that the value of the parallax is probably between 8·780″ and 8·790″. This gives, in round numbers, 93,000,000 miles for the distance of the sun, a result which is probably correct within 100,000 miles. S. NEWCOMB.

**Solar System**: the sun and the bodies which revolve around it as their center of motion. The main features of this system are the great mass of the central body, which is between 700 and 800 times the total mass of all the bodies which revolve around it; the orderly arrangement of the principal bodies of the system, which revolve around the sun in a fairly regular progression of distances, and in nearly circular orbits; and the complete isolation of the system from all the other bodies of the universe, the nearest fixed star being about 9,000 times the distance of the farthest planet.

The bodies which compose the system may be classified as follows:

1. The great central body, the sun.
2. The four inner planets, Mercury, Venus, the Earth, and Mars.
3. A group of several hundred minor planets, or asteroids, revolving outside the orbit of Mars. It is impossible to say how many bodies there are in this group; the number known is more than 400. See ASTEROID.
4. The four outer planets, Jupiter, Saturn, Uranus, and Neptune. These, with the four planets first named, are called *major planets.*
5. Twenty-one satellites revolving around the planets, of which one belongs to the earth, two to Mars, five to Jupiter, eight to Saturn, four to Uranus, and one to Neptune.

To these may be added an unknown number of comets, which may, if we choose, be considered as belonging to the system; and numerous clouds of meteoric particles, invisible in themselves, the presence of which is made evident by their combustion when they strike the atmosphere, forming shooting stars.

Considering these bodies in the order of their masses and influence upon other bodies, the first place must, after the sun, be assigned to the eight major planets. The principal features of the orbits of these bodies are their near approach to circles, and the fact that they lie nearly in the same plane. The most eccentric of their orbits is that of Mercury; yet the eye could scarcely distinguish its deviation from a circle, though it could readily perceive that the sun was not situated in the center of the circle. It is also the planet whose orbit is most inclined to the ecliptic, the inclination being 7°. See PLANET and ORBIT, and the names of the several planets.

The principal elements of the planetary orbits are shown in the following table:

TABLE OF THE PLANETARY ELEMENTS.

| PLANET. | Apparent semi-dia. | Diameter in miles. | Mass (⊙ = 1). | Density (earth = 1). | Diurnal revolution. | Mean distance from ⊙. | | Periodic time (days). | Eccentricity. | Longitude of perihelion. | Inclination of orbit. | Longitude of node. |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | | | h. m. s. | In astronomical units. | In millions of miles. | | | ° ′ ″ | ° ′ ″ | ° ′ ″ |
| Mercury | 3·30″ | 2,955 | $\frac{1}{6000000}$ | 1·25 | 24 5 0 | 0·387099 | 36 | 87·96926 | 0·2056048 | 75 7 14 | 7 0 7·7 | 46 33 9 |
| Venus | 8·50″ | 7,610 | $\frac{1}{408000}$ | 0·875 | 23 21 24 | 0·723332 | 67 | 224·700787 | 0·0068433 | 129 27 14 | 3 23 34·8 | 75 19 52 |
| The Earth | 8·83″ | 7,912 | $\frac{1}{330000}$ | 1·000 | 23 56 41 | 1·000000 | 93 | 365·256358 | 0·0167711 | 280 21 22 | 0 0 0·0 | |

S. NEWCOMB.

**Solder** [(with *l* reinserted by analogy of Lat. *solida're*) from O. Fr. *souder*, to solder < Lat. *solida're*, *solda're*, make solid, fasten, deriv. of *so'lidus*, *sol'dus*, solid]: an alloy employed to unite pieces of metal by fusion upon the proposed joint. There are many solders, each designed for some special use. Three grades of solder are in common use: common solder, of equal parts of tin and lead; fine solder, of 2 parts of tin to 1 of lead; and a cheaper article, of 2 of lead to 1 of tin. The soft solders are usually of lead and tin, or lead, tin, and bismuth; these melt at a low temperature. The hard solders can not be melted at a low temperature; they are commonly of zinc and copper.

**Sold Note**: See BOUGHT NOTE.

**Sole** [viâ O. Fr. from Lat. *so'lea* (so named from its broad flat shape), liter., slipper, whence Eng. *sole* (of a shoe or of the foot)]: a flatfish of the family *Soleidæ*. The common sole, *Solea solea*, has the scales ctenoid, the vertical fins not confluent, the pectorals of both sides developed; it is dark brown on its upper and white on its lower side, with the pectoral fin blackish at its end; it generally ranges between 10 and 20 inches in length, and between 1 and 10 lb. in weight, although the latter dimensions are rarely attained. It is found along almost the entire coast of Europe, and is one of the most esteemed of fishes; the flesh is white and firm, and is in season in all months of the year except the spawning-time, which takes place toward the end of winter. It is chiefly taken on the coasts of the British Islands by trawling. Several attempts have been made by the Fish Commission to introduce it into U. S. waters. Another species found on the British coast is the *Solea* (*Pegusa*) *aurantiaca*, or lemon-sole. *Achirus lineatus* of the Eastern U. S. is the nearest American ally of the European species, but this is more popularly known as the hog-choker, coverclip, or calico; it is a worthless fish. In California several species of true *Pleuronectidæ*—e. g. *Parophrys vetula*, *Lepidopsetta umbrosa*, *Psettichthys melanostictus*, and *Orthopsetta sordida*—are called soles. Revised by F. A. LUCAS.

**Sole'idæ** [Mod. Lat., named from *So'lea*, the typical genus. See SOLE]: a family of flatfishes (*Heterosomata*). The body is oblong or elongated, and nearly equally developed above and below the lateral line; the scales are small, or absent; the lateral line mostly straight (sometimes double or triple); the head small, and with a rounded projecting snout, and more or less hooked upper jaw; the eyes are approximated, and the upper is further forward than the lower; the opercula concealed by the scales; the mouth unsymmetrical, and rather small and curved; teeth generally confined to the blind side of the jaws, and villiform (sometimes wanting); branchial apertures restricted above; the dorsal begins on the snout, the anal under the pectoral fin; pectorals small or (in some genera) absent; ventrals small and variously developed. The vertebræ are very numerous, but unequally distributed, in the typical forms the abdominal or rib-bearing ones being only eight or nine in number, and the caudal about forty. The family is well distinguished by the physiognomy from the *Pleuronectidæ*, especially so far as the European and American species are concerned, but some Australian types lessen the distance between them. Species are most abundant in the tropics, but are found in every sea except the extreme polar ones.
Revised by F. A. LUCAS.

**Solemn League and Covenant**: See COVENANT, NATIONAL.

**Solenocon'chæ** [Mod. Lat.; Gr. σωλήν, channel, pipe + κόγχη, shell]: the *Scaphopoda*, or tooth-shells, in allusion to the tubular nature of the shell. See MOLLUSCA.

**Solenogas'tres** [Mod. Lat.; Gr. σωλήν, channel + γαστήρ, belly]: an order of shell-less molluscs, embracing a few forms from the deep seas. They are of interest to zoölogists as being very simple and primitive forms. See MOLLUSCA.

**Solenog'lypha** [Mod. Lat.; Gr. σωλήν, channel, pipe + γλύφειν, carve, cut]: a sub-order of snakes. The maxillary bones are excessively shortened, and thereby assume a vertical aspect, and are thus adapted to support the venom-fangs; the fangs (except in *Causus*) are competely tubular; the pupils of the eyes are generally erect and elliptical; the occipital region is scaly. The sub-order includes the most poisonous and dreaded snakes of America; some equally dangerous in the Old World belong to the sub-order *Proteroglypha*. By Cope four families are recognized—viz.: (1) *Crotalidæ*, including the rattlesnakes and copperheads; (2) *Viperidæ*, typified by the vipers of Europe and Africa; (3) *Causidæ*; and (4) *Atractaspididæ* of Africa.
Revised by J. S. KINGSLEY.

**Soleure**, sō'lėr' (Germ. *Solothurn*): canton of Northwestern Switzerland; area, 302 sq. miles. The surface is covered by offshoots of the Jura Mountains, which here are very rich in iron and marble. The soil is fertile, and produces more corn and wine than is demanded for home consumption. The rearing of cattle, sheep, and swine is extensively carried on. Manufactures are confined to iron goods, glassware, and watches. Pop. (1894) 89,290, of whom 74 per cent. were Roman Catholics and the rest Protestants; they all speak the German language. The chief town is Soleure (Lat. *Solodurum*); pop. (1888) 8,460.

**Solfeggio**: See SOLMIZATION.

**Solferino**, sōl-fā-ree'nō: village of Mantua, Northern Italy; celebrated for the battle in which the French, under the command-in-chief of Napoleon II., and the Sardinians, under Victor Emmanuel, utterly defeated the Austrians (June 24, 1859) (see map of Italy, ref. 3–C). It was the decisive battle of the war of Italian independence. The forces of the allies numbered about 150,000, while the Austrians brought about 170,000 into the field. After their defeat the latter retreated toward Verona and left all Lombardy open to the allies. Napoleon, not caring to attack the strong position that the Austrians held in the Quadrilateral, concluded the truce of Villafranca.

**Soli**: See CILICIA.

**Solicitor** [in form viâ O. Fr. from Lat. *sollicita'tor*, deriv. of *sollicita're*; in meaning deriv. of Eng. *solicit* (in its legal sense), from Lat. *sollicita're*, urge, entice; *sol'lus*, whole + *cie're*, *ci'tum*, move]: in Great Britain (under the present statutes), an officer of the Supreme Court of Judicature who, and who only, is entitled to sue out any writ or process, or begin, or carry on, solicit, or defend any action or other proceeding in any court, his official title being solicitor of the Supreme Court.

Formerly the term solicitor was applied only to those who conducted such business in the court of chancery, the corresponding terms in the common-law courts being ATTORNEY (*q. v.*), and in the ecclesiastical and admiralty courts PROCTOR (*q. v.*); but it was the general practice to be admitted both as solicitor and attorney. The Scotch term corresponding to solicitor is *law-agent*, and the act regulating the admission to practice the privileges, etc., of law-agents is the Law-agents' Act, 1873 (36 and 37 Vict., c. 63). The solicitor is distinct in Great Britain from the counsel or barrister (called advocate in Scotland), not only as to the work performed by him for his client, but also as to the requirements for his admission to practice and his relations to his clients. These matters are minutely regulated by statute.

The Solicitors' Act of 1843 provides that with certain exceptions no person shall be admitted as solicitor or attorney unless he has served as an articled clerk for five years to a practicing attorney or solicitor, or in case of a person having a university degree three years, or has been previously admitted to the bar, or has been ten years clerk to an attorney previous to being articled. No solicitor is allowed to have articled clerks except when practicing, nor more than two at any time; and the clerk may not engage in any other employment without the consent in writing of the solicitor and the sanction of a judge of the high court. Examinations must be passed at times and upon subjects fixed in accordance with statutes.

A solicitor, unlike a barrister, is liable to his client for negligence in the conduct of his case; and may sue his client for his remuneration, and has a general lien for his costs on his client's papers. The remuneration of solicitors in conveyancing and other noncontentious business is fixed by law with "reference to such matters as the amount of money to which the business relates, and the skill, labor, and responsibility involved on the solicitor's part." He, being an officer of the court, is subject to the summary jurisdiction of the court for professional misconduct, etc.

Solicitors can not practice as advocates in the upper courts, but may before magistrates at petty sessions and quarter sessions where there is no bar, in county courts, at arbitrations, at judges' chambers, coroners' inquests, revising barristers' courts, under-sheriffs' and secondaries' courts, and the court of bankruptcy. He must, under a considerable penalty, take out a yearly certificate authorizing him to practice. See Cordery's *Law Relating to Solicitors* (2d ed. London, 1888); Turner's *Duties of Solicitor to Client* (London, 1884); Begg on *Law Agents*. F. STURGES ALLEN.

**Sol'idus**: the later Latin name for the Roman gold coin called *aureus*. It received this name first in 296 when Diocletian reformed the currency, and it retained its full weight and purity, seventy-two being struck to the pound, as long as the empire lasted. It was adopted by the Franks, under the Merovingians and Carlovingians, but was suppressed by Pepin. Afterward a solidus of silver (*solidus argenteus*), which weighed one-twentieth of a pound, was coined. This, in later times, under the name of solidus, sol or sou, underwent a number of changes in composition and value. In 1793 the sou was abolished in France, but the name has been retained by the equivalent coin of five centimes. The *soldo*, a coin formerly struck in some parts of Italy, and generally of about the same value as a sou, is also, in name at least, an historical representative of the solidus. In the Middle Ages the solidus denoted a money of account, and was translated into the Teutonic languages by the word shilling or its equivalent. It thus survives in the abbreviation *s.* of £ *s. d.*

**Solif'ugæ** [from Lat. *sol*, sun + *fu'gere*, flee, fly]: a group of spider-like animals, in which the head is distinct from the three-jointed thorax, and the abdomen is elongate and plainly segmented. The body is usually densely haired. The first pair of appendages ends in large pincers, the second pair are leglike. These animals, which live in the warmer parts, and especially the desert portions, of both hemispheres, breathe by means of tracheæ. They have the name of being very poisonous, especially in the Old World, and are correspondingly feared. There are about sixty species, distributed among some fifteen genera, of which *Solpuga* and *Galeodes* are best known. J. S. KINGSLEY.

**Solimões**, sō-lē-mois', or **Solimoens**, sō-lē-moiñs': the Brazilian name for the middle Amazon, from the Peruvian frontier to the junction of the Rio Negro. It was originally the name of an Indian tribe. See AMAZON.

**So'lingen**: town of Rhenish Prussia; 13 miles E. of Düsseldorf; famous for its manufactures of iron and steel goods, especially sword-blades, in the Middle Ages, and still an important center for such manufactures, especially of cutlery (see map of German Empire, ref. 4–C). In the district are about 3,700 metallurgical establishments, which employ 30,000 workmen. In the town, besides the large factories, there are 2,000 small forges and shops. Pop. (1895) 40,843.
Revised by M. W. HARRINGTON.

**Soli'nus**, GAIUS JULIUS (surnamed GRAMMATICUS): historian; lived in the first half of the third century, and wrote *Collectanea Rerum Memorabilium Polyhistor*, in which he gives a brief sketch of the world as it was known to him, accompanied with historical notices and remarks on the origin, habits, religious rites, and social conditions of the various nations. The greater part is derived through an intermediate source from the *Natural History* of Pliny and Pomponius Mela, and has no independent value. In the Middle Ages the book was much read. There are editions by Salmasius (1689) and by Mommsen (Berlin, 1864), and an English translation by Golding (1587).
Revised by M. WARREN.

**Solís**, sō-lēēs', JUAN DIAZ, de: navigator; b. probably at Lebrija, Asturias, Spain, about 1470. Of his early voyages nothing definite is known, but Varnhagen considered it probable that he was on the Brazilian coast with Gonçalo Coelho in 1503. In 1506 he was associated with Vicente Yañez Pinzon in an exploration of the coasts of Honduras and part of Yucatan; and in 1508, again with Pinzon, he followed down the eastern side of South America to lat. 40° S., entering the Bay of Rio de Janeiro, and passing the Plata without exploring it. In 1512 he was appointed chief pilot of Spain, succeeding Vespucci. In this capacity he was employed to seek a southwestern passage to the East Indies, sailing from Lepe with three vessels in Oct., 1515. Entering the Plata, he explored it for some distance, but, landing on an island, was killed by the Charruas Indians; the ships then returned to Spain. The Plata was for some time called Rio de Solís, though it is probable that Solís was not its first explorer. HERBERT H. SMITH.

**Solís y Ribadeneyra**, -ee-rēē-bāā-dā-nā'i-rāā, ANTONIO, de: author; b. at Alcalá de Henares, Spain, July 18, 1610. He studied law at Salamanca, and early became known as an author of poems and dramas; these brought him the friendship of Calderon, and the protection of the Count of Oropesa, who made him his secretary; later he was chief clerk of the Secretary of State, and in 1654 was made secretary to Philip IV. In 1666 he was appointed historiographer of the Indies; soon after he took orders, and his subsequent writings are mainly on historical subjects. His fame rests principally on the *Historia de la Conquista de México* (1st ed. 1684), which is one of the Spanish prose classics, and was translated into French, Italian, and English. Aside from its literary merits it shows little profundity of research, and is disfigured by bigotry and by the long imaginary speeches of the principal characters. It is the first connected history of the conquest. D. in Madrid, Apr. 19, 1686. H. H. S.

**Solitaire**, sol-i-tãr [= Fr., liter., solitary < Lat. *solita'rius*, deriv. of *so'lus*, alone]: the *Pezophaps solitaria*, a bird related to the DODO (*q. v.*), formerly inhabiting the island of Rodriguez. François Leguat, who was one of a colony of Huguenots who settled on the island in 1691, describes the solitaire in his *Voyages et Aventures*, and gives a wood-cut representing it. Numerous remains of the solitaire have been found. It was larger than the turkey, and did not use its wings for flight. It was a slow runner and defended itself with its wings and beak. Its flesh was good to eat.

**Solmization, Solfeggio**, or **Solfaing** [*solmization* is from Fr. *solmisa'tion*; *sol* + *mi*, notes of the scale; *solfeg'gio* = Ital., deriv. of *solfa*, the scale; *sol*, sol + *fa*, fa]: in music, the art of giving to each of the seven notes of the scale its proper sound or relative pitch. The acquiring of a true intonation of the scale, first by regular gradation upward and downward, and then by skips from one degree to another, is an object of primary importance in vocal music. To facilitate this, various expedients have been devised, but chiefly the association of the several sounds with articulate utterances, such as the numeral words, *one*, *two*, *three*, etc. Many centuries ago certain syllables, void of any special meaning, but containing the several vowel-sounds, were selected for this purpose, and are in general use. See GAMUT.
Revised by DUDLEY BUCK.

**Solmo'na** (Lat. *Sulmo*): town; in the province of Aquila degl' Abruzzi, Italy; in the plain S. W. of Chieti (see map of Italy, ref. 5–F). The cathedral and the Church of the Annunziata are noteworthy. It is the birthplace of Ovid. Pop. 14,170.

**Sol'omon** [from Heb. *Shᵉlōmōh*, liter., peaceable]: the son and successor of David, King of Israel. His name was given with reference to the peace which, it was promised, should attend his reign (1 Chron. xxii. 7–10). As the recipient of Jehovah's especial promise to the eternal line of David (2 Sam. vii.) he was also named Jedidiah, beloved of Jehovah (2 Sam. xii. 24, 25). His mother was Bathsheba, who had been the wife of Uriah, his birth occurring a considerable time after David's repentance for that worst of sins, his conduct in the matter of Uriah. In 1 Chron. xxiii. 1–xxix. 22a is an account of Solomon's being made king, followed (verses 22b–25) by an account of his being made king "a second time," this second account being clearly a condensation of the narrative in 1 Kings i. Apparently the first coronation occurred at or near the close of the fortieth year of David (his last year but one), and just before the outbreak of Absalom's rebellion (1 Chron. xxvi. 31; 2 Sam. xv. 7). At all events this interpretation gives a consistent meaning to the biblical data, while the different interpretation commonly received makes them inconsistent and unintelligible.

Solomon began his reign humbly and wisely, asking God for wisdom, which was granted. In his fourth year he began his great work, "the house of the Lord," for which David had laid plans and accumulated enormous treasures. It was completed and dedicated seven years later. This was but the beginning of his achievements as a builder. Among the structures attributed to him are his own palace, "the House of the Forest of Lebanon," and his wonderful throne, together with cities, fortifications, stations for commerce, reservoirs, and aqueducts. He also engaged in husbandry and in landscape-gardening. He peacefully consolidated the kingdom which his father had conquered. He reorganized and enlarged the civil service of David. He started the hitherto pastoral or agricultural Hebrews on the new road of commerce, sending ships to "Ophir," India, and Arabia in the East from the new-built port of Ezion-geber on the eastern arm of the Red Sea, and from Jaffa and Tyre, westward to "Tarshish" in Spain. Many kings were his tributaries; untold wealth and the wonders and curiosities of many countries flowed into or through the land. Many foreigners were attracted by his splendor and wisdom, notably the Queen of Sheba, with her marvelous retinue. His harem grew to number 1,000 inmates, and thus to accord with Oriental ideas of his royal magnificence. He appears as a person of fascinating beauty and grace, impetuous, generous, sympathetic, and at first humble; of fine humor and noble intellect, a man of broad views, a far-sighted statesman, most learned in the science of the day. He was an organizer of splendid executive powers, a great builder and artist, poet, philosopher, and had from the Lord preeminently "an understanding heart to judge." Unfortunately, there is another side to the picture. From motives of state policy Solomon married the daughter of Pharaoh of Egypt and many other wives from among the princesses of his tributary kingdoms. This led to latitudinarianism in religion, to extravagance in public expenditures, to oppression and disregard of human rights. The result was that his reign was partly a failure. Before his death Edom and Syria revolted and Jeroboam raised rebellion in Northern Israel. After his death the ten tribes revolted, so that the strictly Israelite portion of his kingdom was divided, while the tributary peoples fell away from their allegiance.

Revised by W. J. BEECHER.

**Solomon ben Gabirol′** (Arab. *Abu Ayyūb Sulaimān ibn Jabirol*; Lat. *Abi-gebrol, Avicebrol, Avicebron*): Jewish philosopher and poet; b. in Cordova, Spain; lived for a time at Saragossa; d. about 1041. His chief poem is the hymn *Kether Malkuth* (Crown of Royalty), a philosophical explanation of Jewish doctrine. His chief prose work, written in Arabic, is the *Source of Life*, in which "the theories of Plotinus are developed and the will plays a part almost as it does in the system of Schopenhauer." This work was freely used by Christian writers in the Middle Ages; the discovery of the identity of the author with Gabirol was made by Munk. Gabirol also wrote a work on ethics. See Steinschneider, *Hebr. Uebersetz. im Mittelal.* (vol. i., § 219); Stössel, *Sol. ben Gabirol als Philosoph* (Leipzig, 1881); Dukes, *Solomon ben Gabirol* (Hanover, 1860); Guttmann, *Die Phil. des Ibn Gabirol* (Göttingen, 1889).

RICHARD GOTTHEIL.

**Solomon ben Isaac**: See RASHI.

**Solomon** (Germ. *Salomon*) **Islands**: an extensive archipelago E. of New Guinea, from which it is separated by the Bismarck Archipelago and Louisiade islands. It extends in a line S. E. and N. W. from about lat. 4° S., lon. 154° E., to lat. 12° S., lon. 162° E., and consists of seven large islands and very many small ones. The islands forming the northern half of the archipelago were taken under German protection in 1886. The largest of these are Bougainville (pop. 10,000), Choiseul (5,850), and Isabel (5,840). The total area of the German Solomon islands is 8,708 sq. miles, with a pop. of 89,000. The remainder of the archipelago has an area of 8,357 sq. miles and a population of 87,000. It was brought within the British protectorate in June, 1893. The inhabitants are Papuan and Polynesian, the latter living especially on the smaller islands, where the population is often very dense. They are intelligent, quick, and crafty, but make good servants, and are in demand on the Bismarck Archipelago as laborers. They are cannibals; their weapons consist of the bow and arrow, spear, and club, which are all characterized by fine finish. Their canoes are the finest in the Pacific. The islands are essentially volcanic, but are surrounded by coral reefs. They were discovered in the sixteenth century, but were lost sight of until 1767, when they were rediscovered by Carteret. They are still the least-known group of the Pacific. See *Voyages* of Dalrymple, Hawkesworth, Fleurien, Labillardière, Dumont d'Urville, Brenchley, and Wood; Wallace, *Australasia*; and Woodford, *A Naturalist among the Headhunters* (1890).

MARK W. HARRINGTON.

**Solomon, Song of**: See CANTICLE.

**Solomon's-seal**: any one of the liliaceous herbs of the genera *Polygonatum*, *Vagnera*, and *Unifolium*. They are found in Europe and North America. The roots are popularly esteemed as a vulnerary, and have some use in domestic medicine. The name properly belongs only to the species of *Polygonatum*; the "seal" is the circular depressed scar left on the root-stock by the death and separation annually of the flowering stem. The common Solomon's-seal, *Polygonatum multiflorum*, is found in woods and copses in many parts of England, and also in a few places in Scotland. It has a stem about 2 feet high, the upper part of which bears a number of large, ovate-elliptical, alternate leaves in two rows. The flower-stalks are generally unbranched; the flowers, which are not large, are white and drooping.

**Solomon's Temple**: See JERUSALEM.

**Solomon, Wisdom of**: See WISDOM, BOOK OF.

**So′lon**: statesman, sage, and poet; the son of Execestides; filled the office of first archon in Athens (Ol. 46, 3; B. C. 594), and in that capacity established there the constitution framed by him. He is the noblest representative of the many-sidedness which distinguished the Athenian more than all other Hellenes. An Eupatrid by birth, he engaged also in trade and commerce by sea. By this means it was possible for him, after finishing all exercises, as well in music and poetry as in gymnastics, to become acquainted with the entire coast of the Archipelago. It was a time of fermentation in society: Psammetichus had opened the Nile region to the Greeks (B. C. 666); the first money had been coined in Ægina; navigation took all at once a gigantic stride forward; young adventurers gained in a few years great riches, and those parts of the communities engaged in trade took form as a new middle class, and stood defiantly opposed to the ancient families; property in land was outstripped by movable capital; around Athens on all sides—in Argos, Corinth, Sicyon, Megara—the old system of things had been broken, the ruling families had been overthrown, and through the downfall of the constitutions single tyrants had come to power, who shone by their riches, employed mercenary troops, and pursued a narrow policy of self-aggrandizement. In this revolutionary time, spite of all splendor, the best possessions of the nation were endangered—namely, the free citizen class and the sovereign authority of the law. For this reason Solon deemed it the work of his life to give his native city the benefit of all progress in culture which the times offered, without causing her to break with the past and be exposed to the deplorable evils connected with a revolution. A written criminal code, such as Dracon had issued (B. C. 621), was not able to supply the want; a thorough, peaceful reform of the state was needed, which should reconcile the differences which tore the communities asunder. For a moral and political renovation of the state was needed more than all else a vigorous self-consciousness. The Athenians, however, were feeling depressed; Megara held possession of Salamis, and was consequently mistress of the sea: the Athenians were like captives in their own land, and in deep despondency had renounced their own islands on the coast. Inflamed by Solon's inspiring poetry, they conquered Salamis (about 604). This was a turning-point for the history of Greece. From that day Megara sank, and Athens rose resistlessly to power.

Solon was the first man in Athens; he was at liberty to secure for himself absolute power for life, but it was his firm resolve to accomplish his purpose without any violation of law. As recognized mediator between all parties, and solely by the force of his genius, his impressive words, and his pure personality, he carried out the most important reforms, applying them to the evils of society at the very root. The radical evil was that the small landowners were hopelessly in debt. Owing to a hard debtor-law, they forfeited even their freedom; a wretched proletariat was thus formed, and the land fell more and more into the hands of the great capitalists. Solon caused Athens to alter its standard of coinage (probably after the example of Corinth) by adopting also for silver the Eubœan gold standard. The result was a lighter drachma, in which debts could be legally paid, so that the poor obtained a relief of 27 per cent. Other measures of alleviation were also introduced: the debtor-laws were made milder, and fixed limits set to the acquisition of large estates; and the surprisingly great success of this legislation (Seisachtheia) in lightening the burdens of the people is most plainly attested by the glorious poem of Solon, in which he calls Mother Earth to witness that she has been happily freed from the burden of many pawn-pillars (which were set up in the ground as tokens of alienated lands). Then followed the great political reform —the conversion of the state, ruled by families, into a timocracy. It seemed to the noble families only a new guaranty of their privileges that none could hold office as archons except the members of the first class, the Pentakosiomedimni (with a minimum of 500 bush. of barley net income, corresponding to a taxable capital of 6,000 drachmæ or one talent), while the citizens of the second class, the knights, with 300, and those of the third (Zeugitæ), with 150 medimni as minimum of each year's income, had access to the council and to the remaining offices. The mass of the people, the Thetes, who did not belong to the three classes, could not become members of the council nor fill any office, but took part in the public assemblies. No one, therefore, was excluded from public life, and even the meanest helped frame the laws which he had to obey. The prerogatives of the first class were also no longer dependent upon birth, but could be forfeited by a careless domestic economy, and won by others through industry. The love for agriculture was encouraged, the worth of landed property was increased, and even commoners could take full share in the management of public affairs if they reached that degree of prosperity which seemed necessary for the attainment of culture and independent leisure. In law, the important reform was carried through that the archons could no longer render final decision in suits, but that appeal to the commonwealth could be made in every case. The statutes by which the sacred, public, and private law was administered were inscribed on wooden frames with three or four sides, and brought to the notice of all. On private life also the laws took a firm hold: they emancipated the citizen from the family; they gave to the head of every household the free disposal of his acquired property; they allowed the claims of aged parents on their children for maintenance only on the condition that they had given them a careful education; they checked the luxurious adornment of tombs and extravagant display in the dirges for the dead.

In all his reforms Solon's purpose was to purify the public morals, banish all barbarous influences, and bring to perfection whatever was peculiarly Hellenic. He united religion, state, and house in a harmonious whole; every citizen was made responsible for the commonwealth, and on the other hand the prosperity of the state was based upon the stability of the family. The legislation of Solon is the greatest work of art which political wisdom has produced, the clarified expression of the Athenian consciousness—a work based upon the needs of the times, inasmuch as Solon gave a place in his laws to whatever of good had struggled to the light in the time of the tyrants, while he avoided violence and lawlessness like theirs. It is true that Solon's external success was slight, and he himself was to live to see a tyranny in Athens, but his laws remained in force; they protected the city like a palladium, and up to the latest times the Athenians found their better self in Solon's laws.

After the decisive year of office, during which he ruled Athens with dictatorial power, Solon is said to have traveled ten years in foreign countries. Solon lived retired in Athens until his death (about Ol. 55, 2; 559 B. C.), surrounded by a narrow circle, of whom Mnesiphilus, the teacher of Themistocles, was one. ERNST CURTIUS.

Revised by J. R. S. STERRETT.

**Solor′**: an island of the Malayan Archipelago, off the eastern extremity of Flores, in lat. 8° 47′ S., lon. 123° 8′ E. Area, 105 sq. miles. Pop. 15,000, mostly engaged in fishing and trading. Sulphur and edible birds' nests are the principal articles of exportation. The inhabitants are Malays, partly Mohammedans, partly Christians. The name is also applied to the small archipelago to which this island belongs. It contains two other larger islands—Adenara and Lomblem. Area of the group about 1,250 sq. miles. Pop. variously estimated at from 40,000 to 180,000.

Revised by M. W. HARRINGTON.

**Solothurn**: Swiss canton. See SOLEURE.

**Solo′viev**, SERGEĬ MIKHAĬLOVICH: historian; b. in Moscow, Russia, May 5, 1820; d. Oct. 4, 1879. During his life he was connected with the University of Moscow, where he studied, taught, and in 1871 was made rector, but resigned in 1877, owing to difficulties with the authorities. His writings are numerous; his *History of the Relations between the Russian Princes of the House of Rurik* (1847) laid down the principles of the modern school of historians just coming in from Germany; his *Historical Letters* (1858), his *History of the Fall of Poland* (1863), his *Schoolbook of Russian History* (7th ed. 1879), and others are of value, but his great work was his *History of Russia*, begun in 1851. He lived to complete twenty-nine volumes, carrying it down to the year 1774. It is a mine of information, clear and impartial, but unsuited for popular use. A. C. COOLIDGE.

**Solstice** [viâ O. Fr. from Lat. *solsti′tium*; *sol*, sun + *-stitium*, a standing, deriv. of *sta′re*, *sta′tum*, stand, stand still]: The inclination of the earth's equator to the ecliptic or plane of its annual motion about the sun is the cause that the latter is during half the year on the northern polar side of the equator, the other half on the southern, causing the vicissitudes of summer and winter to the respective hemispheres. The distance from the sun N. or S. of the equator (see DECLINATION) is thus constantly varying. The two points at which this apparent northern or southern motion ceases (or at which its progressive increase of declination appears to be arrested) are the summer and winter solstices. At these periods the day is the longest or shortest, according as the earth is in the summer (June 21) or winter (Dec. 21) solstice. See EQUINOX.

**Solution** [from Lat. *sol′vere*, *solu′tum*, loose, set free, dissolve, and *solu′bilis*, dissolvable]: the liquid product formed when a solid, a liquid, or a gas dissolves in a liquid. Thus when water is poured upon salt or sugar the solid substance disappears as such and passes into the liquid form. Any liquid which has the power to dissolve a substance is called a solvent, and the substance is said to be soluble in the liquid. Water is used as a solvent much more commonly than any other liquid, both because it is a common substance and because it dissolves many things. Alcohol is also much used, especially in the preparation of solutions for medicinal purposes. The so-called tinctures are such alcoholic solutions of constituents of plants which have value as remedies. Besides water and alcohol many other liquids, perhaps all liquids, have the power to dissolve other things, and some of them find employment for this purpose.

Liquids not only dissolve solids, but other liquids and also gases. Some liquids mix with one another, or, in other words, they dissolve one in the other. This is true, for example, of water and alcohol, which dissolve in all proportions. Other liquids, however, act differently. Thus water, as is well known, does not dissolve oily liquids. Ether and benzene, on the other hand, do dissolve oils. Some gases dissolve in water to a very remarkable extent. Thus water at about freezing temperature has the power to dissolve 1,000 times its own bulk of the gas ammonia. Water also dissolves carbonic acid gas, and all natural waters contain some of this gas in solution. These waters also contain ordinary air in solution. When a liquid is placed in a closed vessel, and gas forced into it by means of a pump, it dissolves more and more gas as the pressure increases, and when the pressure is removed—that is, when the vessel is opened—the gas passes rapidly out of solution, giving rise to the phenomenon known as effervescence. This is most commonly seen in the case of soda-water, which is a solution of carbonic acid gas in water under pressure. When the water is drawn out into the air the gas escapes.

In a solution, whether of a solid, a liquid, or a gas, the dissolved substance is uniformly distributed—that is to say, there is as much of it in one drop of the solution as there is in any other drop. A drop of a concentrated solution of the dye magenta brought into many gallons of water imparts a distinct color to all parts of the liquid. An experiment of this kind gives some idea of the extent to which the division of matter can be carried, for it is evident that in each drop of the dilute solution there must be contained some of the dye, though the quantity must be minute beyond our powers of imagination. While there seems to be no limit to the extent to which a solution can be diluted, and still retain the dissolved substance uniformly distributed through its mass, there is a limit to the amount of every substance that can be brought into solution in any given solvent. Some substances are easily soluble; others are difficultly soluble.

Little is positively known in regard to the nature of solution. There are facts that indicate that the particles of the solvent form unstable compounds with the particles of the dissolved substance. In some cases, further, it appears that the act of solution involves a complete breaking down of the dissolved substance. The subject is being actively investigated. Consult *Solutions*, by W. Ostwald, translated by M. M. P. Muir, 1891. IRA REMSEN.

**Solway Firth**: an inlet of the Irish Sea, 33 miles long, from 2½ to 20 miles broad; it separates Cumberland from the south of Scotland. It is noted for the swiftness and strength of its ebb and flow, the spring tide rushing in with a wave from 3 to 6 feet high, and with a speed of from 8 to 10 miles an hour. It receives the Esk, the Derwent, and several minor streams.

**Solyman**: same as SULEIMAN (*q. v.*).

**Soma′li Coast**: an ill-defined area occupying the eastern horn of Africa, and extending along the Gulf of Aden and the Indian Ocean from Zeila, in lat. 11° 18′ N., to the mouth of the Jub, in lat. 0° 14′ N.; claimed by the British (along the Gulf of Aden) and the Italians (along the Indian Ocean S. to British East Africa); area of the former part about

75,000 sq. miles. By an arrangement of the British and Italian governments in 1894 the limits of their protectorates were strictly defined. It is mountainous, rich in myrrh and incense, and inhabited by tribes related to the Abyssinians and Gallas, mostly nomads and ill famed on account of their savage and predatory habits. The principal port is Berbera, in lat. 10° 22′ N. It has an excellent harbor. During the hot season it is deserted, but in winter comprises a population of about 30,000 people, who gather to exchange the products of their industry. See James, *The Unknown Horn of Africa* (2d ed. 1890). Revised by M. W. HARRINGTON.

**Somatol′ogy** [Gr. σῶμα, σώματος, body + λόγος, discourse, reason]: the science of living organized bodies as far as relates to material conformation and not to psychological phenomena. Thus it is included within biology. In a limited sense it is applied to the science of the human body, when it is equivalent to human anatomy and physiology. The name somatology has also been given to the study of inorganic bodies, in which case it does not differ much in signification from physics. See ANTHROPOLOGY.

**Sombrere′te**: town of the state of Zacatecas, Mexico; 100 miles N. W. of Zacatecas (see map of Mexico, ref. 5–F); 8,432 feet above the sea. It is noted for its silver mines. The celebrated "black vein" of Sombrerete was formerly said to yield the richest ore in the world. The town had a mint in 1810–12. Pop. about 9,000. H. H. S.

**Somers**, JOHN, Lord: statesman; b. at Worcester, England, Mar. 4, 1651; educated at Trinity College, Oxford; studied law at the Middle Temple; called to the bar 1676, but remained at Oxford, engaged in classical, historical, and juridical studies; translated from classic authors and wrote pamphlets in vindication of the exclusion of the Duke of York from the succession and in defense of grand juries (1681); began legal practice at London 1682; soon became a leader of the Whigs; one of the counsel for the seven bishops 1688; sat as member for Worcester in the Convention Parliament Jan., 1689; was chairman of the committee which drew up the Declaration of Right; was made successively Solicitor-General, Attorney-General, Lord Keeper of the Great Seal, and in 1697 was appointed Lord Chancellor and raised to the peerage. His fidelity to William III. exposed him to frequent attacks, one of which resulted in his removal from the chancellorship Apr. 17, 1700, and another caused his arraignment for trial before the House of Lords with a view to impeachment on fourteen very miscellaneous charges Apr. 1, 1701, but the prosecution was withdrawn June 17, 1701. He recovered his influence at court; was chosen president of the Royal Society 1702; drew up the plan for the union of the crowns of England and Scotland 1706; became president of the council Nov., 1708, and resigned 1710. D. in London, Apr. 26, 1716. A valuable collection of state papers, known as the *Somers Tracts*, was edited from originals in his library (16 vols. 4to, 1748–52). A new edition of the *Tracts* was issued by Sir Walter Scott (London, 13 vols. 4to, 1809–15). His *Life* was written by R. Cooksey (1791). Revised by F. M. COLBY.

**Som′erset**: city; capital of Pulaski co., Ky.; on the Cin., N. O. and Tex. Pac. Railway; 6 miles N. of the Cumberland river and 79 S. of Lexington (for location, see map of Kentucky, ref. 4–H). It is in a grain, fruit, and vegetable growing region, near extensive mines of coal and iron, and contains 12 churches, 2 high schools, a national bank with capital of $100,000, a banking company with capital of $80,000, and 2 weekly newspapers. Pop. (1880) 805; (1890) 2,625; (1900) 3,384. EDITOR OF "REPORTER."

**Somerset**: village; Perry co., O.; on the Balt. and Ohio Railroad; 20 miles S. W. of Zanesville, and 24 S. by E. of Newark (for location, see map of Ohio, ref. 6–G). It is in a region abounding in coal, iron ore, and potter's clay, and contains flour-mills, planing-mills, woolen-mills, carriage-factories, a State bank with capital of $15,000, and a weekly newspaper. Pop. (1880) 1,207; (1890) 1,127; (1900) 1,124.

**Somerset**: borough; capital of Somerset co., Pa.; on the Baltimore and Ohio Railroad; 36 miles N. N. W. of Cumberland, Md.; 110 miles E. S. E. of Pittsburg (for location, see map of Pennsylvania, ref. 6–C). It is principally engaged in the lumber-trade and in the manufacture of maple-sugar, butter, and cheese, and contains a public high school, 2 national banks with combined capital of $100,000, and 4 weekly newspapers. Pop. (1890) 1,713; (1900) 1,834.

**Somerset**, EDWARD SEYMOUR, Duke of: b. about 1500; brother of Jane Seymour, third queen of Henry VIII. and mother of Edward VI. After the death of Henry he rose to the head of affairs; was created Duke of Somerset and earl-marshal of England in Feb., 1547, and in March was made lord protector and governor of the realm, becoming king in all but name. When the Scots opposed the marriage of Mary Stuart to Edward VI., Somerset invaded their country and defeated them in the battle of Pinkie. This drove them to form an alliance with France, and war followed between that country and England, resulting in the latter's loss of Boulogne. His arrogance and rashness provoked opposition, and among his political adversaries was his own brother, Sir Thomas Seymour, who was apprehended and executed by his orders Mar., 1549. This brought the protector into great odium, and in Oct., 1549, he was deprived by the young king of his protectorship and thrown into the Tower, but was released with a full pardon in a few months. Among his foremost rivals was the Earl of Warwick, afterward Duke of Northumberland. Somerset entered into a plot against his life; was again arrested, found guilty of felony and constructive treason, and was beheaded on Tower Hill, Jan. 22, 1552.

**Somerset**, FITZROY JAMES HENRY: See RAGLAN.

**Somerset**, ROBERT CARR, Earl of: See OVERBURY, SIR THOMAS.

**Som′ersetshire**: county of Southwestern England; bounded on the N. and W. by the Bristol Channel; area, 1,630 sq. miles. The surface is much diversified by ranges of low, rocky hills; the Mendip Hills in the N. and the Quantock Hills in the W. Coal and freestone are mined, and iron and lead in small quantities. Large tracts of meadow and marshes afford excellent pasturage. The cheese known as Cheddar and cider are largely produced. Good wheat is raised around Bridgewater. Dairy-farming is one of the principal occupations; leather, glass, paper, and iron goods are manufactured. Pop. (1901) 385,059.

**Somers's Islands**: See BERMUDA ISLANDS.

**Som′ervile**, WILLIAM: poet; b. at Edston, Yorkshire, England, in 1677; entered Westminster School in 1690; became a fellow of Oriel College, Oxford, and in 1704 succeeded to his patrimonial estate, where he lived like a jovial country squire, dividing his time between his hounds, his books, and his bottle. His poems are *The Two Springs, a Fable* (1725); *Occasional Poems, Translations*, etc. (1727); *The Chace*, his best production, a didactic blank verse poem in four books on the art of hunting (1735); *Hobbinol, or the Rural Games*, a burlesque in blank verse (1740); and *Field Sports* (1742). D. July 19, 1742. Revised by H. A. BEERS.

**Som′erville**: city; Middlesex co., Mass.; on the Mystic river, and the Boston and Maine and the Fitchburg railways; joining Boston on the N. W. (for location, see map of Massachusetts, ref. 2–H). It was formerly a part of the town of Charlestown, from which it was set off in 1842, and is a residential city whose inhabitants are largely engaged in business in Boston. It is connected with Boston by seven lines of electric and five of steam railway, contains 31 churches, 24 public-school buildings, valued at $790,000, a public library, hospital, old women's home, insane asylum, 3 public parks, a national bank with capital of $100,000, a savings-bank, and 2 weekly newspapers. The U. S. census returns of 1890 showed 387 manufacturing establishments (representing 58 industries), with a combined capital of $3,788,018, employing 3,126 persons, paying $1,716,496 for wages and $4,369,064 for materials, and turning out products valued at $7,324,082. The city was settled in 1629 and incorporated as a city in 1872. It is built on seven hills. The first vessel built in the State was launched from Gov. Winthrop's Ten Hill farm on the Mystic river in 1631; a powder-house erected on Quarry Hill about 1703 is carefully preserved and is now in the center of a public park; the strongest fortifications in the vicinity were built on Winter Hill during the siege of Boston; Gen. Putnam's "impregnable fortress" was on Cobble Hill; and the "citadel," where Washington raised the first colonial union flag, Jan. 1, 1776, was on Prospect Hill. Pop. (1880) 24,933; (1890) 40,152; (1900) 61,643. JOHN S. HAYES.

**Somerville**: borough; capital of Somerset co., N. J.; on the Raritan river, and the Central Railroad of N. J.; 11 miles W. N. W. of New Brunswick, and 36 miles W. S. W. of New York (for location, see map of New Jersey, ref. 3–C). It has gas and electric-light plants, sewers, water-works, 7 churches, graded public school with 16 teachers, a Baptist classical school, 3 primary schools, public library (founded in 1871), 2 national banks with combined capital of $142,340, a savings-bank, and a monthly and 3 weekly periodicals. The borough was founded about 1665, and was known as Raritan till 1809. During the Revolutionary war the American army was encamped in the immediate neighborhood of Somerville for a long time. Pop. (1880) 3,105; (1890) 3,861; (1900) 4,843.

D. N. MESSLER, "SOMERSET DEMOCRAT."

**Somerville**, MARY: scientific writer; b. at Jedburgh, Scotland, Dec. 26, 1780; daughter of Admiral Sir William Fairfax. In 1805 she married Samuel Greig; in 1808 was left a widow with two sons and an independent fortune; went through a course of pure and applied mathematics. In 1812 she married her cousin, William Somerville, who aided her in her studies. In 1830 her *Mechanism of the Heavens* was published. The preparation of this work, an attempt to bring the *Mécanique céleste* of Laplace within the reach of a larger range of students, was undertaken at the solicitation of Lord Brougham. In 1834 she published *Connexion of the Physical Sciences*; in 1849, *Physical Geography*; in 1869, *Microscopical and Molecular Science*. She was elected a fellow of the Royal Astronomical Society in 1832, and afterward a member of several other British and foreign scientific societies. D. in Naples, Nov. 29, 1872. An autobiography edited by her daughter appeared in 1873.

**Somme**, sŭm: a river of France. It rises in the department of Aisne, passes by St.-Quentin, Ham, Amiens, and Abbeville, and falls into the English Channel after a course of 152 miles. It is navigable to Amiens, and is connected with the Seine, Oise, and Scheldt by canals.

**Somme**: department of Northern France; bordering on the English Channel, on both sides of the river Somme; area, 2,379 sq. miles. The surface is flat, but the soil very fertile, and large crops of corn, hemp, hops, and fruit are raised. Cattle-breeding is extensively carried on, and the manufactures of velvet, silk, cotton goods, soap, chemicals, beetroot-sugar, paper, and linen are very important. It is traversed by the Northern Railway and the railway from Amiens to Boulogne. Pop. (1896) 543,279.

**Somnam'bulism** [Lat. *som'nus*, sleep + *ambula're*, walk]: a peculiar perversion of the mental functions during sleep, in which the subject becomes an automaton. The organs of sense remain torpid and the intellectual powers are blunted. During this condition some instinctive excitation may take place, and there may be the production of impulses, in consequence, of different kinds. One individual may walk along the ledge of the roof of a house, and another may jump into a river, or a third may commit homicide. The condition is very much less common than is supposed, although imperfect examples are seen in persons who walk at night in sleep. A slight stimulation of the organs of sense is sufficient to restore the person. Cases have been described where hysteria takes this form. Somnambulism may sometimes be induced by hypnotism, the patient walking about unconscious; but many such cases are fraudulent. See HYPNOTISM. WILLIAM PEPPER.

**Somnath'**: ancient and decayed town of the peninsula of Guzerat, India; in lat. 20° 53' N., lon. 70° 24' E.; contains a famous temple, now in ruins, but at one time one of the richest and most venerated places of Hindu worship (see map of S. India, ref. 2–B). Mahmud of Ghazni sacked the temple in 1024, and carried away its magnificent gates, celebrated as much for their exquisite workmanship as for the costliness of their materials. In 1842 some gates, said to be those of the temple at Somnath, were brought from Afghanistan by the British, but, to avoid exciting jealousy between the two great religious bodies of the Hindus, they were placed in the arsenal of Agra. Pop. about 6,600.

**Sona'ta** [= Ital. (sc. *cosa*, thing), liter., something sounded or played on an instrument, fem. perf. partic. of *sonare*, sound]: originally, in the latter part of the sixteenth century, any kind of composition for instruments, in contradistinction to vocal compositions, which were called *cantata*. Subsequently, especially after the time of Bach, the name was applied principally to compositions for solo instruments and of a certain form, consisting of several movements—first, three, the *allegro*, *adagio*, and *rondo*—to which afterward a fourth was added by Haydn, the *minuetto* or *scherzo*, which differed from each other in time and sentiment, but were held together by the general character pervading all. This form of composition was greatly developed by Haydn and Mozart, and culminated in Beethoven.

**Song-books** (Fr. *chansonnier*; Ital. *canzoniere*; Span. *cancionero*; Portug. *cancioneiro*): the manuscripts in which has come down to us the greater part of the lyric poetry of the Middle Ages in all the chief countries of Europe. As mediæval poets wrote for immediate delivery, either by themselves or by professional singers (*jongleurs*, etc.), their productions were easily scattered or even entirely lost. At first, perhaps, the song-books were merely single sheets containing isolated songs, put together for the sake of convenience; but later it grew to be the fashion for rich patrons of poetry to have collections of lyrics made for their own use. These were of the nature of anthologies, and successive generations of scribes constantly varied the contents of the older books in preparing the new. As poets and poems grew obsolete, their names and places were usurped by new ones. Hence only a small part of the work of any single mediæval lyric poet is extant. The collections that have come down to us, however, are very precious. They often contain the music to which the poems were sung, and are adorned with elaborate miniatures and other decorations.

The number of mediæval song-books in various languages in the libraries of Europe is very great. Those containing Provençal lyrics are enumerated by K. Bartsch, *Grundriss zur Geschichte der provenzalischen Literatur* (Elberfeld, 1872). The French *chansonniers* have been studied by G. Raynaud, *Bibliographie des chansonniers français des XIII^e et XIV^e siècles* (2 vols., 1884), and by J. Brakelmann, *Die 23 altfrz. Chansonniers in den Bibliotheken Frankreichs, Italien und der Schweiz* (in Herrig's *Archiv*, vol. xlii.). The most famous collection of early Italian lyrics is the *Cod. Vat.* 3,793, published by A. d'Ancona and D. Comparetti (5 vols., Bologna, 1875–88), though this has to be supplemented by several others in various libraries in Italy. For the early lyric poets of the Spanish Peninsula, who wrote in the Portuguese-Galician tongue, there are the magnificent *Cod. Vat.* 4,803 (known as the *Cancioneiro da Vaticana*) and several others. The Spanish lyrics of the fourteenth and fifteenth centuries are collected in a whole series of *Cancioneros*, of which the first is the so-called *Cancionero de Baeña*, made about 1450; and the most extensive is the *Cancionero General* of Fernando del Castillo, first printed at Valencia in 1511. Of all mediæval song-books, perhaps the most famous is the great German collection variously known as the Manessian (though with no good reason), the Paris, and the younger Heidelberg manuscript. This splendid volume became known to scholars in the sixteenth century, when it was in the possession of a certain Freiherr Hans Philipp von Hohensax, of Forstech, in the Rheinthal. Later it was at Heidelberg, but after the sack of this place in 1622 it made its way mysteriously into the royal library in Paris. Here it remained till 1889, when the Heidelberg Library obtained it at a valuation, it is said, of $100,000—probably the highest price ever given for a manuscript or book. In England there were many song-books, but not of distinguished character. A. R. MARSH.

**Songkoi**, or **Songtao** [*song* is Annamite for river]: the largest river of Eastern Indo-China and a trade-route of large potential importance. It rises in the mountains of Northern Yunnan, China, flows S. E. and empties into the Gulf of Tonquin after a course of about 750 miles, half of which is in Yunnan and half in Tonquin. The most important affluent is the Songbo, which rises near the source of the Songkoi, parallels its course, and enters the latter on the left hand, not far above Hanoi. Just below its mouth begins an enormous delta, which is increased in size by lateral communications of the Songkoi with the Songkan, the next river to the N. The lower river is subject to floods in the spring and early summer, when the water sometimes rises 15 or 20 feet in twenty-four hours, and much of the lower stream is diked. The waters during the inundations are reddened by the soil, whence the French name of the river (*Rouge*). In 1890 a steamer drawing 28 inches ascended the river to Laokai at the Chinese boundary in sixty hours from Hanoi. The stream has always been an important native trade-route. MARK W. HARRINGTON.

**Song of Birds**: the musical notes uttered by many birds, especially by oscine passerines, although others, as of the snipe family even, like the woodcock and Bartram's sandpiper, have a pleasing combination of notes. Nearly all birds, in fact, utter some kind of a cry, but in the majority it can scarcely be called a song. In man and other mammals sounds are produced in the larynx, but in birds musical sounds are produced in an enlargement of the windpipe, termed the syrinx, just above the forks of the bronchi. To the syrinx are attached the singing muscles, numbering in the oscines from four to six or even eight pairs. The apparatus is simple, and its modifications are comparatively slight. There is no reason to suppose that the tongue takes any, at least any important, part in the production of sounds even in birds which pronounce words. Song is almost exclusively an attribute of male birds, although the female may sing, as does the cardinal of the U. S., and it is heard most often during the time of pairing, so that springtime is pre-eminently the season of song; still some birds sing pretty much throughout the year, and even, like the Carolina wren, in winter. The bobolink, on the other hand, changes his manners with his coat, and sings only in full-dress plumage. Early morning is the favorite hour for song, next to that the sunset-hour, but some birds, like the scarlet tanager, sing during the torrid heat of a southern noonday, and many songsters besides the nightingale sing at night, notably the mocking-bird and yellow-breasted chat of the U. S. The gay-plumaged birds of the tropics belong largely to the harsh-voiced *Clamatores*, but a bright coat is not a sure sign of a discordant voice, for the majority of that strictly American family the tanagers inhabit the tropics, and sing as well as the familiar scarlet tanager of more northern climes. Not only do individuals of a given species vary considerably in their power of song, but certain localities seem to develop musical talent better than others. The meadow-lark sings better in Florida than in the northern parts of the U. S., while the western sub-species excels that of the east. F. A. LUCAS.

**Song of Solomon**: See CANTICLE.

**Songs** [O. Eng. *song*, *sang* : Germ. *sang* : Goth. *saggws*; cf. Gr. ὀμφή, tuneful voice, oracle < Indo-Eur. *songh-*]: from the literary standpoint, short lyric or dramatic poems suitable for setting to vocal music; from the musical standpoint, compositions of relative simplicity of form which carefully illustrate and enhance the sentiment expressed by the words. In the modern sense this form may be flexible as to development. The word *song* represents an indefinite quantity, in that its characteristics may range through a large scope as to musical value. There are short songs which may be compared to gems, in miniature, by the great painters. There are also the folk-songs of various countries (the *canti popolari* of the Italians), full of national characteristics, and immortal in their simplicity. Lastly, there are myriads of songs whose existence, both as to music and text, is fortunately but for a day. DUDLEY BUCK.

**Songtao**: See SONGKOI.

**Sonnet** [either directly or viâ Fr. *sonnet* from Ital. *sonetto*, which in its turn probably came from the Prov. and O. Fr. *sonet*, a diminutive derived from the Lat. *sonus*, a sound or air in music]: a poetical form which, as finally perfected by the Italian poets of the thirteenth and fourteenth centuries, consists of fourteen hendecasyllabic verses (corresponding to English decasyllables), arranged according to a rigid scheme. The main features of this are the division of the whole poem into two parts, the first of eight verses (called the octave), the second of six (called the sestet); the further division of the octave into two tetrastiches (called in Italian *piedi*); the employment of but two rhymes in the octave, arranged *a b b a a b b a*; the use of either two or three rhymes in the sestet, arranged as may suit the poet. The sestet, when it forms an indivisible whole, is often called in Italian *sirima*; when it falls into two tercets, *volte*. This severe form, however, has not been followed by all sonnet-writers, even from the earliest period. Shakspeare, for example, hardly observes the minor divisions of the sonnet at all. He arranges the rhymes of the octave *a b a b a b a b*, or even *a b a b c d c d*, thus neglecting all the subtle modulations of the Petrarchan type. He often allows the sense to run over from the octave to the sestet; and even when he parts the two he makes little effort to contrast the meaning and the harmony of the latter with those of the former. This loose type of the sonnet is often called the bastard or illegitimate sonnet; but this is hardly justified by the history of the form.

There has been much discussion of the origin and development of the sonnet. The word occurs in both the Provençal and the Old French languages earlier than in Italian. Investigation has shown, however, that here *sonet* means simply a short *son*—i. e. musical air or lyric set to music. There are a few real sonnets in Provençal, but all of them are by Italians, or considerably later than the rise of the Italian sonnet. Everything points, therefore, to Italy as the birthplace of the form; but there are difficulties as to the manner of its birth. A very widely accepted theory has been that it was originally simply one stanza of the lyric canzone. It is hard to see, however, the motive that should have led to such use of a single part of what was a very elaborately constructed and balanced poetical form. More probable is the theory first set forth by A. d'Ancona, in his *Poesia popolare italiana* (Leghorn, 1878), that the basis of the sonnet is purely popular. In fact, there exist even to-day popular lyrics, called *strambotti* and *rispetti*, whose existence is fairly assured for the earliest period of Italian poetry. The *strambotto*, whose home seems to have been Sicily, is an eight-lined stanza with rhymes arranged *a b a b a b a b*. The *rispetto*, on the other hand, which was Tuscan in origin, is a precisely similar stanza, but of six lines, with rhymes *c d c d c d*. D'Ancona believed that the sonnet was obtained by one of the early courtly poets of the so-called Sicilian school, through joining these two forms. This theory has been slightly modified by Cesareo (*La Poesia Siciliana sotto gli Svevi*, Catania, 1894), who thinks that a six-lined *strambotto* existed in Sicily, as well as that of eight lines, and that the combination was effected in Sicily alone. Indeed, Cesareo believes that the inventor of the new form was Jacomo da Lentino, the most original of the Sicilian poets, who flourished in the first half of the thirteenth century. These investigations also show that the earliest sonnet scheme was nearer Shakspeare's than Petrarch's, as the rhymes ran *a b a b a b a b c d c d c d*.

Though thus in all probability of popular origin, the sonnet form was from the start employed only by courtly poets. The subject-matter of the earliest sonnets is, like that of the rest of the poems of the first Italian cultivated poets, mainly derived from the poetry of Provence. During the thirteenth century it became more and more popular throughout Italy. Many experiments at refining and elaborating it were made. Gradually the rhyme system, *a b b a a b b a*, drove out the older system in the octave. Under the influence of Provençal poetical theories, the inner divisions were made sharper and clearer. On another side efforts were made to vary the fixed scheme, either by appending a couplet or group of couplets (*cauda* or *coda*) at the end or by inserting at fixed points subsidiary seven-syllabled lines, which rhymed with the preceding eleven-syllabled lines. According to the number of these insertions, such sonnets were called *sonetti doppi* and *sonetti rinterzati*. In some cases sonnets of twenty-eight verses were thus produced. The simpler form, however, proved the permanently satisfactory one; and this was finally fixed by the great master of all the Italian sonnet-writers—Petrarch.

The diffusion of the sonnet form outside of Italy began when the rest of Europe came to feel the powerful influence of the Italian Renaissance. In the Spanish Peninsula this took place in the fifteenth and early sixteenth centuries; and the earliest Catalan and Spanish sonnets belong to this period. In France, according to Joachim du Bellay, the sonnet was introduced from Italy by Mellin de Saint-Gelais, a poet of the early sixteenth century; but du Bellay himself and his friends of the Pléiade were the first to give it real vogue. In England it was introduced toward the middle of the sixteenth century by Wyatt and Surrey. The earliest German sonnet is to be found in a translation of an anti-papal tract by Bernardino Ochino. This translation, made by one Christoph Wirsung, appeared in 1556.

The best general account of the history of the sonnet is to be found in H. Welti, *Geschichte des Sonettes in der deutschen Dichtung* (Leipzig, 1884). The development of the sonnet in Italy is excellently treated by L. Biadene, *Morfologia del Sonetto nei secoli XIII. e XIV.* (fascicolo 10 of *Studi di Filologia Romanza*, Rome, 1888). Of value, but to be used with care, is Louis de Veyrières's *Monographie du sonnet, sonnetistes anciens et modernes* (2 vols., Paris, 1869–70). A. R. MARSH.

**Sonometer**: See RECORDING APPARATUS, PSYCHOLOGICAL, in the Appendix.

**Sono'ra**: the northwesternmost state of Mexico; bounded by the U. S. (Arizona) on the N., Chihuahua on the E., Sinaloa on the S. E., the Gulf of California on the S. W., and the territory of Lower California on the N. W. Area, 77,534 sq. miles. The Sierra Madre Range forms the eastern boundary, and its spurs and sub-ranges cover much of the eastern part of the state, which is very imperfectly known. Succeeding this region are plateaus and valleys with a rich soil, but only available for agriculture by irrigation. The lands along the coast are arid, except in the river valleys. The northwestern part is a desert, resembling the adjacent parts of Arizona. Of the few rivers the Yaqui is the most important. The climate is hot on the lowlands, mild on the plateaus and in the higher valleys; rains (principally from July to September) are scanty, and the northwestern deserts and parts of the coast-belt are essentially rainless. There is no true forest, except in the mountains. The state is rich in minerals; the mines of silver and gold have long been famous, lead occurs in conjunction with silver, and latterly important coal-beds have been opened in the Yaqui valley, the product being exported to Arizona. Mining is the only important industry; cereals, etc., are cultivated in the river valleys, and there are considerable herds of cattle in the north. A kind of guano is found on islands in the Gulf of California. The Sonora Railway (from the port of Guaymas, on the gulf, to Benson, on the Southern Pacific Railroad) was originally built as an outlet for the coal-fields. Pop. (1895 census), 191,281. A large proportion are Indians of the Opata, Pima, and other tribes, who retain their old customs and languages, and in many cases are practically independent. H. H. SMITH.

**Sonora**: city; capital of Tuolumne co., Cal.; on Wood's creek; 60 miles E. of Stockton, 90 miles S. E. of Sacramento; equidistant from the Yosemite valley and the Calaveras bigtree region (for location, see map of California, ref. 7-E). It is the center of a large gold-mining area; is principally engaged in mining, agriculture, lumbering, and grape-growing; and contains water-works, the Snell Library, an academy, foundry, quartz-mills, and three weekly newspapers. Pop. (1880) 1,492; (1890) 1,441; (1900) 1,922.

**Sonson′**: town of the department of Antioquia, Colombia; on the river Sonson; 33 miles S. S. E. of Medellin; 8,350 feet above the sea (see map of South America, ref. 2-B). It is the center of a rich grazing district, and is noted for its mild and salubrious climate and beautiful scenery. The river here forms a triple fall of 200 feet, and causes in its deep ravine a continual *son-son*, or echo, whence the name. Pop. about 12,000. H. H. S.

**Sonsona′te**: town of Salvador; beautifully situated on a plain by the Sonsonate river, and on the railway from Santa Ana to the port of Acajutla; 40 miles W. of San Salvador (see map of Central America, ref. 4-E). It was founded soon after the conquest, and is the center of a rich agricultural district and the capital of a department of the same name. Pop. about 9,000. H. H. S.

**Sontag**, zōn′taăkh, HENRIETTE: opera-singer; b. at Coblenz, Germany, Jan. 3, 1806; was gifted with fine vocal and dramatic powers, which were highly cultivated; excelled in German and Italian music, and at the age of twenty-five rivaled Malibran, Pasta, and Catalani; married Count Rossi, an Italian noble, in 1830, and retired to private life. She resumed her professional career in 1849, made a tour in the U. S. in 1853, and in Mexico. D. of cholera in Vera Cruz, June 18, 1854. Revised by B. B. VALLENTINE.

**Soo-Chow-Foo**: See SU-CHOW.

**Soodan**: another spelling of SUDAN (*q. v.*).

**Soofees**: See SUFIS.

**Soo′soo**, or **Susu**: the *Platanista gangetica*, a cetacean of the Ganges, the only living representative of the family *Platanistidæ*, which is allied to the *Iniidæ*, or fresh-water dolphins of South America. It is some 6 or 8 feet long, and is ordinarily very sluggish, but can move after its prey, which consists of fish and crustaceans, with much vigor. It has long beaked jaws, 120 teeth, and curious rudimentary eyes. Revised by F. A. LUCAS.

**Soot** [O. Eng. *sōt*: Icel. *sōt*; cf. Ir. *suth*: Lith. *sūdis*; Fr. *suie*]: a carbonaceous deposit from smoke, formed in chimneys. That which forms nearest the fire is often shining and varnish-like, consisting chiefly of dried tarry matters mixed with carbon, and giving a brownish-black powder, sometimes used as a pigment under the name of bistre. That which forms further up the chimney is more of the character of LAMPBLACK (*q. v.*).

**Sooty Tern**: See EGG-BIRD.

**Sooysmith**, soi′smith, WILLIAM: civil engineer; b. at Tarlton, O., July 22, 1830; graduated at the Ohio University in 1849, and at the U. S. Military Academy July 1, 1853. In 1854 he resigned from the army to engage in civil engineering; in 1855 became principal of the Buffalo High School. Resuming his profession in 1856 he was in 1859 placed in charge of the construction of a bridge over the Savannah river, the foundations of which consisted of pneumatic piles. In the civil war he served as colonel of the Thirteenth Ohio Volunteers in West Virginia till Jan., 1862, when transferred to the Army of the Ohio, and was engaged at the battle of Shiloh, Apr. 7. Commissioned brigadier-general of volunteers Apr. 15, he participated in the siege of Corinth; commanded a division at the battle of Perryville; was chief of the cavalry department of the Tennessee July-Oct., 1863, and of the division of the Mississippi Oct., 1863-July, 1864, when compelled by ill health to resign. He has since been engaged in sinking foundations for bridges and other structures. He was a member of the U. S. board of 1875-76 for testing iron and steel. Revised by M. MERRIMAN.

**Sophi′a** (anc. *Serdica*: Bulg. *Sredetz*): city; capital of Bulgaria; on a small tributary of the Iskra, and on the main railway between Vienna and Constantinople (see map of Turkey, ref. 3-C). Till 1878 it was "a dirty and pestilential village of wooden huts," but since Russia wrested from the Ottomans a semi-independence for Bulgaria (1878), it has marvelously improved. It now resembles a European city with its straight, clean streets and attractive houses. Over 7,000 Ottomans from among its former residents have emigrated, but the population has almost trebled in seventeen years. Sophia possesses a commodious palace, the residence of the prince, a cathedral, an excellent college and schools, and a public garden. It manufactures leather, earthenware, and woolen cloth, and carries on an active transit trade. Pop. (1893) 47,000. E. A. GROSVENOR.

**Sophists** [from Lat. *sophis′tes* = Gr. σοφιστής, deriv. of σοφίζεσθαι, be or become wise, play the wise man or Sophist]: name applied to the seven wise men of Greece; afterward to the teachers at Athens who gave lessons in the arts and sciences for money. The course of Greek philosophy begins with the establishment of a material first principle —water, air, fire, etc.—and tends toward the recognition of mind as this first principle. Anaxagoras explicitly announced mind (νοῦς) as such first principle. The first and most obvious phase of mind as an activity is its capacity to reflect, and hence to discover grounds and reasons. Each ground or reason in some measure communicates its peculiar character to the fact or opinion which it grounds. Hence from the standpoint of grounds and arguments all truth seems to be an arbitrary affair, depending upon the selection which one makes of grounds and reasons. Truth is supposed to be many-sided, and the point of view taken is supposed to justify one's difference in opinion. The art of presenting grounds or reasons to justify any view is the art of the Sophists. The fact that these many sides or grounds of truth are mutually interdependent, and therefore that each has truth only as seen in view of the rest—this is the further and deeper insight which it belonged to Socrates and Plato to discover and unfold. The universal or general is the net result, as well as the active principle, of that dialectic process which appears in the genesis and mutual destruction of different opinions—"different points of view." As a necessary elementary stage of human thinking, the work of the Sophists is of permanent importance in the history of philosophy. The Eleatics, who set up the doctrine of pure being, found it necessary to deny being to the phases of change, finitude, and negativity that appear in the world. Zeno accordingly discovered the dialectic of self-contradiction involved in those phases. This was adopted by the Sophists, of whom the chief were Protagoras the Individualist (b. 490 B. C.), Gorgias the Nihilist (came to Athens 427 B. C.), Hippias the Polymathist, and Prodicus the Moralist (the two latter being younger contemporaries of Protagoras). Everything that existed in the Greek consciousness as opinion, faith, custom, religious tradition, even the evidence of the senses, was sapped and rendered uncertain by the ratiocination of these Sophists. Protagoras asserted: Man is the measure of all things. Just as each thing appears to each man, so is it for him. All truth is relative. The existence of the gods is uncertain. Gorgias expressed his nihilism in three propositions: (*a*) Nothing exists; (*b*) if anything existed, it would be unknowable; (*c*) if anything existed, and were knowable, the knowledge of it could nevertheless not be communicated to others. "Common sense," so called, is the stage of naïve faith in one's point of view. The discovery of the equal validity of "many points of view" leads on the one hand to sophistical practices, or on the other to skepticism. Pyrrhonic skepticism in Greece connects back through the Megarian school to the dialectic of the Sophists and of Zeno the Eleatic. See articles SOCRATES, PHILOSOPHY (*History of Philosophy*), and MORAL PHILOSOPHY. WILLIAM T. HARRIS.

**Sophocles**, sof'ō-kleez (Gr. Σοφοκλῆς): the second in time of the three great tragic poets of Greece; b. of a wealthy family at Colonus, a beautiful deme of Attica near Athens, in 496 B. C. He was carefully trained in all the arts of a liberal education, in gymnastics and music. At the age of sixteen he led the chorus of boys who danced and sang the pæan in honor of the victory of Salamis, and there is other evidence of his personal beauty and grace. His first play, acted in 468, was a great success, and won the prize over Æschylus after a close contest which was finally referred for decision to Cimon and his fellow generals. For the next ten years Sophocles divided with Æschylus the empire of the stage, the older rival learning from the younger as the younger had already learned much from the older. After the death of Æschylus, Sophocles was the leading dramatist. He never failed of at least the second prize, and coped successfully with such plays as the *Alcestis* and the *Medea* of Euripides. But as Æschylus accepted the improvements of Sophocles, so Sophocles in his later plays was clearly influenced by Euripides, whose greatness he did not fail to recognize. Sophocles took an active part in public life, and was called to hold high positions. In consequence of the sentiments expressed in his *Antigone* (440) he was made a colleague of Pericles in the command of the forces sent against Samos. Before that he had been an Hellenotamias or treasurer of the Alliance, and in the troublous times of the Peloponnesian war he is said to have been one of the *probuli* (πρόβουλοι) or committee of safety appointed in 411. Love played a large part in his life, and his sweet and easy temper was often put to the test. According to a familiar tradition, when far advanced in years Sophocles was brought before a family court by his son Iophon on the charge of disordered intellect. The aged poet recited the famous encomium on Colonus from the *Œdipus Coloneus*, which he had just composed, and the charge was dismissed—as the story may be. He died an easy death in 405.

Of his 123 dramas seven are extant, *Ajax*, *Electra*, *Œdipus Tyrannus*, *Antigone*, *Trachiniæ*, *Philoctetes*, *Œdipus Coloneus*, the first three being the most popular in Byzantine times. Sophocles introduced the third actor and thus increased the life and movement of the drama, and life and movement were also enhanced by the change which made each drama of the trilogy (see ÆSCHYLUS) an independent play. These and other changes in the external form are manifestations of the same spirit that we find working in the heart of the Sophoclean drama. When we study Sophocles we are no longer in the Æschylean realm of Titanic beings, too vast for human sympathy, for while the heroes and heroines whom Sophocles brings before us are lifted above our level, they are of like passions with ourselves, and the motives are motives of flesh and blood, of human character and human will. His *dramatis personæ* are eternal types "writ large." In the construction of the plot Sophocles had no rival. His *Œdipus Tyrannus*, to cite but one instance, is a tragic web of unequaled subtlety and effectiveness. The lyric parts of his plays are in beautiful balance with the dramatic element. His language is more supple than that of Æschylus, but never falls short of elevation. It is sweet and yet does not lack a certain tang of austerity that saves it from cloying.

EDITIONS.—Among the most memorable editions of all the plays are those of G. Hermann (1830–41), Wunder-Wecklein (4th ed. begun in 1875), Schneidewin–Nauck (begun by Schneidewin in 1849 and repeatedly issued since), Campbell, in 2 vols. (1873, 1881, and repeated), Campbell-Abbott, 2 vols. (1886); above all, the monumental edition of Jebb (begun in 1883, nearly complete in 1895, with repeated issues of *Œdipus Tyrannus* and *Antigone*). Select plays by Wolf-Bellermann (begun 1858, often repeated). Text ed. by Dindorf (Teubner collection), by Schubert (Schenkl collection), by Nauck (Weidmann). Of noteworthy editions of single plays may be mentioned *Ajax*, by Lobeck (3d ed. 1866); *Antigone*, by Boeckh (1843), by Humphreys (1891); *Electra*, by Jahn (3d ed. 1882); *Œdipus Tyrannus*, by Elmsley (1821); *Œdipus Coloneus*, by Reisig (1820); *Philoctetes*, by Blaydes (1870), who has edited other plays of Sophocles also. Of translations into English verse may be noted Plumptre (1866) and Campbell (1874); of translations into English prose after Jebb's text, E. P. Coleridge (1893), and Jebb himself in the edition cited. For the enormous bibliography (down to 1874 only), see Genthe's *Index Commentationum Sophoclearum*. Invaluable is Ellendt's *Lexicon Sophocleum* (2d ed. by Genthe, 1872). See also Schöll's *Sophokles* (2d ed. 1870) and Patin's *Sophocle* (5th ed. 1877). B. L. GILDERSLEEVE.

**Sophocles**, EVANGELINUS APOSTOLIDES: Greek scholar; b. at Tsangaranda, Thessaly, Greece, Mar. 8, 1807; studied at the convent on Mt. Sinai; emigrated to the U. S.; entered Amherst College in 1829; was tutor in Harvard College, with a brief intermission, from 1842–49; assistant professor 1849–60, and in 1860 became Professor of Ancient, Modern, and Byzantine Greek. He published a *Greek Grammar* (1838; 3d ed. 1847); *First Lessons in Greek* (1839); *Greek Exercises* (1841); *Greek Lessons for Beginners* (1843); *Catalogue of Greek Verbs* (1844); *History of the Greek Alphabet*, etc. (1848); *Glossary of Later and Byzantine Greek* (1860), revised as *Greek Lexicon of the Roman and Byzantine Periods* (1870), etc. D. at Cambridge, Mass., Dec. 17, 1883.

**Sophonis'ba**: See MASINISSA.

**So'phron**: inventor or rather perfecter of the so-called MIME (*q. v.*); flourished at Syracuse in the middle of the fifth century B. C. The office of the mime was to represent in dramatic form a special situation or a special personage. It was a *commedietta* that lacked a chorus, that lacked an elaborate plot. The mimes of Sophron enjoyed a great reputation in ancient times; Plato read them again and again and slept with them under his pillow, and in Rome they were learned by heart and much imitated. A few fragments have been collected by Blomfield in *Museum Criticum* (vol. ii., 1826), and by Ahrens, *De Græc. Dialect.* (vol. ii., p. 464). Revised by B. L. GILDERSLEEVE.

**Soprano**: the highest type of the voice of women and boys. The compass of the high soprano may be said to extend from lower E on the treble staff to C above, and that of the mezzo-soprano from A below to A above. Among the high sopranos exceptional compass is sometimes found, reaching even to F and G in alt. D. B.

**So'ra**: town; in the province of Caserta, Italy; on the Garigliano; about 58 miles N. N. W. of Naples (see map of Italy, ref. 6–E). The manufactories of paper, woolen, and other stuffs here are on a considerable scale, and are provided with modern machinery. Pop. about 5,400.

**Sorac'te**: the present *Monte di San Oreste*, a mountain of Etruria, an outlying offset of the Apennines, from which it is detached by the valley of the Tiber. It rises with its bold and abrupt masses of the peculiar hard Apennine limestone 2,420 feet above the surrounding plain, and forms, especially when its top is covered with snow, a conspicuous and very picturesque feature in the views of the Campagna. (Horace, *Carm.*, i., 9.) In ancient times it was dedicated to Apollo, and bore on its top a celebrated temple of this god, to which large and peculiarly solemn processions were made from Rome, situated 26 miles to the S. In 746 Carloman, the brother of Pepin, founded the monastery of San Silvestro on the site of the old pagan temple. Its present name the mountain has received from a village, San Oreste, situated on its slope and well known for its sour wine. Revised by J. R. S. STERRETT.

**Sorata**: See ILLAMPU.

**Sorbian Language**: another name for Lusatian-Servian; see SLAVIC LANGUAGES.

**Sorb'ite**, or **Mountain-ash Sugar** [*sorbite* is from Lat. *sor'bum*, sorb-tree]: a saccharine substance formed in the juice of the berries of *Sorbus aucuparia*, the mountain-ash of Europe, as well as in the related American, *Sorbus americana*. The compound has the composition $C_6H_{14}O_6$, being isomeric with mannite. It belongs to the alcohols, and is in turn related to the sugars. I. R.

**Sorbonne**, sŏr'bŭn': the name generally applied to the theological faculty of the ancient University of Paris. It was derived from Robert de Sorbon (b. at Sorbon, in the Ardennes, in 1201, and afterward chaplain to Louis IX.; d. in Paris, renowned for sanctity and eloquence, 1274). In 1252 he founded an institution connected with the University of Paris, in which seven secular priests were to teach theology gratuitously to sixteen poor students, and in the following year the institution received its charter from Louis IX., which was confirmed in 1268 by Pope Clement IV. Connected with it was a preparatory school. Both were under a provisor. The severity of the examinations made its degrees of high esteem. The great care which was taken not to admit among the teachers any but men of the highest talents and attainments soon procured for the school a European fame, and in the fourteenth century the entire theological faculty of the university was merged into it. During the Middle Ages, the period of the Reformation, and even after that time, the Sorbonne was generally considered one of the highest authorities of the Christian Church, and its decisions were appealed to not only in theological controversies, but also in the contests between the popes and the secular powers. It demanded the condemnation of Joan of Arc; it justified the massacre of St. Bartholomew; it vigorously sided with the League and condemned both Henry III. and Henry of Navarre. On the other hand, it introduced printing into Paris immediately after its invention, and prevented the introduction of the Peter's Pence and the Inquisition into France. It was a stanch champion of the freedom of the Gallican Church, and strongly opposed to Ultramontanism. It condemned Jansen and the Jansenists in matters of doctrine, but it sided with them in their fight with the Jesuits. Its culmination was in the time of Cardinal Richelieu, who, himself a graduate of the school, provided it with a magnificent building and enlarged its library (1629). It was then that appeared the famous Latin couplet, which may be thus translated literally: "Renovated the Sorbonne goes to immediate ruin. While it was falling it stood unshaken; restored it will perish." In its contest with the philosophy of the eighteenth century it was unsuccessful, and it had outlived its fame when during the Revolution it was suppressed and bereft of its endowments (1790). At the reconstruction of the university in 1808 by Napoleon I., the building, still called the Sorbonne, became the seat of the *académie*, and between 1816 and 1827 was given to the theological faculty in connection with the faculties of science and *belles-lettres*. New buildings for the Sorbonne were erected 1884–89 at an expense of nearly $4,500,000. See T. I. Duvernet, *Histoire de la Sorbonne* (2 vols., Paris, 1790); A. Franklin, *La Sorbonne* (1867; 2d ed. 1875).

Revised by S. M. Jackson.

**Sorb-tree**, or **Wild Service**: the *Pyrus terminalis*, a small European tree (family *Rosaceæ*), the wood of which is very hard and valuable. Its fruit, the sorb, when overripened, is soft and mellow and very good eating. Hertfordshire, England, is famous for its sorbs, which are largely marketed in London. The name is sometimes applied to *P. domestica*. See Service-tree.

**Sorcery**: See Magic.

**Sorel′** (river): See Richelieu.

**Sorel**: *chef-lieu* of Richelieu co., Quebec, Canada; at the junction of the Richelieu with the St. Lawrence, and on the South Shore Railway, 45 miles below Montreal (see map of Quebec, ref. 5–B). It has an excellent harbor, which is used during the winter months as a place of refuge for the river steamboats. The trade is almost confined to the shipping of grain and farm produce. The manufactures are mostly connected with the repairing of steamboat machinery. The town has for its center a well laid-out square, and occupies the site of a fort built in 1665 by M. de Tracy. Its former name was William Henry. The Duke of Kent, the father of Queen Victoria, resided here for a time. There are 2 newspapers, 2 branch banks, and several hotels. Ship-building was formerly carried on. Pop. (1891) 6,669, of whom not more than 300 are English-speaking. J. M. Harper.

**Sorel**, Agnes: See Agnes Sorel.

**Sorel's Cements**: certain cements named from the inventor, a French chemist. The principle on which they are founded is the mixing of a concentrated solution of a metallic chloride with the oxide of the same metal to a pasty mass, when, in case of several metals, a solid insoluble oxychloride is rapidly formed, which is sometimes quite crystalline and hard. The most approved compositions of this class are those made with the chlorides of zinc and magnesium. A solution of magnesium chloride of a density of 20° to 30° of Baumé's hydrometer is mixed with magnesia to a paste, which may be applied and moulded like plaster. It solidifies to a white mass of the hardness of marble. Chloride-of-zinc solution mixed with oxide of zinc forms a similar cement-composition. Revised by Ira Remsen.

**Sorel-stone**: See Stone.

**Sorghum**: a tall, broad-leaved annual plant of the grass family, regarded as a variety (*Saccharatum*) of the polymorphous *Andropogon sorghum*. Its original home was doubtless the interior of Africa, but modern travelers do not report its having been found there in a wild state, and the wild forms, as in the case of the nearly related sugar-cane, appear to have been lost. Sorghum as a cultivated plant has been known from remote antiquity. It was introduced into Italy at the beginning of the Roman empire, but its culture did not flourish. Experiments were again conducted with it at Florence, Italy, in 1766, by Pietro Arduino, but with no practical results. In China it has been cultivated from the earliest historical times, but only as a cereal and for fuel and forage until recently. In 1840 Abadie sent some seeds to the museum at Paris, and about 1850 Montigny sent some from the north of China to the Geographical Society of Paris. About fifteen varieties were received, some of which contained saccharine juices.

Field of sorghum.

In 1853 W. R. Prince, of Flushing, L. I., obtained a few seeds from France. These produced a few pounds of seed, which were distributed in 1854. In 1857 Leonard W. Wray introduced into the Southern States seed which he obtained from Natal. The African varieties were called Imphee, while those originally derived from China were known as Chinese sugar-cane. In a few years sorghum was very generally known in different parts of the U. S., and some of the early varieties, such as the Amber, were found to mature as far N. as Minnesota.

During the civil war the culture of sorghum was carried on to a considerable extent, and by reason of the high price of sugar the products, mostly molasses, were brought into quite general consumption. Crystallizable sugar had been obtained as early as 1855, and was often made in the laboratory and in small amounts; but no systematic attempts were made to use the plant for making sugar until the subject was taken up in the department of agriculture in 1878 by Dr. Peter Collier. As a result of his investigations he predicted that sorghum could successfully compete with sugar-cane and sugar-beets as an economical source of the sugar-supply of the U. S., and attempts were made in many localities to manufacture sugar. In 1882 the commissioner of agriculture offered ten prizes of $1,200 each for the most successful attempts to make sugar from sorghum. The total amount of sugar reported by the ten successful applicants was 116,165·5 lb., of which 86,603 lb. was made by one firm. The department of agriculture at Washington made 165 lb. of sugar in 1881, and after making nearly 10,000 lb. in 1883 conducted experiments on a somewhat larger scale at Ottawa, Kan., in 1885, and at Fort Scott, Kan., in 1886–87. Large quantities of sugar were produced, but it was not demonstrated that it could be accomplished with economical results. With the exception of two factories in Kansas all commercial attempts at the manufacture of sugar from sorghum on a large scale have (1895) in a short time proved financial failures.

The difficulties attending the manufacture of sugar from sorghum depend on the presence of bodies such as starch, gum, non-crystallizable sugar, etc., which tend to prevent its crystallization. These bodies can be largely separated from the sugars by treating the partially evaporated juices with alcohol. Experiments made by the department of agriculture in 1891 indicated that fully 200 lb. of sugar per ton could be made from sorghum in this way. The character of the U. S. internal revenue laws, however, prevents the use of alcohol except under such restrictions as would render it unprofitable.

Extensive experiments were conducted by the department of agriculture from 1888 to 1893 at Sterling and Medicine Lodge, Kan., in the improvement of sorghum as a sugar-producing plant. New varieties were developed and the content of sugar therein greatly increased. Seeds selected from canes with a high content of sugar were carefully propagated and continued from year to year in a direct line of descent. The most approved varieties of sorghum as thus developed are Amber, Folger, Colman, Collier, McLean, Link, No. 8X, No. 112, No. 161, and Orange.

*Sorghum as a Food.*—Sorghum produces seeds which are quite equal to ordinary cereals for food. The composition of sorghum seed is shown in the following table:

| PARTS. | Seeds with glumes, per cent. | Seeds without glumes, per cent. |
|---|---|---|
| Moisture | 9·93 | 9·63 |
| Albuminoids | 10·54 | 11·39 |
| Petroleum spirit extract (oil) | 3·72 | 3·16 |
| Ether extract | 0·61 | 0·54 |
| Eighty-per-cent. alcohol extract (sugar) | 2·91 | 1·78 |
| Fiber | 3·17 | 1·83 |
| Ash | 2·05 | 1·69 |
| Starch and soluble carbohydrates | 67.07 | 69.98 |

Each ton of sorghum will yield from 100 to 150 lb. of seed. Sorghum is also valuable as forage when sown broadcast and harvested as hay or preserved in silos. It is chiefly cultivated for this purpose in Southern and Southwestern Kansas and in many other of the semi-arid regions of the U. S., as it yields a crop which can be relied upon in all seasons. In all parts of the U. S. sorghum is cultivated in a small way for molasses-making. The method of cultivation is almost identical with that of maize, but the young plants require more care. The ripe canes are relieved of their seed-heads and blades and crushed in small three-roll mills usually driven by animal power. The expressed juices are treated with cream of lime heated to the boiling-point and the scums removed. The clear juice obtained is rapidly concentrated in kettles or shallow pans to the consistence of molasses, yielding when carefully controlled a wholesome and pleasant product.

*Statistical.*—The number of gallons of molasses made in the U. S. from sorghum in the census year 1860 was 6,749,-123; in 1870, 16,050,089; in 1880, 28,444,202; in 1890, 24,-235,219. In the last-named year 415,691 acres were cultivated in sorghum. The yield of sugar reported to the internal revenue for the purpose of receiving bounty for the fiscal year ending June 30, 1892, was 1,136,186 lb., for that ending in 1893 1,026,100 lb., and for that ending in 1894 882,572 lb. The average yield of cane per acre was 5·3 tons, and the average yield per ton of cane manufactured 82·5 lb. Much sugar is also made as an incidental product in the manufacture of molasses. HARVEY W. WILEY.

**Soric'idæ** [Mod. Lat., named from *So'rex*, the typical genus, from Lat. *so'rex*, shrew]: a family of mammals of the order *Insectivora*, including shrews or shrew-mice. Externally they resemble mice, but are readily distinguishable by the longer and pointed snout. In contrast with the *Talpidæ*, to which they are most nearly related, they present the following characters: The skull is long, narrow, and pointed; the zygomatic arch is lacking, and there are no post-orbital processes; the tympanic is ring-like: the tibia and fibula are ankylosed; the halves of the pelvis do not meet; there is no cæcum; the teeth range in number from 26 to 36 (M. $\frac{3}{3}$, P. M. $\frac{1-2}{1-2}$, C. $\frac{1}{1}$, I. $\frac{2-4}{1-2} \times 2$); the cusps of the upper molars are arranged in a W; the upper incisors are large and hook-shaped, the first lower incisors are usually directed forward; the cervical vertebræ have well-developed hypapophyses, and the dorsal and lumbar distinct hyperapophyses; the sternum has a broad but not keeled manubrium. The family is a very homogeneous one, and representatives are found in the entire northern hemisphere, and extend southward into India and Eastern Asia in the Old World and into Mexico in the New. The species are all small, and some of them are among the least of mammals. They have certain glands near the fore limbs, on the sides, and behind at the base of the tail, in which is secreted a musky fluid. They feed not only on insects, worms, etc., but on such young vertebrates (birds, etc.) as they are able to overcome.

Revised by F. A. LUCAS.

**Soris**: the name given by Manetho to *Snofru* (*S-uefer-u*, *Snefru*), the first king of the fourth Egyptian dynasty. Little is known about the man himself except that he waged war in Sinai and opened the copper mines in Wâdi Ma'ârah, where the evidences of his labor are still visible. His tomb was the False Pyramid at Mêdûm, built of Mokattam limestone, well jointed, 115 feet high, but never completed. After death he was the recipient of divine honors, and evidences have survived which indicate that his cult continued throughout the remainder of Egyptian history. Monumental remains begin to be numerous from the time of Soris and his successors during the fourth dynasty, and the representations of scenes of private life preserved on the walls of tombs of the period (see MASTABA) show a remarkable degree of civilization. Unger (*Manetho*, p. 92) refers to Soris-Snofru the mention made by Macrobius (*Saturnaliorum conviviorum*, lib. i., 23, § 10) of Senemures or Senepos, whose name in turn has been compared by some with that of the Assyrian Semiramis. The entire identification is founded on conjecture. CHARLES R. GILLETT.

**Sorites**: See LOGIC.

**Soroban**: the Japanese abacus. It differs from the Chinese *swan-p'an* in having, as a rule, only one bead on each wire of the upper or smaller division. It is used in the same way as the Chinese use theirs. See ABACUS.

**Soroca'ba**: a town of the state of São Paulo, Brazil; on the Sorocaba river, a branch of the Tieté; 60 miles W. of São Paulo, with which it is connected by railway (see map of South America, ref. 6–F). It is the center of an important agricultural and grazing district, and is noted for its annual fairs, principally devoted to the sale of horses and mules; as many as 70,000 animals are sometimes placed on sale. Pop. about 12,000. H. H. S.

**Sorrel**: any one of several sour-leaved plants, especially those of the diœcious section, of the genus *Rumex* (family *Polygonaceæ*), to which genus the coarse herbs called dock also belong. The common sorrel of sterile fields is *Rumex acetosella*. Plants of the genus *Oxyria* (of the same family) are called mountain-sorrels. The wood-sorrels are of the genus *Oxalis* (family *Geraniaceæ*). There are numerous species of the genus *Rumex*, some of which are occasionally used as salad-herbs and as flavors for sauces. In Europe the sorrels, mountain-sorrels, and wood-sorrels are cultivated in gardens for table use. All these sorrels owe their sourness to the presence of oxalic acid and its salts.

Revised by L. H. BAILEY.

**Sorrel-tree**, or **Sourwood**: the *Oxydendrum arboreum*, a handsome tree of the U. S., found in Ohio and Pennsylvania and southward to the Gulf. Its leaves resemble those of the peach. They are sour, and from them a cooling drink is made for the sick. The wood is soft and very difficult to dry. It is sometimes planted as an ornamental tree.

**Sorren'to** (anc. *Surrentum*): town; in the province of Naples, Italy; situated on a small rocky peninsula on the south side of the Bay of Naples, protected from the sirocco by Monte Vico, and from the west wind by Monte Massa (see map of Italy, ref. 7–F). It contains an interesting church and numerous villas, with gardens of almost tropical luxuriance. It was a Greek settlement, was adorned with splendid temples during the Roman period, and after the fall of the Western empire was ruled by its own consuls and dukes. Of the old temples, a few fine marbles, mosaic pavements, etc., alone remain, besides the foundations. The climate of Sorrento, as agreeable as it is salubrious, the luxuriance of the vegetation, and the variety and beauty of the surrounding scenery, have made Sorrento one of the most frequented resorts in Southern Italy. There is a small coasting trade in the rich productions of the vicinity carried on by means of the little harbor. It is the birthplace of Torquato Tasso. Pop. about 6,090.

**Sotades**, sot'ă-deez (Gr. Σωτάδης): Greek poet of Maroneia in Thrace; a composer of indecent farces, whose jest at the marital relations of Ptolemy Philadelphus and his sister Arsinoë cost the jester his life. Sotades has given his name to a variety of Ionic verses, the *Metrum Sotadeum*. The fragments have been collected and restored by G. Hermann, *Elementa Doctrinæ Metricæ*, p. 445. B. L. G.

**Soter**: See PTOLEMY.

**Soteriol′ogy** [Gr. σωτηρία, salvation, deriv. of σωτήρ. savior + λόγος, discourse, reason]: that branch of theology which treats of the redemptive work of Christ. In its wider signification the term includes both the atonement which Christ made and its application through faith to individuals. Thus defined, it would comprise not only the doctrine of expiation, but also those of regeneration, justification, and sanctification. It is, however, used in a more restricted signification, to denote only the atonement. See ATONEMENT.

**Sothern**, sŭth′ern, EDWARD ASKEW: actor; b. in Liverpool, England, Apr. 1, 1830. He disappointed his parents by not entering the Church; made his *début* as an amateur actor in Jersey; went to the U. S. in 1852, and appeared first at the Boston National theater, under the stage name of Douglas Stewart; created the character of Lord Dundreary in the play of *Our American Cousin* at Laura Keene's theater, New York, 1858, and represented it many hundreds of times with great popularity in the U. S. and in England. Favorite parts of his were David Garrick, in the play of that name, Fitz Altamount in *The Crushed Tragedian*, and Brother Sam. Sothern was very popular socially, and a great practical joker. D. in London, Jan. 20, 1881.
Revised by B. B. VALLENTINE.

**Sothic Period** [*Sothic* is from Greek Σῶθις, Egypt. *Sopt*, the dog-star]: a period of 1,460 Julian years (of 365¼ days), equal to 1,461 vague years (of 365 days) of the Egyptian calendar. In the latter the year was reckoned by twelve months of thirty days, with the addition of five intercalary days. The difference between the two thus amounted to about six hours annually, so that the vague year receded about one day in each four years. The beginning of a Sothic period was marked by the coincidence of the heliac rising of Sirius with the calendar new year, and at the rate of divergence between the two systems this coincidence recurred once in about $4 \times 365 = 1,460$ solar years. In the course of a Sothic period any periodic event, such as the inundation of the Nile or the rising of the dog-star, fell upon each and every day of the civil calendar. The difference in the appearance of such periodic events was not marked in the life of an individual, being only about twenty-five days in a century. Consequently little attention was paid to the matter till in the Ptolemaic dynasty, when the Sothic period seems first to have been used in calculating time.

Dr. Mahler, of Vienna, has employed the Sothic period in calculating Egyptian chronology, starting with the statement of Censorious (239 A. D.) that the heliac rising of Sirius occurred on July 21, 139 A. D. Reckoning back, this event occurred on about the same day in (approximately) 1322 B. C., 2782 B. C., and 4242 B. C. By the use of monumental and other data he arrived at the conclusion that the reign of Thothmes III. extended from Mar. 20, 1503, to Feb. 14, 1449, B. C., a result agreeing remarkably with that derived from a "dead-reckoning" by lengths of reign as given by Manetho and the monuments. Similarly Petrie fixes provisionally the date of the beginning of the sixth dynasty at 3410 B. C., and, reckoning the preceding dynasties according to monumental and other evidence, he assigns the beginning of the first dynasty to the year 4777 B. C. There is uncertainty about this result, but it is apparently more exact than any given previously, and it is claimed that it reduces the margin of doubt from a thousand or more years to one or two hundred at the outside. CHARLES R. GILLETT.

**Sothis**: another name of SIRIUS (*q. v.*).

**Soto**, HERNANDO OR FERNANDO, de: discoverer of the Mississippi river; b. at Jerez de los Caballeros, Estremadura, Spain, about 1500. He went to Darien with Pedrarias in 1514, accompanied Cordoba in the conquest of Nicaragua 1524, and opposed his subsequent rebellion. In Apr., 1532, he joined Pizarro with re-enforcements; in the conquest of Peru he acquired great wealth, with which he returned to Spain in 1536. Soon after he was appointed governor of Cuba and Florida, with a commission to explore and settle the latter country, then including all the northern coast of the Gulf of Mexico. On May 12, 1539, he sailed from Havana with nine vessels and 600 (or 950) men. His explorations began at Tampa Bay July 15; they covered a large area, and the route can now be determined only approximately. It is certain that he passed through Northern Florida, Georgia, probably South Carolina, and Tennessee, and perhaps North Carolina, before descending the Alabama river. In Oct., 1540, he had a battle with the Indians near Mobile Bay; thence he again turned northward, and about May, 1541, crossed the Mississippi at the lower Chickasaw Bluffs; explored the river northward nearly to the Missouri, and, returning southward, died of fever near the junction of the Mississippi and Red rivers, probably on May 21, 1542. During the three years' wanderings 250 men had perished of disease and privation or in battle with the Indians. The survivors, under Moscoso, descended the river and reached Mexico. Soto is properly regarded as the true discoverer of the Mississippi, though Pineda found its mouth in 1519, and Cabeza de Vaca must have crossed it near the Gulf in 1528.
HERBERT H. SMITH.

**Souari-nut**: See CARYOCAR.

**Soublette**, soo-blet′, CARLOS: soldier and statesman; b. at Caracas, Venezuela, 1790. He joined the revolutionists in 1810, distinguished himself in the war for independence, especially under Bolivar in the New Granada campaign; attained the rank of general, was vice-president and general-in-chief in Venezuela 1821–23 and Minister of War for Colombia 1826–27. He supported Bolivar's attempt, in 1829, to maintain the union of Colombia; but when Venezuela seceded in 1830 he remained faithful to his native country, presided over the constitutional convention of that year, and was the Venezuelan Secretary of War 1830–34. In 1835 he was envoy to Spain, and was elected vice-president under Vargas; by the resignation of the latter soon after he became acting president. He left the government with Narvarte, and went on a special mission to Spain to arrange a treaty with that kingdom. In this he was unsuccessful. On his return he resumed the presidency, which he retained until Feb. 1, 1839. Under Paez, 1839–43, he was Secretary of War, and he succeeded him as president Jan. 28, 1843, to Mar. 1, 1847. During the disorders of 1848 he was banished, residing at Bogotá until 1858. Subsequently he held cabinet positions, and commanded the Venezuelan army. He was greatly respected. D. at Caracas, Feb. 11, 1870. HERBERT H. SMITH.

**Soudan**: See SUDAN.

**Soul** [O. Eng. *sāwel*, *sāwl*: O. H. Germ. *sēla* (> Mod. Germ. *seele*): Goth. *sai'wala*]: a term variously used to signify either the principle of life in an organic body, or the first and most undeveloped stages of individualized spiritual being, or, finally, all stages of spiritual individuality, incorporeal as well as corporeal. Aristotle, whose treatise *De Anima* (Περὶ ψυχῆς) is the first and perhaps the greatest work on the subject, has himself introduced this confusion by defining the soul in one instance as the self-determining power (ἐντελέχεια) of an organized body, and then afterward attributing to it reason (νοῦς), and making it as reason entirely separable from body. If strictly limited to the phases of relation which the mind has toward its organic conditions, the science of the soul is properly termed anthropology, and treats first of the cosmic, sideric, and telluric influences upon mind—the determining characteristics of race, age, the seasons, the climate, the solar and lunar periods, etc. Next comes the reaction against these determining influences of nature, as manifested in the antithesis of sex, the alternation of waking and sleeping, and in the phenomena of dreams, fœtal life, somnambulism, clairvoyance, catalepsy, St. Vitus's dance, and the various forms of vicarious sense-perception (where seeing, hearing, tasting, etc., are performed by the organ of feeling, the skin, in diseased states of the organism), trance-exaltation, etc. It considers next the questions of arrested development, such as appears in idiocy; the return to the previous stages out of the stage of consciousness, and the mingling of the two (earlier and later) phases in insanity (wherein the Ego is unable to distinguish between the phenomena of sense-perception and those arising from the influence of general external conditions, or from diseased activity of the nervous organism, and is thus confused, now acting upon one set of data and then upon another). Through the stages of feeling and the reduction of external relations to the abstract uniformities of habit, and especially in the creation of conventionalities whereby language becomes possible, and with it the formation and expression of general ideas, mind rises into the phase of Consciousness and Reason, knows itself as individual and independent of external natural influences, and accordingly subordinates and eliminates these in manifold ways through institutions—family, civil society, state, church, science, etc.—and learns to recognize conscious immaterial personality as the highest principle of the universe. The much-debated question of the immortality of the soul implies a definition of soul as including not only its phases of corporeal existence, but also the higher ones of thought and will. Hence if ψυχή (soul) be only the principle of organic life, and νοῦς (reason) be the principle of intelligence elevated above the former and transcending it, the immortality of the former is precluded by definition, for the principle of conscious individuality is placed in the latter.

Previous to Aristotle and Plato the theories regarding the soul were mostly crude suggestions. The Pythagoreans thought that the soul is a harmony—that it dwells in the body as in a prison, being confined there for punishment. Many conjectures as to the location of the soul have been made. Alcmæon of Crotona (according to Theophrastus) taught that the soul was located in the brain, "whither all sensations were conducted from the organs of the senses through canals." Like other Pythagoreans he held that the soul was subject to eternal motion, like the stars. Philolaus the Pythagorean held that the soul is united to the body, which is its organ, and at the same time its prison, by number and harmony, all things being known through number as a common principle of the soul and of things—like being known by like. Anaxagoras attributed souls to plants, and affirmed that they sorrow and rejoice. Democritus, who explained everything through the "atom and the void," held soul and fire to possess "round atoms," because they manifested the maximum of mobility. He affirmed that thought arises when the motions of the soul are "symmetrical"; and, further, that "the soul is the noblest part of man; he who loves its goods, loves what is most divine. He who loves the goods of the body, which is the tent of the soul, loves the merely human." Critias the Sophist considered the blood to be the substratum of the soul. Plato (in the *Phædrus*) makes three souls or phases of the soul: (*a*) the appetitive soul seeking happiness or sensual pleasure, the gratification of desire; (*b*) the irascible or courageous soul, manifesting itself in combative activity, as the former in passive receptivity; (*c*) the rational soul, which alone is immortal. The cognitive or rational soul is the soul in its totality, and the irascible and appetitive souls are merely phases of arrested development occasioned by the confinement of the body. The rational soul dwells in the head (agreeing with Alcmæon), the irascible in the heart, the appetitive in the organs of nourishment and reproduction. Plato defines (*Leg.*, cap. 10) the soul as a self-moving activity (κίνησις ἑαυτὴν κινοῦσα). Transmigration of souls (*Phædo*), a doctrine apparently borrowed from Egypt and the Orient, is consonant with his theory of the pre-existence of the soul, and of the origin of the appetitive and irascible phases of the soul through the descent of the rational soul into a body. Having made the discovery of general and necessary ideas, which could not have originated in sense-perception, he undertook to account for them through reminiscence: the soul had perceived them in a former life. These ideas, *a priori*, were simple and eternal: how could the soul in which they were contemplated be other than simple and eternal? While he condemned the Pythagorean view that the soul was a harmony, Plato employed symbolic expressions quite similar. In the same spirit his successor in the Academy, Speusippus, defined the soul as "extension, shaped harmoniously by number"; hence as, in some higher sense, a unity of the arithmetical and geometrical. So, too, Xenocrates of Chalcedon, the second director of the Academy, taught that the soul is a self-moving number. Aristotle repudiated the use of symbolic language in definitions to avoid ambiguity. He defined soul (*De An.*, ii., 1) as "the first entelechy [self-actualizing energy] of a physical, potentially living and organic body." The first entelechy is not a fully realized being, and hence it has been inferred that he intended to exclude the reason (νοῦς) from his definition of the soul, especially, too, as he makes the νοῦς to be independent of the body. But in another place he makes the soul to be "that by which we live, feel or perceive, move, and understand." The νοῦς ποιητικός = the *actus purus*, or pure reason, exists before the body, and enters it from without (θύραθεν) as something divine and immortal (*De Gen. et Corr.*, ii., 3). The νοῦς παθητικός = passive reason, including the nutritive (vegetable), sensitive (animal), and so much of the rational soul as includes memory, imagination, sense-perception, and discursive intellect, he regarded (*De An.*, ii., 2) as perishable like the body. Exactly what he meant by this was long in dispute. Alexander of Aphrodisias, the great commentator, held that the active reason is the world-soul, and that individuals are mere incarnations of it which perish with the body. Dicæarchus of Messene, pupil of Aristotle, had held this doctrine. The Stoics had held nearly the same doctrine, acknowledging that the soul outlives the body, but is not eternal. Cleanthes the Stoic asserted that all souls would exist until the general conflagration of the world; but Chrysippus limited this to the souls of the wise, while Panætius denied the future life altogether. The statements of Aristotle, taken together, indicate his belief in the existence of the soul independent of the body; and not merely as a general world-soul, but also as individual souls.

In the process of education, culture, or self-development the individual gradually eliminates his lower phases of thought; he depends less upon sense-perception, learning to know a great deal from seeing very little (Cuvier could describe the whole animal from one of its bones; Agassiz, a fish from one of its scales); mechanical memory likewise becomes less important as deduction from principles becomes more prominent; discursive intellect gives place to pure intellect. Thus the lower faculties die out, and give place to more perfect forms; they become useless in the presence of more adequate forms of cognition. Hence Aristotle was correct in describing them as transient and perishable like the body; and yet he did not at all deny, by this, future conscious identity to the individual. The active reason could energize as nutritive, locomotive, appetitive, and sensitive, organizing a new body; for organization was only a self-limitation of the active reason, a self-arrested development of it. Hence when Averroës revived the doctrine of Alexander of Aphrodisias, the great scholastic thinkers devoted themselves to this question until they reconciled Aristotle with himself through this theory of the union of the active and passive reasons—the former as independent and substantial, and the latter as eternally produced through its energy. Albertus Magnus held that the active reason bears within itself the vegetative, sensitive, appetitive, and motive faculties. Thomas Aquinas held, similarly, that as the soul is immaterial, it can not be destroyed through the removal of its substratum. The form-producing principle of the body, the vital force, the appetitive, sensitive, and motive powers, belong to the thinking substance, and do not inhere in the body; hence are immortal. Pure thought acts without organs; the lower functions of the soul act with organs created for temporary manifestation. This view substantially agrees with that of the Neo-Platonists, except as to the origin of the soul. "The soul is immaterial, and whole or entire in every part of the body"; this statement is constantly repeated by thinkers since Aristotle. Plato's doctrine of pre-existence and reminiscence is indorsed by some of the Platonizing Christian thinkers like Origen, Synesius, and Nemesius, but is generally repudiated, as by Arnobius, Justin Martyr, Gregory of Nyssa, St. Augustine, Æneas of Gaza. With Descartes, thinking substance is so sharply distinguished from matter that only divine intervention will account for their interaction. Geulincx, Malebranche, and Leibnitz presented different solutions of this dualism, but Spinoza boldly denied it altogether, making mind and matter two attributes of one substance. La Mettrie, a pupil of Boerhaave, observing the effect of the increased circulation of the blood upon his thoughts during a fever, concluded that psychical functions are all to be explained by the organization of the body. Diderot held that atoms are endowed with sensation, and that when combined in the animal organism they become conscious, thus reviving the doctrine of Democritus and Epicurus, who made the soul material, and perishable upon the separation of its constituent atoms. Carl Vogt makes the phenomena of the soul to be functions of the brain and nerves. Moleschott and Büchner have promulgated and popularized the same doctrine. Kant endeavored to show that the metaphysical argument which proved the immortality of the soul from its nature as simple substance is a paralogism, because the Ego which thinks is subject only, and does not appear as object in consciousness. Herbart, however, defends the idea of the soul as a simple, spaceless essence; and his disciple, Beneke, expounds the same doctrine. Trendelenburg returns to the Aristotelian definition: "The soul is a self-realizing, teleological idea; not a result, but a principle." At present there is great activity among the physiological school of writers, who are investigating the physical correlates of psychical action. See articles on PSYCHO-PHYSICS, PSYCHOMETRY, PSYCHOLOGY, HYPNOTISM, IMMORTALITY, and other topics relating to the soul. WILLIAM T. HARRIS.

**Soulé**, CAROLINE AUGUSTA: See the Appendix.

**Soule**, Joshua, D. D.: bishop; b. at Bristol, Me., Aug. 1, 1781; was licensed as a Methodist preacher 1798; was presiding elder of the Maine district 1804–13; was author of the plan for a delegated general conference of his Church, adopted at Baltimore 1808; was editor of *The Methodist Magazine* 1816–20; declined a bishopric 1820, but was again elected and accepted 1824; resided for several years at Lebanon, O.; was a delegate to the British Wesleyan Conference 1842; adhered to the Methodist Episcopal Church South on the division of the Church 1844; settled at Nashville, Tenn.; visited California on an episcopal tour 1853–54; continued active in the discharge of the duties of the post until his death at Nashville, Mar. 6, 1867.

**Soulé**, soo'lā', Pierre: U. S. Senator; b. at Castillon, France, in Sept., 1802; educated for the Roman Catholic priesthood in the Jesuit college at Toulouse; studied afterward at Bordeaux. Being implicated in a conspiracy against the government of Louis XVIII., he fled to a village in Navarre, where for more than a year he followed the occupation of a shepherd; then went to Paris; became a writer for a republican newspaper, *Le Nain*; was imprisoned in Ste.-Pélagie for an attack on the ministry; escaped to England; removed to the U. S. and settled at New Orleans 1825; was U. S. Senator 1847–53, and distinguished for extreme Southern views; was appointed minister to Spain 1853; had a duel with the French ambassador at Madrid; took part in the Ostend conference of Oct., 1854, intended to facilitate the acquisition of Cuba; returned to the U. S. 1855; opposed the secession of Louisiana, but ultimately adhered to the movement, and visited Europe as Confederate agent 1861; was imprisoned for disloyalty at Fort Lafayette 1862; was released on condition of leaving the country; went to Europe, where he remained six years; returned to Louisiana 1869. D. in New Orleans, Mar. 16, 1870.

**Soulié**, soo'li-ā', Melchior Frédéric: novelist and poet; b. at Foix, department of Ariège, France, Dec. 23, 1800; studied law; made his *début* in literature in 1824 with a volume of poems, *Amours français*, which passed by almost unnoticed, and wrote in 1828 *Roméo et Juliette*, and in 1829 *Christine à Fontainebleau*, which had much effect on the stage. Others of his dramas were also successful—*Clotilde* (1832) and *La Closerie des Genêts* (1846); but it was principally as a novel-writer that he became famous. He wrote about 150 volumes of novels, some of which became very popular, such as *Le Comte de Toulouse* (1835); *Un Été à Meudon* (1836); and *Mémoires du Diable* (1837–38). D. at Bièvre, near Paris, Sept. 23, 1847.
Revised by A. G. Canfield.

**Soulouque**, soo'look', Faustin Élie: soldier and politician; b. at Petit Goyave, Haiti, about 1785. He was originally a Negro slave; took part in the early insurrections and in the civil wars on the side of the blacks; rose to be general of division, and, owing to his race and long services, possessed great influence with the Negroes. On Riché's death the senate elected Soulouque president Mar. 1, 1847. Apparently the senators had imagined that he would be their facile tool, owing to his age and ignorance; but he displayed unexpected energy, and his leadership of the blacks soon gave him dictatorial power. In Mar.–Apr., 1849, he invaded the Dominican Republic, but was repulsed. Notwithstanding this reverse he was able to have himself proclaimed emperor Aug. 26, 1849, and was crowned as Faustin I. in 1852; he promulgated a constitution, but practically had despotic power. His rule in some respects was wise, but his persecution of the mulattoes was unrelenting. In 1855 he was disastrously defeated by Santana in a second invasion of the Dominican Republic. In Jan., 1859, a successful revolt of the mulattoes under Geffrard drove him into exile at Jamaica. He was allowed to return in 1867, and died at Petit Goyave, Aug. 6 of that year. H. H. Smith.

**Soult**, soolt, Nicolas Jean de Dieu, Duke of Dalmatia: soldier; b. Mar. 29, 1769, at St.-Amans-la-Bastide, department of Tarn, France; the son of a farmer; entered the ranks of the army in 1785; became a captain in 1793, brigadier-general in 1794, general of division in 1799, and marshal of France in 1804. He distinguished himself greatly in the battles of Austerlitz and Jena, and was made Duke of Dalmatia after the Peace of Tilsit. He was then placed in command of the second corps in Spain, and succeeded in forcing the British to evacuate the country. In 1809 he became commander-in-chief, and soon afterward gained the victory of Ocaña. On 1811 he lost the battle of Albuera, and, discouraged by his reverses and the obstinacy of Joseph Bonaparte, obtained his recall, but after the defeat of the French and Spanish at Vittoria was again placed in command. Though he displayed great skill and energy he was compelled to retreat into France, and was defeated at Orthez and before Toulouse. Made Minister of War during the first restoration, he joined Napoleon during the Hundred Days, and lived in exile at Düsseldorf from 1815 to 1819. Allowed to return in the latter year and reinstated in his dignities in the army, he soon won the favor of Charles X., and was made a peer of France in 1827. Under Louis Philippe, between 1834 and 1847, he was several times Minister of War, Minister of Foreign Affairs, and president of the cabinet, but in 1847 retired from public life, having been made a marshal-general of France—a dignity which had been conferred previously only on Turenne and Villars. D. at St.-Amans, Nov. 26, 1851. The first part of his *Mémoires* was published by his son in 1854, in three volumes.

**Sound**: See Acoustics.

**Sound, Diffraction of**: the deviation of sound-waves in passing an obstacle. It was shown by Huyghens, in 1678, that if a wave is propagated in an elastic medium each point in the wave-front is a center from which secondary waves are propagated. If the main wave passes an obstacle, the edge of this serves as a center around which the secondary waves become perceptible. The extent of this deviation depends jointly on wave-length and velocity of propagation, increasing with wave-length and diminishing with velocity. It follows that a mathematical shadow is not possible, but in the case of light the waves are so short and they are propagated so rapidly that the deviation due to diffraction is exceedingly small. Sound-waves, on the contrary, may be many feet in length, and the rate of propagation through air is only about a fifth of a mile per second. To render acoustic diffraction effects perceptible the waves must be very short, and this implies high pitch.

Lord Rayleigh was the first to demonstrate the diffraction of sound with any approach to exactness. (Royal Institution lecture, Jan. 20, 1888.) The source of sound was an adjustable whistle, or bird-call, the pitch of which exceeded 20,000 vibrations per second. This exceeds the limit of audibility for the average ear, and therefore a sensitive flame was employed as an indicator. An acoustic diffraction grating served to bring sound-waves to a focus, as light is focalized with a lens. Stevens (*American Journal of Science*, Apr., 1889), using the flame indicator and a whistle giving 13,000 vibrations per second, succeeded in mapping out the lines of interference produced by diffraction behind a screen, through which two openings had been made for the transmission of waves. Also aërial bands of noise and silence were traced out with the flame, these being produced by interference of direct and reflected waves of sound from the whistle. The position of these bands was found to accord well with the results of calculation based on the theory of interference. W. Le Conte Stevens.

**Sound-pendulum**: See Recording Apparatus, Psychological, in the Appendix.

**Sound, Refraction of**: See Refraction.

**Sou'ris**: port of entry of King's County, Prince Edward island, Canada; on both sides of the mouth of the river Souris (see map of Quebec, etc., ref. 1–C). There are two villages, East and West Souris. Fishing and ship-building are carried on. Pop. 700.

**Sour-sop**: the fruit of the *Anona muricata*, a beautiful tree of tropical America. The sour-sop often weighs 2 or 3 lb. Its taste is sour and pleasant. It is very soft and white, and is much eaten in the West Indies.

**Sourwood**: See Sorrel-tree.

**Sousa**, John Philip: See the Appendix.

**Sousa**, or **Souza**, soo'zaă, Martim Affonso, de: soldier and colonizer; b. at Bragança, Portugal, about 1500. He was of noble family, and a member of the royal council. In 1530 he was placed in command of five vessels and 400 men, with orders to explore the coast of Brazil and plant there a permanent Portuguese colony; at the same time he was created governor of New Lusitania, as Brazil was then officially named, and was empowered to distribute lands. After a careful survey, extending to the Rio de la Plata, he founded the first Portuguese colony, São Vicente (near the modern Santos), Jan. 22, 1532; soon after, Piratininga, now São Paulo, was founded by his orders. He then returned to Portugal, and on his recommendation the Brazilian coast was divided into the hereditary captaincies which, with various changes were the bases of the modern states. Martim Affonso himself received a grant of the most important of these captaincies, that of São Vicente, then comprising all of Southern Brazil. He did not personally return to it, but it flourished under governors whom he selected. He was admiral of the seas of India 1534–40, and gained there several brilliant victories; in 1542–45 he was governor of the Portuguese East Indies. D. in Lisbon, July 21, 1564.

HERBERT H. SMITH.

**South**, ROBERT, D. D.: preacher and controversial writer; b. at Hackney, London, England, in 1633; studied as a king's scholar at Westminster School under Dr. Busby; entered Christ Church, Oxford, and graduated 1654 (D. D. 1663); took orders in the Church of England 1658; was university orator 1660; became chaplain to the Earl of Clarendon and tutor to his children 1661; was made prebendary of Westminster 1663; chaplain to the Duke of York 1667; canon of Christ Church 1670; chaplain to Lawrence Hyde (afterward Earl of Rochester) 1676, and accompanied him on an embassy to John Sobieski, King of Poland, 1677; became on his return rector of Islip, Oxfordshire, 1678, and soon afterward chaplain to King Charles II.; was a vigorous advocate of passive obedience and of the divine right of kings, and a powerful opponent of Dissenters, and was esteemed one of the most eloquent preachers of the time. D. in London, July 8, 1716. He caused much talk in his time by his controversial publications against Rev. Dr. William Sherlock, dean of St. Paul's, whom he accused of tritheism. He published collected editions of his sermons (London, 1692, 6 vols.; 4th ed. 1715; new ed. enlarged 1744, 11 vols.; edited by W. G. T. Shedd, New York, 1867, 5 vols.). See his complete works, with memoir (Oxford, 1823, 7 vols.; new ed. 5 vols., 1842). A selection, with memoir, appeared in London 1867. Revised by S. M. JACKSON.

**South African Republic**, or **Transvaal' Republic**: formerly one of the independent Boer states in South Africa, now a colony of Great Britain, lying between the Vaal river on the S., the Limpopo river on the N., between the Portuguese coast possession on the E., and British Bechuanaland on the W. By treaty with Great Britain (1884 and 1890) the New Republic formed by the Boers in Zululand, and a small part of Swaziland and Amatongaland, were added to the South African Republic, which has an area of 113,642 sq. miles and a white population (estimated 1897) of about 250,000. The black population is estimated at about 375,000, East Bechuanas and various other Kaffir tribes. On Feb. 21, 1895, Swaziland was placed under the protection and administration of the republic. It has an area of 6,150 sq. miles, and a population of 60,000 natives, besides 600 (in winter 1,500) whites.

*Physical Features, Products, etc.*—The country is a healthful, high, and undulating plateau, with wide-spreading hill and mountain features extending through the interior, from the southern border almost to the northern frontier. It is abundantly timbered near its eastern border. Its western and northwestern portions are steppe-like in character. Its best agricultural resources are found on the high, well-watered plains of the southern portion, and the greater part of the country is well adapted for farming and stock-raising.

The Boers are pre-eminently stock-raisers and their sheep and cattle form their principal wealth. Great as the resources of the country are, the Boers are not yet able to supply all the food required by the enormous influx of gold-miners. About 50,000 acres are under cultivation.

The southern and southeastern districts are the greatest centers of South African gold-mining, and in a few years have made South Africa the third largest gold-producer in the world. The output in 1892 was 1,325,394 oz., by far the greater part of which came from the Witwatersrand and Barberton districts; in 1893, 1,610,335 oz.; in 1894, about 2,200,000 oz.; and in 1895, 2,494,487 oz. In 1886 the site of Johannesberg on the Witwatersrand was occupied by a few huts where now (1896) stands a city of 102,714 inhabitants. The capital is PRETORIA (*q. v.*). Excellent coal is also found; lead and silver are being mined, and there are rich resources of iron. In its mineral and agricultural resources the republic is one of the richest regions of like extent in the world, but, except in gold-mining, little has yet been done to develop its natural wealth.

The total mileage of railways open in Sept., 1898, was 774, under construction 270, and projected 252. The line from Capetown to Kimberley has been extended to Pretoria. The extension of the Natal line from Charlestown on the southern frontier to the capital was opened in 1895, as was the railway from Delagoa Bay to Pretoria (a distance of 295 miles). Important articles of export are gold, wool, cattle, grain, skins, leather, fruit, tobacco, butter, brandy, ostrich-feathers, ivory, silver, lead, and copper. The revenue in 1898 was £3,983,560 (£1,066,995 was from the gold-fields); expenditure, £3,971,473; imports, £10,632,893; exports, about £9,000,000. The public debt on Dec. 31, 1898, was £2,660,394. See SOUTH AFRICAN REPUBLIC in Appendix.

*History.*—For the early history of the Boers, who are of Dutch and Huguenot descent, see CAPE COLONY. A number of them, who had left Cape Colony for Natal, again removed from under British rule and founded the South African Republic, which was recognized as a free state by the British, in 1852. In consequence of trouble with the natives it was annexed by the British in 1877; but in 1880 the Boers revolted, and in 1881 the retrocession of the country took place under British suzerainty, which underwent a modification in 1884. There have been frequent wars with the Kaffirs, who in 1894 suffered a severe defeat Aug. 29. The constant friction between the Boers and the great number of British subjects, who emigrated into the country through the development of the gold mines, led up to the Transvaal war of 1899–1900. (See AFRICA.) After the capture of Pretoria by Lord Roberts it was made the Transvaal colony of Great Britain.

See Greswell, *Geography of Africa, South of the Zambezi*; Keltie, *The Partition of Africa*; Mather, *Zambesia*; and Silver, *Handbook of South Africa*. C. C. ADAMS.

**South Amboy**: borough (founded in 1835); Middlesex co., N. J.; on Raritan Bay at the mouth of the Raritan river, and on the Penn., the N. Y. and Long Branch, and the Raritan River railways; 37 miles S. W. of New York city, 60 miles N. E. of Philadelphia (for location, see map of New Jersey, ref. 3–D). It is a large coal-shipping point, and contains Baptist, Methodist Episcopal, Methodist Protestant, Presbyterian, Protestant Episcopal, and Roman Catholic churches, two large public schools, a large Roman Catholic parochial school, asphaltum-works, several potteries, clay-pits, sand-pits, a national bank with capital of $50,000, and a weekly newspaper. Pop. (1880) 3,648; (1890) 4,330.

M. N. ROLL, EDITOR OF "CITIZEN."

**South America**: See AMERICA, SOUTH.

**Southampton**, county of England: See HAMPSHIRE.

**Southampton**: seaport in Hampshire, England; on a peninsula, at the head of Southampton Water; between the estuaries of the Test and Itchen; 23 miles N. W. of Portsmouth and 79 miles by rail S. W. of London (see map of England, ref. 13–H). Of the walls built in the time of Richard II. there are considerable remains, and four of the seven gates are well preserved. Southampton contains many old buildings, among which is the *Domus Dei*, an hospital dating from the thirteenth century; also St. Michael's church (1080), since altered and restored. Among modern structures are the Watts Memorial Hall (1876); St. Mary's Church, designed by Street; and the Hartley Institution, a college with thirteen teachers. The old docks (1842 and 1851) have been greatly improved and extended, and a new tidal dock, 18 acres in extent, was opened in 1890. There are also four dry docks. A graving-dock, the largest in Great Britain, was opened in 1895. Mail steamers for the U. S., the West Indies, Brazil, and South Africa arrive and depart here, and vigorous efforts have been made to compete with Liverpool in this respect. There are large exports of British manufactures. Provisions, etc., from France and the Channel islands, and cattle from Spain and Portugal are imported. In 1893 the total tonnage entered and cleared, exclusive of that coastwise, was 2,130,753. Ship-building and the manufacture of engines are carried on. About a mile N. was the Roman station of Clausentum. The present town was founded by the West Saxons soon after 495; it is mentioned as Hantune in Domesday Book. The parliamentary borough returns two members. Pop. (1891) 82,126; (1900) 103,500.

**Southampton** (P. O. name SAUGEEN): a port of entry of Bruce County, Ontario, Canada; at the mouth of Saugeen river, on Lake Huron; 60 miles N. by E. of Goderich (see map of Ontario, ref. 3–C). It is the northwest terminus of the Wellington, Grey, and Bruce Branch of the Grand Trunk Railway. Grain and lumber are the chief exports. Pop. 1,200.

**Southampton**: village (incorporated in 1894); Suffolk co., N. Y.; on the south shore of Long Island, between

Peconic Bay and the Atlantic Ocean, and on the Long Island Railroad; 90 miles E. by S. of New York (see map of the State of New York, ref. 8–F). It is the oldest English settlement in the State of New York; was known to the Indians as Agawam; settled by colonists from Lynn, Mass., in 1640; self-governed till 1645, when it attached itself to Connecticut; granted to the Duke of York by Charles II. in 1664; and has since belonged to New York. It was occupied by the British during the Revolutionary war, and has a well-preserved fort of that period. The village contains 4 churches, graded public school, kindergarten, Rogers Memorial Library (incorporated in 1893, building erected in 1895), a State bank with capital of $25,000, 3 halls, electric lights, and a weekly newspaper. It is principally engaged in agriculture, has brick and tile works, and is a popular summer resort. Pop. (1900) 2,289.

C. A. Jagger, Ph. D., editor of "Seaside Times."

**Southampton**, Henry Wriothesley, Third Earl of: statesman; b. Oct. 6, 1573; was a patron of Shakespeare, who dedicated to him the poems *Venus and Adonis* and *The Rape of Lucrece*. He was a friend of the Earl of Essex, whom he accompanied to Cadiz, and in 1599 to Ireland; was accused of complicity in the treasonable designs of Essex; protested his innocence; was convicted, and sentence of death and attainder was pronounced, but Elizabeth remitted the death-penalty, and the attainder was removed by Parliament soon after the accession of James I. He was an assignee of the patents of settlement of Sir Walter Raleigh, and took a prominent part in the early colonization of America, and in the second charter of Virginia his name occupies a leading position, and he became the governor of the Virginia Company. In Parliament he was a firm supporter of liberty; and in 1621 was committed to close custody by the king, but was released through the influence of Buckingham. He soon after went, accompanied by his son, Lord Wriothesley, to the Netherlands, to aid the Dutch in their struggle against Spain, and took command of a regiment. D. at Bergen-op-Zoom, Holland, Nov. 10, 1624.

**Southard**, Samuel Lewis, LL. D.: U. S. Congressman; son of Henry Southard, also a Congressman; b. at Baskingridge, N. J., June 9, 1787; graduated at Princeton 1804; taught school in New Jersey, and was a family tutor in Virginia several years, during which time he studied law and was admitted to the bar; settled at Flemington, N. J., 1811; appointed law-reporter by the Legislature 1814, associate justice of the Supreme Court 1815; was U. S. Senator from Jan. 22, 1821, to 1823, serving a considerable time as president *pro tem.* of that body; was appointed by President Monroe Secretary of the Navy 1823; was acting Secretary of the Treasury four months 1825, and for a short time acting Secretary of War; was chosen attorney-general of New Jersey 1829; Governor 1832; U. S. Senator 1833; resigned May 3, 1842. He became a trustee of Princeton College 1822, and soon afterward of the Theological Seminary, and was offered, but declined, the Whig nomination for Vice-President on the ticket with William H. Harrison, thereby losing also the post of President, to which he would have succeeded by Harrison's death, on which occasion, however, he was for the second time chosen president *pro tem.* of the Senate. D. at Fredericksburg, Va., June 26, 1842.

**South Australia**: one of the seven British colonies of Australasia, occupying a central north and south band of Australia, from the Arafura Sea to the Southern Ocean, with Queensland, New South Wales, and Victoria on the E. and Western Australia on the W.; between the parallels of 11° S. and 38° S. (see map of Australia). The meridian of 129° E. forms the western boundary; on the E. the boundary is the meridian of 138° from the Gulf of Carpentaria S. to 26° S., thence southward it is the meridian of 141° E. The greatest length is 1,850 miles N. and S., and the average breadth 650 miles. It also embraces a number of islands, of which the largest are Kangaroo island (1,700 sq. miles), off the mouth of St. Vincent Gulf in the Southern Ocean; Melville island (80 miles long by 30 broad) and Bathurst island, both off Port Darwin, in the Arafura Sea; and Groote Eylandt (about 40 miles in each direction) in the Gulf of Carpentaria. Total area, 903,690 sq. miles. The district N. of the parallel of 26° S. is called the Northern Territory.

*Physical Configuration.*—South Australia has a coast 2,000 miles long, of which 1,100 miles are on the Southern Ocean, in large part on the desolate shores of the great Australian Bight, which has a few minor bays, as Port Eyre and Denial, Smoky, Streaky, and Coffin Bays. On the meridian of 137° E. the shore is broken by the great Spencer Gulf, extending N. 200 miles, with a greatest width of 70 miles, and in the extension of its axis, but not connected with it, are Lake Torrens and the Eyre lakes, two of them the largest lakes in the colony. On the west side of Spencer Gulf the country is arid and infertile, but on the east it is fertile and has great mineral wealth. Further E. is the smaller St. Vincent Gulf, separated from Spencer Gulf by Yorke Peninsula and sheltered at its mouth by Kangaroo island. The country to the E. is the most thickly populated in the colony and contains Adelaide, the capital. Next E. is the broad shallow Encounter Bay, and behind its low sandy shores are Lakes Alexandrina and Albert, expansions of the Murray river, and connected with them the long, slender, coastal lagoon called Coorong.

The northern coasts about the great northern peninsula between the Indian Ocean and Gulf of Carpentaria are generally bold, very irregular, in places a continuous series of bays separated by peninsulas of odd and irregular forms. The chief port is Port Darwin, a narrow, deep bay near the northwestern angle of the peninsula, opening on Clarence Straits just S. of Melville island. On it is situated Palmerston, the capital of the Northern Territory and terminus of the transcontinental telegraph line and proposed transcontinental railway line.

The interior is little known, but in the center is a mountainous region, with the ranges running nearly E. and W., and reaching generally but slight elevations, rarely surpassing 3,000 feet anywhere in the colony. The culminating range seems to be the McDonnell, nearly under the Tropic of Cancer. To the S. of the central mountains is a great district with many bodies of water which are called lakes, and occupy much space on the map, but are really salt-water lagoons. W. of the mountainous and lagoon districts and along the whole western boundary is an arid, infertile, desolate region forming an extension of the Great Victoria Desert, the Gibson Desert, and the Great Sand Desert of Western Australia. The northeastern part of the great northern peninsula, or Arnhem Land, is an elevated plateau sloping gently toward the east and abruptly toward the north. To the W. of it the country is better watered and more fertile.

Very few of the streams of the colony reach the sea, and the most of these are in the Northern Territory. The largest are the Roper river, which empties into Limmen's Bight, Daly river, which contributes to Anson Bay, and the Victoria river, the largest on this coast, which empties into Queen's Channel. At less than 50 miles from its mouth it degenerates into a series of ponds, and fails to flow except in the rainy season. On the south coast the Murray passes for a short distance in its lower course through this colony, and, after expanding into Lakes Alexandrina and Albert, forms only a small and shallow stream over the littoral sands. It receives no important tributary in the colony. A few small streams empty into St. Vincent and Spencer Gulfs, but from the extreme of Eyre's Peninsula to the western boundary, along the Australian Bight, there are no streams. The interior streams are insignificant, except at times of flood. They are lost in the sands or find their way at high water to some of the lakes. They drain a great interior basin which, though it reaches within a few miles of the sea at the northern extremity of Spencer's Gulf, never contributes to it, nor apparently has it done so in the present geological period. The basin is broken up into several secondary basins which seem to be remnants left by progressive aridity.

*Climate.*—The temperatures in the settled districts about Adelaide are those of Southern France and Northern Italy. The winter mean temperature is from 50° to 55° F. near the coast, but ice forms inland at slight elevations, with light frosts on the plains. The summer has a moderate mean temperature (65° to 70° F.), but the clear skies, dry air, and hot winds from the interior make it disagreeable, with high shade-temperatures daily. The Northern Territory is tropical and hot, resembling Guinea, Guiana, and Central America, and in the interior the Sahara. The rainfall is less than 5 inches annually over the interior from lat. 20° S. to lat. 32° S., and gradually increases to the southeast to 30 inches and to the north to 60 inches. At Adelaide there are 120 days of rain annually, yielding 21 inches. On the northern coast the annual rainfall may reach 63 inches. Over most of the Northern Territory the rainy season is January and February, when the rain is very heavy; in the southeast there are summer and winter rainy seasons; and in the arid interior rain is very irregular in occurrence, sometimes lacking for years, at others coming in torrents for a few minutes or an hour or two. In general the colony is very healthful for colonists, but the northern coasts have the usual malarial diseases of a virgin tropical soil, with heavy rainfall. These are found to disappear in time after the soil is cultivated.

*Minerals.*—The mineral products of South Australia for 1892, and the entire production to the end of 1892, with the percentage of the total Australasian product, are given in the following table:

| MINERALS. | IN 1892. | | TOTAL TO END OF 1892. | |
|---|---|---|---|---|
| | Value. | Per cent. | Value. | Per cent. |
| Gold | £226,284 | 0·020 | £1,430,622 | 0·004 |
| Silver | ........ | ..... | 101,727 | 0·007 |
| Copper | 175,525 | 0·582 | 20,162,292 | 0·773 |
| Tin | 2,433 | ..... | 20,812 | 0·001 |
| Coal | ........ | ..... | .......... | ..... |
| Other minerals | 2,769 | 0·005 | 402,824 | 0·134 |
| Totals | £316,079 | 0·025 | £22,118,286 | 0·049 |

The most important mineral product is copper, and the colony owes its continued existence at a critical time to the opportune discovery of the famous Burra Burra copper-mining district, 90 miles N. of Adelaide. The mines were developed in 1845 and for some years paid their owners 800 per cent. on the investment, but were temporarily abandoned in 1864 because of the difficulty of transport, and reopened on the construction of the railway from Adelaide to Kuringa. There is a rich and large copper district 300 or 400 miles N. of Adelaide. Gold is obtained from mines in the southern hills S. of Adelaide (at Echunga, etc.), at Wakaringa, about 225 miles N. of Adelaide, and at other places, but chiefly from the Northern Territory, where there is a large alluvial and auriferous quartz region 100 to 150 miles S. of Port Darwin. Gold was discovered in the colony in 1852, the year after the rush to the Ballarat fields. The production of silver, never large, has nearly ceased. Among the other valuable or interesting minerals may be mentioned iron, marble, gypsum, mica (in the McDonnell range), garnets, and coorongite, an elastic mineral similar to elaterite, discovered in the Coorong lagoon on Encounter Bay.

*Agriculture.*—South Australia is essentially an agricultural and pastoral country. The value of the crops for the season 1892–93 was approximately £3,327,286, less than the corresponding values in Victoria, New Zealand, and New South Wales, but more than for the other Australasian colonies. The value of the crop per acre was £1 12*s.* 8*d.*, the least in the seven colonies, the greatest being Tasmania, where it is £5 15*s.* 1*d.*; but the value per head of population was nearly £10, the greatest in the seven colonies. In the season of 1892–93 the total area under crops was only one-third of 1 per cent. of the area of the colony, or 2,037,653 acres. Three-quarters of this was in wheat, 21 per cent. in hay, and only fractions of 1 per cent. in each of the other crops—vines, oats, barley, and potatoes. The area of land under cultivation has increased fivefold since 1861, about the same ratio as that throughout Australasia. Wheat is the staple crop, but the production per acre was only 6·1 bush. in 1892–93, while it was 22 bush. for New Zealand, and nearly 11 bush. for all Australasia; yet owing to favorable conditions of culture 7 bush. in South Australia is considered a satisfactory crop. The colony exported 4,000,000 bush.—as wheat or flour—in 1892. The average yield for oats was 11 bush. per acre, for barley 13 bush., for potatoes 4 tons (worth £10), of hay less than 1 ton per acre. Considerable attention is paid to the vine. In the season of 1891–92 594,000 gal. of wine and 3,640 tons of table-grapes were produced. About 80 gal. of wine per acre was the product for bearing vineyards—about that of Italy and Hungary.

The importance of irrigation has long been recognized in the other colonies, but only recently has it been attempted on a large scale in South Australia. In 1888 a private company began operations at Renmark, on the river Murray, close to the boundary of New South Wales, where an area of 250,000 acres was set apart for this purpose. Search for artesian sources of water has been carried on successfully. On the Nullarbor Plain, a part of the Victoria Desert, and near the shores of the Australian Bight, a well was drilled 777 feet and yielded 68,000 gal. per diem, and other wells have since brought water near to, or above, the surface. More successful are the wells near the central portion of the colony, and those at Herrgott Springs, Coward, Strangways, and Lake Harry give from 50,000 to 1,200,000 gal. a day.

The live stock possessed by the colony in 1892 gave a product valued at £3,086,930, or about 6 per cent. of that for all Australasia, and £9 6*s.* 5*d.* per head of population. Over 40 per cent. was given by the wool-clip alone. The number of animals in 1893 was: Sheep, 7,325,003; cattle, 675,284; horses, 201,484. In general, the number of stock is increasing nearly 3 per cent. yearly, and somewhat less rapidly than the population, but the number of swine is decreasing. The number of animals held by this colony is from 5 to 7 per cent. of those of Australasia, except the horses, of which the number is 11 per cent. The capacity of the colony for sheep is probably nearly reached, as the area adapted for them is relatively small and is being encroached upon by tillage. Should the expectation of finding artesian water over the arid regions generally be realized, however, an enormous area of land now worthless would be easily rendered suitable for tillage and pasture.

*Population.*—The population in 1844 was 17,366; in 1891, 320,431. Of the latter, 4,895 belonged to the Northern Territory, and 133,220 to the capital, Adelaide. On Dec. 31, 1893, the total population was 341,978 (177,219 males, 164,759 females), and that of Adelaide 140,549. In 1886 the number of aborigines living in the settled districts was 3,369. In 1891 the number was 3,134 (1,661 males, 1,473 females), and of Chinese 3,848 (adult males). In 1892 the number of marriages was 2,119; of births, 10,544; of deaths, 3,711; of immigrants, 15,688; of emigrants, 14,499.

The number of churches and chapels in the colony in 1899 was 969. As to religious denominations, the population in 1891 was divided as follows: members of the Church of England, 89,271; Wesleyans and Methodists, 50,813; Roman Catholics, 47,179; Lutherans, 23,328; Presbyterians, 18,206; Baptists, 17,457; Bible Christians, 15,762; Congregationalists, 11,882; Jews, 840. There is no state aid to religious establishments.

Education is compulsory and regulated by the state, but not free. In 1899 there were 284 public schools, 393 provisional schools, and 240 private schools, with an aggregate of 68,329 pupils; also a normal college and the University of Adelaide (founded in 1872).

In 1891 there were 28,847 persons (886 women) engaged in agriculture, 5,332 in pastoral pursuits, 582 in fisheries, and 4,992 in mining industries; 37,680 were engaged in other industrial pursuits, 26,209 in commercial, and 7,266 in professional pursuits.

*Commerce.*—Inclusive of bullion and specie, the value of the total imports in 1899 was £6,884,358, and of the exports £8,388,396, in both cases an increase on the preceding year. The principal exports are wool (£1,511,693 in 1899), wheat and flour (£761,259), and copper ore. The trade is almost entirely with the United Kingdom and the other Australasian colonies. The chief imports are iron, clothing, cottons, woolens, and machinery. In 1899 1,020 vessels entered and 1,025 cleared from the ports of the colony, and there were 227 sailing vessels and 108 steamers registered in it.

In 1899 there were 1,883 miles of railway in the colony, nearly all under state control. In 1886 the connection between Adelaide and Melbourne was completed, thus putting this colony in railway connection with the eastern colonies. In 1893 the transcontinental line between Adelaide and Port Darwin was completed from the S. to Oodnadatta, 686 miles N. of Adelaide, and from the N. to Pine Creek, 151 miles. Between these two places there remain 1,140 miles to be constructed. Aside from this the railways are all in the southeast corner of the colony. At the end of 1899 there were 5,691 miles of telegraph and telephone in use, with 16,937 miles of wire. This includes the 2,000 miles in the transcontinental telegraph line from Adelaide to Port Darwin, where connection is made with a cable to India and Europe.

*Administration.*—The executive functions are vested in a governor appointed by the crown and an executive council of six responsible members, viz., the chief secretary, premier and attorney-general, treasurer, commissioner of crown lands, commissioner of public works, and minister of education and agriculture. The constitution (dated 1856) vests the legislative power in a parliament of two houses—the Legislative Council, now of 24 members, each elected for nine years, and the House of Assembly, of 54 members, elected for three years. Each member of the council and assembly receives £50 a year and a free pass over the Government railways. There are 44 counties, 4 extensive pastoral districts, 33 municipalities, and 140 district councils in South Australia proper.

The administration of the Northern Territory is conducted by a government resident, who is directly responsible to the authorities of South Australia.

The colony has a supreme, a vice-admiralty, an insolvency, and 80 local and police courts. The force for defense consists of an efficient militia of 1,257 men and a volunteer force of 345. The chief port is protected by two forts and by a small armed cruiser of 920 tons. The revenue for the year ending June 30, 1900, was £2,780,858, and the expenditure £2,779,317. The most of the revenue is derived from customs, excise, post, telegraph and railway, and territorial receipts, while the expenditure is chiefly on account of state railways, and interest on the public debt. The last at the end of 1899 was £24,916,310, three-fourths of which was contracted for railways, water-works, and telegraphs, the net earnings from which exceed the interest charge.

*History.*—Lieut. James discovered Northumberland Cape in 1800, and in 1802 Lieut. Flinders completed a sketch of the south coast. The colony was founded in 1836 under the auspices of the South Australian Colonization Association, on a scheme of centralized colonization devised by Edward Gibbon Wakefield. The conditions were that the land should be sold at a high price—not less than £1 per acre—the money thus obtained to be used in importing laborers for pioneering and for the construction of roads, bridges, etc. Wakefield's plan resulted in a colonial bankruptcy in 1841, but the discovery of copper ore in large quantities soon after and gold in 1852, and the enlightened policies of Gov. McDonnell, resulted in the firm establishment of the colony with the constitution of 1856. Since that date the surplus energy of the colony has been chiefly expended in exploring its enormous domain and in constructing its transcontinental telegraph and railway. In 1831 a settlement was made at Port Essington, the northernmost part of the Northern Territory and used as a military post and harbor of refuge, but it was abandoned in 1850. In 1862 Stuart succeeded in crossing the continent from Adelaide to Adam Bay on the north coast, and in 1863 the whole of the Northern Territory was formally granted to South Australia. In 1864 a colony from Adelaide was established at Adam Bay, and in 1870 removed to Port Darwin. For Federation, see AUSTRALIA.

MARK W. HARRINGTON.

**South Bend**: city (settled by the French in 1820, incorporated as a town in 1835, as a city in 1865); capital of St. Joseph co., Ind.; on the St. Joseph river, at the source of the Kankakee river, and on the Chi. and Gr. Trunk, the Lake Shore and Mich. S., the Mich. Cent., the Ind., Ill. and Iowa, and the Vandalia Line railways; 85 miles E. of Chicago (for location, see map of Indiana, ref. 2–E). It is in a rich agricultural region, on a burr-oak plain, is regularly laid out with broad streets, and is noted for its great factories and attractive homes. The city has the stand-pipe system of water-works, supplied with pure artesian water from thirty-two flowing wells, which is pumped into a reservoir for distribution; complete system of trunk and local sewerage; gas and electric-light plants; electric street-railways connecting with Mishawaka, 4 miles distant; metropolitan police and paid fire departments; and many miles of paved streets and cement sidewalks.

*Churches and Schools.*—South Bend has 5 Methodist Episcopal churches, 4 Roman Catholic, 4 Baptist, 4 Lutheran, 3 Presbyterian, 2 Evangelical, 2 United Brethren, and 1 each Protestant Episcopal, Reformed, and Christian. There are 1 public high school and 9 ward schools, with public-school property valued at $1,500,000; St. Joseph's and St. Aloysius's academies; 6 parochial schools; commercial college; conservatory of music; a public and a school library; and a Roman Catholic and a Protestant hospital. South Bend is the seat of the University of Notre Dame (Roman Catholic, founded in 1842), and of St. Mary's Academy for young ladies (Roman Catholic, founded in 1845).

*Business Interests.*—The census returns of 1890 showed 161 manufacturing establishments (representing 46 industries), with a combined capital of $10,141,642, employing 5,341 persons, paying $2,389,858 for wages and $4,150,488 for materials, and turning out products valued at $8,427,158. The principal industry was the manufacture of carriages and wagons, with 9 establishments and $6,155,703 capital, and a product valued at $2,329,391. Agricultural implements ranked second, with 7 establishments and $1,919,708 capital, and products valued at $2,423,442. There were 10 tobacco-factories, 4 flour and grist mills, and 4 foundries and machine-shops. Other manufactures are sewing-machines, paper, pulp, patent medicines, woolen goods, chinaware, brick, varnish, windmills, and furniture.

*Finances and Banking.*—In 1894 the municipal receipts were $305,567; expenditures, $260,971; the net debt was $229,000; assessed property valuation, $20,000,000. There were 3 national banks with combined capital of $305,000 and a savings-bank with deposits of $1,500,000. Four building and loan associations in 1893 had 1,600 members, 495 borrowers, and 12,137 shares in force.

*History.*—South Bend is on historic ground, as past its northern border ran the old portage from the St. Joseph river to the head waters of the Kankakee, traversed by the red man for countless ages, and associated with the discovery of the great West as the spot where the white man first trod the soil of Indiana. Here La Salle landed in 1679 on his tour of exploration to the Mississippi, and here he camped many times thereafter. It was the site of a large village of the Miami Indians at that date and inhabited by the Pottawatomies in later years. Pop. (1880) 13,280; (1890) 21,819; (1900) 35,999.

R. H. LYON, EDITOR OF "TRIBUNE."

**South Berwick**: town; York co., Me.; on the Salmon Falls river, and the Boston and Maine Railroad; 10 miles E. of Rochester (for location, see map of Maine, ref. 11–A). It has manufactories of cotton and woolen goods, shoes, and carriages, and contains Berwick Academy (non-sectarian, chartered in 1791), public library, a national bank with capital of $100,000, and a savings-bank. Pop. (1880) 1,092; (1890) 3,434; (1900) 3,188.

**South Bethlehem**: borough; Northampton co., Pa.; on the Lehigh river, and the Lehigh Val. and the Phila. and Reading railways; 12 miles W. of Easton, the county-seat (for location, see map of Pennsylvania, ref. 4–J). It was settled in 1741, but its growth dates from 1850. The Bethlehem Iron Company, employing about 4,000 men, is the principal manufacturing establishment; it produces steel rails, billets, and forgings, and has large machine-shops, ordnance, and armor-plate works. Other industries are the Lehigh Zinc Works, Lehigh Brass Works, Bethlehem Foundry and Machine Company, several wood-working, knitting, and silk mills, and a cold-storage establishment. The Lehigh University, having eight large buildings and 500 students, is in the southern part of the borough. St. Luke's Hospital is in the western part, as also the Bishopthorpe School for girls. There are 13 churches, 2 daily newspapers, and an opera-house. The borough is lighted by gas and electricity, has two systems of water-supply, and is connected by electric railways with Bethlehem and with Allentown. Pop. (1890) 10,302; (1900) 13,241. M. M.

**Southboro**: town (incorporated in 1727); Worcester co., Mass.; on the N. Y., N. H. and Hart. Railroad; 28 miles S. W. of Boston (for location, see map of Massachusetts, ref. 2–G). It contains the villages of Southboro, Fayville, Cordaville, and Southville; has 4 churches, high school, 9 public schools, St. Mark's Academy, and a public library; and is principally engaged in agriculture and the manufacture of woolen goods. Assessed valuation (1894) nearly $1,500,000. Pop. (1880) 2,142; (1890) 2,114; (1900) 1,921.

**South Boston**: town; Halifax co., Va.; on the Dan river, and the Norfolk and West. and the Southern railways; 32 miles E. by N. of Danville, 109 miles S. W. of Richmond (for location, see map of Virginia, ref. 7–F). It is in a noted tobacco-growing region, has several large manufactories, and contains a public high school, female institute, 2 State banks with combined capital of $153,800, and 2 weekly newspapers. Pop. (1880) 328; (1890) 1,789; (1900) 1,851.

**Southbridge**: town (incorporated in 1816); Worcester co., Mass.; on the Quinnebaug river, and the N. Y. and New Eng. Railroad; 20 miles S. W. of Worcester, 70 miles S. W. of Boston (for location, see map of Massachusetts, ref. 4–F). It contains 7 churches, 19 public schools, 2 parochial schools, public library, a national bank with capital of $150,000, a savings-bank with deposits of over $1,500,000, and 3 weekly papers. The principal industries are the manufacture of optical instruments, cotton, woolen, and print goods, shuttles, and shoe-knives. Pop. (1880) 6,464; (1890) 7,655; (1900) 10,025. EDITOR OF "JOURNAL."

**South Caroli'na**: one of the U. S. of North America (South Atlantic group); the eighth of the original thirteen States that ratified the Federal Constitution; popularly known as the Palmetto State.

*Location and Area.*—It lies between lat. 32° 04′ 30″ and 35° 13′ 02″ N., lon. 78° 28′ and 83° 18′ W.; is bounded on the N. and N. E. by North Carolina, on the S. E. by the Atlantic Ocean, on the S. W. and W. by Georgia; coast-line, 210 miles; longest meridian and longest parallel, about 225 miles each, intersecting near Columbia; area (U. S. census), 30,570 sq. miles (19,564,800 acres), of which 400 sq. miles are water surface.

Seal of South Carolina.

*Physical Features.*—A great geologic break, passing through the State near Cheraw, Columbia, and Aiken, divides it into the "up country" and the "low country," and the two regions show marked differences. The up country is Primary in formation; the low country, Tertiary, with occasional Cretaceous outcroppings. The State is further divided by Mill (1825) and Hammond (1883) as follows: I. The Alpine region (1,000 sq. miles), in the northwest, has gneiss as its characteristic rock, with granite, hornblende, itacolumite-slates, limestones, and clays. The highest peaks in the State—Pinnacle, in Pickens County (3,436 feet), Cæsar's Head (3,118), Paris Mount (2,054), in Greenville, and King's Mount (1,692), in York—are capped with mica-slate, and have steep faces to the S. and E., contrary to the usual rule of the Atlantic slope. The mountains tend to break into isolated masses to the S. The soils are loams and clays, rich in lime and potash. Hills and valleys are clad in hardwood virgin forests. II. The Piedmont region (10,000 sq. miles) embraces the remainder of the up country. Excepting the Sea islands it is the most thickly settled portion of the State, and contains the center of white population. The surface is rolling, rising in places to 800 feet. Granite outcrops in three great parallel ridges. That of Fairfield has a national reputation for hardness, beauty, and ease of cleavage. Trappean rocks underlie large tracts of comparatively level lands. This region contains slates, and quartz is abundant as a surface-rock. The soil is chiefly granitic and porphyritic clays, with gray sands and clay-slates. A tenacious subsoil preserves fertility. The Alpine and Piedmont regions contain gold in paying quantities (Dorn's mine in Edgefield County and Brewer's in Chesterfield having yielded more than $1,000,000 each), besides copper and some silver. Inexhaustible deposits of iron have been partially developed. Limestone, baryta, whet-stone, and flagging-stone have been quarried. Graphite, itacolumite, asbestos, feldspar, spinel rubies, corundum, and beryl exist. III. The Sandhill or Pine region (2,000 sq. miles), the beach of a former age, stretches across the State. Generally level, it rises in the high hills of the Santee to 700 feet. Ironstone, sandstone, buhrstone, and kaolin of great purity outcrop in great beds of sand, whose want of tenacity is unfavorable to vegetation. IV. The Red Hills (1,500 sq. miles), skirting the sandhills, are Eocene, having red clays, yellow sands, buhrstone, and a stone resembling melinite, with excellent fire-clay and inferior lignite. V. The Upper Pine-belt (5,000 sq. miles), varies in breadth from 20 to 40 miles, and comprises some of the finest farming lands of the State. It contains both gray and "mulatto" or chocolate lands, and is comparatively level, rising only to 250 feet. Here was produced the largest yield of corn (256 bush. to an acre) ever gathered. VI. The Lower Pine-belt (9,000 sq. miles) comprises the lower tiers of counties, excepting the salt-water region. The soil is Tertiary. Here occur the famous phosphate deposits lying between Charleston and Beaufort, in river-beds and inland strata, 2 to 10 feet below the surface. They are the detritus of marl-beds subjected to aqueous action. VII. The Coast-region (1,500 sq. miles) is Post-Pliocene, resting on Eocene and Pliocene. A sand-ridge fronts the sea, backed by expanses of mud or sandy loams. Many creeks between Savannah river and Winyah Bay afford inland navigation and form islands which, when drained, are extremely fertile and healthful. The chief of these are Hilton Head, St. Helena, Edisto, John's, James's, North, and South islands. Sullivan's and Pawley's islands are sand-bars noted for surf-bathing.

*Rivers and Bays.*—The up country is hilly, with some level expanses, once prairies. Straight streams have a fall of 4½ feet to the mile, with rapids along the geologic break impeding navigation, but furnishing abundant water-power. The Catawba river falls 178 feet in 8 miles. The Columbia Canal on the Congaree has developed 13,000 horse-power. A potential energy of 1,000,000 horse-power exists in the State. The low country, while having a greater general slope to the ocean, is less undulating. Winding, sluggish streams, with a fall of a few inches to the mile, overflow in floods an area of 5,000 sq. miles. There are 2,400 miles of inland navigation, which might be increased by canals around the rapids. The chief rivers are the Savannah, the Santee (formed by the Congaree and Wateree, the Congaree formed by the Broad and the Saluda, and the Wateree known as the Catawba in its upper course), and the Pee Dee system, consisting of the Great Pee Dee (the Yadkin in North Carolina), the Little Pee Dee, Lynch's, Black, and Waccamaw. The Ashley and the Cooper rivers, forming Charleston harbor, the Edisto, Ashepoo, Combahee, and Coosawhatchie are smaller streams. There are no important lakes. The chief inlets are Port Royal, St. Helena, Stono, Charleston harbor, Bull's Bay, and Winyah Bay. Cape Roman is the chief promontory. Port Royal has one of the finest harbors in the world, with 21 feet of water at low tide, and a mean rise and fall of tide of between 7 and 8 feet. By jetties begun in 1878 Charleston bar has been deepened to 20 feet from Charleston and the ocean. The north jetty is 15,443 feet long, and the south 19,104 feet. Their cost up to 1899 was $4,037,256. Winyah Bay, leading to Georgetown, has 7 feet at low tide, and 10 to 12 feet at high.

*Fauna and Flora.*—Hammond's *Handbook of South Carolina* (1883) gives a list of 48 mammals, 179 birds, 43 serpents, 23 lizards and turtles, 44 amphibians, and 196 fishes, besides thousands of invertebrates not classified. There are 1,310 endogens, 500 exogens, and 2,582 cryptogams. Buffaloes and beavers, once plentiful, are extinct. A few bears and wolves are reported. The magnolia and the palmetto beautify the coast, and the orange, banana, olive, almond, and tea-plant are grown here. Pine and cypress characterize the low country, hardwoods the up country. All nuts, fruits, and berries of the temperate zone grow wild or can be cultivated here. Peaches, apples, grapes, and plums are the commonest fruits.

*Staple Productions.*—Cotton, maize, wheat, rice, peas, hay, and sweet potatoes are the chief staples. The Sea islands grow 10,000 bales of the famous long-staple cotton per annum, and the fields produce from 500,000 to 900,000 bales of the short staple. In 1900 the cotton crop amounted to 830,714 bales, and the rice crop (1899) to 23,054,720 lb. Tobacco-growing, truck-farming, and fruit-growing for market are rapidly developing. Stock-raising, once profitable, then neglected, has been revived with success. Hired field-labor is largely supplied by Negroes, but there are many small farmers among the whites, especially of the Piedmont region, who work their own crops.

The following summary from the census reports of 1880 and 1890 shows the extent of farm operations in the State:

| FARMS. ETC. | 1880. | 1890. | Per cent. |
|---|---|---|---|
| Total number of farms............ | 93,864 | 115,008 | 22·5* |
| Total acreage of farms............ | 13.457,613 | 13,184,652 | 2·1† |
| Value of farms, including buildings and fences........................ | $68,677,482 | $99,104,600 | 44·3* |

* Increase. † Decrease.

The following table shows the acreage, yield, and value of the principal crops in the calendar year 1900:

| CROPS. | Acreage. | Yield. | Value. |
|---|---|---|---|
| Corn...................... | 1,875,591 | 13,129,137 bush. | $8,402.648 |
| Wheat ............ ...... | 238,092 | 2,142.828 " | 2,164,256 |
| Oats...................... | 259,558 | 4,023,149 " | 1,931.112 |
| Rye...................... | 3,902 | 29,265 " | 30.728 |
| Potatoes................. | 4,307 | 335,946 " | 335,916 |
| Hay....................... | 145,798 | 192.453 tons. | 2,213,210 |
| Totals................ | 2.527,248 | .................. | $15,077,870 |

On Jan. 1, 1900, the farm animals comprised 68,319 horses, value $4,237,798; 98,331 mules, value $7,288,769; 122,959 milch-cows, value $2,366,961; 137,264 oxen and other cattle, value $1,478,267; 61,217 sheep, value $104,069; and about 900,000 swine, value $3,000,000—total head, 1,388,090; total value, $18,475,864.

*Climate.*—The climate is mild, and, except in the swamp and rice regions, is salubrious. The equable and dry climate of some portions, especially the pine-lands, is extremely favorable for persons suffering from pulmonary complaints. Aiken and Somerville are noted health resorts. Other localities attract winter tourists, and the Alpine and Piedmont regions are much frequented in summer. The mercury rarely reaches 100° in summer, or falls below 13° above zero in winter. Snow is practically unknown below Columbia. Cyclones visit the coast apparently in periods of four, seven, and eleven years each. One in Aug., 1893, did much damage to life and property in Beaufort, Charleston, and Port Royal, and on the Sea islands. Thunder-storms visit the interior, but tornadoes are rare. A very severe earthquake visited the State in 1886, doing great injury to Charleston. The prevailing winds in Charleston are from the N. W.; in Columbia, from the N. W. and N. E. The oldest record of meteorological observations in America is found in Charleston. It was begun in 1670, and has been continued more or less regularly since 1783. The record for the whole time and that of the U. S. Weather Bureau for twenty-three years, each shows: Annual mean temperature at Charleston, 66°; annual mean rainfall for the whole period, 48·6 inches, and for twenty-three years, 57·42 inches; average mean temperature for Columbia, 63·7°; for the State (at eight stations), 63°; average rainfall, Columbia, 46·76 inches; for the State, 52·31; highest temperature 104°, lowest 11° above zero.

*Divisions.*—For administrative purposes the State is divided into forty counties:

COUNTIES AND COUNTY-TOWNS, WITH POPULATION.

* Reference for location of counties, see map of South Carolina.
† Organized since 1890.

*Principal Cities and Towns, with Population for 1900.*—Charleston, 55,807; Columbia, 21,108; Greenville, 11,860; Spartanburg, 11,395; Sumter, 5,673; Anderson, 5,498; Rock Hill, 5,485; Union, 5,400; Greenwood, 4,824; Florence, 4,647; Newberry, 4,607; Orangeburg, 4,445; Georgetown, 4,138; Beaufort, 4,110; Chester, 4,075; Laurens, 4,029.

*Population and Races.*—In 1860, 703,708; 1870, 705,606; 1880, 995,577; 1890, 1,151,149 (native, 1,144,879; foreign, 6,270; males, 572,337; females, 578,812; white, 462,008; colored, 689,141, of whom 688,934 were persons of African descent, 34 Chinese, and 173 civilized Indians).

*Industries and Business Interests.*—The census returns of 1890 showed 2,382 manufacturing establishments, with a combined capital of $29,276,261 (of which $9,644,578 was invested in machinery, tools, and implements, and $5,591,670 in buildings), employing 24,662 persons, paying $6,590,983 for wages, $18,873,666 for materials, and $1,792,386 for miscellaneous expenses, and turning out products valued at $31,926,681. In 1880 there were 2,078 establishments, with 15,828 employees; wages were only $2,800,000, materials $9,900,000, and products $16,700,000. In 1894 there were 62 cotton-mills containing 655,223 spindles, 17,740 looms, and 1,262 cards, and working up about 115,000,000 lb. of cotton per annum. In 1900 there were 93 mills with 1,693,649 spindles, and 25 new mills under construction. The cotton-seed industry is new but growing. In 1890 27 mills (cost $1,000,000), crushed annually about one-fourth of the crop (75,000 tons of seed worth $800,000) into oil, hulls, meal, and ash, all valuable as food or fertilizers. The phosphate industry is important. Land companies mine their own rock, and river companies pay a royalty of 50 cents (formerly $1) per ton to the State. The royalty sometimes exceeds $200,000 per annum. The rock mined in 1899 aggregated 356,650 long tons. The fertilizer mills do a business of $5,000,000 to $6,000,000. Mineral products have an aggregate value of about $3,000,000 annually.

*Commerce.*—The State has a large foreign and domestic trade. During the fiscal year ending June 30, 1900, the imports at Beaufort and Charleston aggregated in value $1,205,713, and the exports, $7,341,628.

*Finance.*—On Dec. 31, 1898, the bonded debt was $6,494,657.47; in addition there was $350,208 of old debt outstanding. The assessed valuations in Oct., 1894, were—Real property, $102,137,777; personal, $53,120,863; railway, $27,771,973; total, $183,030,613.

*Banking.*—On Sept. 5, 1900, there were 17 national banks with a combined capital of $2,083,000, individual deposits of $5,171,643.71, and surplus and profits of $1,265,335; on June 30, 27 State banks, with capital of $1,307,224, deposits $3,263,144, and surplus and profits $318,297; and 11 stock savings-banks, with capital of $628,150, surplus $451,997, and $5,086,451 in savings-deposits from 25,150 depositors.

*Post-offices and Periodicals.*—In Jan., 1901, there were 1,435 post-offices, of which 36 were presidential (1 first-class, 5 second-class, 30 third-class) and 1,399 fourth-class. Of these 284 were money-order offices, and 4 money-order stations. The newspapers and periodicals in 1901 comprised 10 daily, 1 tri-weekly, 1 semi-weekly, 94 weekly, 2 semi-monthly, 8 monthly, and 2 bi-monthly—total publications, 118.

*Means of Communication.*—Three systems control most of the railways in the State: the Southern (formerly the Richmond and Danville), 688 miles; the Atlantic Coast Line, 423 miles; and the Seaboard Air Line, 211 miles. The Georgia and Carolina (formerly the South Carolina Railroad), one of the first in the U. S., has 267 miles of track, and there are several shorter lines. The total mileage in 1899 was 2,694.

*Churches.*—A majority of the first settlers were Dissenters. The first Huguenot church (the only one in America still preserving its old form of worship) was built about 1681; first English church about 1682; first Baptist, 1685; first Quaker, 1696; first Scotch Presbyterian, 1696; first Jewish, 1750; first Lutheran (in Charleston), 1759; and the first Methodist, 1785; and the first Mass was celebrated (in Charleston) in 1786. An act of the Assembly in 1712 allowed Negro slaves to join the Church. Since emancipation the colored people have generally formed separate associations. The census of 1890 gave the following statistics of the religious bodies having each a membership in the State of over 3,000:

| DENOMINATIONS. | Organizations. | Churches and halls. | Members. | Value of church property. |
|---|---|---|---|---|
| Baptist, Regular, Colored | 892 | 905 | 129,147 | $743,999 |
| African Methodist Episcopal | 229 | 491 | 88,172 | 356,362 |
| Baptist, Regular, South | 727 | 729 | 72,641 | 850,686 |
| Methodist Episcopal South | 686 | 683 | 68,092 | 796,846 |
| African Methodist Episcopal Zion | 130 | 130 | 45,880 | 126,325 |
| Methodist Episcopal | 335 | 337 | 43,200 | 292,235 |
| Presbyterian Church in the U. S. | 226 | 248 | 16,561 | 652,335 |
| Lutheran, United Syn. in the South | 74 | 79 | 8,757 | 339,250 |
| Presb. Church in the U. S. of A. | 77 | 73 | 6,829 | 173,900 |
| Protestant Episcopal | 94 | 87 | 5,742 | 571,833 |
| Roman Catholic | 66 | 26 | 5,360 | 384,500 |
| Colored Methodist Episcopal | 34 | 34 | 3,468 | 65,325 |

*Schools.*—The first free school was established in 1710, ten years after the first public library was opened. In 1785 four colleges were provided for. Two were established, of which one, Charleston College, survives. In 1805 the South Carolina College (known as the University of South Carolina between 1866 and 1877 and 1887 and 1890) was opened in Columbia. Free schools were established in 1811, but private effort bore the chief burden. In 1860 the State ranked fifth in college endowment and sixth in college income. The war of 1861–65 closed many schools. In 1868 a public-school system was provided, which has steadily improved. The races are taught separately. In 1894 there were in round numbers 2,600 white and 1,950 colored teachers, and 106,000 white and 120,000 colored pupils. Almost every town has a graded school. The State has four higher institutions—the South Carolina College, the South Carolina Military Academy (chartered in 1842), the Clemson Agricultural and Mechanical College for males (opened in 1893), and the Winthrop Normal and Industrial College for females. These form the University of South Carolina. The total expenditure for public education in 1899 was $769,815, which was raised by a two-mill tax, a poll-tax of $1, and local taxes. Among the private institutions of note are the College of Charleston (non-sectarian, chartered in 1785); the Presbyterian College of South Carolina (opened 1879); Allen University (Methodist Episcopal colored, chartered 1880); Erskine College (Associate Ref. Presb., opened 1839); Furman University (Baptist, chartered 1850); Newberry College (Lutheran, chartered 1856); Wofford College (Methodist Episcopal South, chartered 1852); Wallingford Academy (Presbyterian); Benedict Institute (colored Baptist); and female colleges and institutes at Columbia, Due West, Gaffney, Greenville, Reidville, Spartanburg, Sumter, and Walhalla. Claflin University, at Orangeburg, chartered in 1872, is endowed by part of the national land grant. Charleston contains the Medical College of the State of South Carolina and the department of pharmacy of the University of South Carolina.

*Libraries.*—According to a U. S. Government report on public libraries of 1,000 volumes and upward each in 1891, South Carolina had 33 libraries which contained 183,982 bound volumes and 19,650 pamphlets. The libraries were classified as follows: General, 9; school, 3; college, 11; college society, 3; law, 1; theological, 3; medical, 1; Y. M. C. A., 1; and scientific, 1.

*Charitable and Penal Institutions.*—The State maintains a lunatic asylum, a penitentiary, and farms for convict labor. There are no reform schools. Almshouses and jails are maintained by the counties.

*Liquor Legislation.*—In 1892 the Legislature prohibited the sale of liquor by private persons and established State and county dispensaries. Liquors, chemically pure, put up in sealed packages, are sold by salaried county dispensers in the daytime to temperate persons, who are not allowed to open the package on the premises. The profits are divided between the State and local treasuries. Constables with extraordinary powers search for and seize illicit liquors. This law was declared unconstitutional by the State Supreme Court in 1893, but with a change in the personnel of the court the decision was soon reversed. On Oct. 31, 1894, there were 69 selling dispensaries; from July 1, 1893, to Oct. 31, 1894, $573,000 worth of liquors had been bought by the State, and this was sold (or was to be sold) to consumers for $679,000.

*Political Organization.*—The constitution of 1776 was changed in 1778. A third instrument, framed in 1790 and in operation till 1865, devolved most of the government upon the Legislature, which elected the Governor, State officers, and many other State officials. The constitution of 1868 gives the Governor, elected by the people for two years, great powers. A Lieutenant-Governor presides over the Senate. The Legislature, meeting annually, is composed of 36 Senators (2 from Charleston and 1 from each other county, elected for four years), and 124 Representatives, elected two years and apportioned according to population. It elects judges and a few other public officers. State and most county officers are chosen by the people. Judicial power is vested in a Supreme Court of three justices (term six years) and eight circuit judges (term four years). Circuit solicitors, county probate judges, and trial justices complete the system. All males over twenty-one years of age, except those convicted of felony, lunatics, and paupers, are allowed to vote. A strict registration law prevails. A voter who has lost his ticket must have it renewed before the next general election or be disfranchised. Eight boxes are provided for separate groups of officials. They are labeled, and the managers must read the labels when required. Outsiders are not allowed inside the booths. Ballots must be of uniform size, color, and unmarked. Votes in the wrong box are not counted. A State board of canvassers has final jurisdiction, except for Governor and Lieutenant-Governor, whose votes are counted by the House of Representatives.

*History.*—1. *The People.*—In 1520 Spaniards visited Port Royal and kidnaped Indians. Returning five years later, they were decimated by Indians and disease and abandoned the idea of settlement. Jean Ribault attempted to establish colonies of Huguenots in 1562 and 1565, but failed. Raleigh accomplished nothing. Heath's patent was repealed for non-performance. Charles II. of England in 1663 granted lands between lat. 31° and 36° N. (extended in 1665 to lands between 29° and 36° 30′) to eight proprietors, who had power to make laws with the assent of the freemen. In 1666 Sandford took possession of the land "by turff and twigge." In 1670 Sayle with three ships reached Port Royal and proceeded to the left bank of the Ashley river, where he founded Charlestown, which ten years later was removed to its present site. Locke and Shaftesbury had prepared "Fundamental Constitutions" resting on church membership and lands, but allowing toleration. The settlers swore allegiance to temporary instructions based on this draft. A second draft established the Church of England. The settlers, chiefly Dissenters, refused to accept either this or four other subsequent drafts, claiming that they had sworn to the first. After 1698 the proprietary government was conducted under the king's charter; but estrangement increased, and in 1719 a revolution overthrew the proprietary *régime.* The king sent Sir Francis Nicholson as first royal Governor in 1721, with instructions that were in force till the Revolutionary war. During all this time the Assembly gained power, and finally claimed all the rights of the House of Commons. In 1765 the people captured Fort Johnson, in which stamps were stored, and sent them back to England. Later they refused to allow tea to be landed and sent £3,000 worth of provisions to aid Boston. A council of safety was formed 1774, and Gov. William Campbell sailed away with the seal of the province in 1775. South Carolina heartily seconded the call for a congress, and was the first to frame a State constitution, May, 1776. In June following Moultrie, behind his palmetto fort, repulsed a British naval attack. This victory, physical as well as moral, gave respite from war for three years. The siege and fall of Charleston, 1780, were followed by partisan warfare, till the rising of the back country and the great victory of King's Mountain in Oct., 1780, forced the British slowly back to Charleston, which was evacuated Dec., 1782. Columbia was made the capital in 1790. After long debate the State made a Federal union possible by accepting conditionally the Constitution of the U. S. May 23, 1788. At this time the low country was generally Federal and the up country anti-Federal. Jefferson's doctrines gained ground, and C. C. Pinckney lost his State in the presidential election of 1800. Since then a strict-construction view has prevailed among the whites. In 1832 a convention nullified the tariff as unconstitutional and also the bill passed to enforce it. After Clay's compromise the anti-tariff ordinance was repealed, but the other was not. All State officers were required to swear paramount allegiance to the State. A small but determined minority opposed nullification. Later on, the idea of complete separation gained ground. A convention in 1852 asserted the right, but thought the occasion did not justify it. Subsequent events fanned the flame. Dec. 20, 1860, a convention unanimously declared South Carolina an independent sovereignty. With other States the Confederacy was formed. South Carolina sent 60,000 men to battle, of whom 12,000 perished. Port Royal was taken in 1861, and the coast was the fighting-ground. Charleston was besieged, but not taken until after the march of Sherman in 1865, when it was evacuated. By the war the assessed property of the State was reduced from $550,000,000 to $100,000,000 ($200,000,000 being the value of the slaves set free). President Johnson appointed B. F. Perry provisional Governor and a government was formed. Congress placed the State under military rule, and ordered a convention, which in Sept., 1865, declared the secession ordinance null and void, repudiated the Confederate State debt, and framed a new constitution. A constitution was adopted in 1865 repealing the ordinance of secession and slavery. A refusal to ratify the Fourteenth Amendment led to a reconstruction by Congress. The Ne-

groes were enfranchised, and a constitution was adopted in 1868, upon which the State was restored to the Union in June of that year. In 1876 the State Government fell into the hands of her more intelligent citizens.

2. *Military History.*—Three years after Sayle landed the Spaniards attacked the colony unsuccessfully. Cardross's colony at Port Royal was destroyed by them in 1686. In 1702 Gov. Moore headed a costly and abortive expedition against St. Augustine, and four years after Gov. Johnson defeated a combined French and Spanish attack on Charleston. The Yamassee and Tuscarora Indians were defeated after a severe struggle. Carolinians accompanied Oglethorpe on his ill-starred campaign against Florida in 1740, and were compelled to repel a counter-attack. Pirates infested neighboring waters, and Bennett and his crew were hanged in Charleston harbor 1718–19. Indians joined the British during the Revolution, but were driven from the State in 1777. The back country, having been settled by inland migration, had little communication with the coast. Lack of tribunals in the interior led to the formation of bands of regulators, who in time became involved with the court. The Revolutionary war renewed old feuds, and partisan warfare was desperate between the regulators or Whigs and the Scovilites or Tories, who were finally crushed. In 1812 Gen. Hampton fought in the Northwest. During the Seminole war South Carolina sent many companies of troops to Florida. In the war with Mexico the Palmetto Regiment fought gallantly, and was the first to plant a banner on the halls of the Montezumas. In the war of 1861–65 South Carolina soldiers displayed great valor. At the time of Sherman's march every able-bodied white male between sixteen and sixty years of age was in service.

GOVERNORS OF SOUTH CAROLINA.

ROBERT MEANS DAVIS.

**South Carolina College**: See the Appendix.

**Southcott**, JOANNA: religious enthusiast; b. at Gittisham, Devonshire, England, Apr., 1750; was a domestic servant at Exeter; joined the Methodist Church about 1790, and in 1792 announced herself as a prophetess, giving forth an extraordinary series of revelations in ungrammatical prose and doggerel verse, e. g. *Effects of Faith* (1801), *Free Exposition of the Bible* (1804), *The Book of Wonders* (1813–14), *Prophecies announcing the Birth of the Prince of Peace* (1814), and many others; and obtained such success that in a few years her believers were numbered by thousands. She established herself at London; announced herself as the woman spoken of in Rev. xii. as being driven into the wilderness; sold 6,400 sealed packets to her followers, which were warranted to secure the salvation of the purchaser; and at last declared herself pregnant, and that she should give birth to "Shiloh" or "the Prince of Peace" at midnight on Oct. 19, 1814, but the occasion was marked only by the prophetess falling into a trance. She died in London, Dec. 27, 1814. A *post-mortem* examination showed that she had been suffering from dropsy. Four congregations of believers, comprising 198 persons, were reported in England by the census of 1851, a community was founded at Wenthorp in 1857, and they were not extinct in 1887. See Roberts, *Observations on the Divine Mission of Joanna Southcott* (1807); Richard Reece, *A Correct Statement of the Circumstances that attended the Last Illness and Death of Mrs. Southcott* (2 eds.. 1815); P. Mathias, *The Case of Joanna Southcott* (1815), and *Joanna Southcott's Prophecies and Case stated* (1832). Revised by S. M. JACKSON.

**South Dako'ta**: one of the U. S. of North America (North Central group), the twenty-seventh State admitted into the Union.

*Location and Area.*—The State lies a little N. of the center of the continent, on the middle section of the Missouri river, between lat. 45° 57 ′N., and 42° 28′ (extreme southeast point; W. of the Missouri the boundary is 43° N.) and between lon. 96° 26′ (extreme east point) and about 104° 03′ W. of Greenwich—the west boundary is 27° W. of Washington. It is bounded on the N. by North Dakota, E. by Minnesota and Iowa, S. by Nebraska, and W. by Wyoming and Montana; extreme length from E. to W., 386 miles; extreme breadth N. to S., 240 miles; area, 76,700 sq. miles, excluding the rivers (Missouri and Big Sioux) and lakes (Big Stone and Traverse) which form part of the boundary of the State; those portions of these properly belonging to South Dakota have an area of about 115 sq. miles.

Great seal of South Dakota.

*Physical Features.*—The Missouri river divides the State into two nearly equal portions. Except a very limited area at the northeast corner, the southeast part is lowest, and all the State slopes and all the streams flow in that direction. That part E. of the Missouri river is generally smooth and gently rolling in surface, rising into hills in a small area in the northeast part and in the central part near the Missouri where are the Wessington Hills and Ree Heights. W. of the Missouri the country rises more rapidly and culminates in the Black Hills, an elevation in elliptical form about 100 by 60 miles in extent, the central point of which is Harney's Peak, with an elevation of 7,400 feet. The western half is more rolling and broken, but has a large part of smooth lands. The Bad Lands (French, *Mauvaises Terres*), near the head of White river and extending into Nebraska, are a striking feature, with cañons, depressions, walls, and castles of white earth, a desert region rich in soil-making chemicals and abounding in highly interesting fossils. The gently sloping lands of the eastern portion, and the intervals and parks of the Black Hills and the valleys near them, are the most fertile soils. The river-bottoms are very rich and fertile, while the more rolling or hilly lands are dry and less productive. The Big Sioux river flows S. near the east border and forms the boundary for 75 miles. Its current is somewhat swift, and there are rapids falling 110 feet at Sioux Falls. The Dakota (or James) river, 80 miles W., is a sluggish stream 200 to 400 feet lower than the Big Sioux. The surface rises westward from this stream, which is thus at the bottom of a wide trough or valley, and follows what was the preglacial course of the Missouri, the latter stream forming its new course along and near the southwestern edge of the great ice-sheet. W. of the Missouri the streams in the order of their size are the Cheyenne, Grand, White, Bad, and Moreau.

*Geology**.—Igneous rocks appear in a few spots, one a dike of diabase, on Split Rock creek, N. E. of Sioux Falls, and five or six small areas in the northern part of the Black Hills, and include the porphyries. The Archæan appears in the east-central part of the Black Hills, lying N. and S., with Harney's Peak a little S. of its center. A somewhat larger area enters the State from Minnesota, in width from Canton to Flandreau and narrowing westward to a point a little S. of Mitchell. There is another small area below the southeast end of Big Stone Lake. In the Black Hills it consists of schists, partly Early Huronian, and slates and quartzites, with eruptive masses of granite. The east area is red quartzite (Huronian), while near Big Stone Lake a reddish granite is exposed only under the drift. The Palæozoic rocks lie around the core of Archæan in the Black Hills, being wider on the W., and comprise 200 to 300 feet of Potsdam sandstone, about 30 feet of Trenton limestone, a few feet of clay (possibly Devonian), then 600 or 700 feet of Carboniferous limestones. The Jura-Trias encircles the Palæozoic of the Black Hills, and includes 200 to 350 feet of red marly clays with purple limestone and gypsum (Trias), and 75 to 150 feet of sandstone, marls, and clays of the Jurassic. Encircling the last-named formation in the Black Hills and bordering the larger Archæan area in the east part, broadly on the S. and W. and less on the N., is the Dakota, a formation of several thick beds of sandstone separated by layers of clay of irregular thickness. The Colorado extends from the Black Hills to a little beyond the branches of the Cheyenne, and includes the intermediate valleys and the country between the Cheyenne and Bad rivers, and nearly all the unmentioned part E. of the Missouri and a margin of irregular width along the west side of the Missouri. It represents the Fort Benton clay, 50 to 100 feet; the Niobrara chalkstone, 50 to 150 feet; and the Fort Pierre clays, 600 to 700 feet. The Fox Hills comprise 100 to 150 feet of sands, clays, and sandstone in the region near the Missouri and N. of the Cheyenne. The Laramie or lignitic is the great lignite-bearing formation, with rocks similar to the Fox Hills, in the northwest part of the State. It comes down near the Belle Fourche, extends E. half way to the Missouri, then N. E. to near that river. The Miocene covers the region S. of Bad river and E. of the south branch of the Cheyenne to near the Missouri, and includes the white clays, marls, and sandstones of the Bad Lands, known as White river beds, also the Loup Fork beds. In this State the two may be 250 to 400 feet thick. The drift or bowlder clay covers all the surface W. to a line a little beyond the Missouri river, following closely its general course to within 60 miles of the northern boundary, where it deflects some 40 miles W. from that stream. The outlines of the older formations are less confidently stated where they are covered by drift. The artesian basin includes the region W. of the following line: Beginning near Vermillion on the Missouri river, thence N. W. to Ethan, S. of Mitchell, thence N. E. some 25 miles, thence a little W. of N. to the northwest corner of Clark County, thence N. N. E. to the northern boundary. On the S. it follows near and a little S. of the Missouri. Many powerful wells flow in the region W. of this line to the Missouri, and the pressure rises rapidly toward the W. It is probable that it extends along the White and Cheyenne rivers to near the Black Hills, where a flowing well was sunk at Belle Fourche. The water-bearing strata, the Dakota sandstone, are somewhat irregular in distribution, conducting power, and depth. The wells are used to supply towns, furnish power, and to irrigate lands.

*Productions.*—At Sioux Falls, Dell Rapids, Spencer, Rockport, and near Alexandria are extensive and valuable quarries of red quartzite, and at Yankton are extensive and thick beds of Fort Benton clay and chalkstone, from which a superior Portland cement is made. Brick clays are found in many localities. Custer County contains manganese, but there is little use for it locally, and the cost of transportation is too great to justify shipments except of the highest grade ore. Tin is found in the Harney Peak and Nigger Hill regions of the Black Hills, and the first tin-mill in the U. S. was opened near the mines in 1890. During the calendar year 1899 the Black Hills mines yielded 312,962 fine ounces of gold, valued at $6,469,500, and 145,600 fine ounces of silver, valued at $188,251. Very rich gold mines were opened in 1895 near Hill City, and the aggregate product is materially increased. The granite produced by the State in 1899 was valued at $91,049, the sandstone at $18,325, and the limestone at $45,808. The Sioux Falls quartzite has been used for paving in Chicago and other Western cities with satisfactory results. The chief industry of the State is agriculture. Stock-raising has become an important interest. The State has a variety of native grasses, and many cultivated species have been introduced profitably in the old settled parts of the east and south. In 1890 South Dakota had 50,158 farms, containing 11,396,460 acres, valued with buildings and fences at $75,310,305. The following table shows the acreage, yield, and value of the principal crops in the calendar year 1900:

| CROPS. | Acreage. | Yield. | Value. |
|---|---|---|---|
| Corn | 1,200,697 | 32,418,819 bush. | $9,401,458 |
| Wheat | 2,920,244 | 20,149,684 " | 11,686.817 |
| Oats | 588,524 | 12,653,266 " | 3,036.784 |
| Rye | 2,623 | 27,804 " | 10,844 |
| Barley | 107,942 | 1,543,571 " | 478,507 |
| Potatoes | 55,217 | 4,030,841 " | 1,451,103 |
| Hay | 1,749,319 | 2,064,196 tons. | 8,153,574 |
| Totals | 6,624,566 | .................. | $34,219,087 |

On Jan. 1, 1900, the farm animals comprised 287,839 horses, value $11,236,671; 6,626 mules, value $330,266; 398,383 milch-cows, value $13,305,992; 48,817 oxen and other cattle, value $14,237,235; 381,882 sheep, value $1,257,156; and about 200,000 swine, value $2,000,000—total head, 1,755,547; total value, $42,367,320.

*Divisions.*—For administrative purposes the State is divided into a number of counties, many of which are still unorganized and have very few inhabitants.

\# Annexed to Meade in 1899.

*Principal Cities and Towns, with Population in 1900.*—Sioux Falls, 10,266; Lead City, 6,210; Yankton, 4,125; Aberdeen, 4,087; Mitchell, 4,055; Deadwood, 3,498; Watertown: 3,352; Huron, 2,793; Madison, 2,550; Brookings, 2,346; Pierre, 2,306; Vermillion, 2,183; Canton, 1,943; Webster, 1,506.

*Population and Races.*—The part of Dakota now in the limits of the State had in 1880 an estimated population of 98,268; in 1890 the population of the State was 328,808 (native, 237,753; foreign, 91,055; males, 180,250; females, 148,558; white, 327,290; colored, 1,518, of whom 541 were of African descent, 195 Chinese, and 782 civilized Indians).

*Manufactures.*—The census returns of 1890 showed 499 manufacturing establishments, with an aggregate capital of $3,207,796 (of which $322,855 were invested in land, $512,142 in buildings, and $1,329,023 in tools, machinery, and implements), employing 2,422 persons, paying $1,098,418 for wages, $268,214 for miscellaneous expenses, and $3,523,840 for materials, and turning out products valued at $5,682,748.

*Finance.*—The assessed valuations in 1900 aggregated $331,269,000, and the total funded debt on July 1, 1900, was $540,811.09. The tax rate is $2 on $1,000.

*Banking.*—On Sept. 5, 1900, there were 28 national banks with combined capital of $1,502,500, surplus and profits of $534,991.43, and individual deposits of $6,081,124.71; on June 30, 109 State banks with capital of $1,245,227, surplus and profits of $351,972, and deposits of $5,322,384; and 70 private banks with capital of $945,076, surplus and profits of $292,732, and deposits of $3,329,486.

*Means of Communication.*—Transportation to and within the State is provided by four great railway lines, the Chicago, Milwaukee and St. Paul, the Chicago and Northwestern, the Fremont, Elkhorn and Missouri Valley, and the Burlington and Missouri River, and by thirteen local and minor ones. The total mileage within the State in 1899 was 2,818, of which the greater part was operated by the four great lines in the order given. The State receives about $250,000 annually from taxes on railway property.

*Churches.*—The census of 1890 gave the following statistics of the religious bodies having a membership of 1,000 or more each in the State:

| DENOMINATIONS. | Organizations. | Churches and halls. | Members. | Value of church property. |
|---|---|---|---|---|
| Roman Catholic | 177 | 169 | 25,720 | $246,030 |
| Methodist Episcopal | 254 | 248 | 11,371 | 375,260 |
| Lutheran, United Norwegian | 148 | 138 | 7,922 | 54,655 |
| Congregational | 138 | 142 | 5,164 | 200,665 |
| Lutheran, General Council | 100 | 97 | 4,770 | 40,125 |
| Presb. in the U. S. of America | 124 | 125 | 4,413 | 156,940 |
| Baptist, Regular | 83 | 85 | 3,856 | 227,175 |
| Lutheran, Synodical Conference | 71 | 35 | 3,097 | 20,770 |
| Lutheran, Norwegian Evang | 46 | 43 | 3,030 | 25,700 |
| Protestant Episcopal | 83 | 74 | 2,649 | 234,532 |
| Lutheran, Hauge's Synod | 36 | 36 | 2,239 | 11,700 |
| Evangelical Association | 74 | 74 | 1,628 | 20,450 |
| Reformed, in the U. S | 16 | 14 | 1,000 | 11,750 |

*Schools.*—The act of Congress creating the State set apart 2,823,320 acres of land for the support of public schools, and both the act and the State constitution fixed the minimum price at which this land should be sold at $10 per acre. More than 100,000 acres have been sold at an advance on the minimum price, and should the remainder fetch only $10 per acre, the permanent school fund would amount to more than $28,000,000. In 1899 there were in the State 119,579 children of school age, of whom 98,540 were enrolled in the public schools. There were 3,755 schools; and 4,806 teachers, receiving an average monthly salary of $33.63. The public-school property was valued at $2,905,924. The total revenue was $1,645,529, and the expenditure (1898) $1,605,623. The institutions for advanced instruction include the University of South Dakota at Vermillion (opened in 1883); Dakota University at Mitchell (Methodist Episcopal, 1885); Pierre University at East Pierre (Presbyterian, 1883); Sioux Falls University at Sioux Falls (Baptist, 1883); Scotland Academy at Scotland (Presbyterian, 1876); Augustana College at Canton (Lutheran, 1884); Redfield College at Redfield (Congregational, 1887); All Saints' School at Sioux Falls (Protestant Episcopal, 1886); Black Hills College at Hot Springs; Academy of the Sacred Heart at Yankton (Roman Catholic); Yankton College at Yankton (Congregational, 1882); Ward Academy at La Roche (Congregational); and the Wessington Springs Seminary (Free Methodist). There are also a State Agricultural College with an experiment station near Brookings and a State School of Mines at Rapid City.

*Libraries.*—According to a U. S. Government report on public libraries of 1,000 volumes and upward each in 1891, South Dakota had 11 libraries, containing 23,366 bound volumes and 8,230 pamphlets. The libraries were classified as follows: General, 3; college, 5; scientific, 1; garrison, 1; and society, 1.

*Post-offices and Periodicals.*—In Jan., 1901, there were 678 post-offices, of which 51 were presidential (8 second-class, 43 third-class) and 627 fourth-class. There were 296 money-order offices. The newspapers and periodicals in 1901 comprised 17 daily, 235 weekly, 3 semi-monthly, and 18 monthly publications—total, 273.

*Charitable, Reformatory, and Penal Institutions.*—These include a State School for Deaf Mutes at Sioux Falls; a Hospital for the Insane at Yankton; a Soldiers' Home at Hot Springs; a Reform School at Plankinton; and a State Penitentiary at South Falls; and the Legislature has authorized an additional hospital for the insane at Redfield and a school for the blind at Gary.

*Political Organization.*—The constitution vests the legislative authority in a Legislature consisting of a Senate and House of Representatives, which in 1900 had 45 and 87 members respectively. The Legislature meets biennially and sessions are limited to sixty days. It is prohibited from enacting private or special laws for granting divorces; changing the names of persons or places; constituting one person the heir-at-law of another; locating or changing county-seats; regulating county and township affairs; granting to an individual, association, or corporation any special or exclusive privilege; or authorizing any game of chance, lottery, or gift enterprise. The executive authority is vested in a Governor elected for two years. There is also a Lieutenant-Governor chosen in the same way and for the same term as the Governor. The Governor may disapprove of any separate item or items in a bill. Bills may be passed over his veto by a two-thirds vote of both houses, and those not returned by him within three days of reception become laws. The Governor is assisted in the discharge of his duties by a secretary of State, auditor, treasurer, superintendent of public instruction, commissioner of school and public lands, and an attorney-general, all elected for terms of two years. The judicial authority is vested in a Supreme Court, circuit courts, county courts, and justices of the peace, and such other courts as may be created for cities and incorporated towns. The constitution contains a "bill of rights," guaranteeing that the right to worship God according to the dictates of conscience shall never be infringed; that no person shall be denied any civil or political right on account of his religious opinions; that no person shall be compelled to attend or support any ministry or place of worship against his consent; and that no money or other property of the State shall be given for any religious or sectarian purpose. The voting privilege is extended to every male person who is a citizen of the U. S. or an alien who has declared his intention of becoming a citizen, who has resided in the U. S. one year, in the State six months, in the county thirty days, and in the precinct ten days, next preceding any election, provided he is not under guardianship, insane, an idiot, or an unpardoned person convicted of treason or felony. Women with the foregoing qualifications may vote at any election held solely for school purposes. A modification of the Australian ballot law is in force. The constitution authorized the enactment of a State prohibition law. The Legislature passed one in 1891. It was immediately contested, and a county court declared it unconstitutional, but on an appeal in 1892 the Supreme Court affirmed its validity.

*History.*—The early history of the State is identical with that of NORTH DAKOTA (*q. v.*). In 1890–91 the Indian Messiah craze among the Sioux led to grave apprehensions, the intervention of U. S. troops, and the death of Sitting Bull, a great Sioux chief; in 1892 the Yankton Sioux Indians signed an agreement with U. S. commissioners to cede to the U. S. a large part of their reservation between the Choteau and Missouri rivers; and in 1893 the Legislature passed acts to promote irrigation, to prohibit the introduction into the State of armed bodies of police or detectives, and to create a number of State commissioners.

GOVERNORS OF SOUTH DAKOTA.

| | | | |
|---|---|---|---|
| Arthur C. Mellette | 1889–93 | Charles N. Herreid | 1901– |
| Charles H. Sheldon | 1893–97 | | |
| Andrew Lee | 1897–1901 | | |

AUTHORITIES.—Child, *South Dakota: Resources, People, Statehood* (1888); Beadle, *Dakota* (1889); Hagerty, *The State of South Dakota: Statistical, Historical, and Political Abstract* (Aberdeen, 1889). WILLIAM H. H. BEADLE.

**South Dakota, University of**: an institution located at Vermillion by the first territorial legislature (1862), and first known as University of Dakota, but not opened by the Territory until 1883. The city and county opened an independent school in the court-house in 1882, to which they applied the original name, University of Dakota, and erected one building, which was, with the school, accepted as the territorial university by the Legislature in 1883, when the first appropriation was made. The name was changed to University of South Dakota in 1891. It has one brick and two large stone buildings, a 20-acre campus, and 86,000 acres of land. There is a College of Arts and Sciences, with four bachelor and four master courses; colleges of music and business; military and preparatory departments. It has three laboratories and a museum on the "typical" plan. The faculty consists of the president, and 27 professors and assistants. The students number 400. J. W. MAUCK.

**South Deerfield**, Mass.: See DEERFIELD.

**Southern Confederacy**: See CONFEDERATE STATES.

**Southern Crown**: See CORONA AUSTRALIS.

**Southern-wood**: a plant. See ARTEMISIA.

**Southey**, CAROLINE ANNE (*Bowles*): poet; b. at Lymington, Hants, England, Dec. 6, 1787. At an early age she wrote for *Blackwood's Magazine* and other periodicals. In 1820 a collection of her pieces was made, which speedily won for her a place in the world of letters. In 1839 she became the second wife of Robert Southey. *The Pauper's Deathbed* is, perhaps, the best known of her poems, which were prevailingly of a moral, religious, and domestic character. Her published works are *Ellen Fitz-Arthur*, a poem (1820); *The Widow's Tale, and other Poems* (1822); *Solitary Hours*, prose and verse (1826); *Chapters on Churchyards* (1829); *The Birthday*, a poem (1836); *Tales of the Factories*, in verse; and *Robin Hood*, a fragment of a poem begun jointly by herself and her husband, to which were added other fragments by both (1847). D. at Lymington, July 20, 1854. See *Southey's Correspondence with Caroline Bowles*, by Dowden (1881). Revised by H. A. BEERS.

**Southey**, ROBERT: author; b. at Bristol, England, Aug. 12, 1774, the son of a linen-draper. Early left an orphan, he was cared for by an uncle; received his early education at Westminster School; in 1793 entered Baliol College, Oxford, with the design of taking holy orders, but, becoming unsettled in his religious and political views, left Oxford after two years, and entered upon a career of authorship in verse and prose, his first published work being a small volume of poems (1794). In 1795 he married Edith Fricker, whose sister soon after became the wife of Coleridge; set out with his uncle for Portugal; published an account of his six months' residence (1797); was made secretary to the Chancellor of the Exchequer for Ireland, a sinecure with a salary of £350; resigned the position, and in 1804 settled for life at Keswick in the lake country. From this time his life is mainly the history of his numerous writings in almost every department of literature. In early manhood he had imbibed strong radical ideas; proposed, in conjunction with Coleridge and Lovel, to set up a socialistic community or "pantisocracy" on the banks of the Susquehanna; and wrote a drama, *Wat Tyler* (printed in 1793, but first published in 1817, without his consent), which was denounced in the House of Commons as seditious. In the course of years he went over to the opposite extreme of conservatism in Church and state, and became considered the exponent of high Tory opinions. He was named poet-laureate in 1813. In 1807 he received a Government pension of £160 a year, increased to £460 in 1835. His wife, who had for several years been hopelessly insane, died in 1837, and two years afterward he married Caroline Bowles. (See SOUTHEY, CAROLINE ANNE.) But Southey's own faculties had begun to give way, and on the day when he brought his wife to their home he fell into a state of mental prostration which soon grew into complete imbecility, that continued to his death, on Mar. 21, 1843. Southey's principal poems are *Joan of Arc* (1795); *Thalaba the Destroyer*, an Arabian tale (1801); *Madoc*, founded on legends of early Welsh voyages to America (1805); *The Curse of Kehama*, based upon Hindu mythology (1810); *Roderick, the Last of the Goths*, founded on Spanish history (1814); *A Vision of Judgment*, an apotheosis of George III. (1821); and *A Tale of Paraguay* (1825). Among his numerous prose works are *History of Brazil* (1810–19); *Life of Nelson* (1813); *Life of John Wesley* (1820); *History of the Peninsular War* (1820–32); *Book of the Church* (1824); *Sir Thomas More, or Colloquies on Society* (1829); *Life of John Bunyan* (1830); and *The Doctor* (1834–37). He also contributed largely to *The Quarterly Review* for many years. His poetical works were collected by himself (10 vols., 1837), and have been several times republished in different forms. His *Life and Correspondence*, edited by his son, Rev. C. C. Southey, appeared in 1849, and a selection from his *Commonplace Book*, by his son-in-law, Rev. J. W. Warter, in 1856. Southey was one of the most indefatigable and voluminous of English authors, his published works in verse and prose numbering over 100 titles. His reputation as a poet, imposing in his own lifetime, has steadily declined. His poetry is commonplace, without inspiration, spontaneity, or charm of style. A few of his less ambitious pieces, such as *My Library*, *The Holly Tree*, and *The Battle of Blenheim*, keep a place in popular remembrance. Of his prose writings the lives of Nelson and Wesley are among the best, and indeed are among the best standard biographies in the language. His whimsical and mystifying book *The Doctor* is a favorite with many readers. The worth of Southey's character, his wide learning and incessant productiveness, his dignified social standing, and his intimate association with Wordsworth and Coleridge, men of a higher genius than his own, still make him an important figure in English literary history. Revised by H. A. BEERS.

**South Framingham**: village; Framingham town, Middlesex co., Mass.; on the Boston and Albany and the N. Y., N. H. and Hart. railways; 21 miles W. by S. of Boston, and 23 miles E. of Worcester (for location, see map of Massachusetts, ref. 2-G). It contains 8 churches, a national bank with capital of $100,000, 2 saving-banks, and 3 weekly newspapers, and is principally engaged in the manufacture of straw goods, woolens, shoes, paper, and rubber goods. Pop. (1895) 5,770; not returned separately in 1900.

**Southgate**, HORATIO, D. D.: clergyman and author; b. at Portland, Me., July 5, 1812; graduated at Bowdoin College 1832, and at Andover Theological Seminary 1835; took orders in the Protestant Episcopal Church 1836; traveled as a missionary in the East; was chosen missionary bishop of Constantinople 1844; resigned his charge in 1850 and returned to the U. S. the following year, in which he became rector of St. Mark's, Portland, of the Church of the Advent, Boston, 1852, of Zion church, New York, 1859–72, and of St. Thomas church, Ravenswood, L. I., 1882. The episcopate of California was tendered to him by a convention of clergy and laity, but the plan miscarried. D. Apr. 11, 1894. He was the author of *A Tour through Armenia, Kurdistan, Persia, and Mesopotamia* (New York, 2 vols., 1840); *A Visit to the Syrian Church of Mesopotamia* (New York, 1844); *The War in the East* (1855); and *Parochial Sermons* (1859). Revised by W. S. PERRY.

**South Georgia**: a group of uninhabited islands, generally icebound, in lat. 54° 30′ S., lon. 36°–38° W.; nearly 800 miles E. by S. of the Falkland islands, of which they are a dependency. Area about 1,000 sq. miles. They were first discovered in 1675.

**South Hadley**: town (incorporated in 1753); Hampshire co., Mass.; on the Connecticut river, which here has a fall of 40 feet, and near the Boston and Me. and the N. Y., N. H. and Hart. railways; 5 miles S. E. of Northampton and 14 miles N. of Springfield (for location, see map of Massachusetts, ref. 3–E). It is the seat of MOUNT HOLYOKE COLLEGE (*q. v.*), the oldest collegiate institution for women in the U. S., and contains the villages of South Hadley and South Hadley Falls, a high school, 21 public schools, 5 churches, and cotton, woolen, and saw mills. In 1894 it had an assessed valuation of nearly $2,000,000. Pop. (1880) 3,538; (1890) 4,261; (1900) 4,526. HENRIETTA E. HOOKER.

**Southington**: town (incorporated in 1779); Hartford co., Conn.; on the N. Y., N. H. and Hart. Railroad; 23 miles N. of New Haven (for location, see map of Connecticut, ref. 9–G). It has manufactories of general and carriage hardware, tinmen's supplies, pocket cutlery, wood screws, and ceiling and floor plates, and contains the Lewis High School, a national bank with capital of $100,000, a savings-bank, and a weekly newspaper. In 1894 it had an assessed valuation of over $2,000,000. Pop. (1890) 5,501; (1900) 5,890, borough 3,411. WILLIAM J. HOLDEN, EDITOR OF "PHŒNIX."

**South McAlester**: town; Choctaw Nation, Ind. Terr.; on the Choctaw, Okl. and Gulf Railroad; 64 miles W. of Wister Junction (for location, see map of Indian Territory, ref. 4–F). It is in a rich coal-mining region, and contains a private bank and three weekly newspapers; and in 1895 was made the headquarters of the part of the U. S. Geological Survey detailed under act of Congress to make a survey of the territory preparatory to its being opened to general settlement. Pop. (1900) 3,479.

**South Manchester**: village; Manchester town, Hartford co., Conn.; on the N. Y. and New England Railroad; 9 miles E. of Hartford (for location, see map of Connecticut, ref. 8–I). It is noted for its extensive manufactories of silk and paper, and contains a public library (founded in 1870) and a weekly and a monthly periodical. Pop. (1890) not separately reported; (1900) not returned separately.

**South Norwalk**: city; Fairfield co., Conn.; on Long Island Sound, the Norwalk river, and the N. Y., N. H. and Hart., and the Shepaug, Litch. and N. railways; 33 miles S. W. of New Haven, and 42 miles N. E. of New York (for location, see map of Connecticut, ref. 13–D). The city has a fine location and an excellent harbor. The surface begins to rise within the city limits and in the western suburbs reaches an altitude of 160 feet above sea-level, affording choice locations for residences, with extensive views of the Sound and harbor. Steam freight-boats ply between the city and New York all the year and passenger boats during the summer season. The city contains a public high school, 2 opera-houses, 2 electric railways, a public library (founded in 1877), 2 national banks with combined capital of $200,000, a savings-bank, and 2 newspapers. The chief industries are the manufacture of hats, corsets, shoes, locks, bronze goods, force-pumps, steam-engines, machinery, air-compressors, stone and earthenware, and paper boxes; ship and boat building; and the cultivation of oysters. Pop. (1880) 3,726; (1890) not separately reported; (1900) 6,591.
EDITOR OF "EVENING SENTINEL."

**South Omaha**, Neb.: See OMAHA.

**South Orange**: village and township; Essex co., N. J.; on the Rahway river, and the Del., Lack. and West. and the Newark and S. Orange electric railways; 15 miles W. of New York and 5 miles N. W. of Newark, the county-seat (for location, see map of New Jersey, ref. 2–D). It is picturesquely located on the Orange Mountains, has many fine residences, particularly of New York business men, and contains a new town-hall (completed in 1895), Seton Hall College (Roman Catholic, opened in 1856), a Roman Catholic parochial school, 3 public and 3 private schools, a public library, and a weekly newspaper. Vailsburg, formerly a part of South Orange township, between South Orange and Newark, was incorporated as a borough in 1894. Pop. of South Orange (1880) 2,178; (1890) 3,106; (1900) 4,608.
EDITOR OF "BULLETIN."

**Southport**: town; in Lancashire, England; at the mouth of the Ribble estuary; 18 miles N. of Liverpool (see map of England, ref. 7–F). Southport from being a sandy waste has rapidly developed into a popular watering-place. It has an esplanade 3 miles long, a pier (1,465 yards), a pavilion and winter gardens, a public library and art gallery, a market-hall (1881), schools of science and art (1887), besides large baths, hotels, etc. Pop. (1891) 43,026.

**South Sea Bubble**: a financial speculation which arose in England about the same time as Law's Mississippi Scheme in France. The South Sea Company was established by Lord Treasurer Harley in 1711 with the design of providing for the extinction of the public debt, then amounting to about £10,000,000. The debt was assumed by a number of merchants, under an engagement of the Government to pay 6 per cent. interest for a certain period, securing this sum by making permanent certain import duties. The Government further granted the purchasers of the fund a monopoly of the trade to the South Sea or the coast of Spanish America, and the company was organized under the name of the South Sea Company. Though the South Sea trade yielded no great profit, the company flourished from the prevailing delusion with regard to the riches of Spanish America, and became so well established as to vie with the Bank of England in controlling the finances of the country. In 1720 the company assumed the entire debt of over £30,000,000, bearing interest of 5 per cent. The ministers intended to give the South Sea Company a good bargain, but when the plan was proposed in the House of Commons that body voted to open the scheme for competition to the Bank of England also. The company was thus compelled to offer £7,500,000 for its privilege. Notwithstanding this drawback the stock of the company was in great demand, under the extravagant expectation of profits from the American trade and the prevalent rage for speculation. It was increased by successive subscriptions, the price of shares rapidly rising till £1,000 was paid for a single share of £100. Other bubbles were started, such as schemes for a fishery of wrecks, to make salt water fresh, to make oil from sunflowers, to extract silver from lead, all with promises of enormous profits. For lack of office-room the streets near 'Change Alley were lined with desks. The action of the South Sea Company itself in proceeding against some of these bubbles turned attention to its own affairs, and distrust arose, under which the stock rapidly declined. Confidence was further weakened when it became known that some of the directors had sold out. The news of the failure of Law's scheme and its consequences in Paris opened all eyes to the delusion, and as the year 1720 closed the bubble burst, bringing ruin to the company and to thousands of families. Revised by F. M. COLBY.

**South Shetland** or **New South Shetland Islands**: an Antarctic archipelago, S. of South America, beween 61° and 63° 30′ S. lat., consisting of Clarence, George First, Livingston, and Smith islands, discovered in 1819. Area about 850 sq. miles. The islands are mountainous, destitute of vegetation, in the interior covered with perpetual snow and ice, and rise out of very deep water. They are visited by whalers, but navigation is dangerous on account of the ice.

**South, University of the**: See the Appendix.

**Southwell**, ROBERT: ecclesiastic and author; b. at Horsham St. Faith's, Norfolk, England, in 1560; educated in Paris and, it is said, also in the Roman Catholic seminary at Douay, France; became a Jesuit at Rome 1578; prefect or rector of the English Jesuits' college at Rome 1585; sent as a missionary to England 1586; chaplain to Anne, Countess of Arundel, and secretly administered the rites of his Church to the English Roman Catholics; was thrown into the Tower July, 1592, on an accusation of complicity in a plot against Queen Elizabeth; was ten times subjected to torture, but made no confession beyond that of being a Jesuit and having exercised his priest's office; was condemned to death for constructive treason in refusing to take the oath of supremacy Feb. 22, 1595, and on the following day was hanged, drawn, and quartered at Tyburn, meeting his fate with firmness and composure. He was the author of several pieces of prose and verse published in London immediately after his death, among which were *The Triumph over Death* and *Epistles of Comfort to those Catholics who Lie under Restraint*. A complete edition of his *Poems* appeared in 1856 (London). Revised by S. M. JACKSON.

**Southwest Pass**: See LIGHTHOUSE.

**Southworth**, CONSTANT: colonist; b. at Leyden, Holland, in 1614, son of Edward Southworth, a merchant and business agent of the Leyden Pilgrims (d. 1621); was taken to Plymouth, Mass., in 1621 by his widowed mother, Alice (Carpenter) Southworth, who became the second wife of Gov. William Bradford, under whose care he was educated; was one of the early colonists of Duxbury; was often a magistrate and representative in the Legislature; served as commissioner for the united colonies; governor of the Kennebec plantation and assistant governor of Plymouth. D. at Duxbury about 1685. He was supposed to be the author of the *Supplement* to the *New England's Memorial* of his cousin, Nathaniel Morton.—His brother THOMAS, b. at Leyden in 1616, was also prominent in public affairs. D. 1690.

**Southworth**, EMMA DOROTHY ELIZA (*Nevitt*): novelist; b. in Washington, D. C., Dec. 26, 1818; was married in 1841 to Frederick H. Southworth, of Utica, N. Y., and two years later was thrown wholly upon her own exertions for a livelihood; engaged in teaching, and wrote for the Washington *National Era* a novel entitled *Retribution*, which was published in book-form in 1849, since which time she has put forth in rapid succession a series of novels numbering nearly sixty. A uniform edition of her stories to date was published at Philadelphia in 1872 and contained forty-two titles, among which were the following: *The Family Doom, The Changed Brides, The Fortune-seeker, The Fatal Marriage, The Lost Heiress, The Three Beauties, The Haunted Homestead, Retribution, India, or the Pearl of Pearl River, The Curse of Clifton,* and *The Spectre Lover.* From 1853 to 1876 Mrs. Southworth resided in a country-house on the Potomac, near Washington. In 1876 she removed to Yonkers, N. Y. Her novels relate largely to Southern life, and have been widely popular, and some of them have been translated into several foreign languages. Their literary value is not high. D. June 30, 1899. Revised by H. A. BEERS.

**Souvestre**, sōō'vest'r', ÉMILE: novelist and dramatist; b. at Morlaix, department of Finistère, France, Apr. 15, 1806. After editing for some time a liberal newspaper at Brest, he settled in 1836 in Paris, where he attracted attention first by his sketches of Brittany, and became soon exceedingly popular as a writer. D. in Paris, July 5, 1854. The most remarkable of his novels are *Les Derniers Bretons, L'Homme et l'Argent, Confessions d'un Ouvrier, Un Philosophe sous les Toits* (the last named receiving in 1851 a prize from the French Academy); and of his dramas, *Henri Hamelin, L'Oncle Baptiste, Le Mousse*, etc. All his works have a strongly marked tendency, representing morality and riches as incompatible. He is sometimes sad, and even bitter, but he often gives most delightful pictures of the innocence of simple surroundings and the cheerfulness of humble circumstances. Revised by A. G. CANFIELD.

**Souza**: See SOUSA.

**Sovereign**: the British coin representing the pound sterling of 20*s.* It first appeared in 1817, and now weighs 123·27447 grains troy, and is worth $4·866 in U. S. money. The English coin first called double royal (afterward replaced by the guinea), first struck about 1489, was often called the sovereign. Its value varied from 20*s.* to 30*s.*, but its original value was 22*s.* sterling. See POUND STERLING.

**Sovereignty** [O. Eng. *soverainetee*, from O. Fr. *sovrainete*, deriv. of *sovrain*, sovereign < Late Lat. *supera'nus*, supreme, principal, deriv. of Lat. *su'perus*, upper, higher, deriv. of *su'per*, above]: the possession of the highest power in any given sphere, as in the state. The debates concerning the supreme power, whether it resides by right in the people—i. e. the organized people—ultimately, or in some ruler who received it from God, led to the application of the word to the former as the source from which the right of the particular magistrate or line of kings was derived, and to the latter as invested by the former with his power according to the will of God. In the English usage the king or queen is called sovereign, although possessed of an authority limited on every side by law. Yet as in theory all executive power is derived from that of the monarch, the term sovereign contains no absolute misnomer.

Sovereignty in public law is the right to exercise uncontrolled the powers of the state.

As a state's relations are of two sorts—(1) with its own subjects, (2) with other states—so its sovereignty is said to be internal and external. The internal sovereignty of a state includes all those powers of government which it possesses over its own subjects and transient foreigners within its territorial limits and on its merchant ships on the high seas. Such powers or rights are those of eminent domain, taxation, legislation, punishment, etc. With their exercise foreign states, unless unduly discriminated against, have nothing to do; nor does it depend upon their recognition. Thus the internal sovereignty of the U. S. was complete from the date and fact of the declaration of its independence.

External sovereignty, however, being the right to enter into relations with other states, for which intercourse their consent is necessary, does depend upon their recognition. In the case of the U. S. this was made by France through the treaty of 1778; by Great Britain in express terms by the treaty of 1782.

When a state exercises some but not all of the powers of external sovereignty it is called a dependent or semi-sovereign state, e. g. Bulgaria.

Under the U. S. Constitution the question whether the several States or the U. S. are invested with the sovereignty has been made a matter of great contention. On this subject the following considerations are especially worthy of notice:

(1) In the provisional articles of peace between the U. S. and Great Britain (1782), and in the definitive treaty of 1783, the king acknowledges the thirteen U. S. "to be free, sovereign, and independent States," "treats with them as such," and "relinquishes all claims to the government, propriety and territorial rights of the same, and of every part thereof." The meaning of this is that he and no one else had any claims of sovereignty over the territory of the U. S., and that by relinquishing those claims he left them in the same condition in which other states independent of all external powers were by the nature of their situation placed. The thirteen States were at that time confederated, but of this confederation he took no notice.

(2) In the new Constitution, framed in 1787, important limitations were put on the power of the thirteen States, all of them tending to throw power into the hands of the general Government. Among these were the powers to declare war, to make peace, to send and receive ambassadors, to raise and support armies, to coin money, to emit bills of credit, to provide for calling forth the militia of the States in order to execute the laws of the Union, to decide in all questions, whether questions of interpretation or of other kinds, arising under the Constitution; and it is added that "the Constitution, and the laws of the U. S. which shall be made in pursuance thereof, and all treaties made or which shall be made under the authority of the U. S., shall be the supreme law of the land; and the judges in every State shall be bound thereby, anything in the constitution or laws of any State to the contrary notwithstanding." (Art. VI., 2.) This section is immediately followed by one to the effect that the Senators and Representatives of the U. S., and all judicial and executive officers, both of the U. S. and of the several States, shall be bound by oath or affirmation to support the Constitution. The President especially is required to declare on oath or affirmation that he will to the best of his ability preserve, protect, and defend the Constitution of the U. S. So far from being sovereigns, then, the States composing the U. S. have not the attributes of sovereignty belonging, according to international law, to a sovereign and independent state. They can have no other or higher relations to foreign powers than any municipality, private corporation, or individual. If they differ with the general Government on the interpretation of laws or treaties, the difference must be drawn before the courts of the Union, and their interpretation must decide the judgments of all State courts thereafter. The Constitution is thus supreme, and as a supreme instrument it prohibits the States (Amendments, Art. X.) from exercising certain powers.

All this is well expressed in President Jackson's proclamation of Dec., 1832: "The States severally have *not* retained their entire sovereignty. It has been shown that in becoming parts of a nation, not members of a league, they surrendered many of their essential parts of sovereignty. The right to make treaties, declare war, levy taxes, exercise exclusive judicial and legislative powers, were all of them functions of sovereign power. The States, then, for these important purposes were no longer sovereign. The allegiance of their citizens was transferred, in the first instance, to the Government of the U. S.; they became U. S. citizens, and owed obedience to the Constitution of the U. S. and to laws made in conformity with the powers it vested in Congress. This last position has not been and can not be denied. How, then, can that State be said to be sovereign and independent whose citizens owe obedience to laws not made by it, and whose magistrates are sworn to disregard [its own] laws when they come into conflict with laws passed by another? What shows conclusively that the States can not be said to have reserved an undivided sovereignty is that they expressly ceded the right to punish treason—not treason against their separate power, but treason against the U. S. Treason is an offense against *sovereignty*, and sovereignty must reside with the power [able] to punish it." See the articles GOVERNMENT, INTERNATIONAL LAW, MONARCHY, NULLIFICATION, REPUBLIC, and TREASON.

Revised by T. S. WOOLSEY.

**Sowerby**, JAMES: painter and botanist; b. at Lambeth, London, Mar. 21, 1757. Among his works are *English Botany*, containing colored figures of all the native plants of Great Britain (36 vols., with descriptions by Sir James Edward Smith, 1792–1807; supplement by his son, James De C. Sowerby, 4 vols., 1815–49; new ed. by J. T. B. Syme, 11 vols., 1863–72); *English Fungi or Mushrooms*, with 440 colored figures (3 vols., 1797–1803); *British Mineralogy*, with 550 colored plates (5 vols., 1804–17); *Exotic Mineralogy*, with 169 colored plates (2 vols., 1811–17); and *Mineral Conchology of Great Britain*, with 600 plates (6 vols.; the last two by his son, J. De C. Sowerby, 1812–30). D. Oct. 25, 1822.

**Sowing and Sowing-machines**: the act or process of depositing seed in the ground, and the machines used for the purpose. When seeds are deposited singly or with only a few in a definite spot, the act is usually called *planting*, the term *sowing* being restricted to cases where the seed is thrown broadcast or deposited in rows or drills. Sowing or planting is usually performed in the spring, but sometimes, and with some kinds of crops, in the autumn, so that the plants may have a fair start when the spring opens. The seeds are usually covered over by harrowing, brushing, or rolling the soil after they have been deposited. As a rule, it may be laid down that when the soil is rather firm and the climate moist, little depth of covering is required; but when the soil is loose and the climate dry, the seeds should be covered to a depth of twice or more their thickness. Machines, more or less complex, have been in use from time immemorial for performing the operation of sowing or planting in all its forms. Some scatter the seed broadcast; others dibble it into the ground in rows or drills, and then cover it, the general principle being that the drills should be at such a distance apart that a horse drawing a light plow may pass between the drills without injuring the plants. In the larger machines, often drawn by horse-power, the seed is often placed in small cups, from which it passes through tubes so arranged as to allow them to drop regularly into shallow furrows cut by coulters just in front of the escape-orifice of the tubes, the furrows being closed up by a kind of rake or harrow following immediately after and forming a part of the machine. There are many kinds of seed-drills and planters in use.

Revised by L. H. BAILEY.

**Soy-bean**: the *Glycine* (or *Soja*) *hispida*; a bean extensively grown in Japan, China, India, and the Spice islands, where it is much used as food. The sauce called soy is, when genuine, made of boiled soy-beans, mixed with wheat-meal and fermented. It is then salted and mixed with water, and after daily stirring for a long time the supernatant liquid is poured off and preserved for use. Good soy is a spirited and excellent sauce, and is believed to improve with age. The plant is coming into notice in the southern parts of the U. S. for forage. Revised by L. H. BAILEY.

**Soyer**, swaa-i-ā', ALEXIS: cook and author of books on gastronomy; b. at Meaux, France, 1809; served as cook in several restaurants in Paris; went to London in 1830; was cook in the Reform Club in that city 1837–50; during the war in the Crimea voluntarily visited the British camps and hospitals there to introduce a better system of cookery for the soldiers. He published *Culinary Relaxations* (1845); *Gastronomic Regenerator* (1847; 9th ed. 1861); *Modern Housewife* (1849; new ed. 1872); *Shilling Cookery-book* (1854; 1858); *Culinary Campaign* (1857); and other works. D. Aug. 5, 1858.

**Space** [viâ O. Fr. from Lat. *spa'tium*, room, space, interval, public square]: as defined by Aristotle (*Phys.*, iv., 1–5), "the first and unmoved limit which bounds body" when taken as finite space or *place*; taken as space in general, it is "the unmoved limit of whatever is moved"—i. e. of all bodies. Time, on the other hand, should be, according to him, the number and measure of movement. The existence of pure space is evident, he says, from the fact that things change places; yet in spite of its three dimensions it is not to be confounded with body, for in that case two bodies would coincide; it is not cause; there is no place in which space itself exists; nor does space grow with what grows. Matter and form are inseparable, but extension and limiting surface are separable; hence matter and form do not explain them, as was thought by Plato in the *Timæus*, where he makes space to be the primitive matter of the universe; it is not form, for space remains when the form is removed. In these distinctions Aristotle lays especial stress on the idea of limit, negation, discreteness in relation to body as essential to the definition of space. In philosophy there is scarcely any subject upon which there is more apparent diversity of opinion or more fruitless attempts at definition. The difference, however, is not really so great as it seems. Space has been made identical with pure extension, but this leaves no definition for time, which likewise involves extension. Leibnitz made it "the order of things coexisting, as time is the order of things successive," so that if the totality of things could be moved, space, being their arrangement, would likewise be moved. It has been defined to be pure nothing, thus omitting its specializing attribute. For while "nothing" may be regarded as the potentiality of all (of events and ideas as well as of bodies), space can be regarded only as the potentiality of bodies. It has been made an accident or attribute or relation inhering in bodies; but this would involve the absurdity that annihilation of bodies destroyed space. As the ultimate logical condition for the coexistence of bodies, space is itself a correlate of time as regards motion and actually existing matter—time by itself being the ultimate logical condition of all succession. As ultimate logical condition it has quite frequently been identified with the infinite, or made to be a divine attribute. Sir Isaac Newton suggested that God by existing constitutes time and space. Samuel Clarke expanded this suggestion into a system of theology, and held a long discussion with Leibnitz on the subject. Akin to this view is that which makes space and time to be forms of mind when it thinks nature. Kant laid great stress on this, making space and time subjective forms of intuition and devoid of objective validity as regards "things in themselves." By this, however, he must not be understood to mean that they are subjective to the mere individual mind, and to be refused validity as regards objects in nature and history; for Kant regards all nature and all history as necessarily conditioned in and through space and time. His doctrine, therefore, does not narrow or belittle space and time, but only magnifies and glorifies mind, which is thus shown to transcend the world and to be of an eternal nature.

Much labor has been expended by sensationalists on the problem of accounting for the origin of the idea of space. Locke thought that he could trace it to the senses of touch and sight; most of his followers have adopted the same doctrine, making it a generalization from experience gained in the perception of bodies. Accordingly, they ignore in different ways the attributes of universality and necessity which are the distinctive characteristics of *a priori* ideas, and make unbroken custom or habit to be the explanation of the inability or impotence of the mind which we call inconceivability. That geometry rests upon the *a priori* cognition of space, as arithmetic and algebra rests upon a similar cognition of time, is not conceded by them. But Kant saw and stated with great clearness the grounds for all transcendental or spiritual philosophy as involved in the question, "Are *a priori* synthetical judgments possible"? i. e. Can we enounce the universal and necessary conditions of experience? The answer being affirmative, instancing mathematics, the next question is, "How are they possible"?—that is, What does this presuppose in regard to mind? Instead of deriving the idea of space from experience in regard to bodies, he saw that by no possibility could the mind conceive a body in the first instance without already having the idea of space. The mind uses the idea of space as an indispensable instrument in thinking the idea of a body. Moreover, space is not a generalized idea (discursive), inasmuch as it is not abstracted from spaces, but is thought as the logical condition of all possible spaces or bodies, and therefore as infinite from the first. (See refutation of Hamilton's doctrine of the inconceivability of infinite space in article on INFINITE.) Hegel unites in his view of space the doctrine of the Christian Mystics with that held by such thinkers as Newton and Clarke; making God's thinking and willing to be identical, he holds this self-knowledge to be a creation of the world—the making an object of himself to be the creative act. The self-consciousness of God being self-externalization, as well as return out of self-externalization through the act of recognition, nature and man (in whom nature is perpetually sacrificed and subordinated for spirit) come into being. Accordingly, the lowest, most elementary, abstract, and inadequate form of the divine self-knowing is space; time being at once the needed correlate to correct its imperfection, and reflect God's unity with himself, which is essential to destroy his self-alienation. The more orthodox view, however, holds that space, time, and the world arise not as direct object of the divine consciousness, but as a secondary reflection upon the derivation implied in the fact that the absolute as subject makes of himself an object of himself. Meister Eckhart, Jacob Böhme, Angelus Silesius, Franz Baader, Schelling, and others have explored this abyss of the creative idea, and with substantially the same results. Indeed, the Oriental mysticism which underlies Gnosticism, Neo-Platonism, and the Jewish Cabbalah is not essentially different as regards its logical movement, but only in its construction of the "return," and its assertion of the principle of emanation instead of creation. Spinoza's "thought and extension" as the two attributes of God suggest the view which he held of the relation of space to the divine activity. WILLIAM T. HARRIS.

**Spaeth**, spāt, ADOLPH, D. D.: theologian; b. at Esslingen, Würtemberg, Germany, Oct. 29, 1839; educated at the University of Tübingen. After being vicar in Würtemberg, and tutor in the family of the Duke of Argyle in Scotland, he went to the U. S. in 1864, and entered upon a pastorate in Philadelphia. In 1874 he became Professor of New Testament Exegesis in the Theological Seminary of the Lutheran Church in Philadelphia. He has been president of the General Council, and actively connected with all its literary and benevolent operations. He is the chief editor of its *German Church Book*, an American edition of Büchner's *Hand-concordance*, and published *Saatkörner* (1893), on the Gospels for the Church Year. H. E. JACOBS.

**Spagna**, spaan'yaa, **Lo**, or **Lo Spagnolo**: the usual name of the painter GIOVANNI DI PIETRO, one of the most distinguished scholars of Pietro Perugino. His work has often been taken for that of Perugino or of the young Raphael. Very little is known about his life. In 1503 he was an established painter, in 1516 he was made a citizen of Spoleto, and in the following year he was elected head of the society of painters there. His masterpiece, *The Madonna Enthroned*, painted in 1516, is in the chapel of St. Stephen in the lower church of St. Francis at Assisi. Lo Spagna was still living in 1530. The National Gallery in London possesses an *Agony in the Garden* by him, formerly attributed to Raphael. W. J. STILLMAN.

**Spagnolet'to, Lo**: See RIBERA, JOSÉ.

**Spahr**, CHARLES B.: lecturer and writer; b. in Columbus, O., July 20, 1860; A. B., Amherst, 1881; Ph. D., Columbia, 1886; studied at Leipzig; assistant editor of *The Outlook* since 1886; on the editorial staff of *The Commercial Advertiser* 1889–91; lecturer on Taxation and the Distribution of Wealth Columbia College, 1890. Author of *Taxation of Labor* (*Political Science Quarterly*, 1886) and *The Single Tax* (*Political Science Quarterly*, 1891). C. H. T.

**Spain** [from Lat. *Hispa'nia* (> Span. *España*), Spain, deriv. of *Hispa'ni*, the name of the people of Hispania or ancient Spain]: a kingdom of Europe occupying more than four-fifths of the Iberian Peninsula, which it divides with Portugal, and separated from France by the Pyrenees. It includes the Balearic islands, in the Mediterranean, and the Canary islands, off the west coast of Africa (as the provinces of Baleares and Canarias respectively), and the town of Ceuta on the Moroccan coast, attached administratively to Cadiz. As thus defined it consists of forty-nine provinces, having an area of 197,670 sq. miles, and a population of 17,565,632 (1887). In 1898 it also had colonies in various parts of the world—in America, Cuba and Puerto Rico; in Asia, the Philippine, Sulu, Caroline, and Marianne islands; in Africa, Rio de Oro, Adrar, and several small towns and islands on the north and west coasts, making altogether under Spanish control an area of 603,000 sq. miles, with a total population of 27,261,200 (1887).

*Configuration.*—The Peninsula is separated from Africa by the Straits of Gibraltar, 15 miles across. The coast measures 1,000 miles on the Atlantic side, and 715 miles on the Mediterranean, and is much indented, with many good harbors. The center of the Peninsula is formed by a mass 1,500 to 3,000 feet high, and separated into several river basins by mountain chains running approximately E. and W. The plateaus of Leon and Old Castile occupy the north, and that of New Castile the center. From these to the N. E. extends the basin of the Ebro, to the E. and S. E. the plains of Valencia and Murcia, to the S. those of Andalusia, and to the W. Portugal. The Pyrenees cross the isthmus from the Bay of Biscay to Cape Creus on the Mediterranean, with an average breadth of 75 miles, and their main mass is in Spain. The principal peaks are in the middle of the chain, and the culminating points are Mt. Perdo (10,997 feet), on the international boundary, and Posets (11,047 feet) and Mt. Aneto (11,170 feet) within Spanish territory. Toward the eastern end of the chain the little republic of Andorra lies between France and Spain. The Pyrenees are continued westward by the Cantabrian Mountains for 350 miles, nearly to Cape Finisterre. They rise directly from the ocean on the N., but on the S. they pass more gently into plains 2,500 to 3,000 feet above sea-level. The highest point is the Torre de Ceredo (8,786 feet). The Sierra Nevada borders the Mediterranean along the south coast, and, although short, is higher than the Pyrenees. Between the northern and southern coast ranges are four other principal and many minor chains, which divide the river-basins, ramify, join together, or are lost in the central mass already mentioned, covering Spain with mountains usually rough and wild, yet not offering material difficulties to intercommunication. The Pyrenees have perpetual snow and some glaciers.

*Rivers.*—The main watershed is along the eastern margin of the central table-land, and the largest streams flow W., through Portugal, into the Atlantic Ocean. The largest stream flowing into the Mediterranean is the Ebro (440 miles long; basin, 38,580 sq. miles), which drains the Pyrenees and Eastern Cantabrian slopes, has a basin of typical triangular form, and projects a considerable delta into the sea. The longest river is the Tagus (566 miles long, 374 miles in Spanish territory; basin, 31,865 sq. miles), which crosses the Peninsula nearly centrally, flowing westward, and empties into the Atlantic through a large estuary, on which Lisbon is placed. The next in size is the Douro, the Portuguese name; the Spanish is Duero. It drains the table-land of Old Castile, for about 60 miles forms the boundary between Spain and Portugal, and empties into the Atlantic at Porto. The Guadalquivir and Guadiana empty into the Atlantic on the Gulf of Cadiz. The former is in exclusive Spanish territory, is 316 miles long (basin, 25,300 sq. miles), and has its mouth at San Lúcar, just N. of Cadiz. The Guadiana rises as the Zancara, on the E. of the plateau of La Mancha, and flows first westward, then southward, forming in part, in the latter part of its course, the boundary between Spain and Portugal. The length of the Guadiana proper is 316 miles, but with the Zancara it is 510 miles. The rivers, so far as they lie in Spanish territory, are of little use for navigation, except the Guadalquivir, but are much used for irrigation, and the waters of the lesser rivers spread on the gardens of Valencia and Murcia give the soil a prodigious productivity. The amount of flow in the rivers generally is unequal, being very small in summer and autumn.

*Climate.*—The climate of the interior table-lands is generally continental, rigorous and dry, that of the east coast dry and mild, that of the south coast moist and hot, and that of the northern slope cool, wet, and stormy. The annual rainfall is generally only from 8 to 20 inches, or about that of the Missouri valley; that of the southern coast from 20 to 50 inches; and that of the northern coast upward of 40 inches (at Oviedo 81). Madrid has only 11 inches of annual rainfall, less than that of Denver, but more than that of El Paso. The summer temperatures in the interior are the hottest in Europe, and are of the same degree as those of the middle Euphrates valley, but the winter temperatures are less extreme, being like those of Sicily and the Peloponnesus.

*Productions.*—The mineral wealth of Spain has been known from the most ancient times, and its richness in gold made it the California of the Carthaginians and Romans. The production of gold has long failed, but Spain still continues the richest country in Europe in other mineral products. Iron is extremely abundant in the mountains, especially in the Biscayan provinces; lead is very abundant, especially in the Sierra de Gador, W. of Almeria; argentiferous lead is extensively distributed, and the mines at

Linares, in Andalusia, are very important; copper is worked at many places, principally to the N. of Huelva; cinnabar has been taken out at Almaden from the time of the Romans; and rock-salt, marble, plaster, mineral fertilizers, and coal offer large resources. In 1899 the production of copper ore was 2,443,044 tons, valued at $8,500,000; of silver-lead ore, 184,906 tons, valued at $7,406,640; of lead ore, 123,750 tons, value $4,641,300. Of the copper ore, over 90 per cent. was exported, chiefly to Great Britain. In 1894 over 15,000 mines were registered, of which about 2,000 were worked.

The wealth of Spain in mineral and thermal springs is even more unique than her wealth in minerals. In 1765 Bedoya enumerated 2,000 such springs; in 1844 the number of such springs used by the sick was more than 1,200, while in France the number was 864. These springs occur chiefly at the foot of the Pyrenees and of the Sierra Nevada. Guipuzcoa, the smallest of the provinces, has the largest number, 84 springs, of which 55 have accommodations for baths; next is Granada, with 65 springs and 25 baths; then Malaga, with 58 springs and 31 baths.

Of the lands, 80 per cent. is classed as productive, and of this 34 per cent. is devoted to agriculture, 21 to fruits, 20 to meadows, 4 to vineyards, and 2 to olives. The great variations in altitudes permit the productions to range through those of the sub-tropic and temperate zones. The cereals are abundant and of excellent quality. The leading crops are wheat, rye, barley, maize, rice, esparto, flax, hemp, and pulse. The product of wine is very large and highly valued; it is the chief item of export; value in 1899, 103,562,987 pesetas ($19,987,656). Raisins, almonds, oranges, olive oil, and conserves are also exported in great quantities. Cork is chiefly furnished by Spain, though the cork-tree grows in Southwestern Europe and Northern Africa. The exported Spanish product in 1892 was valued at over $5,000,000. Pastoral pursuits occupy the peasantry of the interior, and the Spanish races of sheep, cattle, and horses are all celebrated for excellence. The wool export in 1892 was valued at $2,000,000, and that of boots and shoes at $5,000,000.

*Commerce.*—The imports of merchandise in 1900, including the precious metals, were valued at 862,396,600 pesetas ($166,442,544) and the exports at 723,867,883 pesetas ($139,706,501). The imports are chiefly wheat, cotton, raw or manufactured, coal and coke, drugs and chemicals, sugar, machinery, tobacco, and woolen goods. The chief exports were wine, minerals and ores, cork, boots and shoes, cotton textiles, fruits, oil, and wool. The trade was chiefly with France, Great Britain, and the United States. The merchant navy consisted in 1898 of 436 steamers and 1,145 sailing vessels of over 100 tons. In 1900 17,722 vessels entered and 16,910 cleared from the Spanish ports, and about half carried the Spanish flag.

In 1899 there were 8,068 miles of railway open, all of private ownership. On Jan. 1, 1898, there were 19,868 miles of telegraph line, with 45,790 miles of wire.

The unit of money is the *peseta*, of the value of a franc, or 19·3 cents. The gold coins in common use are worth 5, 10, and 20 pesetas, and the silver coins 1 and 5 pesetas. Weight and fineness are those of the corresponding French coins. The ratio of gold to silver is 15½ to 1, and the 5-peseta silver-piece is legal tender. The metric system was introduced in 1859, but the old weights and measures are still largely used. The *libra* is 1·014 lb. avoirdupois, and the *quintal* = 100 libras. The *arroba* = 3¼ imperial gal. for wine or 2¾ gal. for oil, and the *fanega* = 1½ imperial bush.

*Administration.*—Spain is a monarchy, under the constitution of 1876. The legislative power is vested in a parliamentary body called the Cortes, consisting of a Senate and a Congress. The senators in part hold life positions by inheritance or *ex officio*, in part are nominated by the crown, and in part elected, and together number not more than 360. The Congress has 431 elected deputies. All are elected for five years, or until the Cortes are dissolved by the crown. The ministry is responsible, and consists of nine members. The local governments are generally representative.

For the fiscal year 1898–99 the total revenue was 842,532,714 pesetas ($162,608,814) and expenditures 878,398,568 pesetas ($169,530,923). The revenue is derived from direct and indirect taxation, stamp-duties, monopolies, and income of public property. The monopolies are the tobacco-trade, the lottery, the mint, and others. The public debt of all kinds (funded and floating) on July 1, 1900, exceeded 9,307,798,721 pesetas ($1,796,405,153), and the principal item in the public expenditure is the payment of the interest charges.

Spain possesses about fifty fortified places, mostly ports, but Gibraltar, which controls the Straits, is in the hands of the British. The army and navy are recruited by conscription. The permanent army consists of 98,140 men, and this force can be increased to 1,083,595 in time of war. There are 13 military schools and colleges. At the beginning of 1898 Spain had 1 first-class battle-ship, 1 port-defense ship, 10 first-class cruisers, 7 second-class, 11 third-class, 80 gunboats, and 27 torpedo boats, 137 in all, manned by 14,000 seamen, 9,000 marines, and 1,000 officers, including engineer officers; but in the war with the U. S. Spain lost many of her ships and men. See ARMY and SHIPS OF WAR.

Of the colonies in 1898 Rio de Oro and Adrar were governed by the province of Canarias, and the others were controlled by governors appointed by the crown. Cuba had 46 representatives in the Cortes. As a result of the war with the U. S., Cuba, Porto Rico, Guam, and the Philippines were lost to Spain.

*Divisions.*—The forty-nine provinces of Spain, including the Canary islands, with population of each, according to a census taken in 1897, are as follows:

| Provinces. | Pop. | Provinces. | Pop. |
|---|---|---|---|
| Alava | 94,622 | Logroño | 186,223 |
| Albacete | 233,005 | Lugo | 459,119 |
| Alicante | 451,174 | Madrid | 737,444 |
| Almeria | 344,681 | Malaga | 485,132 |
| Avila | 197,636 | Murcia | 518,263 |
| Badajoz | 490,551 | Navarra | 302,978 |
| Baleares | 306,926 | Orense | 402,873 |
| Barcelona | 1,034,538 | Oviedo | 612,663 |
| Burgos | 340,001 | Palencia | 193,668 |
| Caceres | 354,245 | Pontevedra | 447,612 |
| Cadiz | 434,250 | Salamanca | 317,005 |
| Canarias | 334,521 | Santander | 263,673 |
| Castellon de la Plana | 304,477 | Segovia | 156,086 |
| Ciudad-Real | 305,002 | Sevilla | 547,020 |
| Cordoba | 443,582 | Soria | 147,787 |
| Corunna | 631,419 | Tarragona | 334,343 |
| Cuenca | 241,566 | Teruel | 239,831 |
| Gerona | 298,497 | Toledo | 370,012 |
| Granada | 477,768 | Valencia | 775,995 |
| Guadalajara | 199,290 | Valladolid | 276,366 |
| Guipuzcoa | 191,822 | Vizcaya | 290,222 |
| Huelva | 253,970 | Zamora | 275,354 |
| Huesca | 238,935 | Zaragoza | 413,480 |
| Jaen | 463,806 | N. and W. coast of Africa | 11,003 |
| Leon | 384,197 | | |
| Lerida | 274,867 | Total | 18,089,500 |

*Population.*—The native tribes of the Peninsula known to the Romans may be called Iberian. The present population consists of Iberians, modified successively by intermixture with Celts, Carthaginians, Romans, Goths, Jews, and Moors. With the last came some Negro blood, and to the slight intermixture of this blood is probably due the well-known Spanish and Portuguese capacity for tropical colonization. At the same time from Spain has poured out an enormous wave of emigration, which has left its mark on the most of America and several oceanic archipelagoes, and this has had its reaction on purity of Spanish blood. Yet notwithstanding these numerous intermixtures, each lasting through centuries, the people are among the most characteristic, self-contained, and sharply defined of Europe. The linguistic type evolved is essentially Roman, but the ethnic includes the Portuguese, and is clearly distinct from the rest of Europe. The Spaniard, somewhat swarthy, is well-balanced as to virtues and vices, vigorous, original, serious, proud, dignified, courteous, tenacious, patriotic, thrifty, sometimes vain, bigoted, intolerant, and vindictive. In the Roman conquest Spaniards were found gallant and warlike, and when overcome they made the most faithful and conservative of the Roman provinces. They formed a fertile and easy field for early Christian missionary effort, and having accepted the Roman supremacy and Christianity they were tenacious of them, and for the next 1,000 years were chiefly occupied in defending themselves and their religion. With the discovery of America this race displayed to the world its amazing supply of courage, enterprise, and endurance, as well as its indifference to the sufferings of inferior races.

The growth of the population has been slow. Philip II. took a census (imperfect as compared with modern ones) in 1594, giving 8,206,791 inhabitants; in 1797 another census gave 10,268,150—a very small increase in two centuries, due to enormous colonization. The increase during 1877–87 was at the rate of ·47 per cent. per annum. The density of population is over 88 per square mile, and decreases from coast to center. The females are in surplus of 104 to 100. The principal cities are Madrid (pop. (1897) 512,150), Barcelona (509,589), Valencia (204,768), Seville (146,205), Malaga (125,579), and Murcia (108,408), and there are no other cities with a population more than 100,000.

In 1889 4,854,742 persons were following agricultural pursuits, 823,310 the arts and trades, 409,549 domestic service, 243,867 industrial (textile and mineral), 194,755 commercial, 115,764 merchant marine, 97,257 public employees, 91,226 were inmates of asylums, etc., 84,510 professional, 72,077 religious, and 1,719,955 were school and college pupils. In 1892 the surplus of emigration over immigration was 8,258. Emigration is chiefly to Brazil, Uruguay, and Argentina.

The national church is the Roman Catholic, and the only professed dissenters in 1887 were 9,645 rationalists, 6,654 Protestants, 402 Jews, and 510 of other religions. In 1884 there were 32,435 priests, 1,684 monks resident in 161 monastic houses, and 14,592 nuns in 1,027 convents. There were 65 cathedrals, 18,564 churches, 30 religious colleges, and 11,202 other buildings used for religious purposes. Since 1876 private Protestant worship has been permitted.

In 1860 only 20 per cent. of the population could read and write; in 1889 this percentage had grown to 28·5. Compulsory primary education is statutory, but is not enforced. In 1885 there were 24,529 public free primary schools and 5,576 private ones, with a total enrollment of 1,843,183 pupils. The secondary schools are less efficient. There are 10 universities with 16,000 students in all; also various special schools supported by the Government.

*History.*—The colonization of the coasts of the Peninsula by the Phœnicians (Cadiz), Greeks (Saguntum), and Carthaginians (Cartagena) began about 1100 B. C. The Carthaginians extended their conquest over about a half of the Peninsula in the third century B. C. This was inherited by the Romans as the result of the Punic wars, and the conquest was completed 19 B. C. The Spanish provinces were very thoroughly Romanized. The Gothic invasion was begun in the fifth century of our era, but the Gothic kingdom was overthrown by the Arabs in 711, who remained in control of most of the Peninsula for three centuries. Christian kingdoms were gradually established from the eleventh century until the marriage of Ferdinand V. of Aragon and Isabella of Castile united these kingdoms in 1479, and began a career of prosperity, which resulted in the conquest of the Moors and the discovery of America, and gave Spain the form and character which it yet bears. The marriage of Isabella's daughter Johanna with Philip I., son of the Emperor Maximilian, made Spain a part of the Hapsburg empire, with Germany, the Netherlands, Milan, Naples and Sicily, Sardinia, Burgundy, and the colonies, under Charles I. of Spain, V. of Germany (1516). The despotism of Charles was followed by the tyranny of the bigoted Philip II. (1556–98), who, with the aid of the Inquisition, undertook to root out Protestantism, and he with his no less despotic and intolerant successors succeeded in bringing to a close before the eighteenth century the brilliant period of Spanish history, which began with Ferdinand and Isabella. The line of Hapsburg princes closed with Charles II. (1665–1700). On his death followed the war of the Spanish succession (see SUCCESSION WARS), which resulted in placing a Bourbon prince on the throne, and with two brief interruptions this dynasty has since remained in power. The first interruption was in 1808–14, during which time Joseph was kept in power by his brother Napoleon. This was the period of the Peninsular war, in which successful resistance to the self-aggrandizing schemes of Napoleon was for the first time offered. Upon the dethronement of their king and the occupation of his throne by Joseph Bonaparte the entire Spanish people rose in arms, and, though ill disciplined and unorganized, showed such vigor and courage as to require the personal presence of Napoleon in Spain in order to restore the French authority. Subsequently, however, he left to his marshals the difficult task of subduing the Spaniards, whose persistent efforts, aided and directed by the military genius of Wellington, resulted in driving out the intruders and contributed to the final overthrow of Napoleon. (For an account of the causes of the Peninsular war, see NAPOLEON I. (*Spanish Campaign*), and for further details WELLINGTON, ARTHUR WELLESLEY, DUKE OF.) The second interruption of the Bourbon rule was from 1868 to 1874, during which years a regency, a short-lived monarchy under Amadeus, and a republic were successively established. The Bourbons were restored Dec. 30, 1874, in the person of Alfonso XII., eldest son of Isabella. He died in 1885, and was succeeded by his posthumous son, Alfonso XIII., with Maria Christina, his mother, as regent. A rebellion in CUBA (*q. v.*) led, in 1898, to a war with the U. S., in which the flower of the Spanish navy was destroyed. See SPAIN, HISTORY OF, in the Appendix.

REFERENCES.—Murray's *Handbook of Spain* (1888); Willkomm, *Die Pyrenäische Halbinsel* (1885); Gallenga, *Iberian Reminiscences* (1883); Riera y Sans, *España y sus Colonias* (1891). MARK W. HARRINGTON.

**Spal'ato**, or **Spalatro**: town and railway station; in the province of Dalmatia, Austria; on a peninsula jutting out into the Adriatic (see map of Austria-Hungary, ref. 10-E). It has a good harbor, is defended by a citadel, and carries on an active trade in grain, cattle, horses, swine, fruits, wine, and rosoglio, besides an extensive transit trade between Italy and Turkey. It is situated near the ancient *Salona*, on the site of the famous palace of Diocletian, called *Salonæ Palatium*, or, in an abbreviated form, *S. Palatium*; hence the name of the modern town. Of the magnificent palace, which covered 8 acres of ground and which it took twelve years to build, many remains are extant. Pop. (1890) 15,697. Revised by M. W. HARRINGTON.

**Spalax**: a small rodent (*Spalax typhlus*) having the habits and very much the appearance of a mole. The incisors are large, the molars, three on each side of either jaw, have roots. The external ears are rudimentary, as are also the eyes, which are covered by the skin; the tail is rudimentary; the fore feet modified for digging. The silky fur is of a general yellowish brown; the length is 5 or 6 inches. The animal is also known as the mole-rat. It ranges from Southeastern Europe into Asia. F. A. L.

**Spalding**, JOHN FRANKLIN, D. D.: bishop; b. at Belgrade, Me., Aug. 25, 1828; graduated at the North Yarmouth Classical Academy, Maine, in 1849, at Bowdoin College, Maine, in 1853, and at the General Theological Seminary of the Protestant Episcopal Church, New York, in 1857; minister of St. James's church, Oldtown, Me., 1857–59; was rector of St. George's church, Lee, Mass., till 1860, when he became assistant minister of Grace church, Providence, R. I., for one year; rector of St. Paul's church, Erie, Pa., 1862–74: member of the general board of missions from 1865; dean of the Erie convocation Jan., 1866: elected Oct. 24, 1873, missionary bishop of Colorado, with jurisdiction in Wyoming and New Mexico; consecrated bishop Dec. 31, 1873. He published *The Threefold Ministry* (1864), *Manual of Prayers* (1872), and various articles, sermons, pamphlets, etc.

**Spalding**, JOHN LANCASTER: bishop; b. at Lebanon, Ky., June 2, 1840; educated at Mt. St. Mary's, Emmitsburg, Md., at the University of Louvain, and in Rome. He was secretary to the bishop of Louisville in 1865, built a church there for colored Catholics, and became chancellor of the diocese in 1871. He was made bishop of Peoria, Ill., in 1877. His published works include *Essays and Reviews* (1876), *Religious Mission of the Irish People* (1880), *Education and the Higher Life* (1891), *Things of the Mind* (1894), and two volumes of poems.

**Spalding**, MARTIN JOHN, D. D.: bishop; b. in Marion co., Ky., May 23, 1810; graduated at St. Mary's College in 1826, and in 1830 went to Rome to enter the College of the Propaganda; returning to Kentucky, was ordained priest in 1834; appointed pastor of the cathedral church at Bardstown, and established *The Catholic Guardian*, with which he retained his connection until 1858; lectured in favor of Roman Catholicism in the U. S. and Canada, his lectures being published under the title *Evidences of Catholicity* (1847; 4th ed. 1866); in 1848 appointed coadjutor of the Roman Catholic diocese of Louisville; in 1850 became Bishop of Louisville, where he erected a cathedral. In 1864 he succeeded Dr. Kenrick as Archbishop of Baltimore; in 1866, as apostolic delegate, convened the second national council at Baltimore, and drew up the acts of the council. He took a prominent part in the Vatican Council of 1870–71, where he urged an immediate decision on the subject of papal infallibility, but wished it to be indirect and implied, rather than positive and affirmative; but he, with the other Roman Catholic bishops from America, yielded in favor of a positive declaration. His principal works are *Early Catholic Missions of Kentucky* (1844); *History of the Protestant Reformation in Germany and Switzerland*, written in opposition to Merle d'Aubigné (1860); and a translation, with notes and an introduction, of Darras's *General History of the Catholic Church* (1866). His miscellaneous essays have also been published in book form, and his *Life* by John L. Spalding. D. in Baltimore, Feb. 7, 1872.

**Spallanza'ni**, LAZARO: naturalist and physiologist; b. at Scandiano, duchy of Modena, Jan. 12, 1729; was appointed Professor of Logic, Metaphysics, and Greek at Reggio di Modena in 1754, and at Modena in 1761. At the reestablishment of the University of Pavia in 1768 he became Professor of Natural History, made extensive scientific travels in Italy and Sicily, Switzerland and Germany, Turkey, Asia Minor, Corfu, and Cyprus. D. at Pavia, Feb. 12, 1799. His polemics against Needham and Buffon, whose theory of spontaneous generation among the infusoria he contested, attracted special attention, showing by a series of ingenious experiments that these animals originated from germs existing in the atmosphere. Among his works are *Viaggi alle Due Sicilie ed in alcune parti degli Apennini* (Pavia, 1792); *Opuscoli di fisica animale e vegetabile* (Modena, 1780), in which he demonstrated the true nature of digestion; and *Expériences pour servir à l'histoire de la génération des animaux et des plantes* (1786), in which he determined the relative functions of the ovum and spermatozoön. R. A. ROBERTS.

**Spandau**, spaan'dow: an old fortified town and military station; province of Brandenburg, Prussia; at the confluence of the Havel and the Spree; 9 miles W. N. W. of Berlin (see map of German Empire, ref. 3–G). The citadel stands on an island in the Havel, and is used by the Prussian Government as a prison for military and political criminals. The city is well built, has manufactures of hosiery, woolen fabrics, gunpowder, and arms, and carries on a large transit trade between Berlin and Hamburg. Pop. (1895) 55,841.
Revised by M. W. HARRINGTON.

**Spang'enberg**, AUGUST GOTTLIEB: bishop; b. at Klettenberg, Germany, July 15, 1704; graduated Ph. D. at Jena 1726; became a professor at the University of Halle and assistant superintendent of Francke's orphan-house in the same city 1731; was dismissed at the instigation of the Pietists of Halle because he associated with the Moravians, and had expressed the opinion that Pietistic religion was formal and worldly 1733; naturally on his dismission he joined the Moravians and became assistant to Count Zinzendorf at Herrnhut. From 1733–62 his care was the superintendence and organization of their missionary operations. With this end he visited England 1734; obtained lands from the trustees of Georgia for a Moravian settlement in that colony; landed at Savannah with nine Moravian settlers, the first who located in America, 1735; labored as a missionary among his German countrymen in Georgia and Pennsylvania 1735–39, after which he returned to Europe; was instrumental in procuring the establishment of the settlement at Bethlehem, Pa.; founded in London 1741 the first regular Moravian society in England; became general deacon, and in 1744 bishop, of his Church; proceeded to Pennsylvania the same year; repeatedly visited the Oneida Indians; made another visit to Europe 1749–51; organized a Moravian community in North Carolina 1752; was elected successor of Count Zinzendorf in the supreme council; returned finally to Europe 1762. For the next thirty years he was the guide of the Moravians in the consolidation of the home Church, and paid particular attention to their educational methods. He became in 1789 president of the general directory. D. at Berthelsdorf, near Herrnhut, Saxony, Sept. 18, 1792. Author of a *Life of Zinzendorf* (6 vols., Barby, 1772–75; abridged English trans., London, 1838, by B. La Trobe), and of *Idea Fidei Fratrum* (1779; English trans. *Exposition of Christian Doctrine*, London, 1784; 2d ed. 1796), the authoritative manual of Moravian theology. See the biographies by J. Risler (Barby, 1794); C. F. Ledderhose (Heidelberg, 1846; Eng. trans. London, 1855); and G. C. Knapp, *Beiträge zur Lebensgeschichte A. G. Spangenbergs* (Halle, 1884; edited by O. Frick). Revised by S. M. JACKSON.

**Spaniard's Bay**: a fishing-town on the west side of Conception Bay; 7 miles S. of Harbor Grace, Newfoundland; is surrounded by high hills and has some fine views. The inhabitants are mostly engaged in the Labrador cod-fishery. Pop. 1,200.

**Spaniels**: See DOGS and SPRINGER.

**Spanish-American Literature**: the literature of the Spanish-speaking peoples of America. This is of no recent growth. Early in the sixteenth century civilized communities were established in Cuba, Mexico, Peru, and at the mouth of the Plata; and numerous other localities were rapidly colonized. In succeeding centuries intellectual activity steadily increased; so that Spanish America has furnished a long list of eminent men of letters.

Literary culture was more distinctive of the Spanish colonist than of his northern and Saxon brother. While the natural implements of the latter were the axe, the plow, and the hammer, those of the former were the sword and the pen. Moreover, the British settlers of North America were political or religious refugees who received little attention or support from the home government; whereas the colonization of Spanish America was a national project, in the success of which the sympathies, ambitions, and pride of all classes were involved.

The cities of Mexico and Lima had universities half a century before Cape Cod was discovered or John Smith had entered the Chesapeake; and when Harvard College was founded in 1636, Spanish America possessed sixteen flourishing universities and colleges, including the Universidad de Sau Gregorio at Quito and the Universidad de Santo Tomás at Bogotá. Peru with its present shrunken boundaries has six universities and fifty-one colleges, and a national library which contained over 56,000 volumes before the war with Chile in 1882, and now numbers about 35,000; Venezuela has two great universities and six smaller ones, together with fifty-four colleges and other higher institutions of learning; the library of the University of Caracas numbers 30,000 volumes. Spanish America produces many extensive and erudite works of history, archæology, jurisprudence, and natural science, and the most beautiful editions of the classics are to be found there. Educational books and works of direct utility are numerous, and descend to stock-raising, gardening, cooking, carpentry, and locksmithing. An official catalogue shows thirty-seven native text-books in use in the Argentine schools. Spanish-American thoroughness sometimes tends toward prolixity, and voluminous works are not uncommon. The *Historia de México*, by Nieeto de Zamacóis, fills twenty octavo volumes; and the recent collaboration, *México á través de los siglos*—historical and descriptive, from the conquest to the present day—is embellished with nearly 3,000 illustrations.

A great part of the pictorial and hieroglyphic writings of the native races were destroyed by the Spanish conquerors. Yet considerable fragments remain, such as the *Popol Vuh* and the Inca drama of *Ollantay*, translated by Carraseo and others. A great amount of labor was expended, especially by the Jesuit fathers, on these relics and the languages to which they pertain. The *Bibliothèque México-Guatémalienne*, of Brasseur de Bourbourg (Paris, 1871), gives much minute information regarding what has been written on the subjeet in Spanish America.

*Writers of the Colonial Period.*—In the early part of the colonial period writers in Spanish America were generally visitors from the Old World. Yet occasionally there appeared Ameriean writers whose brilliancy was enhanced by their isolation. Chile claims an epic poet prior to the seventeenth century in Pedro de Oña, the author of *El Arauco domado* (pub. 1595). Mexico had Juana Inés de Abajé y Ramírez, or Sor Juana Inés de la Cruz (d. 1695). Reared in the viceregal court of Mexico, she dazzled equally by her beauty and her immense learning; then, disappointed in life, she retired to a convent. Contemporary with her was Carlos de Sigüenza y Góngora (d. 1700), also of Mexico, who was one of the most diligent and versatile writers of the age. His works on all subjects from astronomy to rural life would fill a catalogue.

The very interest that was felt in Spain for matters Spanish-American, and which tended as an incentive and a support to culture in the colonies, eventually acted as a detriment; for the literary decadence in Spain from the latter part of the sixteenth century to the beginning of the eighteenth, could not fail to be reflected in the New World. Still there was no such literary blank in the colonies as existed in Spain. The revival which came with the eighteenth century was quickly felt in America, but the initial movement was scientific rather than literary. A long list of eminent physicists and naturalists might be given, but the three most prominent must suffice. José Antonio Alzate y Ramírez (Mexico, d. 1790), besides being a writer of note, did a great deal indirectly for scientific progress by means of the *Gaceta de Literatura*, of which he was editor. In what is now Colombia, Francisco José de Caldas (1686–1770) and José Celestino Mutis (1732–1800) rendered lasting services to natural science. Their investigations were principally in the fields of botany, geology, and astronomy; but their descriptive writings are extremely interesting and entitle their names to honorable places in the literature of the New World. The most distinguished master of style of this period was Pedro de Peralta y Barnuevo (1670–1748), the Peruvian jurist, historian, and poet. His best-known work is the epic *Lima fundada*.

*Writers of the Nineteenth Century.—Poets.*—The nineteenth century has naturally produced more eminent writers than all previous ages. Foremost of these is Andrés Bello (b. Venezuela, 1781; d. Chile, 1865), revered in South America for his vast and varied learning and for his labors as jurist, educator, and poet, and conceded even by Spanish critics to be one of the greatest masters of Castilian that the nineteenth century has produced. His georgic *La agricultura en la zona tórrida* is especially admirable both for the beauty of its language and sentiment, and for its faithful descriptions of rural scenes and life in South America.

Spanish-American poetry and fiction, as might be expected, treat principally of three themes—the exploits of the early Spanish conquerors, the struggles of the colonies for independence, and the phases of life peculiar to a new country—which impart to the literature a unique and distinctive local coloring. Moreover, a number of poems and romances are founded on Indian legends, or tell of Indian life and customs, after the manner of Cooper and Longfellow. Two of the best of these are the *Painé* and *Relmú* of the Argentine publicist Estanislao S. Zeballos, who combines every form of literary activity. The earliest work of Juan León Mena (Ecuador, b. 1832) was an Indian epic which earned for him the title of Poet of the Indians. The *Huincahual* of the Chilean Alberto del Solar is one of the most powerful productions of this class. The dialect sketches of Estanislao del Campo, descriptive of the gauchos and life on the pampas, are especially quaint and entertaining. Nearly all the contemporaries of the struggles for independence were inspired by the patriotic deeds of America's heroes, but no one gave them more fitting expression than did the "American Pindar," José Joaquín Olmedo (Ecuador, d. 1857), a classicist of the purest type. His *Canto á Junín* is an epic ode without equal in the language. Some of the patriotic poems of Numa Pompilio Llona, of Peru, are especially fine; and the sonnet to Bolívar by the Peruvian Adolfo García is one of the most beautiful compositions of its kind. The best poetic productions based upon the days of the conquerors are *La grandeza de Méjico* of Bishop Valbuena (d. 1625); the beautiful epic *Gonzalo de Oyón*, by Julio Arboleda (Colombia, d. 1862); and Peralta's *Lima fundada* (already mentioned).

The Spanish language lends itself so readily to versification, especially when assonance is accepted instead of rhyme, that it may almost be assumed that every writer, not a scientific specialist, is also a poet. Juan León Mena published in 1868 a critical history of the poets of Ecuador, at a time when few were aware that that country had ever possessed any. Cuba has, of all Spanish-American countries, produced relatively the largest number of lyric poets. Gertrudis Gómez de Avellaneda, the greatest poetess of the language, was a native of Cuba; and persons of the lowest condition break forth in song. There the slave Juan Francisco Manzano (*fl.* 1830) won his freedom by his pen. Gabriel de la Concepción Valdés, another humble Negro, the author of *Siempreviva*, won laurels under the pseudonym of *Plácido*. Ramón Vélez Herrera's tragedy of *Napoleón en Berlín*, the *Pasionarias* of Rafael M. Mendive, and the *Margaritas* of the unfortunate Francisco J. Blanchié may also be mentioned. Some of the odes of the Cuban José María Heredia, in particular *Al Niágara*, *Á la noche*, *Al sol*, and *Versos escritos en una tempestad*, compare well with the best of Coleridge and Bryant. Turning to the continent one finds vigorous descriptive work in *La cena de Baltasar*, by Manuel Carpio (Mexico, d. 1860). In *La salida del sol*, by his compatriot Ignacio M. Altamirano, is description of a more placid kind. Altamirano is also the author of one of the best recent novels, *Clemencia*. The poems of Arnaldo Márquez and Clemente Althaus, of Peru, take very high rank for their beauty and tenderness of sentiment as well as purity of style. The *Noche de dolor en las montañas* and the *Canto de la vida* of the Peruvian Numa Pompilio Llona are compositions which will be admired for centuries. The *Flores del aire* of Dr. Adán Quiroga, of Argentina, is a collection of poems of great merit and originality. Compositions of remarkable beauty will be found in the *Brisas del mar* of the Peruvian Manuel Nicolás Corpancho, the *Lágrimas y recuerdos* of Doña Silveria Espinosa de Rendón, of Colombia, and the *Flores silvestres* of Francisco Javier de Acha, of Uruguay. José Batrés y Montúfar, of Guatemala, a lyric poet of merit, is one of the most noted satirists of America. Matías Córdoba and García Goyena, of Guatemala, have been justly compared as fabulists to Æsop and La Fontaine.

*Novelists and Dramatists.*—The novels most widely known are the *Amalia* of José Mármol (Argentina); the *María* of Jorge Isaacs (Colombia); *La linterna mágica* of José T. de Cuellar (Mexico); *Alberto el jugador*, by Doña Rosario Orrego de Uribe (Chile); the historical novel *El Padre Orani*, by Narciso Aréstegui (Peru); and the sparkling romance of the Colombian Julio Arboleda, entitled *Casimiro el montañés*. The Mexican historian Orozco y Berra wrote a beautiful novel, *Escenas de treinta años*, relating the experiences of an unfortunate, disappointed invalid. Among the most powerful recent novels are the *Libro extraño* of Dr. Francisco Sicardi, of Argentina, and *Contra la marea*, by the Chilean Alberto del Solar.

Among noted dramatists of the century have been, in Mexico, Rodríguez Galván, author of the first national drama, Fernando Calderón, and Manuel E. Gorostiza, author of *Independencia para todos* and *Contigo pan y cebollas*; in Peru, Manuel Nicolás Corpancho and Manuel A. Segura; in Uruguay, Francisco J. Acha.

Two fine specimens of prose word-painting deserve mention here, namely, the description of the Falls of Tequendama, by the Colombian botanist Fran. Antonio Zea (1770–1822), and Simón Bolívar's *Delirio sobre el Chimborazo*.

*Historians and Geographers.*—Spanish America has been especially prolific of historians and writers of descriptive geographical works. The names of some of the most famous of these, with their principal works, are as follows: Rafael María Baralt (d. 1860), *Resumen de la historia antigua y moderna de Venezuela*; Lucas Alamán (d. 1853), *Historia de Méjico*, 5 vols.; José Manuel Restrepo, *Historia de la revolución de Colombia* (1827); José Antonio de Plaza, *Historia de la Nueva Granada*; Joaquín Acosta (d. 1852), *Viajes á las regiones ecuatoriales*; Manuel Orozco y Berra (d. 1885), *Historia antigua y de la conquista de México* (4 vols.); Antonio García Cubas, *Diccionario geográfico, histórico y biográfico de los EE. UU. Mexicanos* (5 vols.); Manuel José Cortés, *Ensayo sobre la historia de Bolivia* (1861); Antonio de Alcedo (Ecuador, d. 1812), *Diccionario geográfico histórico de las Indias occidentales* (5 vols.); Miguel Lobo, *Historia general de las antiguas colonias hispano-americanas*; Pío Benigno Mesa, *Anales del Cuzco*; Miguel Luis and Gregorio Victor Amunátegui, *Los precursores de la independencia de Chile* (1872); Diego Barros Arana, *Historia de la independencia de Chile* (1870); Bartolomé Mitre, *Historia de Belgrano y de la independencia argentina* (3 vols.) and *Historia de San Martín y de la emancipación sud-americana* (4 vols.). Special mention should be given to Antonio Raimondi's great descriptive work, *El Perú*, which was cut short by the author's death in 1890, only four volumes and a part of the atlas having been published, and to the *Historia Argentina* of Mariano A. Pelliza, now in preparation, the fourth volume having been published in 1894.

AUTHORITIES.—*Lira Americana*, by R. Palma (Paris, 1865); *América Poética* and the *Diccionario Biográfico Americano*, by Domingo Cortés (Paris, 1875); Francisco Largomaggiore, *América Literaria* (Buenos Ayres, 1883); Francisco Pimentel, *Historia crítica de la literatura y de las ciencias en Méjico*; J. M. Torres Caicedo, *Ensayos biográficos y de crítica literaria sobre los principales publicistas y literatos de la América Latina*; Marcelino Menéndez y Pelayo, *Antología de poetas hispano-americanos* (3 vols. already published; Madrid, 1893–94); *Bocetos literarios de escritores argentinos*, by Martín García Merou (Buenos Ayres, 1892). García Merou's *Confidencias literarias* (1894), although treating principally of Argentine writers, devotes considerable space to the leading authors of other Spanish-American countries. MARATHON MONTROSE RAMSEY.

**Spanish Armada**: See ARMADA, THE SPANISH.

**Spanish Fly**: See CANTHARIS.

**Spanish Fork**: city (founded in 1851); Utah co., Utah; on the Spanish Fork river, and the Rio Grande W. and the Union Pac. railways; 12 miles S. by E. of Provo (for location, see map of Utah, ref. 4–M). It is a trading-point for a large agricultural region, and contains Lutheran, Mormon, and Presbyterian churches, ten public and denominational schools, an incorporated bank with capital of $25,000, and a weekly newspaper. The battle of Diamond Creek was fought here on June 20, 1866. Pop. (1880) 2,304; (1890) 2,214; (1900) 2,735. EDITOR OF "SUN."

**Spanish Grass**: another name for ESPARTO (*q. v.*).

**Spanish Language**: the national language of Spain and also of some other countries where it has been carried by colonists from Spain, as Mexico and the rest of Spanish America so called. In Spain itself certain regions are not properly included in the territory of the Spanish language; thus the dialect of Galicia belongs rather to Portuguese, and there is a small territory in the north where the language is Basque (see BASQUES), while Catalan is spoken in Catalonia, Valencia, and the Balearic islands. The dialect-forms of Spanish spoken in various parts of Spain have not yet been fully investigated, and the variations and peculiarities of American Spanish also need further study, though something has been done in this direction. (See the references below.) No even approximate statement of the number of those whose native tongue is Spanish in some form or other is possible; for Spain itself estimates vary from less than 11,-000,000 to 14,000,000.

The sounds of the standard or literary language may be approximately described as follows: There are five vowels only, *a, e, i, o, u*; *e* and *o* being intermediate between the close and open sounds of those letters in Italian, for instance. There are twenty-three (or twenty-four) consonants: *p, b* (written *b* and even *v*), *f, v* (a bilabial *v*, written *b* or *v*; it is only as a result of education that *b* and *v* are distinguished as written), *w* (a consonantal *u*, written *u*), *m, t, d* (the last two more dental than in English), a voiceless spirant like *th* in English *thin* (written *z*, or, before *e* or *i, c*; sometimes even *d* is the sign used), a voiced spirant like *th* in English *this* (written *d*), *l, n*, two forms of *r*, one strongly trilled (written *r, rr*), the other (written *r*) not so, *s* (more "cerebral" or "lingual" than in English), a palatalized *l*, nearly like *lli* in English *million* (written *ll*), a palatalized *n*, nearly like *ni* in English *union* (written *ñ*), *y* (two forms of *y* are recognized by Araujo, one a consonantal *i*, written *i*, the other more like German *j*, written *y*), *k, g* (these two varying somewhat in sound according to the following vowel; written *c, g*, or, before *e* or *i, qu* and *gu* respectively), an aspiration resembling *ch* in German *ach* (written *j*, or, before *e* or *i*, sometimes *g*), a voiced spirant (the voiced form of the German sound just mentioned, written *g*), and the sound of *ng* in English *sing, song* (written *n*). The voiced sound of *s*, namely *z*, occurs occasionally, but is not commonly recognized. An important consonant group is that written *ch*, with the sound of *ch* in English *church*. Noteworthy is the almost total lack of doubled consonants in Spanish words. The orthography, as regulated by the Academy, is a fairly good representation of the spoken language.

The pronunciation of modern Spanish is not the same as that of the older language, in which some sibilant sounds existed which have been lost. Thus *x* formerly had in popular words the sound it has in Portuguese, or that of *sh* in English *she* or French *ch*, but this has become the aspiration written *j* or *g*; compare *Quijote*, formerly *Quixote*, with the French form *Quichotte*, or English *sherry*, that is, wine of *Xerez* (now written *Jerez*). An initial *h*, now silent, often stands for older *f*.

The grammatical structure of the language is very similar to that of the other Romance languages. Certain neuter uses, especially of the neuter form (*lo*) of the article with adjectives, are noteworthy; so, too, are the frequent use of a preposition (*á*, "to") before the direct object of a verb, the distinction between the two words *ser* and *estar*, "to be," and that between *haber* and *tener*, "to have." The verb-tenses formed without the aid of separate auxiliary words are the same as in French, with the addition of a second conditional (also used as an imperfect subjunctive, and found in old Spanish in its original sense as a pluperfect indicative), and of a future subjunctive. Among the sources of the Spanish vocabulary, besides Latin, Greek, and old Germanic dialects (Gothic), should be noticed especially the Arabic.

As in the case of the other Romance languages, there is no sharp line of division to be drawn between vulgar Latin and early Spanish, the latter being the vulgar Latin of Spain when this assumes a form characteristic enough to have a new name. Traces of this vulgar speech are to be found in Latin documents as early as the eighth century, but distinctly Spanish texts are not preserved to us from an earlier time than the twelfth century. A Latin-Spanish dictionary (*Universal vocabulario en latin y en romance*) by Palencia belongs to the year 1490, and in 1492 came the lexicon (Latin-Spanish and Spanish-Latin) and the grammar of Lebrija (Lebrixa, Nebrixa). Among the most noteworthy early grammatical or lexicographical works are Aldrete, *Del origen de la lengua castellana* (1606), and the etymological dictionary of Sebastian de Covarrúbias Orozco (*Tesoro de la lengua castellana o española*, 1611). The Spanish Academy, established in 1713, published a *Diccionario de la lengua castellana*, 6 vols. (1726–39), condensed into one volume in 1780 (12th ed. of this condensed form 1884). The Academy published in 1741 an *Orthographia española*, and in 1771 the first edition of its grammar. An outline of the historical grammar of the language is given by Baist in Gröber's *Grundriss der romanischen Philologie*, i. (1888), where many other references are given.

E. S. SHELDON.

**Spanish Law**: See the Appendix.

**Spanish Literature**: the literary productions of Spain, or all compositions in the Spanish language. The latter application seems the more appropriate, but its two divisions are considered separately; the present article is confined to productions of the Iberian Peninsula in the language known as Spanish or *Castilian*,* while the literature of Spanish America is treated in a separate article.

Several circumstances tended to stamp the Spanish character with a distinct individuality. Long a favored Roman province, permeated by the language, the literature, and the religion cultivated in the later empire, Spain learned to look to Italy for support and guidance material, intellectual, and spiritual. Eight hundred years of war against an alien race with an Asiatic tongue and an infidel religion produced in the Spaniard a devotion to country and king and mother Church nowhere else to be found. The wars with the Moors, being largely a matter of border forays, encouraged personal prowess and a spirit of romantic adventure. It thus came about that the literature of Spain had three great sources—love, war, and religion.

*Ballads and Songs.*—As in other countries, the earliest essays at composition were songs, and ballads or tales in verse. Their most usual and seemingly oldest form is in lines of eight syllables, not divided into stanzas, but matching lines 2 and 4, 6 and 8, etc. These did not rhyme, but were assonant—an easy compromise between rhyme and blank verse thought to be native and peculiar to Spanish. The style of these old ballads is extremely diversified; their tone is by turns devout, plaintive, gay, lightly satirical, or intensely heroic, according to the author and his subject, but without the coarse ferocity of the songs of the north. They were a spontaneous growth, preserved only by memory, chanted to simple music in social gatherings or by strolling singers. The first attempt at a printed collection of such

* There remains nothing in this language of a date known to be earlier than A. D. 1150. The Moors had then been in possession of the largest and best part of Spain for nearly 440 years.

songs was the *Cancionero General*, published in 1511. A later and more valuable collection, the *Romancero General*, was completed in 1614. Over 1,000 pieces have thus been rescued from oblivion. Many of them cluster around centers, partly historical, but largely imaginary. Twenty are devoted to Charlemagne and his peers, 50 gather around the name of Bernardo del Carpio, and 200 are songs of the Cid.

*Epic Poetry.*—The earliest Spanish epic is the *Poema del Cid*, which relates the adventures, real and imaginary, of the early hero Rodrigo (or Ruy) Díaz de Vivar. Although his death occurred as early as 1099, no portion of the poem is older than the twelfth century. It is without beginning, date, or name of author, and contains 3,744 assonant lines of fourteen syllables, more or less, arranged in quatrains. In its execution it is one of the finest productions of the Middle Ages. See CID.

It is at least 350 years from the supposed date of the *Poema del Cid* to the next great outburst of the epic Muse, in the reign of Philip II. In 1560 Sempere published the *Carolea*, to glorify the victories of Charles V. Five years later appeared the *Carlo Famoso*, wherein Luis de Zapata celebrates the achievements of the same monarch in 5,000 prosy octave stanzas. Alonso de Ercilla y Zúñiga, courtier, soldier, and poet (d. 1596), wrote an epic, one-third longer than the *Iliad*, on the suppression of the Araucan Indians of Chile, in which he bore an active part. Portions of the poem are of great beauty, and its merit elicited praise even from Voltaire. Gabriel Laso de la Vega published *La Mexicana* (1594) in honor of the conquest of Mexico by Cortés; and five years later Antonio de Saavedra issued a romantic life of the conqueror in his *Pelegrino Indiano*. About the same time Juan de Castellanos composed a rhyming chronicle of the conquests in South America in some 90,000 lines, a narrative that strongly attracted the attention of Humboldt and Southey; and Juan de la Cueva (1603) produced the *Bética*, on the recapture of Seville from the Moors, in imitation of Tasso's *Jerusalem Delivered*.

*Romances.*—Besides epics resting on Spanish history, there were others having either no basis of fact or only a very remote one. All Europe swarmed for many centuries with marvelous recitals that gave rise to the modern words *romance* and *romantic*. The Scriptures, the lives of the saints, Greek and Roman antiquity, the legends of Charlemagne and of King Arthur, afforded inexhaustible material that was handled with the utmost disregard of proprieties of time and place; and peerless knights, giants, necromancers, dragons, and fair ladies imprisoned in enchanted castles were furnished regardless of cost. The earliest Spanish romance was the *Alexandro* of Juan Lorenzo Segura, priest of Astorga, in the second half of the thirteenth century. By far the most important and popular work of this class was the *Amadis de Gaula* (see AMADIS OF GAUL), conjectured to have been written in Portuguese about 1360. It was followed by an extensive aftergrowth of romances and *caballerías* (books of chivalry and knight-errantry) that became ever more fantastic and insipid, until put down by the strong but gentle hand of Cervantes.

In the pastoral romances that supplanted them fancy was not at such a high tension. The earliest of these in Spain was the *Diana Enamorada* of Montemayor (d. 1561)—an imitation of the *Arcadia* of Sannazaro, the Neapolitan. Later appeared the *Fílida* of Gálvez de Montalvo, the *Galatea* of Cervantes, and the *Arcadia* of Lope de Vega.

But romance was destined to seek a still lower level. Diego Hurtado de Mendoza (1503–75), a member of one of the noblest families of Spain, and almost equally distinguished as soldier, statesman, scholar, poet, historian, and writer of fiction, chose a strange subject for a romance. His hero, *Lazarillo de Tormes* (Little Lazarus, Luke xvi. 20), was an outcast from his birth, and the guide of a blind beggar. His genius and assiduity secure promotion, until he reaches the height of roguish ambition as a kind of king among thieves. This was followed in 1599 by Mateo Alemán's similar story of *Guzmán de Alfarache*; and in 1626 appeared the exploits of the *Gran Tacaño Pablo de Segovia*, into which the author, Quevedo, put some of his most brilliant work. This style of literature became and remained popular. It had a foundation in real life, however low, and was called "picaresque" from *pícaro*, rogue. The *pícaro* was an intelligent scoundrel, and had the genial humor of the South that made him almost lovable. Out of the three kinds of fiction named has been developed the modern novel.

*Rise of the Drama.*—While the remains of the Greek and Roman theater had become so debasing that the Church exerted all its power to suppress them, the advantage was seen as early as the fifth century of presenting something to catch the eyes and attention of its less educated members. Representations of the stable, the temptation, Gethsemane, the judgment-hall, and Calvary were given by servants of the churches and school-children. Scriptural readings and choral hymns were added. Buffoons were gradually introduced, and the devil and his imps were given humiliating positions. In time the devils and the fools became the favorite characters, and the Church had unwittingly created a comic theater of its own. A feeble attempt to keep these exhibitions within bounds was made in the code of Alfonso X. (1260). Still they kept growing in number and complexity, until in the seventeenth century, in the hands of Calderón, they became great allegorical sermons. In the meantime the worst of them had been turned into the streets, where they continued to be presented to the multitude. In 1492 appeared *La Celestina*, a book which in the U. S. would be excluded from the mails. Its merit lay in presenting live men and women—even though at their worst—instead of the allegorical figures to which the public had been accustomed. It was never acted nor intended to be acted, yet it had an immense popularity and a powerful effect in developing the drama. More than thirty editions were made of the work, at least seven translations, and a swarm of imitations.

The next important step was made by Juan de la Encina, musician, poet, and priest, who (1496–98) brought out eleven pieces, which show little of the playwright in their construction, but were really acted; hence their author is recognized as the founder of the Spanish stage. Bartolomé de Torres Naharro (1517) composed eight comedies in easy verse, and gave a more regular form to the drama, dividing it into five acts (*jornadas*), and prescribing sound regulations for maintaining consistency and truth to nature. But he gave little heed to his own rules, introducing allegorical and impossible persons and incidents. About 1553 Francisco de Avendaño wrote several plays of three acts. Lope de Rueda (d. 1567), a gold-beater of Seville, who turned actor and dramatist, wrote sixteen plays, and first introduced interludes (*entremeses* and *pasos*) between the acts. Juan de la Cueva, a poet of Seville (1579), adapted the great historical romances to the stage, and introduced the division into four *jornadas*.*

*Religious and Historical Works.*—As might be expected, there were from a very early period pieces in prose and verse intended for edification. The *Life of Saint Mary of Egypt*, the *Adoration of the Three Holy Kings*, and the *Danza General*, or Dance of Death, are so old as to be without known date or author. Then follow at irregular intervals *Miracles of the Virgin*, by Gonzalo de Berceo (1246); the *Caballería Celestial* of Hierónimo de San Pedro (1554); the *Monserrate* of Virués (1581); the *Redención Universal*—30,000 lines—by Fran. Hern. Blasco (1584); and Diego de Hojeda's *Christiada* (1611). The excessive fondness for allegory, prevailing when these poems were written, makes them seem irreverent to modern readers. In the *Caballería*, Christ and Lucifer, as Spanish knights, with their followers, maintain a war with varying success from Bethlehem to Calvary. The *Christiada* covers the period from the Last Supper to the crucifixion. The whole is connected and well sustained, but disfigured by the symbolism which was exuberant in the Middle Ages.

Alfonso X. of Castile (1252–84), surnamed *el Sabio*, the most enlightened prince of the age, has been called the father of Spanish prose, although his part must have been chiefly to foster and direct. To him are due a translation of the Scriptures, *Libros de Astronomía* (containing the famous Alfonsine Tables), a *Lapidario*, a *Crónica General* or Universal History, *La Crónica ó Historia de España* down to his own time, and a great compendium of law still known and respected as the *Siete Partidas*. Other chronicles were written by Fernán Pérez de Guzmán, Diego Enríquez and Alonso de Palencia, Ambrosio de Morales, and Gerónimo Zurita. Fernando del Pulgar and Andrés Bernaldés recorded the reign of Ferdinand and Isabella. But these old chronicles merely narrate a succession of occurrences without logical connection. The first real historical work is the *Historia de España* by the Jesuit Juan de Mariana (1601). In his time Spain produced a galaxy of eminent historians. Among the most prominent works may be mentioned the

* All this time the exhibitions were given in gardens, courtyards, or the public streets, without scenery or costumes. The first theater for the reception of the public was opened in 1743.

*Guerra de Granada* of Hurtado de Mendoza (1602); the *Historia de las Indias* of Herrera, as well as that of Bartolomé de las Casas; Moncada's *Expedición de los Catalanes* (1623); Melo's *Guerra de Cataluña* (1645); and the magnificent work of Antonio Solís, the *Conquista de México*.

*Lyric poetry*, especially that of the highest order, was much indebted to Italian models. Íñigo López de Mendoza, Marquis of Santillana (d. 1458), had an extensive acquaintance with the literature of Provence and Italy, and was largely influenced by their masterpieces. Most of his writings were infected with the learned conceits of the court and the Italian school; yet when he escaped to the free air of the mountains, nothing could exceed the sweet grace of his songs. His *Serranilla*, or the Milkmaid of Finojosa, is often given as a beautiful example, and may be found in Sismondi's *Literature of the South of Europe*, ii., 162. The marquis deserved the love and esteem of his country as much for his encouragement to men of letters as for his own productions. Juan de Mena (d. 1456), one of his *protégés*, was court historian to John II., and a sort of poet-laureate. Also a follower of Italian models, he did much to improve the Castilian language by enlarging its vocabulary and perfecting literary style.

Garcilaso de la Vega (d. 1536), descended from the Cid, and Juan Boscán (d. 1540) were the introducers of blank verse, and in their time the pillars of the Italian school. Cristóbal Castillejo (d. 1556), author of short poems, religious, playful, and satirical, opposed the growing fashion with patriotic zeal. Two priests, Luis Ponce (Fray Luis) de León and Fernando de Herrera (d. 1597), were lyric poets of the first rank. Fray Luis held ideas too advanced, and had to seek solace in song from the consequent persecution. Herrera's principal pieces were a triumphal ode on the battle of Lepanto and an elegy on the defeat and death of Sebastian of Portugal. Luis de Góngora (d. 1627) did so much to promote the growing pedantic style that it took the name of Gongorism. At first simple and natural, he became the most absurd writer of his day. His stanzas became so intricate and full of strange words and meanings, metaphors, and obscure allusions, that a lexicon of 1,500 pages was compiled as a key to them. His style was imitated in the translations, satires, and other short poems of Francisco Gómez de Quevedo (d. 1645).

*The classic era*—1550 to 1650 approximately—produced writers more numerous and more distinguished than any equal period before or immediately after. A fair idea of their numbers may be gained from the long lists given by Cervantes in his *Galatea* and *Viaje al Parnaso*, and by Lope de Vega in his *Laurel de Apolo*.

*Don Quixote de la Mancha* (1605), the classic work of Miguel de Cervantes Saavedra (see CERVANTES SAAVEDRA and NOVEL), marks the central point of the golden era, as it is often called. *El Quijote* (as the Spaniards call the work) was brought out in two parts, the second appearing in 1615. Cervantes also wrote twelve *Novelas Exemplares* (model novels), *Viaje al Parnaso*, and a number of plays, of which few were successful. Cervantes's work was better appreciated after his death, for it soon was considered the perfection of Spanish style. His writings had almost the effect of checking originality of expression, and for many centuries Spanish writers hesitated to say anything in a way not authorized by him. Gregorio Garcés, in his *Fundamento del vigor y elegancia de la lengua castellana* (1790) draws 65 per cent. of his examples from Cervantes.

Lope Félix de Vega Carpio, the contemporary of Cervantes and his junior by fifteen years, far surpassed him in popularity. He wrote 2,200 dramatic pieces, large and small, and an incredible number of other poems. His productions took every form of which poetry is capable—by turns solemn, severe, coarse, and frivolous. Luis Vélez de Guevara (d. 1644), a disciple of Lope, was a favorite both with the court and with the public. Of his 400 plays a few of great power remain. Juan Pérez de Montalbán (d. 1638), a follower and biographer of Lope, wrote about fifty dramatic pieces, of which his tragedy *Los Amantes de Teruel* has remained longest in favor.

The excellent comedies of Gabriel Téllez (d. 1648), better known as Tirso de Molina, and Ruiz de Alarcón (d. 1639) are still admired. Pedro Calderón de la Barca (d. 1681) was one of the most prolific and admired writers of Spain, and is, after Cervantes, the one best known abroad. Among the mass of matter that circulated under his name, he admitted 111 full dramas and seventy sacramental *autos* as genuine. His comedies being generally cast in high life, he made much turn upon "the point of honor." He was the first to give prominence to the *gracioso*—the gentleman's confidential valet, who needed to be a rogue and a wit. He and Lope controlled the theater ninety years.

*Decline of Literature.*—Toward the middle of the seventeenth century, literary activity began to decline, and the period from 1650 to 1750 is almost a blank. The best youth of Spain had been drawn away to colonize America or wasted in fruitless foreign wars. The country was exhausted by insurrections, civil strife, and the War of Succession, while the censorship of the press by Church and state was fatal to all freedom of thought. Philip V., the first Bourbon king of Spain, coming fresh from the brilliant court of his grandfather Louis XIV., set about reviving the literary spirit, and to that end established (1714) the Royal Spanish Academy, after the model of that of France. But the influence of Philip and his court was essentially French, and the old Spanish literature had been too seriously blighted to revive rapidly, so that nothing of importance was effected during the forty-six years of Philip's reign except the inception of the Academy's dictionary. Benito Feijóo, a quiet, laborious monk, had heard of Galileo, and Bacon, and Newton, and what the outside world was thinking of, and between 1726 and 1760 published thirteen volumes entitled *Teatro Crítico* and *Cartas Eruditas*, which did much to advance the intellectual life of his time. Ignacio de Luzán (d. 1754), a disciple of Boileau and an advocate of the French doctrines, wrote an *Arte Poética* based on them. Padre Isla (d. 1781) wrote a satirical romance, *Fray Gerundio*, which had an immense popularity, and translated the *Gil Blas* of Le Sage into Spanish. Nicolás Fernández Moratín (d. 1780) was the author of a small volume of minor poems and two long narrative poems, one, entitled *Diana*, on the chase, and the other on the burning of the ships by Cortés. The last is the finest epic which Spain produced during the century. His *Hormesinda* was the first original drama, according to the principles of Corneille and Racine, admitted to the Spanish stage. José Cadalso (d. 1782) was the author of *Moorish Letters* in imitation of Montesquieu and Marana; also of a satire on the still favorite system of acquiring all knowledge by a few easy lessons. Tomás de Iriarte (d. 1791) issued a little volume exposing the prevailing faults and follies in eighty fables, written with great ingenuity and elegance in half as many kinds of verse. Literature began gradually to revive, and in 1780 the young poet Meléndez Valdés obtained a prize from the Spanish Academy for a most original and delightful eclogue. All his lyric and pastoral poems show a true poetic spirit. Ramón de la Cruz produced (1765–95) a number of clever, short farce-comedies, and Ignacio González Castillo (d. 1800) left about thirty plays, all in a vein of light and graceful satire.

*Literature of the Nineteenth Century.*—From 1793 to 1874 foreign domination, invasion, civil war, and the rapid alternation of hostile parties maintained a state of continual unrest. Interests of Spain, of France, and of Great Britain, claims of royal houses, of the Church, and of the rights of man were the warring elements. Men of liberal sentiments, if timid, were silent; if outspoken, were imprisoned or exiled. The long roll of those persecuted contains the names of many of the brightest lights of the age: Meléndez Valdés, mentioned above, and his disciple Nicasio Alvárez de Cienfuegos; Gaspar Melchor de Jovellanos, philosopher and poet, whose writings stand pre-eminent for purity of style and beauty of diction; Manuel José Quintana and Leandro Fernández Moratín, whose lyrics and comedies are still among the most popular; José Antonio Conde, the distinguished Orientalist, author of *Historia de la dominación de los Árabes en España*; Ruiz de Saravia, Conde de Toreno, the celebrated historian; Fran. Martínez de la Rosa, poet and dramatist; Ángel de Saavedra, Duque de Rivas, lyric poet and romanticist; and José de Espronceda, who has been called the Byron of Spain. Yet the reviving literature steadily gathered strength, and every year saw new authors established in public favor.

Three well known *críticos de costumbres*, Mariano José de Larra (1809–37), Ramón Mesonero Romanos (1803–82), and Serafín Estébanez Calderón (1799–1867), who wrote under the respective pseudonyms of *Fígaro*, *El Curioso Parlante*, and *El Solitario*, were to Spanish manners and customs what *The Spectator* had been to those of England. The most prominent dramatists belonging to the first generation of the century were Juan Eugenio Hartzenbusch (1806–80) and Antonio Gil y Zárate (1796–1861), who were followed by Manuel Tamayo y Baus (b. 1829) and Adelardo López de

Ayala (1828–79). Manuel Bretón de los Herreros (1796–1873) was foremost among writers of comedies. His numerous plays were ably devised, well written, and full of life and gaiety, and many of them are as popular to-day as when first presented. The great literary critics were Alberto Lista (1775–1848), Agustín Durán (1793–1862), Hartzenbusch, and Eugenio de Ochoa (1815–72). Cecilia Böhl de Faber (1796–1877), better known as Fernán Caballero, a woman of extraordinary capacity for seeing, grouping, and delineating real life, was the founder of the modern realistic novel. Gertrudis Gómez de Avellaneda (1816–73), whose writings exhibit every phase of woman's love and sorrow and religious feeling, is reckoned the most brilliant poetess in Spanish literature. Nearly all Spanish authors wrote more or less poetry; but of those who were essentially poets may be named Ventura de la Vega (1807–65) and Gaspar Núñez de Arce (b. 1834), dramatists and lyric poets, José Selgas (1824–82), poet of rural life and scenes, José Zorrilla (b. 1817), who sang of Spain's departed grandeur, and Ramón de Campoamor (b. 1817), the poet philosopher.

With the quiet and prosperity which the termination of the Carlist wars brought to Spain in 1876 came a period of enlightenment as great as that enjoyed by any other country of Europe. The spirit of progress is nowhere more evident than in the domain of letters. In every class of composition there are works of genuine talent, but the subjects in which contemporary Spanish literature chiefly excels are history, criticism, and fiction. Two political leaders, Emilio Castelar (b. 1832), the most eloquent speaker of the present day, and Antonio Cánovas del Castillo (b. 1830) are both eminent historians. Cánovas is moreover an able critic, as are also Juan Valera, the diplomat and novelist, and Emilia Pardo Bazán, the de Staël of modern Spain; but the most brilliant genius in the domain of literary criticism and history is Marcelino Menéndez y Pelayo (b. 1856), whose elegance of style and thoroughness of research have seldom been equaled. In Spain, as in the U. S., the novel is the principal feature of literature as distinguished from science. There too it has attained a high development, and is the chief agency in advancing the public sentiment. Spanish novels are second only to English; among the best-known are those of Pedro Antonio de Alarcón (1833–91), José María de Pereda (b. 1834), Juan Valera (b. 1827), Benito Pérez Galdós (b. 1845), Armando Palacio Valdés (b. 1831), and Doña Emilia Pardo Bazán (b. 1851), and the short stories of Antonio de Trueba (1819–89).

AUTHORITIES.—The American reader who is not a specialist will require nothing more before the nineteenth century than Ticknor's *History of Spanish Literature* (New York, 1849, 3 vols.; 4th ed. Boston, 1872, 3 vols.). Some additions have been made in the Spanish translation (Madrid, 1851–56) and the German (Leipzig, 1852–67). For the nineteenth century, Francisco Blanco García's *Literatura Española en el Siglo XIX.* (2 vols., Madrid, 1891); *Literatas españolas del Siglo XIX.* of Juan P. Criado y Domínguez; and the *Historia de la Literatura Española* of Manuel de la Revilla and Pedro de Alcántara may be consulted. MARATHON MONTROSE RAMSEY.

**Spanish Mackerel**: either of two scombroid fishes. (1) Along the eastern coast of North America, *Scomberomorus maculatus*, a very slender, compressed fish, bluish-green above, satin-like white below, with yellowish spots on the back and sides, and with the first dorsal fin blackish before and along its margin. It attains a length of 2½ feet. It is a native of the tropical seas, but ranges from Southern Brazil to Cape Cod, and is one of the most esteemed of salt-water fishes. (2) In Europe, *Scomber colias*, distinguished externally from the common mackerel (*Scomber scombrus*) by the larger eye and the diminished number of wavy streaks. It is known in the U. S. as the chub-mackerel and the thimble-eye.

**Spanish Main**: an old term still occasionally used for those portions of South and Central America which border on the Caribbean Sea, i. e. the modern Venezuela, Colombia, and the Central American states. The original Spanish term, *Tierra Firme*, included only the coasts from the mouth of the Orinoco to Costa Rica. Some writers erroneously use the name for the Caribbean Sea. H. H. S.

**Spanish War of Succession**: See SUCCESSION WARS.

**Span-worm**, or **Measuring-worm**: the larva of any geometrid moth; so called from the elevation of its body in locomotion, as if measuring. The CANKER-WORM (*q. v.*) is an example.

**Spar**: in mineralogy, a term used vaguely for several crystalline minerals of nonmetallic luster and smooth cleavage. See BARYTA, CALCAREOUS SPAR, FELDSPAR, and FLUORSPAR.

**Spar'idæ** [Mod. Lat., named from *Spa'rus*, the typical genus, from Gr. σπάρος, a kind of fish, the gilt-head]: a family of acanthopterygian fishes, comprising the porgy, sheepshead, and related forms. The body is compressed and oblong; the scales have obsoletely pectinated margins and striæ diagonally crossing the surfaces and meeting the sides at acute angles; lateral line continuous to the caudal fin; head compressed; mouth terminal, with an oblique lateral cleft; upper jaw moderately protractile, and with the supramaxillaries partly sliding under the preorbital bones; teeth in the jaws either developed on the sides as molars, or in front as more or less defined incisors, or of both kinds; dorsal fin elongated, with its spinous portion rather longer than the soft, and folding in a dorsal groove; anal with three spines; caudal fin with pointed lobes; pectoral fins pointed and with the rays branched; ventrals thoracic, each with a spine and five branched rays, and with pointed axillary scales. The family is well represented in all warm and temperate seas. There is a considerable range of variation in dentition and squamation, as well as in osteological characters. No typical sparoids have yet been detected along the Pacific coast of the U. S. See SHEEPSHEAD.

**Spark, Electric**: See ELECTRIC DISCHARGE.

**Sparks**, JARED, LL. D.: historian; b. at Willington, Conn., May 10, 1789; graduated at Harvard 1815; was mathematical tutor there 1817–19, studying theology meanwhile; became pastor of a Unitarian church at Baltimore, Md., May, 1819; was chosen chaplain to the U. S. House of Representatives 1821; conducted at Baltimore a periodical, *The Unitarian Miscellany*, 1821–23; retired from the ministry on account of ill health, and removed to Boston 1823; purchased *The North American Review*, of which he was sole editor until 1830; visited Europe 1828; spent considerable time in examining the English and French archives for materials of American history: founded in 1830 *The American Almanac*; edited for the U. S. Government *The Diplomatic Correspondence of the American Revolution* (12 vols., 1829–30); published *The Writings of George Washington, with a Life of the Author* (12 vols., 1834–37); *The Life of Gouverneur Morris* (3 vols., 1832); conducted two series of a valuable *Library of American Biography* (1st series, 10 vols., 1834–38; 2d series, 15 vols., 1844–48), for which he wrote several of the lives; edited *The Works of Benjamin Franklin, with Notes and a Life of the Author* (10 vols., 1836–40), and *The Correspondence of the American Revolution* (4 vols., 1854); published two or three controversial pamphlets in defense of his editorial conduct in correcting Washington's orthography and grammar, and upon other similar topics, besides a number of works on religious subjects. Dr. Sparks was McLean Professor of History at Harvard 1839–49, and president of that institution 1849–53. D. at Cambridge, Mass., Mar. 14, 1866. See the *Memoir* by Rev. George E. Ellis, D. D. (Cambridge, 1869).

**Sparrow** [M. Eng. *sparwe* < O. Eng. *spearwa*: O. H. Germ. *sparo* (> Mod. Germ. *sper*ling): Goth. *sparwa*]: any one of various birds of the family *Fringillidæ*. The term is generally applied to those *Fringillidæ* with a streaked plumage in which some shade of brown or chestnut predominates. The most familiar species is *Passer domesticus*, called in the U. S. English sparrow, from the country whence it was introduced, and more correctly known in Great Britain as the house-sparrow. It is too well known to need a description. Its original habitat was the greater part of Europe and temperate Asia and Northern Africa. The English sparrow was introduced into the U. S. in the fall of 1850, when Nicolas Pike and other directors of the Brooklyn Institute imported eight pairs. These did not thrive, but others were brought over in 1852 and at numerous subsequent dates, and by the end of 1886 the sparrow had spread over the greater portion of the U. S. E. of the Mississippi and N. of Florida, and extended in the northwestern portion of its range into Iowa and Minnesota and beyond the Missouri. It was also abundant about San Francisco, Salt Lake City, and New Orleans, while there were many scattered colonies beyond the frontiers of its domain. Since then it has steadily spread, but exactly how much territory it covers is not definitely known. The sparrow has also been introduced by thoughtless individuals into Australia, New Zealand, and the Hawaiian islands, where, as in the U. S., it has multiplied and become a pest. Evidence is overwhelmingly against the sparrow. It is convicted of being destructive to various crops, of crowding out native birds by eating their food and occupying their nesting-places, and also of actually driving them away. It is particularly harmful to grain, grapes, peaches, and pears, while the number of injurious insects destroyed by it is trivial. Its phenomenal increase is largely due to its fecundity, as a pair of sparrows raise on an average three or four broods a season, and may, under favorable circumstances, raise as many as six, each brood numbering four or five.

In New Zealand and the Hawaiian islands the injurious effect of the sparrows on the native bird-faunas is particularly obvious and regrettable.

The American sparrows have a more slender bill than the introduced species. See *The English Sparrow in North America*, a Bulletin of the Department of Agriculture (Washington, 1889). F. A. Lucas.

**Sparrow**, Anthony: bishop; b. at Depden, Suffolk, England, in the beginning of the seventeenth century; was a fellow of Queen's College, Cambridge, but was ejected in 1643 for refusing to sign the Covenant. Soon after he became rector of Hawkedon, but in five weeks was ejected for reading the Book of Common Prayer. He was restored in 1660, and was made Bishop of Exeter in 1667 and of Norwich in 1676. D. at Norwich in 1685. He published *A Rationale or Practical Exposition of the Book of Common Prayer of the Church of England* (London, 1643). It has been often reprinted, the last time in 1852. The seventh edition (1722) first contained the celebrated *Lives of the Compilers of the Liturgy, and an Historical Account of its several Reviews*, by Samuel Downes, a work which forms the true source of much of the English liturgical learning that has since been put forth. He also published *A Collection of Articles, Injunctions, Canons, Orders, Ordinances, and Constitutions Ecclesiastical, with other Public Records of the Church of England, chiefly in the Times of Edward VI., Elizabeth, James I., and Charles I.* (London, 1661; often reprinted; best edition that of 1684); also *Confession of Sins and the Power of Absolution, Authority of the Church*, and other works. Revised by W. S. Perry.

**Sparrow-hawk**: any one of several small species of the genus *Falco*. They have two primaries emarginated along their inner webs, the second to third longest, and the first shorter than the fourth; the tarsus longer than the middle claw; and the basal joints of the toes provided with transverse scutellæ; the color of the sexes is very different at all ages, but the old and young of each sex are alike. The common American species is *Falco* (*Tinnunculus*) *sparverius*. Its diagnostic characteristics are the bluish crown (with or without a patch of rufous), whitish front and auriculars, conspicuous "moustache" across the cheeks, the rufous back, the white or whitish abdomen, and the barring of the inner webs of the primaries with white and dusky; in the male the upper part of the head, as well as wings, is ashy blue or slate-colored, the scapulars, back, rump, and tail rufous; the primaries, secondaries at their basal halves, and broad subterminal band of tail, black; in the female the head is bluish above, but the bluish on other parts is replaced by rufous, which is barred by blackish. Its length is about a foot. The species is an inhabitant of North as well as South America, but is divided by Ridgway into five sub-species or races, limited to various countries; the only U. S. form is the typical *sparverius*, and this is found from the sub-polar regions to the Isthmus of Panama. It preys upon small birds as well as mice and reptiles. It may be frequently seen perched on the top of a tree nearly erect and motionless, surveying the country around. It breeds in the northern parts of the U. S., as well as farther N., and selects for its nest a hollow tree, in which it lays five to seven dark cream-colored, nearly spherical eggs. It is one of the most useful of the small hawks, feeding upon insects, and particularly grasshoppers, whenever they can be obtained.

Revised by F. A. Lucas.

**Sparrow's Point**: town; Baltimore co., Md.; on the Patapsco river, and the Northern Central Railway; 10 miles S. E. of Baltimore (for location, see map of Maryland, ref. 2-F). It contains four churches, large Y. M. C. A. building, the largest public school in the county outside of Baltimore, and a weekly newspaper. The Maryland Steel Company began to build a town here in 1887, as a part of the plant of the Pennsylvania Steel Company, of Steelton, Pa.; the enterprise was reorganized in 1892 under the name of the Maryland Steel Company; and in 1893 it had become one of the most prosperous steel-manufacturing places in the U. S. The town has iron-furnaces, rail-mill, foundry, machine-shops, and an extensive plant for ship-building. Pop. (1890) 2,507; not returned separately in 1900.

James Fraser, Ph. D., editor of "Times."

**Sparta** [= Lat. = Gr. Σπάρτη, Sparta, Lacedæmon]: in antiquity, the capital of Laconia and chief city of the Peloponnesus. The Greek name of the city signifies sown land (σπαρτή, sc. γῆ). It is true that the city did not stand upon rocky heights, as was the case with nearly all Hellenic towns, but upon a group of knolls, which are seen on the right bank of the Eurotas, an hour's journey E. of Mistra, at the spot where now stands a new Sparta (see map of Greece, ref. 17-K). The first glance at the surroundings makes it clear that the springing up of a city in this place was only accidental; it was the camp of the Dorians, who, coming from the N., gained a firm foothold first on this spot, while the Achaians still held possession of the strongholds and cities of the land.

The appearance of Sparta was different from all other Grecian cities. The situation had nothing imposing in it. The small hilly undulations by the Eurotas vanish in face of the enormous rocky walls of Taygetus, which rise steeply from the plain to a height of 7,500 feet. No monuments exist which characterize the mistress of Hellas. The whole locality gives only the impression of rural grace, and the prophetic words of Thucydides (i., 10) have been literally fulfilled, that in contrast to Athens, Sparta's ruins would give no sign of the former greatness of the city. Yet the historic character of Sparta is to be plainly seen in all the surroundings. The old city never confined itself within narrow walls; the citizens dwelt beside each other, as it were, in the open country. The canals, whose ditches are seen extending diagonally over the site of the old city, watered the gardens and plantations; there was no distinction between town and country. The laws of Lycurgus forbade the luxury of municipal architecture; even the dwellings of the kings preserved a patriarchal simplicity. The city, as it became powerful, was filled with votive offerings to the gods, especially with tripods, but the sacred center of the land was not Sparta, but the Amyklaion. In Sparta also, after the Persian wars, a more imposing style of architecture was introduced, as is shown by the Persian porch; but the more Athens took the lead in the arts, so much the more remained Sparta behind, and even Lysander's victories brought the city no new adornments. It only lost more and more its old Doric character; the dwindling numbers of the citizens drew closer together; they themselves were no longer a sufficient protection; ditches and intrenchments were constructed against Demetrius (296), and against Pyrrhus (279), and at last the city was inclosed with a wall, the extent of which Polybius gives as 48 stadia (ix., 21). As Polybius says that Sparta within this circuit was much larger than Megalopolis within its wall of 50 stadia, the conclusion is that the wall had a circular form and the city a dense population. The wall was a symptom of degeneration and loss of freedom (Livy, xxxix., 37); under the tyrant Nabis it did not inclose the town completely, but only protected the open sides. It was restored after the capture of the city under Philopœmen, and remained under the Romans, under whose sway Sparta was one of the most populous and prosperous cities of the peninsula.

As Sparta was never destroyed in antiquity, and was uninhabited in the Middle Ages, it is reasonable to suppose that many antiquities are buried in the deep soil. Very remarkable reliefs of the old style have come to light; especially worthy of mention is the four-sided pedestal with the reliefs, published in the *Annali del Instituto* (1861, tav. d'agg. C), and the relief with Dionysus and Ariadne (1870, p. 272). Since the foundation of the kingdom of Greece the capital city of the Eurotas valley is no longer Mistra, situated near Taygetus, but has been removed again to the Eurotas, and new Sparta spreads itself out on the hills of the old city. See Crosby's article on *The Topography of Sparta* in *The American Journal of Archæology* (1893, p. 335 f.). See also Greece, History of Ancient. Ernst Curtius.

Revised by J. R. S. Sterrett.

**Sparta**: city; Randolph co., Ill.; on the Centralia and Chester and the Mobile and Ohio railways; 20 miles N. by E. of Chester, the county-seat, and 50 miles S. E. of St. Louis (for location, see map of Illinois, ref. 10–D). It is the center of a natural-gas region, and contains a woolen-mill, cannery, plow-factory, creameries, an incorporated bank with capital of $25,000, a private bank, and a weekly newspaper. Pop. (1880) 1,754; (1890) 1,979; (1900) 2,941.

**Sparta**: city; capital of Monroe co., Wis.; on the La Crosse river, and the Chi. and N. W. and the Chi., Mil. and St. P. railways; 25 miles N. by E. of La Crosse (for location, see map of Wisconsin, ref. 6–C). It is in an agricultural and fruit-growing region; is a popular summer resort; and contains medicinal artesian wells, free public library, high school, paper-mills, planing-mills, and flour-mills, carriage-factories, machine-shops, 2 State banks with combined capital of $40,000, and 3 weekly newspapers. Pop. (1880), 2,387; (1890) 2,795; (1900) 3,555. EDITOR OF "HERALD."

**Spar′tacus**: leader of the slaves in the Servile war (73–71 B. C.); b. in Thrace; was at first a shepherd and afterward chief of a gang of robbers, but was captured by the Romans, sold as a slave, and trained as a gladiator in a school at Capua. By showing how much better it would be to die in an attempt at freedom than to be butchered in the arena for a Roman holiday, he succeeded in forming a conspiracy among the pupils of the schools. Seventy of the conspirators, headed by Spartacus, fought their way out of Capua and took refuge in the crater of Vesuvius. Here they were soon joined by numbers of runaway slaves; an organization was accomplished: Spartacus was chosen leader, and formidable predatory expeditions were undertaken against the neighboring towns. C. Claudius Pulcher was then sent against them with an army of 3,000 men and blockaded them in the crater, but his force was suddenly attacked in the rear and almost annihilated. After this success the insignificant mutiny of a few slaves rapidly grew into a formidable war. The peculiar state of affairs in Southern Italy contributed much to this result. The soil of that region was almost exclusively owned or leased in large allotments by the Roman nobles, whose estates were cultivated by a numerous slave population, which lived in the most abject condition. Spartacus proclaimed the abolition of slavery, and before long he was at the head of an army of 70,000 men. His plan was to force the passes of the Alps, lead his army out of Italy, and then send every man to his home. With a victorious army of about 100,000 men he passed by Rome, and penetrated into the regions of the Po, where he was met by two consular armies. He defeated and routed them both, and at the funeral games which he celebrated in honor of Crixus he compelled the Roman knights among his prisoners to fight as gladiators in the arena. Unable to induce his soldiers to follow him out of Italy, he marched S. and went into winter quarters in Thurii. The defection of some of his troops and dissensions in his camp led to his defeat by Crassus. He then tried to cross over to Sicily, but was betrayed by the Cilician pirates who had agreed to transport his forces. A part of his army fell into the hands of Crassus, but Spartacus and the remainder of his troops effected their escape. Lucullus was now recalled from the East, Pompey from the West. After new victories, Spartacus went to Brundisium with the purpose of seizing the shipping in the harbor and crossing over to Thrace. Falling in with the army of Crassus, near the source of the river Silarus, he was defeated and slain. The fugitives were hunted down and slaughtered, and the revolt was completely suppressed. Revised by F. M. COLBY.

**Spartanburg**: city; capital of Spartanburg co., S. C.; on the Port Royal and W. Car. and the Southern railways; 73 miles W. S. W. of Charlotte, N. C., 93 miles N. W. of Columbia, the State capital (for location, see map of South Carolina, ref. 4–C). It is in a gold and iron mining and limestone-quarrying region; is the seat of Wofford College (Methodist Episcopal, established in 1853); and contains a high school, a national bank, 2 State banks, and a daily, a semi-weekly, and 3 weekly newspapers. Pop. (1880) 3,253; (1890) 5,544; (1900) 11,395.

**Spartel, Cape**: See the Appendix.

**Spartianus Ælius**: See AUGUSTAN HISTORY.

**Spasm** [from Gr. σπασμός, σπάσμα, spasm, derivs. of σπᾶν, draw, draw apart, pull, rend]: sudden and involuntary muscular contraction. The relaxation and tension of muscular tissue are dependent on nerve-force. Spasm of muscle may result from disturbance of the nerve-centers, from peripheral irritation of the affected part, or from irritation of other organs or surfaces reflected from the nerve-centers. When spasmodic rigidity is persistent for any length of time it is termed *tonic* spasm. Such is the period of rigidity at the beginning of the epileptic attack and the prolonged rigidity of tetanus and cerebro-spinal meningitis. When spasm is brief and recurs rapidly, it is termed *clonic* spasm. Such are the intermitting and repeated muscular contractions following the inception of the true epileptic attack, and constituting the more ordinary epileptiform attacks or "fits" of children. The graver spasmodic diseases are true epilepsy; epileptiform attacks from many causes, as indigestion and worms in children, renal disease in adults, and in the course of severe acute diseases, narcotic poisoning, etc.; chorea or St. Vitus's dance; tetanus; hydrophobia. Many lesser and local states of spasm frequently occur. Sneezing and coughing are spasmodic contractions of the respiratory tracts excited by irritation of the nasal or bronchial mucous membrane. Asthma is spasmodic constriction of many bronchial tubes, producing dyspnœa. Whooping-cough unites extreme hyperæsthesia and spasm of the bronchi with spasmodic constriction of the larynx. Intestinal colic and cholera morbus are conditions of painful spasmodic constriction of the intestines, due to cold or bad diet. In invalids and persons of sensitive nervous system painful spasms of various internal and external parts may develop suddenly from unknown or trivial exciting causes. The immediate relief of spasm is secured by so-called anti-spasmodics or nervines, as valerian, musk, camphor; by anæsthetics, narcotics, and sedatives, as potassium bromide, hyoscyamus, belladonna, opium. The permanent cure, when attainable, follows the correction of known causes. Revised by W. PEPPER.

**Spatan′gidæ**: See ECHINOIDEA.

**Spathe** [from Lat. *spatha* = Gr. σπάθη, any broad flat blade, spatula, stem of a palm-leaf, broadsword, whence (viâ Lat. and O. Eng.) Eng. *spade*]: the single sheathing bract which incloses a cluster of one or more flowers in many species of monocotyledonous plants. Sometimes the inclosed flowers are arranged on a spike of the form called *spadix* (σπάδιξ), and in numerous palms the spadix is branching, and besides the principal spathe there are numerous secondary ones on the spadix. Revised by C. E. BESSEY.

**Spaulding**, LEVI: missionary; b. at Jaffrey, N. H., Aug. 22, 1791; graduated at Dartmouth College 1815 and at Andover 1818; went to Jaffna, Ceylon, as a missionary of the American Board; remained on that island fifty-three years, during which time he made but one visit to the U. S. (1844); superintended a boarding-school for girls at Uduville; prepared tracts, hymns, and school-books in the Tamil language, into which he translated several religious works; prepared (with Rev. J. Knight) a *Tamil Dictionary* (Madras, 1844), and issued a revised translation of the Bible. D. in Ceylon, June 18, 1873.

**Spaulding**, SOLOMON: clergyman; b. at Ashford, Conn., in 1761; was a soldier in the war of the Revolution; graduated at Dartmouth College 1785; became a Congregational minister in Connecticut 1787; settled in Ohio some years later, and while residing at Salem in that State about 1812 wrote a novel entitled *The Manuscript Found*, suggested by the opening of an Indian mound. It is claimed that this fiction became known to Sidney Rigdon at Pittsburg in 1814, and that it was the origin of the *Book of Mormon*. D. at Amity, Pa., Oct. 20, 1816.

**Spa′vin** [M. Eng. *spaveyne*, from O. Fr. *esparvain* > Fr. *éparvin*, spavin]: certain swellings upon the hock-joint of the horse. In bog spavin the swellings and lameness are due to undue secretion of synovia (the lubricating fluid of joints). The most successful treatment is entire rest, with frequent bathing of the parts with cold water, and bandaging, accompanied by firm pressure upon the swelling, secured by means of compresses or spring trusses. Bone spavin, or spavin proper, is bony enlargement (exostosis) of the hock-joint, usually beginning at the lower part of the joint on the inside, and involving the heads of the splint and cannon bones, and of the small bones with which they articulate. It causes lameness, observable even in the early stages, and an imperfect action of the joint, gradually growing worse until finally the various bones become to a great extent united and solidified by the mass of fibrous bone which grows over them. The disease is caused by strains, to which the hock is particularly subject in work-horses drawing heavy loads, especially when starting them, and in race-horses and saddle-horses accustomed to leaping. When taken early, rest and counter-irritants will effect a cure; but when a considerable growth of bone has taken place, no absorption sufficient to cause a permanent cure can be expected, although setons, iodine blisters, or firing may cause an absorption of the bony excrescence, or even of the contiguous bone to some extent. The wisest course in an attempt to cure a spavined horse, when the disease is taken early, is to turn the animal out to grass, or otherwise regulate his diet so that his food shall be nutritious, yet cooling and laxative. At the same time the spavin may be bathed for a week daily with salt and vinegar, and then a blistering salve of iodide of mercury rubbed in. The salve may be applied once in three or four days, and both the strength and frequency of the application should be graduated according to the amount of excitement produced in the skin, avoiding any considerable blistering, but maintaining irritation upon the surface. After several applications, the spavin may be let alone until all heat and evidence of excitement in the skin have gone down, and the treatment then renewed. When not taken at its earliest stage, entire rest in the stall will promote a solid union (ankylosis) of the bones affected, and cooling lotions, salt and vinegar and iodide of potassium in solution in water, with attention to diet, will reduce the swelling of the contiguous parts, which is often considerable. Thus after a while the horse will be able to labor with little or no pain, but with more or less stiffness of the joint. Though caused by strains and overwork, spavin is peculiarly hereditary, and a spavined horse or mare should never be used as a breeder.

**Speaker of the House**: the presiding officer of the British Houses of Parliament, of the House of Representatives of the Congress of the U. S., of the lower houses of State Legislatures in the U. S., and in legislatures of the British colonies. In England the title was first employed in the reign of Edward III., but the office is much more ancient. The Lord Chancellor is usually the Speaker of the House of Lords. As the representative of the House, the Speaker communicates its resolutions to others and conveys its thanks or censures. In the U. S. House of Representatives the Speaker presides over the deliberations of that body, appoints its committees, supervises its journal, certifies to the amount of compensation due its members, signs its bills, resolutions, writs, warrants, subpœnas, etc., and has the right as a member to participate in debate after calling another member to the chair. He is chosen by the House from its own number, and can be removed from office by the House.

**Speaking-trumpet**: an instrument, usually in the form of a hollow truncated cone, the mouth-piece at the smaller end, and the larger end with a reflected lip. It is used for intensifying the sound of human speech and causing its further propagation in one direction. Its chief uses are on shipboard and in giving commands to firemen during conflagrations. The trumpet is of wood or metal. Its invention is ascribed to Kircher and to Sir Samuel Morland. When the instrument is used the air immediately in front is acted upon over so wide a surface that it becomes subject to greater compression and rarefaction, in consequence of the diminished lateral overflow or inflow. Thus the air retains its vibrations better and propagates the sound more effectively.

**Spear**: a weapon of offense, consisting of a wooden handle of greater or less length and a pointed head usually of metal. The general name spear includes all weapons of this class, such as darts, javelins, pikes, lances, etc., whether used as missile or thrusting weapons. The Macedonian and Swiss pikes were from 15 to 20 feet long, the mediæval lance of equal length, and the more modern pike from 10 to 14 feet. The dart and javelin were usually from 4 to 6 feet long and were essentially the same as the Zulu assagai. J. M.

**Spear, Cape**: See Cape Spear.

**Spearmint**: a plant, *Mentha viridis*, of the family *Labiatæ*, found abundantly in Europe and the U. S., generally upon moist soil. It is frequently cultivated for the sake of its leaves, which are used as the chief ingredient in a popular sauce for roast meats and for imparting a flavor to alcoholic beverages. An oil is also distilled from spearmint, and from this an essence is prepared, both possessing valuable medicinal uses. It is a handsome plant, with deep-green, lanceolate, acutely serrate, and nearly sessile leaves, and pale-purple flowers springing from an erect stem, usually 2 feet in height. Revised by Charles E. Bessey.

**Special Issue** (in law): See Issue.

**Spe′cies**: [≐ Lat., liter., sight, look, hence appearance, form, kind; deriv. of *spe′cere*, look, look at]: in biology, the smallest group recognized in ordinary classification. In general words the members of a species differ only in minor features, they are capable of interbreeding indefinitely among themselves, and the characters which separate them from other allied forms are capable of definition and are practically permanent. It must be noted, however, that the idea of species belongs rather to metaphysics than to nature, for in the living world sharp distinctions do not really exist, and if we take into account extinct forms all so-called species really intergrade. In classification the species is the lowest subdivision to which a name is usually applied, and in the binomial nomenclature the specific name is always written after that of the genus. Thus in the name of the lion, *Felis leo*, *Felis* is the generic name and indicates a cat-like animal, while the specific name *leo* indicates the particular kind of cat. J. S. Kingsley.

**Specific Gravity**: See Gravity, Specific.

**Specific Heat**: the thermal capacity of a substance expressed in terms of the thermal capacity of water.

Specific heats are usually measured by heating the body in question to a known high temperature and determining the amount of heat in calories which it gives up in falling to a second, lower, known temperature. This quantity, divided by the number of degrees between the lower and the higher temperature and also by the mass of body in grammes, gives the mean specific heat for the interval of temperatures used. The amount of heat above mentioned is either measured (1) by noting the rise of temperature which it will cause in a given mass of water (method of mixtures), or it is measured (2) by determining the amount of ice which it will melt (method of the ice-calorimeter).

By far the most delicate of all calorimetric operations is the modification of the latter method invented by Bunsen, in which the amount of ice liquefied is indicated by the change of volume which it undergoes (method of the Bunsen ice-calorimeter).

The following tables give the specific heats of some well-known elements and compounds:

TABLE I.—METALS.

| | | | |
|---|---|---|---|
| Aluminium | 0·2140 | Magnesium | 0·2450 |
| Antimony | 0·0510 | Mercury (solid) | 0·0319 |
| Bismuth | 0·0305 | Mercury (liquid) | 0·3332 |
| Copper | 0·0933 | Platinum | 0·0323 |
| Iron | 0·1116 | Silver | 0·0559 |
| Lead | 0·0314 | Tin | 0·0550 |
| Lithium | 0·9408 | Zinc | 0·0935 |

TABLE II.—MISCELLANEOUS SOLIDS AND LIQUIDS.

| | | | |
|---|---|---|---|
| Ice | 0·51 | Sulphur | 0·176 |
| Glass | 0·1 | Iodine | 0·054 |
| Wood | 0·5–0·6 | | |
| Alcohol | 0·566 | Glycerin | 0·555 |
| Benzene | 0·392 | Chloroform | 0·233 |
| Carbon disulphide | 0·218 | Turpentine | 0·423 |
| | | Ether | 0·520 |

TABLE III.—GASES AND VAPORS.

| SUBSTANCE. | Specific heat (by constant pressure). | Relative specific heats. |
|---|---|---|
| Air | 0·2375 | 0·2375 |
| Oxygen | 0·2175 | 0·2405 |
| Nitrogen | 0·2438 | 0·2370 |
| Hydrogen | 0·4090 | 0·2359 |
| Carbon monoxide | 0·2479 | 0·2399 |
| Chlorine | 0·1214 | 0·2962 |
| Carbon dioxide | 0·2164 | 0·3308 |

The specific heats of water and of steam are given in the article Steam (*q. v.*).

Specific heat depends upon the temperature. Thus for platinum, which may be taken as typical, the values (according to Kayser, *Physik*, p. 182) are as follows:

| Range of temperature. | Mean specific heat. |
|---|---|
| 0° to 100° C. | 0·0335 |
| 0° to 300° | 0·0343 |
| 0° to 500° | 0·0352 |
| 0° to 1,200° | 0·0382 |

The effect of temperature upon the specific heat of liquids is in general more than in the case of solids. There are, however, some anomalies among the latter. The diamond, for example, according to Weber, possesses a specific heat of 0·0947 at 0° C., which becomes 0·1905 at 100° and 0·2791 at 200°.

See, further, HEAT, LIQUIDS, and STEAM; also Regnault, *Quelques Expériences*; Preston, *On Heat*; Stewart, *Heat*; Tait, *On Heat*; or any of the larger treatises on physics.

E. L. NICHOLS.

**Specific Inductive Capacity**: See INDUCTIVE CAPACITY.

**Specific Performance**: in the equitable jurisprudence of the U. S. and of England, the species of remedy conferred by courts of equity, in which a party is compelled to perform the very thing which he has undertaken to perform in behalf of the person to whom the undertaking is given. In its broadest sense, the phrase would properly describe all the varieties of equitable relief which consist in procuring a defendant upon whom an obligation rests to do the very specific acts which such obligation requires him to do; but in its technical and more restricted signification it is confined to cases in which the obligation arises out of a contract entered into by the defendant. The common law knows but one form of remedy for the breach of any and all contracts—a recovery of money either as debt or damages. Whatever be the nature of the agreement, whatever be its subject-matter, whatever acts or omissions it calls for, a pecuniary compensation for its non-performance is the only judgment that can ever be obtained against the defaulting party by means of the common-law courts. It is very plain that in the innumerable variety of relations incident to modern society contracts will necessarily be made for whose breach this mere pecuniary payment would be an utterly inadequate and often impracticable relief; and a system of municipal law which provided no other kind would fail in maintaining and dispensing the justice which is the final object of all enlightened jurisprudence. To supply this defect in the common-law methods the courts of equity began long since to decree the specific performance of contracts in certain cases; and the general principles which determine the classes of agreements to which this remedy may be applied are now ascertained and well settled, and constitute a distinct department of equity. The doctrine as thus established is shown in the simplest and clearest manner by enumerating the instances in which a specific performance will not be decreed, and which are therefore left within the exclusive jurisdiction of the common-law tribunals and to the application of the common-law remedies:

1. The fundamental and most important rule is, that a specific performance will not be ordered when the complaining party can obtain adequate relief by means of a purely legal judgment. If, therefore, the contract vests the plaintiff with property in a chattel, so that he can recover its possession through an action at law, or if by the money recovered he can restore himself to the same position, in contemplation of law, which he would have occupied if the defendant had fulfilled his agreement, he will be left to his legal remedy alone, and courts of equity will not interfere in his behalf. As an illustration: If the contract relates to ordinary goods and chattels, or to any kind of personal property having a marketable value, and contemplates a delivery thereof in any manner or a transfer of title, since a sufficient sum of money paid to the injured party will always enable him to purchase or procure other articles of a like nature, amount, and value to those stipulated for such a pecuniary compensation is deemed an adequate remedy, and a specific performance will be refused. The example here given, and the fundamental rule which it illustrates, have a very wide application, and they remove at one blow all ordinary agreements concerning personal property, especially those which are mercantile in their character, from the operation of this equitable mode of enforcement. The mere fact, however, that an agreement deals with or relates to personal property does not necessarily withdraw it from the jurisdiction of a court of equity. The subject-matter may be a chattel of some peculiar, intrinsic, but not marketable value, which can not be elsewhere purchased or reproduced, so that the pecuniary damages will not compensate for its loss; and in such cases, although they are exceedingly rare, the specific relief may be obtained. A certain class of covenants, also, wherein the parties promise to execute some further and more formal agreements—as, for example, to execute a marriage or family settlement on wife and children—may be specifically enforced by compelling an execution of the contemplated instrument, although it relates to personal property and not to real estate. These instances, however, are comparatively few, and in the vast majority of contracts concerning personal property or personal services the money-recovery granted by the law courts is regarded as an adequate relief, and the extraordinary remedy administered by the equity tribunals is denied. In all the subsequent rules it is of course assumed that the agreement, if judged by the principle alone which has already been stated, is one to which the equitable method of enforcement might be applied.

2. In order that a specific performance may be decreed, such a performance must be reasonably possible by the contracting party. If, therefore, by the original terms of the contract he did not have the power to fulfill, or if from circumstances occurring after its execution the power has been lost, even through his own voluntary act, a court of equity will not go through the empty form of ordering an impossibility to be accomplished, and the plaintiff must be contented with an award of pecuniary damages, which perhaps may be enhanced by reason of the defendant's conduct. For example, if the owner of a farm should, by a valid agreement of sale, bind himself to convey it to the purchaser on a future day named, but before that time had arrived should actually convey it to another *bona-fide* grantee, a specific performance of the contract would not be decreed at the suit of the original vendee, because a transfer of the title to him by the vender would then be impossible, and he would be left to his action for damages. Specific performance can be obtained, however, against a person who buys with notice of a prior contract for the sale of land, or who acquires title to the property without paying value. As a corollary of this rule, it is requisite that the terms of the contract should be so plain and unambiguous that there can be no reasonable doubt as to the intention of the parties, and that this design may be directly carried into effect by the judgment.

3. Not only must the performance be possible by the party upon whom the obligation rests, but the subject-matter of the agreement, and its stipulations in regard thereto, must be of such a nature that the court, by means of its ordinary administrative instruments and machinery, can compel the specific performance which it decrees. Cases may arise, and are not infrequent, in which the court, after directing a performance according to the provisions of the contract, would have no power to enforce its decision directly without departing from its customary functions or incurring an amount of trouble, care, and responsibility incompatible with the discharge of its regular duties; a specific performance will then be refused, however inadequate might be a mere recovery of damages. Under the operation of this principle the agreement of an actor, a singer, a painter, or other artist to employ his talents in a specified manner can not be specifically enforced; and the rule applies in general to all stipulations for personal services, notwithstanding the fact that these services may be of such exceptional value that they can not be procured from any other person but the defendant. For the same reason it has been decided that the specific performance of a contract to construct a railway will not be decreed, since such an undertaking is too extensive and burdensome to be carried on under the direction of a court of equity. See, however, *Wilson* vs. *Furness Railway Co.*, L. R. 9 Eq. 28; *Lawrence* vs. *Saratoga R. R. Co.*, 36 Hun. 467.

4. Finally, the agreement and the relations of the parties must be such that a decree of specific performance will be reasonable, just, and equitable. It is sometimes said that this remedy is never a claim of right, but is always a matter of discretion. The doctrine as thus stated simply means that in determining whether the relief shall be granted in a given case certain equitable considerations are to be taken into account, and not the mere fact that the agreement is valid in law. The beneficent principle is applied that he who seeks equity must do equity. If, therefore, the contract was procured by overreaching or artifice, although not so tainted with fraud as to be invalid, if it is unfair or oppressive in its terms, if the consideration is grossly inadequate, if its specific enforcement would be unreasonably burdensome to the defendant without any corresponding benefit to the plaintiff, if the plaintiff has been guilty of unnecessary delay in prosecuting the action whereby his opponent has been prejudiced—in these and in similar cases showing a want of good faith or diligence on one side or serious injury on the other, the equitable considerations become controlling, and lead to a denial of the specific remedy.

As the practical result of these rules, the usual contracts enforceable by a decree for a specific performance are those directly relating to land as their subject-matter. It is a settled doctrine of the equity courts that money-damages are not an adequate relief for the breach of such agreements.

This conclusion is partly based upon the fact that a special value may be attributed to the very premises bargained for which is not susceptible of pecuniary estimate and compensation, but chiefly upon the pre-eminence which the English law has always given to the ownership of land in comparison with every other species of property. Subject, however, to the qualifications hereinbefore stated, specific performance will be decreed of any contract where the remedy at law is inadequate and specific performance is reasonably possible. On this principle specific performance has been decreed of contracts for the sale of property that could not be purchased in the market (*Thorn* vs. *Commissioners*, 32 Beavan 190; *Equitable Gas Light Co.* vs. *Baltimore Coal Tar Co.*, 63 Md. 285), of contracts for the sale of debts of an insolvent (*Adderly* vs. *Dixon*, 1 Sim. and St. 590; *Cutting* vs. *Dana*, 25 N. J. Eq. 265), of contracts to give security for a debt (*Taylor* vs. *Eckersley*, 2 Chancery Division 302), and of contracts for the sale of letters patent (*Somerly* vs. *Buntin*, 118 Mass. 279). A contract for the conveyance of land, or for the creation of an estate therein, if valid by the statute of frauds, and if complying with the conditions above described, will in general be enforced by a decree of specific performance compelling the execution of the proper instruments and the creation or transfer of the proper interests. What contracts are thus valid under the statute, and how far courts of equity have grafted exceptions upon this enactment, enforcing specific performance of oral contracts, are questions of the highest importance, but can not be treated here. It may be stated, however, in general terms that if the vendee has so far performed the contract that he can not be put *in statu quo*, an oral contract will be enforced, notwithstanding the statute of frauds requires a memorandum in writing of contracts for the sale of an interest in land. This exception is put upon the ground that the defendant shall not be allowed to plead the statute of frauds to perpetrate a fraud, a clear case of judicial repeal of legislation. See FRAUDS, STATUTE OF.

Revised by WILLIAM A. KEENER.

**Specific Volume of Gases**: See HEAT (*Density of Gases and Vapors*).

**Spectacles** [from Lat. *specta'culum*, sight, show, spectacle, deriv. of *specta're*, frequentative of *spe'cere*, look at]: a device for the improvement of defective sight. (See the article VISION, DEFECTS OF.) The invention of spectacles has been variously ascribed to Alexander da Spina, of Florence, or to his contemporary and fellow townsman, Salvinus Armatus (d. 1317); also to Roger Bacon (d. about 1294). It is more probable, however, that the knowledge of them in Europe came through the Saracen Alhazen (d. 1038). The Chinese have for ages employed spectacles for the relief of defective eyesight, and probably they were known to the ancients. (Consult *History of Spectacles*, by Dr. L. W. Fox, in *Medical and Surgical Reporter*, May 3, 1890.) Lenses for spectacles are spherical and cylindrical. In a *spherical lens* the surface on one or both sides is a section of a sphere. Rays of light passing through it are refracted equally in all planes. In a *cylindrical lens* the surface on one side is a section of a cylinder parallel to its axis. Light passing through a cylindrical lens in a plane parallel to its axis is not refracted. At right angles to its axis parallel rays are rendered convergent or divergent according as the cylindrical surface is convex or concave.

*Convex spherical lenses* ground into spectacles are used (*a*) to correct presbyopia (a diminution of the range of accommodation, interfering with vision of near objects); (*b*) to correct hypermetropia, or far sight (over-sight), by increasing the refraction of the eye, so that distant rays instead of coming to a focus behind the retina are accurately focused upon it; (*c*) to supply the loss of refractive power caused by removal of the crystalline lens, e. g. after extraction of cataract; these must be powerful glasses having an optical value of about eleven diopters. *Concave spherical lenses* are used to correct myopia, or short sight, by lessening the refraction of the eye, so that distant rays instead of coming to a focus in front of the retina are focused accurately upon it. *Cylindrical lenses* are used to correct astigmatism, or a condition in which the refraction varies in the different meridians of the eye. The cylindrical surfaces may be either concave or convex, according as the faulty meridian is myopic or hypermetropic. *Prismatic glasses* are used to relieve muscular weakness of the eye, because a prism will alter the direction of the ray from the point of fixation, so that it coincides with the visual line of the weaker eye.

If there is a combination of astigmatism and hypermetropia or myopia, *compound lenses* are used. On one face of the glass is ground the spherical curvature (convex or concave, according as there is hypermetropia or myopia), and on the other the cylindric curvature, to neutralize the astigmatism. Prisms may also be combined with this formula.

Lenses are numbered according to one of two systems. In the first or old system a strong lens of 1-inch focal length is the unit. Lenses weaker than the unit are expressed by fractions; thus a lens of 2 inches focus is expressed as $\frac{1}{2}$, one of 10 inches focus as $\frac{1}{10}$, etc. In the second or new system a weak lens of 1 meter (100 cm.) focus is the unit, and is called a *diopter* (abbreviated D.); a lens twice the strength of the unit is 2 D., and has a focal length of 50 cm. Prisms may be designated by their refracting angles or by their angular deviation.

Lenses used to correct optical defects may be mounted in spectacle-frames or in eye-glasses. When separate glasses are required for distance and reading they may be combined in one frame by cementing the stronger lens upon the lower portion of the distance glass. These are called cemented bifocals or double-focus glasses, and have replaced largely the old-fashioned Franklin glasses, which were made of two pieces divided horizontally and joined by their cut surfaces. Instead of double-focus glasses the reading-lens may be added as a separate glass in a hook-front.

Spectacles should never be worn unless the eyes have been carefully examined by a competent physician, who then writes the formula from which an optician may grind the proper lenses. Glass used in spectacles should be of the best quality, and have an index of refraction of 1·53. Pebble-glass is sometimes employed, but has no special advantages.

GEORGE E. DE SCHWEINITZ.

**Spectacle-snake**: See COBRA DE CAPELLO.

**Spectrophotom'eter**: an instrument for the comparison of any color or wave-length from any given source of light with the same color or wave-length from a standard source.

In the instruments described under PHOTOMETER (*q. v.*) the comparison is made between the two lights as a whole, and furnishes no indication of the relative intensities of different wave-lengths with each other or with the same wave-lengths from a standard source. For the more detailed comparison of the lights from two sources, each must be resolved into its constituent parts as shown by its spectrum and the two spectra compared, small similar regions of each at a time.

The use of the instrument depends on the fact that the eye readily and accurately compares lights of the same wave-length, while between different wave-lengths only the roughest comparison is possible. See PHOTOMETRY.

The instrument is exceedingly variable in form, according to the particular purpose in view. It must, however, include the following elements: (1) Provision for producing in juxtaposition the two spectra with a definite line of demarkation between. (2) Provision for bringing into the field of view separately any given small region of the two spectra. (3) Provision for varying the relative intensity of the light from the two sources so that the intensities of the two constituent parts under observation as judged by the eye may be made equal. The extent to which the relative intensities as a whole are thus modified becomes then a means for the comparison of the intensities of the two particular wave-lengths under observation.

Requirement (1) may be provided either by prisms, as in the ordinary spectroscope, or by a ruled grating, proper provision being made for the introduction and collimation of the two beams of light. Requirement (2) is provided by adjustments similar to those in the spectroscope, and by an adjustable diaphragm in the focal plane of the eyepiece, by means of which the field of vision may be reduced to as narrow a region as desired. Requirement (3) may be provided (*a*) by an adjustable slit, whereby the extent of the openings for the two beams may be made to vary relatively; (*b*) by a pair of Nicol's prisms in the optical path of each beam, whereby the relative intensity may be varied according to the relative angle between the polarizer and analyzer; (*c*) by varying the relative distances between the instrument and the two sources of light, as in the ordinary photometer; (*d*) by a combination of the preceding.

So far as possible the optical paths of the two beams should be similar, i. e. they should consist of the same number of reflections, refractions, and polarizations, and at the same angles, and they should traverse the same amounts of glass, calcite, and other media. If the paths are essentially different in these particulars, selective absorption and reflection and other disturbing causes may introduce errors into the final comparison.

Various sources of light, such as the sun, the incandescent filament of the glow-lamp, and a standard gas-flame, have been used as standards in work with this instrument.

W. F. DURAND.

**Spec′troscope** [Mod. Lat. *spec′trum* + Gr. σκοπεῖν, view]: any instrument for the production and study of spectra. Spectroscopes designed for the precise determination of wave-length are called spectrometers. Spectroscopes may be classified with reference to the nature of the dispersing device, whether prism or grating; or with reference to the dispersing power (high or low); or according to the special purpose to which the instrument is to be put (telespectroscope, microspectroscope, etc.).

Whatever the type of spectroscope, its action is always based upon the principles stated in the article SPECTRUM (*q. v.*). The essential parts are the slit and the dispersing device, to which may be added the focusing arrangement, and the means of identifying and determining the positions of the various regions of the spectrum under investigation. The slit possesses the same features in nearly all forms of spectroscope. It consists of two parallel jaws of metal, very accurately worked and adjusted. One or both have freedom of motion in a direction at right angles to the length of the slit. Fig. 1 shows one of the best-known methods of producing these motions. The device is due to Hilger. The two edges should be so true in workmanship that when brought within a small fraction of a millimeter of one another the aperture will still be approximately of uniform width throughout. This aperture when illuminated from behind forms the source of light the image of which, dispersed and focused upon a screen, or within the eyepiece of an observing telescope, is to form the spectrum.

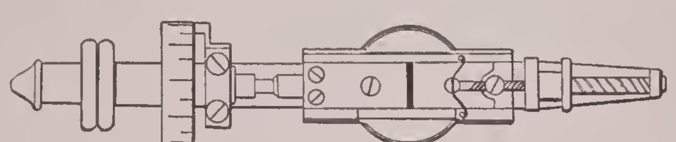

FIG. 1.

*Dispersing Devices.*—(1) *The Prism.*—The usual material is glass, although for special purposes rock-salt, quartz, fluorspar, carbon bisulphide, etc., are used. Rock-salt possesses the advantage of extreme transparency for the longer waves of the infra-red to which glass is opaque; quartz has the equally desirable property of transparency in the ultra-violet. Fluor-spar is unique in having a law of dispersion which gives great separation to the longer waves, thus permitting the extension of measurements to regions unattainable with prisms of other materials. This property combined with very complete transparency in the same regions makes fluor-spar one of the most valuable of substances to the student of radiation. Carbon bisulphide is used where a dispersing medium is desired, the law of dispersion of which is known. Cauchy's formula,

$$N_\lambda = \alpha + \frac{\beta}{\lambda^2} + \frac{\gamma}{\lambda^4},$$

where $N_\lambda$ is the index of refraction for a wave-length, $\lambda$, and $\alpha$, $\beta$ and $\gamma$ are constants, when applied to nearly all substances available in spectroscopy, gives false values for the infra-red. Carbon bisulphide appears to obey the above law for all wave-lengths.

In glass an important quality is high dispersing power, and this is a property which the variety known as flint glass possesses in a high degree. How great is the difference between different sorts of glass will appear from Fig. 2, which shows the spectra produced by similar prisms of crown and of flint glass under like conditions. It will be seen that the distance between the Fraunhofer lines A and H, or, in other words, between the extreme red and the extreme violet, is nearly twice as great in the one case as in the other. Flint glass has one very serious disadvantage for spectroscopic work, viz., that as its dispersive power increases, its transparency, particularly for the shorter wave-lengths, diminishes. Even ordinary optical glasses are far from completely transparent, and the densest varieties are nearly opaque to the extreme violet of the spectrum. In spectroscopes with a single prism the latter is usually equiangular. Where a train of prisms is used to secure high dispersion, lesser angles are frequently employed.

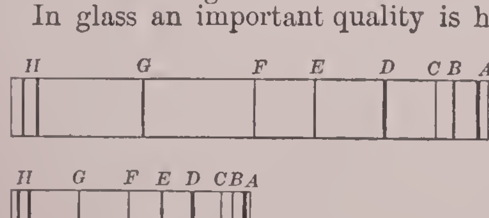

FIG. 2.

*Trains of Prisms and Direct Vision Combinations.*—Whenever high dispersion is desired and a prismatic spectrum is preferred to the normal spectrum produced by means of the diffraction grating, a train of prisms is employed. Kirchhoff and Bunsen used for this purpose simply a set of independent equiangular prisms, each mounted upon three pins. These were set up upon a metallic plate, and were adjusted separately by hand until the entire train was symmetrically arranged. As the positions for minimum deviation differed with the wave-length, this laborious operation had to be continually repeated. Later workers with the spectroscope devised automatic trains, such that the movement of the eye-telescope shifted all the prisms simultaneously into their proper positions. Fig. 3 shows the automatic arrangement due to Rutherfurd. In the astronomical spectroscope depicted in Fig. 11 a similar train is used.

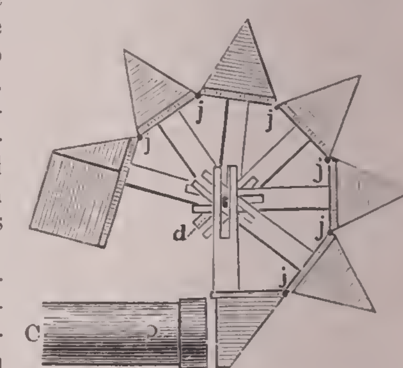

FIG. 3.

To avoid the inconvenience of having the collimator and observing telescopes make an angle with one another, as in Figs. 8, 12, and 13, combinations of flint and crown glass prisms are sometimes used in spectroscopes of small dispersion to produce a spectrum without any considerable deviation of the rays from direction of their original path. Fig. 4 shows the usual arrangement, in which *c c c* are crown-glass and *f f* are flint prisms. It is an extension by Jansen of the original idea of Amici, who used three prisms, two crown prisms with one flint prism between them. The action of both the three and five prism systems depends upon the difference in the dispersing powers of crown and of flint glass.

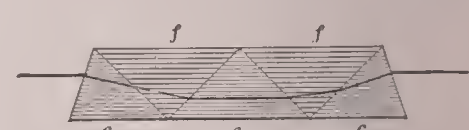

FIG. 4.

It is evident that if the system is so constructed that a certain ray of wave-length, $\lambda$, so selected as to lie near the center of the spectrum, emerges with its path parallel to the incident path (as in Fig. 4), rays of other wave-lengths will suffer more or less divergence from that direction. There is a resultant dispersion by such a system, although the mean direction is unchanged.

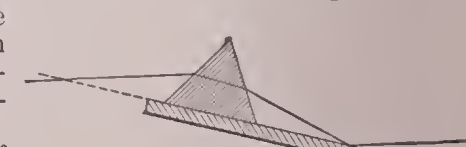

FIG. 5.

There are a variety of other methods for rectifying the direction of the dispersed rays in the spectroscope, some involving subsequent reflection by means of a mirror (Fig. 5), others total reflection either within the dispersing prism (Fig. 6) itself (a construction ascribed to Herschel) or by means of a separate rectangular prism properly placed for that purpose (Fig. 7). None of these devices, however, has come into very general use.

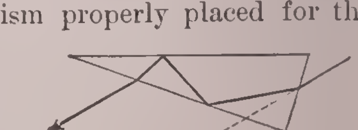

FIG. 6.

FIG. 7.

(2) *Gratings* for the production of diffraction-spectra are frequently used in the spectroscope instead of prisms as dispersing apparatus. It is used in spectroscopic work (1) whenever a normal spectrum rather than a prismatic spectrum is desired—that is to say, when direct absolute determinations of wave-length are to be made; (2) when high dispersion is wanted. Gratings give relatively greater openness in the longer wave-lengths and less in the violet and ultra-violet than do

prisms. They are objectionable in some kinds of work on account of the faintness of the spectra produced, of the overlapping of the spectra, and of the fortuitous and altogether irregular distribution of intensities. For photographic work, however, gratings are especially advantageous because the strong absorption which violet light suffers in passing through flint glass (as indicated in a previous paragraph) may be avoided.

*Collimator and Observing Telescope.*—Spectroscopes of the usual form (Fig. 8) have between the prism or grating and the slit a lens (C), the purpose of which is to bring light to the prism in parallel rays. This lens is attached by means of the connecting tube to the slit at such a distance that the latter is at the principal focus. This arrangement is called the collimator. Beyond the prism the dispersed rays enter the observing telescope (T), which having been focused for parallel light brings the portion of the spectrum under observation to a focus in the eyepiece. Collimator-tube and telescope swing upon a common vertical axis at the center of the instrument. By means of the position of the telescope, as indicated upon a divided circle ($a$), about which it moves, the region of the spectrum which is in coincidence with the cross-hairs in the eyepiece is identified.

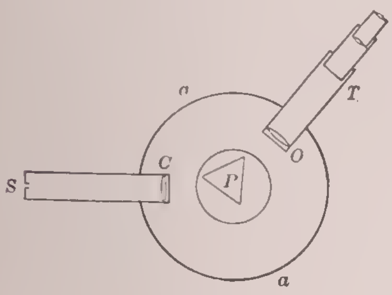

Fig. 8.

Where a grating is used the position of the parts of the spectroscope is that shown in Fig. 9, the telescope being placed on either side of the collimator according as the right-handed or left-handed spectra are to be observed, and at various angles according to the order of the spectrum.

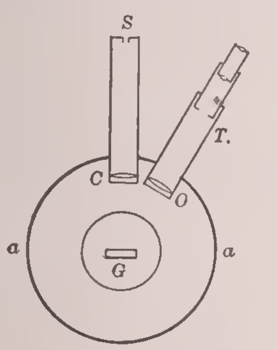

Fig. 9.

Formerly a train of prisms was used, as in the spectrometer of Kirchhoff and Bunsen (Fig. 10). The automatic train depicted in Fig. 3 was a later form. It found one of its most important applications in the telespectroscope, a well-known form of which is shown in Fig. 11. This instrument, which could be adjusted so as to give any dispersion up to that corresponding to twelve prisms, is constructed in compact form and attached as an eyepiece of a large telescope.

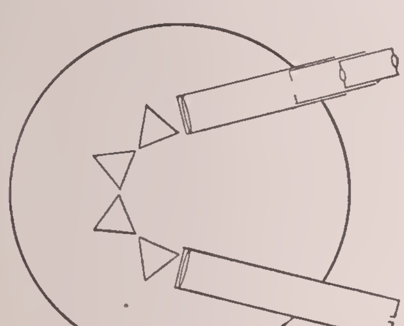

Fig. 10.

*Chemical Spectroscopes.*—For many purposes the exact but laborious method of determining the position of lines in the spectrum by making readings upon a finely divided circle may be advantageously supplanted by a less precise but more expeditious process. This is true, for example, in the identification of substances by means of their bright-line spectra or in the study of absorption spectra. The first instrument especially designed for such work was the chemical spectroscope of Bunsen (Fig. 12). The circle in this apparatus is dispensed with and both collimator and telescope are fixed. The dispersion is so small as to bring the entire spectrum into the field of view. A third tube, S, carries a transparent scale (photographed upon glass). In Fig. 13 the letter $a$ shows the position of this scale. There is a lens at $b$ by means of which the image of the scale is brought to focus in the eyepiece of the telescope. The rays are reflected from the face of the prism as shown in the figure. The scale is illuminated from behind by means of a flame, $L_2$. The appearance of the field of view when a spectrum consisting of bright lines is under observation is shown in Fig. 14.

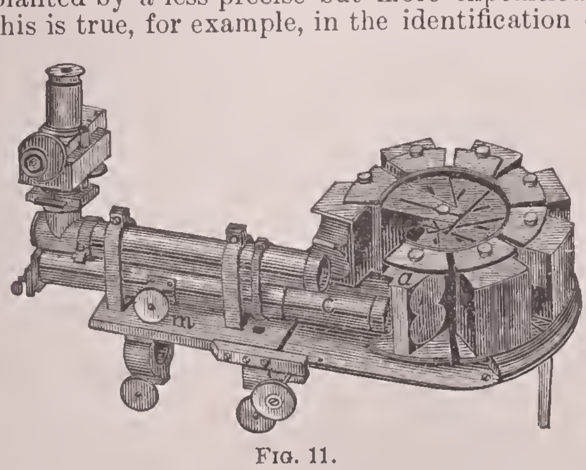

Fig. 11.

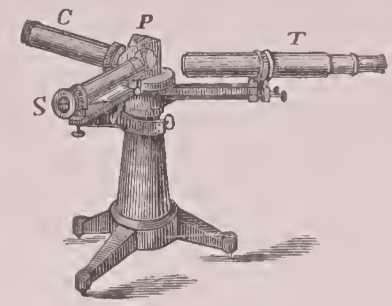

Fig. 12.

At the hands of Hofmann and of Krüss and others, the chemical spectroscope has undergone many improvements, among which may be mentioned the introduction of direct-vision prisms and of a scale reading directly in wave-lengths. Fig. 15 shows such an instrument, with diagram of its parts. In the microspectroscope also, or spectroscopic eyepiece, direct-vision prisms are used and the direct-reading scale. This instrument indeed is simply a direct-vision spectroscope of small proportions and adapted to the eyepiece of the compound microscope. In Fig. 16 the cross-section of a microspectroscope is shown, with prism ($p$) for introduction of a reference spectrum and a scale ($s$).

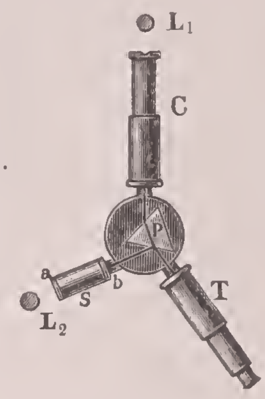

Fig. 13.

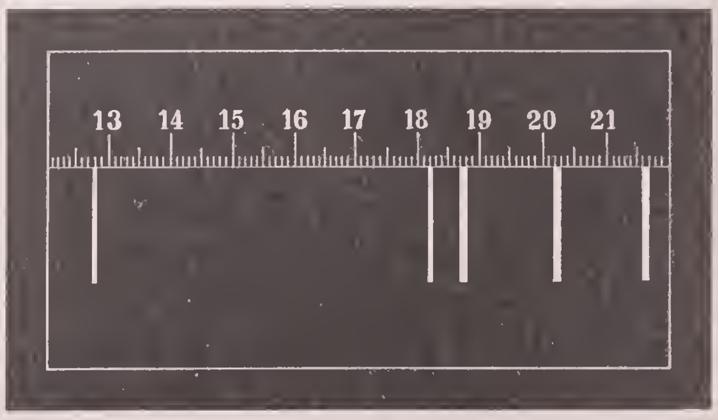

Fig. 14.

*Spectroscopes for the Infra-red and the Ultra-violet.*—For the study of the invisible spectrum spectroscopes of the usual forms are ill adapted. Various special types have accordingly been developed.

*In the infra-red* the conditions are transparency to the longer waves and sufficient dispersion of that part of the spectrum. Rubens uses in such work an instrument with a prism of fluor-spar. Lenses are dispensed with altogether in favor of concave mirrors, which bring the spectral image to a focus upon the filament of a linear bolometer.

*In the ultra-violet*, where the method is photographic, the best results are obtained by the use of the concave grating of Rowland.

Fig. 15.

Brashear, in his grating spectroscope for the ultra-violet, mounts grating (G) and plate-holder (P) at the ends of a rigid bar (B, Fig. 17). The grating is placed upon a car with two wheels, which runs along a metal track, S $R_1$. This track extends from the slit in the incident ray. Another track (S $R_2$) at right angles to the

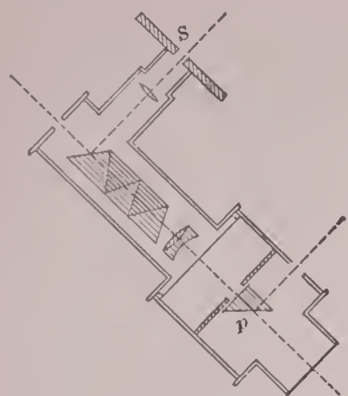

Fig. 16.

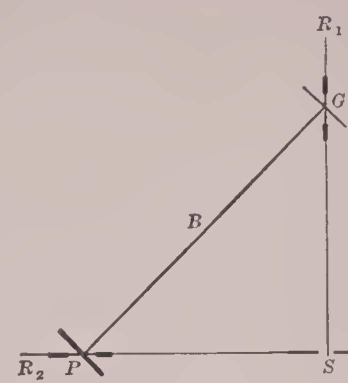

Fig. 17.

first carries a plate-holder. The bases upon which grating and plate-holder are mounted are pivoted to the cars on which they are placed, so that the bar can be brought to any angle with the incident ray, both grating and plate-holder remaining always normal to the direction of the bar and at the same distance apart. The law of the grating is such that if the distance between the grating and plate is equal to the radius of the curvature of the former the spectrum will be in focus upon the plate in all positions of the bar. The light to be investigated is focused upon the slit by means of a quartz lens or sometimes by a concave mirror of long focus. Fig. 18 shows the general form of the apparatus.

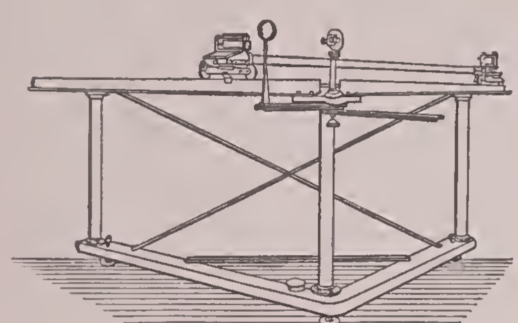

Fig. 18.

A description of some of the varied applications of the spectroscope is given in the article Spectrum (*q. v.*); see also Spectrophotometer: also the various treatises named at the end of the former article. E. L. Nichols.

**Spec'trum** [= Mod. Lat., from Lat. *spec'trum*, appearance, image, apparition, deriv. of *spe'cere*, look at]: in optics, the image obtained when a ray after dispersion, either by passage through a prism or by diffraction, is brought to a focus. The composite nature of light, through which a spectrum is possible, is explained in the article Light.

The first systematic studies of the spectrum were made by Newton, 1666, and it was he who appears to have first recognized the supreme importance of the phenomena encountered in such observations. Modern spectroscopy, however, may be regarded as having its beginning in the experiments of Fraunhofer, who in 1817, by the use of a narrow slit, first produced well-defined and pure spectra.

The essential parts of the apparatus for the production of such a spectrum are (1) a slit illuminated from behind; (2) a dispersing device (usually a prism or a diffraction grating); (3) a focusing device (a lens or system of lenses, or sometimes a mirror); (4) a screen or an observing telescope, according to the method to be pursued in studying the spectrum.

In Fig. 1 is shown a slit through which light of a wave-length, λ, passes in the direction indicated by the arrow. But for the interposition of the prism P, the lens L would produce an image of the slit $S_1$ at the conjugate focus $S_2$. The prism, however, diverts the ray, and it comes to focus upon the screen *i*, *u*. The position of this refracted image depends upon the wave-length. If, for example, the wave-length is one which produces the impression of red upon the retina it will come to focus at *r*; if of violet, at *v*. If the ray passing through the slit be of white light, the entire space between *r* and *v*, which we may suppose to be respectively the longest and the shortest rays capable of affecting the eye, will be filled by colored images of the slit, each differing insensibly from its neighbors in hue. This infinite series of elementary images constitutes what is called a continuous spectrum. Each image has a width proportional to that of the slit, but the centers of contiguous members of the series are only infinitesimally distant from one another. Neighboring images overlap, therefore, with consequent color-mixing.

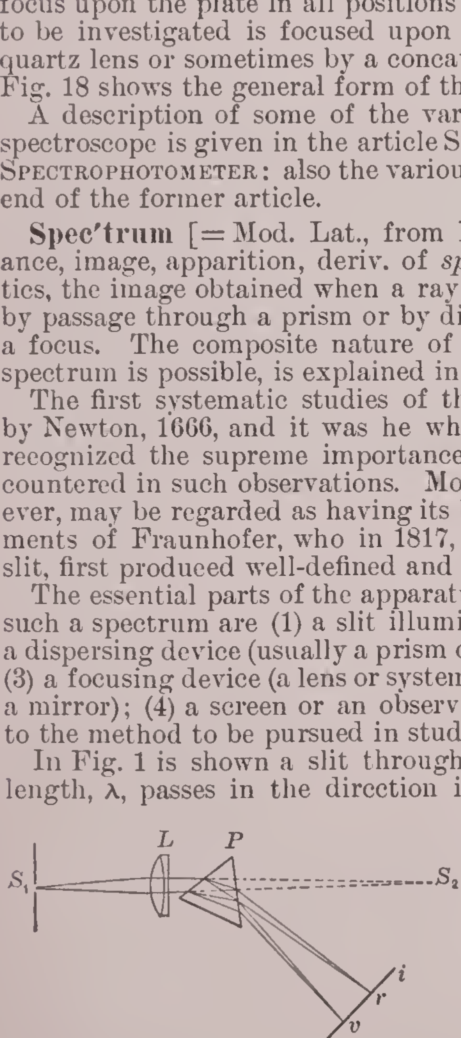

Fig. 1.

*A pure spectrum*, in the language of the spectroscopist, is one in which the effect of this color-mixing by fusion of the overlapping images is absent. In a strict geometrical sense a pure spectrum would be produced only by the use of a linear slit. The successive elementary images differ from one another, however, only infinitesimally in color, and a definite finite difference must exist before the effect of the blended images upon the retina will differ from that of their components. In practice the spectra produced by the dispersion of the light from any narrow slit (up to perhaps ·05 cm. for an ordinary spectroscope) may be regarded as pure. The distribution of wave-lengths, and consequently of colors, in the prismatic spectrum is determined by what is called the *law of dispersion* of the prism. It has not been found possible to give a general expression to this law, applicable to all substances. The phenomenon of dispersion differs indeed in various transparent media, such as calcite, fluorite, rock-salt, quartz, etc., in ways the explanation of which has not yet been attained. In glass, which is an artificial mixture with varying components, the dispersion is to a considerable extent under the control of the maker.

For any particular case the dispersion can be indicated graphically in a simple manner. An important example is that of an equiangular prism of flint glass, the dispersion diagram of which appears in Fig. 2. The ordinates of the

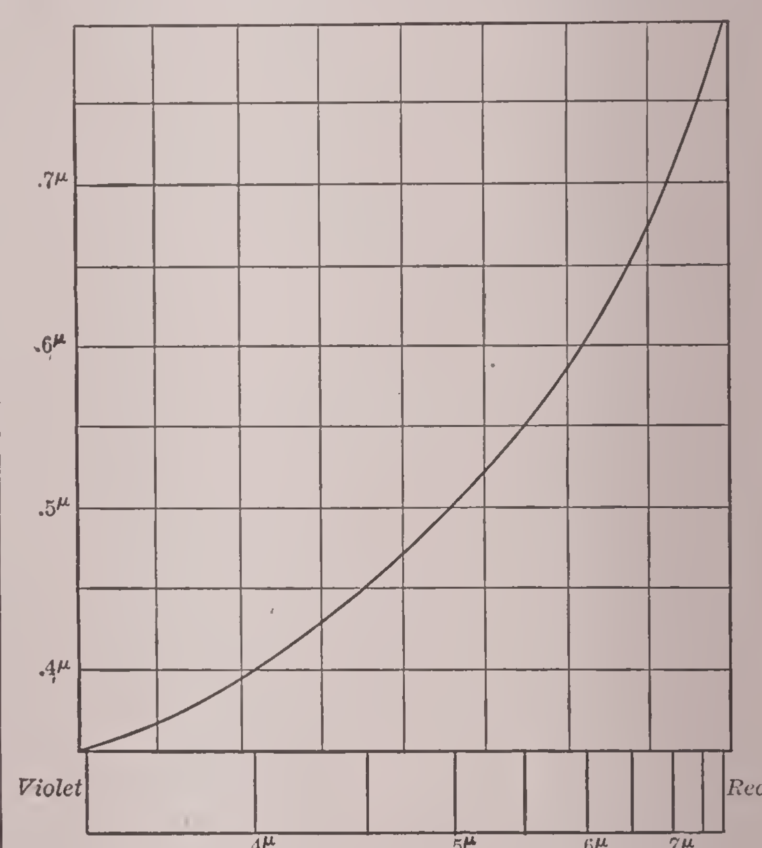

Fig. 2.

curve are wave-lengths in millionths of a meter; the abscissas are distances in passing through the spectrum from violet to red. The vertical lines at the base of the diagram show by their distances apart the relative spaces which exist between wave-lengths 0·40μ, 0·50μ, etc.

While this diagram applies only to a particular specimen of glass, it is characteristic to a certain extent of nearly all cases of prismatic dispersion, the peculiarity of which is the increasing separation of the rays as the wave-length diminishes, so that the red end of the spectrum is relatively much more crowded together than the violet end.

*The diffraction spectrum* (normal spectrum) is produced by means of apparatus, of which that shown in Fig. 3 is typical. The diagram gives only the essential parts, which are the same as those in Fig. 1, with the exception that a reflecting diffraction grating (G) is used instead of a prism. This grating, according to modern practice, would consist of a plate of speculum metal, the surface of which is accurately ground to form a plane mirror, or sometimes a concave mirror with a radius of several feet. Upon this surface are ruled straight equidistant lines to the number of several thousand per centimeter. The process is that described in

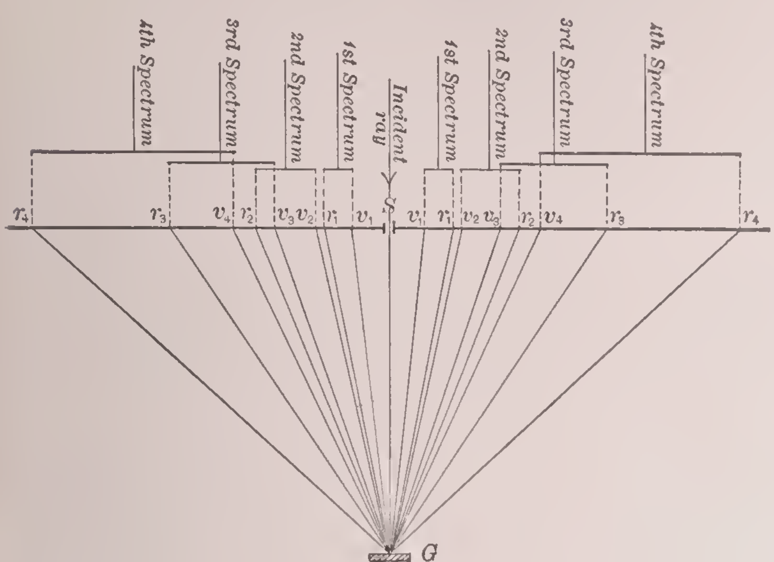

FIG 3

the article RULING-MACHINES (*q. v.*). If monochromatic light from the slit falls upon this ruled surface, it is sent back by reflection from the lines in all directions, in a plane perpendicular to the ruling and to the face of the mirror, and diffraction-bands are formed. These are alternately black and of the color of the light. The law of the position of the colored bands, which are distributed symmetrically with reference to a plane normal to the grating, parallel to the ruling and passing through the slit, is given by the equation

$$\text{Sin } \alpha_n = \frac{n\lambda}{a+b}.$$

In this formula $\alpha_n$ is the angle that the rays which go to form the $n$th band of the series make with the incident ray from the slit, $\lambda$ is the wave-length, while $n$ may be 1, 2, 3, or 4, etc., according to the number of the band which we are considering. The quantity $a + b$ is the distance from the edge of one line upon the grating to the corresponding edge of the next—$a$ being the width of the line, and $b$ the unruled space between it and the next line. The position of the bands with reference to the slit S and the grating G is shown in Fig. 3 ($r_1$ $r_2$ $r_3$, etc.).

If the light which enters the slit be violet instead of red, the diffraction bands will have positions nearer the slit ($v_1$ $v_2$ $v_3$, etc.). If white or other composite light be used overlapping diffraction images of the slit will be produced, and these will be so arranged with reference to each other as to form as a series of spectra on either side of the slit.

If, as in the discussion of the prismatic spectrum, we take $r_1$, etc., to represent the longest visible wave-length, and $v_1$, etc., the shortest, we shall have the intervening spaces in the diagram, viz., $v_1$ - - - $r_1$, $v_2$ - - - $r_2$, $v_3$ - - - $r_3$, etc., occupied by spectra. These are called for convenience spectra of the first, second, third, etc., order. It will be noticed that with the exception of the first and second all the spectra overlap.

The formula given above defines completely the position and character of the spectra produced by a grating. It will be seen, for example, that the distance out from the slit to the position occupied by any given wave-length, measured by the sine of the angle $\alpha$, is proportional to the wave-length. The violet end of the diffraction-spectrum is therefore always nearest the slit. The distribution of wave-lengths throughout the spectrum, moreover, is a uniform one, instead of varying as in prismatic spectra. It is on account of this property that the name *normal spectrum* is applied to a spectrum produced by means of a grating. It is obvious from the formula likewise that sin $\alpha$ for a given wave-length is directly proportional to the number of lines in a centimeter contained upon the grating, so that the dispersion is entirely a question of the fineness of the ruled surface.

*Advantages and Disadvantages of Diffraction-spectra.*—The chief advantage of the diffraction-spectrum lies in the simplicity of the law of distribution of wave-lengths. On this account it affords much the best means for the accurate measurement of wave-lengths. It is also a great advantage to be able to secure any desired degree of dispersion without recourse to the complication and inconvenience arising from the use of a train of prisms. On the other hand, the prismatic spectrum, by equal dispersion, is much more intense, since all the dispersed light goes to the formation of a single spectrum instead of a double series of spectra, and because the losses by reflection, etc., are much less important. Spectra furnished by gratings, moreover, show vagaries in the distribution of intensities, which depend in a complicated manner upon the nature of the ruling. Certain spectra will be very weak or altogether missing, others of abnormal brilliancy. Some spectra will be strong in a certain color and faint in others, etc. The consequence is that diffraction-spectra are ill fitted for use where the question of the relative intensity of the various wave-lengths of a source of light is to be determined.

*Classes of Spectra.*—Thus far those spectra have been considered in which all wave-lengths between the extreme red and the extreme violet are present. Such spectra are produced by the radiation from glowing solids or liquids; they are called *continuous spectra.*

Where the source of light is an incandescent vapor or gas, radiation is confined to one or more definite wave-lengths. Spectral images corresponding to these wave-lengths only are present in the spectrum, which consists of a group of bright lines, each possessing the color due to its particular wave-length. The intervals lying between are black. Such spectra are called *bright-line spectra.*

A third and very important class of spectra consists of those produced by the passage of light (which would otherwise form a continuous spectrum) through an absorbent medium. This medium may be a solid or liquid, or it may be a vapor. In accordance with the law of Kirchhoff, there is, however, a perfectly definite relation between radiation and absorbing power. Each material, in a word, absorbs the precise wave-length or wave-lengths which it is capable of radiating, and in the same proportion. Gases and vapors, therefore, cut out well-defined and perfectly monochromatic lines from the transmitted light, and thus produce what are called *dark-line spectra.* Solids and liquids, on the other hand, absorb selectively and continuously throughout extended regions, and the spectrum of the rays transmitted by them is crossed by dark transverse bands, varying in position and width and also in density and sharpness of definition according to the character of the medium. Frequently the absorption is such as to weaken or destroy one end of the spectrum instead of producing a band.

*Relation of Bright-line and Dark-line Spectra: the Fraunhofer Lines.*—When, in 1817, Fraunhofer made the first application of the narrow slit to the analysis of sunlight, he observed that the solar spectrum was crossed by numerous fine black lines. Repetition of the experiment showed him that these lines were always present, and that they were always in the same positions. Fraunhofer made a map of the spectrum in which he designated some of the lines alphabetically. It is by the letters which he assigned

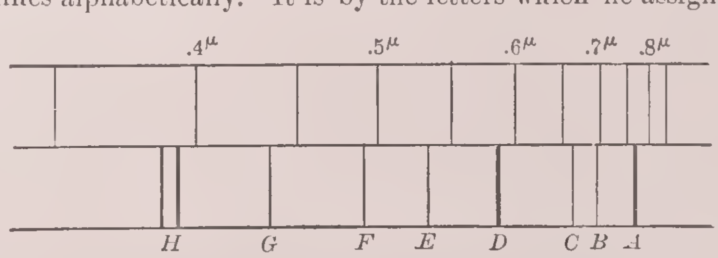

FIG. 4.

to them that they are still known. Fig. 4 shows the positions of a few of the most important Fraunhofer lines in the prismatic spectrum. The wave-lengths are given in the following table:

TABLE I.

Wave-lengths, in millionths of a meter, of the principal Fraunhofer lines. Rowland's values to four places.

| Line. | Wave-length. | Line. | Wave-length. |
|---|---|---|---|
| A | 0·7594μ | E | 0·5270μ |
| B | 0·6867 | F | 0·4861 |
| C | 0·6563 | G | 0·4308 |
| D | 0·5896 ($D_1$)<br>0·5890 ($D_2$) | H | 0·3968 ($H_1$)<br>0·3933 ($H_2$ or K) |

It was nearly half a century after Fraunhofer's observations before the cause of the dark lines in the solar spectrum was determined and their supreme importance in the science of spectroscopy was appreciated. In the meantime the bright-line spectra obtained from the burning vapors of various metals had been described, and finally, about the middle of the century, certain coincidences of position having been noticed, it began to be suspected that there was some connection between the two classes. Finally Kirchhoff and Bunsen in Heidelberg took the matter up, and by means of an exhaustive series of experiments demonstrated that the dark lines of Fraunhofer are produced by absorption, by the sun's atmosphere, and by that of the earth; also that the materials producing absorption in the sun's atmosphere are, in part at least, identical with those which go to form the crust of the earth. The proof is based in part upon the celebrated experiment of the reversal of the sodium lines, which consists essentially in placing in the path of the rays from any incandescent source of light which gives a continuous spectrum a layer of sodium vapor, the temperature of which is lower than that of the source. A favorite method of repeating the experiment for purposes of demonstration is as follows:

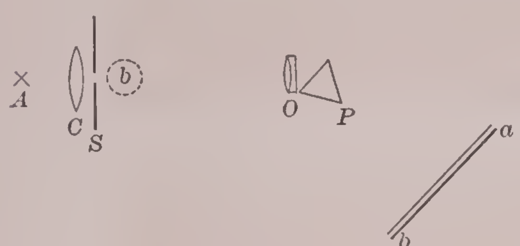

FIG. 5.

In front of an arc-lamp (A, Fig. 5) is placed a condensing lens (C), a vertical slit (S), an object-lens (O), and a prism (P). The lamp A should be tipped back so as give the bright continuous spectrum of the light from the crater of the upper carbon. Before the slit, at *b*, a Bunsen burner is placed, into the flame of which metallic sodium is introduced. The sodium vapor thus produced rises into the path of the ray from A and absorbs light of wave-lengths ·5890 and ·5896, to which rays it is opaque.

In the spectrum upon the screen *a b* two dark lines are formed, but these lie so close together that under ordinary conditions they are merged into a single heavy black band. By slight modifications of the apparatus it is possible to project upon the screen, one above another, spectra containing the bright line due to incandescent sodium, superimposed upon a continuous spectrum, and the artificially produced Fraunhofer line D, and thus to note the precise coincidence in the positions of the two. See Fig. 6.

FIG. 6.

The direct evidence of experiments like the above was supported by measurement of the position of thousands of dark lines in the solar spectrum and of the positions of the thousands of lines obtained by the incandescence of the various chemical elements. The comparison of the two showed the identity of many of the solar lines with those of well-known terrestrial substances. In the cases of metals possessing complicated-line spectra, such as iron, nickel, and calcium, the number of lines in coincidence was so great as to preclude all question of agreement by chance.

A most important example is afforded by the metal iron,

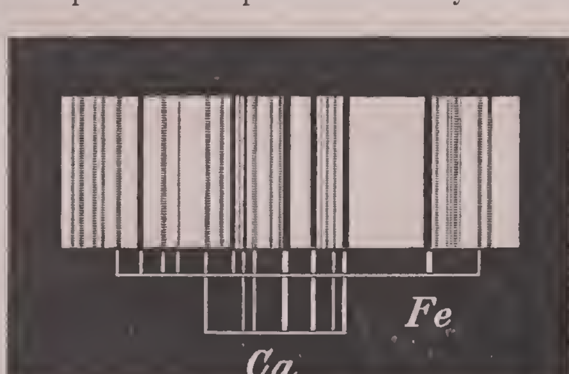

FIG. 7.

in the spectrum of the vapor of which hundreds of lines have been mapped and found to coincide with solar lines.

Kirchhoff and Bunsen explored the entire visible spectrum in the most painstaking and precise manner, measuring the position of thousands of lines in the spectrum of the sun and in those of the different elements. For this purpose they used a spectrometer with a train of four prisms. The results were mapped upon a large scale. Ångström and Thalén made a set of equally careful measurements, and produced maps agreeing well with that of the former observers. By the use of concave gratings and photographic plates Rowland has since been able to obtain absolute values of wave-lengths much more accurate than any hitherto made by the system of hand measurements, while Abney and also Cornu, likewise by photographic methods, have extended the spectrum map to regions lying far beyond the limits of visibility in the direction of the red and of the violet. Fig. 7 shows a small portion of the solar map (in the green), which contains lines due to the vapors of iron and of calcium. The coincidence of these with certain bright lines in the spectra of those metals is also indicated.

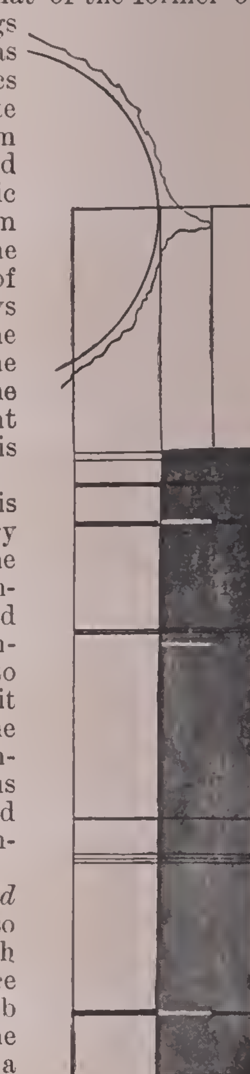

FIG. 8.

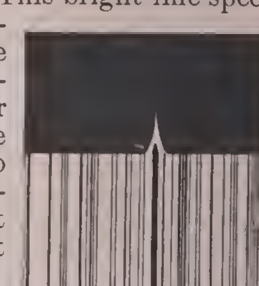
The application of spectrum analysis in astronomy has led to extraordinary extensions of our knowledge of the chemical constitution and physical condition of the sun, and even of fixed stars, comets, and nebulæ. The attachment of the spectroscopic eyepiece to the telescope, for example, has made it possible to explore the surface of the sun in detail with reference to its constitution. Only a few of the numerous striking and beautiful results obtained in this field of research can be mentioned here.

*Spectrum of the Chromosphere and Protuberances.*—If the telescope be so adjusted that the field of view, through the slit of the spectroscopic eyepiece (the slit being perpendicular to the limb of the sun), comprises a portion of the sun's face, the chromosphere, with a protuberance, and the sky lying beyond the limits of the latter, as shown in Fig. 8, a triple spectrum will be formed: (1) The spectrum of the photosphere, consisting of the continuous spectrum of the underlying molten constituents of the body of the sun, crossed by the black lines produced by passage through the cooler gases of the solar atmosphere; (2) the spectrum of the protuberance, which consists of the bright lines of hydrogen corresponding to C and F of Fraunhofer, and a bright line known as $D_3$. Until 1895 it was believed that this line had no counterpart among the lines of terrestrial elements, and it was accordingly ascribed to a hypothetical solar substance to which the name *helium* was given. In that year, however, the chemist Ramsay announced the discovery of the helium line in the spark discharge of a gas obtained from cleveite, a mineral found in Norway. This bright-line spectrum is superimposed upon a faint solar spectrum of the usual character, due to diffused or stray sunlight. (3) Diffused sunlight also fills the remainder of the slit, which otherwise would have for its field the blackness of space, so that beyond the limits of the chromosphere we can still distinguish the faint spectrum to which reference has just been made.

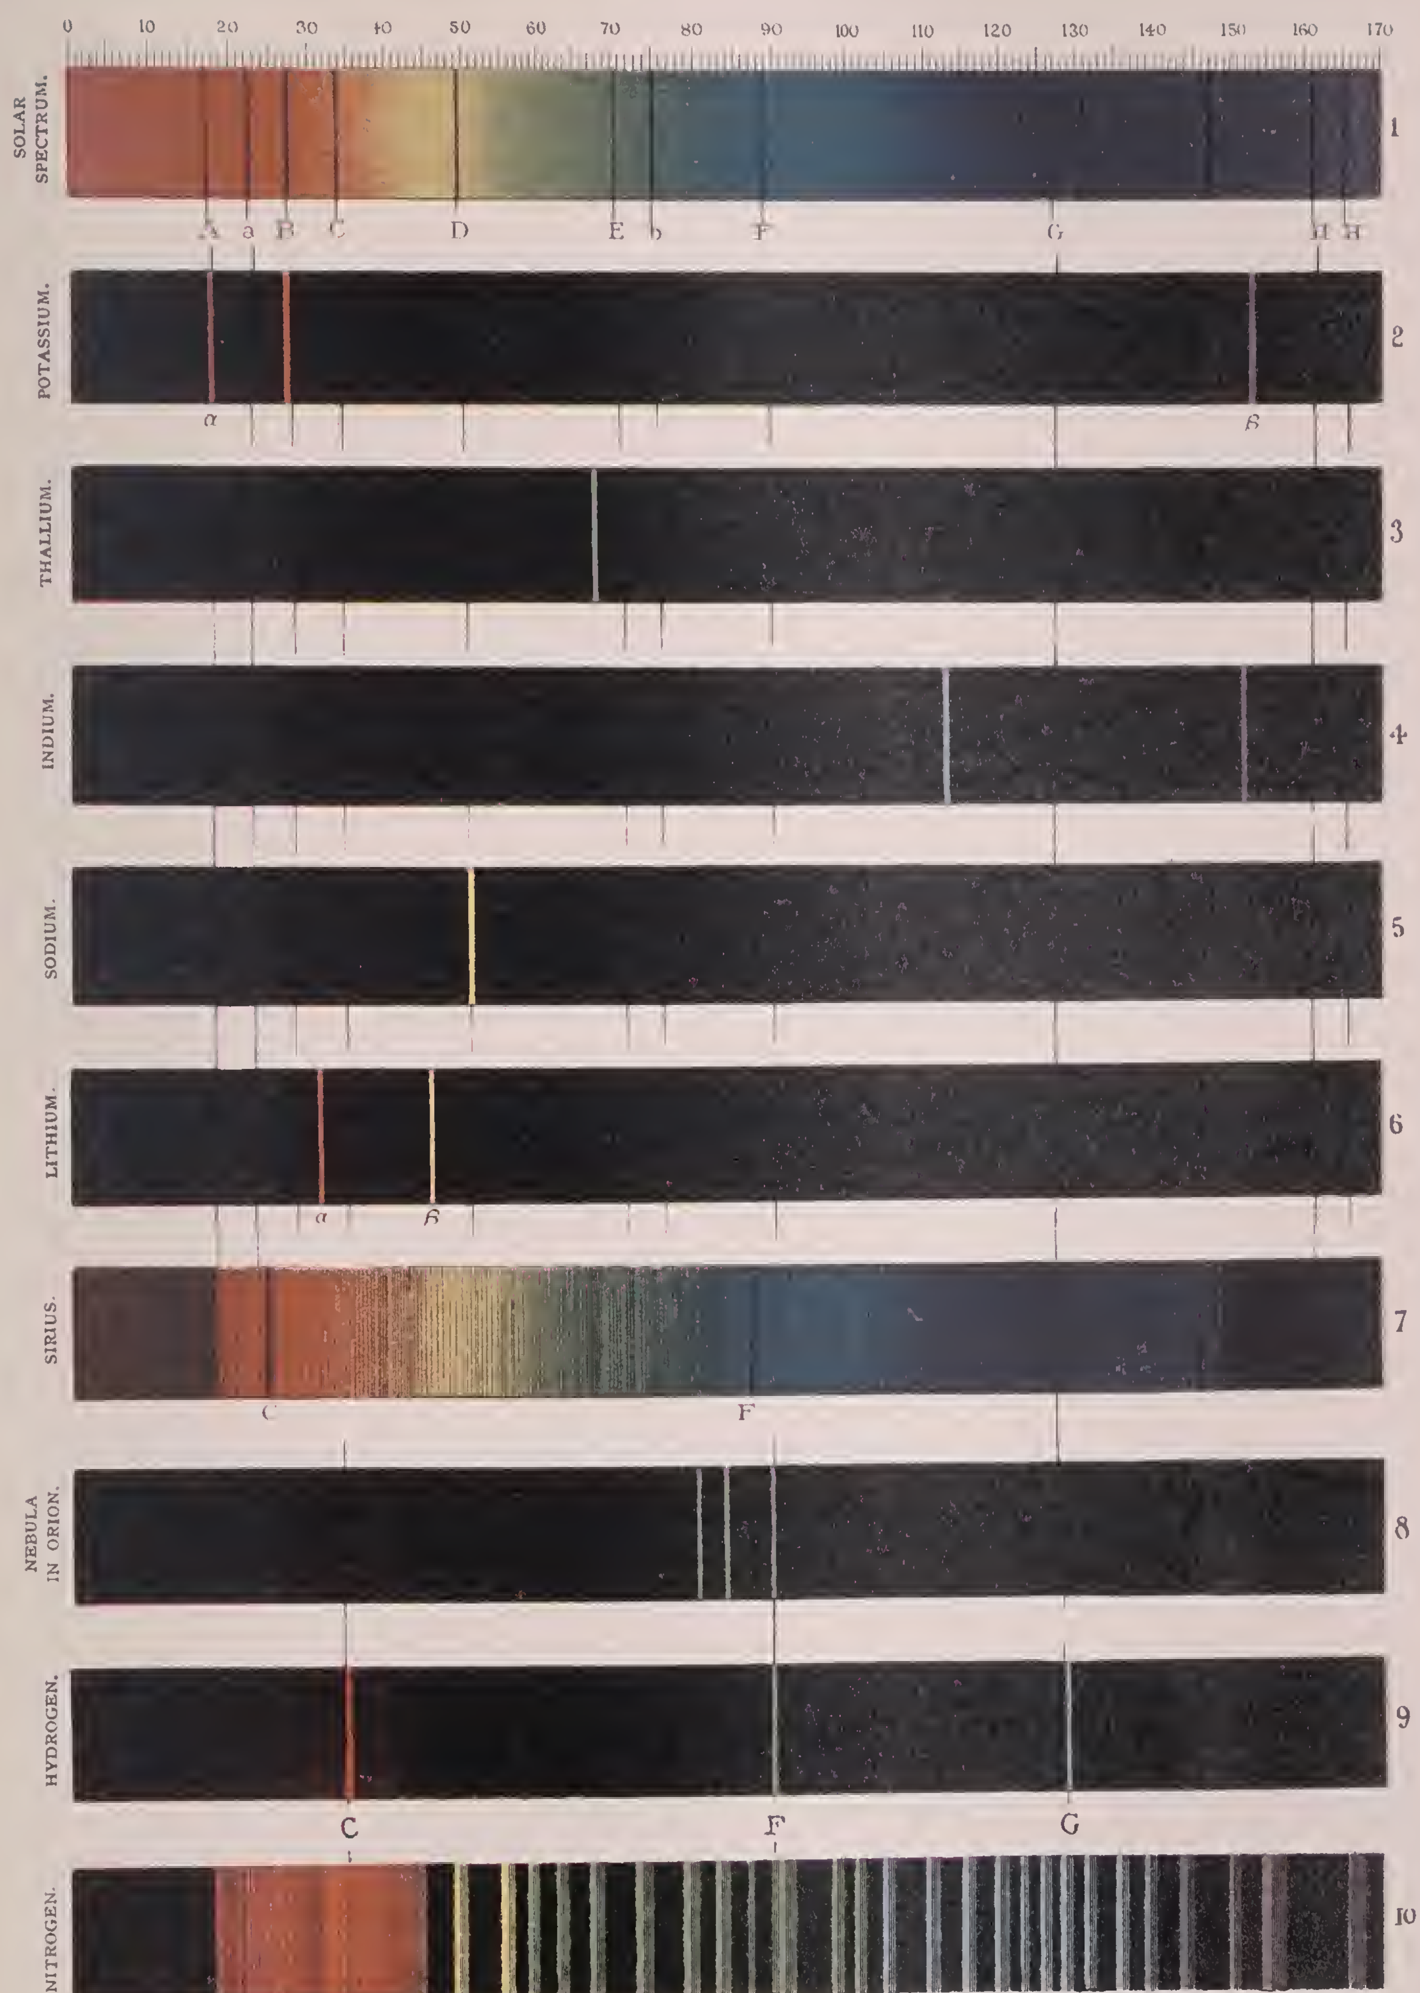


F
FIG. 9.

This method makes it possible to determine the height to which a given constituent of the chromosphere, such as hydrogen, rises above the limb of the sun, the pressures under which it exists, and even the motions which it undergoes.

The hydrogen-line (F), for example, seen through a narrow slit, the field of which extends across the limb of sun into and through the chromosphere, sometimes appears as in Fig. 9, the line being reversed at the limb and then dwindling to a point. This effect is indicative of the diminishing pressure. Frequently the reversed line of the chromosphere is distorted in a manner of which Fig. 10 is typical, and its displacement shows that the glowing gases are moving either

## TABLE OF THE SOLAR AND SOME OTHER SPECTRA.



toward the observer (when the displacement is to the violet) or away from him (when the displacement is toward the red). The same displacement of the lines in the spectra of fixed stars is used in computing the component of their velocity which lies in the line of sight.

Fig. 10.

*The spectra of nebulæ and comets* show for these bodies a gaseous constitution. Instead of a continuous spectrum with absorption lines, we find in the case of the former class two or three bright lines, ascribable to hydrogen and nitrogen. (See Fig. 11.) Comets also show bright bands which correspond in position to the groups of lines which constitute the spark spectrum of the hydrocarbons. See Fig. 12.

*Applications to Chemical Analysis.*—The fact that each metal when vaporized and heated emits light of certain definite wave-lengths affords an important means of detecting its presence. The method is used chiefly for the determination of the alkaline metals and the metals of the alkaline earths, since these almost without exception can be made to give their characteristic colors at the temperature of the Bunsen flame. For such purposes a one-prism spectroscope with an arbitrary scale is commonly used, and the bright lines are mapped with reference to that scale. No accurate determination of wave-lengths is necessary, since the object is simply to recognize the existence of certain well-defined lines, or groups of lines, and to distinguish them from one another. Fig. 13 shows the grouping of lines in the prismatic spectra of the most important of the above-mentioned classes of metals.

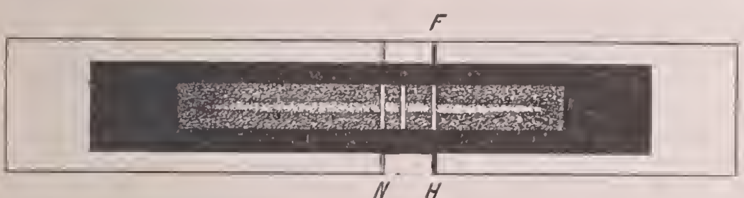


Fig. 11.

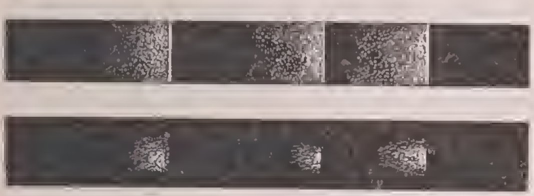

Fig. 12.

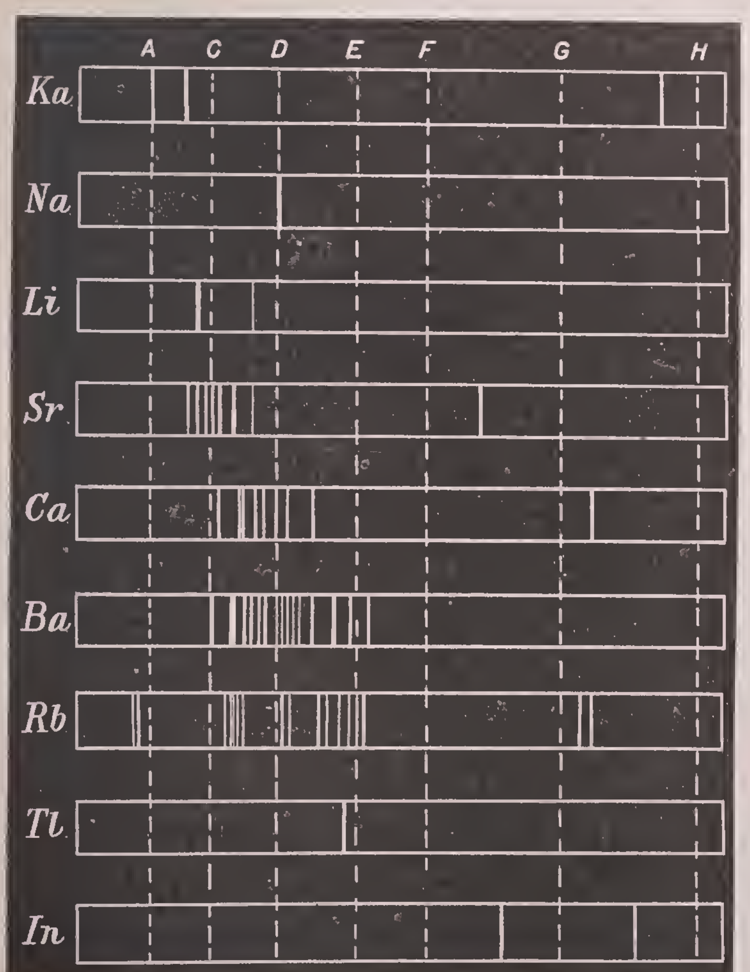

Fig. 13.

Spectrum analysis by means of the bright lines of the elements is a qualitative method of the greatest delicacy.

In the case of the metals easily volatilized in the Bunsen burner it is possible, according to the determinations of Kirchhoff and Bunsen, and of Simmler, of Cappel, and others (see Kayser, *Lehrbuch der Spektral Analyse*, p. 88), to detect the following minute quantities:

TABLE II.

| Metal. | Amount detected, grammes. | Metal. | Amount detected, grammes. |
|---|---|---|---|
| Caesium | $4{\cdot}00\times10^{-8}$ | Strontium | $3{\cdot}33\times10^{-8}$ |
| Rubidium | $1{\cdot}43\times10^{-7}$ | Calcium | $2{\cdot}00\times10^{-8}$ |
| Potassium | $3{\cdot}33\times10^{-7}$ | Manganese | $1{\cdot}2\times10^{-5}$ |
| Sodium | $7{\cdot}16\times10^{-11}$ | Indium | $5{\cdot}00\times10^{-7}$ |
| Lithium | $1{\cdot}66\times10^{-9}$ | Thallium | $2{\cdot}00\times10^{-8}$ |
| Barium | $5{\cdot}00\times10^{-7}$ | Copper | $3{\cdot}5\times10^{-6}$ |

The spectrum of the metals depends to a great extent upon the temperature of the incandescent vapor. Heating does not shift the position of the lines, but it increases their brilliancy and brings into view new ones, which had been too weak to be seen in the spectrum of the cooler vapor. Sodium, for example, which in the Bunsen flame shows only the well-known double line D, has been found by Liveing and Dewar to possess at higher temperatures at least seven other pairs of lines distributed throughout the spectrum from red to violet. A convenient method of getting high-temperature spectra consists in volatilizing the metals in the electric spark. In this way the brilliancy of the spectrum is enhanced, and new metals, too refractory for vaporization at flame-temperatures, are made amenable to the methods of spectrum analysis. The delicacy of the method of the spark-spectrum, in the case of various metals, many of which give no line-spectrum whatever in the Bunsen flame, is given in table III.

TABLE III.

| Metal. | Amount detected, grammes. | Metal. | Amount detected, grammes. |
|---|---|---|---|
| Caesium | $2{\cdot}5\times10^{-7}$ | Cobalt | $6{\cdot}66\times10^{-8}$ |
| Rubidium | $1{\cdot}00\times10^{-6}$ | Nickel | $1{\cdot}66\times10^{-6}$ |
| Potassium | $2{\cdot}5\times10^{-6}$ | Iron | $3{\cdot}84\times10^{-8}$ |
| Lithium | $2{\cdot}5\times10^{-11}$ | Thallium | $1{\cdot}25\times10^{-11}$ |
| Barium | $1{\cdot}11\times10^{-9}$ | Cadmium | $5{\cdot}55\times10^{-8}$ |

*Absorption Phenomena by Transmission through Solids and Liquids.*—Spectrum analysis is not confined to the detection of elements by means of the bright lines of their emission spectra and the corresponding black lines in the spectra of the sun and stars. It makes use also of the selective absorption which light suffers when transmitted through various solids and solutions. In cases in which the absorption is confined to certain definite regions dark bands are formed, the position of which indicates the character of the absorbing medium, while the density and width of the bands enables the experimenter to estimate the strength of the solution with considerable accuracy. Well-known cases are those of chlorophyl and blood, the spectra of which are shown in Fig. 14. Cerium, didymium, and other of the

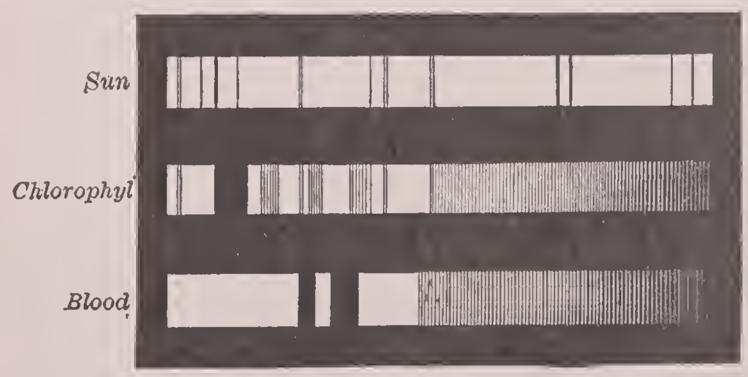

Fig. 14.

rare earths lend themselves peculiarly to this method, on account of the sharpness of their bands. (See Fig. 15.) When

Fig. 15.—Absorption bands due to didymium.

small dispersion is used some of the narrower bands might easily be mistaken for true Fraunhofer lines, but higher dispersion shows them in their true character.

Even when no sharply marked bands are produced a spectrophotometric study of the absorption spectrum often

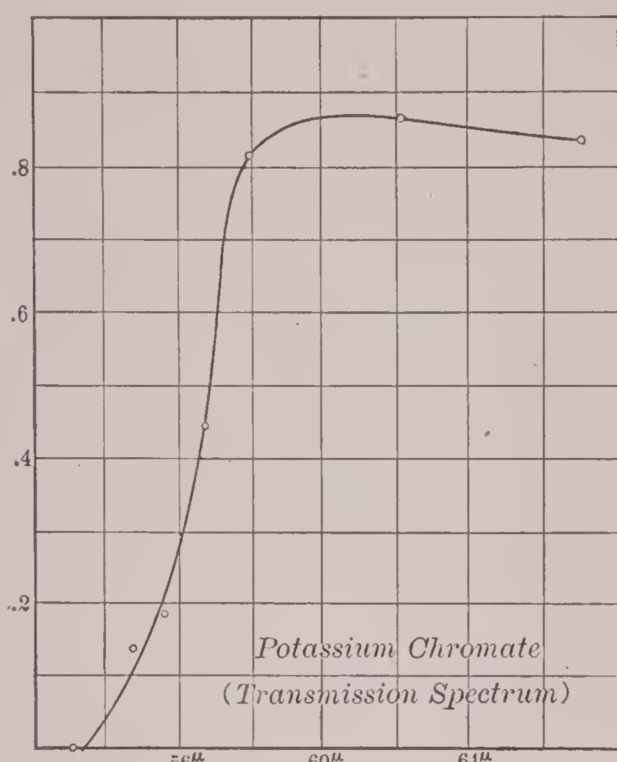

Fig. 16.

affords definite information concerning the character of the transmitting medium. A solution of potassium chromate, for example, submitted to measurement gave the curve of brightness shown in Fig. 16, in which abscissas are wave-lengths and ordinates are percentages of light transmitted. Pigments, viewed by reflected light, give spectra, likewise capable of spectrophotometric analysis and characteristic of the chromatic properties of the material. Figs. 17 *a* and 17 *b* will serve to illustrate this method of expressing or defining the color of a pigment. The curves refer to sulphur, mercuric sulphide, chromic oxide, and artificial ultramarine. Abscissas are wave-lengths and ordinates are intensitives in terms of the intensity of an ideal white substance, which is defined as reflecting all visible wave-lengths as magnesium oxide reflects light of the wave-length ·59μ. For the details of the methods by which these results were obtained, see *Philosophical Magazine* (5), vol. xxxii., p. 405; also vol. xxxiii., p. 19.

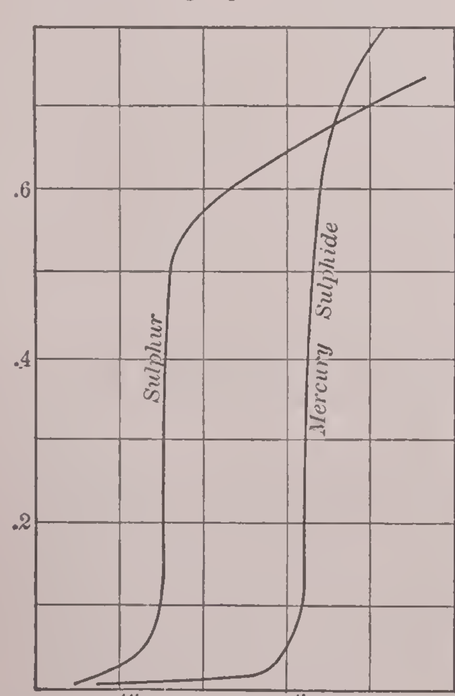

Fig. 17 *a*.

Similarly, by observation of the spectrum of a glowing body at different stages of incandescence and comparison of the same, wave-length by wave-length, with the spectrum of a standard lamp, the development of radiation with rise of temperature can be definitely determined. Fig. 18 shows the results of such an investigation of the spectrum of platinum between 700° C. and 1,000° C. The ordinates are ratios of the brightness of the platinum spectrum to that of the standard lamp, which was an electric glow-lamp maintained as nearly as possible at a temperature of incandescence corresponding to that of a luminous gas-flame. The adjustment was such that the brightness of the platinum spectrum at 1,000°, wave-length ·59μ, was equal to that of the corresponding wave-length in the spectrum of the standard.

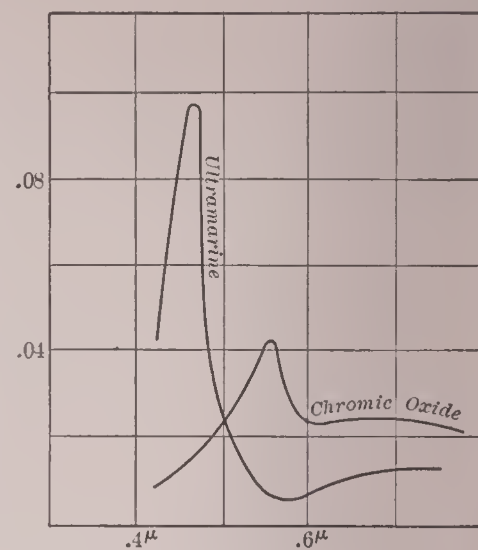

Fig. 17 *b*.

*Invisible Parts of the Spectrum (the Infra-red and Ultra-violet).*—When a spectrum is produced by refraction or diffraction, the only rays capable of affecting the retina lie between wave-lengths ·39μ and ·76μ. Rays of wave-lengths both longer and shorter than the above are present, however, and these constitute the *invisible spectrum.* Waves greater than ·76μ find positions lying beyond the extreme limit of the red. They form what is termed the region of the *infra-red.* Waves shorter than ·39μ are all more strongly refracted than the rays of the visible spectrum. They lie beyond the limits of the violet and constitute the *ultra-violet* spectrum.

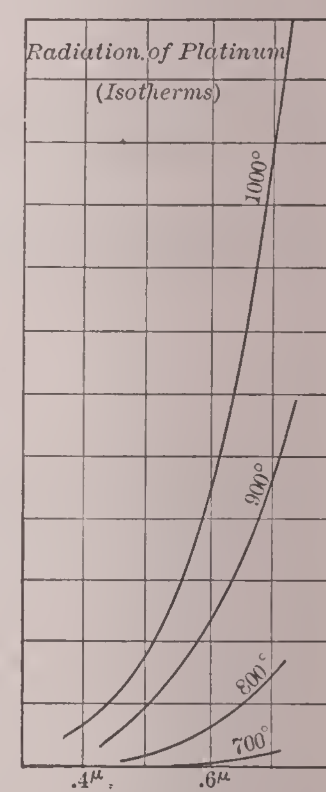

Fig. 18.

In the investigation of these invisible rays indirect methods have to be used. For the infra-red the rays may be allowed to fall upon some surface which becomes luminescent (phosphorescent) under their action. This is the method used by Draper, by Becquerel, and by Lommel and others.

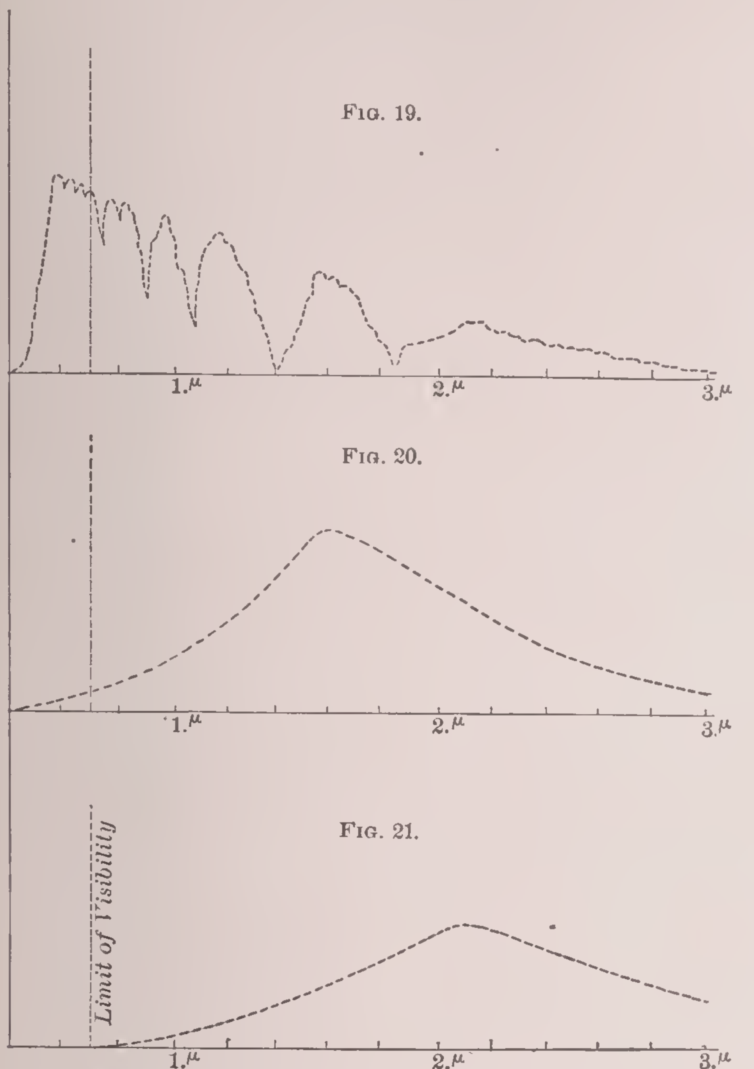
The result of this process is to cause those portions of the luminescent surface upon which the infra-red rays fall to shine, while the other portions remain dark. In this way the intenser portions of the infra-red spectrum can be explored, and if the law of the dispersion apparatus is known they can be mapped.

It is possible also, as has been shown by Abney, to obtain photographic plates which are sensitive to long wave-lengths, and by the use of these to photograph a considerable portion of the infra-red spectrum.

The most complete method of studying the invisible regions beyond the red consists in measuring the intensity of the rays directly by means of their heating effect. For this purpose Fizeau and Foucault used thermometers; Lamansky, Mouton, Dessains, Nichols, and others the linear thermopile; Langley, Ångström, Snow, Paschen, and many other observers the bolometer.

By these various methods it is known that the region of the infra-red is similar to the visible region of the spectrum in nearly every particular, but that it comprises a very much greater range of wave-lengths. While the visible spectrum is all included within about an octave, the bolometer gives evidence of waves more than ten times as long as the longest visible ray. If the spectrum of an incandescent solid be explored by means of thermopile or bolometer, the infra-red spectrum will be found to be continuous, the intensities rising to a maximum in some region, the wave-length of which depends upon the temperature of the source. See Fig. 20, which gives Langley's curve of intensities in the spectrum of a luminous gas-flame.

If the source have a temperature below the red heat an infra-red spectrum will still be found to exist, the intensities of which are all less and the maximum in a region of greater wave-length. The curve of intensities, moreover, will disappear on the side toward the red, before the boundary of the visible spectrum is reached. See Fig. 21.



FIGS. 19, 20, and 21, showing the curves of intensities of sunlight, of gas flame, and of a solid below red heat, respectively.

If the source be sunlight we find its spectrum crossed by dark lines and also by bands due to absorption on the part of the atmosphere of the earth. The curve then appears as in Fig. 19, which is also from measurements by Langley.

If the source be a metallic vapor the bolometer indicates the extension of a bright-line spectrum characteristic of that metal throughout the infra-red. Fig. 22 is a diagram giving the results of bolometric exploration of the spectrum of potassium, made by Snow. Abscissas are wave-lengths and

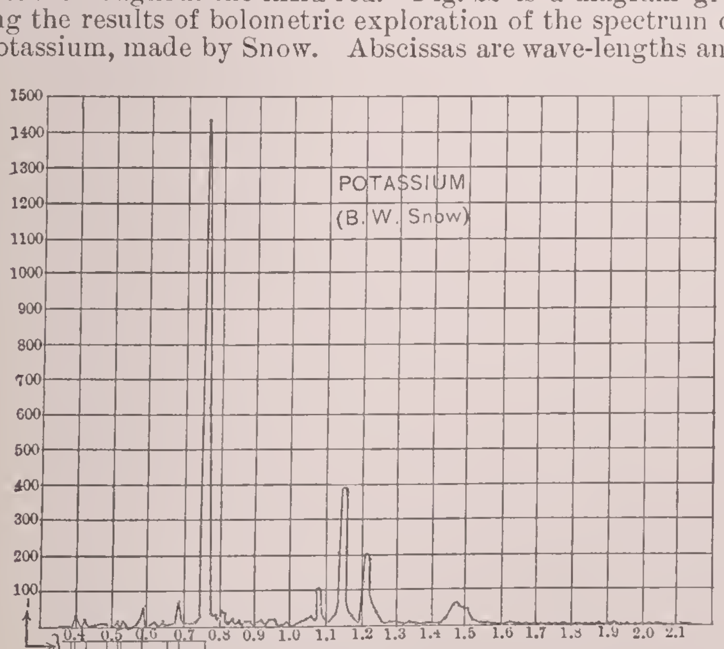


FIG. 22.

ordinates are intensities. It will be seen that there are three bright lines between 1·0μ and 1·3μ, and probably a group of lines, which could not be resolved by means of the bolometer, in the region 1·5μ.

In the ultra-violet region of the spectrum the intensity of radiation is too small to admit of the general use of bolometric measurements. These shorter wave-lengths are, however, readily studied by photography, and they can also be rendered visible by the use of a luminescent (fluorescent) substance, as has been shown by H. Becquerel, Soret, and others. Among the materials which give back visible rays when exposed to the action of the ultra-violet are chlorophyll solution, petroleum, various coal-tar dyes in solution; also uranium-glass and some sorts of fluor-spar. See FLUORESCENCE.

Of the two methods, the photographic is by far the more complete and satisfactory. By means of the sensitive plate and the concave grating, maps giving every detail may be obtained. If the apparatus be of such a character that the rays pass through glass, the spectrum will seem to come to an end in the neighborhood of ·32μ, because glass becomes opaque to still shorter wave-lengths. If quartz lenses be substituted, or if concave mirrors be used instead of lenses, the map can be extended even further beyond the violet.

The results of investigations in the ultra-violet, as in the case of those upon the infra-red of the spectrum, show that no sudden changes take place as we pass beyond the limit of visibility. Sunlight, in the ultra-violet, still shows a continuous spectrum crossed by a multitude of dark lines; glowing vapors, such as those of the electric arc, show groups of lines which to an eye capable of vision in such rays would constitute a bright-line spectrum of the usual type.

See, further, article SPECTROSCOPE; also Schellen, *Spectrum Analysis*; Roscoe, *Lectures on Spectrum Analysis*; and the works of Lockyer, Huggins, Langley, Vogel, K. Ångström, Abney, H. Becquerel, Soret, etc. E. L. NICHOLS.

**Spectrum Analysis**: See SPECTROSCOPE and SPECTRUM.

**Speculation**: See POLITICAL ECONOMY.

**Spec'ulum** [Lat., mirror]: in optics and astronomy, a reflecting surface, usually of metal, though the term has also been frequently applied to unsilvered glass since the introduction of silvered-glass telescopes by Foucault and Steinheil in 1857. See TELESCOPE.

**Spedding**, JAMES: scholar; b. near Bassenthwaite, Cumberland, England, in June, 1808. He studied at Trinity College, Cambridge, of which college he was afterward made an honorary fellow; graduated in 1831. His life-work was the study and exposition of Bacon, begun by a pitiless exposure of Macaulay's showy and inaccurate essay on Bacon, *Evenings with a Reviewer* (privately printed in 1848 and reissued in 1882). His great edition of the *Works of Francis Bacon* was published in 7 vols. in 1857–59. In this he was assisted by R. L. Ellis and D. D. Heath. In 1870–76 he published a *Life and Letters of Francis Bacon*, including all his occasional writings, also in 7 vols.; and in 1878 *Life and Times of Francis Bacon* (2 vols.). Besides his work on Bacon he was the author of *Publishers and Authors* (1867) and *Reviews and Discussions* (1869). D. in London, Mar. 9, 1881. H. A. BEERS.

**Speech**: See LANGUAGE and ACOUSTICS (*The Voice*).

**Speed**, JAMES: lawyer; b. in Jefferson co., Ky., Mar. 11, 1812; graduated at St. Joseph's College 1828; studied law at Transylvania University; began its practice at Louisville 1833; was a member of the Legislature in 1847, State Senator 1861, U. S. Attorney-General Nov., 1864–July, 1866, and in the same year was chosen president of the Philadelphia Loyalists' convention; was Professor of Law in the University of Louisville. D. at Louisville, Ky., June 25, 1887.

**Speed**, JOHN: antiquary; b. at Farrington, Cheshire, England, in 1542; was a tailor in London until late in life, but at the same time was amassing an extensive knowledge of English antiquities, and was enabled by Sir Fulke Greville to publish a costly and valuable series of works. He published anonymously about 1590 a treatise on the *Genealogies of the Scriptures*, afterward prefixed to the first edition of King James's Bible (1611), but his first appearance as an author was in 1608, when he printed fifty-four maps of various counties and cities, and engravings of antiquities of England and Wales, which were incorporated into *The Theatre of the Empire of Great Britain* (folio, 1611). In the same year he published his *History of Great Britain under the Conquests of the Romans, Saxons, Danes, and Normans*. D. in London, July 28, 1629.

**Speedwell**: a plant of the genus *Veronica* of the family *Scrophulariaceæ*. The species are very numerous, comprising annual and perennial herbaceous plants and small shrubs, natives of temperate and cold climates in all parts of the globe, some of them growing in wet ditches or in marshes, others on the driest soils, but all having very beautiful blue, white, or pink flowers. Revised by CHARLES E. BESSEY.

**Speer**, WILLIAM: See the Appendix.

**Speichern**, or **Spichern**: See SAARBRÜCKEN.

**Speier**: See SPEYER.

**Speke**, JOHN HANNING: explorer; b. at Jordans, Somersetshire, England, May 4, 1827; entered the army in 1841; served in India and in the Crimean war; accompanied Capt. Richard F. Burton in the expedition which resulted in the discovery of the great lakes of Central Africa, and afterward was at the head of another expedition (with Capt. Grant) which discovered the connection of the Nile with those lakes. Capt. Speke published a *Journal of the Discovery of the Source of the Nile* (1863), and *What Led to the Discovery of the Source of the Nile* (1864); received gold medals from the geographical societies of France (1860) and England (1861), and from the King of Italy; and was engaged after his second expedition in a bitter controversy with Capt. Burton as to the merits of their respective discoveries. He accidentally shot himself near Bath, Sept. 15, 1864, and died on the same day.

**Spelman**, Sir HENRY: antiquary; b. at Congham, Norfolk, England, in 1562; graduated at Cambridge about 1580; studied law at Lincoln's Inn, but devoted himself chiefly to archæology; was in 1604 high sheriff of Norfolk; was employed by James I. upon important commissions; was knighted about 1612, in which year he withdrew from public business and settled in London; published his treatise *De Non Temerandis Ecclesiis; of the Rights and Respects due to Churches* (1613). D. in London in 1641, and, by special order of Charles I., was buried in Westminster Abbey, near the monument of Camden. Vol. i. of his *Glossarium Archæologicum*, extending to the letter L, was published 1626; vol. ii., completed by his son, Sir John, and by William Dugdale, appeared in 1664, and the whole work was issued in a single folio volume in 1687. Vol. i. of the *Concilia* was issued in 1639: vol. ii., chiefly by Dugdale, in 1664. The *Reliquiæ Spelmannianæ* (Oxford, folio, 1698), with a *Life*, was edited by Bishop Edmund Gibson.—His son, Sir JOHN, was knighted 1641 "in consideration of his father's good services both to Church and state," and was made master of Sutton's Hospital. He edited the *Saxon Psalter* (1641) and a *Life of Alfred the Great* (Lat. trans. 1678; Eng. original edited by Thomas Hearne, 1709). D. at Oxford, July 25, 1643.—EDWARD SPELMAN, a great-grandson of Sir Henry, published an elegant translation of Xenophon's *Anabasis* (1742) and of the *Roman Antiquities* of Dionysius Halicarnassus (4 vols. 4to, 1758). D. in Norfolk in 1767.

**Spelt** [O. Eng. *spelt*, from Lat. *spel'ta*, spelt]: the *Triticum spelta*, probably the *far* of the ancient Romans and the *zea* of the Greeks; a grain somewhat resembling wheat, but distinct from it. It can be grown on poorer soils than those which are required for wheat. It is much raised in parts of Europe, and crops of it are occasionally seen in the U. S., as in Virginia. In quality it is much inferior to wheat. *T. bengalense* is raised in India. Lesser spelt, or St. Peter's corn (*Triticum monococcum*), called also one-grained wheat, is raised to some extent on poor soils in Europe.

**Spelter**: commercial name for pig or block ZINC (*q. v.*).

**Spence**, HENRY D. M.: See the Appendix.

**Spencer**: city; capital of Owen co., Ind.; on the White river, and the Penn. Railroad; 52 miles S. W. of Indianapolis (for location, see map of Indiana, ref. 8–C). It is in an agricultural, stock-raising, and lumbering region; has valuable building-stone quarries, block and cannel coal mines, woolen, flour, saw, and planing mills, machine-shops, and pork-packing house; and contains a State bank with capital of $50,000, a private bank, and two weekly newspapers. Pop. (1880) 1,655; (1890) 1,868; (1900) 2,026.

**Spencer**: town; capital of Clay co., Ia.; on the Little Sioux river, and the Chi., Mil. and St. P. Railway; 80 miles N. W. of Fort Dodge (for location, see map of Iowa, ref. 2–E). It is in an agricultural and stock-raising region, and contains a national bank with capital of $100,000, a State bank with capital of $25,000, 2 private banks, and 3 weekly newspapers. Pop. (1880) 1,392; (1890) 1,813; (1900) 3,095.

**Spencer**: town; Worcester co., Mass.; on the Boston and Albany Railroad; 11 miles S. W. of Worcester, one of the county-seats (for location, see map of Massachusetts, ref. 3–F). It contains a public high school, the Richard Sugden Public Library (founded in 1857), electric railway, a national bank with capital of $150,000, a savings-bank, and three weekly newspapers. The principal industries are the manufacture of shoes and wire. Here, it is claimed, is the largest shoe-factory in the world. Spencer was originally in the grant of Leicester; was made the West Parish of Leicester in 1744; incorporated as a town under its present name in 1753; and its first church was organized in 1744. Pop. (1880) 7,466; (1890) 8,747; (1900) 7,627. EDITOR OF "LEADER."

**Spencer**, HERBERT: philosopher; b. in Derby, England, Apr. 27, 1820; was an only surviving child. His father and grandfather were teachers. Of delicate health in boyhood, he was subjected to little outside pressure, his father, a man of strong character, more than usual breadth of culture, and original views, supervising his early education, but leaving him very much to himself. At the age of thirteen he was sent to study with an uncle, the Rev. Thomas Spencer, a liberal clergyman and a scholar, at that time perpetual curate of Hinton Charterhouse, near Bath. Here he remained three years, carrying on the study of natural history, begun in early childhood under his father's encouragement, and devoting himself to mathematics, where the originality of his mind was strikingly shown by the development of a taste and capacity for working out original problems. He then, too, became familiar with physical and chemical operations, his intellectual bias being strongly in the direction of experimental inquiry and original research. Deciding, in opposition to his uncle's wishes, not to prepare himself for a university career, he returned to Derby, where he was busied for a short time with inventions and miscellaneous study, and, after a brief interval of teaching, in 1837 entered the office of Sir Charles Fox, and began work as a civil engineer. After this he was engaged for several years on railways, devoting his spare time to scientific experiments and studies, and to occasional contributions to *The Civil Engineer and Architect's Journal*. The first indication of his awakening interest in other directions was given in 1842 by the publication in *The Nonconformist* of a series of letters on *The Proper Sphere of Government*. These were reprinted in pamphlet form during the following year, and are interesting as containing, in crude form, the first suggestions of many opinions on social questions afterward so fully developed in his maturer works. Growing discouraged with the prospects of his profession, he presently gave up engineering work and moved to London, where he secured a position on the staff of *The Economist* newspaper, of which in 1848 he became sub-editor. In 1850 he published his first considerable work, *Social Statics*, which was largely a development in more scientific form of the ethical and sociological ideas contained in his letters on government. The work was a treatise on social science, based upon the conception of the evolution of society through the operation of natural laws; and, though Spencer afterward grew dissatisfied with its metaphysical implications, it excited widespread interest at the time on account of its original and advanced views. He then devoted himself to literary work, contributing elaborate articles on a large variety of subjects to the leading English reviews. But though the subject-matter of his work led him into widely diversified fields of knowledge and inquiry, his course of thought was systematic; and the numerous masterly essays which he published from 1852 to 1860 were mainly devoted to the elaboration and application to various important questions of the principle of evolution. These papers reappeared in the U. S. in the collections entitled *Illustrations of Universal Progress*; *Essays, Moral, Political, and Æsthetic*; *Education, Intellectual, Moral, and Physical*; and *Recent Discussions in Science, Philosophy, and Morals.* In 1855 Spencer published a very able and original work entitled *The Principles of Psychology*, pronounced by J. S. Mill to be "the finest example we possess of the psychological method in its full power." In this work (afterward included in his larger treatise on the same subject) the doctrine of evolution was applied to the science of mind. Life is conceived as "the definite combination of heterogeneous changes, both simultaneous and successive, in correspondence with external coexistences and sequences"; and the ground taken is therefore that mental faculties throughout the whole scale of animal life, from lowest to highest, have been developed by experience through the intercourse of organisms with their environment, the principles of variation and heredity being marked out as the causes of the slow modifications which have taken place during vast periods of time. The work was so profound in exposition, and so greatly in advance of the thought of the day, that it produced but little public impression. Spencer had grasped the conception of evolution in its broad relations, and in 1858, while engaged on an essay on the nebular hypothesis, he reached the conclusion that it is a universal process, dependent upon the laws of matter and force, conformed to by all orders of phenomena, and capable of being resolved and formulated. Being the great principle or law of the successive changes of phenomena, involving the unfolding and (on its obverse side and as its necessary corollary) the dissolution of all things, it seemed to offer the basis of a philosophy of nature from the genetic point of view—understanding by the term "philosophy" the completest unification of positive knowledge by universal principles. In other words, the conception of evolution presented itself to him as the basis of a system of thought under which was to be generalized the complete history of the knowable universe, and by virtue of which all branches of scientific knowledge were to be unified by affiliation upon the primal laws underlying them all. Though a rough sketch of the main outlines of the system, as they occurred to him at the time, was mapped out almost immediately, it was not till the following year, 1859 (a year otherwise memorable for the publication of Darwin's *Origin of Species*), that a detailed plan of the various connected works in which these conceptions were to be developed was finally drawn up, and not till 1860 that it was given to the small handful of readers interested in such subjects in the form of a prospectus. This prospectus contained a complete outline of the ten volumes which were to be devoted to the carrying out of the task, and brief comparison of the analysis there given with the works themselves, so far as they have been issued, will show how clearly he must have had the whole vast scheme sketched out in his mind, down to the minutest details, before he set himself to the penning of a single line. To the prosecution of this great enterprise the major part of the energies of his life has from that time forth been devoted, and the *System of Synthetic Philosophy* has been actually brought within measurable distance of completion. Blanks have been left in the sociological divisions, and will probably never be altogether filled up; but save for these lacunæ the work stands in practically finished form. The introductory volume of the series, *First Principles*, was published in 1862, and was concerned with the establishment of those first or foundation principles which, there classed together in their most general and abstract statements, were in subsequent volumes to be worked out through the special phenomena of biology, psychology, sociology, and ethics. The initial task was to define the limits of philosophy, and this is done by the postulation of two categories, the unknowable and the knowable, to the former of which is relegated the absolute, infinite, or unconditioned, and all that pertains thereto, while the latter is seen to include the relative, finite, or conditioned, which alone constitutes the sphere and subject-matter of philosophy properly so called. In this way Spencer aimed to clear the field of his inquiry of what he deemed to be the fruitless speculations of metaphysics, so that his proper work might be coextensive with the sphere of science and strictly conform to its methods. Yet, while confining his attention within the limits of the phenomenal universe, Spencer shows that by the very terms of its cognitions the mind can not escape the consciousness of an unknowable power, of which all phenomena are manifestations, and which remains the ultimate and unresolvable basis of consciousness, though, from the nature of human intelligence, it can be neither grasped nor understood. Covering these preliminary considerations in the space of something over 100 pages, *First Principles* proceeds to deal with the foundations of the scheme; and here the law of evolution is broadly worked out and formulated in terms of matter and motion, or rather in terms of force, into which our conceptions of matter and motion alike are shown to be in the last analysis resolvable. These, as legitimate concepts of science, furnish a proper basis for a superstructure of philosophy. All the "phenomena of the universe," from their great features down to their minutest details, are necessary results of the persistence of force under its forms of matter and motion. This persistence of force gives rise "throughout the universe in general and detail," to unceasing redistributions of matter and motion; and these redistributions constitute evolution "where there is a predominant integration of matter and dissipation of motion," and dissolution "where there is a predominant absorption of motion and disintegration of matter." The rhythm thus set up by these changes and counterchanges "is, so far as we can see, universal and eternal, each alternate phase of the process predominating now in this region of space and now in that, as local conditions determine"; the tendency in that portion of the universe with which we are acquainted being now in the direction of evolution. There is thus reached the famous definition of evolution as "a change from an indefinite, incoherent, homogeneity to a definite, coherent, heterogeneity, accompanying the dissipation of motion and integration of matter" (or, as the earlier statement read, "through continuous differentiations and integrations"). This formula sums up and covers all the processes of development in nature and in mind (in other words, all changes along what we should call the ascending scale as contradistinguished from the descending scale of dissolution), from the unrolling of a planetary system to the sprouting of a wayside flower, and from the genesis of intelligence to the latest variations of social life. These first principles being thus laid down in their broadest and most abstract statements, Spencer proceeded to the task of working them out in greater detail through all the varied phenomena presented by the universe at large. First in order should properly have come the application of such principles to inorganic nature, but this great division was passed over entirely, partly (to quote his own words) because "even without it the scheme is too extensive, and partly because the interpretation of organic nature after the proposed method is of more immediate importance." Spencer therefore at once went to work upon the *Principles of Biology*, which he completed in two volumes in 1867. Here the principles of evolution are traced out through the phenomena of life and the laws of organization, one of the most profound and noteworthy parts being that dealing with the "laws of multiplication," and the inferences to be deduced from them in regard to the "multiplication of the human race" and "human evolution in the future." This leads forward insensibly (since we know intelligence only as a concomitant of organization) into the region of psychology; and in 1872 Spencer published *The Principles of Psychology*, also in two volumes. This new work was based upon the treatise of 1855, but embraced many important modifications and extensions to which he had been led by his subsequent studies. It is an elaborate exposition of mental science grounded on biology and interpenetrated everywhere by the doctrines of evolution; and in it, in the opinion of many good judges, Spencer's powers as a thinker and writer reached their culminating point. The fourth division of the system, *The Principles of Sociology*, outlined to occupy three volumes, was completed in Nov., 1896. The first volume, of great bulk, comprising the *Data* and the *Inductions of Sociology*, and a consideration of domestic relations, was finished in 1876; and this was followed at irregular intervals by parts iv., v., and vi., treating of *Ceremonial Institutions*, *Political Institutions*, and *Ecclesiastical Institutions*, all from the standpoint of evolution. But meanwhile, led by increasing ill health to fear lest persistence in the order sketched out in the original prospectus might result in the final and most important portion of the work—*The Principles of Ethics*—being left untouched altogether, Spencer decided to drop the uncompleted part of the *Sociology*, and to devote what remained of life and energy to carrying his principles forward as far as possible into the region of ethics. As a result of this determination appeared in 1879 the first installment of the proposed *Principles of Morality*, *The Data of Ethics*, which, as the first systematic attempt to place ethical questions upon the new basis of evolution, merits the closest attention. This was followed in 1891 by part iv., on *Justice*, a little work dealing with some of the most important issues at present under discussion; in 1892, by parts iii. and iv., the *Inductions of Ethics*, and the *Ethics of Individual Life*; and in 1893 by parts v. and vi., on negative and positive beneficence: the treatise on morality being thus completed in two volumes. The volumes comprising the *Synthetic Philosophy*, vast as is the labor which they represent, do not exhaust the list of Spencer's works. In 1872 appeared, in the International Scientific Series, his delightful little introductory treatise on *The Study of Sociology*; and in preparation for his work in that subject, he also supervised the publication of the *Descriptive Sociology*—an immense cyclopædia of facts designed to exhibit the characters of human societies of all types and in every stage of development. Eight out of the proposed eighteen parts of this were produced, and then, owing to the enormous expense incurred and the scanty public support, Spencer found himself forced to relinquish the undertaking. The astounding extent of Spencer's life labors becomes all the more marvelous when one considers the impaired health which has for many years past incapacitated him for regular and persistent work. His life has thus necessarily been a very retired and, externally considered, a very uneventful one. He has never married, and has uniformly declined all university honors and invitations to join scientific societies. He visited the U. S. in 1882, remaining from August to November. See POSITIVISM. WILLIAM HENRY HUDSON.

**Spencer**, JESSE AMES, D. D.: educator and author; b. at Hyde Park, N. Y., June 17, 1816; graduated at Columbia College 1837; studied theology at the General Seminary of the Protestant Episcopal Church; was ordained 1840; was rector of St. James's church, Goshen, N. Y., 1840–42; Professor of Latin and of Oriental Languages at Burlington College, New Jersey, 1849–50; editor and secretary of the Episcopal Sunday-school Union and Church Book Society 1851–57; declined the vice-presidency of Troy University 1858; was rector of St. Paul's, Flatbush, L. I., 1863–65, and in 1869–79 was Professor of Greek in the College of the City of New York. He was the author of a volume of religious *Discourses* (1843); *History of the English Reformation* (1846); *The East, Sketches of Travel in Egypt and the Holy Land* (1850); a widely circulated *History of the United States* (4 vols., 1856–69); *Greek Praxis* (1870); and *A Course of English Reading* (1873). Dr. Spencer was editor of *The Young Churchman's Miscellany* (1846–68); of 6 vols. of the Classical Series of Thomas K. Arnold (1846–50); of a *New Testament in Greek* (1847), with notes; *Cæsar's Commentaries* (1848), with notes and a lexicon; of Pycroft's *Course of Reading* (1844); of Archbishop Trench's *Poems* (1856); of a new edition of Prof. Alpheus Crosby's *Anabasis* (1875); and *Origen's Works* (vol. iv. in Ante-Nicene Library, 1885). D. Sept. 2, 1898.

**Spencer**, JOHN, D. D.: b. at Bocton, Kent, England, in 1630; educated at the King's School, Canterbury; graduated at Cambridge about 1650; obtained a fellowship at Corpus Christi College 1655; took orders in the Church of England; became rector of Landbeach, master of Corpus, and archdeacon of Sudbury 1667; prebendary of Ely 1672 and dean of Ely 1677. D. at Cambridge, May 27, 1695. He was the author of *A Discourse concerning Prodigies* (1663; 2d ed. 1665); *Dissertatio de Urim et Thummin* (1669). He is best remembered by his *De Legibus Hebræorum Ritualibus et earum Rationibus* (Cambridge, 1685), a work of great learning which excited much controversy. It maintained that the Hebrew ritual was almost entirely borrowed from the Egyptian—a view previously upheld by Maimonides in his *More Nevochim*, and by Sir John Marsham in his *Canon Chronicus Ægyptiacus*, defended by Bishop Warburton and combated by Witsius, Shuckford, Dr. Woodward, and William Jones of Nayland, but now abandoned. Editions of this work were published at The Hague (1686), and at Leipzig (1705). A new edition, brought out by Dr. Leonard Chappelow (Cambridge, 2 vols., 1727), contained a supplementary book (the fourth) left in MS. by the author, and the whole work, with a memoir and a commentary by C. M. Pfaff, was published at Tübingen (2 vols., 1732).
Revised by S. M. JACKSON.

**Spencer**, JOHN CANFIELD, LL.D.: lawyer; son of Ambrose Spencer (1765–1848), chief justice of the State of New York; b. at Hudson, N. Y., Jan. 8, 1788; graduated at Union College 1806; was private secretary to Gov. Daniel D. Tompkins 1807–08; admitted to the bar at Canandaigua 1809; became master in chancery 1811, judge-advocate-general on the northern frontier 1813, assistant attorney-general for Western New York 1815, member of Congress 1817–19, of the State Assembly 1819–20, being Speaker the latter year; State Senator 1824–28; commissioner to revise the statutes of New York 1829; special attorney-general to prosecute the murderers of William Morgan; was secretary of State and superintendent of common schools 1839–41; Secretary of War under President Tyler from Oct., 1841, to Mar., 1843, when he was transferred to the Treasury Department; resigned the latter post 1844 in consequence of his opposition to the annexation of Texas, and thenceforth devoted himself to the practice of his profession. The organization of the State asylum for idiots and the improvement of the common-school system were largely due to him, and he served on many important State commissions. He edited, with a preface and notes, de Tocqueville's *Democracy in America* (2 vols., New York, 1838), and with John Duer and Benjamin F. Butler a *Revision of the Statutes of New York* (3 vols., Albany, 1846). D. at Albany, N. Y., May 18, 1855.

**Spencer**, JOHN CHARLES, third Earl Spencer, better known as Lord Althorp: statesman; b. May 30, 1782; eldest son of George John, second Earl of Spencer; educated at Harrow and at Trinity College, Cambridge; was elected to Parliament 1804; held office under Fox as Junior Lord of the Treasury from Feb. 11, 1806 to Mar., 1807; sat in Parliament for the county of Northampton from Dec., 1806, till the passage of the Reform Bill 1832, during which long period he was one of the leading members of the opposition; was especially prominent in the attacks upon the financial policy of the Tory administrations; was Chancellor of the Exchequer and ministerial leader of the House of Commons in the reform ministry of Earl Grey 1830–34; succeeded his father as Earl Spencer in Nov., 1834, and soon afterward withdrew from active political life; devoted himself to scientific agriculture; was many years president of the Smithfield Cattle Club; was one of the founders and the first president of the Royal Agricultural Society 1838; was an active member of the Roxburghe Club for reprinting rare books; and vice-chairman of the Society for the Diffusion of Useful Knowledge. D. at Wiseton Hall, Nottinghamshire, Oct. 1, 1845. See Bagehot, *Biographical Studies* (1881), and Myers, *Lord Althorp* (1890). F. M. COLBY.

**Spencer**, JOHN POYNTZ, Earl: statesman; b. at Spencer House, London, Oct. 27, 1835; educated at Harrow and Cambridge; entered Parliament 1857, but succeeded to the peerage in the same year; Lord-Lieutenant of Ireland 1868–74; Lord President of the Council 1880; again Lord-Lieutenant of Ireland 1882–85; for a second time Lord President of the Council in the Gladstone administration 1886; First Lord of the Admiralty in the Gladstone government of 1892.

**Spencer**, SARA (*Andrews*): reformer; b. at Savona, N. Y., Oct. 21, 1837; educated in high and normal schools in St. Louis, Mo.; was a teacher from the age of sixteen till her marriage in 1864 with Henry C. Spencer. They removed to Washington, D. C., where they founded a Spencerian Business College. In 1871–72 Mrs. Spencer defeated attempts to license the "social evil" in Washington. On Apr. 14, 1871, Mrs. Spencer and seventy-two other ladies in Washington were refused the right to register and vote. She brought suit in the D. C. Supreme Court, and Judge Cartter's decision that "women are citizens, but have not the right to vote without local legislation" was reaffirmed by the U. S. Supreme Court in 1874. Mrs. Spencer represented the National Woman's Suffrage Association at the Republican presidential convention in Cincinnati in 1876, addressing the platform committee and the convention; engrossed, signed, and with five other women presented the woman's *Declaration of Rights* at the Centennial celebration in Independence Square, Philadelphia, Pa., July 4, 1876. She was vice-president of the first seven congresses of women 1873–90, representing the District of Columbia; was official delegate from the District to national conference of charities seven years, 1881–88; since the death of her husband in 1891 has been president and proprietor of Spencerian Business College, District of Columbia. She has published *Problems on the Woman Question* (Washington, 1871) and *Thirty Lessons in the English Language* (1873). SUSAN B. ANTHONY.

**Spencer Rifle**: a breech-loading magazine-gun, extensively used as an arm for the Union cavalry during the civil war in the U. S. It is characterized by having in the butt of the stock a magazine holding seven cartridges, which are brought one by one into the chamber by a movement of the trigger-guard as a lever, which at the same time throws out the shell of the exploded cartridge. A new magazine can be inserted whenever the cartridges have been exhausted, or the magazine may be shut off and the rifle used as a single breech-loader. See MAGAZINE-GUNS.

**Spener**, PHILIPP JAKOB: "The Father of Pietism"; b. at Rappoltsweiler, Upper Alsace, Jan. 13, 1635; studied at Strassburg, Tübingen, and Basel, principally theology; became private tutor to the princes Christian and Charles of the Palatinate, and pastor in Strassburg and lecturer in the university in philology and history 1663; was appointed first pastor in 1666 at Frankfort, where he instituted his famous *collegia pietatis* (prayer-meetings), which finally brought him into conflict with the orthodox clergy; became preacher to

the electoral court of Saxony at Dresden in 1686, but lost favor here by reproving the elector (privately) for his vices; was invited in 1695 to Berlin, where he was appointed provost of the Church of St. Nicolai. D. in Berlin, Feb. 5, 1705. He owed his religious views chiefly to English Puritan writers, and neither in his writings nor in his person was there anything of that mysticism and eccentricity which characterized some of his adherents, whose excesses were charged falsely upon him. The Pietism which he developed was quite unlike that developed in Halle and elsewhere, which was formal and lifeless. In opposition to the orthodox theological system of his time, he conceived Christianity principally as a living duty and comfort, not as a science; and, leaving all subtle definitions to others, he simply recommended his hearers to look at the Bible in the light of their own lives, and then to look at their lives in the light of the Bible. The impression he made was both wide and deep. He was the object of virulent and persistent abuse and misrepresentation, but the way he bore these attacks was eloquent testimony to the sincerity and depth of his piety. He was a voluminous writer. Perhaps the best of his works are *Pia, theologische Bedenken* (4 parts, Halle, 1700–02); *Letzte theologische Bedenken* (1711); *Concilia et judicia Theologica Latina* (Frankfort, 1709); *Pia Desideria* (Frankfort, 1675); *Das geistliche Priesterthum* (1677); *Des thätigen Christenthums Nothwendigkeit* (1679); *Evangelische Glaubenslehre* (1688). His *Life* was written by W. Hossbach (2 vols., Berlin, 1828; 3d ed. 1861) and C. A. Wildenhahn (Leipzig, 1842; 2d ed. 1847: Eng. trans. Philadelphia, 1881).
Revised by S. M. JACKSON.

**Spengel**, LEONHARD: Greek scholar; b. in Munich, Germany, Sept. 24, 1803; became privat docent in the university of his native city in 1827, professor at Heidelberg in 1842; recalled to Munich in 1847, where he died Nov. 9, 1880. Spengel's fame rests upon his work in Greek rhetoric, which field he made especially his own. See his *Συναγωγὴ τεχνῶν* (1828), an attempt to reconstruct from extant fragments the systematic development of Greek rhetoric; *Rhetores Græci* (3 vols., new ed. 1893); Aristotle's *Rhetoric* (1844); *Rhetoric* of Anaximenes; *Aristotelische Studien* (4 parts, 1868). He also published, besides many smaller treatises on his favorite subject, an elaborate text edition of Varro's *De Lingua Latina* (new ed. by his son Andreas, 1893). See Bursian's *Biographisches Jahrbuch* (iii., pp. 39–59); W. Christ, *Leonhard Spengel* (1881); Ch. Thurot, *Revue de Philologie* (v. pp. 181–190). ALFRED GUDEMAN.

**Spenser**, EDMUND: poet; b. at East Smithfield, near the Tower, London, England, in 1552. Nothing is known with certainty of his family, but it is almost proved that he was descended from the Spencers of Hurstwood, Lancashire, and was related to the Spencers of Althorp. He was educated at Merchant Taylors' School. He entered as a sizar at Pembroke Hall, Cambridge, May 20, 1569, in which month he contributed a number of sonnets and epigrams to *The Theatre of Worldlings*, a volume printed at London by Dr. John van der Noodt, a Flemish physician; graduated Jan. 16, 1573. In 1576 he left Cambridge without a fellowship and visited his relatives in Lancashire, where he fell in love with a lady supposed to have been Rose Dynley, whose charms he celebrated under the name of Rosalinde in a pastoral poem, *The Shephearde's Calendar*, published anonymously in 1579, the dedication of which to Sir Philip Sidney had been preceded by personal acquaintance in London; printed soon afterward *Three Proper and Wittie Familiar Letters lately passed between two Universitie Men* (1580), being a literary correspondence with his college friend, Gabriel Harvey; obtained in the autumn of 1580, through the influence of Sidney, the post of secretary to the Government under Lord Grey of Wilton, Lord-Lieutenant of Ireland; was probably resident in Dublin from 1582 to 1588, when he resigned his clerkship of decrees; his services were rewarded in 1589 by a grant from the crown of an estate forfeited by the Earl of Desmond, consisting of 3,028 acres of land, including the castle and manor of Kilcolman, near Doneraile, in the county of Cork, where he resided, and where he completed the composition of his *Faerie Queene*; wrote in 1586 his *Astrophel*, a pastoral elegy on the death of Sir Philip Sidney—not published till 1595; was in 1588 appointed clerk of the council of Munster; received in 1589 a memorable visit from Sir Walter Raleigh on his return from the Lisbon expedition; read to Raleigh the first two books of his great poem, which the latter thought "a dish to set before a queen," and accordingly persuaded the poet to accompany him to London. Spenser's reception by Queen Elizabeth appears to have been appreciative, for the publication of the first three books of the *Faerie Queene* in 1590 not only placed him in the front rank of poets, but procured him a pension of £50. In 1590 he also published *Muiopotmos*. During this visit to London Spenser also published in 1591 *Complaints, containing Sundrie Small Poemes of the World's Vanitie* (1591), *The Ruines of Time*, *The Teares of the Muses*, and *Prosopopoia*. His marriage in 1594 to an Elizabeth, whose surname has not been preserved, inspired his beautiful love sonnets entitled *Amoretti* and a magnificent *Epithalamium* (1595), which were shortly followed by *Colin Clout's come Home Again*. In 1596 he published *The Second Part of the Faerie Queene, containing the Fourth, Fifth, and Sixth Bookes*, and *Foure Hymnes* addressed to the Countess of Cumberland; he also presented the queen a MS. dialogue in prose, *A View of the State of Ireland*, not published until 1633. Spenser was appointed in 1598 sheriff of the county of Cork, thus incurring the enmity of the insurgents of "the Earl of Tyrone's rebellion," who toward the close of that year burned his house and plundered his estate, forcing him to fly to England, on which occasion an infant child of the poet is said to have perished in the flames. Reduced to poverty, Spenser passed a few miserable months in London, and died in King Street, Westminster, Jan. 16, 1599. According to Ben Jonson, he "died for lack of bread," after having refused twenty pieces (of gold?) sent him by the Earl of Essex, saying that "he had no time to spend them"; these details are recorded by Drummond of Hawthornden. He was buried in Westminster Abbey, near the tomb of Chaucer, as he had desired, the funeral being at the expense of the Earl of Essex; and a monument in his honor was erected in 1620 by Anne Clifford, Countess of Dorset, afterward Countess of Pembroke. He left two sons, Sylvanus and Peregrine. Hugolin, a son of Peregrine, was outlawed for adhesion to James II., and was living, "very old and unmarried," in 1700. Many editions of Spenser's complete works have appeared, the best being the variorum edition of Henry J. Todd (London, 8 vols., 1805), that of J. Payne Collier (London, 5 vols., 1862), with glossary, notes, and a *Life*, and that of Rev. R. Morris (Globe ed., 1869). These were, however, superseded by a critical edition published by the Rev. A. B. Grosart in 1882, with the assistance of a number of eminent English scholars. G. L. Craik's *Spenser and his Poetry* (3 vols., 1845) is a satisfactory critical work. Dean Church's excellent study on this poet was published in 1879. An edition by Prof. Francis J. Child, of Harvard (1855, 1878), is highly esteemed. Revised by EDMUND GOSSE.

**Speos Artem'idos** [Gr., grotto of Artemis; Arab. *Stabl Antar*, stable of Antar]: an Egyptian rock-hewn temple dedicated to the local deity, the lion-headed goddess Pachet, whom the Greeks identified with Artemis. It was situated just S. of Beni-Hasan (28° N. lat.), on the east side of the Nile. Apparently it was the work of Thothmes III., but under his cartouche there are traces of an earlier name which has been identified by Golenischeff with that of Hatasu. The name of Seti I. is also found. The grotto is cut from the solid rock, and consists of a vestibule, a corridor, and a rectangular chamber with a naos, at the rear of which is a niche for the image of the goddess. In the vestibule only two of the original eight pillars are now standing. The mural texts are nearly all of a religious character, and there are representations of several deities besides Pachet. The whole is considerably dilapidated. C. R. G.

**Spergula**: See SPURREY.

**Spermace'ti, Spermaceti-fat**, or **Cetine** [*spermace'ti* is Mod. Lat.; Lat. *sperma*, sperm + *ce'tus* = Gr. *κῆτος*, whale]: a substance ($C_{32}H_{64}O_4$) which exists ready formed in the cavities of the head of the sperm-whale (*Physeter macrocephalus*), and also in that of some other whales and of *Delphinus edentulus*. It crystallizes out of the sperm oil of the head-cavities after the vital heat is lost, forming a magma or mirole, from which in cold weather the sperm oil is expressed by hydraulic pressure ("cold-drawn sperm oil"), the spermaceti being left behind. It is purified by melting it by steam to separate mechanical impurities, and recrystallizing. It then forms a lustrous, pearly, white mass of eminent crystalline texture, feeling soft and soapy to the touch; does not grease paper if quite freed from oil. If pure, it is without taste or odor, and has a neutral reaction. The natural product, freed from sperm oil by cold alcohol and repeatedly crystallized from hot alcohol or ether, is the cetine of Chevreul, which melts at 120°–128°. It yields by saponification (see FATS) cetyl alcohol and palmitic acid. The ethereal nature of spermaceti was distinctly recognized by Chevreul (*Recherches sur les Corps gras*). Spermaceti was formerly much used in the production of sperm-candles, which are no longer so common as in the prosperous days of the sperm-whale fisheries, the decline of which dates from the general introduction of refined petroleum and paraffin. Spermaceti burns with a bright, clear flame like wax. The standard sperm-candle, which is the common unit of comparison for photometric experiments in Great Britain and the U. S., is taken to burn 120 grains of sperm in an hour, which it rarely does with accuracy. Revised by IRA REMSEN.

**Sper'maphytes** [from Gr. σπέρμα, seed + φυτόν, plant]: another name for the ANTHOPHYTES (*q. v.*).

**Spermatozo'a** [Mod. Lat.; Gr. σπέρμα, seed + ζῷον (plur. ζῷα), animal, living creature]: the male reproductive cells of animals, which by union with the female cell (egg) render the latter able to develop. They consist largely of the cell-nucleus with the addition of other accessory structures to facilitate the union with the egg (impregnation). In shape they vary greatly, but the most common shape recalls the tadpole. In these forms there is a head, composed of the nucleus, followed by a "middle piece," and this in turn by the tail, which may either be thread-like, or may have an undulatory membrane attached to it. Usually the spermatozoa have the power of motion, by means of the vibrations of the tail, but in some forms they are motionless. Recent investigations show that both nucleus and "middle piece" are concerned in impregnation; the tail and analogous structures play no part after the union. J. S. KINGSLEY.

**Sperm Oil**: See OILS and SPERMACETI.

**Spermophile**: any rodent of the genus *Spermophilus*. See PRAIRIE-SQUIRREL.

**Sperm-whale**: See CACHALOT and PHYSETERIDÆ.

**Spessartite**: See GARNET.

**Speusip'pus** (in Gr. Σπεύσιππος): philosopher; b. at Athens about 395 B. C.; a nephew of Plato; received the instruction of his uncle, whom he accompanied to Syracuse, and succeeded as president of the Academy. D. at Athens in 339 B. C. Of his writings nothing is left. J. R. S. S.

**Speyer**, or **Speier**, spī'er: city and railway junction; capital of Rhenish Bavaria, at the junction of the Speyerbach with the Rhine (see map of German Empire, ref. 6–D). It has some sugar-refineries and manufactures of vinegar and tobacco, and carries on an active trade in grain, timber, and wine on the Rhine. It is one of the oldest cities of Germany, and in the Middle Ages the German emperors often resided and held their diets here. Nevertheless, it has only one monumental building, the cathedral, erected in the eleventh century, thoroughly restored in 1858, and one of the finest church buildings of Germany. The other great edifices Speyer once possessed were destroyed by the French, who twice conquered and devastated the city. Pop. (1895) 19,045. Revised by M. W. HARRINGTON.

**Spezia**, spăt'si-ă̈a: town; in the province of Genoa, Italy; beautifully situated on a gulf of the same name in lat. 44° 7' N., lon. 9° 48' E. (see map of Italy, ref. 4–C). The old walls and gates of Spezia have been mostly demolished in the course of the changes necessitated by the rapid growth of the town consequent upon the construction of the naval arsenal. The town is the chief naval station of Italy and is defended by formidable batteries; it has extensive shipbuilding yards, docks, etc., a foundry, and manufactures of sail-cloth, white lead, cables, and leather. It is the seat of a school of navigation, and is much frequented as a seaside resort. Pop. about 19,860.

**Spezzia**, spet'si-ă̈a: an island at the entrance of the Gulf of Nauplia, Greece; has a fine harbor; became distinguished in the Greek revolution (1821–29). The inhabitants are mostly engaged in commerce and navigation. Area, 26 sq. miles. Pop. (1890) 5,192. E. A. G.

**Sphag'num** [Mod. Lat., from Gr. σφάγνος, a kind of moss]: a large and interesting genus of mosses, many species of which grow in the U. S., mainly in bogs, forming deep, spongy masses, almost always damp. They are called peat-mosses, being the principal ingredient in pure peat. See MOSSWORTS. Revised by CHARLES E. BESSEY.

**Spheg'idæ** [Mod. Lat., named irregularly from *Sphex*, the typical genus, from Gr. σφήξ, σφηκός, wasp]: a family of hymenopterous insects, including the so-called sand-wasps and mud-wasps. See HYMENOPTERA.

**Sphenis'cidæ**: See PENGUIN.

**Sphen'odon**: See HATTERIA.

**Sphenoid Bone** [*sphenoid* is from Gr. σφήν, wedge + suffix *-oid*, like]: a bone of the skull, situated in man at the anterior part of the base. It has been likened in shape to a bat with open wings. It consists of a body, four wings, two greater and two less, and the two pterygoid processes. The body is quadrilateral, and hollowed out into a mere shell. This body is conceived to represent the centrum of the third cephalic vertebra (constituting the posterior portion of the sphenoid), joined to the centrum of the second vertebra (the anterior portion). The two greater wings are the neurapophyses of the third vertebra, and the two lesser wings are neurapophyses of the second vertebra. The sphenoid is exceedingly complicated and irregular in its outlines. It is developed from ten centers. It is usually joined anteriorly in the adult to the two sphenoidal spongy bones (a pair of thin, curved irregular plates). Posteriorly, it becomes continuously united to the occipital bone. It articulates with all the bones of the skull and with five of those of the face.

**Sphere** [(readapted to Latin) < M. Eng. *spere*, viâ O. Fr. from Lat. *sphæra* = Gr. σφαῖρα, ball, sphere]: a surface all of whose points are equally distant from a point within called the *center*. It may be generated by a semicircle revolving about its diameter as an axis. Any line from the center to a point of the surface is a *radius*, and any line drawn through the center and limited by the surface is a *diameter*; all radii of the same sphere are equal; also all diameters of the same sphere are equal. Every plane section of a sphere is a circle; if the plane passes through the center, the section is called a *great circle*; if it does not pass through the center, the section is called a *small circle*; the radius of a great circle is equal to that of the sphere; the radius of a small circles may have any value from the radius of the sphere to 0, in which case the cutting plane merges into a tangent plane. The surface of a sphere is equal to four great circles, or it is equal to the circumference of a great circle multiplied by its diameter. The surface of a zone, viz., the portion of surface included between two parallel planes, is equal to the circumference of a great circle multiplied by the altitude of the zone. The volume of a sphere is equal to its surface multiplied by one-third of its radius. The volume of a spherical sector is equal to the zone which forms its base multiplied by one-third of the radius of the sphere.

In analysis, the surface of a sphere is a surface of the second order, whose equation in rectangular Cartesian coordinates is of the form

$$(x-\alpha)^2+(y-\beta)^2+(z-\gamma)^2=R^2,$$

in which $\alpha, \beta$, and $\gamma$ are the co-ordinates of the center, and $R$ is the radius of the sphere. Revised by S. NEWCOMB.

**Spherical Trigonometry**: See TRIGONOMETRY.

**Sphe'roid** [from Gr. σφαῖρα, sphere + suffix *-oid*, like]: a surface generated by an ellipse revolving about one of its principal axes. If the ellipse revolves about its conjugate axis, it generates a surface resembling a flattened sphere called an *oblate* spheroid; if it revolves about its transverse axis, it generates an elongated surface called a *prolate* spheroid. The surface of the earth is very approximately an oblate spheroid.

**Spheroidal State**: See HEAT and LIQUIDS.

**Spherom'eter**: an instrument for measuring the radius of a sphere when only a portion of the spherical surface, as, for instance, a lens, is given. The usual form consists of a vertical screw turning in a socket, which is equidistant from three supporting legs with sharp steel points. Above the sockets the screw has a graduated circular head. The points of the legs are brought in contact with the spherical surface, and the screw is turned until its extremity also touches it. This process is repeated with a plane. Thus the distance between the center of the circle through the ends of the legs and its pole on the sphere is obtained, from which the radius of the sphere can be calculated. R. A. R.

**Sphincter** [Mod. Lat., from Gr. σφιγκτήρ, anything which binds tight, deriv. of σφίγγειν, compress, squeeze, bind tight]: in anatomy, a muscle the fibers of which, generally circular, surround some passage in the animal organism, closing the passage, in opposition to certain other muscles called dilators. Some of the sphincters are composed of striped fiber, some of unstriped, and some of both combined. The eyes, pupils, mouth, rectum, vagina, bladder, and urethra are the most important passages which are provided with sphincters; but there are numerous other sets of circular fibers which have more or less of the action of sphincter muscles.

**Sphin′gidæ**: a family of moths including the hawk-moths. See HAWK-MOTH and LEPIDOPTERA.

**Sphinx** [Lat. = Gr. σφίγξ, σφιγγός]: in Grecian mythology and art, a malevolent being, usually represented as having the head of a woman, the breast, feet, and claws of a lion, the tail of a serpent, and the wings of a bird. It was also represented as having the fore part of a lion, the body of a man, the claws of a vulture, and the wings of an eagle. It was reputed to have originated in Ethiopia. In this latter point there may be an historical reminiscence, but in respect to the features which were combined to form the Greek sphinx there are few items of similarity with the Egyptian prototype. The Egyptian sphinx proper is composed of the head of a man and the body, legs, feet, and tail of a lion, but it was represented as destitute of wings, except in the period when Greek influence had come to be felt, and its artistic designs to be copied. In Egyptian symbolism the sphinx was the guardian of temples and tombs, the incorporation of Rā-Harmachis. The face, however, was sculptured presumably to represent the reigning Pharaoh. It was the form assumed by Rā and Horus when opposed to their enemies, and it was supposed properly to be a quadruped of the desert. Similar figures are frequent in which the human head is replaced by that of the ram (criosphinx) or of the hawk (hieracosphinx); but when applied to these composites the name sphinx is a misnomer, as they are merely variations in the forms given to the deities to whom these animals were sacred. The ram-headed figure and the real sphinx (androsphinx) were, however, used for similar purposes, as they alternate in the "avenues of sphinxes" which mark the passageways from the Nile to the temples. Used thus they were supposed to ward off evil from the dwellings of the gods and of their sacred animals.

There are few, if any, specimens of this style of sculpture from the old kingdom; from the twelfth dynasty there are several, and during the remainder of Egyptian history it was a favorite device. The so-called Hyksos sphinxes from Tanis are of a different type from those found in other parts of Egypt, and also from some other examples found even in Tanis itself. Their bodies are shorter, more sinewy and powerful, and the human heads are also of a different type, with high cheek-bones, broad faces, and powerful features. They are also adorned with manes and shaggy breasts. Several theories have been advanced to account for the variations. It was at first supposed that they were genuine Hyksos remains, produced by foreign artists settled in Tanis; but against this is the fact that the name of Apepi, the Hyksos, is merely scratched upon the shoulder, and does not occupy the place of honor—that it resembles a graffito rather than an inscription. The main argument rests upon the un-Egyptian cast of feature shown. Mariette proposed this view, and it has heretofore been generally accepted. It has also been suggested that they are productions of a local Egyptian school of sculpture not under the ordinary canons of Egyptian art. Meyer holds that they are memorials of an invading race, which apparently gained the upper hand in Egypt between the ninth and tenth dynasties, of which Khyan is the representative. (See Petrie, *History of Egypt*, i., p. 117 ff.) Golenischeff considers that they were memorials of Amenemha III. of the twelfth dynasty (*Recueil de Travaux*, xv., 131), to whom they bear a striking resemblance. The whole subject, however, is involved in much doubt.

The date of the Great Sphinx of Gizeh, located about half a mile S. E. of the Great Pyramid, is absolutely unknown (see illustration in the article EGYPTOLOGY). It has been assigned to prehistoric times, to the age of Cheops (Khufu), and Khafra of the fourth dynasty, and even to Thothmes IV., but of proof there is none. Fundamental to the whole discussion are two facts—no dated sphinxes earlier than the twelfth dynasty can be proved, and the Egyptian inscriptions of the Old Kingdom do not contain the sphinx-hieroglyphic sign at all, as do those of later periods. The assignment to a period antedating the fourth dynasty rests upon an inscription found in a neighboring temple, which purported to be from the fourth dynasty, but which was really composed in the twenty-first. It alleges that at the earlier date the sphinx was in need of repairs, but internal evidence points to the probable conclusion that the story is entirely unhistorical. The assignment to Khafra was based upon the fact that a statue of that king was found in the immediate neighborhood. On a pillar in the small temple, between the paws of the figure, was found a tablet of Thothmes IV., in which he is understood to record a dream in which Rā-Harmachis, whose emblem the sphinx was, appeared to him and promised him long life and prosperity if he would clear the figure from the desert sand that had encroached upon it, and repair it. The question of age promises to remain a riddle, and the assignment of it to the time of the Heracleopolite dynasties (ninth and tenth) is only a guess which has something in its favor. It is certain that it was uncovered twice in ancient times, once under Thothmes IV. and once under Ramses II., but little else is known. Curiously enough, it is not mentioned by Herodotus, though it finds place in other ancient writings. In modern times it has been thrice cleared, by Caviglia, Mariette, and Maspero. When uncovered it was found to be hewn out of the native rock, the head having been carved with great care, but the body left comparatively rough. Breaks or inequalities in the stone were patched with rough masonry, apparently of the Roman period. The whole figure faces eastward, and is about 150 feet long. The top of the head is about 66 feet above the pavement between the paws. The paws are 50 feet long, the head 30 feet long and nearly 14 feet broad. The face was originally colored red, but all traces of the tint have disappeared. It is supposed to have been veneered, in part, at least, with a limestone covering. The face is much damaged and the nose and beard have disappeared. This defacement was largely due to the fact that the Mamelukes used it for a target. The mouth is broad and pleasing, and the face has a benign aspect. It is quite probable that it originally represented the face of the Pharaoh by whom it was cut.

Between the paws of the sphinx is a stone platform approached by a flight of steps, and close to the breast is a small open temple, which is divided into two parts. Three pillars form the rear, and on the central one was the tablet of Thothmes IV., dated from his first year. Another temple is near at hand, which has the general appearance of a tomb or mastaba, and it has been supposed that the sphinx was regarded as the guardian of this building and its contents. CHARLES R. GILLETT.

**Sphinx-caterpillar**: See HAWK-MOTH.

**Sphyg′mograph** [Gr. σφυγμός, pulse, heart-beat + γράφειν, write]: an instrument for measuring and recording the shape, frequency, and force of the blood-wave in an artery. It consists of a series of delicate levers set in motion by the pulse-beat, and of a moving surface of paper, on which are recorded the results of the measurement. There are several forms of sphygmograph. They simply amplify on the record the successive changes in the caliber of the blood-vessel. In diseased conditions of the heart the records have a diagnostic value. See RECORDING APPARATUS, PSYCHOLOGICAL, in the Appendix.

**Spice** [M. Eng. *spice*, *spece*, from O. Fr. *espice*, *espece* (> Fr. *épice*): Ital. *spezie* < Lat. **specia*, *species*, appearance, kind, wares, goods, spices]: certain aromatic seeds, barks, roots, dried fruits, etc., used in cookery for their flavoring qualities, and in medicine as stimulants and carminatives. Such are cloves, ginger, allspice, nutmeg, pepper, mace, capsicum, cinnamon, cassia, vanilla, etc. Besides the above, which are extensively exported from tropical countries, and especially from the East, there are others now nearly forgotten, such as cassamunar, zerumbet, zedoary, culilawan, and the so-called clove-bark. These have nearly disappeared from general commerce—some because they are inferior in quality, and others on account of their limited supply. Most of the spices are natives of the Old World, but a few are American, and nearly all the important ones are now generally naturalized throughout the tropical world.

**Spice Bush**: See FEVER BUSH.

**Spice Islands**: See MOLUCCAS.

**Spichern**, or **Speichern**: See SAARBRÜCKEN.

**Spider-crab**: See CRAB.

**Spiders** [M. Eng. *spither*, or *spiþre* < O. Eng. **spīdre* for **spin-þer*; deriv. of verb *spinnan*, to spin]: an order of arachnid animals, the *Araneida*. The chief characters which distinguish them from other groups are the possession of a body divided into two regions, cephalothorax and abdomen, both without distinct joints, and the latter, which is joined to the former by a slender stalk, bearing spinning mammillæ on the hinder end. The cephalothorax bears four pairs of legs and two pairs of smaller appendages, the first of which are the poison-jaws, while the second are curiously modified in the male for reproductive purposes. There are usually eight eyes (sometimes six or fewer) upon the front of the cephalothorax. Respiration is accomplished by lungs or lungs and tracheæ. When lungs alone are present there are two pairs of these organs on the under side of the abdomen. In other forms there is a single pair of lungs, the other pair being replaced by air-tubes like those of true insects.

Orb web spider, *Epeira insularis*.

Spiders are carnivorous, and live upon other insects which they kill by the poison forced through the poison-jaws. They do not eat the prey, but merely suck its juices. Some spiders hunt their prey, jumping upon it like a miniature tiger, but the majority form webs of silken threads covered with a viscid substance. The shape and character of these webs varies exceedingly. In general it may be said that the spider has a lair where he can recognize any vibration of the web, and whence he can rush out to further entangle the prey. The web is secreted by glands inside the body, and as it comes in contact with the air in its passage through the spinning organs it hardens into the familiar thread, which in reality is a cable formed of a number of smaller fibers. Besides its use in forming webs the silk is employed in making nests, as a means of flying, and for the formation of cocoons to contain the eggs. "The males are smaller than the females, and their approaches to the latter are made with extreme caution, as they run the risk of being devoured; extending their pedipalps, they deposit the spermatophores in the female genital aperture and betake themselves to flight" (*Huxley*). In their habits spiders are among the most interesting of animals, well repaying observation. Besides the European works of Thorell and Semon, the student should consult papers by Emerton, *Trans. Connecticut Acad. Science* (1882–94); Peckham, *Trans. Wisconsin Acad. Science* (1888); and McCook, *American Spiders* (3 vols., Philadelphia, 1889–94). J. S. Kingsley.

**Spie'gel**, Friedrich: Orientalist; b. at Kitzingen, near Würzburg, Bavaria, July 11, 1820; studied Oriental languages at Erlangen, Leipzig, and Bonn 1838–42, and at Copenhagen and Oxford 1842–47, and in 1849 was appointed Professor of Oriental Languages at the University of Erlangen. Besides editions of various Persian works and grammars of the Old Persian and Old Bactrian languages, he published *Einleitung in die traditionellen Schriften der Parsen* (2 vols., Leipzig, 1856–60); *Die Altpersischen Keilinschriften* (1862; 2d ed. 1881); *Eran, das Land zwischen Indus und Tigris* (1863); *Eranische Alterthumskunde* (3 vols., Leipzig, 1871–78); *Vergleichende Grammatik der alteranischen Sprachen* (1882); *Die arische Periode und ihre Zustände* (1887).

**Spiel'hagen**, Friedrich: novelist; b. at Magdeburg, Germany, Feb. 24, 1829; studied jurisprudence, and afterward philosophy, philology, and literature at Berlin, Bonn, and Greifswald; taught for some time at the university at Leipzig, and finally devoted himself entirely to literary pursuits. In 1859 he removed from Leipzig to Hanover, where he became literary editor of the *Zeitung für Norddeutschland*; but in 1862 he took up his permanent residence in Berlin. Spielhagen has successfully aspired to treat the great questions of the day in a series of novels distinguished by their artistic composition, their elegant style, and their philosophic thought. The most important of these novels, many of which have passed through numerous editions, are *Problematische Naturen* (1860); *Durch Nacht zum Licht* (1861); *Die von Hohenstein* (1863); *In Reih und Glied* (1866); *Hammer und Amboss* (1869); *Sturmflut* (1877); *Quisisana* (1880); *Angela* (1881); *Was soll das werden* (1886); *Noblesse oblige* (1888); *Der neue Pharao* (1889). In his excellent book *Beiträge zur Theorie und Technik des Romans* (1883), Spielhagen attempts to fix the æsthetic laws which govern the art of novel-writing, and in his autobiography, *Finder und Erfinder* (1890), he gives a charming account of the influences which conspired to make him a novel-writer. An edition of selected novels appeared in 1889–92, comprising twenty-three volumes. Julius Goebel.

**Spiers**, Alexander, Ph. D.: lexicographer; b. at Gosport, England, in 1807; graduated at the Universities of Paris and Giessen; settled at Paris 1829; was Professor of English successively at the School of Commerce, at the School of Public Works (Ponts et Chaussées), at the Lycée Bonaparte (1833), and at the University of France; became inspector of colleges; received from Napoleon III. in 1869 the cross of the Legion of Honor in acknowledgment of the value of his series of English grammars, and especially of his standard French-English and English-French *Dictionary* (Paris and London, 2 vols., 1846–49), of which two editions appeared in the U. S.—one edited by G. P. Quackenbos (New York, 1852), the other by J. L. Jewett (1856). D. at Passy, near Paris, France, Aug. 26, 1869.

**Spike** [from Lat. *spi'ca*, point, spike, ear of corn, tuft or head of a plant]: in botany, a flower-cluster, of the centripetal or indeterminate order, in which sessile flowers are arranged along an axis. The spadix and ament are varieties of the spike. The ears of wheat and rye are familiar instances of the spike, which in some instances is compound—that is, contains many sessile spikelets. When the flowers are stalked instead of sessile, the spike becomes a raceme.

**Spikenard**, or **Nard** [*spikenard* is *spike* (see Spike) + *nard* < O. Eng. *nard*, from Lat. *nar'dus* = Gr. νάρδος; cf. Heb. *nērd*, Pers. *nard*]: (1) in the East the *Nardostachys jatamansi*, a valerianaceous plant of India. Its strong odor is disagreeable to most persons of European and American birth, but it is considered very precious in the East. Its medicinal properties are precisely those of valerian. (2) Roots of various species of valerian are exported from Europe to the Levant under the name of Frankish nard, Celtic nard, and mountain nard. Cretan nard is also the root of a valerian. These are much used in the East as substitutes for the true spikenard. (3) In England the fragrant oil of *Andropogon nardus*, an East Indian grass, is called oil of spikenard. It is used in perfumery. (4) In the U. S. the name spikenard is given to *Aralia racemosa*, and the *A. nudicaulis*, or false sarsaparilla, is called small spikenard. They have each a limited use in domestic medicine.

**Spike, Oil of**: the volatile oil of the *Lavandula spica*, the broad-leaf lavender of Europe. It has an odor much like that of oil of turpentine. It is used by artists in preparing their varnishes, and by veterinarians as a horse medicine. Much of the commercial oil of spike is an entirely factitious mixture, of which oil of turpentine is the basis.

**Spinach**, or **Spinage**: the *Spinacia oleracea*, a chenopodiaceous Old World herb, much cultivated in nearly all parts of the world as a potherb, especially for use in the spring. There are about twenty varieties grown in the U. S. Other plants of this and of other genera having similar uses are locally called by this name.

**Spinal Caries**, or **Potts's Disease of the Spine**: an inflammatory condition of the vertebræ, a spondylitis, destructive in its nature, usually tuberculous in character, and slow in its course. A slight injury is often sufficient to awaken the process in an individual predisposed to struma. Gradual disintegration of the bodies of one or more vertebræ takes place with subsequent bending, which produces a kyphosis or sharp projection backward. The early symptoms are colicky pains in the abdomen (often mistaken for indigestion), reflex pains in the limbs, and a peculiar rigidity of the back in walking and stooping. If the disease is situated in the cervical or upper dorsal regions, an irritative cough is often among the earliest symptoms.

The name Potts's disease was given to this affection from the fact that Dr. Percival Potts, in 1779, was the first physician to describe accurately this special condition of the bones which gives rise to the hunch-back deformity. That this disease existed in prehistoric times is evidenced by the specimens in the Peabody Museum at Cambridge, Mass.

The treatment consists in keeping the diseased bones perfectly at rest until nature throws a bony bridge across the diseased gap and anchyloses the spine. This result may be accomplished by placing the patient continuously in the recumbent posture, or by the application of a steel support, a hard leather or rigid jacket, plaster-of-Paris splint, or other device. The disease is necessarily long and tedious, its course often extending over many years. Abscesses frequently form in the back or groin, more commonly in the latter situation. The latter condition is known as a psoas abscess, from the fact that the pus follows the sheath of the psoas muscle. When the pus seeks exit in the back, the process constitutes a lumbar abscess.

Paralysis of the lower limbs occasionally results, which though tedious is usually curable, provided extension and fixation are rigidly enforced. Laminectomy is rarely required. See CARIES.

DE FOREST WILLARD.

**Spinal Column** [*spinal* is from Lat. *spina'lis*, deriv. of *spi'na*, back-bone, liter., thorn, spine. So called from the shape of a vertebra]: the back-bone, the composite bony column of the back of vertebrated animals which affords attachments, direct or indirect, for the ribs and other bony parts, and for the numerous groups of voluntary muscles. In man it is a flexible column of thirty-three vertebræ united by ligaments, with interposed cartilaginous cushions. The column is from 2 to 2½ feet in length, and viewed laterally presents marked curves, which add to the grace and free movements of the trunk. (Fig. 1.) The column is divided into regions—the *cervical*, *dorsal*, *lumbar*, and *pelvic*—corresponding to the neck, chest, abdomen, and pelvis. The vertebræ, excepting in the pelvic region, rotate freely and flex both antero-posteriorly and laterally. A single vertebra (Fig. 2) consists of the *body*, which unites it to other vertebræ, and a bony ring which incloses the vertebral foramen or vertebral canal, protecting the spinal cord; this ring has articular and spinous processes for attachment of ribs, ligaments, and muscles.

FIG. 1.—Lateral view of spine.

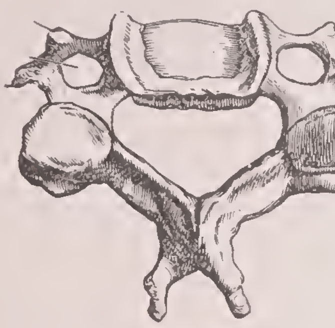

FIG. 2.—A vertebra.

Revised by W. PEPPER.

**Spinal Cord**: See MEDULLA SPINALIS.

**Spinal Curvatures**: three kinds—(1) rachitic curvature; (2) lateral curvature; (3) angular curvature. The curvature of rickets (rachitis) is usually a simple exaggeration of the normal curves of the spine—convexity or kyphosis in the dorsal, and concavity or lordosis in the lumbar region; occasionally there is a lateral bending (scoliosis), but unaccompanied with the rotation of true lateral curvature. Lateral curvature is a deviation of the spinal column at one or several points from the position which it occupies in health in the median line of the back, accompanied by marked rotation of the bodies of the vertebræ around the axis of the spinal column, which is thus much more distorted in front than behind. It occurs in children, in young, imperfectly developed, feeble, and growing adults, more especially women, and less often in men. The spine normally occupies the middle of the back, with a slight convexity to the right in the dorsal region; in this central position it is acted upon by many forces—the weight of the head and trunk, the lateral traction of the arms in all physical efforts, of the thoracic and abdominal muscles in breathing—and beneath has a divided support of the two lower extremities through the intervention of the pelvis. A lateral curvature may develop connected with any one of these forces; when the tissues are poorly nourished the spine may yield to the weight it supports. Habitual use of one arm to the exclusion of the other may cause deviation of the spine, cervico-dorsal, to the stronger side—a common occurrence in weakly children at school, housemaids, and in some confining mechanical vocations. Disease of one lung, as phthisis, chronic pneumonia, pleuritic adhesions and chest-contraction, by limiting respiratory movement on one side, often causes dorsal curvature to the more active side. Shortening of one limb, hip-joint disease, persistent limping from any cause, by tilting the pelvis throws the spine out of center and develops lumbar curvature. Whenever a curvature is thus primarily established, a secondary curvature develops at another part of the vertebral column, and to the opposite side, and thus the erect position of the body is maintained. The affected spine, viewed anteriorly or posteriorly, presents a double curvature, a tortuous line whose upper and lower ends can be connected by a vertical straight line, representing the component of all the forces, weight, etc., which the spine sustains. Occasionally there are four curves, two in the dorsal and two in the lumbar region.

Lateral curvature, if of long standing, may so modify the size and conformation of the lung, so change the nutrition and structure of the intervertebral cartilages and the muscular volume of the two sides of the body, that cure is impossible or incomplete. More often it is curable by correcting bad habits, as favoring one side in standing, sitting, or sleeping, by resort to light gymnastics and special passive movements, and by the use of apparatus which removes weight from the spine and applies pressure or traction to counteract the curves. Great advantage may, in early cases, be derived from dividing the period during which the body is erect, by lying flat on the back, without a pillow and on a hard mattress, for at least an hour in the mid part of the day. General tonic treatment, cod-liver oil, and phosphates, out-of-door life, warm clothing, stimulating baths, and regulated diet are indicated in all cases.

Angular curvature, or SPINAL CARIES (*q. v.*), is of more serious nature. It may be followed by paralysis of the lower extremities, due to pressure on or inflammation of the spinal cord, but paralysis and abscess do not usually coexist in the same cases. Revised by JOHN ASHHURST, Jr.

**Spinal Diseases**: See MENINGITIS and SPINAL CURVATURES.

**Spindler**, KARL: novelist; b. at Breslau, Prussian Silesia, Oct. 16, 1796: educated at Strassburg, afterward at Augsburg; was connected for some time with a company of strolling actors; published in 1824 his first novel, *Eugen von Kronstein* (2 vols.); chose literature for his occupation; lived at Hanau, Stuttgart, Munich, and finally at Baden-Baden. D. at Freiersbach, Baden, July 12, 1855. The best of his novels are *Der Bastard* (3 vols., 1826); *Der Jude* (4 vols., 1827); *Der Jesuit* (3 vols., 1829); and especially *Der Invalide* (1831). The latter story is an excellent specimen of the early historical novel in Germany, giving a picture of the French Revolution and the subsequent *rôle* of Napoleon which has not yet been surpassed in fiction. Many of his minor novels were published in a periodical, *Vergissmeinnicht*, which he edited after 1831. A collected edition of his works appeared in 102 vols. at Stuttgart from 1831 to 1854.

Revised by JULIUS GOEBEL.

**Spindle-tree, Staff-tree**, or **Bittersweet Family**: the *Celastraceæ*; a small family containing 300 species of discifloral, choripetalous, dicotyledonous shrubs and trees. The perianth is 4- to 5-merous, and the compound, superior ovary three to five celled, with two ovules in each cell. The species are widely distributed in temperate and tropical climates, eighteen of which occur in North America. The climbing bittersweet (*Celastrus scandens*) is one of the prettiest woody climbers of the U. S., especially in the winter, when its red-arilled seeds remain long in conspicuous clusters. The genus *Euonymus* includes the spindle-trees proper. *E. atropurpureus* is the ornamental shrub known in the U. S. as the WAHOO (*q. v.*), or burning-bush. CHARLES E. BESSEY.

**Spine**: See SPINAL COLUMN.

**Spinel** (Fr. *spinelle*): a mineral, essentially a compound of alumina and magnesia, but with variations and admixtures that give rise to a great variety of colors and tints. It crystallizes in regular octahedrons, sometimes of large size in the black and opaque kinds. The transparent spinels make beautiful gems, especially the deep-red, flame-red, and carmine-colored stones, which are known as ruby spinels, and command high prices, from one-eighth to one-half that of diamonds, the finest having often been erroneously sold for true rubies. The pink variety is known as balas-ruby or rubicelle, the blue sapphire spinel, the green chlorospinel, the purple almandine spinel. They are also blue, green, yellow, and purple, and even white. The so-called Black Prince's ruby in the English crown is a spinel. The best spinel gems are from Ceylon, Burma, and Siam. G. F. KUNZ.

**Spinel'lo di Luca Spinelli**, called SPINELLO ARETINO: painter; b. at Arezzo, Italy, about 1333. He was the pupil of

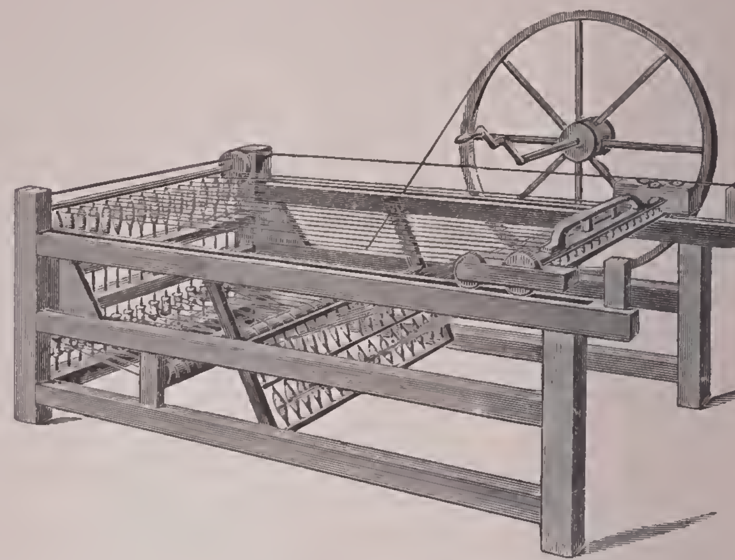
Jacopo di Casentino, and at the age of twenty surpassed his master. It is supposed that in 1347 he was assisting his master to decorate the Church of Santa Maria Novella in Florence with frescoes representing the Virgin and St. Anthony. Of these little remains. Some scenes from the life of St. Benedict, by Spinello, at San Miniato, near Florence, are still in good preservation. These were painted in 1384, when Spinello took refuge in Florence after the sack of Arezzo. Before this date he had decorated many churches in his native city; in San Francesco an *Annunciation* still exists in the chapel of St. Michael. He painted a fantastic composition of the archangel driving Lucifer from heaven, a fragment of which fresco is in the National Gallery, London. This composition was afterward repeated by him for the guild of St. Angelo. In 1361 Spinello painted a panel for the abbey of the Camaldolesi, in the Casentino. The side-frescoes for the altar of Monte Oliveto Maggiore of Chiusi are to be seen in the Ramboux collection at Cologne. In 1387 Spinello was invited to Pisa to work in the Campo Santo there, and painted pictures considered his masterpieces, but now nearly destroyed. He left Pisa on account of political disturbances, and after a year in Florence he returned to Arezzo about 1394. Here he worked, decorating many churches with frescoes till 1405, when he went with his son and assistant, Parri, to Sienna, to paint the series of frescoes still preserved in the town-hall of that city. The last that is heard of him in Sienna is in 1408, after which he returned to his birthplace, where he died in Mar., 1410. For further information, see Vasari (Le Monneer), vol. ii., and Kugler's *Handbook* (1887). W. J. S.

**Spinet**: a musical instrument, stringed and provided with a keyboard; one of the forerunners of the piano, but much weaker, and entirely out of fashion.

**Spinner**, Francis Elias: financier; b. at German Flats (now Mohawk), Herkimer co., N. Y., Jan. 21, 1802; son of a German clergyman; was successively apprentice to a confectioner at Albany and to a saddle and harness maker at Amsterdam, N. Y.; became in 1824 a merchant at Herkimer; was deputy sheriff of Herkimer County 1829–34, and sheriff 1835–37; served in the militia and became major-general; was for twenty years connected with a bank at Mohawk, N. Y., and became its president; was auditor and deputy naval officer of the port of New York 1845–49; Democratic member of the Thirty-fourth Congress 1855–57; was an original member of the Republican party, and re-elected by it to Congress by 9,000 majority in 1856, and again by a similar majority in 1858; was chairman of the committee on accounts 1859–61; was appointed by President Lincoln, on the recommendation of Secretary Chase, to the post of treasurer of the U. S. Mar., 1861; and held the office until July, 1875. During this period his name was a synonym for official integrity, and his curious signature on the "greenbacks" became more familiar in the U. S. than the autograph of any other living man. He was defeated in 1875 as Republican candidate for comptroller of the State of New York. D. at Jacksonville, Fla., Dec. 31, 1890.

**Spinning**: the art of producing from vegetable or animal fibers an even and compact thread suitable for sewing or weaving. It is one of the most ancient of industries, and is still practiced in many parts of the globe by the spindle and distaff in the same manner that the process is pictured on Egyptian monuments. The distaff, held in the left hand, was a simple stick around which the fiber was loosely coiled; the spindle was a species of top which was set in motion by a twirl of the hand, and by combining its rotary motion with a gradual movement away from the spinner, who equalized the size of the fiber by passing it between the finger and thumb of the right hand until the motion of the spindle was exhausted, when the thread was wound around it, and the process was repeated. The first and most obvious improvement consisted in placing the spindle in a frame and making it revolve by mechanical action of the hand or foot in connection with a wheel and treadle. This constituted the spinning-wheel, which, notwithstanding its simplicity, can not be traced further back than 1530. Modern invention has added little to this implement, the chief improvement being a bobbin for winding the yarn by a motion separate from that of the spindle. See Cotton Manufactures.

**Spinning-jenny**: the earliest form of spinning-machine in which more than one thread was spun at a time. Cotton, in the course of manufacture, is reduced from the state of the fleecy roll called carding into the state of spun thread by repeated though similar operations. The first draws out the carding and gives it a very slight twist, so as to make it into a loose thread about the thickness of a candle-wick, in which state it is called a roving or slubbin. The subsequent processes draw out the roving much finer, and



The spinning-jenny.

at length reduce it into yarn. The spinning-jenny, invented about 1764 by James Hargreaves (*q. v.*), was not, like Arkwright's spinning-frame (1769), capable of being applied to the preparation of the roving itself. In 1779 Samuel Crompton completed his invention of the mule, which combined in one machine the principles of both the jenny and the frame, and by which the jenny was ultimately superseded. See Cotton Manufactures.

The person operating the jenny turned the wheel with the right hand and with the left drew out from the slubbin-box the rovings, which were twisted by the turn of the wheel. Next a piece of wood, lifted up by the toe, let down a wire, which so pressed out the threads that they wound regularly upon bobbins placed in the spindles. The number of spindles in the jenny was at first eight; when the patent was obtained it was sixteen. It soon came to be twenty or thirty, and as many as 120 have been used. The introduction of the spinning-jenny met with great opposition. In 1779 a mob destroyed the jennies for several miles around Blackburn, and with them all the carding-engines, spinning-frames, and every machine turned by water or horses. The spinning industry was driven from Blackburn to Manchester and other places. Nevertheless, the jenny and the frame revolutionized the cotton manufacture. William Kent.

**Spi'nola**, Ambrosio, Marquis de: soldier in the service of Spain; b. in Genoa, Italy, about 1571, son of a wealthy Levant merchant and of a princess of Salerno; took service at an early age under his brother, an admiral in the Spanish navy; participated in the war against the Dutch and English 1588; raised and equipped at his own expense in Spain a numerous corps of veterans, at whose head he proceeded to the Spanish Netherlands 1602; was instrumental in rescuing the Archduke Albert from the superior forces of Prince Maurice of Nassau; became chief commander of the Spanish armies in Flanders 1603; and in the fall of that year took command of the forces around Ostend, which had been besieged for two years. The city capitulated in Sept., 1604. He conducted the war with great ability, but varying success, until the truce of twelve years (1609), which he favored; commanded in the interval the Spanish forces in Germany; took Aix-la-Chapelle, Wesel, and Jülich 1622; was repulsed from Bergen-op-Zoom 1623; captured Breda after a protracted siege 1625; was subsequently commander of the Spanish army in Italy, and captured the city of Casale, Piedmont, but died while pressing the siege of the citadel, Sept. 25, 1630. His death is said to have been hastened by his chagrin at the ingratitude of the Spanish Government in disregarding his pecuniary claims.

**Spinoylic Acid**: See Salicylic Acid.

**Spino'za**, (Baruch) Benedict: philosopher; b. at Amsterdam, Holland, Nov. 24, 1632; a member of the Spanish-Portuguese Jewish community at that place, then the chief seat of European Judaism. His father, who was a trader, noticing the extraordinary faculties of the son, gave him a good education. Accordingly, he entered upon the customary path of a Jewish scholar, passing through all the steps of the ordinary rabbinistic school, from the elements of Hebrew to the holy writings of the Old Testament, thence to the Talmud, the Jewish commentaries, and the scholastic writers of the Middle Ages. Jewish literature led him, through the literature of the scholastics, wherein the Cabbalistic doctrine played so prominent a part, gradually to the portals of the then developing modern views of the school of Descartes. In short, the rabbi Spinoza became a skeptic, even as Descartes, the scholar of the Jesuits, had become a skeptic before him. Descartes, however, was enabled to fall back upon Christianity for salvation from skepticism. This Spinoza could not do. Cut loose from Judaism, unable or perhaps traditionally so opposed to it that he did not feel any way inclined to accept Christianity, he was left without any support or guidance. The Jewish God, as the cause and creator of the universe, he had discarded; the Christian conception of God, as the moral harmony and order of the universe, was utterly repugnant to his originally Jewish mind; and thus he had no other recourse left than the so-called pantheism of Substantiality. This rupture with Jewish theology brought about a dispute between him and his rabbinistic teachers, which finally led to his expulsion from the synagogue at Amsterdam (July, 1656). Spinoza wrote a protest against the anathema pronounced against him, but otherwise paid little attention to it. He simply changed his name from *Baruch* to *Benedict* Spinoza, by which last name he is generally known, and when he discovered that he was still persecuted by both the orthodox Jews and orthodox Christians of Amsterdam, he retired to the country-house of a friend in the vicinity of Amsterdam, a member of one of the persecuted sects of Protestants of that time, with whom he lived in deep seclusion from 1656 to 1661. He subsequently accompanied him to Rynsburg, where he remained till 1664, in May of which year he removed to Voorburg, where he remained in the house of the painter Tydenau till 1669. He then, at the entreaty of his friends, removed in 1671 to Scheveningen, near The Hague, where he remained till his death on Feb. 21. 1677. In personal appearance Spinoza was of middle height; his features were regular and well formed, complexion dark, hair curly and black, long black eyelashes, and, as Leibnitz remarks, "with somewhat of the Spanish in his face." To earn his livelihood he learned to grind optical glasses, and also the art of painting. His mode of living was throughout extremely frugal and secluded. He never married.

The ground of the extraordinary interest taken in Spinoza is to be found in the pantheistic view of the universe which he has carried out in the completest of extant forms in his *Ethics*. Hence none of the other works of Spinoza claim special notice. Interesting as they may be in connection with the *Ethics*, they have no intrinsic merit of their own. All his few published minor works, as well as his published correspondence, have their central point in the *Ethics*. Students of Spinoza are here referred, first, to the remarks of Goethe concerning Spinoza's philosophical system; second, to the remarks of G. E. Lessing; and, in this connection, third, to the essays of Jacobi on Spinoza and Lessing. Fichte's works are also full of references to Spinoza. Spinoza's view of the universe may be very concisely described as follows: Adopting the category of substantiality, he altogether abandoned the Jewish conception of a First Cause—a self-conscious Jehovah calling the world into existence by his mere word—and adopted in its place the Oriental notion of an unconscious substance of the universe as a whole, of which all the separate phenomena of that universe—stars, heaven, earth, mankind, animals, plants, and minerals—were but so many attributes. In his scheme there were therefore no God, no Freedom, no Immortality. Whenever he uses the word "God," it is to be interpreted as equivalent to the word "nature" or "universal substance"; when he uses the word "freedom," it is to be understood as the equivalent of "necessity"; and his conception of the word "immortality" means simply that the human soul, after death of the body, will merge again into the infinite substance, wherein no self-consciousness can possibly exist. His God is therefore no God, in the ordinary acceptance of the term; his freedom, no freedom; his immortality, the very reverse of what men mean when they lay claim to being immortal.

To understand thoroughly the style of the *Ethics*, it must always be kept in mind that Spinoza was a Jew, and that the Jewish tendency of mind betrays itself not only in the subject-matter under discussion, but also and equally in its mode of utterance. The style of all Jewish writers is abrupt, disregarding transition, and loving above everything parallelisms, as every chapter of the Bible shows. This explains, although seemingly in a paradoxical way, why Spinoza chose what he calls the "geometrical or mathematical" method for his chief work. The opening sentences are as disjointed as the opening propositions of Euclid; the first does not involve the second, nor the second the third, etc.; and none are proven, nor is there any attempt in the whole book to prove any of them. Hence the very fundamental principles of philosophy, about which alone there is any dispute, are at the beginning of the work laid down as axioms; and, what is equally objectionable, at the beginning of each new part of the *Ethics*, of which there are four parts, new axioms are introduced in the same arbitrary, abrupt manner. That the word freedom had no significance to him in its current meaning is abundantly evident from the following extracts that occur in his letters, wherein he is usually a little more outspoken than in his very guardedly worded published works. Taking the example of a stone thrown by some hand, and hence impelled by an external cause: "Now conceive, further, that the stone as it proceeds in its motion thinks and knows that it is striving, so far as in it lies, to continue in motion; then, inasmuch as it is conscious only of its endeavor, and in nowise indifferent, it will believe itself to be most free, and to persevere in its motion from no other cause than that it wills to do so. *And this is precisely that human freedom of which all men boast themselves possessed, but which consists of this alone—that men are conscious of their desires, and ignorant of the causes by which these are determined.*" To remove the last objection, that we might be free at least in thinking, Spinoza adds: "Your friend, however, affirms that we can use our reason with perfect freedom. . . . 'Who,' he asks, 'without a contradiction of his proper consciousness, can deny that he is free to think his thoughts, to write what he pleases, or to leave writing alone?' . . . I, for my part, and that I may not contradict my consciousness—that is, that I may not contradict reason and experience, and yield to ignorance and prejudice—*deny that I possess any absolute power of thinking, and that at pleasure I can will, or not will, to do this or that—to write, for example.*" The same criticism applies to his doctrine of immortality. There are numerous Latin and German editions of the *Ethics*, and of most of the other of Spinoza's works. English translations and expositions of his works are as follows: *Benedict de Spinoza, his Life, Correspondence, and Ethics*, by R. Willis, M. D. (London, 1870); *The Ethics of Benedict de Spinoza* (anon.) (New York, 1876); *Spinoza, his Life and Philosophy*, by Frederick Pollock (London, 1880); *A Study of Spinoza*, by James Martineau (London, 1882); *The Chief Works of Benedict de Spinoza* (2 vols., Bohn's Library, London, 1883); *Ethics*, translated by W. H. White and Amelia H. Stirling (1894). It includes all his correspondence, a very valuable feature. In German, Kuno Fischer's *Geschichte der neuern Philosophie* (vol. i., part 2) is devoted entirely to Spinoza and his antecedents, and is the most satisfactory work extant on this subject.
Revised by W. T. HARRIS.

**Spiræ'a** [Mod. Lat., from Lat. *spiræ'a* = Gr. σπειραία, meadowsweet, deriv. of σπεῖρα, coil, spire. So called from the shape of its follicles]: a genus of herbs and shrubs of the family *Rosaceæ*, including numerous species, such as hardhack (*S. tomentosa*), queen-of-the-prairie (*S. lobata*), and several other American, besides numerous Old World species, many of them very fine in garden-culture. Some species of *Astilbe* (family *Saxifragaceæ*), having somewhat the aspect of *Spiræa*, are cultivated under this name, incorrectly bestowed.
Revised by CHARLES E. BESSEY.

**Spiral** [from Lat. *spira'lis*, spiral, deriv. of *spi'ra* = Gr. σπεῖρα, coil, spire]: a curve that may be generated by a point moving along a straight line in accordance with a fixed law, while the line revolves uniformly about one of its points, always remaining in the same plane. The portion generated during one revolution of the line is called a *spire*; the fixed point is the *pole*; and the distance from the pole to any point of the curve is the *radius-vector*. If we take any position of the revolving line as the initial radius, and denote the angle through which the line has revolved by $\theta$, and the corresponding value of the radius-vector by $r$, the equation of any spiral may be written $r = f(\theta)$. The most interesting spirals are the spiral of Archimedes and the logarithmic spiral. The former is determined by the law that the radius vector increases uniformly as it revolves, so that the successive spires intersect it at equidistant points along its length.

In the logarithmic spiral the logarithm of the radius-vector increases uniformly, and the radius-vector itself increases by a constant ratio for every equal increment of the angle of revolution. Thus the distances of the points of intersection from the pole form a geometric progression. At every point of this curve the tangent makes a constant angle with the radius-vector. On the inner side the curve continually approaches the pole, which it only reaches after an infinite number of convolutions. The RHUMB (*q. v.*) is a similar curve on the surface of a sphere. Revised by S. NEWCOMB.

**Spiral Ducts** or **Spiral Vessels**: See HISTOLOGY, VEGETABLE.

**Spirants** [from Lat. *spi'rans*, partic. of *spira're*, to breathe]: in phonetics, a class of consonants produced by a friction of the current of breath against the walls of the narrowed organs of the mouth. They are also called fricatives (Germ. *Reibelaute*, *Dauerlaute*, *Schleifer*). Such are *s*, *z*, *sh*, *zh*. *f*, *v*, þ, ð, *ch* (in Germ. *ich*, *ach*), ʒ, and to some extent *r* and *l*. They are distinguished from explosives or stops, *p*, *t*, *k*, etc., by being continuous and not momentary. See CONSONANT. BENJ. IDE WHEELER.

**Spire**, or **Spires**: English name of SPEYER (*q. v.*).

**Spirillum**: See BACTERIOLOGY.

**Spirit-duck**: a common North American duck (*Charitonetta albeola*). The male has the head very puffy and iridescent, hence the name bufflehead. It is an expert diver.

**Spiritism**: See ANIMISM and RELIGION, COMPARATIVE.

**Spirit-level**: See LEVELS AND LEVELING and HYPSOMETRY.

**Spirit-plant**: the HOLY GHOST FLOWER (*q. v.*).

**Spirit-rapping**: See SPIRITUALISM.

**Spiritualism** [from Late Lat. *spiritua'lis*, spiritual, of a spirit, deriv. of Lat. *spi'ritus*, breath, life, spirit, soul (in Late Lat.) ghost, deriv. of *spira're*, breathe]: the creed of those who believe in the communication of the spirits of the dead with the living, usually through the agency of peculiarly constituted persons called mediums, and also in certain physical phenomena, transcending ordinary natural laws, believed to accompany frequently such spiritual communication, and attributed either to the direct action of spirits, or to some force developed by the medium's own personality.

*Revival of Spiritualism.*—The elements of the spiritualistic creed are not in themselves new, but are traceable severally to a high antiquity among different races and in widely separated localities, and have usually been associated with some form of religion; they have been revived, though not of conscious purpose, and gathered into one body of beliefs by a movement having its origin as the result of certain incidents which took place at Hydesville, a small town in the State of New York, in 1848.

In March of that year rapping sounds were heard, apparently proceeding from the furniture, walls, and ceilings, of a house in Hydesville, belonging to a family of German descent named originally Voss, a name anglicized into Fox. It was found that these sounds were always perceived in the presence of one or both of the young daughters of Mr. Fox, and that a code of communication could be established by which conversation was carried on with the intelligence supposed to produce them. It was said that in this way evidence was obtained concerning a murder believed to have been committed in the house some time before, and the sounds purported to come from the spirit of the murdered man. Many years after, in 1888, Mrs. Kane (Margaretta Fox) came before the public with a confession that she and her sister had made the sounds with their toes; but before her death she repudiated this confession.

*Noted Mediums.*—The reported phenomena at the time excited widespread attention in the U. S. and led to the formation of numerous circles of experimenters, where rappings of a similar kind were produced, and supposed communication with the spirits of the dead was established. To the spirit-rappings were added other phenomena, such as table-turning, automatic writing, trance-speaking, etc.; and the persons who developed them received the name of mediums. Mediums, according to the spiritualistic view, are endowed with a special faculty enabling them to be the agents of the communications and other manifestations of spirits. Some show evidence of this gift in early youth, and others gradually develop it in later years. The first medium, after the Fox sisters, was Andrew Jackson Davis, who attracted notice in 1845 as a clairvoyant and later as a trance-speaker. Judge Edmonds, a well-known lawyer of New York, may also be mentioned; he began an investigation of the subject, became convinced that he was himself in communication with spirits, and wrote an elaborate work on spiritualism. Mrs. Hayden, another native of the U. S., went to England in 1852, and her séances there started the spiritualistic movement which eventually spread over all Europe. In 1855 the celebrated Daniel D. Home also went to England, and later to the Continent. With Home spiritualism reached its highest development, and private and professional séances were established in almost every European town.

Home overshadowed all contemporary mediums, and gained adherents to spiritualism from every intellectual and social class. He was, according to numerous witnesses, equally successful in receiving spiritual communications and in producing physical phenomena, which were witnessed and often severely tested by competent observers. Notable experiments in testing Home's powers were made by William Crookes, by means of apparatus of his own construction, with successful results.

Some years later Slade, and also Eglinton, attracted much attention in Europe by their so-called psychography, or spirit-writing (usually produced on slates), which led to interminable discussion in the press occupied with such matters. The spiritualists attributed this psychography to the spirits, and the non-spiritualists asserted it to be due to conjuring. Slade also gave séances for a variety of spiritualistic phenomena, and achieved special notoriety from a series of sittings with Prof. Zöllner, of Leipzig, who, in *Transcendental Physics*, recorded his belief that the phenomena he had witnessed were due to intelligent "fourth-dimensional" beings.

One of the most noted mediums in England was the Rev. William Stainton Moses, who died in 1892. A full account of his experiences has been published in the *Proceedings* of the Society for Psychical Research. He claimed to receive communications from spirits, both of those recently departed and of personages belonging to remote generations. The list of his physical phenomena, according to his own account and the evidence recorded by the witnesses at his séances, comprised most of those produced by Home and other manifestations as remarkable. Mr. Moses was for several years editor of *Light*, a London spiritualistic periodical, and was, besides, a busy clergyman and school-master of high reputation, and in no sense a professional medium.

In 1892 a series of sittings under unusually stringent if not perfect conditions was held by a committee of Italian savants, among others Schiaparelli, director of the Observatory of Milan, Profs. Gerosa and Brofferio, with a Neapolitan medium, Madame Eusapia Palladino, with the result that several of this committee were convinced of the supernormal character of the phenomena observed, while the others, if not quite convinced, were unable to offer any satisfactory explanation of what they had seen. The phenomena consisted in alterations in the weight of the medium, raps, moving of furniture, and materialization of hands. The séances of Madame Palladino have attracted much attention in Italy, and are remarkable for having influenced the thought of numerous persons of high intellectual standing.

*Spiritual Communications.*—Spiritualistic communications or messages are received through the automatic writing with pencil or planchette, or trance-speaking of the medium when under spirit-control; by direct writing of the spirits on paper or slates with pencil or chalk; by precipitated writing—that is, writing supposed to be produced on paper without visible means; by table-turning, either with or without contact of the medium, and interpreted by a conventional code; and by raps on the furniture or walls of a room, made intelligible by a code as in table-turning. These communications are supposed to have two objects—one is to convey proof of the survival of the dead, the other to instruct in moral and philosophical knowledge. They are acknowledged by spiritualists to vary greatly in character and in value. Some are merely the expression of the ideas and opinions of the medium himself or of the sitters; some are trivial or false, and are attributed to a low order of mischievous spirits: others, however, it is asserted, are genuine and imply a knowledge of events or of facts beyond the range of the medium or of the inquirers, and proving their supernormal origin.

*Physical Phenomena.*—The principal so-called physical phenomena of spiritualism are lights, musical sounds, as of invisible instruments played on or playing of real instruments by invisible or materialized hands; moving of furniture and other heavy objects; the passage of matter through matter, as bringing flowers or other material objects into closed rooms; materializations of hands or other parts of the body or of complete human figures; spirit-photography; and, finally, phenomena immediately affecting the medium, such as levitation or floating in the air without visible support, the elongation or shortening of his body, and fire-tests, when the medium handles live coals and gives them to others to handle without injury, phenomena for which Home was especially renowned.

The object of these phenomena is considered by spiritualists to be the attestation of the genuineness of the communication, and they bear to spiritualistic belief much the same relation that miracles do to revealed religion. Phenomena of undignified character, like the corresponding communications, are attributed to the lower orders of spiritual beings. All these phenomena do not occur at all séances or with all mediums, and the latter are often classified according to the predominant character of their special "development." Thus there are writing mediums, trance mediums, materializing mediums, etc. A few, such as Home and Stainton Moses, seem to have been equally successful in every variety of manifestation.

*Non-spiritualistic Evidence for "Phenomena."*—Count Agénor de Gasparin carried out an elaborate series of experiments in moving tables without contact, a full account of which he published under the title *Des Tables Tournantes*. His circle consisted of himself and his family and a few skeptical witnesses whom he admitted to his séances. The experiments were made in full light, the members of the circle joining hands and concentrating their will upon the object to be moved, a condition considered by de Gasparin to be essential to success. De Gasparin, scouted the idea of the intervention of spirits in the movements he describes, and attributed them to a mental force capable of acting upon matter without the agency of muscular action. *Des Tables Tournantes* is a body of evidence very carefully recorded, and deserves attentive consideration in connection with the study of these obscure and disputed phenomena. Prof. Barrett and others have also placed on record experiences in various phenomena usually called spiritualistic, but in their case not produced in the presence of professional mediums, where, too, the hypothesis of fraud seemed to be a difficult one.

*Theories of Apparitions and Materialized Spirits.*—A typical belief is that of Allan Kardec, who asserts that the human personality consists of the body, the soul or spirit, and a spiritual body ("périsprit") of a rarefied material, and that after death the spirit can manifest itself to the senses through the périsprit, which by some force of the will or through the agency of the medium becomes visible like vapor condensed under certain atmospheric conditions.

Another theory of the materialization of spirits is that the spirit draws from the medium certain emanations by which it can make itself wholly or in part visible in a temporary reduplication of the medium's body. While materialized the spirit remains in close rapport with the medium, and at the end of the séance or on any sudden disturbance repercussion takes place—that is, the materialized body at once withdraws into the organism of the medium.

*Exposures of Fraud.*—Spiritualists acknowledge that many exposures of fraud in mediums have been made. They assert, however, that such fraud is to be expected occasionally in professional mediums, since their living depends upon the production of phenomena and the necessary power is very uncertain. They also say that the trickery is generally of a rather simple kind, and that the genuine phenomena are unmistakable and not to be so explained, and that therefore occasional trickery does not necessarily prove habitual bad faith on the part of a medium.

Spiritualists further contend that numerous exposures have been only apparent, and that much injustice has been done. This view is founded on the theory of repercussion, namely, that the materialized form when disturbed disappears, thus leaving the medium in the exposer's grasp and creating the impression that the medium has himself impersonated the spirit-form.

*Relation of Spiritualism to Religion.*—Spiritualism is not an independent religion, but its manifestations are regarded by spiritualists as corroborating those ethical teachings of Christ in which all the sects of the Christian religion substantially agree. It does not modify in any specific manner the creeds or dogmas of Christian sects, and among spiritualists are to be found persons of every shade of belief from Roman Catholic to Unitarian. To this general statement one important exception may be noted. There is in France a large class of spiritualists who believe that the existence of the soul is one of alternate spirit-life and reincarnation.

The main points of spiritualistic belief, then, as it touches religion are that at death the character undergoes no sudden change, but retains the impress of the actions and thoughts of the earthly life; that the soul enters upon a course of steady progress toward improvement; that there are in the other life occupations and interests as in this world; that all work together for the attainment of the perfect life; and that happiness depends upon the degree of moral advancement.

In 1900 there were 334 spiritualistic organizations in the U. S., with 45,030 members.

THOMAS C. FELTON.

**Spirochæ'tæ**: See BACTERIOLOGY.

**Spir'ula** [Mod. Lat., dimin. of Lat. *spi'ra*, coil]: a genus of ten-armed dibranchiate cephalopods, of which there are three species, found in most warm seas. They constitute a family, *Spirulidæ*, which has interesting relations to the nautilus and the ammonites. The extremely delicate, nacreous, chambered shell is especially common on the New Zealand shores, but the animal itself is very rarely seen in a perfect condition. Revised by D. S. JORDAN.

**Spit'head**: a roadstead off Portsmouth, England, being the eastern portion of the sea-channel separating the Isle of Wight from the English mainland. (See PORTSMOUTH.) Its security as an anchorage, being protected from all winds except those from the S. E., its contiguity to the great naval establishment at Portsmouth, and its proximity to the coasts of the Continent make it a favorite rendezvous of the British navy. Spithead has been strongly fortified since 1864. Besides the works on the Isle of Wight and on the mainland there are five iron-plated works, built from the bottom, which are among the most remarkable specimens of modern iron-plated fortification.

**Spitzberg'en**: Arctic archipelago; 400 miles N. of North Cape of Norway; between 76° 30′ and 80° 30′ N. lat., and 10° and 30° E. lon.; consisting of West Spitzbergen, Northeast Land, Stans Foreland, King Charles Land, Prince Charles Foreland, and many smaller islands. Area, 27,000 sq. miles, with no permanent inhabitants. The islands are mountainous, the peaks often rising between 4,000 and 5,000 feet, and mostly covered with perpetual snow and ice. Only along the shore between the ocean and the mountains are in some places found patches of land, where during the two summer months, when the thermometer rises 10° F. above the freezing-point, the snow melts and a few herbs appear. The mountains contain granite, marble, and coal. Bears, reindeer, and foxes are found, and innumerable whales, seals, and sea-fowl gather along the shores. The islands were discovered in 1553, and visited in 1596 by the Dutch navigator Barentz while seeking a northeast passage to India. The group forms occasionally the base of operations for Arctic expeditions. Revised by M. W. HARRINGTON.

**Spitz Dog** [used as transl. of Germ. *spitzhund*]: the Pomeranian dog, a small variety which is thought to be a cross between some of the Arctic wolf-dogs and the Arctic fox, like the Esquimaux, Siberian, Lapland, and Iceland dogs, to which, though much smaller, it has a marked resemblance. It is characterized by short and erect ears, a pointed muzzle, a curved bushy tail, and long hair, usually pure white, but sometimes cream-color or even deep black. It is brisk in its movements, useful as a watch-dog, somewhat snappish, handsome, quick of apprehension, and a favorite lapdog in Europe and the U. S.

**Spitzka**, EDWARD CHARLES, M. D.: neurologist; b. in New York Nov. 10, 1852; M. D., University of City of New York, 1873; studied University of Leipzig 1873; University of Vienna 1874; Assistant Professor of Embryology at Vienna 1874–75; Professor of Medical Jurisprudence, New York Post Graduate Medical School, 1881–82; Professor of Neurology there 1882–84; consulting neurologist St. Mark's Hospital and Northeastern Dispensary; vice-president International Medical Congress at Washington 1887; honorary president Pan-American Medical Congress 1893; author of *Insanity, its Classification, Diagnosis, and Treatment*; articles on *Organic Brain* and *Spinal Cord Diseases* in Pepper's *System of Medicine*; *The Architecture and Mechanism of the Brain* in Wood's *Handbook of Medicine*; *Insanity in Children* in Keating's *Cyclopædia*; and numerous professional essays. C. H. THURBER.

**Spleen** [from Lat. *splen* = Gr. *σπλήν*; cf. Lat. *lien*: Sanskr. *plīhán-*, spleen]; the largest of the ductless glands of the body. In man, it is situated in the left hypochondriac region, its outer convex surface corresponding with the ninth, tenth, and eleventh ribs, from which it is separated by the descending muscular attachments of the diaphragm; its inner concave surface adjoins the great pouch of the stomach. It also comes near to the pancreas, left kidney, left lobe of the liver, and arch of the colon. It is held in position by a peritoneal reflection from the diaphragm, called the suspensory ligament. It is even more directly related to these adjacent viscera by its blood-supply, the splenic artery being the largest branch of the cœliac axis, the trunk which gives off the nutrient vessels of the stomach, liver, and parts of the small intestine. The variable size and gross and minute structure of the spleen indicate that it is a great vascular reservoir. In health it is 5 inches long, 3 to 4 thick, and 1 to 1½ in breadth, and weighs 7 oz.; it is larger immediately after eating, and in malarial and certain other diseases may weigh 15 or 20 lb., and occupy the abdomen down to the pelvic bones. The fibrous capsule of the spleen is very elastic; it is reflected inward on the vessels as they subdivide, thus forming a system of ramifying partitions, which constitutes the fibrous framework of the spleen. The interspaces of this structure are occupied by the substance of the spleen, a soft, pulpy mass of dark, reddish-brown color, consisting of granular matter, red and white blood-cells, and the Malpighian corpuscles—masses of lymphoid cells closely packed about the terminal arterioles.

The functions of the spleen are not definitely known, but it is certainly the birthplace of both white and red blood-corpuscles. It is active also in the destruction of red corpuscles, but less so than was formerly supposed. It is not an indispensable organ, for it has been removed in animals and men with no serious or marked result. The spleen is frequently congested in the course of infectious diseases, such as typhoid fever, malaria, typhus fever, and the like, and is often permanently enlarged by repeated congestions, infiltration, and hypertrophy of its tissue. There may be supernumerary spleens. The spleen is liable to rupture and fissure from external violence. See HISTOLOGY.

Revised by W. PEPPER.

**Splint**: a bony growth, generally upon the inside of the fore leg of the horse, below the knee. In young horses it is usually caused by overwork. Rest, poulticing, and packing with cold wet compresses are recommended for the early stages. At a later stage, iodine, mercurial ointment, blisters, and the actual cautery may be usefully employed, but not till the inflammation is gone. If the tendons are interfered with, veterinary surgeons sometimes remove the splint.

**Splint**: in surgery, a piece of wood, leather, pasteboard, gutta-percha, metal, or other material employed to prevent displacement of the fractured ends of bones or for other analogous purposes. In many cases surgeons use bandages stiffened with gypsum, starch, dextrine, or gum-arabic in the place, and a very great number of splints have been devised for special purposes in surgery. See FRACTURE.

**Splü'gen**: a mountain-pass of the Alps leading from the Swiss canton of the Grisons into Italy over an elevation of 6,946 feet. On the Italian side it is covered at many places with galleries of solid masonry to protect travelers from avalanches. These galleries were built by the Austrian Government, and finished in 1834.

**Spofford**, AINSWORTH RAND, LL. D.: librarian; b. at Gilmanton, N. H., Sept. 12, 1825; received a classical education by private tuition; was employed in publishing and editing; became principal librarian of Congress 1865, and first assistant 1897; is member of many historical and philosophical societies; has written much for the press on historical topics. He has published *Catalogues of the Library of Congress*; *The American Almanac and Treasury of Facts* (1878–89); *The Library of Choice Literature* (1881); *Library of Historic Characters and Famous Events* (1894); and other works. During his tenure of the office of librarian the national collection grew from 90,000 to over 700,000 volumes, and the change in the law of copyright was effected by which all copyrights are entered and all facts regarding literary property verified at one central office at the Library of Congress, Washington, D. C., instead of being scattered, as was the case prior to 1870, in the offices of the district clerks throughout the country.

**Spofford**, HARRIET ELIZABETH (*Prescott*): poet and story-writer; b. at Calais, Me., Apr. 3, 1835; removed at the age of fourteen to Newburyport, Mass.; attended school at Derry, N. H., and early began writing stories for the magazines; married in 1865 Richard S. Spofford, a lawyer of Boston, and subsequently resided at Amesbury, Mass. Among her publications are *Sir Rohan's Ghost* (1859); *The Amber Gods, and other Stories* (1863); *Azarian* (1864); *New England Legends* (1871); *A Thief in the Night* (1872); *Art Decoration applied to Furniture* (1881); *The Marquis of Carabas* (1882); *Poems* (1882); *Hester Stanley at St. Mark's* (1883); *Ballads about Authors* (1887); and *A Scarlet Poppy* (1894). Revised by H. A. BEERS.

**Spohr**, LUDWIG: composer; b. at Brunswick, Germany, Apr. 5, 1784. His father was a physician. He was early noticed by the Duke of Brunswick, placed on the civil list, and furnished with means for study and travel. His masters on the violin were Maurer and Eck; visited Russia; in 1804 began his professional career in Germany; was concert conductor under the Duke of Saxe-Coburg-Gotha; in 1813 was in Vienna, in 1816 in Italy, in 1817 in Frankfort and London. A residence of some years in Dresden followed, and continued till he was called to the office of chapel-master at Cassel. D. Oct. 22, 1859. Spohr was possessed of fine sensibility and immense activity. Skillful in construction, elaborate in finish, a master of harmony and instrumentation, poetic in sentiment, imaginative, sympathetic, he ranks with the great, although not the greatest, composers. He was the violinist *par excellence* of his day. His book of instruction for the violin is a standard work. He composed in nearly every style—duos, quartettes, quintettes, sonatas, variations, overtures, cantatas, nine symphonies, five or six operas, several oratorios, songs with pianoforte accompaniments. His most famous pieces are the symphony *The Consecration of Tones* and the oratorio *The Last Judgment*, which is rather a collection of musical gems than an evenly developed structure. A vein of mournful tenderness pervading his compositions suggests monotony and mannerism. A critic has said that "if all the works of Spohr could be destroyed except one specimen in each class of composition, it would be of advantage to his reputation."

Revised by DUDLEY BUCK.

**Spoils System**: in politics, the system of bestowing public offices upon members of the party in power as rewards for political services. See CIVIL SERVICE AND CIVIL SERVICE REFORM.

**Spokane'**: city; capital of Spokane co., Wash.; on the Spokane river, and the Gt. Northern, the N. Pac., the Or. Railway and Nav. Co., and the Spokane Falls and N. railways, the Central Washington R. R., the Kootenai Valley R. R., the Spokane and Idaho R. R., and the Spokane and Palouse R. R.; about 15 miles W. of the boundary-line between Washington and Idaho (for location, see map of Washington, ref. 3–J). It is at the falls of Spokane river, and has a very picturesque location. The business portion is built about the falls, with broad streets running N. and S. and E. and W., and some of the residence districts are on higher ground. The streets are lighted by electricity, and the view from the hill, S. of the city, is at night particularly striking. The more important buildings are the city-hall, of brick and granite; the opera-house, seating 1,500; and the county court-house. The city has an excellent system of drainage and of water-works. The business streets are paved with asphalt.

*Churches and Schools.*—Spokane is the seat of a bishopric in the Protestant Episcopal Church, and the Jesuits have two or three church buildings, several parochial schools, and a college—Gonzaga College. The Jesuit missionaries came to Spokane when it was a mere village, and acquired an extensive tract of land, now within the city limits, by which their college has become well endowed, and it is now one of the finest educational institutions in the Northwest. The city has 16 public-school buildings, including a high-school building, ranging in cost from $15,000 to $100,000. One hundred and forty-eight teachers are employed, and there is a daily attendance of 6,233 pupils. The Sisters of the Sacred Heart maintain a hospital and an orphan home, and the Protestant women have established a Home for the Friendless, and a Protestant hospital (St. Luke's).

*Finances and Banking.*—In 1900 the city had a property valuation of $19,500,000 and a bonded debt of $1,320,000. The receipts from all sources are about $400.000 per annum and expenditures something less. The tax levy is 11 mills. There are four national banks with combined capital of $850,000 and surplus of $362,000. Bank deposits $4.948.775.

*Business Interests.*—The river is not only a source of abundant and superior water-supply, but it has a series of falls over a distance of half a mile as it passes through the city, from which power is obtained to operate about 36 miles of electric street-railway, many mills and factories, an electric-lighting plant, printing-presses, elevators, and small machinery generally. This admirable water-power has made Spokane an important center for the manufacture of flour. The output of the mills for 1900 was 357,080 barrels, mostly exported to Japan and China. Four breweries have an annual output of 55,000 barrels.

*History.*—In 1879 the site of Spokane was occupied by an Indian trading-store and a sawmill. The Northern Pacific Railroad was completed as far as Spokane in 1884, and from that time the place had a rapid growth. It became the chief supply-point for numerous mines of gold and silver in Washington, Idaho, and British Columbia, and a very rich agricultural region to the S. When at the height of its prosperity, in Aug., 1890, it was almost wholly destroyed by fire, the burnt area covering about 60 acres. More than $6.000.000 was invested in business blocks within two years. During the same period there was a rapid concentration of railways here. The Union Pacific was the second transcontinental line to arrive, and the Great Northern came in 1892. The main lines built numerous branches in all directions from the city, and the Spokane and Northern, an independent road, was built into British Columbia. At the close of 1892 Spokane had eight railways, and had become one of the most important railway centers of the Pacific coast. In the winter of 1894–95 its citizens gave 1,000 acres of land adjoining the city to the U. S. Government in consideration of the establishment thereon of a large military post, and Congress passed a law in Jan., 1895, creating the post, Fort Wright. Pop. (1880) 350; (1890) 19.992; (1900) 36.848. EDITOR OF "SPOKESMAN-REVIEW."

**Spole'to** (anc. *Spole'tium*): town: in the province of Perugia, Italy; about 60 miles N. N. E. of Rome, on a slight elevation, the crater of an extinct volcano (see map of Italy, ref. 5–E). The old castle, whose foundations date from the time of Theodoric, stands on a height above the town, from which it is separated by a chasm-like valley spanned by a bridge 670 feet long and 280 feet high, originally Roman, but rebuilt, probably in the tenth century, and now serving as an aqueduct as well as bridge. The old Roman arched gateway, known as the Porta della Fuga, is, according to Livy, a monument of Hannibal's time. The grand Palazzo Comunale has a tower of the eleventh century. Pop. 7,690.

**Spondias**: See HOG-PLUM.

**Sponge-fisheries**: those industries which consist in gathering the sponge of commerce, which is the fibrous, horny framework remaining when the fleshy matter has been washed away from one of the *Ceratospongia*. The softness, and consequent value, of a sponge depends on the fineness and elasticity of the fibers, and this varies, even in the same species, according to the conditions under which the sponge has lived. The best sponges grow in clear, quiet water, from 150 to 200 feet deep, those found where the water is shallow or turbid being coarser in texture. The principal commercial sponges are *Spongia officinalis*, which includes the toilet-sponges and Turkey sponges of the Mediterranean and the glove-sponge of Florida and the Bahamas; *Spongia equina*, containing the horse-sponge of the Mediterranean and the sheep's-wool-sponge, velvet-sponge, and the grass-sponge of American waters; *Spongia agaricina*, comprising the zimocca of the Mediterranean and the yellow and hard-head sponges of America. There are numerous varieties of these species, while commercially from fifteen to twenty-five grades are recognized. These range in value from twenty-five cents to $50 per pound, the fine Turkey sponges being the most expensive. The greater portion of the sponges of commerce, as well as the best qualities, come from the Mediterranean and Adriatic, along the line of coast extending from Ceuta, on the northern coast of Africa, to Trieste. Some sponges are also taken in the Red Sea, and large quantities, mostly of the coarser varieties, in Florida and the Bahamas. Good sponges also occur off the Australian coast and at other points in the Pacific, but as yet they have been gathered only for local use.

*Methods of Gathering Sponges.*—Sponge-fisheries are mostly carried on from small rowboats, and where larger craft—ranging from 5 to 50 tons—are employed they are used to transport the boats to the fishing-grounds and to market the catch. The greater portion of the sponges are wrenched from the bottom by a spear with four or five prongs; but, owing to the weight of the handle, this implement can be used only in water under 40 feet deep; beyond that depth divers are employed, or in some localities a dredge. In connection with the spear a water-glass is commonly used, this being a tube of wood or metal 3 or 4 feet long, with an end of plain glass. When this is lowered into the water the bottom can be seen through it plainly. In some localities in the Mediterranean the primitive method is followed of tossing a stone dipped in oil ahead of the boat. There are some variations in the process of preparing sponges for market, but in the main it is as follows: After the sponge has been taken from the sea it is exposed to the air until decomposition sets in, and is then beaten with a stick or trodden under foot in water till the soft parts are removed. In Florida the practice is to place the sponges in pens, where the animal matter decomposes, and is washed out by the tide. After cleaning, the sponges are bleached, dried, and baled. The annual import of sponges into Great Britain is about $1,000,000. The Florida sponge-fishery for 1890 amounted to 366,772 lb., worth $438,682. Successful experiments have been made in cultivating sponges, but as yet the work has not been carried on on a large scale. Fresh sponges are cut into pieces about an inch square, care being taken to injure the outer skin as little as possible. The cuttings are skewered on bamboo rods, each rod bearing three pieces, and these are attached to boards and sunk in favorable localities. The drawback to sponge-culture is the fact that it requires from three to seven years for a sponge to attain a marketable size; on the other hand, small or ill-shaped sponges, which would otherwise be of little or no use, can be used in this way. F. A. LUCAS.

**Sponges** [from O. Fr. *esponge* > Fr. *éponge* : Ital. *spunga* : Span. *esponja* < Lat. *spongia* = Gr. *σπογγιά, σπόγγος*]: the members of the group *Spongida* or *Porifera* of zoölogists. The sponges are animals of remarkably uniform structure, although varying greatly in appearance. In all forms three layers may be distinguished: (1) a flattened layer of epithelial cells (ectoderm) covering the outer surface; (2) a digestive layer (entoderm) of columnar cells, each with its free end surrounded by a delicate collar, from which projects a whip-like flagellum; and (3) between these two a third layer (mesoderm), in which the skeletal elements and the reproductive cells arise. In the simplest sponges these layers are arranged in the form of a cup, the hollow or cloaca being lined with entoderm, the outer surface covered by ectoderm, the mesoderm being between the two. In other forms the arrangement becomes more complicated. All over the outer surface are minute openings or pores which communicate with canals, and through these water enters the mass of the sponge. In this the canals branch and supply large numbers of chambers (*ampullæ*) lined with entoderm, and from these ampullæ the water is collected into excurrent canals and transported through the cloaca to the exterior. In any common sponge the general course of these canals

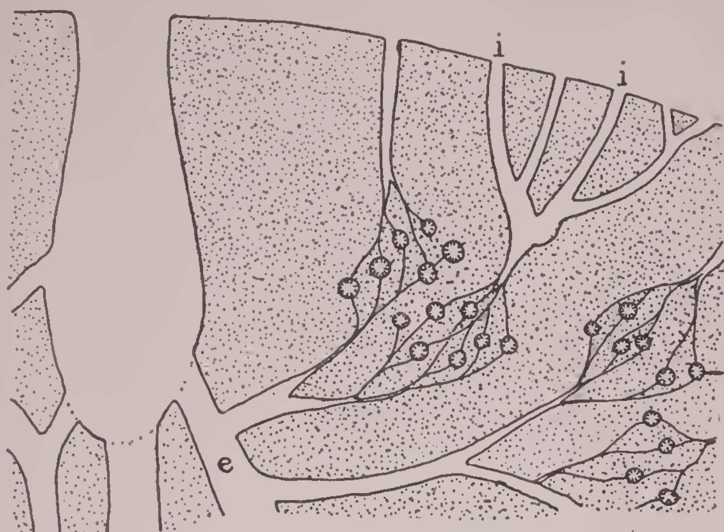

Fig. 1.—Diagram of a part of a sponge showing the pores and incurrent canals, *i*, communicating with the ampullæ, *a*; and the excurrent canals, *e*, leading from the ampullæ to the cloaca.

can be traced among the fibers. (See Fig. 2.) In these forms the digestive layer is restricted to the ampullæ, while the ectoderm lines all the canals. Nourishment is obtained from minute particles drawn in with the water which is constantly passing through the body.

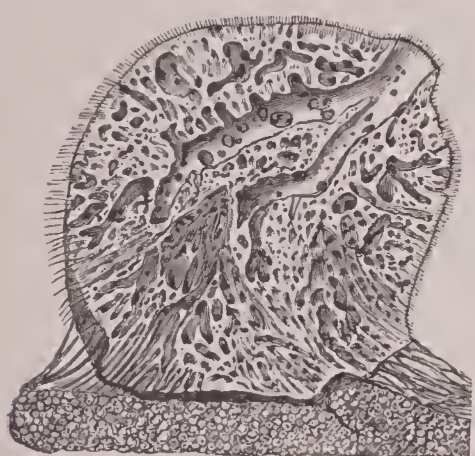

Fig. 2.—Section of a sponge (*Tethya*) showing the cloaca and the canal system in outline.

In some sponges no skeleton occurs, but in the majority some framework is necessary to support the weight of the flesh. The skeletal elements are of two kinds, spicules and fibers, and these are greatly different, both in appearance and in origin. The spicules are extremely regular, although they vary greatly among different sponges. Each spicule is the product of a single cell, and is formed on the outer surface of the secreting body. These spicules are of two kinds; in the one they are composed of calcium carbonate, in the other

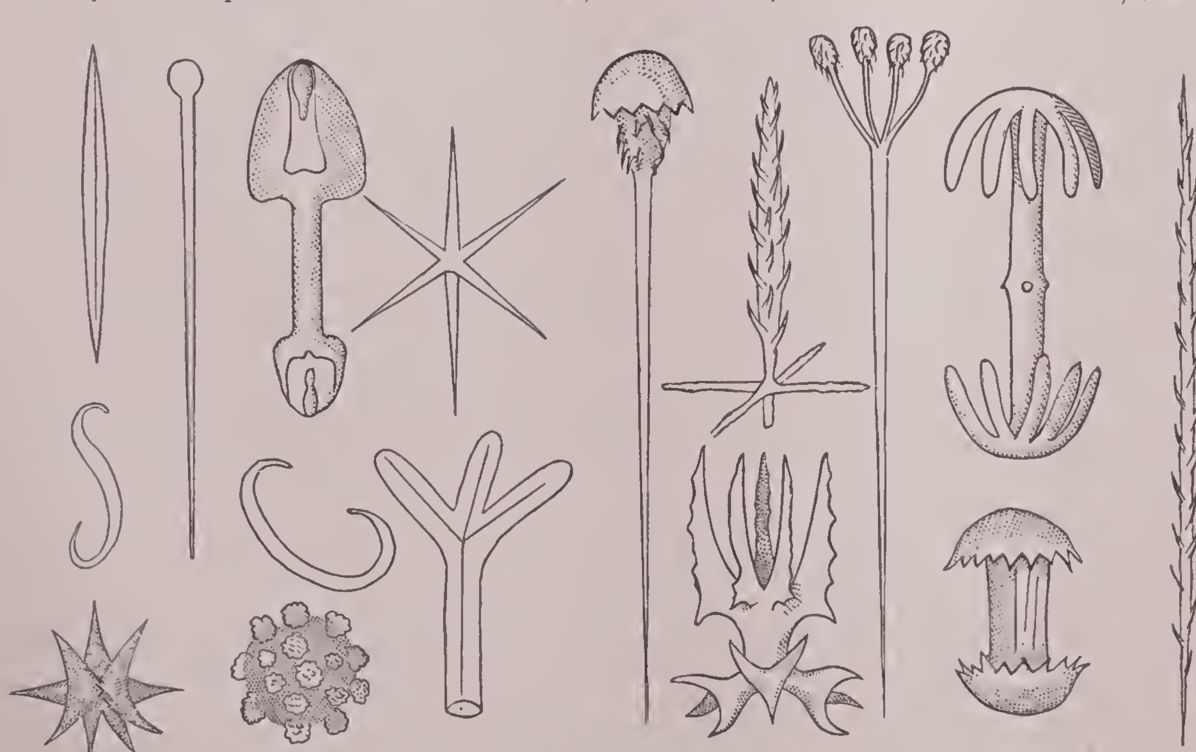

Fig. 3.—Different kinds of sponge spicules, enlarged.

of silica; and upon this chemical basis sponges are divided into two classes. Fibers and siliceous spicules may occur in the same sponge. The fibers form a continuous network, and are the result of secretion from the ends of numerous cells. Chemically they consist of a peculiar organic sub-

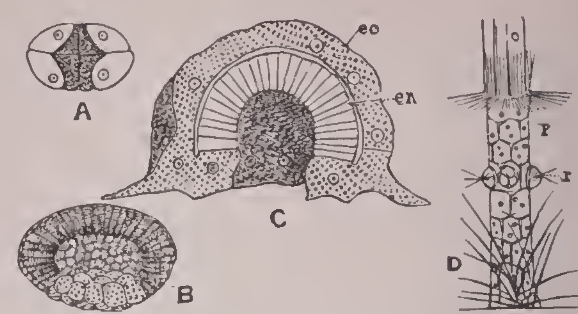

Fig. 4.—Development of a calcareous sponge (after F. E. Schulze): A, early segmentation of egg; B, blastosphere stage (close of segmentation); C, gastrula after fixation; D, young sponge after formation of spicules; *ec*, ectoderm; *en*, endoderm; *p*, incurrent pores; *o*, ostiole; *r*, radial tubes.

stance known as spongin. When spicules and fibers occur in the same sponge the spicules are imbedded in the fibers.

In the mesoderm (the layer which forms the skeletal elements) are the reproductive elements. These consist of eggs and sperm-cells, and it is only after the union of these two that the egg will develop. In the process of development the egg segments (see Embryology), and then, in the forms most studied, one side of the egg pushes into the other, thus giving rise to the embryo known as a gastrula, in which ectoderm and entoderm are differentiated. The gastrula becomes fixed to some solid body, and pores break through the wall, forming the beginning of the incurrent-canal system. Later the excurrent opening or ostiole is formed, and all subsequent changes are the result of partial division or budding from this larva. The skeleton arises early, and in its future growth keeps pace with the general growth of the sponge.

Fig. 5.—*Leucosolenia*, one of the calcareous sponges, and three of its spicules, enlarged.

Various systems of classification of sponges have been advanced. The best seems to be that which divides the group or branch into two classes, *Calcarea* and *Silicea*. The *Calcarea* (those with calcareous spicules) are all small, marine, and without any economic importance. According to the complication of structure they are subdivided into three orders. Fig. 5 is an illustration of one of the simplest forms.

The great majority of sponges belong to the *Silicea*, in which spicules, when present, are siliceous in character. Some forms, however, are degenerate, and have lost the spicules, while in a few, which form their incrusting sheets, all skeletal structures are absent. Three orders of *Silicea* may be recognized. In the first, or *Hexactinellidæ*, the spicules are six-rayed, and the resulting skeleton is extremely regular. These forms occur as fossils and in the deeper parts of the ocean, and include the "glass-rope sponges" and that beautiful form termed the "Venus's flower-

basket sponge." In the second order, *Lithospongiæ*, the spicules are never united by horny fibers. Here belong the large sponges known as "Neptune's-cup," and from this group have apparently come those forms without skeleton. The last division, the *Cornacuspongiæ*, have horny fibers, while spicules may or may not be present. In this group belong the only fresh-water sponges, several species of which inhabit the rivers and ponds of the U. S. The decay of these frequently injures the water-supply of cities. To this same group also belong the sponges of commerce. For the preparation, etc., see SPONGE-FISHERIES. The literature of the sponges embraces nearly 2,000 titles. The list to 1886 can be found in Lendenfeld, *Systematic Position and Classification of Sponges* in *Proc. Zoöt. Soc. London* (1886). Important later papers are Vosmaer, *Porifera*, in Bronn's *Klassen und Ordnungen des Thierreichs* (1887); Schulze, *Hexactinellids*, in vol. xxi. of *Zoölogy* of Challenger voyage.
J. S. KINGSLEY.

**Sponsors** [from Lat. *spon'sor*, promiser, surety, (in Late Lat.) sponsor, deriv. of *sponde're*, *sponsum*, promise solemnly; cf. Gr. σπένδειν, make a libation to the gods]: in general, those who in any way become surety for another; specifically, one who at the baptism of an infant promises in its name that it shall lead a Christian life: a godfather or godmother. The sponsors also bind themselves to see to it that the child shall receive Christian training. Usually, in the Roman Church, there are two sponsors, a man and a woman, and the relation of godfather or godmother and godchild is held to be a real one, precisely as though it were one of consanguinity. The rule of the Church of England calls for three sponsors, two of whom are of the same sex as the godchild, and no impediment to marriage is created by this relation; the present Anglican rule also permits parents to act as sponsors.

**Spontane'ity** [Mediæv. Lat. *spontaneitas*]: a term used in philosophy to express self-origination. It is sometimes confounded with freedom. Freedom involves not only spontaneity, but also conformity to law or consistency with itself. Mere spontaneity may contradict each act by its successor, and thus its entire series may reduce to zero, thus preventing its realization by external acts. The existence of spontaneity is denied by strict necessitarians, who think all events under the form of causality, making each effect to flow from an external cause; but an examination of the presuppositions of necessity discovers that the ultimate cause—the "totality of conditions"—must be self-determining or spontaneous. Everything that happens must ultimately flow from a spontaneous activity. This spontaneity—all spontaneity—likewise can be shown to be personal will or else dependent on it in the last analysis. Cousin laid much stress in his philosophy upon the spontaineity of reason as contradistinguished from its reflective activity. While reflection depends on the arbitrary will of the individual, and is subject to error, the spontaneous original activity of reason is above reflection and arbitrariness, and not liable to error. Such a theory of reason was applied to the support of *a priori* ideas upon which the eclectic system was built. Schelling's "intellectual intuition" and Reid's "common sense" were used much in the same way; also, "intuition of the reason," which cognizes *a priori* ideas, according to many contemporary philosophers, corresponds to Cousin's "spontaneity." It is noteworthy that Fichte regarded the philosophic perception of the principles of the true science of knowledge to be a higher order of reflection—as it were, a third intention of the mind (see PHILOSOPHY), whereas Cousin would make it a first intention.
WILLIAM T. HARRIS.

**Sponta'neous Combustion**: combustion which takes place without the application of heat or other means specially designed to promote that end. Lucifer matches have ignited when exposed to the sun's rays, and phosphorus, when in a dry state, has often taken fire at the touch of the hand, on account of its affinity for oxygen. In fact, it is this same readiness to combine with oxygen which causes spontaneous combustion in the case of other bodies, so that anything which will increase it will increase the tendency to such combustion. Mechanical division increases it greatly, by affording a larger surface to the action of oxygen, and by lessening the conducting powers of the bodies acted on. If the oxides of nickel, cobalt, or iron are reduced by hydrogen below a red heat, the resulting finely divided metals take fire when poured into the air; but if heated too highly, they become agglomerated and lose the property, unless some finely divided powder is present to keep them porous, such as alumina precipitated with the metallic oxides. Freshly burned charcoal is liable to take fire, owing probably to condensation of oxygen in its pores; on this account it is not ground for making gunpowder until it has been kept for a time. Recently expressed fixed oils absorb oxygen and give out carbon and hydrogen; the temperature of heaps of rags, tow, sawdust, and similar bodies soaked with oil, grease, turpentine, varnishes, etc., will rise on this account, and the low conducting power of such materials helps the process, until very often the mass takes fire. Serious conflagrations have resulted from this cause. Bituminous coal, especially when containing much pyrites, is liable to spontaneous combustion, when moistened with water. Moisture aids spontaneous combustion also in the cases where piles of damp hay or freshly mown grass have taken fire. Barns have probably been burned in this way. Strong nitric acid will act on straw, hay, and such bodies so as to render them spontaneously combustible. Some gases ignite spontaneously, as phosphuretted hydrogen. The illuminating oil distilled from petroleum sometimes gives off gases that inflame spontaneously before it is refined in the "agitator." There are also spontaneously combustible liquids, of which cacodyl is an example. (See PYROPHORI). There are a number of alleged cases of spontaneous combustion of the human body, but there is hardly an instance which admits of no other explanation. Liebig considered that the dead body of a fat man, who had been saturated with alcohol, might possibly burn, but that in no circumstances could a body, in which the blood is circulating, take fire.
Revised by R. A. ROBERTS.

**Spontaneous Generation**: See GENERATION, SPONTANEOUS.

**Spoonbill**: any one of five or six species of wading birds closely related to the ibises, and remarkable for their spoon-shaped bills. The family *Ptatateidæ* to which they belong has been divided into two genera: *Ajaja*, in which the lower portion of the trachea is simple, and *Platatea* in which it is convoluted. The roseate spoonbill (*Ajaja ajaja*) of tropical and sub-tropical America, the sole representative of the first-named genus, is from 30 to 36 inches long; the back, wings, and under parts are of a delicate rose color; the lower neck, smaller wing-coverts, and tail-coverts of a rich carmine hue; legs darker. The bill and bald head are varied with tints of green, yellow, and black. This bird occurs in the southern parts of the U. S., but is yearly growing scarcer as it is much sought after. The birds of the genus *Platalea*

European spoonbill (*Platalea leucorodia*).

are mostly white, and are found in Europe, Asia, and Australia. *Platalea leucorodia*, the only species found in Europe, was formerly in some demand for the table. In the U. S. the name spoonbill is often applied to the SHOVELER (*q. v.*). The spoonbill sandpiper is *Eurynorhynchus pygmæus*, of Northeastern Asia, occurring occasionally in Alaska.
F. A. LUCAS.

**Spooner**, SHEARJASHUB, M. D.: author; b. at Brandon, Vt., in 1809; graduated at Middlebury College 1830, and at New York College of Physicians and Surgeons 1835; was a dentist in New York. He was the author of several professional treatises, of *Anecdotes of Painters, Engravers, etc.* (3 vols., 1853), and of a *Biographical and Critical Dictionary* *of Painters, Engravers, Sculptors, and Architects* (1853; new ed., 2 vols., 1865), containing notices of 12,000 artists. D. at Plainfield, N. J., in Mar., 1859.

**Sporades**, spor'ă-deez [= Lat. = Gr. Σποράδες (sc. νῆσοι, islands), liter., fem. plur. of adj. σποράς, σποράδος, scattered, deriv. of σπείρειν, scatter]: those islands in the Grecian Archipelago which are not included in the group of the Cyclades. In a restricted and more accurate sense it includes only the islands near the west coast of Asia Minor between Samos and Rhodes. The more important are Samos, Nicaria, Patmos, Kalymno, Cos, Syme, Telos, Scarpanto, and Rhodes. All belong to the Ottoman empire and are comprised in the vilayet of the Archipelago. The cluster of islands N. of Negropont is sometimes called the Northern Sporades. Scyros, Scopelos, Sciathos, and Halonnesos are the chief. They belong to Greece. E. A. GROSVENOR.

**Spore** [from Gr. σπόρος, sowing, seed, deriv. of σπείρειν, scatter, sow]: in botany, a "single cell which becomes free and is capable of developing into a new plant" (*de Bary*). Sachs attempted to limit the term by defining a spore as "a reproductive cell produced directly or indirectly by an act of fertilization," reserving the term gonidium for those reproductive cells which are produced without any previous act of fertilization. Bennett and Murray, on the contrary, apply the term to "any cell produced by ordinary processes of vegetation, and not directly by a union of sexual elements, which becomes detached for the purpose of direct vegetative propagation." Adopting de Bary's definition, spores in Sachs's sense are sexually produced, or briefly sexual spores, while those of Bennett and Murray are asexual spores.

Many kinds of spores are distinguished by botanists, only the more common of which are noticed here. *Æcidiospores* are cells formed by abstriction in the "cluster-cup" stage of a rust. (See RUSTS.) *Ascospores* are spores formed by internal division of the protoplasm of a cell, termed an ascus. (See ASCOMYCETES.) *Auxospores* are the larger cells occurring in the life-history of diatoms, each the starting-point of a new series of divisions. *Basidiospores* are cells formed by pullulation and abstriction from a cell termed a basidium. (See BASIDIOMYCETES.) *Carpospores* are spores formed in a sporocarp, e. g. in liverworts and mosses. *Chlamydospores* are thick-walled spores formed singly and asexually in the cells of various simple algæ and moulds. *Conidiospores*, *conidia*, or *gonidia* are cells formed asexually, usually by abstriction of a little-modified hypha. *Macrospores*, in pteridophytes, are the large spores which upon germination form prothallia-bearing female organs. In anthophytes the embryo-sac is the homologue of the macrospore. *Microspores*, in pteridophytes, are the small spores which upon germination form minute prothallia-bearing antherids. In anthophytes the pollen-cell (pollen-spore) is the homologue of the microspore. *Oöspores* are cells produced by the fertilization of oöspheres by antherids. When thick-walled they are often called *resting-spores*. A *sporidesm* is a compound spore, or a spore-cluster; each spore in such a structure is known as a *merispore*. A *sporidium* is a small spore abjointed on a promycelium. *Stylospores* are stalked spores; the term is sometimes restricted to those formed in pycnidia. *Teleutospores* are the spores, one to many, formed in the tightly fitting asci of the *Uredineæ*; the term is commonly applied to the asci with their contents. *Tetraspores*, in the red seaweeds (*Florideæ*), are the spores formed in tetrads by the fission of a mother-cell. *Uredospores* are the stylospores of the *Uredineæ*. *Zoöspores* are motile spores, always aquatic. *Zygospores* are cells produced by the union of similar cells; known also as *resting-spores*. See FUNGI. CHARLES E. BESSEY.

**Sporozo'a** [from Gr. σπόρος, seed + ζῷον, animal]: a class of protozoans the members of which are parasitic in all stages of their existence. They lack all special organs of locomotion, and reproduce by the conversion of the protoplasm of the cell into minute particles or spores, which, frequently passing through an amœba-like stage, develop into the adults. Four sub-classes are recognized: GREGARINIDA (*q. v.*), *Amœbosporida*, *Sarcosporida*, and *Myxosporida*, of which only the first contains many species. By many writers the disease known as cancer (*carcinoma*) is regarded as the result of parasitism of sporozoans in the body. J. S. K.

**Sports**: in general, diversions of the field or of the turf; in a special sense, contests between athletes. Apparently the earliest competitive athletic sports were those of Greece and Rome, from 1,000 to 2,000 years B. C., though the name athletic is of recent application and in its Greek origin referred only to those who competed for prizes in public games, thus separating into a distinct class the ἀγωνισταί, who exercised and competed with each other for pleasure or improvement. In earliest times the best citizens competed at the Olympian, Pythian, Nemean, Isthmian, and Panathenæan games, and highest honors were paid to the winners, but a professionalism very similar to that of these times appeared, and the dignity given to the contests was lost. The events open to competition were foot-racing, leaping, throwing the discus, wrestling, boxing, and the pancratium, a combination of boxing and wrestling, and, separate from these, chariot-racing.

When the Romans invaded Britain they brought with them the games of the soldiery, such as jumping, running, hunting, swimming, and combats on horseback. With the advent of the Saxons came skating, hawking, and wrestling, and in the Norman era were introduced the more accomplished arts of the tourney and joust. In the seventeenth century cards, dice, hawking, following the hounds in chase, football, bowling, quoits, wrestling, fencing, shovelboard, shuttlecock, and billiards were of prevalent interest. Bull and bear baiting and cock-fighting came in the eighteenth century, and were popular with people of both sexes. It is interesting to note the revival of football in the eighteenth century, it having been a sport of so much prominence in the early part of the fourteenth century. It was prohibited in England in 1349 because it interfered with the other sports. Falconry, or hawking, has almost disappeared from England, its place being largely taken by fox-hunting. Fox-hunting, so called, is popular in some parts of the U. S., where often the presence of a fox is made unnecessary by dragging a bag of anise seed, which leaves a scent in its trail, over the ground where the hunt (?) is to take place. The hounds follow this scent readily.

Wrestling, boxing, and pedestrianism have been popular for centuries, but it was not until well along into the nineteenth century that the interest in athletic sports developed into a passion.

The schools and colleges of Great Britain early took active part in organizing athletic clubs. In 1837 the Rugby Crick Run was founded, and Mar. 27, 1858, an annual steeplechase was inaugurated, both at Rugby, and the School Hunt was started at Shrewsbury in 1842.

Oxford and Cambridge met at Christ Church Cricket-grounds, Oxford, Mar. 5. 1864, for the first inter-'varsity athletic competition. The events were running 100 yards, 440 yards, and 1 mile; jumping, both for height and distance; hurdling, 120 and 200 yards, and steeplechasing. Each of the competing teams won four of the events.

The first important athletic meeting held in London was that of the Civil Service Athletic Sports at Walham Green, on Apr. 22 and 23, 1864. In 1863 the Mincing Lane Athletic Club was formed, which in 1866 became the now famous London Athletic Club.

From about 1861 the development and spread of athletics all over the civilized world has been prodigious. Since the civil war the U. S. has kept pace with Great Britain, and scarcely a city of 20,000 inhabitants can be found in North America or Great Britain which has not at least one flourishing club for the promotion of general athletics. In Germany and France the same interest is noticeable, and it has developed in a large degree all over Europe, Australia, and the British colonies.

Since 1880 athletics has become a most important feature of scholastic life throughout the U. S., and seems to be substituting itself for the lawlessness exhibited by students in class rushes and hazing affairs. In many institutions of learning the encroachment of organized sports upon purely scholastic occupations has caused some of the governing bodies to place practically prohibitory restrictions on some of the games, most notably upon football.

*Professionalism* has played a most important part in general athletics, and that part has not in all respects been good, so that very carefully prepared definitions of an amateur have been adopted by practically all amateur clubs in the U. S., Great Britain, Canada, and France, and competitors at the amateur meets are obliged to qualify in accordance with their terms.

In the eastern part of the U. S. the definition of an amateur, as adopted by the Amateur Athletic Union, is generally accepted, and is as follows:

"One who has not entered in an open competition; or for either a stake, public or admission money or entrance-fee; or under a fictitious name; or has not competed with or against a professional for any prize or where admission-fee is charged; or who has not instructed, pursued, or assisted in the pursuit of athletic exercises as a means of livelihood, or for gain or any emolument; or whose membership of any athletic club of any kind was not brought about or does not continue because of any mutual understanding, express or implied, whereby his becoming or continuing a member of such club would be of any pecuniary benefit to him whatever, direct or indirect, and who shall in other and all respects conform to the rules and regulations of this organization.

"*Definition of a Novice.*—The sports over which the A. A. U. claims jurisdiction shall be divided into the following classes: Baseball, billiards, bowling, boxing, fencing, football, gymnastics, hurdle-racing, jumping, lacrosse, lawn-tennis, pole-leaping, putting shot, quoits, racquets, rowing, running, sculling, skating, swimming, throwing the hammer, tug of war, walking, and wrestling. An athlete shall be held to be a novice in each of these twenty-four classes until he shall have won a prize in competition in that class open to the members of two or more clubs. The winning of such a prize shall prevent his future competition as a novice in that class, although his entry may have been made before he lost his standing as a novice."

The English Amateur Association has adopted the following definition:

"An amateur is any person who has never engaged in, nor assisted in, nor taught any recognized athletic exercise for money, or who has never, either in public or in private, raced or exhibited his skill for a public or for a private stake, or other remuneration, or for a purse or for gate-money, and never backed or allowed himself to be backed either in a public or private race.

"A novice is one who has never won a prize in a similar class of competition—i. e. winning a prize for walking would not disqualify for running, and *vice versa*; but winning a prize for running any distance would disqualify for running. This rule does not apply to school and boys' races."

The Pacific Coast Association is somewhat more liberal in its definition, as are the associations of Canada and France.

Professionals are found in nearly all branches of sport, and while they undoubtedly raise the standard of the sports in that they make the records high, it is a fair question if it would not be better if amateur effort alone set the mark for amateur competitors. Pedestrianism, which was popular with professionals a few years ago, is fast disappearing from all competitions. Walking-matches are no longer popular, and largely because of the difficulty of differentiating a walk from a run. Archery, which was and still is popular in Great Britain, has never been very popular in the U. S. The same may be said of the game of cricket, its place being largely taken by baseball.

Meets of Scottish and Irish clubs are held annually wherever Scotchmen or Irishmen are to be found. The Irish games are very similar to those held throughout the U. S., but the Scotch offer variety in tossing the caber—a log 16 feet long with a diameter of 11 inches at one end and 5 at the other—quoit-pitching, and a sword and hornpipe dance. A Scottish winter game called curling is becoming deservedly popular in North America, especially in Canada.

Most of the popular interest in general athletics in the U. S. gathers about the annual meets of the metropolitan and intercollegiate clubs. The records of these meets are annually published in the principal newspapers, and in several almanacs and sporting annuals.

Fishing and hunting will always be popular with sportsmen, and nowhere are better opportunities afforded than in the U. S. and Canada. Stringent game-laws have been passed in most of the States, so that the wanton destruction of game—as evidenced by the entire destruction of the buffalo, and of the pigeon-roosts in Ohio, and of the salmon in many of the Eastern rivers—is no longer possible. The U. S. Fish Commission is restocking lakes and rivers with game fish, and game protective associations are seeing that game-laws are enforced.

For extended accounts of various sports, see BASEBALL, CRICKET, CURLING, FOOTBALL, GOLF, LACROSSE, LAWN-TENNIS, ROWING, WRESTLING, YACHTS AND YACHTING, etc.

BIBLIOGRAPHY.—Strutt, *Sports and Pastimes of the English People*; *The Badminton Library*; Bell's *Handbook of Athletic Sports*. EDWARD HITCHCOCK, JR.

**Sports, Book of**: a proclamation by James I. of Great Britain, issued in 1618, setting forth certain games which might lawfully be indulged in on Sundays after church service. Among the sports allowed were "dancing, archery, leaping, vaulting, May-games, Whitsun-ales, morris-dances, and the setting up of May-poles." It was designed to prevent unlawful interference by Puritanical magistrates with popular recreations. Bear-baiting, bull-baiting, bowling, and "interludes" were forbidden on Sundays. Charles I. reissued the proclamation in 1633. In 1644 the Long Parliament directed that all copies of the *Book of Sports* be burned by the common hangman. In both instances the publication of the *Book of Sports* gave rise to intense excitement, and aroused the strongest opposition among the Puritans. See Govett, *The King's Book of Sports* (1890).

**Spots, Solar**: See SUN.

**Spotswood**, ALEXANDER: governor of Virginia; b. at Tangier, Africa, 1676; was deputy quartermaster-general under the Duke of Marlborough; went to Virginia as governor 1710, and held office until removed in 1722; deputy postmaster-general 1730–39; was the pioneer of iron-manufacturing in Virginia; was originator of an act improving the staple of tobacco, and making tobacco-notes a medium of common exchange; lent great aid to William and Mary College; was made major-general 1740 and placed in command of an expedition to the West Indies; died at Annapolis, Md., June 7, 1740, before the embarkation took place.

**Spotswood**, or **Spottiswood**, JOHN: prelate and historical writer; b. in Scotland in 1565; was educated at Glasgow, and in 1601 went to France as chaplain to the Scottish ambassador. He accompanied James VI. to London in 1603, and in the same year was made Archbishop of Glasgow and a member of the privy council for Scotland; in 1615 was made Archbishop of St. Andrews and Primate of Scotland. Through his influence the Perth Assembly sanctioned the Five Articles (1618). In 1633 he crowned Charles I. at Holyrood, and in 1625 became chancellor of Scotland. He drew great obloquy on himself for the part he took in the examination of John Ogilvie, a Jesuit priest who was apprehended at Glasgow and hanged for refusing to disown the temporal power of the pope, and in the prosecution of Lord Balmerino, who was condemned to death for the crime of "lease-making" (verbal sedition), and pardoned only after a long imprisonment, Spotswood, his personal enemy, taking an active part in the proceedings. In 1637 he endeavored to introduce the new liturgy and book of canons into Scotland, urged on by the king and Laud, and, as is said, contrary to his own wish. Removed from the chancellorship by King Charles, deposed from his bishopric by the assembly convened at Glasgow in Nov., 1638, excommunicated, and declared infamous, he fled to London, where he died Nov. 26, 1639. He wrote a *History of the Church of Scotland* (published in 1625), the greater part of which treats of the history of his own times. Among his other writings is a Latin treatise (*Refutatio Libelli de Regimine Ecclesiæ Scoticanæ*), written in answer to a tract of Calderwood's, published in 1620. His *Life* was written by Bishop Duppa and by Bishop Russell, the latter prefixed to the Spottiswood Society edition of his *History of the Church of Scotland*.

**Spottsylvania Court-house, Battles at**: See WILDERNESS.

**Sprague**: town; Lincoln co., Wash.; located on the Northern Pac. Railroad, 42 miles S. W. of Spokane (for location, see map of Washington, ref. 4–J). It is in an agricultural and stock-raising region, is the trade-center of the Big Bend country, and contains railway machine-shops and car-works that cost $250,000, a national bank with capital of $50,000, and a daily and three weekly newspapers. Pop. (1890) 1,689; (1900) 695.

**Sprague**, CHARLES: poet; b. in Boston, Mass., Oct. 26, 1791; educated at the Franklin School, Boston. He entered mercantile life at the age of thirteen and was cashier of the Globe Bank from 1825 to 1865. He wrote prize prologues for the opening of theaters and delivered Φ. Β. Κ. poems, centennial and anniversary odes, and other occasional pieces, the best known of which is his *Shakspeare Ode*, recited at the Boston theater in 1823. A collected edition of his writings in verse and prose was published in Boston in 1841 (revised editions in 1850, 1855, and 1876). D. in Boston, Jan. 14, 1875. H. A. BEERS.

**Sprague**, WILLIAM BUELL, D. D., LL. D.: clergyman and annalist; b. at Andover, Conn., Oct. 16, 1795; graduated at Yale College 1815; studied at Princeton Theological Seminary 1816–19; was colleague with Dr. Lathrop over the Congregational church of West Springfield, Mass., 1819–21, and pastor 1821–29; pastor of the Second Presbyterian church of Albany, N. Y., 1829–69; visited Europe in 1828 and 1836; engaged exclusively in literary work at Flushing, L. I., 1869–76. D. at Flushing, L. I., May 7, 1876. Dr. Sprague was a preacher and public speaker of special eminence; made a collection of autographs (nearly 100,000 in number) and religious pamphlets, presenting the latter to the New York State Library; won the title biographer of the Church by his most important publication, begun in his fifty-seventh year, *Annals of the American Pulpit*, sketches of the most prominent clergymen of all denominations from the earliest dates to 1855 (10 vols., New York, 1857–76); and among other works *Letters to a Daughter* (New York, 1822; republished under the title *The Daughter's Own Book*); *Letters from Europe* (1828); *Lectures on Revivals* (1832); *True Christianity and other Systems* (1837); *Life of Rev. Edward Dorr Griffin, D. D.* (1838); *Letters to Young Men* (1845); *Women of the Bible* (1850); *Visits to European Celebrities* (1855); and *Life of Rev. Jedidiah Morse* (1874). C. K. HOYT.

**Sprain**, or **Subluxation** [*sprain* is deriv. of *sprain* (verb), from O. Fr. *espreindre* > Fr. *épreindre*, press, wring < Lat. *expri'mere*, press out; *ex*, out + *pri'mere*, press. *Subluxation* is from *sub-*, partially + *luxation*, from Lat. *luxa're*, dislocate]: a stretching or wrenching of the non-osseous parts of a joint, without displacement of the bones, and either with or without lesion of ligaments or tendons. Severe sprains are sometimes as serious and lasting in their effects as dislocations, especially on account of the liability of the patient to attempt to use the part before the inflammation has wholly subsided. Perfect rest, cold or sometimes hot lotions (if the latter be more agreeable to the patient), accompanied by the use of splints for mechanical support and of opiates for the relief of pain, are required in the treatment. Revised by W. PEPPER.

**Sprat**, or **Garvie**: the *Harengulus sprattus*, a little herring of the European seas. Sprats are spiced, salted, dried, and potted in many ways, and are very good when fresh, but are generally eaten only by the poorer classes. The French preserve great quantities of small sprats and sell them for sardines. Great quantities are also used for fertilizing land. The sprat is seldom over 6 inches long. See WHITEBAIT.

**Sprecher**, SAMUEL, D. D., LL. D.: theologian; b. near Williamsport, Md., Dec. 28, 1810; studied in Pennsylvania College and Theological Seminary, Gettysburg, Pa.; pastor at Harrisburg, Pa., 1836–39; principal of Emmaus Institute, Middletown, Pa., 1839–42; pastor Martinsburg, Va., 1842–43, and Chambersburg, Pa., 1843–49; president of Wittenberg Theological Seminary Springfield, O., 1849–74. He combined with it until 1884 the chair of Systematic Theology. Removing to the Pacific coast, he filled for a time the presidency of the college at San Diego, Cal. Dr. Sprecher's chief book is his *Groundwork of a System of Lutheran Theology* (Philadelphia, 1879). H. E. JACOBS.

**Spree**, sprā: a river of Prussia; rises in the kingdom of Saxony, passes through Berlin, and joins the Havel at Spandau, after a course of 220 miles. At Leibsch it becomes navigable for small craft, and considerable traffic is carried on along its whole course.

**Sprengel**, HERMANN JOHANN PHILIPP, Ph. D., F. R. S.: chemist; b. at Schillerslage, Hanover, Germany, in 1834; studied at the Universities of Göttingen and Heidelberg, from the latter of which he took his degree in 1858 with the highest honor; moved to England 1859; discovered and described in *The Journal of the Chemical Society*, 1865, the method of producing vacua by the fall of water or mercury in tubes. He first drew attention to picrid acid, which he suggested as a detonating charge for shells; and was the first who described and patented in England a number of so-called safety-explosives, among which are hellhoffite, oxonite, panclastite, rackarock, etc. Hellhoffite and rackarock were used by Gen. John Newton in blowing up Flood Rock at Hell Gate. C. H. THURBER.

**Sprengel's Air-pump**: See PNEUMATICS.

**Sprenger**, ALOYS: Orientalist; b. at Nassereut, Tyrol, Sept. 3, 1813; educated at Innsbruck and Vienna (1832); went to London (1836) to assist the Earl of Munster in his work, *The Military Sciences of the Mohammedan Nations*; then to Calcutta (1843) and became (1845) president of the College of Delhi, where he introduced European methods of teaching, established a lithographic press, and issued a penny magazine, *Kiran Alsadain*; was assistant resident at Lucknow (1848), where he catalogued the royal library; examiner at the College of Fort William (1850); head of the Calcutta and Hugli Mohammedan Schools; Government interpreter and secretary of the Asiatic Society of Bengal. He was pensioned in 1857, returned to Europe, and became Professor of Oriental Languages at Berne. D. Dec. 19, 1893, at Heidelberg, to which place he had retired. His most important work is *Das Leben und die Lehre des Mohammed* (Berlin, 1861–65, 3 vols.), the most comprehensive life of the prophet by a European, but written too much from the point of view of a physician. Of his *Bibliotheca Indica*, which he published in conjunction with other scholars, may be mentioned: *Dictionary of the Technical Terms used in the Sciences of the Mussulmans* (Calcutta, 1854); *Ibn Hajar's Dictionary of Persons who knew Mohammed* (1856); *Soyuti's Itkân* (1856), etc. He also published *Otby's History of Mahmud of Ghaznah* (Delhi, 1847); *Masudî's Meadows of Gold* (London, 1849); *Die Alte Geographie Arabiens* (Bern, 1875). RICHARD GOTTHEIL.

**Spring** [liter., origin, source, beginning, time of beginning (cf. *dayspring*), deriv. of *spring*, to arise, take birth, rise, or origin]: the season of the year which follows winter and precedes summer. In the temperate regions of the northern hemisphere it includes, in a vague and indefinite way, the months of February, March, and April (as in Great Britain), or March, April, and May (as in North America); astronomically, it would extend from Mar. 21 to June 21. In the temperate regions of the southern hemisphere the spring months are September, October, and November. In the tropical regions there is strictly neither spring nor autumn, but only two seasons, the wet and the dry; in the polar regions, only two seasons, summer and winter.

**Spring**, GARDINER, D. D., LL. D.: clergyman; b. at Newburyport, Mass., Feb. 24, 1785; was valedictorian at Yale College 1805; studied law and taught in New Haven 1805–06; established an English school and taught in Bermuda 1806–08; admitted to the bar 1808; studied theology at Andover Theological Seminary 1809–10; and was pastor of the Brick church (Presbyterian), New York, 1810–73. D. in New York, Aug. 18, 1873. Many of his publications have passed through several editions, and have been reprinted and translated in Europe. They include *Essays on the Distinguishing Traits of Christian Character* (New York, 1813); *Memoir of Rev. Samuel J. Mills* (1820); *Fragments from the Study of a Pastor* (1838); *Obligations of the World to the Bible* (1839); *The Attractions of the Cross* (1846); *The Bible not of Man* (1847); *Discourses to Seamen* (1847); *The Power of the Pulpit* (1848); *The Mercy-seat* (1850); *First Things* (2 vols., 1851); *Contrast between Good and Bad Men* (2 vols., 1855); *Pulpit Ministration* (2 vols., 1864); and his autobiography, *Personal Reminiscences of the Life and Times of Gardiner Spring* (2 vols., 1866). The *Memorial Discourse*, by Rev. John O. Murray, D. D., has been published (New York, 1873). C. K. HOYT.

**Spring**, LEVERETT WILSON, A. M., D. D.; teacher and author; b. at Grafton, Vt., Jan. 5, 1840; graduated at Williams College 1863, at Hartford Theological Seminary 1866; pastor of Rollstone Congregational church, Fitchburg, Mass., 1868–75; pastor of Plymouth church, Lawrence, Kan., 1876–81; Professor of English Literature, University of Kansas, 1881–86; Morris Professor of Rhetoric at Williams College since 1886; author of *Kansas* (in the American Commonwealth Series); *Mark Hopkins, Teacher* (1885). C. H. T.

**Spring-bok** [Dutch for spring-buck, so called from its habit of leaping when alarmed]: a very beautiful, active, and graceful antelope of South Africa, the *Gazella euchore*. It goes in immense herds upon the plains. Its flesh is in some estimation as food, and the hides are much sought for by tanners. This timid creature, when taken in hand young, becomes very tame and sportive.

**Spring City**: borough; Chester co., Pa.; on the Schuylkill river, the Schuylkill Canal, and the Penn. Railroad; opposite Rogersford, 32 miles N. of Philadelphia (for location, see map of Pennsylvania, ref. 6–I). It has manufactories of wood-pulp, stoves, glass, stove-moulders' facing, fire-brick, tile, paper, sash, and lumber, a national bank with capital of $200,000, and a weekly newspaper. Pop. (1880) 1,112; (1890) 1,797; (1900) 2,566.

**Springer**: a name given by sportsmen to several varieties of the hunting spaniel, used for starting birds from bushy coverts. The Clumber, Sussex, and Norfolk breeds are the best. The springer should weigh from 14 to 40 lb., and should have a good coat, a feathery tail, carried low, and an active, graceful style of work. The Clumber is especially liked, because it gives no tongue while at its duty.

**Springfield**: city; capital of the State of Illinois and of Sangamon County; on the Balt. and Ohio S. W., the Chi. and Alt., the Chi., Peoria and St. L., the Ill. Cent., and the Wabash railways; 3 miles S. of the Sangamon river, and 185 miles S. W. of Chicago (for location, see map of Illinois, ref. 6–D). It lies on the western border of an undulating prairie stretching from near the river to the timbered lands that line its tributaries on the S. The original city was 2 miles square, surrounded by an avenue 80 feet wide. It now contains 5·84 sq. miles, and is of irregular outline, the greatest length north and south being approximately 4 miles, and east and west 3 miles. The streets and avenues intersect each other at right angles, and the residence portions are ornamented with shade-trees and grass-plots. The city is lighted by electricity; has excellent water-works, with a $60,000 pumping plant with a daily capacity of 12,000,000 gallons; a complete system of sewerage; 7 fire companies; a municipal light plant; 7 seven lines of electric street-railway with 20 miles of track; 366 acres of improved park lands, with connecting boulevards, and 29 miles of paved streets, mostly of vitrified brick.

*Public Buildings.*—The most conspicuous of the public buildings are the State-house, the U. S. court-house and post-office, the county court-house, the Governor's mansion, the State arsenal, the city-hall, and the public library. The Capitol, completed in 1887, stands in a park of about 8 acres. The ground-plan is in the form of a huge cross, and the superstructure is of the modern classic style of

State-house, Springfield, Ill.

architecture. The extreme length from N. to S., including the northern portico, is 379 feet, and the extreme width from E. to W., including the eastern portico, is 286 feet. The exterior walls are of dressed Joliet limestone, and the large and lofty porticoes of sandstone, supported by columns of polished gray granite. The edifice is three full stories in height, with a mansard roof and two turrets. Over the center rises a stately dome, surmounted by a lantern and iron flagstaff, reaching a total altitude of 364 feet. The whole cost of the building was over $4,000,000. The county court-house (formerly the old State-house), the corner-stone of which was laid July 4, 1837, occupies the center of the public square in the heart of the city. It is a massive structure, built of solid limestone in the form of a rectangle, being longest from E. to W. The original edifice was two stories high, with a basement, and surmounted by a handsome dome. The total cost was $240,000. In 1900 the building was raised bodily, a ground-floor story added, the interior remodeled after modern plans, a new dome built, and other improvements made at a cost of nearly $150,000. The U. S. court-house and post-office stands on the Government block at the intersection of Sixth and Monroe Streets. It is built of Nauvoo stone, three stories high, and was completed in 1868 at a cost of $320,000. The interior was remodeled in 1900 to meet the increased requirements of the post-office department. The Governor's mansion and grounds occupy

The Lincoln residence, Springfield, Ill. (belongs to the State).

an entire block in the southern part of the city. The mansion is a fine and imposing brick structure. It, too, was remodeled and modernized recently at a cost of $40,000. The city-hall is built of cream-colored brick with stone trimmings, and is four stories high.

*The Lincoln Monument.*—Among the chief historical attractions of Springfield are the Lincoln residence and the Lincoln national monument. The latter stands in Oak Ridge Cemetery, about 1½ miles N. of the new State-house. This mausoleum contains the remains of President Lincoln, his wife, two of his children, and one grandson. It was designed by Larkin G. Mead, of Vermont, and was built by William D. Richardson, of Springfield, Ill. The exterior walls of the terrace, pedestal, and shaft are faced with Massachusetts gray granite, and the total height of the monument, which originally was 98 ft. 5 in., now is 120 ft. 2 in. It was dedicated Oct. 15, 1874. The whole cost, including the statue of Lincoln and four groups of bronze statuary, was about $325,000. In 1900 the monument was taken down and rebuilt upon a foundation extending to the solid rock at the base of Monument Hill. The reconstructed monument is identical in outline with the original except that the shaft is greatly increased in altitude.

The Lincoln home is owned by the State and is maintained as it was when the President's family left it, with as much as possible of the furnishings intact. A custodian, appointed by the Governor, has charge of the premises, which are open to visitors daily.

*Churches and Schools.*—The churches and mission chapels of the city and suburbs number 48, classified as follows: 4 Protestant Episcopal, 6 Roman Catholic, 4 Lutheran, 7 Baptist, 8 Methodist Episcopal, 6 Presbyterian, 3 Congregational, 2 Christian, 2 Hebrew, 1 United Brethren, 1 Seventh-day Advent, 1 Church of Christ (Scientist), 1 Evangelist, 1 Volunteers of America, and 1 Salvation Army barracks. The public schools consist of a new central high school, built in 1897 at a cost of $100,000, and 21 graded schools. The money expended for public-school purposes in the fiscal year ending Aug. 31, 1901, was $124,814.50. Besides the public schools there are Concordia College (Lutheran), the Bettie Stuart Institute, St. Agatha's School, the Ursuline Convent, the Convent of Our Lady of the Sacred Heart, SS. Peter and Paul's Convent, 7 parochial schools, and 2 business colleges. Among the charitable institutions are the Home of the Friendless, the Home for Aged Women, the Colored Old Folks' Home, the Orphanage of the Holy Child (Episcopal), and the Springfield Associated Charities, maintained by the churches and citizens generally; also four hospitals—St. John's, the Springfield, the Wabash Railway, and the Prince Sanitarium.

*Libraries.*—The free public library is claimed to be the largest in the United States in proportion to the size of the city, containing, in January, 1901, over 45,400 volumes. In addition, the city has the Illinois State library of 55,000 volumes, the Illinois State Historical library of 3,500 volumes, and the Supreme Court library of 18,000 volumes.

Near the city is Camp Lincoln, the permanent training-grounds of the Illinois National Guard, with rifle-range, a State arsenal, and headquarters of the Second brigade.

*Finances and Banking.*—The gross receipts of the corporation for city purposes for the fiscal year ending Feb. 28, 1901, were $456,899.85; the bonded debt on Mar. 1, 1901, was $898,700; and the estimated value of city property $1,747,050. In 1901 there were 5 national banks with combined capital of $1,450,000, 1 State bank with capital of $300,000, and 1 loan and trust company with capital of $100,000. There are also 9 building and loan associations, all serial, with 3,672 shareholders and 37,151 shares in force.

*Business Interests.*—The census of 1890 showed 374 manufacturing establishments (representing 63 industries), with a combined capital of $3,641,415, employing 3,269 persons, paying $1,746,228 for wages and $3,789,139 for materials, and turning out products valued at $6,562,070. The principal industries, according to capital invested, were those connected with the building trades, 102 establishments, $558,573 capital; printing and publishing, 12 establishments, $261,031 capital; textiles, $257,215 capital; foundry and machine-shop products, $202,837; planing-mills, $58,500 capital. The city is also an important coal-mining center.

*History.*—Springfield was settled in 1819 and platted in 1823, when it became the county-seat. It was incorporated as a town Apr. 2, 1832, and as a city Apr. 6, 1840. By acts of 1837 it was made the permanent seat of the State government, and the first session of the Legislature held here was convened Dec. 9, 1839. Pop. (1880) 19,743; (1890) 24,963; (1900) 34,159. S. LEIGH CALL.

**Springfield**: city; port of delivery; county-seat of Hampden co., Mass.; on the Connecticut river, and the Boston and Albany, the Boston and Maine, and the N. Y., N. H. and Hart. railways; 99 miles W. by S. of Boston, and 138 miles N. N. E. of New York (for location, see map of Massachusetts, ref. 3–E). The city is beautifully situated, is laid out with wide streets, adorned with fine shade-trees, and is noted for the variety and taste of its private dwellings and the beauty of its churches and public buildings. There are two parks—Forest, comprising 463 acres, laid out with ponds, carriage roads, and promenades, and Hampden, containing about 60 acres, famous for its horse-races and cycling tournaments. The steam-railways entering the city use a union dépôt erected in 1889 at a cost of $500,000. A street-railway connects the extreme sections of the city and offers communication north to Northampton, west to Westfield, south to Warehouse Point, Ct., and east to Palmer.

*Churches and Schools.*—Springfield has 46 churches, of which 12 are Congregational, 7 Methodist Episcopal, 5 Roman Catholic (also a mission), 7 Baptist, 2 Union, 2 Protestant Episcopalian, 2 Lutheran, and 1 each Unitarian, Universalist, Advent, Swedenborgian, Presbyterian, Jewish, and Spiritualist. The public-school system comprises 2 high schools and 10 grammar, 16 primary, 5 ungraded, 8 evening, 9 kindergarten, 1 manual-training, 3 cooking and 2 drawing schools, located in 33 buildings, and having 323 teachers and over 9,300 pupils. Various parochial schools have about 1,400 pupils, and private schools about 100. The city also contains a French-American (Protestant) college, Bible Normal College, and the International Y. M. C. A. School. The Public Library and museum buildings are among the finest in the city, including besides a library of over 100,000 volumes, with a free reading-room, art and science museums, each in a handsome building of its own.

*Finances and Banking.*—The city has an assessed property valuation of over $72,000,000 and a funded debt of $2,727,100, of which $1,500,000 is water debt; deducting sinking funds, the net debt is (1900) $2,131,818. The receipts and expenditures are nearly equal, and are more than $2,100,000. In 1900 there were 10 national banks with combined capital of $3,300,000, 3 savings-banks with aggregate deposits of $25,199,103, a co-operative bank with assets of $500,000, 2 safe-deposit companies, with a combined capital of $600,000, a bank clearing-house, which in 1900 cleared over $68,000,000, and 4 insurance companies.

*Business Interests.*—The census returns of 1895 showed 574 manufacturing establishments (representing 107 industries), with a combined capital of $10,540,680, employing 7,703 persons, paying $3,804,763 for wages and $8,436,384 for materials, and turning out products valued at $16,569,228. The city has a great variety of skilled industries, extensive manufactories of railway-cars, pistols, sporting-arms, cotton and woolen goods, paper, envelopes, paper boxes, and collars, toys, needles, watches, buttons, skates, machinery, knit goods, confectionery, corrugated iron, paints and chemicals, sewing-machines, etc. The U. S. armory is located here and gives employment to about 1,000 men. Large additions have been made to the shops and machinery, and the output of rifles is 1,500 a week. The arsenal is 200 by 70 feet, and accommodates 300,000 stand of arms. The U. S. Government building, completed in 1891 at a cost of about $150,000, contains the post-office and the customs-office. The value of the imports for the year ending June 30, 1900, was $88,693, and for the 9 months ending Mar. 30, 1901, $81,531, and the duty collected in the year ending June, 1900, $40,958. The city has a flourishing board of trade. There are 4 daily, 9 weekly, 1 monthly, 1 semi-monthly, and 2 Sunday periodicals.

*History.*—Springfield was settled in 1636 by emigrants from Roxbury under the leadership of William Pynchon, and was first called Agawam, the Indian name for a portion of the territory occupied. West Springfield, Chicopee, and several of the neighboring towns were then included in its boundaries. In 1640 the name of the settlement was changed to Springfield in compliment to Mr. Pynchon, whose country residence in England bore that name. In 1675, during King Philip's war, the town was burned by the Indians. During Shays's rebellion in 1787 the U. S. arsenal was attacked, but the insurgents were dispersed by the State militia. Pop. (1880) 33,340; (1890) 44,179; (1900) 62,059. Revised by EDITOR OF "REPUBLICAN."

**Springfield**: city; capital of Greene co., Mo.; on the St. L. and San Fran., and the Kan. City, Ft. Scott and Memphis railways; 130 miles S. of Jefferson City, the State capital, and 240 miles W. S. W. of St. Louis (for location, see map of Missouri, ref. 7–F). It is on one of the highest plateaus of the Ozark Mountains, 1,450 feet above sea-level, is built in a grove of forest-trees with prairies on three sides, and is in an agricultural and lead and zinc mining region. The streets cross at right angles and are from 60 to 80 feet in width; many are macadamized or paved with brick. The city is lighted by gas and electricity, and has electric street-railways, improved water-works and sewerage, and two public parks. There is a U. S. Government building which cost with grounds $150,000, and contains the post-office, land-office, Federal courts, internal-revenue office, and signal-service quarters. Immediately S. of the city is a National Cemetery, containing the remains of more than 2,000 Union and Confederate soldiers.

*Churches and Schools.*—There are about 40 churches, a high school with building and ground that cost $50,000, a commodious central building, and 9 ward schools, with 65 teachers and more than 6,000 enrolled pupils. A normal school with accommodations for 2,000 pupils was opened in 1893. There are also 3 Roman Catholic parochial schools and 2 private kindergartens. For higher instruction there are Drury College (Congregational, chartered in 1873), a Roman Catholic college; and several academies. Springfield has a circulating library, and 3 daily and 6 weekly newspapers.

*Finance and Banking.*—In 1894 the city revenue was $89,753; expenditures, $80,962; bonded debt, $188,800; and assessed property valuation, $7,790,923. There were 5 State banks, a national bank, a private bank, with aggregate capital of $725,000 and deposits of $1,890,000, and 4 loan and trust companies.

*Business Interests.*—The city has a large jobbing trade, embracing the chief lines of merchandise, and covering principally Southwestern Missouri and Northwestern Arkansas. The industrial establishments comprise railway-car and repair shops, the largest wagon-factory in the State, 4 candy-factories, 4 roller flour-mills, 3 tobacco-factories, 2 iron-foundries, a furniture-factory, a cooperage, and a stove-factory. Pop. (1880) 6,522; (1890) 21,850; (1900) 23,267.

JOHN B. WADDILL.

**Springfield**: city; capital of Clark co., O.; on the Mad river, Lagonda creek, the Cleve., Cin., Chi. and St. L., the Erie, the Ohio S., and the Pitts., Cin., Chi. and St. L. railways; 45 miles W. of Columbus, and 80 miles N. E. of Cincinnati (for location, see map of Ohio, ref. 5–D). Connected with Dayton and Urbana by electric lines. It is in an agricultural region, but best known for its extensive manufactures. The city has gas and electric-light plants, water-works, sewers, and street-railways, and obtains some power for manufacturing purposes from the river and creek. Water for domestic use is supplied from springs. Natural gas for fuel is piped from other territory and extensively used. The public buildings include a city-hall (costing $225,000), U. S. Government building (costing $115,000), a free library presented to the city by B. H. Warder (costing $100,000), and a city hospital.

In the suburbs of the city are located the Ohio Masonic

Home, which cost $150,000 and has 145 inmates (97 adults and 48 children); the Ohio Pythian Home, nearly completed, which will cost when finished $120,000, and now provides for 138 children. Also the Ohio Odd Fellows' Home, which cost $100,000 and has now 175 inmates (125 children and 50 adults).

There are nearly 50 churches and other places of worship, 16 public-school buildings, public-school property valued at over $250,000, high school, seminary, 4 Catholic schools, 2 kindergartens, a business college, 2 colleges of shorthand, 4 dailies and 13 other periodicals.

It is the seat of Wittenberg College (Lutheran, chartered in 1845), which in 1900 had 21 instructors, 405 students of both sexes, and 19,000 volumes in its general and society libraries, and has graduated 700 students since its opening.

The manufactures include mowers and reapers, grain-drills, grain-separators, lawn-mower and reaper knives, lawn-mowers, stationary and portable steam-engines, turbine water-wheels, hay-rakes, hay-tedders, bicycles, machine tools, rubber tires, warm-air furnaces, stoves, piano-plates and piano hardware, shoes, shipping-tags, metallic caskets, grave-vaults, coffins, gas and gasoline engines, emery-wheels, metal wheels, water-purifiers, ensilaged feed and cane cutters, corn-planters and corn-harvesters, paper-mill machinery, pumps, road-rollers, leather, and proprietary medicine. One of the great industries of the city is flowering plants, there being eight large establishments that issue catalogues and do a large mail-order and wholesale business.

The city had in 1900 an assessed valuation of $17,894,095, and a net debt of $728,644. There are 5 national banks with a combined capital of $1,000,000 and a surplus of $300,000, and 1 savings-bank, and 3 building and loan associations, with 1,664 shareholders, and 6,472 shares. Pop. (1890) 31,895; (1900) 38,253. R. S. THOMPSON.

**Springfield**: town; capital of Robertson co., Tenn.; on the Louisv. and Nashv. Railroad; 30 miles N. W. of Nashville (for location, see map of Tennessee, ref. 5–E). It is in an agricultural and stock-raising region; is engaged in growing tobacco, corn, wheat, and grass; and contains flour-mills, sawmills, brick-works, a tannery, a national bank with capital of $60,000, a State bank with capital of $50,000, and 2 weekly papers. Pop. (1890) 1,372; (1900) 1,732.

**Springs**: fountains or streams of water flowing out of the earth and fed by rains on higher lands, frequently at some distance. As the water of springs often flows through subterranean channels which are beyond the reach of changes in surface temperature, it is little affected by the seasons, and is often maintained at about the average annual temperature of the locality. When it emanates from a deeper source it is sometimes highly heated, producing THERMAL SPRINGS (*q. v.*). When, as is often the case, the water is impregnated with chemical substances, such springs are called mineral springs. See WATER and MINERAL WATERS.

**Spring Valley**: city; Bureau co., Ill.; on the Burlington Route, the Chi. and N. W., and the Chi., Rock Is. and Pac. railways; 100 miles S. W. of Chicago (for location of county, see map of Illinois, ref. 3–E). It is in a coal-mining region, has important manufacturing interests, and contains a national bank with capital of $50,000 and two weekly newspapers. Pop. (1890) 3,837; (1900) 6,214.

**Springville**: village; Erie co., N. Y.; on the Buffalo, Rochester and Pitts. Railway; 30 miles S. of Buffalo (for location, see map of New York, ref. 5–C). It contains the headquarters of the Springville cheese-factory combination, which uses the milk of 8,000 cows daily and produces 2,000,000 lb. of cheese annually. There are 9 churches, an endowed academy and union free school, public library, 2 parks, soldiers' monument, natural gas-supply for fuel, electric light and power plant, excellent water-system, numerous manufactories, a national bank with capital of $50,000, a private bank, and 2 weekly newspapers. Pop. (1880) 1,227; (1890) 1,883; (1900) 1,992. EDITOR OF "JOURNAL AND HERALD."

**Springville**: city (founded in 1850); Utah co., Utah; on the Rio Grande W. and the U. Pac. railways; 6 miles S. of Provo, the county-seat, and 50 S. by E. of Salt Lake City (for location, see map of Utah, ref. 4–M). It is in a beautiful valley near the east end of Utah Lake; has abundant water-power, and is engaged in farming, stock-raising, and manufacturing. There are 5 district schoolhouses, an academy, a Mormon and a Presbyterian church, a State bank with capital of $50,000, and a weekly newspaper. Pop. (1890) 2,849; (1900) 3,422. EDITOR OF "INDEPENDENT."

**Spruce** [from M. Eng. *spruce*, variant of *Pruse*, Prussia, the tree being first known as a native of Prussia]: any one of several trees of the genus *Picea*, in the U. S. especially *P. nigra*, black or double spruce, and *P. alba*, white or single spruce. Both of these afford much useful timber, superior to that of hemlock, but inferior to the best pine. There are also several trees called spruce on the Pacific coast. (See also FIR and PINE.) The so-called Norway spruce, *P. excelsa*, very widely planted, is a noble forest-tree of the north of Europe. The native spruces of the U. S. afford a resinous substance called spruce-gum, much used as a masticatory. The tops are often brewed to make a pleasant drink called spruce-beer. It is made by adding the essence of spruce to water in which sugar or treacle has been dissolved, in the proportion of about 4 oz. of essence to 10 lb. of sugar or three parts of treacle, and 10 or 11 gal. of water, with about half a pint of yeast. Revised by L. H. BAILEY.

**Spuller**, spü'lār', EUGÈNE: publicist and politician; b. at Seurre, Côte-d'Or, France, Dec. 8, 1835; studied law, and was admitted to the bar in Paris, but abandoned the legal profession to devote himself to journalism and politics. Took part in the formation of Gambetta's journal, *La République Française*, and afterward became its editor-in-chief, but resigned after his election to the Chamber in 1876. In the Chamber he was active on several important commissions, concerning himself especially with questions relating to education and foreign affairs. He was Under-Secretary for Foreign Affairs in the short-lived cabinet of Gambetta 1881–82, Minister of Public Instruction in the cabinet of Rouvier 1887, and Minister of Foreign Affairs in that of Tirard 1889–90. He was elected to the Senate Apr. 24, 1892. D. at Dijon, July 23, 1896. Among his writings are *Petite histoire du second Empire, utile à lire avant le Plébiscite* (1870); *Ignace de Loyola et la Compagnie de Jésus* (1876); *Michelet, sa vie et ses œuvres* (1876); *Conférences populaires* (1879 and 1881); *Figures disparues* (1886); and *Au ministère de l'instruction publique* (1889). F. M. C.

**Spur**: See ERGOT.

**Spurge**: See EUPHORBIA.

**Spurgeon**, CHARLES HADDON: preacher and writer; b. at Kelvedon, Essex, England, June 19, 1834, the son of an Independent preacher; was educated at Colchester; became usher of a school at Newmarket, but, embracing Baptist views, joined a congregation of that denomination in Cambridge; became a tract-distributer and village preacher, and at the age of eighteen minister of a small chapel at Waterbeach, where he soon became noted for his zeal and eloquence. He went to London in 1853, where he at once attracted audiences so numerous that the congregation was compelled to remove first to Exeter Hall, and thence to the still larger Surrey Hall. In 1861 an immense chapel, called the Tabernacle, was built for him in Newington Butts, London, where he afterward preached. Nearly 20,000 persons were admitted to his church, and thirty-six other chapels were opened in London, the ministers of which were trained at a college founded and directed by him. His sermons were printed weekly, and from them thirty-seven volumes were made up. He also published *The Saint and his Saviour* (1857); a *Commentary on the Psalms* (7 vols., 1865–80); *Gleanings among the Sheaves* (1868); *John Ploughman's Talk* (1868); *Evening by Evening* and *Readings for the Closet* (1869); *Feathers for Arrows* (1870); *Types and Emblems* and *Lectures to my Students* (1875); *Storm Signals* (1886); *Messages to the Multitude* (1892), and other works. In 1867 he laid the foundation of an orphanage at Stockwell established by his congregation, and in 1865 became editor of a journal, *The Sword and the Trowel*. D. at Menton, France, Jan. 31, 1892. See the *Life* by Shindler (1892).—His son, THOMAS SPURGEON, was elected pastor of the Tabernacle in 1894. Revised by W. H. WHITSITT.

**Spurgeworts**: the *Euphorbiaceæ*; a family of about 3,000 species of dicotyledonous herbs, shrubs, and trees, for the most part natives of the tropics, but with many representatives in all regions. The flowers are often monœcious or diœcious, and the perianth is generally small. The ovary is usually tricarpellary, with one or two anatropous ovules in each cell. The stamens are generally numerous, and are commonly clustered and branched. Nearly all species have well-developed laticiferous tubes in their stems and leaves containing a milky fluid (latex). They are much-modified relatives of the mallows, with which they should be associated in spite of their usually apetalous structure.

More than 200 are North American, fully one-half belonging to the genus *Euphorbia*, commonly represented by *E. maculata*, *E. nutans*, both prostrate spreading species, and *E. corollata*, an erect, white-flowered, weedy herb.

Economically the family is of great importance; medicines are supplied by species of *Croton*, *Euphorbia*, *Jatropha*, *Joannesia*, *Mercurialis*, *Ricinus*, *Stillingia*, etc.; caoutchouc by the latex of *Hevea*, *Mabea*, *Manihot*, and *Sapium*; food by species of *Manihot*, slender plants of the tropics, with large starchy roots, the product being known as tapioca and cassava. The box-tree (*Buxus sempervirens*) is ornamental, and its wood (box-wood) is most useful, especially for engravers' purposes. Many species are grown in conservatories, some of them resembling cactuses in their succulent, leafless stems. CHARLES E. BESSEY.

**Spurrey**: any plant of either of the genera *Spergula* and *Tissa* (*Spergularia*), belonging to the family *Caryophyllaceæ*. *Spergula arvensis*, well known to farmers of Europe and North America as a weed, is profitably cultivated in the Low Countries and Germany as a forage-plant, and its seeds yield a valuable oil and oil-cake. *S. pilifera*, a dwarf alpine plant, has been recommended as a lawn-plant in proper climates, being handsomer than grass and requiring much less care. Revised by CHARLES E. BESSEY.

**Spur-winged Goose**: the *Plectropterus gambensis*; a goose deriving its popular name from the strong tubercle, or blunt spur, on the bend of the wing, formed by the projecting wrist-bone (radiale). The body is slender, neck and legs long; there is an excrescence at the base of the beak. The bird is about 3 feet long; chin, throat, center of breast, under side, and scapulars white, rest of plumage greenish black. It is found in Central and South Africa. F. A. L.

**Spurzheim**, spoorts'hīm, KASPAR: phrenologist; b. at Longwich, near Treves, Rhenish Prussia, Dec. 31, 1776; studied medicine at Treves and Vienna, and became a zealous disciple of Dr. Gall, whom he accompanied on his travels in Germany and France, and assisted in popularizing his phrenological doctrines by lecturing, newspaper articles, etc. In 1813 he separated from Gall, and undertook the introduction of the new doctrines in England, where he resided from 1814 to 1817, and from 1825 to 1828, and gave very popular lectures. From 1817 to 1825 he lived in Paris. In 1832 he removed to the U. S., and had just begun to excite interest when he died in Boston, Nov. 10, 1832. Among his writings are *The Physiognomical System of Drs. Gall and Spurzheim* (London, 1815); *Outlines of the Physiognomical System* (1815); *Sur la Folie* (Paris, 1818); *Essai philosophique sur la Nature morale et intellectuelle de l'Homme* (1820); *A View of the Elementary Principles of Education* (1821). See the memoir by Carmichael (1833).

**Sputum**: in pathology, the substance expectorated from the lungs. See EXPECTORATION.

**Spuyten Duyvil** (spī ten-dī'vil) **Creek** [probably from the Dutch *Spuyt den Duyvil*, in spite of the devil]: the channel connecting the Hudson river with the Harlem river, and thence with the East river, on Long Island Sound. The creek forms the northern boundary of Manhattan Island.

**Spy** [deriv. of *spy* (verb), from O. Fr. *espier* (> Fr. *épier*), from O. H. Germ. *spehōn* > Mod. Germ. *spähen* < Teuton. *speh-*: Lat. *spe'cere*, look at, view]: in the laws of war, a person who goes in disguise or under false pretenses within the lines or territory of a belligerent to observe his strength and obtain information concerning his works and movements for the purpose of communicating the same to the enemy. The rules of warfare among all modern civilized nations permit the infliction of the death penalty upon spies taken in disguise within the enemy's lines. The employment of spies, however, is considered a kind of deceit allowable by the rules of war, and, notwithstanding the ignominious method of inflicting death (usually by hanging), it has not infrequently happened that men of high honor have undertaken the office. Two of the most notable instances in all history are those of Capt. Nathan Hale and Maj. André during the Revolutionary war.

Because of the treachery involved in acting as a spy all authorities are agreed that although a sovereign may hold out an inducement or the temptation of a reward to persons to engage in such service, yet the service can not be required of subjects, except, perhaps, in some singular case of the last importance. In Great Britain by the Naval Discipline Act (29 and 30 Vict., c. 109, § 6) spies can be tried by a naval court martial, and shall suffer death or other punishment. In the U. S. the instructions for the government of the armies of the U. S. in the field provides (General Orders No. 100, sec. v., § 88) that "the spy is punishable with death by hanging by the neck, whether or not he succeed in obtaining the information or in conveying it to the enemy."

Exactly what acts shall bring a person within the definition of a spy is not definitely determined, nor when he ceases to be a spy after once having had that character. In the Franco-German war of 1870 the Germans claimed that persons crossing their lines in balloons were spies; but this is not in accordance with the treatment of the subject of spies in the rules proposed at the Conference of Brussels in 1874 (Project of an International Declaration concerning the Law and Custom of War, Arts. 19–22), which expresses the opinion generally accepted among the nations of Europe. See Vattel's *Law of Nations*; Kent's *Commentaries*; and Halleck's *International Law*. F. STURGES ALLEN.

**Squali** [Mod. Lat., from plur. of Lat. *squa'lus*, a kind of sea-fish]: See SHARK.

**Squalls**: bursts of wind, usually of brief duration, and when accompanied with the proper precipitation called rain-squalls or snow-squalls. They are of many varieties as to origin. One of the commonest is the falling wind which descends on the water from mountainous coasts. On the northwest coast of Lake Superior they descend from the bluffs and low mountains only a few hundred feet high, yet with such violence and suddenness in calm, warm weather, and in the heat of the day, that they are very dangerous to sailing-vessels. In the Aleutian islands they often descend the mountains behind a head of white wool-like fog, and are therefore called "woollies." The papagayos of Lakes Nicaragua and Managua, and of the Papagayo Bight on the west coast of Nicaragua and Costa Rica, are of the same character, but of longer duration. They usually fall on the ocean at from 10 to 20 miles from land, and the navigator must keep within 10 or beyond 40 miles from shore if he wishes to escape them. Of the same character also are the nevados, a falling diurnal wind in Ecuador and Peru, when the air descends on the plains from the snow-fields of the higher mountains. Of another type is the derecho of the western parts of the U. S., an occasional non-vortical wind which spreads in a fan shape as it advances from the N. W. These squalls are often mistaken for tornadoes, which are vortical local storms. The white squalls of the tropical seas on the west coast of Africa are sudden and furious bursts, whose approach is indicated by an advancing but harmless-looking white cloud. MARK W. HARRINGTON.

**Squarcione**, squär-chō'nā, FRANCESCO: painter; b. at Padua, Italy, 1394. His love of art led him to travel much in Greece and Italy, where he became acquainted with the masterpieces of ancient sculpture. He then formed a collection of busts, torsos, and bas-reliefs, with which he adorned his studio, and opened a school which became very popular, and in which Andrea Mantegna studied. He employed the help of his assistants to such an extent that only one picture exists in Padua which is supposed to be entirely his work, viz., the *St. Jerome and other Saints*, painted for the Lazzare family and placed in the Carmelite church. D. at Venice, 1474. W. J. S.

**Square Root**: See ROOT.

**Squares, Method of Least** [*square* is from O. Fr. *esquarre* > Fr. *équerre*, carpenter's square, deriv. of *équarrer*, as Ital. *squadra* of *squadrare* < Lat. **exquadra're*, make square; *ex* + *quadra*, a square]: a process used for the purpose of obtaining the most probable value of a quantity from a series of observations. In all measures, from the ordinary rude weighings and measurings of agriculture and commerce up to the most refined astronomical work, there is a liability to error which can not be avoided. An ordinary scale, for instance, can be used to measure down to a sixteenth of an inch; that is, if carefully used, its results will be correct to that limit. The level of a transit-instrument can make its measures, when used with care, to a ten-thousandth of an inch or even less; but in this case the hundred-thousandths will be uncertain. An ordinary observer notes his time to minutes only, and is likely to state the time incorrectly to the extent of at least half a minute; the man who is trying a fine watch will note its errors to seconds, or even half seconds; the astronomer uses tenths of seconds in his rough data and hundredths or thousandths in his calculations, but even here there is always uncertainty in the fractions of a second.

Observations or measures of the same thing never agree perfectly—that is, in the minutest fractions; how shall the true result be ascertained from discordant evidence? The ordinary experience of mankind has shown that it is best to "strike an average." When, for instance, two equally good surveyors measure a field a little differently, the half sum of their results is taken. The average prices of commodities are taken for their real prices, or at least for a better estimate of their real value than the extreme prices either way as affected by temporary fluctuations. The whole business of insurance rests upon this law of averages.

The "method of least squares" is the application of this law to the results of physical measurements, especially in astronomy and geodesy. The mathematicians whose names are most prominently connected with it are Legendre, Gauss, Bessel, and Encke; Legendre and Gauss seem to have discovered it independently. A short sketch of the history of the method will help in its explanation. Before the method of least squares, as we now have it, was discovered, the method of averages, or of the arithmetical mean, was applied to all physical measures which give a direct result. But in astronomy the things to be found out can not always be directly measured, but must be indirectly inferred from measurements of other things. The observations upon the transit of Venus afford an instance. Here the main thing to be found out is the solar parallax; the thing directly observed is the planet's ingress upon or egress from the sun. The time of this depends upon several unknown quantities, of which the solar parallax is one, and also the unknown time of conjunction, and the unknown distance of the planet's and sun's center at that time, as well as the apparent angular diameters of planet and sun. Each observation, then, gives an equation of condition between these five unknown quantities, and at any one place four observations of contacts are made. At thirty stations there would be 120 equations for five unknown quantities; if the best five of these were selected, a good value of the solar parallax might be obtained; but many thousand good combinations can be made, each of which gives a different result, owing to the errors of the observations. How, then, can such a combination be made as to answer to the average in more direct measures? or, to express it mathematically, How can the superfluous equations of condition be combined so as to give the best possible result? The mathematical problem here treated is analogous to the combination of ordinarily discordant evidence in a perplexed case in the courts of law: when the result here needed is one capable of numerical expression, as in the assessment of damages, the average is taken; but where not, the evidence is reconciled as well as possible. Gauss has shown that in simple cases the ordinary law of averages is justified, and that in complex work, like the transit-of-Venus reductions, the following rule is to be used, which is the more general form of the same law: "In treating observations of equal precision the unknown quantities are to be so determined that, after allowing for constant error, the sum of squares of the remaining errors shall be the least possible." This is the "method of least squares." Its practical working is easy after the data are put into proper shape, and its advantages are so great that it is very largely used. It affords a thorough criticism upon one's own work and that of others, and for this reason is in great favor where the observers are most delicate, keen, and courageous, especially in Russia, Germany, and the U. S. Revised by S. NEWCOMB.

**Squaring of the Circle**: See QUADRATURE OF THE CIRCLE.

**Squash** [from Massachusetts Ind. *asquash*, plur. of *asq*, green, raw]: a name applied in North America to fruits and plants of *Cucurbita maxima*, to the bush or summer varieties of *C. pepo*, and also sometimes to varieties of *C. moschata*. Usage varies as to the application of the name, but it belongs to *C. maxima* rather than to the others. (See PUMPKIN.) The fruits of *C. maxima* have soft, cylindrical stems which are not inflated at their insertion, the flesh is dry and orange-yellow, and the seeds are large and not thin-margined. Varieties of this species are Hubbard, Boston Marrow, the Turbans, Marblehead, and the like. L. H. B.

**Squash-bug**: the *Anasa tristis*, a hemipterous insect, well known for its ravages upon squash and pumpkin vines. It belongs to the *Coreidæ*. It is six-tenths of an inch long, about three-tenths of an inch in breadth, and of a dirty brown. It emits a powerful and offensive odor. The striped squash-bug is *Diabrotica vittata*, a beetle of the family *Chrysomelidæ*, a much smaller but even more destructive insect, which infests cucurbitaceous vines of almost all kinds in the U. S. As a rule, these insects are most destructive while the plants are young; and the squash-hills should be protected by a frame covered with millinet, or powdered gypsum and shell-lime may be freely sprinkled upon the plants, and will be found to impede the destructive work, particularly that of the striped bug. The use of salt in the manure is no avail with respect to the bug, and is injurious to the plant. Revised by J. S. KINGSLEY.

**Squash Family**: the *Cucurbitaceæ*. See the article on the GOURD FAMILY.

**Squatter Sovereignty**: a term used in the political history of the U. S. to deride the principle of leaving to the settlers within the Territories of the U. S. the decision of the question whether slavery should be permitted by the constitutions to be adopted when the Territories became States. See KANSAS (*History*) and UNITED STATES (*History*).

**Squeteague**: See WEAKFISH.

**Squid**: a popular name for many decapod cephalopods, particularly those of the family *Teuthidæ* (calamaries), but also extended to the *Sepiidæ* or true cuttlefishes, and even to the poulpes or *Octopodidæ*. The squids proper are found in nearly all seas; they form an important part of the food of many fishes and crustaceans, are extensively used as fish-bait, and in many countries are much used as food. (See CEPHALOPODA, CUTTLEFISH, FLYING SQUID, HOOK-SQUID, etc.) There are several true squids which are common on the U. S. coasts. Revised by D. S. JORDAN.

**Squier**, EPHRAIM GEORGE: archæologist; b. at Bethlehem, N. Y., June 17, 1821. He received the ordinary education of a farmer's son, was a school-teacher, and subsequently editor of country papers in New York and Ohio, and studied engineering. He was early interested in Indian antiquities, and in 1843–48 made, with Dr. E. H. Davis, an investigation of the mounds of Ohio and the neighboring States; the results were published in the *Smithsonian Contributions to Knowledge* (1848) as *Ancient Monuments of the Mississippi Valley*. Similar investigations in his native State resulted in the *Antiquities of the State of New York* (1851). In 1849–50 he was special *chargé d'affaires* to Central America, arranging treaties with several of the states; and in 1853 he was engaged to examine the line for a proposed interoceanic railway in the same region. He published *Nicaragua, its People, Monuments, etc.* (1852); *Waikna, or Adventures on the Mosquito Coast* (first published with the pseudonym *Samuel A. Bard*, 1856); *The States of Central America* (1857); and several other books and reports in English and French. His work on *The Serpent Symbol* (1852) attracted wide attention. In 1863–65 he was U. S. commissioner to Peru, and his investigations of the Incarian antiquities were the most important and exact that had been made up to the time. Returning, he took up his residence at New York, where from 1868 he was consul-general of Honduras. He was prominent in organizing the American Anthropological Society, and was its first president in 1871. The French Geographical Society voted him its gold medal, and he was a member of many other foreign and American learned societies. Several years were spent in the preparation of a work on Peru, and it was nearly ready for the press when, in 1874, a severe illness incapacitated him for continuous mental labor. The work was published in 1876, and is one of the most important contributions to our knowledge of Peru. D. in Brooklyn, Apr. 17, 1888. Besides the works mentioned, he was the author of numerous scientific papers and magazine articles. Many of his books were translated into Spanish and French. HERBERT H. SMITH.

**Squill** [viâ O. Fr. from Lat. *squil'la*, *scilla* = Gr. σκίλλα]: a drug made from the bulb of *Urginea maritima* (sea-onion), a perennial plant of the family *Liliaceæ*, growing on the Mediterranean coast. The bulb is pear-shaped, of the size of a man's fist, or even larger. It is made up of concentric scales, like other tunicated bulbs, of which the outer are dry and dark colored, but the inner fleshy and juicy, and either colorless or of a pale roseate tint. For use in medicine the bulbs are dried and sliced, and offer the varieties known as white and red squill, according to the tint of the bulb. Squill has little smell, but an acrid, nauseous, bitter taste. It contains a good deal of mucilage, but there is still much uncertainty concerning the nature of the active principles. A resin and a bitter principle probably have to do with the medicinal effects. Squill has been known as a medicine from a very remote period. It is an acrid irritant, affecting the mucous membranes and glands, and in large dose causes vomiting, purging, strangury, and may even prove fatally poisonous. Its medicinal use is from its producing, in small dose, an increased flow of urine, and also modifying in some unknown way the morbid condition of a mucous membrane affected with catarrh, and especially of the bronchiæ. Revised by H. A. HARE.

**Squilla**: one of the stomapod crustaceans. See the article on the STOMAPODA.

**Squinting**, technically termed **Strabis'mus** [Mod. Lat. from Gr. *στραβισμός*, a squinting, deriv. of *στραβός*, distorted, squinting]: the condition of vision when the visual axis of one eye is deviated from the point of fixation. The eye whose visual axis is directed to the object fixed is termed the *fixing* eye; the other is called the *squinting* or *deviating* eye. The deviation may be inward, *convergent strabismus*, outward, *divergent strabismus*, upward or downward, *vertical strabismus*. In convergent squint the visual line of the squinting eye is deviated inward, and intersects that of the sound eye at some point nearer than the object fixed; in divergent squint it lacks the necessary movement inward to intersect that of its fellow at the point of fixation, and hence it deviates outward. Strabismus may be paralytic or concomitant.

(1) In *paralytic* squint the deviation is caused by a paralysis of one of the muscles of the eyeball. The normal position of the eye and the correct direction of its visual line depend upon the tonicity of the four straight muscles, attached one above, one beneath, and one on each side of the eyeball. If one muscle is paralyzed, the eye is deflected to the opposite side by the stronger or intact muscle. Generally with paralytic squint, in addition to the deviation, there is loss of movement in the direction of the action of the affected muscle. Thus, if the outer straight muscle of the right eye were paralyzed, the affected eye could not move toward the temple on that side, and would be turned inward by the action of the inner straight muscle which is unaffected—that is, there would be a convergent squint. There is also generally double vision, because the images from an object do not fall upon identical points in the two retinas, and hence are no longer fused, as is the case when the eyes are normally moved by the muscles. Paralytic squint is caused by diseases of the brain, meningitis, and spinal cord, especially locomotor ataxia, certain general diseases like syphilis, rheumatism, diphtheria, diabetes, etc.; poisons, e. g. lead, and injuries.

(2) In *concomitant* squint the deviating eye is able to follow the movements of the other in all directions. The squint may be either periodic or permanent, and it may affect one eye or it may alternate. The average age for the appearance of concomitant squint is about four years, being usually first noticed when the child is beginning to learn to spell or read with small letters. There are a number of causes for concomitant squint, but the most important is a disturbance in the relation of the power of accommodation in an eye to the power of convergence, i. e. of bringing the eyes closer together. When the eye is far-sighted (hypermetropic) to a given degree, i. e. when it has a low refractive power, a short antero-posterior diameter, and the rays of light are not focused on the retina, it requires an accommodation, i. e. power to adjust itself for different distances and objects, of an equivalent degree to neutralize it, the visual lines being parallel. Generally, however, some convergence will accompany the effort of accommodation. The point of convergence is then nearer than the point for which the eye is accommodated, or, in other words, there is a convergent squint. Far-sightedness is consequently often accompanied by convergent squint. In near-sightedness, on the other hand, or in that condition in which there is a high refractive power and a long antero-posterior diameter, the visual lines often intersect at a greater distance than the point for which they are accommodated, and there is divergent squint. In a great majority of the cases of permanent squint there is amblyopia or imperfect vision of the squinting eye. Two views have been held in regard to this amblyopia, one being that it is due to lack of use on the part of the squinting eye, i. e. that the squint causes the amblyopia; the other that it is congenital and depends upon an imperfect development of the centers of vision in the brain, i. e. that the amblyopia causes the squint. The double vision, which is so marked a feature in squint when it is caused by paralysis, is usually absent in concomitant squint, because the eye involuntarily suppresses the false image, or else has learned to disregard it. In rare cases squint is due to spasm of the internal straight muscle. In paralytic squint the treatment consists in finding the cause and applying the proper remedies. In the low degrees, especially of the periodic varieties of concomitant squint, the eyes may often be straightened by prescribing the proper spectacles to correct the error or refraction which is at the bottom of the trouble. When the squint is marked and persistent it calls for operation: Incision of the ocular conjunctiva or mucous membrane, hooking up the tendon close to the cornea, and severing it. Very young children should not be operated upon. It is better to wait until the sixth or seventh year. G. E. DE SCHWEINITZ.

**Squirrel** [from O. Fr. *esquirel* > Fr. *écureuil*: Span. *esquirol* < Lat. **scurius* for *sciu'rus* = Gr. *σκίουρος*, squirrel]: any one of certain species of the family *Sciuridæ*. The name is more properly applicable to the slender arboreal forms constituting the genus *Sciurus*. These are of moderate size or small, have a rather slender head, no cheek-pouches, rather long ears, no lateral wing-like extension of the skin, a large bushy tail, and the teeth are, as in all the other genera of the family, 24—viz., M. $\frac{4}{4}$, I. $\frac{1}{1}$ × 2—but the foremost upper molars are often early deciduous, and when present very small. The genus grades into *Tamias*, or the chipmunks, and *Spermophilus*, or the ground-squirrels. There are about 150 species, and representatives are found in almost every region, Australasia and Polynesia, the southern extremity of South America, and the West Indies being the only considerable bodies of land in the temperate or tropical zones destitute of them. Eighteen species, with sixteen geographical races, or sub-species, are found in North America N. of Mexico. In time they existed, according to some authors, as early as the Eocene Tertiary, but the affinities of those early forms are doubtful. In habits the living species are all essentially similar. Most of their life is spent among the trees, and they exhibit great agility in running up the trunks and leaping from branch to branch. Their principal food consists of the nuts of trees, and in nut-bearing forests they are especially to be found; they also eat to some extent the larvæ of insects, and attack the nests of birds for their eggs, and even for their young. Their favorite attitude in eating is to sit on their haunches, with their tail thrown upward on the back, and holding the eatables in their paws. In the colder countries they lay up stores of provisions in holes and nooks in or near the trees in which they live. They are mostly readily tamed, and are generally kept in cages with revolving wheels or treadmills, wherein they exercise. Revised by F. A. LUCAS.

**Squirrel-corn**: See DICENTRA.

**Squirrel, Flying**: See FLYING SQUIRREL.

**Srinagar'**, or **Serinagur**: capital of Kashmir, situated in a broad, marvelously beautiful valley at an elevation of 5,276 feet, and with a mean temperature of 56·8° F. (see map of N. India, ref. 3–D). It is built on both sides of the navigable river Jhilam, from which numerous canals, spanned with light wooden bridges, branch off, the lively traffic by boat reminding one of Venice. The most remarkable building is the palace of the maharajah; it is called the Shergarh (citadel), and a large, beautiful flight of stairs leads from it down to the river. Close by the city is Lake Dal, which boasts of the far-famed isle Chinars (*Platinus orientalis*). Vegetables are raised here on floating rafts called gardens. About 21 miles N. W. of the city is Wular Lake, which covers 103 sq. miles. A small steamboat plies between the two lakes. Pop. (1901) 122,536, mostly Mohammedans.
Revised by M. W. HARRINGTON.

**Staal**, MARGUERITE JEANNE CORDIER DE LAUNAY, Baroness de: memoir writer; b. in Paris in 1684, the daughter of a poor painter; was educated in a convent at Rouen; became maid to the Duchess of Maine; took part in Cellamare's conspiracy for depriving the Duke of Orleans of the regency, and was imprisoned in the Bastile 1718–20; married afterward a Baron de Staal, who held a company in the guard of the Duke of Maine, and spent the rest of her life at the ducal court at Sceaux. D. in Paris, June 15, 1750. Her *Mémoires* were published in 1755, and republished in 1846 and 1878; her letters appeared in 1806, her *Œuvres complètes* (2 vols.) in 1821. Her *Mémoires* and letters have considerable interest to the student of history. See Sainte-Beuve, *Portraits Littéraires*.

**Stabat Mater** [Lat., *stabat*, was standing, third sing., imperf. indic. of *sta're*, stand + *ma'ter*, the mother]: the first words, and hence the name, of a Latin hymn ranked among the seven great hymns of the mediæval Church (*The Celestial Country* [from the *De Contemptu Mundi*], *Dies Iræ*, *Stabat Mater*, *Veni Sancte Spiritus*, *Veni Creator Spiritus*, *Vexilla Regis*, *Cantemus Cuncti Melodum nunc*, *Alleluia*, also known as *The Alleluiatic Sequence*). It begins—

| | |
|---|---|
| Stabat Mater dolorosa, | By the cross, sad vigil keeping, |
| Juxta crucem lacrymosa. | Stood the mournful mother weeping. |

As the DIES IRÆ (*q. v.*) has been pronounced the greatest, so the *Stabat Mater* is deemed the most pathetic of hymns. Its author is unknown, but it is customarily assigned either to Pope Innocent III. (d. 1216) or Jacopone da Todi (d. 1306). The hymn is still in constant use in the Roman Catholic Church, being sung during the Holy Week and on the festival of the Seven Dolors of the Virgin Mary, and it is well known in a musical sense to all through the very beautiful and sympathetic music of Rossini. It has been the theme of several of the world's great composers of different eras. Prior to Rossini, Pergolesi perhaps produced the most famous and masterly, if not the most popular, work upon it.

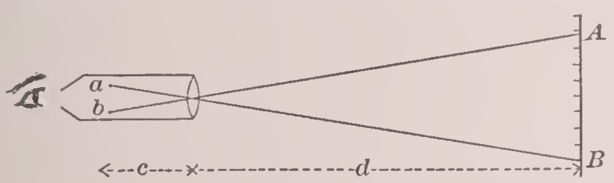
Revised by S. M. JACKSON.

**Stabroek**, staab'rook: See GEORGETOWN, British Guiana.

**Stachys**, stā'kis [Gr. στάχυς, an ear of grain; name of a plant, woundwort]: a genus of labiate plants, with a few species cultivated for ornament, and one, *S. sieboldii* (but generally known as *S. tuberifera* and *S. affinis*), now somewhat grown for its edible tubers. See CHOROGI. L. H. B.

**Stade**, staa'de: an old fortified town of Prussia, province of Hanover; on the Schwinge, near its influx in the Elbe (see map of German Empire, ref. 2–E). The so-called Stade dues, a toll which Hanover levied on all merchandise carried up the Elbe, but which was abolished in 1864, were paid here. Its manufactures are woolen, linen, and cotton stuffs, tobacco, and beer. Pop. (1895) 10,058.

**Stadia Measurement**: in surveying, a method of determining distances by graduated rods and the cross-hairs in the telescope of a transit instrument. The principle of the



Stadia measurement.

method is that of similar triangles, shown in the figure, the two hairs $a$ and $b$ seeming to be projected on the rod at $A$ and $B$. Let $c$ be the distance from the hairs to the object-glass and $d$ the distance from the object-glass to the rod, then

$$d = \frac{AB}{ab}c = \frac{c}{ab}AB,$$

or $d = AB$ if the rod be graduated so that $c \div ab$ represents the unit of distance. This principle is slightly modified by the optical theory of the lens, since $c$ varies for different distances, so that the expression for $d$ becomes

$$d = \frac{f}{ab}AB + f,$$

in which $f$ is the principal focal length of the lens, and in reality the lengths indicated by the intercept $AB$ do not begin at the object-glass, but at a distance $f$ in front of it. As, however, $f$ is small in comparison with $d$, it is generally neglected in topographic work.

When the telescope and line of sight are not horizontal the angle of inclination is read, and the rod held vertical. Then the reading on the rod is to be multiplied by the square of the cosine of the inclination to give the horizontal distance, and by one-half the sine of twice the inclination to give the vertical distance. By the help of tables these computations are readily made in the field, and thus both the horizontal distances and the elevations of points with respect to a given station are quickly obtained.

The precision of stadia-work is fully equal to that of ordinary chaining on rough ground, the uncertainty being about $\frac{1}{500}$th of the length of the line. Stadia measurements were introduced by Porro, an Italian engineer, about 1840; soon after used in topographical work in Switzerland, and introduced into the U. S. by J. R. Mayer about 1850. The word *telemeter* is generally employed instead of stadia on the U. S. Coast and Geodetic Survey, which seems to be alone in this usage. Most text-books on surveying give the principles and practice of the method. A small work with tables is Winslow's *Stadia Surveying* (New York, 1884).

MANSFIELD MERRIMAN.

**Sta'dium** [= Lat. = Gr. στάδιον]: the principal Greek measure of length for journeys, used in later times also for other linear measurements, especially by the Romans. Its length was fixed by that of the foot-race course (*stadium*) at Olympia, and was 600 Greek = 625 Roman = $606\frac{3}{4}$ English feet, or one-eighth of the Roman mile. Stadium was originally the name of the foot-race course in which running and other athletic exercises took place. Stadia existed at many Greek cities, but the most famous was that of Olympia. The stadium was laid out in two parallel oblong areas, connected at one end by a semicircular tract. The whole was surrounded by seats for spectators.

Revised by J. R. S. STERRETT.

**Stadt'holder** [Dutch *Stadhouder*, town-holder]: a governor of a country or province. In the course of the revolt of the Netherlands against Spain the seven United Provinces chose William, Prince of Orange, as their stadtholder. The title was intentionally a modest one, intimating that the revolt was not against the sovereign, but against the tyranny of his viceroy, the Duke of Alva. It involved the chief civil and military command, was given to Maurice, son of William, in 1587, and was held with some intermissions by the head of the state until the annexation of Holland to the French empire in 1802. On the restoration of the house of Orange in 1814 the title of king was assumed.

**Staël-Holstein**, Fr. pron. stāal'ōl-stān', ANNE LOUISE GERMAINE (*Necker*), Baroness de: historian, essayist, and novelist; b. in Paris, Apr. 22, 1766; daughter of Jacques Necker, the famous finance-minister of Louis XVI. She showed a precocious intelligence, and grew up in the brilliant salon of her mother, where she imbibed the intellectual curiosity and scientific spirit of the men who frequented it. In 1786 she married Baron de Staël-Holstein, Swedish ambassador at Paris, to whom she bore two sons and a daughter. Her marriage was not happy, and she was later separated from her husband, and mainly lived apart from him. Possessing remarkable gifts for conversation, she drew about her a circle of literary and public men, whom she charmed and dazzled. She greeted the beginning of the Revolution with sympathy, and her salon was the gathering-place of the admirers of the English Constitution. In 1792 she fled from the growing violence to her estate at Coppet, near Geneva, and then for a time to England; but in 1795 she returned to Paris and sought to re-establish her salon. In the same year she fell under the suspicion of the Directory, and withdrew again to Coppet, but returned once more in 1797, and her salon attained to new brilliancy and power. Among its assiduous visitors were Mme. Récamier, Mme. de Beaumont, C. Jordan, Fauriel, and especially Benjamin Constant, with whom she fell in love and from whose capricious and unhappy character she had much to suffer. Her salon was decidedly hostile to Napoleon, who in Oct., 1803, sent her away from Paris. She traveled then in Germany and Italy, and in 1805 established herself again in Coppet, where her old friends and many new ones flocked about her, and where she held a kind of intellectual court. She traveled again in Germany in 1807, and upon her return announced her religious conversion. The appearance of her book on Germany was the signal for still severer measures by Napoleon. The French edition was destroyed, and she was ordered to retire to Coppet, where she was kept under surveillance, a virtual prisoner, and forbidden to receive her friends. She escaped in 1812 and took refuge successively in St. Petersburg, Sweden, and England. On the fall of Napoleon she returned to Paris in 1815, but she was disappointed at the tendencies of the restored monarchy. D. July 14, 1817. In 1811 she had secretly married Albert de Rocca, an officer but twenty-three years old, to whom she bore a son. Though her conspicuous influence upon her contemporaries was wielded by personal contact, and her written works were considered to fall far behind the power and brilliancy of her improvisation in the excitement of conversation, her books are among the most important of the post-revolutionary period, and furnished a great stimulus to the new currents of French literature that were preparing romanticism. They are marked by fervid and sometimes hysterical sentiment, that often appears to protest against social conventions, especially in the essay *De l'Influence des passions sur le bonheur des individus et des nations* (1796), and the novels *Delphine* (1802) and *Corinne*

(1807); and by a wide range of intellectual view and just and profound ideas, which some have denied her the credit of originating, but which she at least grasped, communicated, and made available. These are exhibited especially in *De la Littérature considérée dans ses rapports avec les institutions sociales* (1800); *De l'Allemagne* (1810); and *Considérations sur la Révolution française*, her last work, published by her son in 1818. *De l'Allemagne* was of great importance in stimulating the influence of German thought and literature in France by giving the French public a more complete and sympathetic revelation of Germany than it had ever had. Other works are *Lettres sur les écrits et le caractère de J. J. Rousseau* (1788) and *Dix années d'exil* (posthumous). Her son published her *Œuvres complètes* (17 vols., 1821). See Lady Blennerhasset, *Frau von Staël* (3 vols., 1888–89); A. Sorel, *Madame de Staël* (Paris, 1890).

A. G. Canfield.

**Staff**: an exterior covering for buildings, resembling plaster or stucco, first used at the Paris Exposition of 1889, and employed for most of the buildings and exterior decorative work of the Columbian Exposition at Chicago in 1893. It is made of hydraulic cement, sand, and a binding material of jute fiber. M. M.

**Staf'fa**: a small, uninhabited island of Argyleshire, Scotland; 6 miles W. of Mull; celebrated for its curious caverns, among which that called Fingal's Cave (*q. v.*) is the most remarkable. Among the other caves are the Cormorant and the Clam-shell. The greater part of the coast is girt with cliffs from 84 to 112 feet high. In the N. E., however, in the lee of the prevailing winds, is a tract of low shore stretching out in beaches and forming a landing-place, and the interior table-land is covered with rich soil and luxuriant grass, which feeds a number of black cattle.

Revised by M. W. Harrington.

**Staff and Staff Schools**: the assistants of the general-in-chief of an army and of his generals, and the institutions in which they are trained for service on the staff. The term staff as commonly used includes (1) the heads of departments (such as artillery and engineers, military law, medical, quartermaster, pay, etc.), (2) the personal staff (including aides, orderly officers, etc.), (3) adjutants, and (4) a special body of officers, intrusted with duties connected directly with military operations, entitled the *general staff*.

The general staff has been universally recognized as an essential part of modern army organization. Its purpose is to convert the ideas of the general commanding into orders, not only by conveying them to the troops, but far more by working out all the necessary matters of detail (Clausewitz); and to watch over and preserve the fighting condition and material welfare of the troops (Schellendorf).

*Germany.*—All European states since the great success of the Prussian armies in their contests with Denmark, with Austria, and with France, in the campaigns of 1864, 1866, 1870–71, have made the Prussian staff system in some degree their exemplar. The origin of a general staff is probably to be found in the Swedish organization of the seventeenth century (then regarded as a model), and traces of it (no doubt taken therefrom) are found in the army of the great Elector of Brandenburg, who had, in 1655, two quartermaster-generals, officers doing special duty other than the direct command of troops—the germ of the German general staff of to-day. In 1657 were added to the general staff a field-marshal, a commissary-general and his assistant, 2 adjutant-generals, a judge-advocate, a provision-master, a quartermaster, a paymaster, a chaplain, a surgeon and an apothecary, a wagon-master, a provost-marshal with 3 assistants, and 11 clerks.

Frederick the Great had few staff officers. This great captain was not only his own chief of general staff, but he often assumed the functions of a staff officer of an inferior grade. The staff of the quartermaster-general then had merely a nominal existence. In 1741 there were 5 colonels, 4 adjutant-generals, 1 brigade-major, 5 majors (wing-adjutants), 1 quartermaster-general with 1 colonel and 2 majors as assistants, and 9 colonels and lieutenant-colonels of the army on general staff-duty. The king's instructions to his quartermaster-general, dated 1757, contain the principles of the construction, attack, and defense of fortresses and fortified camps; reconnoissance duty was performed by his engineers; the captain of the guides conducted columns of route, as no maps then existed, while the brigade majors regulated the guard duties in camp. In 1796 the survey of the kingdom was intrusted to the quartermaster-general's staff.

These were the beginnings of the general staff, but it was not until 1806 that Col. von Massenbach gave it a definite organization, and had assigned to its officers their proper duties, which, in general outlines, are still retained.

After the destruction of the Prussian army by Napoleon in the campaign of 1806, Col. von Scharnhorst in 1808 became lieutenant quartermaster-general of the Prussian army, with rank of major-general. His staff consisted of thirty-four officers in all; one officer was attached to each brigade, and one (sometimes two) to each corps. After 1815 the organization of the staff, which had rendered distinguished and important services during the closing campaigns against Napoleon, was seriously studied. A part of its officers, placed under a special chief as the *great general staff*, was assembled at Berlin, while its other officers, doing staff duty in the general and divisional commands, were in direct contact with the troops. The general staff was under the Minister of War till 1821, when the king named Lieut.-Gen. von Mueffling chief of the general staff, which then acquired an independent position, taking its orders directly from the chief of the state and commander-in-chief of the army—a position it retains. To this independence of all subordinate authority the Prussian staff attributes its ability to render the services in its later campaigns which have placed it as first among military organizations. Lieut.-Gen. von Mueffling was succeeded in 1829 by Lieut.-Gen. von Krauseneck, who was followed in 1848 by Lieut.-Gen. von Reyer, on whose death, in 1857, Gen. von Moltke became chief of the general staff. The part played by this general staff in changing the map of Europe makes its history one of great interest.

The campaign of 1866 showed the necessity of having ready at the moment of mobilization of the army a great general staff, capable of being doubled, and of leaving behind it when the army takes the field a sufficient number of trained staff officers to make sure of the means and measures of military transportation, and to insure the continuance of the supplies necessary for the army of operations. In 1867 a royal order established the staff on the following footing: *Principal list*: chief of general staff of the army; chiefs of division at the offices of the great general staff; chiefs of staff of the army-corps, etc.; total, 88 officers. *Scientific list*: 21 officers at the office of the great general staff. Total, 109 officers, 46 belonging to the great general staff.

At the breaking out of the war of 1870 the German army contained 200 staff officers, which number was considerably increased in the course of the campaign. In 1891 the general staff proper consisted of 186 officers—127 attached to the staff of the corps, divisions, etc., 49 to the great general staff of Berlin, 10 to that of Munich; the auxiliary staff (*scientific list*), officers simply detached from their regiments and doing duty under the great general staff, consists of 68 officers. Besides these, the general staff comprises military *attachés* (about 10), directors of military schools (about 20), commissaries of railroads residing at important railway centers (25), and officers undergoing probation as staff officers (80). Moreover, there are some 400 adjutants, selected and assigned to duty by the chief of the general staff, so that there are about 800 officers employed on general staff duty.

The work of the great general staff is distributed to separate divisions. The chief of the general staff directs the whole. In his office, under direction of his aide-de-camp, questions relating to the personnel of the staff, to its organization and administration, are considered. The work of collecting military information, domestic and foreign, the use of railways, the pursuit of military science, preparation of maps, etc., are distributed to various sections, grouped according to their work or the countries to whose study they are devoted. The staff is divided into three sections, whose duty is to study attentively all military events, domestic and foreign; to keep themselves acquainted with the changes affecting the organization, recruiting, arming, and equipment of armies; to study the military geography of different countries, the establishment or demolition of fortresses, the development of the network of roads, railways, canals, etc. Each is directed by a chief. Several staff officers, and a number of officers ordered on staff duty and charged with the special study of military questions in different countries, are under the orders of each chief.

The fourth section is that of railways. This section is charged with all that relates to military transportation. It should know the connections of the railways at home and abroad, the equipment and rolling stock; and it elaborates the great schemes for army transportation by railway. In consequence of the great number of officers needed to manage the movement of a great army by railway, as many officers as possible are from time to time attached to this section with a view to their instruction in these duties.

In the scientific corps of the staff are the officers who have charge of the section of military history, of the archives, and of the library. In this scientific corps belong also the section of geography and statistics and the preparation of military maps of foreign countries. The general service of charts belongs, under a chief of the trigonometric survey, to another part of the great general staff.

The officers of the general staff are selected from the ablest graduates of the military schools after a certain term of service in the line. They serve on the staff in greater number than can possibly become permanent staff officers. They return to the line and serve a term with their regiments. As vacancies occur in the permanent staff, they are filled by selection, at the discretion of the chief of the general staff, from those officers who have, while under his eye, given proof of greatest capacity and devotion.*

*France.*—In the French army, previous to 1880, the general staff was a separate corps of officers, but since that year it has been merely a service to which officers of the line are detailed for a term of years, these officers still belonging to their respective arms and being regularly promoted therein. By the law of June 24, 1890, the number of officers in the general staff was limited to 640, comprising 30 colonels, 40 lieutenant-colonels, 170 majors, and 400 captains, under whose orders are placed 180 archivists, constituting a special corps of officers, employed in clerical work and in keeping the records.

In time of peace the general staff comprises (1) the military household of the president; (2) the special staff of the Minister of War; (3) the general staff of the army; (4) the staffs of the military governors of Paris and of Lyons; (5) the staffs of army-corps, divisions, and brigades; (6) the staffs of territorial divisions and subdivisions; (7) the staffs attached to fortified places; (8) the staffs of marshals of France and general officers specially employed; (9) military *attachés* abroad; (10) the staff of the commanders of the artillery and the engineers.

The supply of officers for the staff comes mainly from the superior war school (see MILITARY ACADEMIES), but officers who have not gone through this school are allowed to compete for a staff certificate at examinations held concurrently with the final examination at this school. The officers who pass serve a probationary term of two years in the staff, after which the best are selected as required.

The personnel of the staff is brought up to the war footing by calling in all officers possessing the staff certificate who are in the active army, and by recalling all certified officers and archivists belonging to the reserve or the territorial army.

The general staff of an army-corps is composed of (1) 1 chief of staff (general or colonel), 1 colonel or lieutenant-colonel, 2 majors (sometimes 3), 3 captains, 2 orderly officers, 2 archivists and 8 secretaries in time of peace; in time of war, of 14 officers and 66 men; (2) the staff of the artillery, 8 officers and 19 men; (3) the staff of the engineers, 4 officers and 8 men.

A division has, in time of peace, 1 chief (lieutenant-colonel or major) and 1 orderly officer (captain or lieutenant); in time of war, 1 captain or lieutenant, and 30 men in addition.

A brigade has, in time of peace, 1 orderly officer (lieutenant or captain possessing the staff certificate), and 1 corporal or private as secretary; in time of war, 1 lieutenant of the reserve as orderly officer, and 9 men in addition.

The artillery and engineers have also a special staff, that of the former comprising 310 colonels, lieutenant-colonels, majors, and captains, also the second lieutenants of the school of application; that of the latter comprising 486 officers. The duties of the former consist in superintending the various establishments of that arm and supplying the troops with ammunition; those of the latter in constructing and repairing fortifications and military buildings, directing the engineer schools, military telegraphy, and the military pigeon-houses.

*Russia.*—The officers of the general staff in Russia form a special corps, and are exclusively graduates of the general staff school (Nicolas Academy) at St. Petersburg. Entrance to this school is by competitive examination, open to officers of all arms who have served at least three years; the course is two and a half years, the last six months being devoted entirely to practical work in the field; about 80 students enter every year and about 60 graduate. Upon graduation the 30 best enter the general staff. There is also a geodetic subdivision of 20 officers, who, after a two and a quarter years' course here, have a two years' course at the observatory at Pulkowa and then enter the general staff. The general staff comprises about 480 colonels, lieutenant-colonels, and captains, who do duty in the different bureaus of the great general staff at the office of the Minister of War, or in the military schools, or in the general staff of the generals exercising command. Before being promoted they are always required to have served with troops, exercising certain commands, so that a number is always detached on such duty. The corps also comprises about 80 general officers doing general staff duty and about 170 on special duties of various kinds. Topographical work is not done by the general staff, as in other armies, but by a special corps of military topographers, about 450 officers; and there is still another corps, doing duty related to that of the general staff, viz., the *Feldjaeger*, about 45 officers, selected from various arms, for reconnoissance work, carrying important orders to a distance, etc. General officers also have their aides-de-camp, selected from the officers of their commands, and simply detached, but not considered part of the general staff.

*Austria-Hungary.*—The general staff of Austria-Hungary, suppressed as a special corps in 1871, but re-established as such by the law of Dec. 23, 1875, comprises on the peace footing 260 officers, besides a number attached for temporary duty. The corps proper is a closed corps, and an officer once admitted remains a part of it, whether he afterward does duty with troops or continues on general staff duty, but it is open for admission to all officers up to the rank of major.

Before entrance lieutenants are generally required to pass at the staff school (*Kriegsschule*),* located in Vienna. Admission to this school is by competitive examination, open to first or second lieutenants of at least three years' service, who are under thirty years of age and unmarried; each year about 45 enter. The course is two years, terminated by an examination, at which other officers who have not taken the course may also compete. Those who pass are assigned to the staff for a probationary tour of duty as required; they number usually about 135. If acceptable they become captains of the general staff; if not, they return to their regiments. Majors may come directly from the line, either by passing a special examination or by selection of the chief of the general staff. Promotion in the corps is by seniority.

Employed in the bureaus of the general staff of the army are about 30 officers, taken either from the retired list or from a special body of officers, not fit for active service, but who can be utilized for sedentary duties, called the *Armeestand*, who have their own uniform and are promoted among themselves. Besides these about 100 officers, detached from their regiments, are detailed on topographical work. The total on general staff duty is about 700.

*Italy.*—General staff duty in Italy is performed by a special corps of about 150 officers, drawn from the captains, graduates of the general staff school, who have commanded a company, squadron, or battery for at least one year. Upon promotion they generally return to the line, and are not again recalled to the general staff as majors until after serving another year with troops; but captains who served two years before admission may be promoted in the corps.

There are also about 120 officers temporarily attached to the general staff, including those graduates of the staff school (usually about 24) who are making their trial tour. Generals in command, besides their general staffs, have also orderly officers, selected from among the troops of their command and detailed for a term not exceeding three years; brigade commanders have neither general staffs nor orderly officers, but aides-de-camp are detailed to the brigade (not to its commander) by the Minister of War. The number of orderly officers and aides-de-camp is about 100. There are, therefore, about 370 officers on general staff duty.

* Saxony has its own cadet corps, and Bavaria has its own cadet corps, war school, artillery and engineer school, and war academy.

* Austria-Hungary also has a military orphan asylum at Fischau, 4 lower military realschools at St. Pölten, Güns, Eisenstadt, and Koschau, a higher military realschool at Mährisch-Weisskirchen, 12 infantry cadet schools, 1 cavalry, 1 artillery, 1 engineer, and 1 pioneer school, the military academy (for cavalry and infantry) at Wiener-Neustadt, the technical military academy (for artillery, engineers, and pioneers) at Vienna, the higher artillery and engineer course, and the field officers' course, besides regimental and other schools for soldiers and schools of practice and application for officers.

*Great Britain.*—It can scarcely be said that there is any British military staff as a separate and distinct corps of officers. The British War Department is dual, embracing both political and military officers. Command and administration are separate. The War Office and the Horse Guards, long distinct, were united into one department by act of Parliament in 1870. The general commanding-in-chief was thus brought into the War Office, which is under the Secretary of State for War. The latter is alone responsible to Parliament, while the former is subordinate, and can exercise his authority only under approval of the secretary; in practice, however, the secretary concerns himself with the army estimates only, and exercises merely a general control over the general-in-chief, who has immediate direction of all military affairs; two Under-Secretaries of State are placed immediately under the Secretary of State for War—the parliamentary secretary and the permanent under-secretary. The first retires at a change of ministry, and assists his chief in Parliament; the second does not sit in Parliament: he has the real direction of business, and does not go out with the ministry.

The military affairs come under the military department of the secretary, and are arranged under several bureaus: (1) That of the military secretary, dealing with matters relating to officers personally, such as orders, leaves of absence, detail to staff-duty, etc.; (2) that of the adjutant-general of the army, concerned with all questions of recruitment, organization, mobilization, instruction, and discipline; (3) that of the quartermaster-general, comprising clothing, equipment, quartering, food, forage, and transportation: the quartermaster-general has control of the commissariat and transport corps and the pay department; (4) that of the inspector-general of engineers and fortifications; (5) that of the director-general of artillery; (6) that of the director of military intelligence; (7) the director of military education, surgeon-general, chaplain-general, and principal veterinary surgeon.

The yearly army estimates and administrative matters are under the financial department, at the head of which is the financial secretary (a civil officer), under whom are four bureaus: (1) The accountant-general (specially charged with the army estimates); (2) the director of contracts; (3) the director of clothing; (4) the director of ordnance-factories.

There are two branches of general staff service in England; viz., the staff of the commands and the personal staff. The former comprises those officers who form the staff proper of general officers, those on topographical work, and those sent on special missions. The staff of a general officer is divided into two distinct bureaus, the adjutant-general's and the quartermaster-general's. In brigades a single officer, called brigade-major, combines the duties of both.

The personal staffs of generals comprise aides-de-camp and military secretaries.

The officers of the staff are taken exclusively from the regular army, and should have spent two years at the staff college or passed the final examination for graduation at that college. A condition of eligibility to examination for admission to the staff college is five years' service in the army. Every officer who presents himself for the graduating examination at Sandhurst Staff College (see MILITARY ACADEMIES) must have had seven years' service.

Officers on staff duty generally serve but five years, after which they return to their regiments and are not again available for at least two years.

*United States.*—In the U. S. there is no general staff properly so called, but (as in Great Britain) some of the duties of this body are performed by officers of certain departments or by officers of the line temporarily detailed. The so-called staff departments are (1) the adjutant-general's, comprising 1 brigadier-general, 4 colonels, 6 lieutenant-colonels, and 6 majors, their principal duties being the ordinary routine of office-work, the wording and issue of the orders of commanding generals, and in the war department all matters relating to recruitment; (2) the inspector-general's (1 brigadier-general, 2 colonels, 2 lieutenant-colonels, and 2 majors), their duties consisting in inspecting the various posts, garrisons, military schools, and military departments of colleges to which officers are detailed, and the money accounts of disbursing officers; (3) the quartermaster's department (1 brigadier-general, 4 colonels, 8 lieutenant-colonels, 14 majors, and 30 captains), whose duties consist in constructing and repairing quarters and other public buildings, roads, etc., furnishing transportation and supplying fuel, forage, clothing, and material; (4) the subsistence department (1 brigadier-general, 4 colonels, 3 lieutenant-colonels, 8 majors, 12 captains), furnishing supplies of food (principally the ration) and certain other articles; (5) the judge advocate-general's department (1 brigadier-general, 1 colonel, 3 lieutenant-colonels, and 3 majors), who attend to questions of law and assist in revising charges and court-martial proceedings; (6) the medical department; (7) the pay department; (8) the Corps of Engineers, part of the line in European armies, but forming a closed corps in the U. S., recruited exclusively from the highest graduates of the military academy, mainly employed in time of peace on river and harbor work, a few in charge of repairs to forts or serving with the battalion of engineers, and one on the staff of the commander of each military department in the country; (9) the ordnance department (corresponding to the construction branch of European artilleries), employed in the various arsenals, work-shops, and gun-foundries, one on the staff of each department commander; (10) the signal corps; (11) the post chaplains. The chiefs of these departments, together with a certain number of officers of each, constitute a kind of staff to the Secretary of War and the general of the army. An intelligence bureau has been organized at the War Department. Each military department commander usually has one officer of each staff department on his staff; quartermasters, commissaries, and surgeons are also located in the large cities in charge of dépôts, etc. Each department commander has also his personal aides—a major-general 3, a brigadier-general 2.

Each regiment has also a regimental staff, comprising the adjutant and quartermaster of the regiment, detailed from the lieutenants for four years. Each post, moreover, has a post adjutant and a post quartermaster and commissary, detailed by the commanding officer from the lieutenants of the post.

For further information consult von Schellendorf, *Duties of the General Staff*; Rau, *L'état militaire des puissances étrangères* (1891); von Löbell, *Jahresberichte über die Veränderungen und Fortschritte im Militärwesen*; and L. Beaugé, *Manuel de législation, d'administration et de comptabilité militaires* (1892).

Revised by JOHN P. WISSER.

**Staffeldt**, ADOLF WILHELM SHACK, von: poet; b. on the island of Rügen, Germany, 1769; studied in the military academy at Copenhagen, and entered the Danish army. In 1791 resigned, and studied law, archæology, and the history of art at Göttingen, after which he spent several years in travel. In 1800 he returned to Denmark, and held important Government positions there until his death in 1826. His earliest collections of poems (1803 and 1808) attracted little attention at the time of their appearance, and on account of their depth of thought and frequent obscurity of language they have never won general popularity. Unlike Oehlenschläger, Staffeldt continued to be strongly influenced by German romanticism. Among his later works are the romances *Troubadouren*; *Trende Nætter* (Three Nights); *Roserne* (The Roses); and *Indvielsen* (The Consecration). See his *Collected Poems* (2 vols., Copenhagen, 1843). D. K. D.

**Stafford**: county town of Staffordshire, England; on the Sow; 29 miles N. N. W. of Birmingham, and 133 N. W. of London (see map of England, ref. 9-G). Among the churches are St. Mary's, restored by Sir G. Scott in 1845, and St. Chad, originally of Saxon origin, restored 1855-85. Shoemaking is carried on. Stafford returns one member to Parliament. Pop. (1891) 20,270.

**Stafford**, WILLIAM HOWARD, Viscount: statesman; b. in England, Nov. 20, 1612; was brought up a Roman Catholic; married a sister of Baron Stafford, to whose title Howard succeeded. During the civil war Stafford adhered to the royal cause, but after the Restoration often opposed in the House of Peers the measures of the court; was intimate with Shaftesbury, and was, on account of his religion, selected by the infamous Titus Oates as one of his victims. Accused of participation in the "Popish plot" by Oates in his first examination before the House of Commons, Stafford surrendered himself on the following day, and was committed to the Tower with four other accused noblemen Oct. 30, 1678. On Nov. 30, 1680, his trial for high treason was begun before the House of Lords, Sir Heneage Finch (afterward Earl of Nottingham) presiding as lord high steward. Stephen Dugdale and one Turberville, the chief witnesses, swore that Stafford had offered them rewards to participate in a conspiracy against the life of the king, and Bedloe, Dangerfield, and Denis offered confirmatory testimony.

Stafford defended himself with spirit, but he was convicted Dec. 7, by 55 votes against 31, four of the Howard family being of the majority. Stafford was executed on Tower Hill, Dec. 29, 1680, protesting his innocence in terms which carried great weight with the spectators. His widow was created countess, and his eldest son Earl of Stafford, by James II. (1688); but the title became extinct on the death of the fourth earl in 1762. The attainder was reversed by act of Parliament in 1824, and Sir George William Jerningham was recognized as Baron Stafford in 1825.

Revised by F. M. Colby.

**Staf'fordshire**: a west midland county of England; area, 1,169 sq. miles. The central part of the county is low and undulating, but in the north and the south the ground rises and the surface becomes hilly. The soil is generally cold, clayey, and not very productive. The coal-fields are very rich in the northern and southern parts of the county; iron, copper, and lead are found, together with marble, freestone, and an excellent potter's clay. With respect to its manufactures, chiefly china, earthenware, and iron, this county is the third in rank in England. Seven members are returned to Parliament. Pop. (1901) 879,625.

**Stafford Springs**: borough; Tolland co., Conn.; on the Willimantic river, and the Central Vt. Railroad; 20 miles N. by W. of Willimantic, 50 miles N. of New London (for location, see map of Connecticut, ref. 7–J). It contains manufactories of woolen and iron goods, Congregational, Methodist Episcopal, Protestant Episcopal, and Roman Catholic churches, high and graded schools, public library (founded in 1874), a national bank with capital of $50,000, a savings-bank, and a weekly paper. Mineral springs add to the attractions of the place as a summer resort for invalids and pleasure-seekers. Pop. (1890) 2,353; (1900) 2,460. Editor of "Press."

**Staff-tree Family**: See Spindle-tree Family.

**Stag**, or **Red Deer**: the largest deer of Europe, the *Cervus elaphus*, a species much resembling the American wapiti. The male is called the *hart*, the female the *hind*, and the young the *calf*; the male under three years is called a *brocket*; under four, a *spayad*; under five, a *staggard*; and under six, a *stag*; so that strictly, in sporting parlance, a stag is a red deer five years old. At six years he is a *hart of ten*, and when seven years old he is a *hart crowned*, and is considered fair game. The stag is distributed over the greater part of Europe, and is found in Northern Asia as far as the Lena and Lake Baikal. It inhabits Exmoor, in England, and the Highlands of Scotland. Its horns are lofty and branching. In summer it is yellowish-brown; in winter, reddish-brown; the color deepens much with age, and in winter the old stags are nearly black. The flesh is inferior to that of the fallow deer. Revised by F. A. Lucas.

**Stag-beetle**, or **Horn-bug**: any one of several large beetles of the family *Lucanidæ*, remarkable for the great size of the head and for the large horn-like mandibles. *Lucanus dama* of the U. S. is a well-known inhabitant of decaying wood, piles of chips, etc., and is capable of inflicting a severe bite. *L. cervus* is European.

**Stage**: See Theater.

**Stage-coach**: See Carriages.

**Staggers**: a popular name for several diseases of horses and sheep. Blind staggers in horses is a sort of epilepsy; mad staggers, an inflammation of the brain; grass staggers, an acute and dangerous gastritis. The treatment of the first is by setons about the head, but the disease is incurable. The second usually receives treatment by means of blisters, cathartics, and thorough bleeding. The last-mentioned disease calls for active enemata and good-sized doses of calomel and opium. Staggers in sheep is caused by larvæ of *Œstrus ovis* in the nostrils; they may sometimes be removed by throwing into the nostrils snuff mixed with whisky.

**Staghound**: a large, rough-haired dog, much like the greyhound in general build, although somewhat heavier. It is strong, swift, and fearless, and the rival of the bloodhound in powers of scent. It is supposed to be a cross-breed of the bloodhound and the greyhound, and is used in Europe for hunting the stag, and, to some extent, in the western parts of the U. S. for hunting antelope. F. A. L.

**Stagi'ra** [= Lat. = Gr. Στάγειρα]: town of Chalcidice, in Macedonia. It was a colony from Andros, but fell into decay during the Peloponnesian war. It was the birthplace of Aristotle, and in honor of his great tutor Alexander restored the city, but its prosperity was merely temporary.

**Stagirite, Aristotle the**: See Aristotle.

**Stagne'lius**, Erik Johan: poet: b. in Gärdslösa, Sweden, Oct. 14, 1793. Although at first strongly influenced by Phosphorism (see Swedish Literature) and never entirely freeing himself from its obscurity, Stagnelius developed a style and view of life quite his own. All his works are treatments, in one form or another, of the different aspects of gnosticism, and in these speculations he goes to the furthest extreme. In some of his aspects he has not inaptly been compared to Shelley. Among his works are *Wladimir den store* (1817); *Liljor i Saran* (Lilies of Sharon, 1821), his most characteristic collection of poems; *Martyrerne* (The Martyrs, 1821), his best drama; and *Bacchanterna* (The Bacchantes, 1822). D. Apr. 13, 1823. His collected works were published in 1867–68 (11 vols., Stockholm).

D. K. Dodge.

**Stahl**, Friedrich Julius: jurist; b. in Munich, Jan. 16, 1802, of Jewish parents; embraced Christianity in 1819; studied law at Würzburg, Heidelberg, and Erlangen; was appointed Professor of Jurisprudence in 1832 at Erlangen, and in 1840 at Berlin. His specialty was the philosophy of law, and in his system he was a disciple of Schelling. Assuming that human reason is incapable of arriving at a positive conception of truth by itself, he deduces the ideas of state, government, etc., from the doctrines of Christian revelation, and bases the authority of officials and the obedience of citizens on a divine ordinance. As a member of the upper house of the Prussian Diet he became the leader of the feudal and aristocratic party during the period of reaction which followed the abortive revolution of 1848 in Berlin. D. at Brückenau, Bavaria, Aug. 10, 1861. His principal works are *Philosophie des Rechts* (3 vols., 1830); *Ueber den Christlichen Staat* (1847); *Was ist Revolution?* (1853).

**Stahl**, Georg Ernst: chemist and physician; b. at Ansbach, Bavaria, Oct. 21, 1660; studied medicine at Jena; was appointed physician to the Duke of Weimar in 1687, Professor of Medicine at the University of Halle in 1694, and physician to the King of Prussia in 1716. D. in Berlin, May 14, 1734. He invented a theory of phlogiston which was generally adopted, and considered valid up to the time of Lavoisier. (See Chemistry.) His principal works are *Experimenta et Observationes Chemicæ* (1731) and *Theoria Medica Vera* (1707).

**Stahr**, staar, Adolf Wilhelm Theodor: author; b. at Prenzlau, Brandenburg, Prussia, Oct. 22, 1805; studied classical languages and literature at Halle; was appointed professor at the gymnasium of Oldenburg in 1836; settled in 1852 at Berlin, where he married the authoress Fanny Lewald in 1855. He was a very prolific writer; his numerous books and articles for periodicals treat subjects of antiquity and modern times, history and art, critically and in a descriptive manner. Some of his works have been translated into English, as, for instance, *Torso, oder Kunst, Künstler, und Kunstwerke der Alten* (2 vols., 1854–55), in *The Crayon* (New York, 1858–59); and his somewhat superficial but cleverly written biography of Lessing, *G. E. Lessing, sein Leben und seine Werke* (2 vols., 1859), by Prof. E. P. Evans, of Michigan University (Boston, 1866). He wrote the text to Kaulbach's *Goethe Gallerie* (part i., Goethe's *Frauengestalten*). His *Oldenburgische Theaterschau* (2 vols., 1845) drew great attention to the stage of Oldenburg. D. at Wiesbaden, Oct. 3, 1876. Revised by Julius Goebel.

**Staigg**, Richard Morrell: painter; b. in Leeds, England, Sept. 17, 1817; removed to the U. S. in 1831; became a mechanic at Newport, R. I., where he took lessons in painting from Washington Allston and Jane Stuart; became eminent as a miniature-painter, a branch of art which he subsequently relinquished for genre-pictures and coast-scenes. Among his best productions are *The Crossing-sweeper*, *Cat's Cradle*, *Knitting*, *The Love-letter*, *The Sailor's Grave*, and *News from the War*. D. at Newport, R. I., Oct. 11, 1881.

**Stained Glass**: See Glass.

**Stainer**, Sir John: composer and organist; b. in London, June 6, 1840; studied entirely in England; entered the choir of St. Paul's Cathedral when seven years of age, remaining until his voice broke in 1856, playing the organ on occasion. He occupied several positions as organist till 1872, when, on the resignation of Sir John Goss, he was appointed organist of St. Paul's, and remained until 1888, when he was obliged to resign on account of failing eyesight. In that year he was knighted, and on the death of

Sir F. A. Gore Ouseley in 1889 was appointed to succeed him as Professor of Music in Oxford University. His degrees and honors are as follows: Mus. Bac. Oxon. 1859; B. A. 1863; Mus. Doc. Oxon. 1865; M. A. 1866; Hon. Mus. Doc., Durham, 1885; Chevalier of the Legion of Honor 1878. He is also honorary member of the Royal Academy of Music and honorary fellow of the Tonic Sol-Fa College. His compositions are chiefly sacred and include three sacred cantatas, *The Daughter of Jairus*, Worcester festival, 1878; *St. Mary Magdalene*, Gloucester festival, 1883; *The Crucifixion*, 1887; the oratorio *Gideon*, an early work; and many church anthems and services. He has also written several theoretical works, a treatise on the *Music of the Bible*, and a *Dictionary of Musical Terms*. D. E. HERVEY.

**Stair**, JAMES DALRYMPLE, Seventh Baron and First Viscount: jurist; b. at Drummurchie, Ayrshire, Scotland, in May, 1619; graduated M. A. at the University of Glasgow 1637; obtained a commission as captain in the Scottish army, but at the age of twenty-two accepted the professorship of philosophy at Glasgow, which he held till 1647; was admitted an advocate at the Scottish bar Feb., 1648; was secretary to the commissioners sent to treat with Charles II. at Breda 1649–50; became a lord of session July 1, 1657; was knighted by Charles II. 1660, and confirmed as lord of session Feb. 13, 1661; resigned office 1663 from unwillingness to subscribe the declaration against the Covenants of 1638 and 1643 appended to the oath of allegiance, but his resignation was declined, and he was made a baronet June, 1664; became lord president of the court of session Jan., 1671; refused to take the new test oath, and was removed from his offices 1681; published in that year his *Modus Litigandi* and *The Institutions of the Law of Scotland*—a work which has been called the Scottish Blackstone; becoming involved in a dispute with Claverhouse he was forced to flee to Holland Oct., 1684; prepared there his *Decisions of the Lord of Council and Sessions 1661–81* (Edinburgh, 2 vols. folio, 1683–87); published at Leyden his Latin treatises *Physiologia Nova Experimentalis* (1686); received a pardon 1686; accompanied the Prince of Orange to England 1688; was reinstated in the presidency of the court of session, and made Viscount Stair Apr. 21, 1690; published an *Apology* for his political course (1690) and a *Vindication of the Divine Perfections* (1695). D. in Edinburgh, Nov. 29, 1695.

**Stair**, JOHN DALRYMPLE, First Earl of, better known as the Master of Stair, son of Viscount Stair: b. in Scotland about 1648; was admitted as advocate in the court of session Feb., 1672; was one of the council for the Earl of Argyll on his trial for treason 1681; was twice imprisoned between 1681 and 1685; was received into favor on the accession of James II., by whom he was made lord advocate 1685 and lord of session and lord justice clerk 1686; supported the Revolution 1688; was a leading Scottish member of the Convention Parliament Mar., 1689; was one of the three commissioners sent to London to offer the crown of Scotland to William and Mary May, 1689; was reappointed lord advocate 1690; became one of the Secretaries of State for Scotland 1691; plotted the massacre of GLENCOE (*q. v.*), Jan., 1692, for which act he was dismissed from office 1695 and censured by a parliamentary committee of inquiry, but was never subjected to prosecution; succeeded his father as Viscount Stair in 1695; was sworn of the privy council on the accession of Anne 1702; was created Earl of Stair Apr. 8, 1703; was one of the commissioners who negotiated the treaty of union between Scotland and England 1706, and was mainly instrumental in passing that measure through the Scottish Parliament. D. Jan. 8, 1707. See Graham, *Stair Annals* (1875).

**Stair**, JOHN DALRYMPLE, Second Earl of: soldier; b. in Edinburgh, July 20, 1673; had the misfortune in boyhood to kill his elder brother by the accidental discharge of a pistol; educated at the University of Leyden, where he was distinguished for scholarship; entered the army as a volunteer under the Earl of Angus, and commanded the Cameronian Regiment at the battle of Steinkirk 1692; was aide-decamp to the Duke of Marlborough at Venloo and Liège 1702; succeeded to the earldom 1707; obtained command of the Scots Greys; was commissioned general; distinguished himself at Ramillies and Oudenarde 1706, and at Malplaquet 1709; withdrew from the army in 1711; became privy councilor and representative peer for Scotland 1714; was appointed commander-in-chief of the forces in Scotland on the accession of George I. (1715); was ambassador to France 1715–20; resided on his estate at New Liston, Scotland, and devoted himself to scientific agriculture 1720–40; was made field-marshal commander-in-chief of British forces in Flanders and ambassador extraordinary to the States-General of Holland 1741; won the battle of Dettingen June 27, 1743, and subsequently filled several important public posts under the Walpole administration. D. in Edinburgh, May 9, 1747. The *Memoirs of the House of Dalrymple*, published from family papers (1876), contains important historical data.

**Stalac'tites** [from Gr. σταλακτός, dropping, oozing out in drops, deriv. of σταλάζειν, to drop]: icicle-like masses of lime, limonite, chalcedony, pyrites, etc., attached to the roofs of caverns; they are formed by the evaporation of water holding these substances in solution. Stalactites sometimes form columns reaching from floor to roof of high chambers; sometimes they imitate curtains, waterfalls, etc., and constitute notable features in some of the most famous caves. The name *stalagmite* (Gr. στάλαγμα, a drop) is given to accumulations of material of the same nature as stalactites, but deposited on the floors of caverns. This sometimes forms continuous sheets over the surface, sometimes rises into columns, which meet and blend with the stalactites above. Stalactites are often tubular, and, indeed, generally begin to form as tubes, since the solid matter held in solution by a drop of water when precipitated by evaporation forms a ring at the base and outside of the drop.
Revised by ISRAEL C. RUSSELL.

**Staley**, CADY, Ph. D., LL. D.: civil engineer and educator; b. at Scotch Bush, Montgomery co., N. Y., Dec. 12, 1840; educated at Union College. He has been in engineering work on the Central Pacific Railroad, Professor of Civil Engineering in Union College 1867–86, and dean of the faculty, and since 1884 president of the Case School of Applied Science in Cleveland, O. He is the editor of recent editions of Gillespie's *Surveys* and *Roads and Railroads*, and (with G. S. Pierson) author of *The Separate System of Sewerage* (1886).

**Stalker**, JAMES, D. D.: minister; b. at Crieff, Perthshire, Scotland, Feb. 21, 1848; was educated at the University and New College of Edinburgh, Universities of Berlin and Halle; minister of St. Brycedale Free church, Kirkcaldy, 1874–87; since 1887 of St. Matthew's, Glasgow. He was Cunningham fellow at New College 1874, and Lyman Beecher lecturer at Yale Theological Seminary 1891. Dr. Stalker has published *The Life of Jesus Christ* (Edinburgh and New York, 1879; many later editions; translated into several foreign languages); *The New Song: Sermons for Children* (1883); *Life of St. Paul* (1884; several later editions); *Imago Christi* (1889; 7th edition, 1894; translated into Norwegian, German, Japanese, and other languages); *The Preacher and his Models*, Lyman Beecher lectures (New York, 1891; 2d ed. 1892); *Men and Morals* (1892); *The Four Men and Other Chapters* (1892); *The Trial and Death of Jesus Christ* (1894). C. K. HOYT.

**Stall**, SYLVANUS: See the Appendix.

**Stalwarts**: a name applied to the section of the Republican party that in 1881 opposed the administration of President Garfield. The quarrel arose from the appointment of a collector of the port of New York in opposition to the wishes of Conkling and Platt, the Senators from that State. The party was divided into Stalwarts and "Half-breeds," as friends of the administration were called, and this helped the Democrats to win in 1884. See REPUBLICAN PARTY.

**Stamboul**, stăm-bool': the wealthiest, most populous, and important of the territorial divisions forming the city of CONSTANTINOPLE (*q. v.*), called Istamboul by the Ottomans. Stamboul is a triangular-shaped promontory, projecting eastward toward the Bosphorus from the mainland, and included between the Golden Horn and Marmora. It comprises thirteen of the fourteen *regions* or *climata* of the Nova Roma of Constantine. E. A. G.

**Stamen** [= Lat., liter., warp in an upright loom, thread, fiber, deriv. of *sta're*, stand; cf. Gr. στήμων, warp (in an upright loom), deriv. of ἱστάναι, stand]: the pollen-bearing organ in plants. Morphologically it is a leaf, upon which one or more pollen-sacs (spore-sacs or sporangia) are produced. On account of its special function it is rarely an expanded structure, although it is so in water-lilies, cannas, and some other cases (Fig. 1, *a*). In its usual form (Fig. 1, *b*) the slender stalk (*filament*) is surmounted by the pollen-sac (*anther*), which at maturity contains many loose cells, the

POLLEN (*q. v.*). In *Taxus* (*c*) several pollen-sacs are attached to the under side of the peltate stamen, while in *Ginkgo* (*d*)

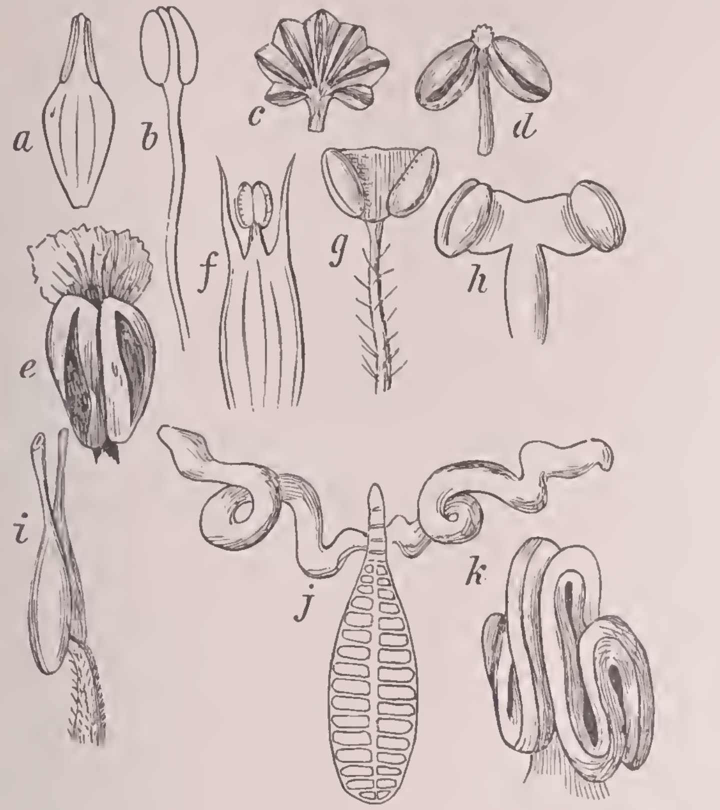


FIG. 1.—Stamens: *a*, water-lily; *b*, anemone; *c*, *Taxus*; *d*, *Ginkgo*; *e*, *Picea*; *f*, *Allium*; *g*, *Tradescantia*; *h*, *Thymus*; *i*, *Oxycoccus*; *j*, *Acalypha*; *k*, *Cucurbita*.

the two sacs are attached by the tips only. In *Picea* (*e*) and the pines the sacs are attached at the back of the leaf-like stamen. Other forms are shown in *f* to *k*, the most curious being found in *Acalypha* (*j*), where the sacs are long and spirally twisted.

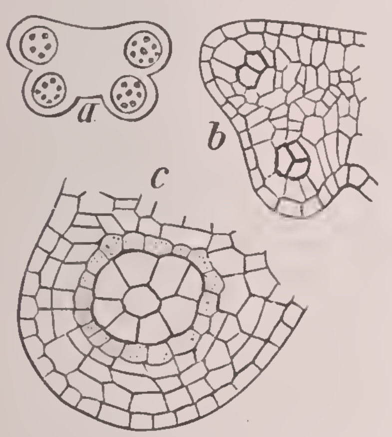

FIG. 2.—*a*, cross-section of a mature anther; *b c*. cross-sections of young anther-lobes showing differentiated cells, highly magnified.

When young, the pollen-sacs are composed of uniform tissue, but soon certain cells in vertical rows become differentiated (Fig. 2, *b c*), and eventually by subdivision produce the pollen-cells. At maturity there may therefore be one, two, or four cavities (Fig. 2, *a*) containing pollen, and this is set free by the longitudinal rupture of the anther (Fig. 1, *b e k*), or by the opening of a terminal or lateral pore (Fig. 1, *i*).

When associated with the pistil in the same flower the stamens are usually below it (hypogynous), but by the adhesion of the floral parts they may be above it (epigynous). Normally they are separate from one another, but in some cases they are more or less united by their filaments, as in peas and beans, or even by their anthers, as in the *Compositæ*. See FLOWER.

CHARLES E. BESSEY.

**Stamford**: town and city; Fairfield co., Conn.; on Long Island Sound, Mill river, and the N. Y., N. H. and Hart. Railroad; 34 miles N. E. of New York, 78 miles S. W. of Hartford (for location, see map of Connecticut, ref. 13–D). The main part of the town lies in a valley, with hills on three sides and the Sound on the S. The harbor has been improved by the U. S. Government and is suitable for vessels of large draught. There is a daily steamboat line to New York. At Shippan Point, on the shore, are fine cottages, hotels, and other public resorts, and the Stamford Yacht Club building. The city comprises four-fifths of the population of the town, and has an excellent water-supply from Trinity Lake, sewerage system, paid police and fire departments, well-organized public-school system with high-school building erected in 1895, several private boarding and day schools and seminaries, a hospital and home maintained by St. John's church (Protestant Episcopal), the Ferguson Library, 2 national, a State, and 3 savings-banks, electric-light and railway plants, and a daily and 3 weekly newspapers. The town and city have a combined bonded debt of $600.000. There are extensive lumber-mills, a woolen-mill, a pottery, and manufactories of locks, builders' hardware, hoisting appliances, post-office equipments, pianos, stoves, shoes, patent medicines, chemicals, straw hats, carriages, and other articles. Stamford was settled in 1641; had its name changed from the Indian, Rippowam, in 1642; and was incorporated as a borough in 1830 and as a city in 1893. The assessed valuation of city property is about $17,000,000. Pop. (1880) 11,298; (1890) 15,700; (1900) 15,997.

ROBERT WHITTAKER.

**Stammering** [from O. Eng. *stamor*, adjec. stammering; cf. O. H. Germ. *stammalōn* > Germ. *stammeln*, whose root appears in Goth. *stamms*, stammering, in Germ. *stemmen*, make to halt (**stamjan*), and in *ungestüm*, violent, unchecked]: an affection of the faculty of speech characterized by irregular, imperfect, or spasmodic actions of the muscles concerned in articulation. It is in reality a choreiform, often hysterical, condition of the muscles concerned, a defective power of co-ordination. It may be manifested under two somewhat different forms. In the one there is a difficulty in beginning the enunciation of words, and this is shown especially in regard to those words which begin with what are called the "explosive consonants" (*b*, *p*), and which require the sudden opening of the lips. In the other form the word is begun, but after the enunciation of a syllable there is a spasmodic, and for a time uncontrollable, reiteration of the same syllable. To this variety the term *stuttering* is sometimes applied. Stammering is one of the mimic diseases, and may be acquired by carelessness in speech or by association with others similarly affected, or even by mocking such persons. In the majority of cases it disappears after the attainment of adult age, probably in consequence of the constant efforts of the subject to improve his habit of speaking. It is generally increased by emotional disturbance, especially fright and apprehension, and is much mitigated, and often cured, by the patient acquiring confidence in himself, never attempting to speak in a hurry or when the chest is empty of air, or by reading measured sentences slowly and with deliberation. Stammerers never have any difficulty in singing, for they know that a certain definite manner is to be observed, and this gives them the confidence they require. The affection is sometimes permanently removed in time by the patient performing some trifling muscular action consentaneously with the enunciation of the words over which he stumbles. Thus he can sometimes prevent the fault by moving a finger at the very instant that he begins to utter the word. Revised by W. PEPPER.

**Stamp Acts**: laws requiring that stamps purchased from the government be placed on certain legal documents. In the history of the British colonies in North America the term Stamp Act refers to a law passed by the British Parliament Mar. 22, 1765, "for granting and applying certain stamp duties and other duties in the British colonies and plantations in America." It took effect from Nov. 1, 1765, but was the occasion of such excitement, protests, and overt resistance in most of the colonies that it was repealed Mar. 18, 1766, and a bill of indemnity for those who had incurred penalties was passed June 6 of the same year.

**Stamp-mill**: See GRINDING AND CRUSHING MACHINERY.

**Stamps**: official marks set upon things chargeable with some duty or tax, showing that the tax has been paid. These stamps may be either embossed, or printed separately and made adhesive by being gummed on the back. The British Government has long required the use of such stamps on checks, receipts, bank drafts, and legal documents of all kinds, and during the civil war in the U. S. (1861–65) a similar use of stamps was made for revenue purposes. Stamp duties were also levied during the same period on proprietary articles, lucifer matches, and a great variety of other commodities. Internal revenue stamps are used in the U. S. only for such articles as tobacco, snuff, cigars, ales, etc., and since 1894 for playing-cards.

*Postage-stamps* are also of two kinds: (1) those that are impressed on envelopes, newspaper wrappers, and post cards, and (2) adhesive labels. Their use is an evidence of prepayment of postage. Before their introduction it was the custom to take letters to the nearest post-office and prepay the postage or tax in cash, the postmaster then stamping such mail matter as prepaid. The introduction of the postage-stamp did away with this cumbersome method by enabling the corresponding public to purchase in advance the evidence of prepayment, and facilitated not only correspondence, but also the work of the postal authorities by obviating the necessity for a separate handling of each piece of mail matter.

The first introduction of postage-stamps for regular issue took place in Great Britain on May 6, 1840, and was the result of the earnest efforts of Sir Rowland Hill, who had fought for three years in the House of Commons for postal reform. Prior to that time, James Chalmers, of Dundee, Scotland, had invented an adhesive label intended to be used as a postage-stamp, but he was unable to introduce his invention, and the real credit must remain with Sir Rowland Hill, who carried through successfully his scheme for the reduction of postage, and at the same time the introduction of evidences of prepayment. It is true that Sir Rowland Hill did not attach so much importance to the adhesive label as to prepaid envelopes, and his fame rests on the Mulready envelopes (engraved by W. A. Mulready), representing Britannia sending letters to all parts of the world; these were first placed on sale on May 6, 1840. The envelopes were received with ridicule throughout the United Kingdom, and were soon dropped out of use, the adhesive label taking their place.

It was in France that the first attempt was made to prepay letters by means of a cover, envelope, or band at a fixed rate. De Velayer, master of petitions, was the inventor; the idea of cheap postage might also be ascribed to him, although it was only for the Paris local post. A postal system already existed in France and other countries, but no city had a delivery system. De Velayer obtained in 1653 a special privilege from King Louis XIV. to establish a little post-office in Paris, and placed numerous boxes all over the city, which were to be emptied each day. He announced that in order to expedite the service his clerks would not receive any money, but that the letters must be accompanied by a ticket showing prepayment, which ticket must be attached to, wrapped around, or placed within the letter in such a manner that the clerk could easily remove it; when an answer was required the sender had to attach or inclose a second ticket. These tickets cost one sou (about a cent) each, and the principal office for their sale was at the palace. The postal system had some success as a curiosity, but it was in advance of its time, and, besides suffering from the indifference of the public, it was soon attacked by evil-wishers; the boxes were soiled, malicious people going so far as to put rats, mice, and even worse things into them, and the enterprise was soon abandoned.

Some collectors of postage-stamps accept certain letter-sheets stamped in the kingdom of Sardinia in 1818 and 1819. These stamps, however, represent the exact contrary of a postage-stamp, as they indicate the amount of tax paid by the writer for the privilege of sending his letter by other means than the regular postal service; this is a revenue tax, and not in any sense a postal tax.

The example of Great Britain was first imitated in the U. S., where the proprietors of local delivery companies began to sell postage-stamps to their patrons as early as the year 1842. The first one was the City Dispatch Post, owned by Alexander M. Greig, operating in the city of New York; in Aug., 1842, he sold the entire outfit to the U. S. Government, which retained his design for the postage-stamp, a three-quarter face portrait of Washington, changing the inscription to read "United States City Despatch Post." The Government of the U. S. was rather tardy in accepting the new system, and until 1847, when the first stamp for general use was issued, the postal service depended either upon the old cumbersome system or the individual enterprise of the postmasters in various towns, who, on their individual responsibility, had postage-stamps printed and sold to the patrons of their respective offices. This occurred in the following cities: Baltimore, Md. (1845); Brattleboro, Vt. (1846); Millbury, Mass. (1847); New Haven, Conn. (1845); New York, N. Y. (1845); Providence, R. I. (1846); St. Louis, Mo. (1845). It is of interest to note that before the introduction of postage-stamps in the U. S. the post-office authorities in large cities kept regular running accounts with all well-known merchants. Business houses sent their mail matter to the post-office daily, and the cost of postage was calculated by the clerks and charged up to the merchants, bills being rendered at the end of each month.

Among established governments, Brazil was the first to follow the example of Great Britain with an issue of stamps for general postal use. These appeared on July 1, 1843, and were of three values, 30, 60, and 90 reis; each bore simply the numeral of value on an engine-turned groundwork. Postage-stamps were first issued by France on Jan. 1, 1849, in a set of two, bearing an allegorical head of Liberty; and by Belgium in Nov., 1849, in a set of two, with the portrait of King Leopold. Bavaria, which issued stamps in Nov., 1849, was the first of the many states and principalities which now constitute the German empire to adopt the new system; Prussia and Hanover followed in 1850, and Baden, Würtemberg, and Saxony in 1851. The Princes of Thurn and Taxis, who for centuries had enjoyed the monopoly of the postal service in certain of the German states, issued their first stamps in 1852. These continued in use till 1868, or until the formation of the North German Confederation, which included all the states that employed the service of the Princes of Thurn and Taxis, with the addition of Prussia and Saxony. On the formation of the German empire in 1871 all the separate postal administrations, except those of Bavaria and Würtemberg, were superseded by the service of the central Government.

The federal administration in Switzerland did not issue postage-stamps until 1850, but of the separate cantons Geneva and Zurich had issued them in 1843 and Basel in 1845. Most of the other prominent governments in Europe followed in rapid succession, but some were very slow in accepting the reform, as appears from the following list: Spain (1850), Italy (1851), Denmark (1851), Portugal (1853), Norway (1854), Russia (1857), Sweden (1858), Greece (1861), Turkey (1863).

In North America, Canada, New Brunswick, and Nova Scotia made their first issues in 1851, Mexico in 1856, and Newfoundland in 1857. In South America Brazil was followed by British Guiana in 1850, Chili in 1852, and Uruguay in 1856, while Ecuador waited until 1865, Bolivia until 1867, and Paraguay until 1870.

Every colony in Australia adopted the reform early in the fifties, while Mauritius, the Cape of Good Hope, and Natal were the first in Africa, Egypt being next in order in 1866, with a set of seven stamps bearing a representation of a pyramid. India in 1854 was the first government to issue postage-stamps in Asia, using the familiar portrait of Queen Victoria.

The processes employed for the manufacture of postage-stamps are extremely varied in character, every style of engraving and printing having been used in various parts of the world. Among them the most used are engraving on steel, on copper, on zinc, and on wood, surface-printing from steel, copper, and wood, and lithography. All early issues of postage-stamps were imperforate or with plain edges, until in 1848 Henry Archer, in London, invented a machine for perforating. The first experiments were in the nature of trials, and the device was not officially used until 1854, when Mr. Archer sold his device to the British Government.

The number of stamps issued by different countries, as well as the extremes, both high and low, of denomination, vary greatly. The U. S. enjoys the distinction of having had in regular use at one time a larger number than any other country. From 1873 to 1884, besides the regular issue for general use, which consisted of 13 adhesive stamps, 13 envelopes, and 2 wrappers, each department of the Government had its own series, with a total of 92 adhesives, 12 envelopes, and 2 wrappers; besides these there were 7 postage-due and 24 newspaper and periodical stamps. This enumeration does not take into account minor varieties of die or the different colors of paper used for the envelopes. The postage-stamps which have the lowest face value are the $\frac{1}{2}$ milesimo stamp of Cuba and Porto Rico and the $\frac{1}{4}$ centimo of Spain, each representing about $\frac{1}{20}$th of a cent. These are used for local newspaper postage. The stamp of largest denomination is the £20 of South Australia, which is available for both postage and revenue purposes.

*Overprinted Stamps, etc.*—One of the most interesting developments of the use of postage-stamps is the means employed by postmasters in various parts of the world for providing a particular value the stock of which may have become exhausted. The usual method is to surcharge or overprint stamps of some other value with the new value intended to be given to the stamp, and the first instance of such practice appears in France in 1850, when, to supply the demand for a 25-centime stamp, to meet a newly established rate of postage, a quantity of 20-centime stamps, which had been printed by error in blue, were overprinted with the figures "25." These were not, however, placed in circulation, as a new supply of the desired value was prepared in time.

Philadelphia local delivery stamp, Blood & Co., 1841.

Baltimore, Md., 1846.

Brattleboro, Vt., 1846.

New Haven, Conn., 1845.

New York city carrier stamp, 1843.

Providence, R. I., 1846.

Livingston, Ala. Victoria, Tex.
Confederate postmasters' stamps.

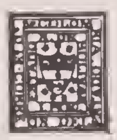
Anjouan (Johanna).
Current type for all French colonial stamps.

Trinidad, 1852.
Type used also in Barbados and Mauritius.

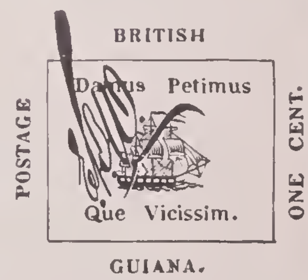
Barbados, 1892.

Afghanistan.
Printed from ivory.

British Guiana, 1850.
The plainest stamp.



Bolivar, Colombia, 1863.
The smallest stamp.



British Guiana, 1856. The rarest stamp; only one known.

Korea, 1884.
Used only one day.

Canada, 1851.

Cape of Good Hope, 1853.
The first triangular stamp.

Congo, 1894.
The handsomest stamp.

North Borneo, 1894.
One of the handsomest stamps.

Spain, 1855. Type used for all Spanish colonies.

Great Britain, 1840. Mulready envelope, greatly reduced. The first stamp issued.

Hankow, 1893. One of the Chinese treaty-port issues.

Hawaii, 1851.
One of the rarest stamps.

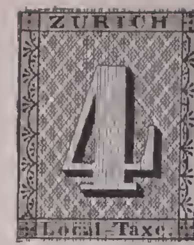
Basel.

Vaud.

Geneva.

Swiss cantonal stamps.



Zurich.

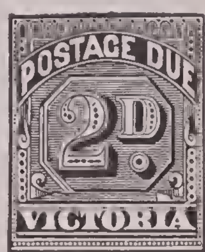
Portuguese India. Type used for all Portuguese colonies.

Bavaria, 1849. The first German stamp.

Guadalajara, 1867. Issued during Mexican revolution.

New Caledonia, 1858. The worst engraved stamp.

Dominica, 1882. Stamp cut in half and surcharged.



Victoria, 1890. Unpaid letter stamp.

Obock, 1894. Camel post.

Portugal. Type introduced in 1871 and afterward used for all colonies.

Labuan, 1880. Stamp surcharged by pen and ink.

Surcharged stamps.

San Marino, 1894. Issued to celebrate the opening of a new palace.

Pacific Steam Navigation Co. Also used by Peru as an experiment.

Portugal. 1893. Jubilee issue in memory of Prince Henry the Navigator.

Salvador, 1892. Issued to commemorate the Columbus celebration.

Mauritius, 1847. One of the greatest rarities.

Brazil, 1843.

New Brunswick, 1851.

New South Wales, 1850. View of Sydney harbor.

REPRESENTATIVE TYPES OF POSTAGE-STAMPS.

As almost all such overprinted or surcharged stamps are made to supply a temporary want, in the nature of things they are rarer than the ordinary issues, and the increase in the number of collectors in recent years has opened this as a profitable field for speculation. Collectors and dealers in various parts of the world have succeeded in inducing postmasters and other officials to surcharge small quantities of stamps, supplying a few to the public for its correspondence and turning over the remainder to the speculator. In many such cases, the postmaster has participated in the profits. Another means of providing a temporary or provisional issue is to cut in half, in quarter, or in other sections stamps of a higher denomination, using the fraction to indicate such portion of the value of the original stamp as the fraction will represent. The most prolific producers of surcharged stamps have been the British and French colonial possessions; but the Colonial Office in London has taken steps to stop further abuse by requiring responsible officials to maintain a sufficient supply of every value, imposing a fine in case this requirement should be neglected.

*Memorial Stamps.*—Another interesting feature of the use of postage-stamps, and a direct result of the wide and varied interest manifested in all parts of the world, is the issue of a special kind of stamps on the occasion of any celebration or jubilee. The first issue of this description was made in Great Britain in 1887, on the fiftieth anniversary of the accession of Queen Victoria to the throne. The example was not followed for some years, but it has become fashionable to make such issues, and among them may be mentioned especially the Columbus issue made by the U. S. in 1893 to celebrate the discovery of America, and similar issues made in the Argentine Republic, Nicaragua, Salvador, Honduras, Venezuela, and Porto Rico in 1892 and 1893. All of these were legitimate issues, made to commemorate an event of real importance, but they have opened the eyes of other governments to the speculative value of such stamps, and 1894 saw a flood of jubilee and commemorative issues. Flagrant examples of such abuse are an issue in the republic of San Marino to commemorate the opening of a new palace, and an issue in Portugal to commemorate the 700th anniversary of the birth of St. Anthony of Padua, both of which are avowedly made solely on account of the profits to be derived from the sale to postage-stamp collectors.

*Stamp-collecting.*—The collecting of postage-stamps for amusement is said to have begun about the year 1850, or as soon as it was noticed that stamps of different colors, designs, and values were being received in mails from various parts of the world. The value and rarity of any particular specimen was not taken into account at all, and one frequently hears of exchanges made among collectors in years gone by of specimens, some of which are now worth hundreds of dollars, for others which still have no appreciable value. As the practice of collecting became more general, the study of postage-stamps became more and more minute, and the collector of early times can hardly realize the extent to which the study of postage-stamps has been carried. Every minute variation of paper, style of printing, perforation, gum, water-mark, etc., is considered as marking a different issue, and in some instances as many as fifty distinct variations of a single stamp are collected where in former years a single specimen would have been considered fully representative of the type.

Full recognition is also accorded to certain classes of adhesive labels which can not, in any sense, be justly termed postage-stamps, but in some instances represent the exact contrary. Prominent among these are the postage-due stamps issued by many countries for the convenience of the postal administration, and which indicate that the postage has not been prepaid, and the newspaper and periodical stamps issued by the U. S., which are never sold to the public but are used only as vouchers in the books of the Post-office Department.

The literature of philately (as the study of postage-stamps is called) embraces every section of the globe, and monthly and weekly journals are published even in India, China, Australia, and Africa. The chief books of reference are *A Catalogue for Advanced Collectors of Postage-stamps*, by the Scott Stamp and Coin Company (New York); *Catalogue de Timbres-Poste*, by J. B. Moens (Brussels); and the publications of the London (England) Philatelic Society. The leading philatelic journals are *The American Journal of Philately*) Scott Stamp and Coin Company, New York); *The London Philatelist* (The London Philatelic Society); *The Monthly Journal* (Stanley Gibbons, London); *Le Timbre-Poste* (J. B. Moens, Brussels); *Der Philatelist* (Dresden); and *Illustriertes Briefmarken-Journal* (Gebrüder Senf, Leipzig). HENRY L. CALMAN.

**Stanberry**: city; Gentry co., Mo.; on the Omaha and St. L. Railway; 50 miles N. by E. of St. Joseph, 110 miles S. E. of Omaha, Neb. (for location, see map of Missouri, ref. 1–D). It is in an agricultural region, and contains a State bank with capital of $20,000, a private bank, and a semi-weekly, a bi-weekly, a monthly, and 3 weekly periodicals. Pop. (1880) 1,207; (1890) 2,035; (1900) 2,654.

**Stanbery**, HENRY: jurist; b. in New York, Feb. 20, 1803; graduated at Washington College, Pennsylvania, in 1819; admitted to the bar in 1824; removed to Ohio and became attorney-general of the State in 1846; appointed Attorney-General of the U. S. in 1866 under the administration of President Johnson, for whom he acted as leading counsel in the impeachment trial of 1868; returned to the practice of his profession at Cincinnati. D. in New York, June 26, 1881.

**Stanbridge**, JOHN: teacher and author; b. at Heyford, Northamptonshire, England, about 1450; became perpetual fellow of New College, Oxford, 1481; first usher of the free school connected with Magdalen College about 1486, and afterward for many years its head master. D. about 1525. He was the first author of school-books that were extensively printed and used in England, though now so rare as to have become bibliographical curiosities. Among them were *The Accydence of Mayster Stanbrydge's owne Makynge* (printed before 1500); *Embryon Relimatum, sive Vocabularium* (of which at least eight editions were printed by Wynken de Worde); and *Vocabula Magistri Stanbrigi* (1510).

**Stanchio**: See Cos.

**Standards**: See BANNER and FLAG.

**Standards of Value**: See MONETARY STANDARDS.

**Standard Time**: See TIME.

**Standish**, MILES: soldier; b. in Lancashire, England, about 1584; claimed to be descended from the knightly family of Standish of Duxbury Hall, Lancashire; served on the Continent, probably with the English forces; became a captain; settled in Leyden, and, though not a member of the English Church or congregation, accompanied the Pilgrims of the Mayflower to New England 1620; lost his wife, Rose, during the first winter; is said by tradition to have employed his friend John Alden to negotiate his marriage with the fair Priscilla Mullins (see Longfellow's *Courtship of Miles Standish*), with the well-known result that Alden married the maiden; rendered important services to the colonists in preserving them from the open and secret hostilities of the Indians, having with his own hand killed at Weymouth (1623) Pecksuot, an Indian chief who had planned a massacre; visited England as agent for the colony 1625, returning with supplies 1626; broke up the settlement at Merry Mount (see MORTON, THOMAS) 1628; was one of the original proprietors and settlers of Duxbury, having given that name to the town in memory of the seat of his English ancestors; was for the remainder of his life either magistrate or a member of the board of assistants to the governor, and took part in the settlement of Bridgewater 1649. D. at Duxbury, Oct. 3 O. S., 13 N. S., 1656. He was of small stature and choleric temper, and possessed great energy and force of will. One of his swords and other relics are preserved in the Pilgrim Hall, Plymouth. A monument to his memory stands on the commanding eminence in South Duxbury, formerly called Captain's Hill, from having been the place of his residence. Many incidents of his career are given, with a partial genealogy of his descendants, in Justin Winsor's *History of Duxbury* (1849). Also see De Costa, *Footprints of Miles Standish* (Charlestown, Mass., 1864).

**Stand-pipe**: a vertical cylindrical tower connected with a water-supply system to provide pressure and sometimes to serve partly as a storage-tank. Stand-pipes are made of wrought-iron or steel plates riveted together, and usually vary in diameter from 3 to 20 feet, although a few have been built 50 feet in diameter. The height depends upon the pressure required, and is usually from 60 to 150 feet, although some are nearly 250 feet high. Sometimes the upper part of the tower constitutes a tank supported by a trestle, the water being carried to it by a pipe of much smaller diameter. A stand-pipe is used only in connection with a pumping system, and is most effective when placed near the pump.

The water is forced up against the head in the stand-pipe, and this in turn maintains the pressure throughout the pipe system. Stand-pipes are sometimes destroyed by wind or by accidents due to other causes. For an account of these, see a series of articles by Pence in *Engineering News* during 1884. MANSFIELD MERRIMAN.

**Stanfield**, WILLIAM CLARKSON: landscape and marine painter; b. at Sunderland, Durham, England, in 1793; d. at Hampstead, May 18, 1867. He was a sailor in the British navy, became a scene-painter while still a young man, and taking up painting of landscape and naval battle scenes attained success and was elected a Royal Academician in 1835. Among his most celebrated works are *Battle of Trafalgar* (1836) and *Battle of Roveredo* (1851). W. A. C.

**Stanford**: town; capital of Lincoln co., Ky.; on the Lexington and East. Railway; 38 miles S. by W. of Lexington, 104 miles S. E. of Louisville (for location, see map of Kentucky, ref. 4–H). It is in an agricultural region, and contains woolen, flour, and grist mills, the Stanford Female College, a national bank with capital of $200,000, a banking and trust company with capital of $200,000, and a semi-weekly newspaper. Pop. (1890) 1,385; (1900) 1,651.

**Stanford**, CHARLES VILLIERS: composer; b. in Dublin, Ireland, Sept. 30, 1852; went to Leipzig to study in 1874, and then to Berlin, returning home in 1876. His compositions include several symphonies, much sacred music in large forms, the two oratorios *The Three Holy Children*, for the Birmingham festival of 1885, and *Eden*, for the Birmingham festival of 1891; three operas—*The Veiled Prophet*, produced at Hanover, Feb. 6, 1881, *Savonarola*, Hamburg, Apr. 18, 1884, and *The Canterbury Pilgrims*, for the Carl Rosa Company, Apr. 28, 1884; the cantata *Elegiac Ode*, 1884, being a setting of Walt Whitman's *Burial Hymn*; music to the Greek plays *Eumenides* and *Œdipus Tyrannus*; and Psalm cl. in cantata form (1887). He received the degree of Mus. Doc. from Cambridge in 1883, succeeded Otto Goldschmidt as conductor of the Bach Choir in 1885, and was appointed Professor of Music in Cambridge University Dec., 1887, on the death of Sir George Macfarren. D. E. HERVEY.

**Stanford**, LELAND: capitalist and philanthropist; b. at Watervliet, N. Y., Mar. 9, 1824; received a common-school education; studied law, and was admitted to the bar in 1849; soon afterward removed to Port Washington, Wis., where he practiced law till 1852, when he went to California and engaged in gold-mining; settled in San Francisco in 1856, and entered into business with three of his brothers. He first appeared in politics as a delegate to the convention at Chicago in 1860 which nominated Abraham Lincoln for the presidency; was elected Governor of California in 1861, and in his inaugural address urged the importance of building the Pacific Railroad, and a company for that purpose, of which he was elected president, was formed on July 1 of that year. He superintended the construction of that part of the road that crossed the mountains, spending personally more than $20,000,000 on a stretch of roadway of 100 miles. He became interested in the construction of other railways and in the development of the agriculture and manufactures of California. He was elected to the U. S. Senate as a Republican for the term 1885–91. With his wife he founded LELAND STANFORD JUNIOR UNIVERSITY (*q. v.*). D. at Palo Alto, Cal., June 20, 1893.

**Stanhope**, CHARLES MAHON, F. R. S., Third Earl Stanhope and Viscount Mahon: inventor; b. in London, England, Aug. 3, 1753; entered Parliament 1780; succeeded to the peerage 1786; was noted for his radical opinions; declared himself a republican, and laid aside the insignia of nobility; distinguished himself by his scientific researches; made many improvements in the art of printing, and in 1816 invented the Stanhope printing-press. D. in London, Dec. 15, 1816.

**Stanhope**, EDWARD: statesman; second son of the fifth Earl of Stanhope; b. in London, Sept. 24, 1840; educated at Harrow and Oxford; called to the bar 1865; entered Parliament 1874; Under-Secretary of State for India 1878–80; vice-president of the committee of council on education 1885; president of the Board of Trade 1885–86; Secretary of State for the Colonies 1886; Secretary of State for War 1887–92. D. at Sevenoaks, Dec. 22, 1893.

**Stanhope**, Lady HESTER LUCY: daughter of Charles, third Earl Stanhope; b. at Chevening, Kent, England, Mar. 12, 1776; was for ten years a member of the family of her uncle, William Pitt, to whom she acted as confidential secretary until his death in 1806; received thereafter a pension of £1,200, upon which she resided some years in Wales; proceeded in 1810 to Syria; visited Jerusalem, Damascus, Baalbec, and Palmyra; acquired by her magnificent and singular ways of living the respect and veneration of the Arabs, who treated her almost as a queen; established herself in 1814 in the deserted convent of Mar Elias, 8 miles from Sidon, upon a crag of Lebanon; adopted the dress and style of an emir, having at her command a guard of Albanians, over whom she exercised an absolute authority; became a benefactress to political refugees and to the poor of every kind; exerted considerable political influence; and practiced astrology. D. at Mar Elias, June 23, 1839. Her *Memoirs* (3 vols., 1845) and *Seven Years' Travels* (3 vols., 1846) were published by her physician, Dr. Meryon.

**Stanhope**, JAMES, First Earl Stanhope: soldier; b. in Paris, France, in 1673; resided in Spain, where his father was minister during 1690–94; entered the army 1694; was wounded at the siege of Namur 1695; served in Flanders until the Peace of Ryswick; was elected to Parliament 1702; took part in the expeditions of 1702 and 1704 in Spain; was a brigadier-general at the siege of Barcelona 1705; major-general 1707; commander-in-chief in Spain, and took Port Mahon, Minorca, 1708; defeated the Spaniards at Almenara and Saragossa (Aug., 1710), but was forced to surrender to the Duke of Vendôme at Brihuega, Dec. 8, 1710; was appointed Secretary of State on the accession of George I., 1714; became First Lord of the Treasury and Chancellor of the Exchequer 1717; was created Viscount Stanhope of Mahon July 2, 1717, and Earl Stanhope Apr., 1718; was again Secretary of State, and took part in negotiating the Quadruple Alliance 1718. D. in London, Feb. 5, 1721.

**Stanhope**, PHILIP DORMER: See CHESTERFIELD.

**Stanhope**, PHILIP HENRY, Fifth Earl Stanhope, better known as Lord Mahon: statesman and author; b. at Walmer, Kent, England, Jan. 31, 1805; was a grandson of Charles, the third earl; graduated from Christ Church, Oxford, 1827; was elected to Parliament in 1830; was Under-Secretary of State for Foreign Affairs (the Duke of Wellington being the secretary) in the first Peel ministry 1834; was secretary to the board of control in the last year of the second Peel ministry 1845–46; supported the repeal of the corn-laws; introduced and carried the copyright act of 1842; was chosen president of the Society of Antiquaries 1846; was defeated at the parliamentary elections of 1852 in consequence of having voted with the protectionists against the modification of the navigation laws; succeeded to the earldom Mar. 2, 1855; founded the Stanhope prize for the study of modern history at Oxford 1855; was chosen lord rector of the University of Aberdeen 1858, and one of the six foreign members of the Academy of Moral and Political Sciences at Paris May 11, 1872. D. at Bournemouth, Hampshire, Dec. 24, 1875. Author of *History of the War of Succession in Spain* (1832); *History of England from the Peace of Utrecht to the Peace of Versailles, 1713–83* (7 vols. 8vo, 1836–53); *Essai sur la Vie du Grand Condé* (privately printed, 1842, and afterward appeared in English as *The Life of Louis, Prince of Condé*, 1845); *The Life of the Right Hon. William Pitt, with Extracts from his Unpublished Correspondence and MS. Papers* (4 vols., 1861–62; 4th ed. 1867); and a *History of England, comprising the Reign of Anne, until the Peace of Utrecht* (1870). Several fragments of his great work have been separately published, as *The Forty-Five, being a Narrative of the Rebellion in Scotland in 1745* (1851) and *The Rise of Our Indian Empire* (1858). Lord Stanhope edited, with notes, *The Letters of Philip Dormer Stanhope, Earl of Chesterfield* (4 vols., 1845); *The Memoirs of Sir Robert Peel* (2 vols., 1856–57).

**Stan'islas Augustus**, King of Poland: See PONIATOWSKI.

**Stanislas Leszczynski**, -lesh-tseēn'skēē: King of Poland; b. at Lemberg, Galicia, Oct. 20, 1677, of one of the oldest and wealthiest families of the Polish nobility; held a high position at the Polish court, and was palatine of Posen when the war broke out between Charles XII. of Sweden and Augustus II. of Poland and Saxony. By the diplomatic negotiations which he carried on between Augustus and Charles he won the favor, and even the friendship, of the latter, and when, after the complete defeat of Augustus, Charles declared the Polish throne vacant, Stanislas was by his influence elected King of Poland in 1705. He was a noble character, and not without talent as a ruler, but after the disaster of Charles at Poltava in 1709 he was compelled to flee from Poland, where even his private fortune was confiscated. He joined his friends at Bender, and was in 1714 made governor of the duchy of Zweibrücken, but after the death of Charles in 1718 he fled to France, and settled at Weissenburg in Alsace. In 1725 his daughter, Marie Leszczynski, was married to Louis XV., and at the death of Augustus II. (in 1733) he was re-elected King of Poland by French influence. Russia, however, was opposed to his restoration, and by the intervention of a powerful Russian army Augustus III. was raised to the Polish throne. After a desperate resistance at Dantzic, where he was besieged by the Russians, he fled for the second time from his native country, but by the Peace of Vienna (1735) his family estates were restored to him, he received the duchy of Lorraine as a pension, and retained the title of King of Poland. He subsequently resided at Lunéville or Nancy, where he held a brilliant court, gathered scientific men around him, founded splendid educational institutions, erected magnificent public buildings, and was generally called *Le Bienfaisant*. D. Feb. 23, 1766. Among his *Œuvres du Philosophe bienfaisant* (4 vols., 1767) is a little essay, *Voix d'un Citoyen*, in which he predicts the division of Poland.

**Stanislow'**: town and railway junction in the province of Galicia, Austria; pleasantly situated between two branches of the Bistricza, in the center of a very fertile and well-cultivated plain; 75 miles S. E. of Lemberg (see map of Austria-Hungary, ref. 4–L). It has several good educational institutions and some manufactures and trade. Pop. (1890) 22,391.

**Stanley**, Arthur Penrhyn, D. D., LL. D.: clergyman and author; son of Bishop Edward and nephew of the first Lord Stanley of Alderley; b. at Alderley, Cheshire, England, Dec. 13, 1815; was a favorite student of Dr. Thomas Arnold at Rugby 1829–34; gained a scholarship at Baliol College, Oxford, 1834; took the Newdigate prize for his English poem, *The Gypsies*, the Ireland scholarship, and a first class in classics (1837); a fellowship at University College 1838; and was tutor for twelve years, and examiner 1841; obtained the chancellor's Latin essay 1839 and the chancellor's English essay and the Ellerton theological essay 1840; took orders in the Church of England 1840, affiliating himself with the Broad Church party; was selected preacher to the University of Oxford 1846–47, secretary to the Oxford University commission 1850–52; canon of Canterbury 1851–58, Regius Professor of Ecclesiastical History at Oxford 1856–64, and canon of Christ Church 1858–64; became chaplain to Prince Albert 1854, to Dr. Tait, Bishop of London, 1857, and to Queen Victoria and the Prince of Wales 1862; declined the archbishopric of Dublin 1863, was installed dean of Westminster Jan. 9, 1864, and was elected lord rector of the University of St. Andrews Nov., 1874. He made a tour in the East, visiting Egypt and Palestine, 1852–53, and again as chaplain and traveling companion to the Prince of Wales 1862; was prominent as a defender of broadmindedness in the Church of England in the controversies connected with the celebrated *Essays and Reviews* (1861), Bishop Colenso's work on the *Pentateuch* (1862), and the later series of ecclesiastical prosecutions; was an active promoter of charitable, missionary, and educational enterprises and of biblical, antiquarian, and scientific researches, cultivated friendly relations with Dissenters to an extraordinary degree, and was much more popular with them than in his own church; and was for some years regarded as the leading representative of the progressive school of British theology. Dec. 23, 1862, he married Lady Augusta Bruce (1822–76), daughter of the Earl of Elgin, and the most intimate friend of the Queen. Her death broke his heart. He was a sensitive, highly gifted, poetic, spiritual, pure, and very picturesque personality. He was the author of many publications, which have passed through numerous editions and been reprinted in America. The chief of these are *The Life and Correspondence of Thomas Arnold* (1844); *Sermons and Essays on the Apostolic Age* (1847); *The Epistles of St. Paul to the Corinthians, with Critical Notes and Dissertations* (2 vols., 1855; 4th ed. 1876); *Historical Memorials of Canterbury Cathedral* (1855); *Sinai and Palestine, in connection with their History* (1856; 20th ed. 1874); *Lectures on the History of the Eastern Church* (1861; New York, 1862; new ed. 1870); *Lectures on the History of the Jewish Church* (vol. i., 1862; vol. ii., 1865, vol. iii., 1876); *Historical Memorials of Westminster Abbey* (1867: 4th ed. 1874); *Lectures on the History of the Church of Scotland* (1872); and *Christian Institutions* (1878). He was a voluminous contributor to reviews and periodicals; furnished a valuable series of biblical biographies to Dr. William Smith's *Dictionary of the Bible*; and published many notable sermons. See the bibliography in Prothero's *Stanley* (vol. ii., 575–582). He was a member of the Bible revision committee. In 1878 he visited the U. S., and in 1879 published a volume of addresses and sermons delivered there. D. in the deanery, Westminster, July 18, 1881, and was buried in Henry VII.'s chapel, Westminster Abbey. See his *Life* by R. E. Prothero (London and New York, 1894, 2 vols.).

Revised by S. M. Jackson.

**Stanley**, David Sloane: soldier; b. at Chester, Wayne co., O., June 1, 1828; graduated at the U. S. Military Academy July 1, 1852, and was appointed brevet second lieutenant in the Second Dragoons. As a cavalry officer he served almost constantly on frontier duty, and in 1859 was complimented by Gen. Scott in general orders for a successful fight with the Comanches. On the outbreak of the civil war in 1861, having attained the rank of captain in the First Cavalry, he was sent to the field of active operations in Missouri, and on Sept. 28 was commissioned a brigadier-general of volunteers. He commanded the second division of the army of the Mississippi at the capture of Island No. 10; in the Corinth campaign, including the battle of Farmington and pursuit of the enemy upon the evacuation of Corinth; at the battles of Iuka (Sept. 19) and Corinth (Oct. 3–4). In Nov., 1862, he was appointed chief of cavalry of the army of the Cumberland, and the same month promoted to be major-general of volunteers, and was engaged in the battle of Murfreesboro, the Tullahoma campaign, including the action of Shelbyville and frequent minor engagements until Sept., 1863, when compelled by sickness to take a short leave. Returning to duty in November, he was assigned to the first division of the Fourth Army-corps, and held command of the corps from July, 1864, until the close of the war. In Sherman's invasion of Georgia he bore a conspicuous part in the severe and almost constant fighting from Dalton to Atlanta, being wounded at the battle of Jonesboro, Sept. 1. During the month of October his command was engaged in pursuit of Hood's army until the 27th, when it was detached from the army of Gen. Sherman to strengthen Gen. Thomas at Nashville, to whom was intrusted the duty of opposing an invasion of Tennessee. With numerous skirmishes the Fourth and Twenty-third Corps had arrived at Franklin, Tenn., Nov. 30, where, being closely followed by the enemy, a stand was made and a notable victory gained. During the fight Gen. Stanley was severely wounded. He was breveted lieutenant-colonel, colonel, brigadier-general, and major-general for gallantry in battle. On Feb. 1, 1866, he was mustered out of the volunteer service, and resumed his commission in the regular army, having become major of the Fifth Calvary in 1863. He was appointed colonel Twenty-second Infantry July, 1866; in command of Yellowstone expedition 1872–73; of various military posts 1873–84; promoted to be brigadier-general U. S. army Mar. 24, 1884; commanded the district of New Mexico and the department of Texas until he was retired June 1, 1892. Revised by James Mercur.

**Stanley**, Edward John, second Baron Stanley of Alderley: statesman; b. at Alderley Park, Crewe, England, Nov. 13, 1802; studied at Eton; took the degree of B. A. at Oxford, 1823; entered Parliament as a Liberal 1831; was Under-Secretary of State for the Colonies 1833–34; patronage Secretary of the Treasury 1835–41; paymaster-general of the forces several months in 1841; Under-Secretary of State for Foreign Affairs in the Russell administration 1846–51; was raised to the House of Peers as Baron Eddisbury 1848; succeeded to his father's title 1850; held the conjoint offices of paymaster of the forces and vice-president of the Board of Trade a few weeks in 1852, and again 1853–55; was president of the Board of Trade 1855–58, and Postmaster-General 1860–66. D. in London, June 16, 1869.

**Stanley**, Frederick Arthur, G. C. B., Baron Stanley of Preston: b. Jan. 15, 1841; educated at Eton. He is the second son of the fourteenth Earl of Derby; was formerly a captain in the Grenadier Guards. He was civil lord of the Admiralty Aug. to Nov., 1868; financial secretary to the War Office 1874–77; Secretary to the Treasury 1877–78; Secretary of State for War 1878–80; Secretary of State for the Colonies 1885–86; and president of the Board of Trade 1886–88. He was Governor-General of Canada May 6, 1888, to July 15, 1893. He married (May 31, 1864) Lady Constance Villiers, eldest daughter of the fourth Earl of Clarendon;

was created Baron Stanley of Preston in the peerage of Great Britain in 1886, and on the death of his brother in 1893 became sixteenth Earl of Derby. NEIL MACDONALD.

**Stanley**, HENRY MORTON, D. C. L.: African explorer; b. near Denbigh, Wales, in 1841, of humble parentage. He was placed in the poorhouse, where he remained until his thirteenth year, after which he taught in a school, and subsequently shipped as cabin-boy for New Orleans, where he was adopted by a merchant, whose name he assumed instead of his own, which was John Rowlands. His adoptive father having died without a will, and the civil war breaking out, he enlisted in the Confederate army; was taken prisoner; volunteered in the U. S. navy, and became acting ensign on an ironclad. After the close of the war he went as a newspaper correspondent to Turkey and Asia Minor, and in 1868 accompanied the British expedition to Abyssinia as correspondent of *The New York Herald*, a portion of his correspondence being subsequently embodied in a volume. In Oct., 1869, being then in Spain, he was employed by the *Herald* to head an expedition to learn the fate of Livingstone, the African explorer, from whom only vague intimations had been heard for two years. He reached Zanzibar in Jan., 1871, and toward the end of March set out for the interior, with a company of 192 men. In November he found Livingstone, who was living near Lake Tanganyika, and furnished him with supplies for further explorations. After having explored the northern portion of the lake, Stanley set out on his return journey in Mar., 1872, reaching England in July, where he was received with distinguished honor, the Queen sending him a gold snuff-box set with diamonds, and the Royal Geographical Society awarding to him in 1873 its patron's medal. Tidings having been received of the death of Livingstone in Central Africa, Stanley was placed at the head of an expedition, the cost of which was jointly undertaken by *The New York Herald* and the London *Daily Telegraph*, to explore the lake region of equatorial Africa. He left the coast in Nov., 1874, at the head of 300 men, and after many hardships and some severe contests with the natives reached Lake Victoria Nyanza Feb. 27, 1875, having in the meantime lost 194 men by death and desertion. He circumnavigated the lake in a boat brought with him in pieces, and found it to be a single large lake, and not, as supposed by Burton and Livingstone, a group of lagoons, thus confirming the opinions of Speke and Grant. He started Apr. 17, 1875, to continue his explorations in the direction of Lake Albert Edward Nyanza. He arrived at the mouth of the Congo river Aug. 12, 1877, having explored its whole course; returned to the Congo in 1879, at the head of a Belgian international expedition; lectured in the U. S., on Africa, in Dec., 1886; returned to Congo Free State in 1887 with an expedition for the relief of Emin Bey, whom he found on the Albert Nyanza Apr. 28, 1888. He returned with Emin toward the east coast in May, 1889, and reached the coast himself on Dec. 6 of the same year. On the return trip he discovered the Ruwenzori Mountains S. of Albert Nyanza. On his return to England in 1890 he received honorary degrees from the universities, and a special medal from the Royal Geographical Society. In the following year he visited the U. S. and Australia on lecturing tours, returning to London in 1892. In 1895 he was elected to Parliament as a Unionist from Lambeth (N.). His principal works are *How I found Livingstone* (London and New York, 1872); *Coomassie and Magdala* (1874); *Through the Dark Continent* (1878); *The Congo, and the Founding of its Free State* (2 vols., 1885); *In Darkest Africa* (1890); *My Dark Companions* (1893); and *Slavery and the Slave-trade in Africa* (1893).
Revised by M. W. HARRINGTON.

**Stanley**, THOMAS: classical scholar; b. at Comberlow, Hertfordshire, England, in 1625; was carefully educated at home; graduated at Cambridge 1641: studied law at the Middle Temple; published in 1647 a volume of *Poems and Translations* (from Anacreon, Bion, Moschus, etc.), frequently reprinted; issued his chief work, *The History of Philosophy, containing the Lives, Opinions, Actions, and Discourses of the Philosophers of every Sect*, in 4 vols., at intervals between 1655 and 1662 (2d ed. folio. 1687; best ed., with *Life* of the author, 4to. 1743), and in 1663–64 his elaborate edition of *The Tragedies of Æschylus*, with Latin translation, Greek scholia, and commentary, which long maintained its ground among English scholars (best ed. by Butler, 1809–16). D. in London, Apr. 12, 1678. See Brydges's edition of Stanley's *Poems* with *Life* (1814–15).

**Stannard**, HENRIETTA ELIZA VAUGHAN (*Palmer*): novelist; b. at York, England, Jan. 13, 1856; daughter of Rev. Henry Vaughan Palmer, rector of St. Margaret's, York; married, 1884, Arthur Stannard, a civil engineer. Her father had been an artillery officer before taking holy orders, and Mrs. Stannard's numerous fictions have dealt mainly with army life. Among these, published under the pseudonyms of John Strange Winter and Violet Whyte, are *Cavalry Life* (1881); *Regimental Legends* (1883); the very popular *Bootle's Baby* (1885); *Houp-la* (1885); *Army Society Life in a Garrison Town* (1886); *Garrison Gossip* (1887); and *A Siege Baby* (1887). H. A. BEERS.

**Stan'naries** [from Lat. *stan'num*, tin]: in general, tin mines; in a special sense, those of Cornwall and Devon, concerning which there are peculiar laws and usages. The court of the stannaries is very ancient, exercising a jurisdiction in the time of Lord Coke which was "guided by special laws, by customs, and by prescription time out of mind." It was established in order that the workers in these mines might sue and be sued in their own court, "and not be drawn from their business to their own private loss and to the public detriment by attending their lawsuits in other courts." The early charters, records, and acts of Parliament relating to this subject are summarized in Coke's *Fourth Institute*, chap. xlv. The principal modern statutes bearing upon the stannaries are 6 and 7 Will. IV., c. 106, as amended by subsequent acts, which regulates the constitution and the procedure in these courts, and 32 and 33 Vict., c. 19, amended by 50 and 51 Vict., c. 23, relating to mining partnerships within their jurisdiction. The judges of the stannaries court are appointed by the Duke of Cornwall (the Prince of Wales), or, when there is none of full age, by the crown. See Bainbridge on *Mines*, ch. vi., §§ 3–5, and Batten's *Stannaries Act*.
FRANCIS M. BURDICK.

**Stannic Acid**: a hydrate, $SnO(OH)_2$, obtained from stannous oxide. See TIN (*Compounds of Tin*).

**Stanovoi' Range** [Russ. *Stanovoi Khrebet*, i. e. backbone]: name given by Pallas to the mountains at the source of the Olekma, but since expanded to embrace the whole Siberian watershed between the Arctic and Pacific drainage systems. It is very imperfectly known, but appears to extend N. E. from near Urga, in North Central Mongolia, to the Chukchu Peninsula, a distance of 2,700 miles. It consists of parallel ranges of mountains with elevated plateaus, which are often very marshy, is more rugged on its eastern than on the western slopes, and is through much of its extent clothed with forests and rich in minerals. A principal range on the western side is the Yablonnoi Khrebet, which borders the plateau of Vitim. The highest point is Mt. Sokhondo (lat. about 50° N., lon. 110° E.), about 9,250 feet.
MARK W. HARRINGTON.

**Stanstead**: the *chef-lieu* of Stanstead County, Quebec, Canada, and the terminus of a branch of the Boston and Maine Railway line, which runs through the Masawippi valley (see map of Quebec, ref. 6–C). It is close to the boundary-line of the U. S., which separates it from North Derby or Derby Line, Vt. It includes Stanstead Plain and Rock Island: in the former there is a Wesleyan College and several churches; in the latter are several factories. It is on the edge of a rich farming and grazing country. Pop. 4,200. J. M. H.

**Stanton**: city; capital of Montcalm co., Mich.; on the Detroit, Lans., and N. Railroad; 15 miles N. E. of Greenville, 62 miles N. N. W. of Lansing (for location, see map of Michigan, ref. 6–I). It is in an agricultural region, and contains a public high school, flour-mills, planing-mills, foundry, machine-shops, a private bank, and two weekly newspapers. Pop. (1890) 1,352; (1900) 1,234.

**Stanton**, EDWIN MCMASTERS: lawyer and Secretary of War; b. at Steubenville, O., Dec. 19, 1814; admitted to the bar in 1836; reporter of the Supreme Court of Ohio 1842–45, reporting vols. xi.–xiii. of *Ohio Reports*. In 1845 he successfully and with distinction defended in the criminal court at Washington Caleb J. McNulty, clerk of the House of Representatives, tried for embezzlement. He first acquired national reputation as a lawyer in the important case of *The State of Pennsylvania* vs. *The Wheeling Bridge Company*, involving the question whether control of bridges over navigable rivers of the West flowing between the several States is vested by the Constitution in Congress or the State Legislatures. It was decided that Pennsylvania's interest in the controversy gave her standing in that court, and that regulation of bridges over navigable rivers of the

West is vested in Congress, exclusive of State control. Successive arguments in the case by Stanton were so marked by legal learning, logic, and eloquence that at once and at a comparatively early age he took place in the front rank of national lawyers. In 1856 he removed to Washington to attend to his practice before the U. S. Supreme Court, and in 1858 went to California and remained nearly a year as counsel for the U. S. in certain land-cases involving many millions of dollars. Besides carrying to a successful issue those cases to which his employment especially related, his services were invaluable in the collection, collation, and translation of Mexican archives. The archives collected through his efforts furnished conclusive evidence of an organized system of fabricating land-titles carried on for a long time in California. The value of lands claimed under forged grants was estimated at not less than $150,000,000. Afterward, however, these archives furnished the means of distinguishing valid from forged grants, and enabled a successful defense to be made to every fraudulent claim.

In Dec., 1860, when active preparations were being made for secession and the indications as to the political future of the republic were appalling, Cass, Secretary of State, suddenly resigned, and Black, Attorney-General, succeeded him. Stanton, then in Cincinnati arguing a case before the U. S. circuit court, was appointed Attorney-General. Acceptance of the office involved relinquishment of profitable professional business and assumption of great responsibility, with little prospect of personal distinction. He accepted the office, and in it his attitude was that of resolute maintenance of national honor and determined opposition to treason. Only a handful of U. S. troops was assembled at Washington, and the residents of the capital were mainly in sympathy with secession. To a greater extent probably than any of his associates in the cabinet, Stanton perceived the danger of an attempt to prevent Lincoln's inauguration, to seize and hold the capital and insignia of government for the seceding States, and thus to exhibit the latter to the world as a government *de facto*, succeeding to the power and authority of the U. S. On Mar. 4, 1861, Stanton retired with the outgoing administration and resumed his profession. After the civil war had existed several months, patriotic citizens and eminent capitalists, without Stanton's knowledge, urged President Lincoln to place him in charge of the War Department. On Jan. 20, 1862, he became Secretary of War. Excepting a brief meeting in 1857 in Cincinnati, in a lawsuit in which they were both of counsel, there had previously been no intercourse between Lincoln and Stanton; but after the latter entered the War Department their mutual friendship and confidence grew with every day. The characteristics of Stanton's administration were integrity, energy, determination, singleness of purpose, and capacity to comprehend the magnitude of the insurrection and the labor and cost in blood and treasure involved in suppressing it.

After Lincoln's assassination and Johnson's accession to the presidency, Stanton was connected with the latter's administration for three years. He supported many measures which were vetoed by the President and re-enacted by Congress, including those for the establishment of the Freedmen's Bureau, for protection of civil rights, for admission of Colorado as a State, for organization of governments in insurrectionary States, and for conferring suffrage without regard to color in the District of Columbia. These differences of opinion and the continued adherence of Stanton to the Republican party and the President's separation from and aggressive hostility toward it, led the President on Aug. 5, 1867, to notify Stanton that public considerations of a high character constrained him to request the latter's resignation; to which Stanton answered that public considerations of a high character, which alone had induced him to remain at the head of the department, constrained him not to resign before the next meeting of Congress. On Aug. 12 the President notified him of his suspension from office. After Congress convened, the Senate refused by a vote of 35 to 6 its concurrence in the suspension. Having received official information of this from the Senate, Stanton on the next day (Jan. 13, 1868) resumed his office. On Feb. 21, 1868, the President undertook to remove him and to appoint Lorenzo Thomas Secretary of War *ad interim*. The Senate, being on the same day officially informed by the President of this action, resolved that under the Constitution and laws the President had no power to remove the Secretary of War and designate another officer to perform the duties of that office, and officially communicated this resolution to Stanton. The House of Representatives immediately decided to impeach the President. In consequence of this action of both houses of Congress and the general apprehension of revolutionary purposes on the part of the President, Stanton refused to relinquish control of his department. After the trial and acquittal of the President under articles of impeachment, Stanton relinquished his office. The Senate on May 28 again resolved that he had not been legally removed, and based its confirmation of his successor, Gen. Schofield, upon Stanton's voluntary retirement. Soon afterward both houses of Congress passed a vote of thanks to him for his great ability, purity, and fidelity.

With his health shattered by his labors in the War Department, he resumed his profession and argued several important cases. The last was *Whitney* vs. *Mowry*, an important patent cause, which, in consequence of Stanton's feeble health, was heard by Judge Swayne in Stanton's own library two weeks before the latter's death. He never again left his chamber. On Dec. 20, 1869, he was nominated by President Grant as an associate justice of the U. S. Supreme Court, and was immediately confirmed by the Senate; but on Dec. 24 he died without having entered upon the duties of his new office. Revised by C. K. ADAMS.

**Stanton**, ELIZABETH (*Cady*): reformer; b. at Johnstown, N. Y., Nov. 12, 1815; daughter of Judge Daniel Cady; educated at the Johnstown Academy, where she studied with a class of boys; was fitted for college at the age of fifteen, and pursued her studies at Mrs. Willard's Seminary at Troy; had her attention turned to the disabilities of sex by her own educational experience and a study of Blackstone, Story, and Kent; married, in 1840, Henry B. Stanton (reformer, author, and State Senator; d. 1887); accompanied him to the World's Anti-Slavery convention at London; there made the acquaintance of Lucretia Mott; resided in Boston until 1847, when they settled at Seneca Falls, N. Y.; with Lucretia Mott signed the call for the first woman's rights convention, which met at her place of residence July 19–20, 1848, on which occasion the first formal claim of suffrage for women was made; circulated petitions for the married woman's property bill, and had a hearing before a legislative committee 1844; addressed the New York Legislature in 1854 on the right of suffrage, in 1860 in advocacy of divorce for drunkenness, and in 1867 both the Legislature and the constitutional convention, maintaining that during the revision of the constitution the State was resolved into its original elements, and that all the citizens had therefore a right to vote for members of that convention. Since 1869 she has frequently addressed congressional committees and State constitutional conventions. She canvassed Kansas in 1867, and Michigan in 1874, when the question of woman suffrage was submitted in those States; was one of the editors of *The Revolution*. Most of the calls and resolutions for conventions, addresses to women, legislatures, and Congress, have been from her pen. She was president of the national woman's rights committee 1855–65, of the Woman's Loyal League 1863, and of the National Association until she withdrew in 1892; spoke many times in great conventions in England and Scotland, and at parlor meetings in London; contributed articles to *The Westminster Review* and to journals and magazines in the U. S. She was president of the first International Council of Women held in Washington in 1888. With Miss Susan B. Anthony and Mrs. Matilda J. Gage she is the author of *The History of Woman Suffrage* (New York, 1881–86). SUSAN B. ANTHONY.

**Stanton**, OSCAR F.: See the Appendix.

**Stanton**, THEODORE, M. A.: journalist; son of Mrs. Elizabeth Cady Stanton; b. at Seneca Falls, N. Y., Feb. 10, 1851; educated at the College of the City of New York and at Cornell University; was Berlin correspondent of *The New York Tribune* 1880; settled in Paris to engage in journalism; member International Jury, Paris Exposition, 1889; resident commissioner in France, Columbian Exposition, 1893; Chevalier of the Legion of Honor; translator and editor of Le Goff's *Life of Thiers* (New York, 1879); author of *The Woman Question in Europe* (1884) and of contributions to periodicals.

**Stanwix**, JOHN: soldier; b. in England about 1690; entered the British army 1706; served as an officer of grenadiers and marines; became lieutenant-colonel 1745; equerry to Frederick, Prince of Wales, 1749; was governor of Carlisle and its representative in Parliament 1750; became deputy quartermaster-general of the forces 1754; was made colonel commanding the first battalion of the Sixtieth Regiment (Royal Americans) Jan. 1, 1756; was in command of the southern district of the American colonies, with headquarters at Carlisle, Pa., 1757; was appointed brigadier-general Dec. 27, 1757; was relieved by Gen. Forbes early in 1758, and intrusted (1758) with the erection of the important fortress known as Fort Stanwix at the "Oneida carrying-place" (now Rome) on Mohawk river, at an expense of £60,000, as a defense against incursions from the French in Canada; returned to Pennsylvania; was appointed major-general June 19, 1759; repaired and fortified the old fort Du Quesne at Pittsburg, securing the good will of the Ohio Indians; resigned his commission in America to Gen. Monckton May 4, 1760, and returned to England; was appointed lieutenant-general Jan. 19, 1761; was made lieutenant-governor of the Isle of Wight and colonel of the Eighth Foot, and was elected member of Parliament for Appleby. He was lost at sea in Dec., 1765, while crossing the Irish Channel from Dublin to Holyhead in a packet.

**Stan'yhurst**, Richard: historian and theologian; b. in Dublin about 1545; educated at University College, Oxford; studied law; returned to Ireland; married, became a Roman Catholic, and went to the Continent. On the death of his wife he became a priest, and was appointed chaplain to Archduke Albert, governor of the Spanish Netherlands. D. at Brussels in 1618. He translated into English heroic verse *The First Foure Bookes of Virgils Æneis* (1583); furnished a *Description of Ireland* to Holinshed's *Chronicles*; wrote historical treatises (in Latin) on Ireland, and English and Latin theological works.

**Staphylin'idæ**: the Rove-beetles (*q. v.*).

**Stapleton**, Thomas, D. D.: theologian, b. at Henfield, Sussex, England, in 1535; educated at Canterbury and Winchester schools and at New College, Oxford, where he was admitted perpetual fellow 1554; took orders in the Church; became a Roman Catholic; was appointed by Queen Mary prebendary of Chichester; retired on the accession of Elizabeth to Louvain, where he acquired publicity by his polemical writings against Calvin and Beza, Jewel, Horne, Whitaker, and other Protestant divines; became Regius Professor of Divinity at the University of Douay, where he had already become doctor of theology; returned to Louvain, where he was appointed divinity professor as successor to Baius. D. at Louvain, Oct. 12, 1599. His best-known works are *Principiorum fidei doctrinalium Demonstratio, Relectio principiorum fidei doctrinalium, Defensio auctoritatis ecclesiasticæ, De Justificatione, De magnitudine Ecclesiæ Romanæ, Propugnaculum fidei primitivæ Anglorum, Antidota Evangelica, Antidota Apostolica, Promptuarium Morale, Promptuarium Dogmaticum, Tres Thomæ.* Cardinal Duperron looked on him as the greatest of the polemical theologians, and Döllinger says that he was the greatest champion of the Church against the new doctrines. His works were published at Paris, 1620 (4 vols. fol.).

J. J. Keane.

**Star**: See Stars.

**Star-anise**: See Anise-seed.

**Star-apple Family**: the *Sapotaceæ*, a small family (400 species) of gamopetalous, dicotyledonous shrubs and trees, mostly latex-bearing. The flowers are regular and hermaphrodite in the axils of the leaves, and have one or two series of stamens, and a superior two to five celled, few-ovuled ovary. They are mainly tropical and sub-tropical. In the Southern U. S. there are nine or ten species, five of which are small trees of the genus *Bumelia*. "Several species of this family are useful to man. The fruits of *Lucuma mammosa*, the marmalade of the West Indies, are a very agreeable food, as are those of *Achras sapota* (the sapodilla-plum) and various species of *Chrysophyllum* (star-apples), which are much sought after in the Antilles." Some species of *Bassia*, the butter-trees, yield a fatty substance by pressure of the seeds. Gutta-percha is obtained from *Isonandra gutta*, a large tree of the East Indies, by the evaporation of its milky juice. Charles E. Bessey.

**Starch** [deriv. of *starch*, stiff < O. Eng. *stearc*, strong] ($C_6H_{10}O_5$ or $C_{12}H_{20}O_{10}$): a substance (also called *fecula*, *amidon*, and *amylum*) widely diffused in the vegetable kingdom, being found in almost every plant, at least at some period of its development. It is especially abundant in some families of plants, and often occurs in large quantities in the seeds, pith, stalks, bark, bulbs, tubers, roots, etc. There are two other substances found in plants which resemble starch in many respects—the inulin, which occurs in the dahlia, elecampane, dandelion, chicory, mustard-seed, etc., and the lichen-starch which is found in Iceland moss, carrageen-moss, and several of the lichen and fucus tribes of plants. See Inulin and Lichenine.

*Preparation.*—Starch is extracted from a great variety of plants, chiefly from wheat, Indian corn, rice, pototoes, the root of manioc or cassava, *Jatropha manihot* (tapioca), the root of several species of the *Maranta* (arrowroot), and the pith of a great variety of palms (sago). Wheat-flour contains from 50 to 80 per cent. of starch. The starch is extracted from the whole wheat by "softening" in cold water and pressing under millstones or rollers, or in bags under water, as long as milky water runs off from it. This liquid, when left to itself, deposits starch containing gluten; the latter, however, dissolves for the most part in the supernatant liquid, which gradually turns sour; and on decanting this acid liquid, repeatedly stirring up the starch with fresh water, and leaving it to settle, it is at length obtained pure, and may be dried in suitable desiccating chambers. Corn-starch is extensively manufactured in the U. S. by soaking corn in water containing caustic soda or hydrochloric acid to dissolve the gluten, grinding, washing on sieves, etc. The cheapness and excellence of this starch has put an end to the importation of starch from foreign countries, and large quantities are now exported. Rice-starch is largely manufactured in Great Britain, France, and Belgium. The rice is first soaked in a weak lye, then ground, and washed on a sieve. Potato-starch is largely manufactured in Europe and in the U. S. Horse-chestnut starch is made in France. A solution of sodic carbonate is used to remove the bitter principle. The yield is about 20 per cent. For Arrowroot, Sago, and Tapioca, see those articles.

*Properties.*—"Starch is a white shining powder, soft to the touch, grating between the fingers or the teeth, sometimes consisting of amorphous masses, but more frequently of granules recognizable by the microscope. . . . Starch, so long as it retains its natural state of aggregation, is insoluble in *water, alcohol*, and *ether*; but when placed in contact with *hot water*, the water penetrates between the different layers of which the granules are composed, swelling them up and forming a gelatinous mass known as *starch-paste*, and used for stiffening linen, etc."—*Watts's Dictionary.*

*Applications of Starch.*—Starch is used for stiffening cotton and linen cloth, paper, etc. Wiesner says corn-starch possesses the highest, and potato-starch the lowest stiffening qualities. It is used for food in the form of arrowroot, tapioca, sago, etc., for making paste, for powdering the hair, for the manufacture of dextrin, glucose (corn-sirup), etc. See Food. Revised by Ira Remsen.

**Star Chamber**: an English high court of justice prominent in the fifteenth, sixteenth, and seventeenth centuries, supposed to have derived its name from the fact that the room in which it was held at Westminster was decorated with gilt stars. The first historical instance of the use of the title is in the reign of Edward III., when the chancellor, treasurer, justices, and others are mentioned as exercising jurisdiction in the "star chamber." Its powers are thought to have been derived from the council which in 1453 was recognized as having jurisdiction over all cases not determinable by common law, but which declined in power during the Wars of the Roses. By the act of 1488 Henry VII. empowered a committee of the council, consisting of the chancellor, treasurer, keeper of the privy seal, chief justices (or, in their absence, two other justices), a bishop, and a temporal lord to act as a court of justice with jurisdiction over cases in which the operation of the law was wrongfully impeded. It had the right to punish without a jury the misdemeanors of sheriffs and juries, and in spite of its arbitrary nature was of use in quelling the turbulent spirit of the great nobles and bringing in a period of good order. In Henry VIII.'s reign its powers were reabsorbed by the council, but thenceforth the composition of the court was uncertain. Its jurisdiction, which was equally vague, comprised in practice almost every class of offenses, and it could inflict any penalty short of death. The peculiar uncertainty of its legal rules made it the defense of absolute power, and under the Stuarts its arbitrary decisions and cruel punishments brought down upon it the popular hatred. It was abolished by the Long Parliament in 1641. F. M. Colby.

**Stare Decisis**, stā'rē-dē-sī'sis [Lat.]: a shortened form of the maxim, "*stare decisis, et non quieta movere*"—"to stand by decisions and not to disturb matters once settled."

Ordinarily, it applies only to decisions of the court in which the question is again mooted, or to those of its superior. At times, however, the rule is followed with regard to decisions of inferior courts and even to decisions of executive departments, which have been acquiesced in by the public and under which rights have been acquired. (*Schell* vs. *Fauché*, 138 U. S. 562.) The reasons for the rule and its limitations are considered in the article on PRECEDENTS (*q. v.*).

FRANCIS M. BURDICK.

**Starfish**: any animal belonging to the class of *Echinodermata*, order *Asteroidea*; characterized by having the body more or less plainly star-shaped, and without sharp distinction between the five or more rays or arms and the central disk. The body-wall is hardened with calcareous plates and spines; the mouth is in the center of the lower surface of the disk, and the vent, when present, is above. Each arm bears on its lower surface two zigzag rows of tubular suckers (ambulacra), by means of which the animal moves about or anchors itself; while at the tip of each ray is an eye-spot. The round spot noticeable on the upper surface is a strainer (madreporite) through which water is admitted to tubes connected with the ambulacra. The sexes of the starfish are separate, and the eggs, which are usually committed to the waves, undergo in most forms strange metamorphoses in their development. Starfish lack all hard armature to the mouth, and they eat by protruding the stomach, inserting it into the mollusc upon which they feed. They are extremely destructive to oysters. See Alexander Agassiz, *North American Starfishes* (1877); *Development*, Field, *Quarterly Jour. Micros. Sci.* (1892); Fewkes, *Bulletin Mus. Comp. Zoöl.* (xiii., 1887). J. S. KINGSLEY.

**Stargazers**: marine fishes of the family *Uranoscopidæ*. The best-known species is *Uranoscopus scaber* of the Mediterranean; *Astroscopus anoplos* and *Upsilonphorus y-græcum* are found on the Atlantic coast of the U. S., but most of the species are East Indian. They are spiny fishes, having the eyes on top of the head, whence the name. The cyprinodont fishes of the genus *Anableps*, found in Guiana, are also called stargazers. See ANABLEPS.

**Starke**, JOHN: soldier; b. at Londonderry, N. H., Aug. 28, 1728; became a farmer, and in 1752 was taken prisoner by the St. Francis Indians, but after six weeks was ransomed, having in the meantime gained so much favor with his captors that he was subsequently adopted into their tribe. In 1755 he was appointed a lieutenant in Rogers's Rangers; took part in Abercrombie's campaign in 1758, and in Amherst's reduction of Crown Point and Ticonderoga in 1759; early in 1775 was chosen a member of the New Hampshire committee of safety; as colonel of the New Hampshire troops took part in the battle of Bunker Hill; accompanied Montgomery's expedition to Canada 1775–76; joined Washington at Newton, N. J., Dec., 1776, and took part in the battle of Trenton. Being aggrieved at the action of Congress in regard to promotions, he resigned his commission in Apr., 1777. Upon the advance of Burgoyne from Canada, the authorities of New Hampshire commissioned him to raise a force for the defense of the State, which was then held to include Vermont. He attacked the Hessian colonel Baum near Bennington Aug. 16, 1777, routed him, and later in the day defeated a force under Col. Breymann. For this he received from Congress a commission as brigadier-general; served under Gates in the Saratoga campaign; was with Gates in Rhode Island in 1778–79, and in 1780 joined Washington at Morristown; was a member of the court martial for the trial of Maj. André, and in 1781 was placed in command of the northern department. After the close of the war he retired to his farm. D. at Manchester, N. H., May 8, 1822. His *Biography* was written by Edward Everett for Sparks's *American Biography*, and his *Life and Official Correspondence*, edited by his grandson, was published in 1860 (Concord, N. H.).

**Starkie**, THOMAS: jurist; b. at Blakeburn, England, Apr. 12, 1782; graduated at Cambridge, where he was senior wrangler and Smith's prizeman 1803; was called to the bar at Lincoln's Inn May, 1810; became Downing Professor of Law 1823, and a judge of the county court at Clerkenwell 1847. His most important service in a public capacity was his labor in a commission appointed for the amendment of the law, and for digesting it into a code, for which his fullness of information especially fitted him. D. in London, Apr. 15, 1849. Besides *A Practical Treatise on the Law of Slander, Libel, and, incidentally, of Malicious Prosecutions* (1812), *A Treatise on Criminal Pleading* (2 vols., 1814), and *A Practical Treatise on the Law of Evidence and Digest of Proofs in Civil and Criminal Proceedings* (3 vols., 1824), which (especially the last) are his most important works and have been repeatedly reprinted, he published *Reports of Cases Determined at Nisi Prius, King's Bench, and Common Pleas* (1817–23), and numerous magazine articles.

Revised by F. STURGES ALLEN.

**Starkville**: town; capital of Oktibbeha co., Miss.; on the Ill. Cent. and the Mobile and Ohio railways; 20 miles S. W. of Aberdeen, 25 miles W. of Columbus (for location, see map of Mississippi, ref. 5–H). It is in a stock-raising and hay-making region, is the seat of the Mississippi Agricultural and Mechanical College, and contains the Starkville Female Institute, a savings-bank with capital of $25,000, and two weekly newspapers. Pop. (1880) 1,500; (1890) 1,725; (1900) 1,986.

**Starling** [M. Eng. *sterlyng*, dimin. of *stare* < O. Eng. *stær* (> Eng. *stare*, starling): O. H. Germ. *stara* > Mod. Germ. *star*, starling; cf. Lat. *stur'nus*, starling]: the *Sturnus vulgaris*, a common European bird of the family *Sturnidæ*. It is a great favorite, especially with the Germans, who often have it caged, and teach it to whistle tunes and even speak words very plainly. It makes a nest of twigs, straw, grass, and roots in holes of rocks and buildings and in hollow trees. The bird is 8½ inches long, black, with violet and green reflections and buff spots.

Revised by F. A. LUCAS.

**Starni'na**, GHERARDO: painter; b. in Florence in 1354; a pupil of Antonio Veneziano. After painting the history of St. Nicholas and St. Anthony on the ceiling of the Castellani chapel in Santa Croce, he was taken to Spain by some Spaniards who were enthusiastic admirers of his art. In that country he worked for the king and other patrons, and returned to Italy rich and covered with honor. Of his frescoes for the chapel of St. Jerome in the Carmelite church, executed soon after his return, nothing remains but the *Death of St. Jerome*. When Pisa was conquered by the Florentine republic Starnina was commissioned to paint on the façade of the Guelph palace an effigy of St. Denis, it being on his day that the city surrendered. He was one of the most consummate draughtsman of his time. Masolino da Panicale, Masaccio, and Antonio da Pistoia were his pupils. D. about 1407. W. J. STILLMAN.

**Star-of-Bethlehem**: the *Ornithogalum umbellatum*, a common spring garden-flower of the family *Liliaceæ*. The genus includes many bulbous-rooted plants of the Old World and of Southern Africa, several of which are cultivated. The above-mentioned species (white star-of-Bethlehem) is a native of Europe, and is sparingly naturalized in the U. S.

**Star of India, Order of the**: a British order of knighthood, provided to reward distinction in the Government service in India. It was instituted in 1861, and reorganized in 1866 and 1878. It consists of the sovereign, the viceroy of India, and three classes of members, viz.: 1, knights grand commanders (G. C. S. I.); 2, knights commanders (K. C. S. I.); and 3, companions (C. S. I.). The badge of the order is a light-blue ribbon with white stripes and the motto "Heaven's Light our Guide."

**Staroverski**: See PHILIPPINS.

**Starr**, FREDERICK: See the Appendix.

**Starr**, MOSES ALLEN, M. D., LL. D.: neurologist; b. in Brooklyn, N. Y., May 16, 1854; educated at Princeton College (A. B. 1876, A. M. 1879, Ph. D. 1884, LL. D. 1899), and at the College of Physicians and Surgeons, New York (M. D. 1880); studied at the Universities of Berlin, Heidelberg, Vienna, and Paris; was Professor of Nervous Diseases, New York Polyclinic, 1886–88, and has been Professor of Diseases of the Mind and Nervous System, College of Physicians and Surgeons, New York, since 1888; is attending and consulting physician to a number of hospitals; corresponding secretary of New York Academy of Medicine 1888 to 1895; president New York Neurological Society 1892–94. He delivered the Middleton Goldsmith lectures of the New York Pathological Society in 1887, his subject being *Multiple Neuritis*. Among his works are *Familiar Forms of Nervous Diseases* (New York, 1890); *Lectures on Insanity* (1891); and *Brain Surgery* (New York, 1893). S. T. ARMSTRONG.

**Stars** [M. Eng. *sterre* < O. Eng. *steorra*: O. H. Germ. *sterro*, *sterno* (> Mod. Germ. *stern*: Goth. *stairnō* < Teuton. *ster(n)*-: Lat. *stel'la* (for **ste'rula*): Gr. ἀστήρ]: in general, immense masses of matter, at a temperature so high as to be self-luminous, scattered through the celestial spaces, and of the same general nature as the sun. From the standpoint of the nebular hypothesis, each mass is hot because it has never had time to cool since it was first formed from the condensation of the nebulæ. Like the sun, the stars are surrounded by atmospheres of vapor, cooler than themselves, and spectrum analysis shows that they are composed of chemical elements similar to those found upon the earth.

*Number of Stars.*—The number of stars which can be seen at one time by the average eye, on a clear evening, may be estimated as between 2,000 and 2,500. As only half the celestial sphere is above the horizon, and few stars can be seen near the horizon, owing to the vapors in the lower part of the atmosphere, the number in the whole celestial sphere is more than double that visible at any one time. The total number in the heavens which the ordinary eye can see may be roughly estimated at 5,000; but these are only a small proportion of the whole number, the great majority being invisible without telescopic aid. It was estimated by Struve that 20,000,000 were visible with Herschel's 20-foot telescope. The more powerful the telescope, the greater the number. No exact estimate has ever been made of the total number visible with the great refractor of the Lick Observatory, but it would probably exceed 50,000,000.

*Magnitudes of the Stars.*—A glance at the nocturnal sky shows that the stars are of widely different degrees of brightness. A system of estimating the apparent magnitudes or brightness of the stars, which has come down to us from ancient times, is still in use by astronomers. On this system, in its original form, the stars were divided into six different orders of brilliancy. About twenty of the brightest stars in the heavens were called of the first magnitude. Next in order came the brightest stars of the Great Bear and of Cassiopeia. These were called of the second magnitude. The successive magnitudes corresponded with the continually diminishing degree of light, until the sixth was reached, which included the faintest visible with the naked eye. The original division into magnitudes was not founded on any exact photometric scale, but merely on general impressions derived from estimates by means of the eye. In modern times greater exactness has been aimed at. The general system which astronomers have attempted to follow is that the amounts of light represented by increasing magnitudes shall decrease in geometrical progression. Supposing this system to be exactly followed, a star of the second magnitude would be one which emitted two-fifths as much light as one of the first; one of the third magnitude would be two-fifths as bright as one of the second, and so on. Computing this ratio down to the sixth magnitude, we see that it would represent but little more than one-hundredth part of the light of a star of the first magnitude. The same ratio is continued in the star invisible to the naked eye; a star of the eleventh magnitude means one emitting about 1 per cent. as much light as one of the sixth magnitude. This scale of increase, however, is not perfectly exact, owing to the difficulties of making precise photometric comparisons between stars of greatly different magnitudes. The general rule has been that the magnitudes have been determined merely by estimates, and thus the results given by some observers have been systematically different from those given by others. This is especially true in the case of telescopic stars. Even in the case of the stars visible to the naked eye the difference of light is probably greater than that given by the above rule, some magnitudes being, in a general average, three times as bright as those next below them. The most recent investigators have gone far, however, toward removing all these discrepancies by using a uniform light ratio of two and a half for a unit difference of magnitude.

On the ancient system every star was supposed to belong to one of the six orders of magnitude, and no distinction was made between those belonging to the same order; but, as a matter of fact, the stars range over every degree of brilliancy from the first to the sixth, and the classification into magnitudes is arbitrary. How exact soever we might make it, the brightest star of the fifth magnitude would be equal with the faintest star of the fourth, the brightest star of the fourth equal to the faintest star of the third, etc.; hence astronomers have striven to express the magnitudes more exactly by introducing subdivisions. At first each magnitude was divided into three subdivisions: a bright one, a medium, and a faint one. The two extreme subdivisions were designated by writing the number both of that magnitude and the one next to it. For example, the magnitude of an average third-magnitude star was represented by the number 3 simply. A star between the third and fourth, but nearer to the third, was represented by the number 3·4. The next class in order would be the brightest stars of the fourth magnitude, which were represented by 4·3. Then the average fourth-magnitude stars were represented by 4 simply. Next, the fainter stars of this order, or those which approached the fifth magnitude, were called 4·5. Next came the brighter fifth-magnitude stars, which approached the fourth magnitude, and were called 5·4, etc. This system, though very recently in use, is too clumsy to meet the requirements of exactness in science, and it is now common to consider the magnitudes as regularly variable quantities, and represent them in the usual way by numbers and decimals. Accordingly, in modern photometry units and tenths are used. An average third-magnitude star is represented by 3·0; one fainter by a certain amount is called 3·1; next, 3·2, etc. The progression of 0·1 in each magnitude corresponds to an increase in light of nearly one-tenth; that is to say, a star of magnitude 2·9 is about one-tenth brighter than one of 3·0; one of 2·8 a tenth brighter than one of 2·9, etc. This rate of increase is such that a change of a whole magnitude will correspond to an increase of about two and a half times. Indeed, in the most recent photometrics the decimals are carried to hundredths.

This system does not express the amount of light emitted by a star, but rather the negative of its logarithm. It is more convenient, however, than one which would attempt to express the exact amount of light. Photometric estimates are necessarily made by the eye, and do not admit of direct measures. Now a geometrical progression of this sort can be estimated better by the eye than one in which an attempt is made to measure the quantity of light.

The number of stars of each magnitude increases with their minuteness. Roughly speaking, there are three times as many of the second magnitude as of the first; three times as many of the third as of the second, and so on. In the case of the fainter stars, however, the progression is not so rapid. There are between two and three times as many stars of the sixth magnitude as of the fifth; probably about twice as many of the seventh as of the sixth, and so on. An idea of this order may be gained by saying that the absolute amount of light emitted by the entire number of all the stars of any given order of magnitudes is not extravagantly different from the third down to the fainter telescopic stars. For example, each star of the sixth magnitude emits about two-fifths as much light as one of the fifth; but as there are two and a half times as many stars, the greater number nearly compensates for their smaller brilliancy, so that the total amount of light emitted by all of the sixth magnitude is about the same as the total amount emitted by all of the fifth.

*Constellations and Names.*—In former ages the figures of men, animals, or natural objects were supposed to be delineated on the face of the nocturnal sky, so as to include all the principal stars, and the stars were designated by the particular limb or part of the animal in which they were found. The bright red star, Aldebaran, for example, in the constellation Taurus, formed the eye of the bull, and two other smaller stars were at the ends of his horns. So we have three stars forming the belt of Orion, and three others his sword. In ancient times special names were given to several of the brighter stars; thus Arcturus is alluded to in the book of Job. The Arabs introduced special names for 100 or 200 of the stars. Some of these names are still used, but the tendency in astronomical practice is to drop them and designate the stars according to the system of Bayer. This system, now in vogue for all the more conspicuous stars, was introduced by Bayer about the year 1600. It is analogous to that which is used in distinguishing persons by two names, the surname and the Christian name. All the stars of a constellation have the name of that constellation as a surname. The Christian names are the letters of the Greek alphabet, $\alpha$ $\beta$, etc. These letters are used in each constellation in the same manner that persons of different families may have the same Christian name. The first letters of the alphabet are applied to the brighter stars, but their order as laid down by Bayer on his maps is not exactly that of brilliancy. Thus $\alpha$ Ursa Minoris is one of the two brightest stars in Ursa Minor; $\beta$ Ursa Minoris is the other; $\gamma$ Minoris is the third in the order of brilliancy, etc. So $\alpha$ Aquilæ is the brightest star in the constellation Aquila; $\beta$ Aquilæ the next brightest, etc. When the Greek alphabet was exhausted, in the case of any one constellation, the Italic alphabet was used. In modern times several stars are represented by one of Bayer's letters and a number attached to it. Thus two stars in Aquarius are represented by $h_1$ and $h_2$ respectively. Flamsteed, in making his great catalogue of stars, found that he had to include so many stars not lettered by Bayer that he adopted the plan of using numbers, instead of the Greek and Italic letters. These numbers were arranged in the orders of right ascension; thus 1 Scorpii was the first star in Scorpius which passed the meridian, 2 Scorpii the second, etc. The system commonly used now is to designate the star by Bayer's letter, when it has one, otherwise by Flamsteed's number. Stars which have neither letter nor number are distinguished simply by their magnitude, right ascension, and declination, or by their number in some well-known catalogue; but for uniformity the constellation to which they belong is frequently indicated.

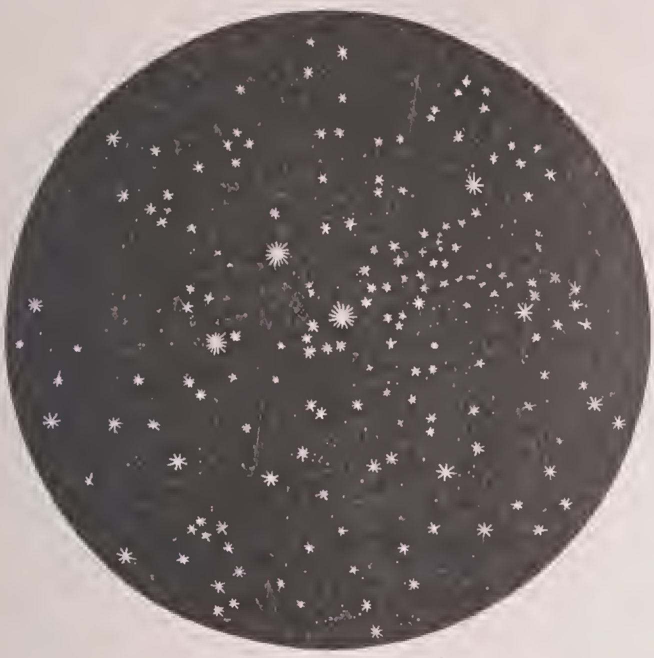


FIG. 1.—Portion of the group in Perseus.

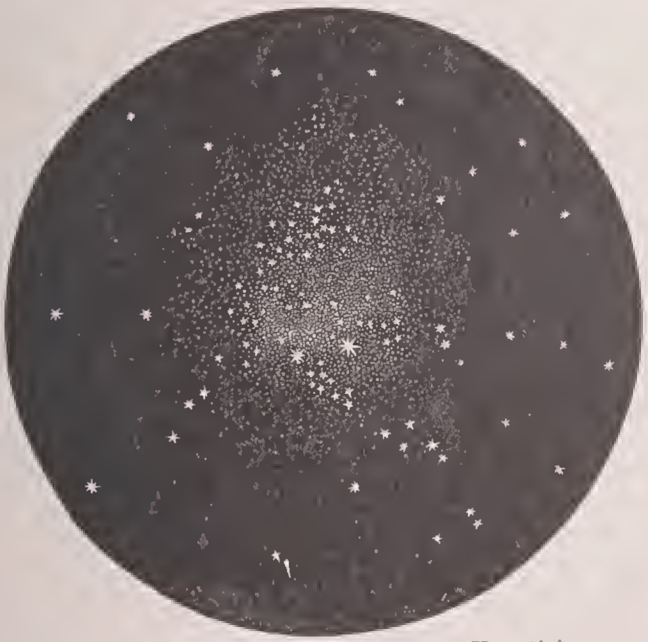

FIG. 2.—Globular cluster in Canes Venatici.

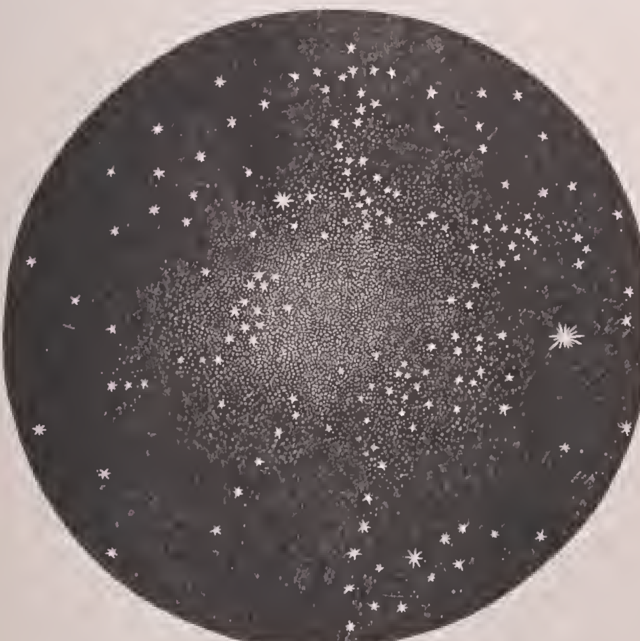

FIG. 3.—Globular cluster in Aquarius.

*Distribution of the Stars.*—The distribution of the stars in space has been considered by Herschel and other astronomers, but, though some traces of arrangement have been discerned, no distinct law has yet been formulated. (See GALAXY.) In certain parts of the heavens the stars are heaped together in clusters. The telescope reveals wonderful groups, such as that in Hercules, which contains thousands of stars in a small space, spreading at the edge into curved sprays. A group near $\kappa$ of the Southern Cross shows an aggregation of variously colored stars. In Fig. 1 the central portion of the group in Perseus is exhibited. Figs. 2 and 3, representing clusters in Canes Venatici and Aquarius, give an idea of groups composed of immense numbers of small stars arranged in a globular form.

TABLE A.—DISTRIBUTION OF STARS ACCORDING TO THEIR CONSTELLATIONS AND MAGNITUDES. (STARS VISIBLE TO THE NAKED EYE IN THE LATITUDES OF THE NORTHERN UNITED STATES.) SEE ALSO CONSTELLATION.

*Variable Stars.*—It has long been known that certain stars vary in brilliancy from time to time. The two most remarkable ones, which have long been known, are *o* Ceti and *β* Persei, or Algol. During the greater part of the time the former of these stars is invisible to the naked eye; But at intervals of about eleven months it increases so as to become plainly visible, and after retaining a maximum brilliancy for some two weeks fades away again. Its maximum brilliancy, however, is very different at different appearances, ranging from the second all the way to the fifth. The law of variation is so irregular as not to admit of any exact statement; even the period of 331 days varies from time to time. Owing to the manner in which it blazes up, it was formerly called Mira Ceti. For an account of the variations in the light of Algol, and the discoveries to which they have given rise, see ALGOL.

In the southern hemisphere there is a star, *η* Argus, which for several centuries past has varied in the most singular manner. The first record of it was by Halley in 1677, when it was classed as of the fourth magnitude. In 1837 Sir John Herschel, while making observations at the Cape of Good Hope, was astonished by the appearance of a new star of the first magnitude, which on referring to a map he found to be *η* Argus. Its light was, however, nearly trebled, being then greater than that of Rigel. He states that the light continued to increase until the beginning of 1838, when it was brighter than most of the stars of the first magnitude. It then gradually faded away for two or three years, but in 1842 and 1843 blazed up brighter than ever, so as to be the brightest star in the heavens, except Sirius. Since that time it has been steadily diminishing; in 1868 it was no longer visible to the naked eye, and since that time has sunk to about the eighth magnitude.

Why some stars vary while others do not science has not been able to explain, except in a few cases. One of these is Algol, whose variations are due to a partial eclipse by a dark body revolving around it. There are a few other stars whose light slightly fades away at certain intervals, and whose variations are therefore presumed to be due to a similar cause. With most of the variable stars, however, the changes of light go on so continuously as to show that it is due to the constitution of the star itself. It has been suggested that such stars are brighter on one side than on the other, and show different faces as they revolve. This hypothesis is a purely speculative one, not only without proof, but without any great degree of probability. The theory which at present seems to rest upon the best foundation is that the variations are due to a process analogous to that of the formation of spots on the sun. The actual area of the sun covered by spots is so small that the variation of the light thus caused would evade photometric measurement: but it may easily be supposed that this spotted area upon a few of the stars so much exceeds that of the sun, both in variation and amount, as to be sensible to such measurement. The spots on the sun go through a regular period in eleven years. It may therefore be called a variable star, with a period of eleven years. It may therefore be said, with a considerable degree of probability, that variations in brilliancy among the stars are due to the regular formation of spots like those on the sun, at intervals which are sometimes fairly regular, and at other times very irregular, according to the constitution of the star itself.

*Colored Stars.*—A very slight examination will show to any observer of the heavens that the stars are of different colors. The great majority are what would be called white. A few, however, such as Sirius and Alpha Lyræ, have a slightly bluish tint. Many others, as Aldebaran, Arcturus, Antares, and Alpha Orionis, have a reddish tinge. These differences of color are probably due in part to differences in the temperature of the stars, and in the absorbing power of the atmospheres which surround them. It is familiarly known that the color of the light emitted by a piece of heated iron is at first red, and then it changes toward white as the iron gets hotter. This law is so well established in the case of terrestrial bodies that little doubt is felt that the red stars are not at so high temperature as those of other colors. Another curious fact in connection with this is that variability predominates among the red stars. It is thus rendered likely that the red stars are those in the most advanced stage of cooling, and most subject to the formation of spots. Probably if such a star were brought as near to us as the sun is we should find the spots frequently covering half the disk, or more, and changing from time to time in amount, as the spots on the sun change.

*Stellar spectra* can be distinguished into four categories or types. The first is that of the white or azure-tinted stars, like Sirius, Lyra, etc., *β*, *γ*, *δ*, *ε*, *ζ*, *η* of the Great Bear, etc. The spectra of these are almost continuous, except that they are furrowed by four strong black lines, which are absorption-lines of hydrogen. All four lines can be seen in the most brilliant, as Sirius, Lyra, etc.; in the feeblest only the $H\beta$, or the F of the sun, is ordinarily visible; but in general this is broad and dilated, and frequently diffused at the edges, especially in Sirius. This is an indication of a very high temperature, and of great density in the hydrogen atmosphere of the stars of this order. There are also seen traces of other lines, as of magnesium, sodium, and some of iron; but these are extremely feeble, and require for their observation an atmosphere of great purity. Many stars appear of uniform light, without lines, which studied with care are found to belong to this type.

The second type is that of the yellow stars. They have very fine lines, and their spectra are perfectly similar in character to that of the sun. Capella, Pollux, and many others feebly yellow have such a character. The fineness of the lines requires that in these researches the atmosphere should be very clear and quiet. Sodium, hydrogen, and iron are very conspicuous in them. Arcturus and Aldebaran, in their periods of lively yellow light, approach this type, and in the periods of red light the following. It is curious that *α* Ursæ Majoris is of this type, while all the others of that constellation belong to the first.

The third type is that which is exhibited by the orange and red stars. It is formed of lines and zones or nebulous bands. A specially striking example is *α* Orionis, the prototype of this class, to which belong also *α* Scorpionis, *o* Ceti, *β* Pegasi, *α* Herculis, and many other beautiful examples. This spectrum ought to be considered as really composed of two spectra superposed—one formed of broad zones of gradually deepening cloudiness, producing the effect of lights and shadows in a fluted column; the other formed of black absorption-lines of the metals. This, for the structure of the broad zones, has for type *α* Herculis, where the principal channelings are seven in number, but upon these channelings, in the periods of lively red color, the black lines can be perceived. In some variable red stars, in the period of feebleness, is seen a spectrum of a few lively bright lines, as, for example, in *o* Ceti. The black reversion-lines of hydrogen are feeble, and sometimes not present at all in these spectra, while the sodium, iron, and magnesium lines are very strong; hydrogen is truly there, but is difficult of detection, because the lines are not perfectly reversed.

The fourth type embraces some curious stars, for the most part red. They have only three bands, coinciding in limits with those of the third type, but having twice the breadth; and they are bright notwithstanding the minuteness of the stars. There are lucid lines in some of them, but in general these are feeble and few. They have the bright and well-defined side of their channelings turned toward the violet, while those of the third type turn it toward the red. They appear to give a spectrum similar to that of carbon as it is seen in the central part of the voltaic arch projected between two carbon points: except that, in the stars, the shading off is in the opposite direction—that is, the maximum light is turned toward the violet, while in the carbon arch it is turned toward the red. Many of these stars exhibit only a few luminous lines, and are without the channeled and cloudy spaces; all such are of a deep red, and among them are found the most beautiful spectra.

TABLE B.—THE MORE REMARKABLE STARS OF THE FOURTH TYPE.

| Right ascension. | Declination. | Magnitude. |
|---|---|---|
| 4*h*. 36·2*m*. | +67° 54′ | 6. Fine. |
| 4 42·8 | +28 16 | 8 |

| 21 25·8 | +50 58 | 9 |
| 21 38·6 | +37 13 | 8·5 |
| 23 39·2 | + 2 42 | 6. Fine. |

*New Stars.*—The view has sometimes been entertained that new stars show themselves in the heavens from time to time and that old ones disappear; but neither of these impressions is correct. There is no well-established case of a known star disappearing from the heavens. The supposed cases were those when an observer had made some mistake in recording the position of a star, so that future observers on looking at the place found it vacant. The direct proof that no really new star ever appears is not so easy. As a matter of fact, stars apparently new do appear in the heavens from time to time. The most extraordinary on record was that of 1752, which was described by Tycho Brahe. For nearly a month it was so bright as to be discernible in full daylight. It then faded away, and at the end of another year gradually became invisible. The position of the star was determined by Tycho as well as his instruments would permit, and there is now found to be a telescopic star near the place. Kepler records a similar star, which appeared in 1604, in the constellation Ophiuchus. In October of that year it was of the first magnitude, and remained visible during 1605. It faded away early in 1606.

The question whether such stars were new might have been considered an open one until the appearance of T Coronæ in May, 1866. It was first seen on the 11th of that month, when it had attained the second magnitude. On the question whether the star was visible before that day the testimony is conflicting. The most important circumstance connected with this star is that it was found to have been already recorded in Argenlander's catalogue, being a telescopic star of the ninth magnitude. A few days after it blazed forth in the way just described it began to fade again, and has since diminished to its former state. In 1892 a new star appeared in the constellation Aurigæ, but it did not rise above the fifth magnitude, and would therefore have passed unnoticed but for the watchful eyes constantly directed at the heavens. No certain explanation can be given of these phenomena. In the case of T Coronæ spectroscopic observation seemed to show that the increase of light was due to glowing hydrogen. The suggestion has been made that the outburst was caused by a collision, perhaps by a planet falling into the star. The explanation is purely hypothetical.

*Proper Motions of the Stars.*—To the unaided vision the stars seem to preserve the same relative position in the heavens from year to year and from century to century. The earliest maps of the constellations show the same arrangement of the stars as the latest ones, but the refined measurements of modern astronomy show a slow motion to be taking place in at least all the brighter stars. This motion, however, does not follow any exact law that has yet been discovered, except to the extent that there is a preponderance of motions in a certain direction in the heavens which may be described as from the constellation Hercules in the northern hemisphere toward that of Pictor in the southern. The common and natural explanation of this is that the sun has a proper motion toward the constellation Hercules. The preponderance of motions on which this view rests is, however, only the result of a general average; the actual motions of the individual stars take place in all directions. Clusters of stars frequently have a common motion among themselves. This is especially true of the Pleiades, which are moving southward at the rate of about six seconds in a century. The proper motions of the stars all take place in straight lines, so far as observations have yet shown. If any deviations occur, many centuries will be required to show them. For shooting stars, see METEORS.

BIBLIOGRAPHY.—For a very complete general outline of stellar astronomy, reference may be made to the book of Miss Agnes M. Clerke, *The System of the Stars.* The best accounts of the methods of measuring the magnitudes of the stars, and the results of such work, are found in the *Annals of the Harvard Observatory*, especially vols. xiv. and xxiv., and in the *Publicationen* of the Potsdam observatory, vol. ix., 1894. For details concerning the spectra of the stars, see Scheiner, *Spectrum Analysis*, translated by E. B. Frost (Boston, 1894). A catalogue of the variable stars, by Chandler, is found in *Gould's Astronomical Journal*, vol. xiii. Among star maps are Proctor's and Cottam's, published in England, and Heis's, in Germany. S. NEWCOMB.

**Starstone**: a variety of sapphire, the *asteria* of Pliny and the ancients, found in Ceylon. It presents, when cut *en cabochon*, or in a hemispherical form, and viewed in a direction perpendicular to the axis, a peculiar reflection of light in the form of a star.

**Starvation**, or **Inanition** [*starvation* is deriv. of *starve* < M. Eng. *sterven*, die < O. Eng. *steorfan* : O. H. Germ. *sterban* > Mod. Germ. *sterben*, die; cf. Icel. *starf*, toil, labor. *Inanition* is from Lat. *inani'tio*, emptiness, deriv. of *inani're*, to empty, deriv. of *ina'nis*, empty]: the condition of tissue-waste, exhausted vitality, and death resulting from prolonged privation of food. A slower starvation ensues when food is scanty and impure, or is persistently deficient in one or more of the several constituents essential to the mixed diet of man. Animals have been fed experimentally on single classes of food—one upon albuminoid matter, another partaking of only farinaceous substances, a third only of the hydrocarbons or fats. Such exclusive diet, of whichever kind, proved disastrous; emaciation, enfeeblement, and death by starvation ensued. The phenomena of starvation, complete and partial, have often been studied and recorded by the shipwrecked, by persons immured in mines, soldiers deprived of supplies, Arctic explorers, as also in the case of the insane and others practicing voluntary starvation. Prolonged abstinence necessitates bodily waste; hence the reported cases of prolonged subsistence without food, usually women apparently in a state of trance or catalepsy, are not to be accredited; carefully investigated, they invariably prove to be artful deceptions by hysterical or demented persons. Rigid exclusion of food and drink causes death, on an average, in from five to eight days. Water, freely supplied, with exclusion of solid food, may prolong life two or three weeks, exceptionally longer. Water constitutes over half the weight and bulk of the body; it is the solvent for all nutritive matter entering the body, and all azotized products which are to be excreted. Even solid food, so called, is in part water. If desiccated food alone be supplied, with no drink, death will result in a few days. Starvation at the outset produces urgent hunger; this may gradually lessen, be replaced by faintness, loss of appetite, and even loathing of food. The strength fails, the body wastes, the mind becomes enfeebled; in some cases there is listlessness and stupor, in others marked nervous excitement and delirium—phenomena excited by non-excreted effete matter accumulated in the blood. The starving person is liable to intercurrent disease, and the community suffering privation is often visited by epidemics of contagious and infectious diseases, which assume an unusually malignant and fatal type, consequent upon the nervous depression and vitiated blood of the persons attacked. Starving persons, when rescued, should not be supplied too suddenly or freely with food; the enervated digestive apparatus can retain and assimilate but small quantities at a time, an excess exciting irritation and dangerous and fatal diarrhœa. Certain diseased conditions may cause starvation; such are stricture and cancer of the œsophagus and upper orifice of the stomach, gastric ulcer, atrophy of the peptic and intestinal glands, and tubercle of the intestine. Revised by W. PEPPER.

**Stass'furt**: town and railway junction; in province of Saxony, Prussia; on the Bode; 20 miles S. S. W. of Magdeburg (see map of German Empire, ref. 4–F). It is noted for the immense layer of rock-salt in its vicinity, which was discovered in 1837 at a depth of 826 feet and with a thickness of about 1,000 feet. A shaft was finally opened in 1852 and steam-engines used to operate the mine. The total production in 1887 was 201,962 tons of rock-salt and 1,294,081 tons of other salts. An extensive chemical industry has been built up. Pop. (1895) 18,981.

**State** [M. Eng. *stat*, from O. Fr. *estat* < Fr. *état* : Ital. *stato* < Lat. *sta'tus*, a standing, position, condition, status, rank, public condition, the commonwealth]: in its present sense, a body politic; a self-governing community organized under permanent law which has for its aim justice and the security of all. It is the best term for denoting communities on their political side whatever their form of government be. The term *nation* implies common origin and language, and so Cicero spoke of the *Greek nation*, although the Greeks never formed a state, nor even a confederation, embracing all who spoke the Greek tongue; and, on the other hand, the kingdom of the Netherlands, such as it was before the disruption in 1830, consisted of inhabitants speaking three languages—Dutch, Flemish, and French—with various earlier institutions and political connections. This was in no sense a nation, but was a state. So Austria at present is not a nation, but is a state where three nationalities at least—a German, a Hungarian, and a Slavonic, to say nothing of Polish and Roumanian and other subjects—are bound together under the same political institutions.

The political senses which the word state and others from the same source took on were more than one. Thus the estates of the later feudal kingdoms were the three or four groups holding the property and represented in the assemblies called the assemblies of the estates. These were the clergy, nobles, burghers, and, in a few countries, the peasants. In the Dutch republic much later each province held a meeting of its estates, and the general meeting of the provinces was called the States-General, where all were represented. The abstract sense of an organized body politic also came into the word. When the North American colonies called themselves free and independent states this sense was adopted, and this sense remained in the term *United States*, which was attached to the new federal republic for want of a better. The reasoning from this term and from sovereignty as to what the rights of the States and of the Union are under the Constitution, instead of discovering from their attributions and powers what they are, has been a source of much confusion and error. Political science, however, is not responsible for this confusion. It knows of independent and of dependent states, of states formed out of states and of simple states, of states under the most varied and dissimilar forms. From the word state, then, we can argue nothing positively of the attributes of that which is so called. The most that can be said is that a state entirely independent and self-governing in order to carry out the ends of its existence ought to have such and such powers. See also SOVEREIGNTY and INTERNATIONAL LAW.

Revised by T. S. WOOLSEY.

**State, Department of**: the name of an executive department in the U. S. Government, having charge of the relations of that Government with foreign powers. Its head is the Secretary of State, who ranks as the first of the cabinet officers, and is aided in the administration of his office by an assistant secretary, and second and third assistant secretaries. The Secretary not only is charged, under the direction of the President, with all negotiations relating to foreign affairs, but is the medium of correspondence between the President and the executive of the several States, is custodian of the great seal of the U. S., and publishes the laws and resolutions of Congress, proclamations admitting new States into the Union, and amendments to the constitutions. He is further required to issue annual reports to Congress containing information received from members of the consular and diplomatic service.

**Staten Island** [named by the Dutch in honor of the States-(Dutch *Staten*) General]: largest island in New York harbor; formerly Richmond co., N. Y., now the Borough of Richmond, New York city (see map of New York, 8–A). It has an extreme length of 13 miles, extreme width of 8 miles, and area of 58½ sq. miles, and is bounded on the N. by the Kill von Kull, E. by New York harbor, New York Bay, and the Narrows, S. S. E. by Raritan Bay and the lower bay of New York, and W. by Staten Island Sound. On Jan. 1, 1898, it was annexed to the city of New York as the Borough of Richmond, and the five towns into which it was formerly divided became wards instead. Staten Island is connected with Manhattan by steam-ferry from St. George, with Perth Amboy, N. J., by ferry from Tottenville, and with Elizabeth, N. J., by a railway bridge across the Arthur Kill. The island is very hilly, but has lines of railway extending from St. George to Tottenville and from South Beach to Erastina. A mile S. E. of Clifton is Fort Wadsworth with a long line of water-batteries, on the north shore is the Sailors' Snug Harbor, and between St. George and Tompkinsville is a U. S. lighthouse station. The island contains many churches, public and private schools, libraries, newspapers, and manufacturing establishments, has excellent drives, and is a place of residence of many New York business men. Pop. (1880) 38,991; (1890) 51,693 (Castleton, 16,423; Middletown, 10,557; Northfield, 9,811; Southfield, 6,644; Westfield, 8,258); (1900) 67,021.

**State Rights**: See SOVEREIGNTY.

**State's Evidence**, or (in Great Britain) **King's** or **Queen's Evidence**: a phrase popularly used to describe the evidence of an accomplice, generally given under an arrangement made with the officer representing the state (in Great Britain the crown) that the witness so testifying shall not himself be prosecuted for the crime of which he confesses himself to be guilty while he is disclosing the guilt of the party on trial. It is often necessary, in order that the ends of justice may not be defeated, that one of several criminals, whether indicted jointly with the others or indicted separately, or perhaps not indicted at all, should be procured or suffered by the prosecution to become a witness for the state and to testify on the trial of his fellows, although his evidence may show himself to be guilty of the same offense or of some other offense. When this is done there is generally a tacit understanding or an express agreement with the prosecuting officer that the person whose disclosures are thus used on behalf of the public shall not be brought to trial and conviction. When and with whom such an arrangement shall be made rests on the sound discretion of the officer who represents the people, or, if suit has already been instituted, of the court, and largely depends upon the exigencies of each particular case. The evidence given under such circumstances is of course very suspicious, and it has even been said that as a matter of law no conviction can be had upon the uncorroborated testimony of an accomplice. The better doctrine, however, is, that this is a rule not of the law, but of practice and of expediency. A jury has the power to convict upon such evidence, and their verdict could not be set aside as illegal. The judge should always instruct the jury that the testimony of an accomplice is to be most carefully scrutinized, and that, unless confirmed in material points by other and reliable evidence, a conviction upon it is inexpedient—that the corroboration should extend not merely to the circumstances of the crime itself, but also to the participation therein by the accused who is on trial. Still, such instructions are rather in the nature of advice than of direction or command, and they may therefore be disregarded.

Revised by F. STURGES ALLEN.

**States-General**: an assembly composed of representatives of the nation. In France it consisted of representatives of the three orders of the kingdom—the nobility, the clergy, and the third estate, or the *bourgeoisie*. Its origin seems to date back to the time of Charlemagne. The first convocation of which history gives an elaborate and authentic report is that of Blois, 1302, by which Philippe le Bel tried to give a greater weight to the course he had adopted in his quarrel with Pope Boniface VIII. The most memorable convocation was that of 1789, which ushered in the Revolution. (See FRANCE, HISTORY OF.) In Holland the name States-General is applied to the legislative body of the kingdom, there distinguishing that assembly from the merely provincial states. The Dutch States-General is composed of two chambers—the upper, elected by the provincial states, and the lower, chosen by the citizens.

**States of the Church**: See PAPAL STATES.

**Statesville**: city; capital of Iredell co., N. C.; on the Southern Railway; 25 miles W. by N. of Salisbury, 45 miles N. of Charlotte (for location, see map of North Carolina, ref. 3–E). It is in a stock-raising, a corundum-mining, and a cotton, tobacco, and grain growing region, and contains a U. S. Government building, 7 churches, academy for boys, several public and private schools, manufactories of cotton and tobacco, a national bank with capital of $50,000, and 2 weekly newspapers. Pop. (1880) 1,062; (1890) 2,318; (1900) 3,141.

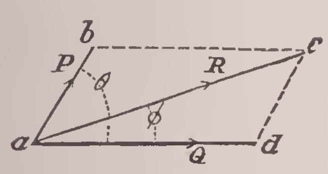
EDITOR OF "LANDMARK."

**Statice**: a genus of plants to which the MARSH ROSEMARY (*q. v.*) belongs.

**Statics** [plur. of *static*, from Gr. στατική (sc. τέχνη, art), the art of weighing, liter., fem. of στατικός, causing to stand, skilled in weighing, deriv. of ἱστάναι, cause to stand]: that branch of mechanics which treats of the properties and relations of forces in equilibrium. By equilibrium is meant that the forces are in perfect balance, so that the body upon which they act is in a state of rest. According to the classification presented in some text-books on the subject, and, in fact, usually employed by engineers, the word statics is used in opposition to dynamics, the former being the science of equilibrium or rest, the latter of motion, and both together constituting mechanics. Other books regard statics as a subdivision of dynamics. See DYNAMICS.

In statics, forces are measured by the pressures that they will produce, and for convenience the unit of pressure is a certain effect of the force of gravitation as indicated by a spring-balance (not by a steelyard or scales) acted upon at some assigned place by a definite quantity of matter. Thus the unit may be the pressure called an ounce, a pound, or a kilogramme, as may be agreed upon beforehand. In the discussions of statics it is convenient to represent forces by lines, the lengths of the lines being proportional to the intensities of the forces, their directions parallel to the directions of the forces, and their ends denoting the points of application of the forces; reasoning upon the properties of the lines then leads to the properties and relations of the forces themselves.

The resultant of two or more forces is a single force which produces the same effect as the several forces acting together. The components of a single force are forces whose united action produces the same effect as the single one. The process of combining forces into a resultant is called composition, and that of separating a single force into components is called resolution. These processes are effected by means of the principle of the parallelogram of forces, which is thus stated: If two forces $P$ and $Q$ acting upon the material point $a$ are represented in intensity and direction by the lines $a\ b$ and $a\ d$, their resultant $R$ will be represented in intensity and direction by the diagonal $a\ c$ of the parallelogram $a\ b\ c\ d$ constructed upon the two given sides. Since the relations between the forces $P$, $Q$, and $R$ are the same as between the corresponding lines in the parallelogram, the two following equations result:



$$R^2 = P^2 + Q^2 + 2PQ \cos \theta, \text{and } \cos \phi = \frac{R^2 + Q^2 - P^2}{2RQ}.$$

The first determines the intensity of $R$ when $P$, $Q$, and the angle $\theta$ are given, and the second determines the direction of $R$, or the angle $\phi$ which it makes with the given force $Q$. These two equations contain five quantities, and hence, if three of them are given, the other two may be found. The two forces $P$ and $Q$, acting at a given angle $\theta$, may thus be compounded into their resultant, and the single force $R$ may be resolved into any two components whose directions are given. If the resultant $R$ act as represented in the figure from $a$ toward $c$, it will replace the two forces $P$ and $Q$; if it be taken as acting from $c$ toward $a$ it will hold them in equilibrium.

Another fundamental law of the greatest importance is the principle of moments. (See MOMENT.) This teaches that if several forces acting upon a body be in equilibrium there will be no tendency to rotation in any direction, while that of the parallelogram of forces teaches that there will be no tendency to a motion of translation in any direction. Text-books on statics, after having established and illustrated these fundamental principles, proceed to the consideration of parallel forces and to the determination of centers of gravity and moments of inertia of bodies, after which the equilibrium of forces acting through the cord, lever, pulley, inclined plane, and screw, of which all machines are compounded, is discussed, both in its simplest theoretic conception and as modified by the forces of friction and cohesion. The laws of the equilibrium of gases and of liquids (hydrostatics), with their applications to the barometer, pump, and hydrostatic press, are then developed and illustrated. The treatment of these questions in the elementary text-books exhibits, however, only the first principles, and forms merely the introduction to the science, whose complete development in its several departments must be sought for in special and technical treatises. Among these, where experiment lends its aid to theory by determining the necessary constants for the full discussion and application of the laws of friction, elasticity, and tension, may be mentioned the theory of the equilibrium of arches and bridges, the theory of the flexure of elastic bodies, the theory of the strength of materials subject to forces of tension, compression, shearing, or torsion, the theory of the tension of fluids, and the statics of molecules.

The forces which come under consideration in statical investigations are all the forces of nature which can be measured by pressures. As to their origin, they may be forces of gravitation, of molecular attraction and repulsion, of friction, or of muscular strength. If the equilibrium of a system of forces is disturbed, motion ensues, and statics passes into kinetics. The very disturbance of equilibrium, however, calls into action the resistance of inertia, and by the consideration of this resistance as a force the laws of statics become applicable, even though the body be not at rest. For by the principle of d'Alembert (which is nothing more than a particular case of Newton's third law of motion) the resistance of the inertia of a body at any instant of its motion is equal and opposite to the resultant of all the exterior forces acting upon it. Hence, regarding inertia as a force, all the forces acting upon a moving body at any instant are in equilibrium, and the principles of statics suffice for their discussion. It thus appears that statics is but a special case of kinetics, and that the law of d'Alembert furnishes the means of passing from one to the other.

HISTORY AND LITERATURE.—The first recorded principle of statics is that of the equilibrium of weights on a lever, which is a special case of the principle of moments. This was discovered by Archimedes (B. C. 287–212), as also its application to the determination of the centers of gravity of plane figures; in his writings also appear the first investigations concerning the equilibrium of bodies floating or immersed in liquids. For 1800 years after his time there was no further advance. The next step was made by Stevinus (1548–1603), who represented the intensity and direction of forces by straight lines, deduced the principle of the resolution of forces in rectangular directions, and investigated the equilibrium of a body resting upon an inclined plane. Next followed the principle of the parallelogram of forces, which, partially implied by the methods of Stevinus, was only completely established by the labors of Galileo (1564–1642), Varignon (1654–1722), and Newton (1642–1727). To Varignon is also due the development of the simpler properties of the force and equilibrium polygons. About the same time the statics of fluids began to receive attention, the first true explanation of their equilibrium being due to Torricelli (1608–47), the inventor of the barometer. The application of these principles has since those days occupied the attention of a host of writers, and the science has grown to a vast extent. The new branch of graphic statics may be said to have been entirely developed since 1866, when Culmann's work appeared. For detailed information concerning the early history of the subject, see the section on mechanics in Whewell's *History of the Inductive Sciences* (London, 1847; New York, 1859). See COMPOSITION OF FORCES, DYNAMICS, FORCE, GRAPHIC STATICS, HYDROSTATICS, MECHANICS, MOMENT, and STRESSES. MANSFIELD MERRIMAN.

**Stations of the Cross**: a series of figures or pictures, usually fourteen in number, representing the various stages of the *Via Dolorosa*, or our Lord's Passion on the way to Calvary. They are generally found in every Roman Catholic church. In Roman Catholic countries they are often erected by the wayside, in cemeteries, on prominent sites, etc. J. J. K.

**Statis'tics** [plur. of *statistic*, liter., pertaining to a statist or to matters of state]: in its simplest meaning, a description of any class of facts expressed by means of figures. The credit of having founded a science of statistics is usually given to Prof. Achenwall (1712–72), of the University of Göttingen. According to him the total of *Staatsmerkwürdigkeiten* (the remarkable things pertaining to the state) makes up the constitution of a state in its broadest sense, and "an account of such constitutions of one or more states is statistics." In the development of statistics since Achenwall there seems to have been two stages, or, as Maurice Block prefers to express it, a twofold tendency. The one confines itself to descriptive statistics, that is to say, to a picture of society or of the state, or of any phase of human activity, drawn in figures, and in this manner reduced to measurements. The chief merit of this phase of statistics lies in the fact that it permits a study of conditions by means of comparison. The other tendency in the development of statistics goes a step further than description, and by submitting any class of facts at different times to systematic observation reduces change itself to numerical measurement, and in this way seeks to prove relationships and to discover laws of growth.

*Historical Sketch.*—(a) *Statistics as a Branch of Government Service.*—The collection of facts pertaining to a state was undertaken long before scientific statistics were thought of. The book of Numbers is in fact a statistical report. There is record of statistical work in China in 2300 B. C. In Greece and Rome also there was considerable activity in systematic collections of data pertaining to national life. In 594 B. C. a census was taken in Greece for the purpose of levying taxes which divided the people into four classes according to wealth. Athens took a census of population in 309 B. C. The constitution of Servius Tullius, 550 B. C., distinguished six property classes. These are all instances of work which in modern times would be called statistical. Also there is evidence that in the Middle Ages there was national enumeration of population or of property. The work, however, was suggested by some practical necessity,

L. of C.

as, for example, the *Domesday Book* of William I., 1088 A. D., or the *Land Register* of Waldemar II., 1231 A. D. In the fifteenth century evidently there was an unusual interest in systematic investigations into the conditions of the various countries of Europe. A second revival of interest in statistical work took place in the latter part of the eighteenth century, due to the new measures, the new hopes, and the new ideas which came in with the French Revolution. In France the need of definite information was formally recognized, and a commission established to collect data for reforms in administration and finance. This finally led to the establishment of statistical bureaus in France, as also in all other countries which felt the influence of modern political life. The need of statistical investigation is one which increases as the spirit of popular government becomes more intense, or the means of realizing popular government more perfect.

(*b*) *Statistics as a Branch of Knowledge.*—When statistics was first recognized as an independent study, the claims made for it were very broad and comprehensive. The course of lectures in which Achenwall founded this branch of investigation placed before itself this purpose, "To gain political wisdom by means of a knowledge of the various states." His plan contemplated a comparative study of all modern states under seven distinct heads: Literature, geography, physiography and fertility, the number and character of inhabitants, the rights of the several classes, the organization of the state, and a consideration of the needs of the state. The work of Achenwall exerted a great influence throughout Europe. The name of Süssmilch (1707–67) must also be mentioned, since his work was the first which conclusively proved the existence of a rigid law in the matter of births and deaths. Annuities and life-insurance, which presupposed such a law, existed indeed in the Middle Ages, but they were not regarded as a business which could be conducted on a scientific basis. The view taken by Süssmilch was carried further by the well-known Belgian writer, Quetelet (1796–1874), whose work entitled *Sur l'homme et le développement de ses facultés ou essai de physique sociale* declares that the constant averages in moral statistics are a proof that the actions of mankind are regulated by laws. The field of statistics as it was first defined was curtailed by the rise of independent sciences in the latter part of the eighteenth century. The development of political economy at the hands of Adam Smith took from statistics one phase of its investigation. The development of public and administrative law and of practical life-insurance deprived it of other lines of investigation. Thus the scope of statistics as originally held has been very materially narrowed.

*Is there a Science of Statistics?*—The phrase "science of statistics" has been loosely used to convey a number of indefinite ideas. Its claim to be a science usually rests on the observation of uniformity in those domains of human activity which are commonly regarded as subject to the control of the individual. For example, one would suppose that suicides, being wholly under the direction of the individual will, would show no rule of recurrence, but a study of the statistics of suicides shows that nothing is more constant in its recurrence than the cause for which, the time in which, and the manner by which suicides are committed. The same is true in any domain of human activity, so much so indeed that by the use of statistics one is able to predict with a very great degree of assurance what is likely to happen. This fact, however, does not seem to make good the claim that statistics may be regarded as an independent science, but indicates rather the possibility of scientific treatment of all social and moral questions. From this point of view statistics comes to be a method of investigation. It is not an independent science, but a branch of the science of logic. Were the existence of a science of statistics admitted, it would necessarily be a science that would include investigations into every department of political, social, and industrial life, since all of these may be studied by the statistical method. Accepting then statistics as a science of method, it may be regarded as consisting in a systematic observation and classification of facts.

*Methods of Comparison in Statistics.*—The chief use of statistical investigation, in addition to the discovery of laws of constant recurrence, is the discovery of laws of change. It is the peculiar office of statistics to discern the direction of progress and to measure both the actual and the relative strength of the forces which impel it, and this it does by providing the means of accurate comparison between conditions of society and phases of human activity at various times. This, however, is no light task. The difficulty in carrying it through arises from the fact that the mass of data necessary for accurate description is likely to be so great that the mind can not grasp it. The student who avails himself of statistics as a means of reasoning is, on this account, obliged to reduce the mass of information presented to him in the form of tables of figures to some simple equivalent for the purpose of comparison, or, if the data comprises incongruous factors, they must be reduced to some common denominator. There are several methods by which this may be accomplished, and the trustworthiness of the conclusions arrived at depends in very large measure upon the intelligence with which these methods are followed. Three of these methods may be noted: First, statistics may make use of percentages as a basis of comparison either for the purpose of measuring the relative importance of similar factors, which, taken in the aggregate, comprise a total, or for the purpose of measuring the progress or regress of specific lines of facts during a definite period of time. The chief error to which the use of percentages as a basis of comparison is liable arises from the failure to observe the basal numbers upon which percentages are computed. For example, an increase of 10 miles in railway mileage in a district which had but 10 miles to start with would show a higher percentage of increase than an increase of 1,000 miles in a district which had 10,000 miles of line at the outset. One who reasons by means of percentages must hold constantly in mind that he is dealing with ratios and not with absolute facts. A second method of bringing large masses of facts into usable shape is by means of "index figures." All investigations must of course begin at some definite period of time, and all the facts subjected to observation are arbitrarily reduced to some common basis. The subsequent changes for each line of facts are then set down in their relation to this assumed basis, and the divergence which in this manner is brought to light shows clearly the relative movements. For the purpose of illustration let it be assumed that one desires to investigate the changes in the prices of various commodities. The price of all articles considered will be set down, let us say, as 100; subsequent variations from what may be termed the original price are noted with relation to this figure, and the divergence of quotations from the assumed index figure shows the changes in price of any particular commodity as compared with other commodities. The general movement also in the price of commodities as compared with the index figure indicates the trend of general prices. Thus the index figure serves for the statistician a purpose similar to that which the "bench mark" serves for the civil engineer. Third, the most common basis of comparison is by means of averages. The idea of an average is to obtain a typical unit. A typical unit may be accepted as the representative of the mass of facts from which it is deduced, and as such can be used as a basis of comparison. There is great danger, however, in reasoning upon a basis of averages. This is not because the theory of averages is incorrect, but is due to the difficulty of obtaining an average which is really typical in character. Two rules must be observed in arriving at a true average. In the first place, a sufficiently large number of individual facts must be collected to nullify the influence of any unusual or abnormal cases. In the second place, individual facts should be allowed to influence the average in proportion to their relative importance. For example, wheat is relatively of more vital importance to the people than silks, and any investigation which holds in view the effect of changes in prices upon the wellbeing of a community must lay greater stress on variations in the price of wheat than in that of silks. Again, it will not do in determining the average of wages to rely upon the daily rate of wages reported as paid, but the number of days in the year for which the workmen receive the stated wages must also be taken into account. As in the case of percentages, it is necessary that averages should be used in an intelligent manner, and with a clear appreciation of what they mean and how they are obtained.

*Use of Statistics.*—The most familiar use made of statistics is to portray existing social conditions and to measure the strength of existing social forces. A statistical inquiry has been aptly termed an instantaneous photograph expressed in figures. They are of immense importance to the statesman in gaining a knowledge of the exact condition of the country, and if several statistical investigations, taken at different times, be subjected to comparative scrutiny and studied in the light of current history, the knowledge thus gained should guarantee society against pernicious legislation. This is the original idea of statistics, and it is perhaps at present the most significant. The economist and the student of philosophy also derive great assistance from statistical investigations in that they throw light upon the character of nations and the character of individuals, without which no trustworthy conclusions may be arrived at. At present, however, there is another and a more practical use which statistics are in some degree coming to serve. The tendency toward combination of industries and concentration of capital is very marked. The trust and various forms of combinations among corporations seem to have become a permanent form of industrial organization. This tendency has brought society face to face with the monopoly problem, and the question frequently presents itself, How will society be able to control this great aggregation of capital and at the same time maintain the conditions of individual liberty? Without attempting a discussion of this question, it is suggested that the more clearly the organic character of society is recognized the more complete will be the reliance placed upon the principle of publicity as a principle of control. Wherever the principle of publicity is realized, however, there statistics must become of relatively more and more importance. The final use of statistics, then, as here suggested, is that they may serve as the medium for realizing the conservative influence which lies in the principle of publicity. The revival of interest in statistics since 1870 can only be explained by a recognition of their great importance from the point of view of administrative control.

*Branches of Statistical Inquiry.*—There is no limit, so far as theory is concerned, to the possible development of statistical investigation, nor is there any universally accepted classification. The classification here submitted is the one adopted by Haushofer, professor in the School of Technology at Munich, and gives four heads: Population statistics, industrial statistics, statistics of social and political life, and moral statistics. Under population statistics are included an extensive class of facts. Thus in addition to the actual count there is included a classification of population by territorial groups for the purpose of discovering the density of population. Changes in population are also included, thus bringing into notice all questions of birth-rate and death-rate (see VITAL STATISTICS) and immigration. The facts pertaining to the physical life of the people are also included under population statistics, as, for example, expectation of life at various ages (see LIFE-INSURANCE), classification on a basis of age, and other like facts. Under industrial statistics are included all facts pertaining to the production, the exchange, the distribution, and the consumption of wealth, as also to the means or instruments by which the industrial process is carried on. Statistics of wages, capital, railways, money, prices, and the like are all included under the head of industrial statistics. The statistics of social and political life include that large range of facts descriptive of the manner in which people live and of the governments under which they live. Under the head of moral statistics are included all facts which indicate the character and habits of the people. Here are to be found the statistics of education, of religion, of crime, of marriage, of the dependent classes, and others of like character.

*Official Statistics in the U. S.*—It is not possible to give a complete list of the bureaus of investigation for which the State and Federal governments have made provision in the U. S., but a few of the more important may be mentioned. In the Federal Constitution it is provided that a census shall be taken once in ten years, and many of the States also require that a State census shall be taken at certain intervals. In 1870 the scope of the Federal census was greatly extended until at present it may be regarded as a statistical bureau in the widest sense of that term. (See CENSUS.) The Agricultural Department has a bureau of statistics which aims to collect all facts of interest to the growers and consumers of farm products. The Treasury Department, in addition to financial statistics, maintains a bureau of statistics which makes regular reports on the imports and exports of the U. S. The comptroller of the currency makes annual reports upon the condition of banking, and the director of the mint upon coinage and the production of the precious metals. The commissioner of education publishes a yearly report on education in the U. S., showing the number of schools, colleges, and universities in the republic, the number of pupils attending each grade of school, the number of teachers, their compensation, and other similar facts. There is also a department of labor established by Congress for the purpose of collecting statistics of especial interest to the working classes. The interstate commerce commission also provides for an annual publication of the statistics of railways. In addition to these provisions for the collection and compilation of statistics, Congress frequently authorizes special investigations into special topics. The public documents of the Federal Government are rich in statistical material, while many of the States maintain efficient bureaus for the collection of facts of local interest.

LITERATURE.—The following are some of the important statistical works: *Lehr- und Handbuch der Statistik*, by Dr. Max Haushofer; *Traité Théorique et Pratique de Statistique*, by Maurice Block; *The History, Theory, and Technique of Statistics*, by August Meitzen, translation into English by Roland Falkner; *Die Moralstatistik*, by Alexander von Oettingen; *Journal of the London Statistical Society*; publications of the American Statistical Association; *Bulletin de l'Institut International de Statistique.*

HENRY C. ADAMS.

**Sta'tius**, CÆCILIUS: See CÆCILIUS STATIUS.

**Statius**, PUBLIUS PAPINIUS: author; b. about 45 A. D. in Naples; seems to have acquired early and rapidly a great fame by his victories in the Alban poetical contests, and then to have lost it again as rapidly after his defeat in the quinquennial contest instituted by Domitian, but very little is known of his personal life. He lived at one time in Rome and enjoyed the favor of Domitian, but died about 96 A. D., in retirement at Naples. Juvenal is the only contemporary author who mentions him. For the story that Domitian stabbed him in a fit of anger there is no foundation. Of his works are still extant *Silvarum Libri V.*, a collection of miscellaneous poems; *Thebaidos Libri XII.*, translated into English, the first book by Pope, the first five books by Thomas Stephens (1648), the whole poem by W. L. Lewis (1767); *Achilleidos Libri II.*, unfinished, translated into English by Howard (1660); best editions by Amar and Lemaire (4 vols., Paris, 1825–30); *Thebaidos Libri I.–VI.*, by O. Müller (Leipzig, 1870); *Silvæ*, by Bährens (Leipzig, 1876); and *Achilleis und Thebais*, by Kohlmann (Leipzig, 1879–84).

Revised by M. WARREN.

**Statoblast**: one of the peculiar thick-walled buds occurring in fresh-water sponges and polyzoans, which serve to carry the species over periods of drought or of freezing weather.

**Statuary**: See SCULPTURE.

**Sta'tus**: a term of the Roman law, borrowed thence by the jurisprudence of continental Europe, denoting the legal condition of a person, or the sum of his capacities and incapacities to hold legal rights or to be subjected to legal duties. The word does not belong to the technical nomenclature of the American and English law, although it is used by some modern text-writers in the same general sense in which it was employed by the Roman jurists. In the Roman law there were three grades of status or legal condition, the lower and more general of which might exist without the others, while the higher and more special always presupposed the lesser. The first and most general was that of liberty (*status libertatis*), by virtue of which a person was either a freeman (*liber*) or a slave (*servus*). The second was that of citizenship (*status civitatis*), by virtue of which a person was either a citizen (*civis*) or a stranger (*peregrinus*). The highest was that of the family (*status familiæ*), by virtue of which a person might be the head of a household (*paterfamilias*) and his own master (*sui juris*), or under the control of another (*alieni juris*), as a son, daughter, wife, ward, and the like. An individual might be a freeman without being a citizen or the head of a household, but he could not be the head of a household without being at the same time a freeman and a citizen. It was possible that a person might lose a higher status, and yet remain in a lower condition; he might cease to be *sui juris*, and still be a citizen; he might forfeit his citizenship, and yet remain free; finally, in the earlier periods of Roman history at least, he might sink from freedom into slavery. Although there is not in U. S. law the technical term *status*, it is plain that to a certain extent the facts denoted by it are present. It is true that at birth a person becomes clothed with the great mass of rights conferred by the law of the U. S., but he may be subjected to certain special capacities or incapacities depending upon the existence of particular circumstances. Among these incapacities are those resulting from infancy, lunacy, marriage in case of the wife, conviction or imprisonment for crime, public pauperism, and the like. Among the special capacities the most important are those pertaining to citizenship and to the electoral franchise. In the U. S. the differences of legal condition or status belonging to class, rank, profession, or trade have no existence, for every person—at least every sane person—is clothed with the same capacity in respect to these subjects. See LIBERTY, CITIZEN, and MARRIAGE. Revised by F. M. BURDICK.

**Statute of Frauds**: See FRAUDS, STATUTE OF.

**Statutes** [viâ O. Fr. from Late Lat. *statu'tum*, liter., something established, neut. perf. partic. of *statu'ere*, *statutum*, set up, establish, deriv. of *sta'tus*, condition, status]: laws in a written form enacted by the supreme legislative authority of a nation or commonwealth, as contradistinguished from laws established by judicial decision. In its generic sense the term includes all legislative as opposed to judicial creations of the law, whatever be the nature and organization of the body—persons or person—which exercises the creative function.

*Their Sources.*—The sources from which statutes have emanated or may emanate, according to the varying political constitutions of different states, are the general or partial assemblies of the citizens, the emperors, kings, or other single heads of despotic governments, and the representative assemblies, either hereditary or elective. The *leges* and *plebiscita* of the Roman citizens during the republic were produced by the first class of legislators; the "constitutions" of the Roman emperors by the second; while the parliaments of Great Britain and of many other European nations, the U. S. Congress, and the State Legislatures are the modern forms of the third. The extent of the powers held by these bodies is determined by the organic law of each country. The British Parliament is said to be omnipotent; which simply means that the restrictions under which it ordinarily acts are self-imposed. In the U. S. the most remarkable feature of the political organization is the express, positive, and extensive limitation of the legislative function contained in all the written constitutions, which are themselves fundamental statutes adopted by the people in their sovereign capacity. With every new revision of the State constitutions this limitation in reference to the forms and modes of legislation, as well as its subject-matter, is made more far-reaching, minute, and prohibitory.

*Their Kinds.*—Statutes are variously classified, according to their external form and according to their subject-matter and effects. See LAW and JURISPRUDENCE.

*Their Parts.*—Statutes in Great Britain and the U. S. may, and sometimes do, comprise the following distinct parts: the title, the beginning or enacting clause, the preamble, and the purview. The *title* is a brief preliminary description, e. g. "An act for the amendment of the law." It has become of great importance in the law of the U. S., since most of the State constitutions prescribe in substance that every statute shall contain but one subject, and that this shall be properly expressed in the title. By the *commencement* is meant the formal enacting clause—namely, "Be it enacted by the Senate and House of Representatives of the U. S. of America, in Congress assembled," and "Be it enacted by the queen's most excellent majesty, by and with the advice and consent of the Lords spiritual and temporal and Commons in this present Parliament assembled, and by the authority of the same." The *preamble* is a preface setting forth the reasons and motives for the act. Once very common, it is now generally omitted. The *purview* is the main body, the effective portion of the statute, which contains a statement of the legislative will, and declares its object and purpose. Among the special clauses or subdivisions which may be found in it are the interpretation clause, the saving clause, the repealing clause, the provisoes, the exceptions, and the schedules, the objects of which are sufficiently indicated by their names. In codes, whether complete or partial, a more orderly and scientific arrangement of parts is always made, and a division, according to some general plan, into books, titles, chapters, sections, and the like is universal.

*When Operative.*—The time when statutes take effect is fixed in most of the States of the U. S. either by a constitutional provision or by a general law. In some they become operative at the expiration of a specified number of days after the close of the session, in others at a specified period after the day of their passage; but the Legislature may in the body of a statute prescribe a different time, as, for example, that it shall take effect immediately. The common law made an act operative from the first day of the session at which it was passed, but this absurd doctrine was abolished in the thirty-third year of George III., and all laws were declared to be binding from the time when they received the royal assent. The repeal of a statute may be either express or by implication. It is express when effected by a clause inserted for that specific purpose in a subsequent act; it is by implication when the provisions of a later enactment are wholly and irreconcilably inconsistent with those contained in an earlier one. Repeal by implication is not favored. If the two statutes concerning the same subject-matter can possibly be harmonized, both will stand; if the contradiction is absolute, the prior one gives way. For a treatment of other topics connected with the general theory of statutes, see INTERPRETATION, CONSTITUTION, CODE, LAW, and LAW-MAKING, METHODS OF.

Revised by F. STURGES ALLEN.

**Statutes of Limitation**: See LIMITATION OF ACTIONS.

**Stäudlin**, stoid-leen', KARL FRIEDRICH: author; b. at Stuttgart, July 25, 1761; studied theology at Tübingen 1779–84; traveled in Switzerland, France, and England, and was appointed in 1790 Professor of Theology at Göttingen, where he died July 5, 1826. His numerous writings relate mostly to Church history, such as *Universalgeschichte der christlichen Kirche* (Göttingen, 1806; 5th ed. 1833); *Kirchliche Geographie und Statistik* (2 vols., 1804); *Allgemeine Kirchengeschichte von Grossbritannien* (2 vols., 1819); or to the history of special theological disciplines, such as *Geschichte der Sittenlehre Jesu* (4 vols., 1799–1822); *Geschichte der christlichen Moral seit dem Wiederaufleben der Wissenschaften* (1808); *Geschichte der Moralphilosophie* (1822), etc. His first work, strongly impregnated by the reigning rationalism, was *Geschichte und Geist des Skepticismus* (2 vols., 1794). His autobiography was published by J. T. Hemsen (1826). Revised by S. M. JACKSON.

**Staunton**: village; Macoupin co., Ill.; on the Chi., Peoria, and St. L. and the Wabash railways; 14 miles S. S. W. of Litchfield, 36 miles N. E. of St. Louis (for location, see map of Illinois, ref. 8–D). It is in an agricultural and coal-mining region, and contains a private bank and a weekly newspaper. Pop. (1880) 1,358; (1890) 2,209; (1900) 2,786.

**Staunton**: city (incorporated in 1749); capital of Augusta co., Va.; on the Balt. and Ohio and the Ches. and Ohio railways; 39 miles W. by N. of Charlottesville, 60 miles N. of Lynchburg (for location, see map of Virginia, ref. 5–F). It is in an agricultural region; has important manufactories; is the seat of the State Deaf, Dumb, and Blind Institution and of the Western Lunatic Asylum; and is noted for its educational institutions, which include a military academy, 4 seminaries for young ladies, and 2 business colleges. There are 2 national banks with combined capital of $300,000, a savings-bank, and a daily, a monthly, and 8 weekly newspapers. Pop. (1880) 6,664; (1890) 6,975; (1900) 7,289. EDITOR OF "NEWS."

**Staunton**, Sir GEORGE LEONARD: traveler and diplomatist; b. at Cargin, Galway, Ireland, Apr. 19, 1737; educated at Dublin and at Montpellier, France, where he graduated in medicine; returned to England 1760; wrote for London periodicals, acquiring the friendship of Dr. Johnson and other eminent men of letters; settled in 1762 as a physician in the island of Grenada in the West Indies, where he held several official positions, including that of attorney-general, for which he had qualified himself by legal study, and acquired a considerable fortune, which he invested in landed estates; formed in 1774 an intimate friendship with Lord Macartney, the new governor of the island, with whom he was sent prisoner to France on the capture of Grenada in 1779, and whom he accompanied as secretary during his governorship of Madras (1781–84) and his celebrated embassy to China (1792), of which he published in 1797 an interesting narrative. D. in London, Jan. 14, 1801. He was made a baronet 1784 in reward for his success in negotiating a treaty with Tippoo Sahib.—His son, Sir GEORGE THOMAS, b. at Milford, England, May 26, 1781, accompanied his father to China in 1792; learned the Chinese language; held important posts in China in the service of the East India Company; returned to England 1817, and was a member of Parliament, with short intervals, from 1818 to 1852. D. Aug. 10, 1859. He wrote a *Memoir* of his father (1823), an autobiography (1856), and published various works on China.

**Staunton**, HOWARD: Shakspearean scholar and chess-player; b. in England in 1810; educated at Oxford; settled in London; was the champion chess-player of his day; edited for many years *The Chess-players' Chronicle* and the chess column of *The Illustrated London News*; published several manuals of the game, including the *Handbook* (1847), the *Companion* (1849), the *Chess Tournament* (1851), and *Chess Praxis* (1860). He published an edition of Shakspeare's *Plays and Poems* (3 vols., 1857–60, and library ed., 4 vols., 1863), preceded by a *Life*, a photo-lithographic facsimile of the celebrated "first folio" of 1623 (1866); *Memorials of Shakspeare, his Will, Indentures of Conveyance, etc.*, photographed (Apr., 1864); also published *The Great Schools of England* (1865; 2d ed. 1869). He was extremely familiar with Elizabethan dramatic literature, and sometimes acted, chiefly in Shakspearean dramas. D. in London, June 22, 1874. Revised by H. A. BEERS.

**Staunton**, WILLIAM, D. D.: clergyman; b. at Chester, England, Apr. 20, 1803; removed to the U. S. in 1818; was ordained deacon in the Protestant Episcopal Church June 9, 1833, and priest Sept. 7, 1834; rector of churches at Roxbury, Mass., Morristown, N. J., Brooklyn, N. Y., and Potsdam, N. Y. He was the author of *A Dictionary of the Church* (New York, 12mo, 1844), republished, much enlarged, as *An Ecclesiastical Dictionary* (New York, 8vo, 1861); *The Book of Chants, Songs, and Prayers for the Family Altar* (1860); *The Book of Common Praise* (1866); *Voluntaries for the Organ*; and a prize *Te Deum*. D. in New York, Sept. 29, 1889.

**Staunton River**: a stream of Southern Virginia; rising in the Alleghany Mountains in Montgomery County, flowing E. and S. E. through a pass in the Blue Mountains, and uniting with the Dan at Clarksville, Mecklenburg County, to form the Roanoke. In the first 20 miles of its course it descends 1,000 feet; its entire length is about 200 miles.

**Staupitz**, stow'pits, JOHANN, von: ecclesiastic; descended from a noble family in Meissen, but his parentage and birthdate are unknown; entered the Augustinian order; became prior of its convent in Tübingen 1497, where he took D. D. 1500. Turning entirely from the barren method of the schoolmen, he found in the writings of Augustine and the mediæval mystics his spiritual models; took a very active part in the foundation of the University of Wittenberg 1502, and was appointed its first Professor of Theology; became, as vicar-general of the Augustine order in Germany (1503), acquainted with the young Luther, for whom he conceived a warm friendship, and on whom he exercised considerable influence; procured his appointment as professor in Wittenberg 1508, approved fully of his theses against the sale of indulgences, and gave him, during the first stage of his contest with the Roman Catholic Church, his valuable and effective support. Subsequently, when the controversy became too violent, and an open breach with the Church took place, he retired from Wittenberg 1512, but continued to be vicar-general until 1520. He then went to Salzburg as court-preacher to the archbishop and became abbot of a Benedictine monastery 1522. D. there of apoplexy, Dec. 28, 1524. His friendship for Luther remained unabated to his death; all the Reformer's writings were found in his library, and his own works, *De Amore Dei* and *De Fide Christiana*, show the spiritual sympathy he felt for the Reformation. Roman Catholic writers have explained the support he gave Luther as an act of jealousy because the sale of indulgences was given to the Dominican and not to the Augustine order. A new edition of his works was begun by J. K. F. Knaake (vol. i., *Deutsche Schriften*, Gotha, 1867). For his *Biography*, see works by T. Kolde (Gotha, 1879) and L. Keller (Leipzig, 1888).

**Stavang'er**: an old town of Norway; at the head of Buknefjord; about 100 miles S. of Bergen (see map of Norway and Sweden, ref. 11–A). It has a cathedral dating from the eleventh century and two harbors. It exports timber and salt herrings. Pop. (1891) 23,930.

**Stave**, or **Staff**: in music, the lines and spaces on which the notes are placed. See NOTATION.

**Stavenhagen**, BERNHARD: See the Appendix.

**Stavro'pol**: government of Russia, bordering on the Caspian Sea; area, 23,397 sq. miles. It is mostly low and flat, dotted all over with shallow lakes and covered with extensive swamps. In the southwestern part agriculture is the principal occupation; wheat, millet, wine, and mulberries are cultivated. In the northeastern part the inhabitants are nomads, and immense herds of cattle, horses, and sheep are reared. Pop. (1897) 873,863.

**Stavropol**: capital of the government of Stavropol, Russia; a fortified town with a trade in cattle, horses, sheep, skins, wool, and honey (see map of Russia, ref. 11–F). Its sulphur springs are much frequented. Pop. (1897) 41,621.

**Stchedrin**, stched-reen': pseudonym of MIKHAIL EVGRAFOVICH SALTYKOV', a satirical writer born in the government of Tver, Russia, Jan. 15, 1826. He entered the Government service in St. Petersburg in 1844, but was removed two years later to Viatka for his two first published stories. Pardoned in 1855, he continued his official career till 1863, after which he devoted himself exclusively to literature. He ranks with the greatest Russian authors of his day, and with the chief satirical ones of all time. In his numerous tales and sketches he touched on every class of society, bringing out with masterly skill their characteristics, at times with brilliant wit, at others with deep pathos, alternately scathing, sad, and amusing, full of originality as well as of the most acute observation. Unfortunately, his works demand an intimate acquaintance with Russian affairs, and, owing to the necessity of escaping the jealousy of the censors, often have to convey their meaning by allusions almost impossible for a foreigner to grasp. Of the many volumes of his works, among the best known are the *Satiry v Proze* (Satires in Prose) and *Nevinnye Raskazy* (Innocent Tales, both in 1863); *Dvevnik Provintsiala* (Diary of a Provincial), *Tashkentsy* (The People of Tashkend), *Blagonamerennyia Rechi* (Well-meant Speeches, 1876), etc. Two or three of his stories have been translated into English; more into French and German. D. in St. Petersburg, May 10, 1889. A. C. C.

**Stead**, WILLIAM THOMAS: journalist; b. at Embleton, Northumberland, England, July 5, 1849; son of a Congregational minister; became editor of *The Northern Echo*, a halfpenny daily, 1871; assistant editor to John Morley on *The Pall Mall Gazette* Sept., 1880; editor of that paper 1883–90; founded *The Review of Reviews* Jan., 1890. As the editor of *The Pall Mall Gazette* he introduced the system of interviewing and illustrations into the daily newspapers of Great Britain. In July, 1885, he published *The Maiden Tribute of Modern Babylon*. For some of his acts in procuring the evidence on which his statements were based he was imprisoned for three months. The Criminal Law Amendment Act of 1885 was passed in consequence of his exposures. In 1893 he established *Borderland*, a periodical devoted to Spiritualism. He has also published *No Reduction, No Rent, a Plea for the Plan of Campaign*; *Truth about Russia*; *The Pope and the New Era*; and *If Christ came to Chicago*. C. H. THURBER.

**Steam** [M. Eng. *stem* < O. Eng. *stēam*, vapor, smoke: Dutch, *stoom*: Fris. *stoame*, steam]: aqueous vapor. This substance is of great interest to students of physics and likewise, on account of its application in nearly all thermal engines, to the engineer.

The physical properties of steam, which, like those of other vapors, are less simple than those of a perfect gas, have been exhaustively studied. Some of these properties will be briefly described.

*Fluctuations of Boiling-point, Maximum Tension.*—Water is converted into steam, at all temperatures, by evaporation. Even below the freezing-point the solid aqueous materials known as ice and snow evaporate slowly unless surrounded by an atmosphere saturated with aqueous vapor.

The process by which steam is obtained for practical purposes, however, is ebullition, which begins whenever, at any temperature, the tension of the forming vapor within the mass of the liquid becomes equal to the pressure exerted upon it by the liquid itself and by the superincumbent atmosphere above the surface of the latter. Boiling depends then upon a property of steam which enables it to exert pressure, an expansive power which is a function of the temperature. This property, for which the term tension, or sometimes vapor-tension, is used, has been determined with the utmost exactitude by Regnault. His results are given in Table I., in which the vapor-tension is expressed by means of the height (in centimeters) of the column of pure mercury which the steam is capable of sustaining. This is the quantity given in the second column. It is also expressed in terms of the pressure in grammes which the steam exerts upon a square centimeter of surface (third column of the table).

If the data given in the first two columns of Table I. are plotted with temperatures as abscissas and tensions as ordinates, the result will be a graphical representation of the results obtained by Regnault. This method of presentation

TABLE I.—TENSION OF STEAM AT VARIOUS TEMPERATURES.

| Temperature. | Tension in cm. | Pressure upon 1 sq. cm. | Temperature. | Tension in cm. | Pressure upon 1 sq. cm. |
|---|---|---|---|---|---|
| | | Grammes. | | | Grammes. |
| −30° C. | 0·0386 | 0·52 | 105° C. | 90·641 | 1,232·36 |
| −25 | 0·0605 | 0·82 | 110 | 107·537 | 1,462·10 |
| −20 | 0·0927 | 1·26 | 115 | 126·941 | 1,725·90 |
| −15 | 0·1400 | 1·90 | 120 | 149·128 | 2.027·55 |
| −10 | 0·2093 | 2·85 | 125 | 174·388 | 2,370·98 |
| −5 | 0·3113 | 4·23 | 130 | 203·028 | 2,760·37 |
| 0 | 0·4600 | 6·25 | 135 | 235·373 | 3,200·13 |
| +5 | 0·6534 | 8·88 | 140 | 271·763 | 3,694 90 |
| 10 | 0·9165 | 12·46 | 145 | 312·555 | 4,249·50 |
| 15 | 1·2699 | 17·27 | 150 | 358·123 | 4,869·04 |
| 20 | 1·7391 | 23·65 | 155 | 408·856 | 5,558·81 |
| 25 | 2·3550 | 32·02 | 160 | 465·162 | 6,324·34 |
| 30 | 3·1548 | 42·89 | 165 | 527·454 | 7,171·27 |
| 35 | 4·1827 | 56·87 | 170 | 596·166 | 8,105·47 |
| 40 | 5·4906 | 74·65 | 175 | 671·743 | 9,133·02 |
| 45 | 7·1391 | 97·06 | 180 | 754·639 | 10,260·1 |
| 50 | 9·1981 | 125·05 | 185 | 845·323 | 11,493·0 |
| 55 | 11·7478 | 159·72 | 190 | 944·270 | 12,838·3 |
| 60 | 14·8791 | 203·23 | 195 | 1,051·963 | 14.302·5 |
| 65 | 18·6945 | 254·17 | 200 | 1.168·896 | 15,892·3 |
| 70 | 23·3093 | 316·92 | 205 | 1,295·566 | 17,614·5 |
| 75 | 28·8517 | 392·27 | 210 | 1.432·480 | 19,476·0 |
| 80 | 35·4643 | 482·17 | 215 | 1,580·133 | 21,483·5 |
| 85 | 43·3041 | 588·77 | 220 | 1,739·00 | 23,643·9 |
| 90 | 52·5450 | 714·40 | 225 | 19.097·04 | 25,964·3 |
| 95 | 63·3778 | 861·68 | 230 | 20,926·40 | 28,451·5 |
| 100 | 76·0000 | 1,033·30 | | | |

offers many advantages over a table, but in order to make it of service in a case like the above it must be plotted to a very large scale. Fig. 1 shows the general form of the curve between + 40° and + 230° upon a scale too small to be of service for actual readings.

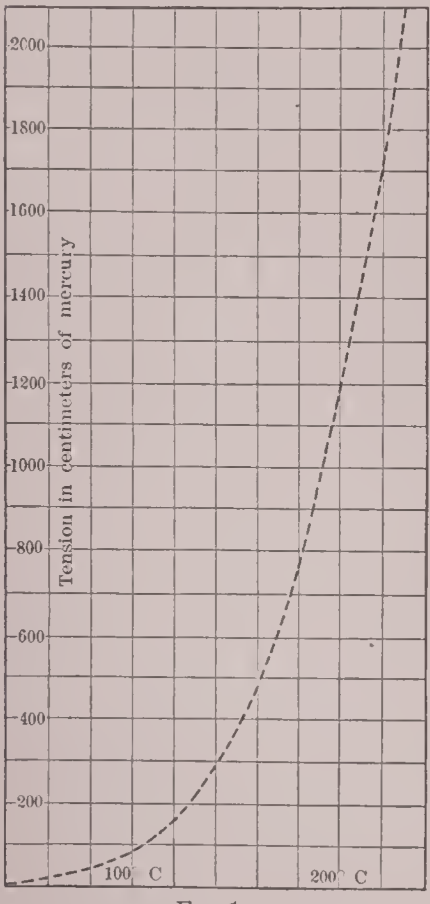


FIG. 1.

For many practical purposes one needs to use only a small portion of the entire range of temperatures. If, for example, the change in boiling-point under ordinary barometric fluctuations is desired, the extreme range of ordinates to be considered is from 70 cm. to 80 cm. Fig. 2 is such a boiling-point curve. It follows from the definition of ebullition given in an earlier paragraph that the boiling-point corresponding to a given pressure is simply the temperature at which steam acquires a tension equivalent to the pressure in question. Since tensions, like atmospheric pressures, are measured in centimeters of mercury, the tension-curve for a vapor is also the boiling-point curve of the liquid for the same range. Thus in Fig. 2 abscissas give temperatures at which aqueous vapor attains various tensions, and also the temperatures at which water boils when subjected to atmospheric pressures represented by the ordinates of the curve.

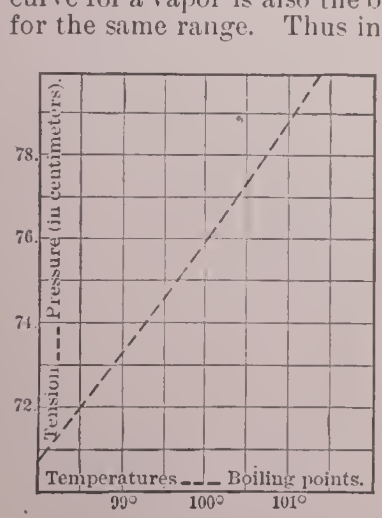

FIG. 2.

Closely related to the property of steam just described, and equally important, are its variations of volume when subjected to changes of temperature and pressure. A perfect gas possesses a coefficient of expansion (by constant pressure) of 0·00367, a coefficient constant for the range of pressures and temperatures within which the gas obeys Charles's law. Steam, according to Hirn (*Théorie mécanique de la Chaleur*), possesses a coefficient considerably larger than the above at ordinary temperatures and gradually approaches it as the temperature rises. See Table II.

TABLE II.—COEFFICIENT OF EXPANSION OF STEAM AT CONSTANT PRESSURES.

| Range of temperature. | Mean coefficient. |
|---|---|
| 0° to 119° | 0·004187 |
| 0° to 141° | 0·004089 |
| 0° to 162° | 0 004071 |
| 0° to 200° | 0·003938 |
| 0° to 247° | 0·003799 |

The behavior of a gas or vapor when subjected to simultaneous changes of *pressure* and *temperature* can be expressed by means of a surface, the three Cartesian co-ordinates of which are *volume* ($v$), *pressure* ($p$), and *temperature* ($t$). For a perfect gas this surface is hyperbolic, its intersection with any plane parallel to the axes $v$ and $p$ being a rectangular hyperbola (Fig. 3). This hyperbola is an isothermal curve for the gas. The intersection of the surface with planes parallel to the axes $v$ and $t$ forms a series of straight lines, showing the relation between $t$ and $v$ for constant $p$. The characteristics of vapors, as distinguished from true gases, as has been pointed out in the article PNEUMATICS (*q. v.*), are too great compressibility to satisfy Mariotte's law and too great a change of volume when heated or cooled to satisfy the law of Charles. The result of these peculiarities is to alter the form of surface which exhibits the relation between $p$, $v$, and $t$ in such a manner as to cause the isothermal curves to deviate from the hyperbolic form, while at the same time the intersections with planes parallel to the plane $t\ v$ are no longer straight lines. The existence of such a divergence in the case of steam appears at once from inspection of Table II. The curve marked *Vapor* in Fig. 3 shows the character of the divergence of the isothermal curve from the hyperbolic form.

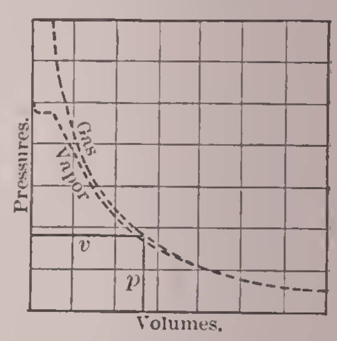

FIG. 3.

The conditions under which steam is made and used compel the consideration of its behavior under conditions different from those of an isolated mass of vapor, which loses nothing by condensation and gains nothing from the evaporation of contiguous liquid. Ordinarily we have steam in the presence of unvaporized water, from which it receives or to which it gives up portions of its substance at every change of condition. Steam thus situated is said to be saturated. It is much easier to study the properties of saturated than of unsaturated steam, and its behavior when in that condition is of prime importance.

*Energy required for the Production of Steam.*—In the conversion of a gramme of water at 0° C. into steam at any given temperature there is a double process: (1) the heating of the liquid up to the boiling-point, and (2) ebullition of the liquid. If the given temperature lies above the boiling-point for the pressure at which the experiment is to be performed—if, that is to say, we are to produce superheated instead of saturated steam—a third process must be added: (3) the heating of the vapor resulting from ebullition from the boiling-point to the required temperature.

To compute the expenditure of energy in these three processes the specific heat of water throughout the range of temperature, from 0° to the boiling-point, the heat of vaporization at the latter temperature, and the specific heat of steam must be known.

*The specific heat of water*, although taken as a reference unit in calorimetry, was found by Regnault to vary slightly from its value at low temperatures when the investigation was extended over a considerable range. This variation, the existence of which has been abundantly verified by subsequent observers, is of the nature of a very slight increase in the specific heat. Regnault expressed the change by means of the empirical formula,

$$c = 1 + 0{\cdot}00004t + 0{\cdot}0000009t^2,$$

in which $c$ is the specific heat and $t$ the temperature. Table III. gives the results of Regnault's determination.

*The heat of vaporization* of water is likewise a function of the temperature, diminishing as the temperature rises,

TABLE III.—SPECIFIC HEAT OF WATER (AFTER REGNAULT).

| Temperature. | Sp. heat. | Temperature. | Sp. heat. |
|---|---|---|---|
| 0° C. | 1·0000 | 120° C. | 1·0177 |
| 10 | 1·0005 | 130 | 1·0204 |
| 20 | 1·0012 | 140 | 1·0232 |
| 30 | 1·0020 | 150 | 1·0262 |
| 40 | 1·0030 | 160 | 1·0294 |
| 50 | 1·0042 | 170 | 1·0328 |
| 60 | 1·0056 | 180 | 1·0364 |
| 70 | 1·0072 | 190 | 1·0401 |
| 80 | 1·0098 | 200 | 1·0440 |
| 90 | 1·0109 | 210 | 1·0481 |
| 100 | 1·0130 | 220 | 1·0524 |
| 110 | 1·0153 | 230 | 1·0568 |

and finally disappearing altogether at the "critical temperature" of the liquid.

The heat of vaporization of water between 0° C. and 200° C., and the *total heat* in lesser calories necessary to convert a gramme of water at 0° into steam at the required temperature, are given in Table IV. The quantity designated as *total heat* is calculated by means of the equation

$$\gamma = \int_0^t c dt + r,$$

where $\gamma$ is the total heat, $c$ the specific heat of water, $o - - - t$ is the range of temperatures through which it is necessary to raise the water to bring it to the boiling-point, and $r$ is the heat of vaporization at the boiling-temperature.

TABLE IV.—HEAT OF VAPORIZATION AND "TOTAL HEAT" OF STEAM.*

* From Zeuner's *Grundzüge der mechanischen Wärmetheorie.*

The relations of *heat of vaporization* and *total heat* to one another and to the temperature are shown graphically in Fig. 4, in which abscissas are temperatures. The curve marked $r$ represents the heat of vaporization, and that marked $\gamma$ the total heat.

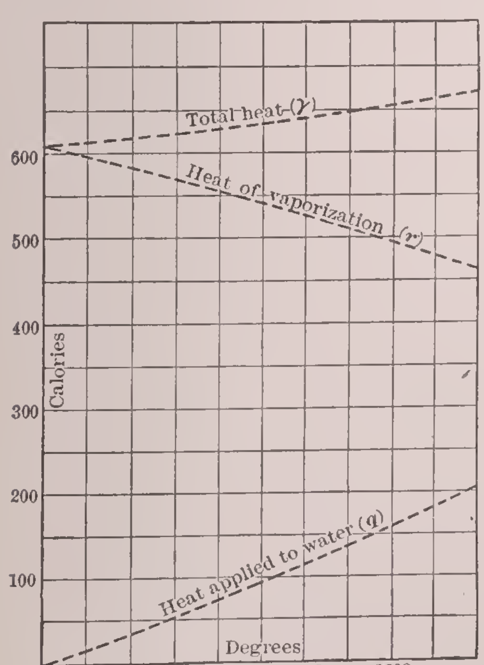

FIG. 4.

*The specific heat of steam* is a subject the experimental investigation of which presents great difficulty. The data thus far obtained show, as might be expected, wide divergence. Thus Regnault found the mean specific heat between 128° and 217° C. to be 0·48051, while Gray (*Philosophical Magazine*, 5, xiii., 1882) obtained for the lower range of temperatures, 100° - - - 125°, the value 0·3787.

Fortunately a precise knowledge of the specific heat is not of prime importance in most practical cases, since the total amount of heat-energy expended in superheating steam is insignificant when compared with that necessary to its production. The study of the properties of a vapor like steam are rendered difficult on account of the presence of finely divided water in the unvaporized form of spray, by the admixture of air, and likewise by the fact that any complete investigation involves the use of temperatures difficult to measure with precision, and of pressures hard to deal with experimentally. The engineer, for his part, is embarrassed by the fact that he must use steam sometimes wet and sometimes superheated, and under circumstances such that it is often impossible to know its precise condition. See Regnault, *Quelques Expériences*; Hirn, *Théorie mécanique de la Chaleur*; Clausius, *Theory of Heat*; Preston on *Heat*; also the chapters on heat, and especially thermodynamics, in the various larger text-books of physics. For the applications of steam in theory and practice, see Rankine's classical work on the steam-engine; Ewing, *Steam and other Heat Engines*; the treatises by Thurston on the same subject, and Carpenter's *Manual of Steam Engineering*. See also LIQUIDS (*Properties of Liquids*), GAS, HEAT, PNEUMATICS, and STEAM-ENGINE. E. L. NICHOLS.

**Steam-boiler**: an apparatus for generating steam by the application of heat. It may be described in general terms as a closed metallic vessel, kept partly filled with water, with arrangements for imparting heat to the water by means of the combustion of fuel. The steam generated is confined in the vessel above the water until it is required for use, when it is drawn off through pipes. This metallic vessel, with its compartments and openings, takes the name of "boiler" in the shops where it is manufactured; but in many classes or forms of boilers the steam-generating apparatus is not complete until the boiler is set up in brickwork, with an external furnace constructed for the combustion of the fuel, and external flues made for conducting the heated gases to the chimney along the sides of the boiler. In others the boiler is ready for use as it comes from the manufacturer, having within its external shell all these necessary arrangements for combustion and draught. In all cases certain adjuncts and appurtenances are necessary, such as the feed-pump or other means of supplying water, with the necessary pipes and attachments, the safety-valve, the steam and water gauges, and grate-bars for the furnace.

Connected with its uses as an instrument of industrial economy the boiler has become an object deserving and requiring the most thorough and critical study. The primary conditions which steam-generators should fulfill are (1) strength to sustain the internal pressures to which they will be subjected; (2) durability; (3) economy or efficiency in evaporating qualities; (4) economy of construction in materials and workmanship; (5) adaptation to the particular circumstances of their use. (6) To these conditions must be added safety, which depends on form, construction, strength, and qualities of materials, as well as upon management.

*Types of Boilers.*—In regard to forms and adaptation to various uses, boilers may be classified under a few types, which serve to illustrate not only general principles of construction, but the adaptability of the various forms to particular circumstances of use.

While the sphere is a form of inclosing envelope which is best adapted for the resistance of internal fluid pressure, it is not the best adapted for the application of heat, nor is it the form of cheapest construction. By having every section a circle, no cross strain is brought upon the metal, but is in uniform tension in every direction. The nearest approach to it which is practicable is the cylinder with hemispherical ends, and it will therefore be found that the cylinder is the initial form of most of the steam-generators.

Boilers may be divided into two great groups known as the externally fired boilers and the internally fired boilers, respectively. In the first class are included all the boilers whose furnace is external to the proper structure of the boiler, and in the second class all those in which the water to be evaporated surrounds the furnace. The first class require a brick setting, while the second class do not, but are self-contained. The latter, while usually more costly, have these advantages: There is less loss of heat from radiation; they make steam rapidly; and a great evaporative capacity is secured in a very compact form.

Of the *externally fired* class, a form much used where gaseous fuels are employed and where the water contains chemical salts liable to precipitation upon boiling is the plain cylinder type shown in Fig. 1. A modification of it to secure additional heating-surface without increased diameter is known as the French or Elephant boiler, shown in Figs. 2

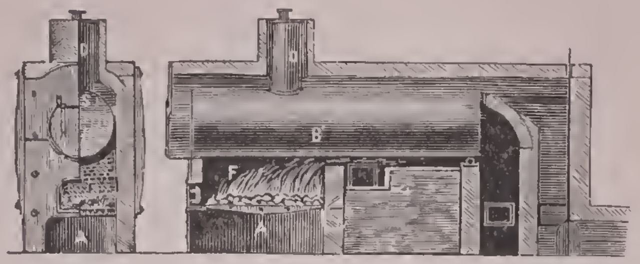

Fig. 1.—Plain cylinder boiler set in brickwork.

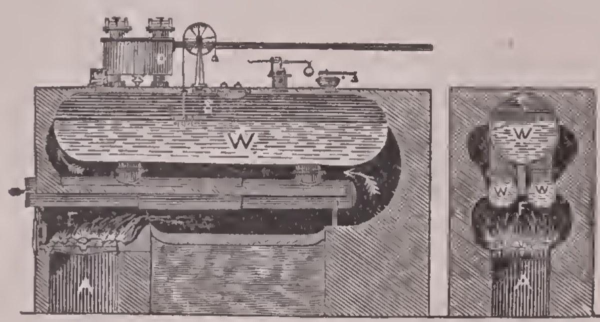
and 3. This type has been much used in iron-works practice, where it is desired that a large volume of water serve to



Figs. 2 and 3.—French boiler. A, ash-pit; F, furnace; W, water-space; S, steam-space; D, steam-dome.

store the heat given off from metallurgical furnaces when there may be considerable variation in the intensity of combustion from time to time.

The next types of externally fired boilers are those containing, in the space devoted to water, flues or tubes through which the hot gases pass on their way to the chimney. The difference between a flue and a tube is that of size merely, a tube larger than 8 inches in diameter being designated as a flue. The flue boiler is shown in Figs. 4 and 5, and the

Figs. 4 and 5.—Cylinder-flue boiler.

tubular boiler in Fig. 6. The flue boiler is preferred where the fuel has a long flame from the presence of combustible gas, since the fine subdivision of the products of partial combustion in the tubes tends to extinguish the flame before the union with oxygen is complete. On the other hand, where the fuel is anthracite, or where the combustion can be completed before the gases enter the tubes, the extended

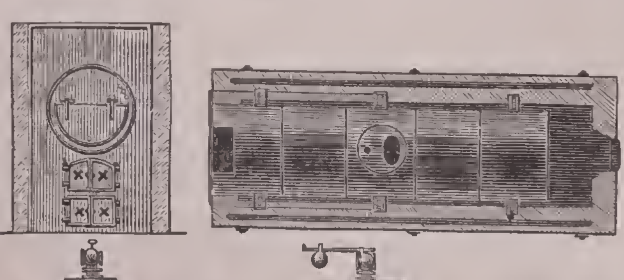


Fig. 6.—Cylinder tubular boiler set in brickwork.

heating-surface of the multitubular boiler gives it the preference, provided the quality of the water is consistent with a design of boiler which has parts to which access is so difficult as in the small spaces about the tubes.

The fourth type of externally fired boiler is what is known as the sectional boiler. It consists essentially of a system of tubes or small units so arranged that a continuous circulation of the water is maintained through the tubes from the mechanical action arising from some portions of the

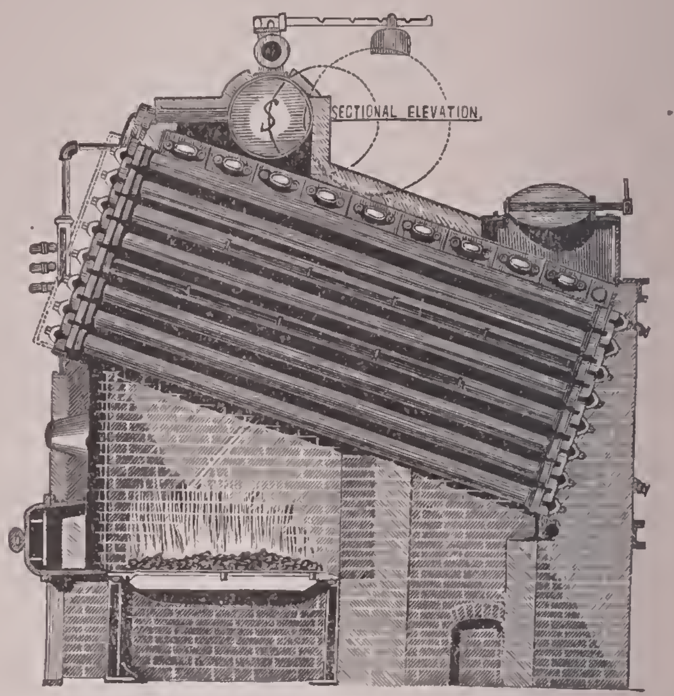

Fig. 7.—The sectional boiler.

tubes being maintained at a higher temperature than others, the heated and lighter water ascending and the cooler and heavier water descending. The large shell is dispensed with, and the heat applied directly by both radiation and contact to the exterior surfaces of the tubes. The steam-space is usually a large drum or a system of drums with which the various sections of tubes are connected, and there are various devices in practical use for connecting and arranging the tubes, so that they shall form a compact arrangement with all the necessary conditions for applying heat, for accessibility, and for securing circulation and disengagement of steam from the water. Fig. 7 shows a side elevation of one of the early pioneers among boilers of this type in the U. S., but many other forms, and the modern type of the form illustrated, are improvements in many respects upon the original type. The origination of this system is generally ascribed to Jacob Perkins, who in 1831 obtained a patent in England for improvements in generating steam, in which he insisted on the advantages to be gained by causing the water to circulate rapidly over the heating-surfaces exposed to the direct action of the fire. In 1839 Perkins obtained a patent for a more complete apparatus involving this idea, under the title "apparatus for transmitting heat by circulating water." Steam-generators constructed with special reference to this idea had already been tried, however, by John Fitch, John Stevens, and others, 1787–1804; later they were abandoned, owing to practical difficulties in their construction and keeping them in repair.

From the sectional type have been derived the water-tube or coil boilers, in which the heating-surface is made up of a great surface of tubes of small diameter in curved or spiral sections within which the water to be evaporated circulates at high velocity either naturally or by means of a forced circulation. The compactness of such boilers and their availability for high pressures have made them popular for small high-speed marine vessels.

Of the *internally fired* boilers, one representative is the locomotive boiler, in which a rectangular fire-box is surrounded by the water to be evaporated on all sides except the bottom. From the front side of this fire-box the tubes carry the hot gases through the water in the barrel of the boiler to discharge them into the smoke-box at the extreme front.

The flatness of the upper side of the fire-box or crown sheet necessitates an elaborate system of bracing or staying for that exposed surface. The sides or water-legs are prevented from bulging by being tied together by stay-bolts. Fig. 8 shows a typical construction of a locomotive-engine boiler without the extension smoke-box, which is designed to catch and hold the cinders and sparks which the intensely rapid draught of the locomotive-engine boiler carries out of the fire-box in great quantities. Many so-called portable boilers are of the locomotive type.

A modification of the locomotive boiler, much used for portable and stationary engines, is known as the *upright*

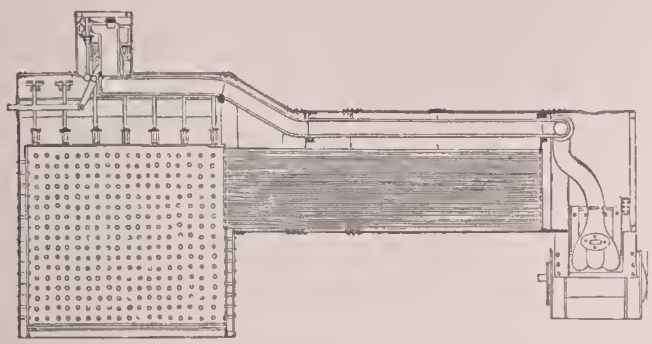

FIG. 8.—Locomotive-engine boiler.

*boiler*, an illustration of which is given in Fig. 9. The simplicity of construction, convenience of access, and small space occupied by these boilers, together with their evaporative qualities and strength, render them peculiarly adaptable for some conditions of use.

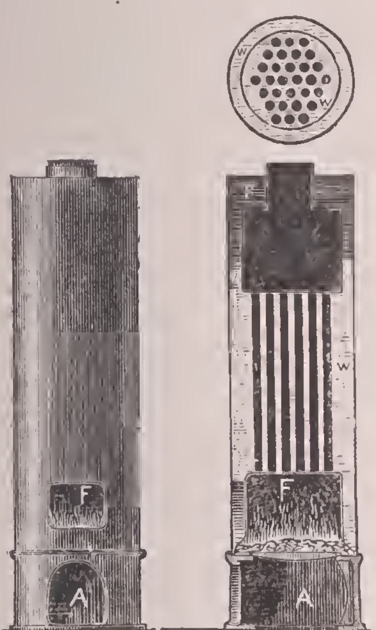

FIG. 9.—Upright boiler.

A form of this boiler which demands special interest and attention is found in the *fire-engine boiler* represented in Fig. 10. This is essentially an upright boiler of the locomotive type, but its peculiarity consists in the great number of tubes and the great extent of heating-surface, compared with the cubic dimensions and the water-space. The tubes are comparatively thin (usually made of brass or copper), thus not only permitting the introduction of a larger number in a given space, but also lessening the time for the first development of steam. The dimensions of the boiler represented in Fig. 10 are as follows: Total height, 5 ft. 4 in.; outside diameter, 31$\frac{3}{4}$ inches; number of brass tubes, 301; diameter of tubes, 1$\frac{1}{4}$ inches; length of tubes, 16 inches; distance from center to center of tubes, 1$\frac{17}{32}$ inches; heating-surface, 157 sq. feet.

For marine practice, where a boiler thoroughly self-contained is a necessity, the internally fired type has received great development. In the days of early and lighter pressures it was usual to give the boiler a shape which would adapt it to fill the cramped quarters assigned to it in the hull.

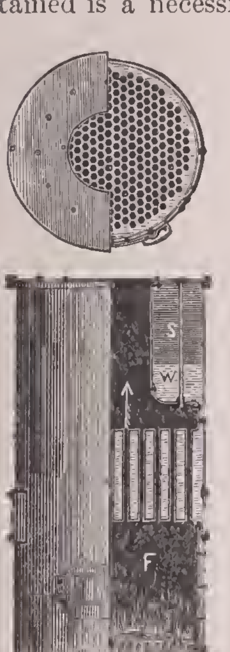

FIG. 10.—Fire-engine boiler.

Fig. 11 represents varieties of a class of boilers which are known as *return-flue boilers*. They were at one time in very general use in steamboats and steamships in the U. S., and are still employed to some extent for lower pressures. They are characterized by having internal furnaces and internal flues, with no external furnaces or brickwork. The shell in these boilers is made sufficiently large to receive within it the direct flues from the furnace, from front to rear, and also the return flues, the arrangements being as exhibited in the plate. As these boilers have large diameters, it is necessary to strengthen the various parts by stays, as shown in Fig. 13. Around the furnaces the plates are stayed and kept in position by sockets and bolts, the sockets acting as struts and the bolts as stays.

Fig. 12 represents a modification of the return-tubular boiler suited to marine purposes. Such a boiler contains several furnaces, and two or more boilers are usually set together on opposite sides of the hold of the vessel, in such a manner as to have a common chimney. Figs. 13–16 show the more prevalent type of boilers for the recent high pressure requirements of both naval and merchant service. They have received the general name of Scotch boilers, while the

FIG. 11.—Return-flue boiler.

type shown in Fig. 12 is usually known as the Martin boiler. The cylindrical furnaces shown in Figs. 13–14 are flues

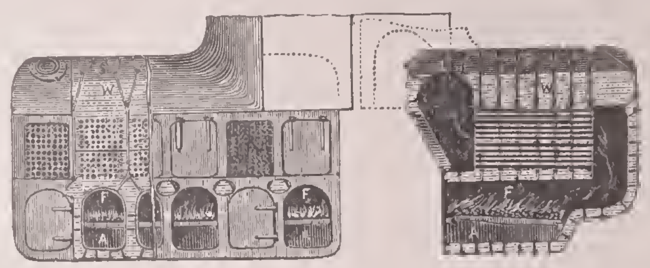

FIG. 12.

corrugated crosswise, so as to secure by this means a greater resistance to the tendency to collapse, which is always pres-

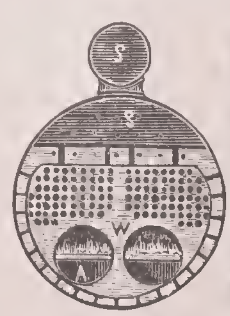

FIG. 13.

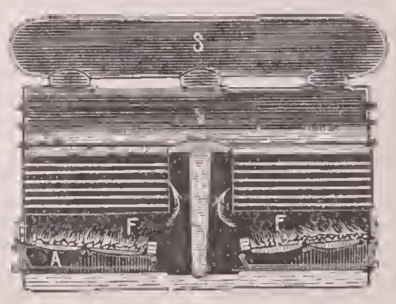

FIG. 14.

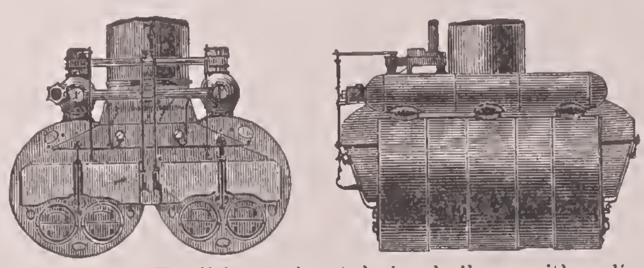
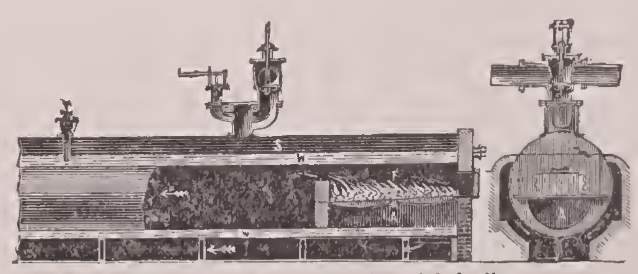
ent in flues of such large diameter. Where the flue is not corrugated it can be stiffened by means of rings of proper



FIGS. 15 and 16.—English marine tubular boilers, with cylindrical shells.

dimensions, to which the more flexible furnace can be attached.

A type of internally fired boiler which has received considerable development in Great Britain is called the Cornish boiler (Fig. 17–18); it has the ordinary form of large in-



FIGS. 17 and 18.—The Cornish boiler.

ternal flue inclosing the fire. The double Cornish boiler has two such flues. The gases pass back through the flue, return to the front at the sides of the boiler, and turn again to the back underneath. This secures abundant contact between the heating-surface and the gases.

What is commonly known as a Galloway boiler is usually a Cornish boiler across whose flue or flues conical water-tubes are inserted, so that the gases shall impinge against surfaces within which the water is circulating. The Field tubes, often applied to the upright or fire-engine boiler and to other internally fired types, consist of tubes closed at the outer end, and each containing concentrically within it a smaller tube. The heavier water descends in the inner tube, while the lighter hot water and steam ascend in the annular space between the inner and outer tube, thus causing a rapid circulation and a rapid transfer of heat.

*Constituent Parts of a Boiler.*—There are many appurtenances or parts of a boiler which are common to all the types. Such details, which are represented wholly or in part in nearly all boilers under the same names, are: (1) The *shell*, or external envelope. (2) The *furnace*, the chamber in which combustion takes place. (3) The *flue* or flues, the passages for the heated gases to the chimney. (4) The *bridge*, or rear wall of the furnace, which forms, with the shell of the boiler above it, the boundary of the *draught-area*. (5) The *ash-pit*, the bottom part of the furnace-chamber, which serves as a receptacle for the ashes and cinders, and also as an entrance for air underneath the grate. (6) The *grate*, which is composed of *grate-bars* or *fire-bars*, forming the bottom of the furnace on which the fuel is laid. (7) The *furnace door*. (8) The *ash-pit door*. (9) The *combustion-chamber*. This is an enlargement of the main flue in the rear of the bridge, formed by dropping the bottom of this flue. This part of the main flue is often called the combustion-chamber, under the assumption that the combustion of the volatile portions of the fuel is not completed in the furnace, and that an enlargement of this flue into a sort of chamber favors a more thorough mixing of the air and the volatile or combustible gases, and thus produces complete combustion. This is especially true where air is admitted by a special arrangement behind the bridge or through holes in the furnace door. When bituminous coal, or fuel containing a large quantity of volatile matter, is used, some such arrangement for burning the volatile matters should be made. (10) The *smoke-box* or smoke-connection is more important in the internally fired than in the other classes of boilers. (11) The *steam-dome* is a vertical chamber set upon the upper surface of the shell, and communicating with it freely through holes in the shell or through a single large aperture. Its object is to furnish a chamber in which the steam may be removed as far as possible from the liquid water, and brought to a quiescent state, so that any particles of water which are carried up with it may be separated by precipitation. In some boilers, especially those for marine purposes, this dome takes the form of an annular space, which is traversed by the smoke-stack or chimney, and is then called the *steam-chimney*. (12) *Water-room* and *steam-room*. The interior of the shell of the boiler is divided by the surface of the water into two spaces, called the water-room and steam-room, or water-space and steam-space; all the space occupied by water below the water-level being water-space, and the space or spaces above the water-level, including the steam-dome, being steam-room. The water-room of a plain cylinder boiler occupies about three-fourths of the whole space, and generally in other boilers about three-fourths of the internal capacity of the shell when the water is at its mean level. (13) *Man-holes, hand-holes*. It is important in the management of boilers to examine all accessible parts frequently, and accessibility to every part is a fundamental principle of construction, not only for cleaning, but for facilitating repairs. *Man-holes* are apertures left in the shell, and closed by strong plates which can be removed at will, the opening being large enough to admit a man. *Hand-holes* are smaller openings, generally near the bottom, which enable cleaning to be done by means of tools. (14) *Heating-surface*. In all boilers portions of the metal plates which form the shell, flues, or tubes, are exposed on one side to the heat of the furnace, or the heat of the gases in their course to the chimney, and on the other side to the contact of the water or steam, the transfer of heat being from the furnace and flues to the water through these portions of the structure. A heating-surface in a steam-generator may therefore be defined to be any surface which acts as a medium for the transfer of heat from the furnace or gases to the water or steam within the boiler. The efficiency of such a surface depends on the conducting power and on the difference between the temperatures of the furnace or gases and the water, and the thorough and rapid circulation of the fluids and gases in contact with the surfaces.

Several appurtenances give efficiency and safety to the boiler, viz.: (15) The *feed-apparatus*, composed of a pump, an injector, or other device, with the necessary pipes for supplying water to the boiler. The injector, often called Giffard's injector, from Giffard, who first reduced it to a practical form, is a jet pump in which a jet of steam is changed by rapid condensation to a water jet. The latter, being much smaller and retaining the same velocity, concentrates its pressure on a much smaller area, and by the conversion of its energy into work is enabled to force other water into the boiler. (16) The *safety-valve*, a valve opening outward, and so adjusted and arranged that it will be opened by the internal pressure of the steam when that pressure exceeds a given amount per square inch. (17) The *steam-gauge*, an instrument which exhibits at all times to the eye of the engineman or stoker the pressure of the steam in the boiler. (18) *Water-gauges* and *gauge-cocks*, which are intended to show at any instant the level of the water within the boiler. (19) The *low-water detector*, an instrument attached to many boilers for the purpose of giving an alarm if the water falls below a given point.

*Chimneys.*—The chimney, in all cases in which the draught is produced by a simple chimney-draught, performs the functions of a machine, and its dimensions (its height and cross-section), taken in connection with the area of the grate and the surface of contact of the fuel exposed to the action of the air, are the principal elements on which not only complete or perfect combustion depends, but also the quantity of fuel burned in a given time. In boilers provided with any other means of draught, such as the steam-jet or the blower, the dimensions of the chimney are not so important. In almost all stationary and in many marine boilers the draught is produced solely by a chimney, which forms an indispensable and important part of the apparatus. The determination of the proper proportions between the heating-surface and the grate-surface depends on the initial temperature of the gases; and as the initial temperature varies with the rate of combustion or the height of the chimney, the height of the chimney indirectly enters into the consideration of this proportion. As is well known, the draught of a chimney is caused by a difference of pressure at the base of the chimney acting in an upward direction, due to the difference between the weight of the heated gases in the chimney and that of a column of the external air of equal height and cross-section.

*Heating-surfaces.*—The quantity of heat transmitted by any surface depends on the extent of the surface and the difference of temperature between the source of heat and the absorbent; or, in the case of steam-generators, the difference in temperature of the incandescent fuel or heated gases and the water in the boiler. The extent or amount of heating-surface is fixed with reference to the initial temperatures of the furnace and gases; or, since these temperatures are proportional to the rate of combustion, the extent of heating-surface will depend on the rate of combustion to be employed. The extent of heating-surface must evidently also be in proportion to the absolute quantity of fuel burned in a given time; or, what is the same thing, it must have a direct relation to the grate-surface.

Inasmuch as it is impossible to vary the heating-surface at will, after a steam-generator is constructed, it is customary to fix the extent of this surface according to average conditions of use, taking into account average rates of combustion. The following proportions represent as near as can be ascertained the usual rules of practice. The grate-surface being 1, the heating-surfaces are for—

| | | |
|---|---|---|
| Plain cylinder boilers | 10 to 15, | average 12 |
| Cornish boilers | 30 to 40, | " 35 |
| French cylinder boilers | 25 to 40, | " 33 |
| Cylinder-flue boilers | 17 to 25, | " 21 |
| Cylinder-tubular boilers (chimney-draught) | 25 to 30, | " 28 |
| Traction-engine boilers | | " 32 |
| Marine tubular and flue boilers—French, English, and American practice | | " 25 |
| Locomotive boilers | 40 to 100, | " 75 |

The rates of combustion per hour and per square foot of grate, in ordinary practice, are, according to Rankine—

| | |
|---|---|
| Slowest rate in Cornish boilers | 4 lb. per hour. |
| Ordinary rate | 10 " " |
| Ordinary rate in factory boilers | 12 to 16 lb. per hour. |
| Ordinary rate in marine boilers | 16 to 24 " " |
| Locomotive boilers | 40 to 120 " " |

The amount of heating-surface required to evaporate 1 cubic foot of water per hour at 212° is for—

| | |
|---|---|
| Plain cylinder boilers | 8·8 sq. feet. |
| Galloway multitubular boiler (water-tube boiler) | 8·5 " |
| Marine tubular boiler | 14·0 " |
| Double-flue Cornish | 11·7 " |

For these the rate of combustion is such that the total heating-surfaces are sufficient to evaporate 9 lb. of water for 1 lb. of coal.

The following conclusions are deduced from Isherwood's experiments. The boilers of various steamships on which experiments were made, with the results, are indicated by the names of the vessels:

First column, heating-surface required per one indicated H. P.; second column, number of pounds of water evaporated per hour per pound of combustible; third column, combustible in pounds burned per hour per square foot of grate.

The practice of the Navy Department has been to allow 8 lb. of anthracite coal per hour to evaporate 1 cubic foot of water at 212°, under a pressure of 30 lb. per square inch, which requires two-thirds square foot of grate and 16⅔ sq. feet of heating-surface.

The quantity of water evaporated per pound of coal for the plain cylinder boiler, the cylinder-flue boiler, and the cylinder-tubular boiler, in the order given, is, under the most favorable circumstances, 7, 8, and 9 lb. of water for each pound of coal burned. The boiler of the railway locomotive is the only one in which the rates of combustion are frequently and greatly varied while in use; and in these boilers it is necessary to provide for very high rates of combustion by giving an extreme amount of heating-surface. The locomotive boiler, with ordinary rates of combustion, corresponds, in evaporative efficiency, to the ordinary marine tubular boiler.

*Causes which affect the Efficiency of Evaporation.*—These are, 1, those which influence the *rate of combustion*; and, 2, those which influence the *rate of transfer of heat*. Among the causes which influence the rate of combustion may be mentioned the temperature of the external air, the temperature of the chimney-gases, the presence of moisture in the air, the management of the fires, the quality of the fuel, and defective combustion. The principal causes which affect the transfer of heat are the rate of combustion, which determines the initial temperatures in the boiler; the temperature of the water in the boiler; the accumulations of incrustations and dust in the tubes; and generally all those circumstances which impair the qualities of the heating-surfaces. The management of the fires and the quality of coal are most important influences on the rate of combustion and economy of fuel.

*Supply of Feed-water.*—The supply of water to a boiler is of course indispensable to its performance. It is usually accomplished by an independent apparatus, a pump or an injector being employed. The capacity of the feeding apparatus should be such as to supply sufficient water not only for the highest rate of evaporation likely to be attained, but to supply all losses from priming, leakage, blowing off, etc. Care should be taken that the feed-water does not impinge on the plates or flues, as the sudden cooling at one point is liable to fracture the plates. Such fractures can not always be discovered when the boilers are inspected, and are always a source of danger. For land-engines a capacity of two and a half times the net feed-water required by the engine is the rule given by Rankine. Proper arrangements for regulating the supply to the boiler are required. Where steam is used for heating, the condensed steam is returned to the boiler by the action of gravity, the waste being supplied from time to time by the attendant.

Feed-water heaters or economizers are devices by which the heat which would otherwise be wasted as rejected from the boiler setting or the engine is utilized to raise the temperature of the feed-water before it enters the boiler. They are therefore known as flue-heaters, when so placed as to avail of waste heat in the chimney flues, and exhaust-steam-heaters when the waste steam from the engine performs this same office. Where the feed-water contains mineral matter which can be precipitated in the heater, an obvious advantage is secured by keeping this objectionable material out of the generator. Open heaters are those in which the exhaust steam comes into direct contact with the feed-water. In closed heaters either the steam passes through a coil of pipes on the other side of which is the water, or the water is in pipes surrounded by steam.

*Boiler-explosions.*—The disaster which is known as a boiler-explosion consists of two distinct steps, although one usually succeeds the other instantaneously. (1) There occurs a rupture of the shell or envelope caused by a pressure within the shell greater than it was able to withstand. (2) Through the orifice thus made there is a release of pressure, and the hot water remaining in the boiler forms steam-gas at this reduced pressure with a velocity which is comparable to the rapid formation of gas when a flame is touched to an explosive compound. It can be shown that when the water is under pressure there is stored a force in foot-pounds sufficient if released all at once to produce the phenomena of a most disastrous explosion, so that the study of an explosion is usually mainly concerned with determining the conditions which caused the relative over-strain and the initial rupture. This state of affairs may result because the boiler was too weak for its working pressure by reason of deterioration, old age, defective design, or bad adjustment of the working pressure to its strength. It may also occur because some sudden strain of unequal contraction produced a local superposition of strain which the metal at such weakened place was unable to resist.

Such excessive strains can also follow when, by the sudden opening of a large steam-valve permitting the escape of steam into a cold pipe, there is such a drop of pressure as to cause an ebullition almost concussive in its character, so that the reaction of the weight of water results in such superposition of strains as to cause the first rupture. This explains the frequency of rupture at the moment when steam is turned on and the work-day is about to begin. In the second place, it is surprising in how short a time the pressure within a boiler will increase if there is a constant rate of ordinary evaporation and no outlet for the steam.

The rate of increase of pressure may be found theoretically by means of a formula given by Prof. Zeuner in his work on the *Mechanical Theory of Heat*. Let $T$ be the time, in minutes, which must elapse from the instant that all efflux of steam is prevented in a boiler to the instant when a dangerous or bursting pressure must follow; let $W$ represent the weight of water in the boiler; $t_1$ the temperature of the water at a dangerous pressure; $t$ the temperature at the working pressure; $Q$ the quantity of heat, in British units, transferred to the water per minute—then the equation

$$T = \frac{W(t_1 - t)}{Q}$$

is approximately correct. This formula shows that the time will be proportional directly to the amount of water in the boiler, to the difference of temperatures $t_1$ and $t$, and inversely proportional to the quantity $Q$. The fluctuations of pressure will be less rapid in boilers which contain large quantities of water and have at the same time a low rate of evaporation. Such conditions are found especially in marine boilers, while the reverse is true for boilers containing small quantities of water and having rapid rates of evaporation, such as locomotive and fire-engine boilers. The fluctuations will also evidently be more rapid at high pressures than at low pressures, since at high pressures a greater change of pressure occurs with an equal difference of temperatures.

*Safety-valves.*—It is supposed that the gradual increase of pressure above discussed can never take place if the safety-valve is in good working order and if it have proper proportions. Engineers do not, in practice, place their trust in the safety-valve alone, and it is principally to their watchfulness and attention that the public is indebted for safety.

The theoretical area of orifice $O$ for the efflux of a given quantity of steam from a boiler into the atmosphere, supposing this orifice to be a circular area, may be determined by first ascertaining the theoretical velocity of efflux, and multiplying this by a coefficient ascertained by experiments. The experiments made by R. D. Napier on the efflux of steam at different pressures and with different orifices have not only furnished the means of determining the coefficients of efflux, but for determining formulas for the area required for the discharge of a given weight of steam per second. An approximate formula given by Rankine is as follows: When the pressure in the boiler is equal to or greater than five-thirds the external pressure, then $W = \frac{p_2}{70}$ where $W$ is the number of pounds of steam discharged per square inch of area per second, and $p_2$ is the boiler-pressure in pounds per square inch. Letting $W_o$ represent the pounds of steam per second discharged through the orifice of area $O$, then $W_o = \frac{p_2}{70} \times O$, and therefore $O = \frac{70\ W_o}{p_2}$.

An English empirical rule is that the safety-valve area shall have half a square inch for each square foot of fire-grate, or ·025 of a square inch for each square foot of heating-surface. Another, quoted by Rankine, is as follows: Let $A$ be the area of the piston, $V$ its velocity in feet per minute, $P$ the excess of pressure in the boiler above that of the atmosphere in pounds per square inch; then the area will be $A\ \frac{V}{300P}$, nearly. Still another quoted by the same author is: "$a$ = area in square inches = from $\frac{1}{25}$th to $\frac{1}{30}$th of the number of pounds of coal burned per hour, or $a$ the area in square inches = $\frac{1}{150}$th to $\frac{1}{180}$th of the water evaporated per hour."

In all cases it is not only a matter of observation, but a theoretical law, that as soon as efflux begins there is a considerable diminution of pressure underneath the valve; and numerous devices have been proposed by which the opening of the valve shall not be influenced by the pressure in the orifice, but by the action of the pressure at a point remote from the orifice. Such valves are called pop-valves.

Thére are supposed to be, in some circumstances, sudden evolutions of steam in such quantities that no relief is possible through safety-valves. In regard to such cases, it can easily be shown that by reason of the high specific heat of water, as compared with iron, it is very difficult for any large quantity of steam to be made even from overheated plates, so that the disasters perhaps rightly attributed to low water are the result, not of excessive internal pressure, but of the strain from contraction when such overheated plates are suddenly cooled by contact with water.

The term "horse-power" of boilers is often used as a measure of the work which a steam-generator can do. Such use is liable to misunderstanding, inasmuch as it implies a rate of work, and a boiler ordinarily does no work, but merely supplies to a machine the means for doing it. The term has, however, acquired a conventional significance among engineers. It has been agreed that the commercial horse-power of a boiler shall be an evaporation of 30 lb. of water per hour from a feed-water temperature of 100° F. into steam at 70 lb. gauge-pressure. This is equivalent to 34½ lb. of water evaporated from a feed-water temperature of 212° F. into steam at the same temperature, which corresponds to 33,305 thermal units per hour. A boiler rated upon the above standard of evaporative capacity should be capable of developing that power with easy firing, moderate draught, and ordinary fuel, while exhibiting good economy; and should be capable of being driven to develop at least one-third more than its rated power to meet emergencies when maximum economy is not the most important object to be attained.

**Steam-engine**: a device or apparatus for converting into work-units the energy of heat, using the expansive force of the vapor of water as a medium. The steam-engine consists therefore necessarily of two parts—the engine proper, in which the expansive force is expended, and the generator, or boiler, in which the energy of a burning fuel is transferred to the water. (See Steam-boiler.) Essentially the same mechanism as is required by the steam-engine can be used with ammonia, ether, bisulphide of carbon, etc., as a vehicle for the heat. Water has the great advantage of being cheap, everywhere accessible, without odor, and with a vapor which is not combustible. It has further the great advantage that by reason of its low specific heat a given volume of the vapor of water will carry more heat than the same volume of any other medium at the same pressure.

The earliest notice of the use of steam as a motive power is in the *Pneumatica* of Hero (*q. v.*). After many trivial machines by various inventors, the first really useful steam-engine was made by Edward Somerset, second Marquis of Worcester, and described in his *Century of Inventions* (1663). It was designed to raise water. Thomas Savery improved this, and received a patent in 1698; his engine was the first to come into extensive use. Both these engines applied the expansive force of steam directly to the column of water: Savery's then condensed the steam, and by means of valves made use also of the atmospheric pressure. The invention of the piston is due to Denis Papin (1647–1712), but the first practical cylinder-and-piston steam-engine was made by Newcomen (see Newcomen, Thomas). James Watt (*q. v.*) improved this engine by providing a separate vessel to serve as condenser and by making the engine double-acting. The first automatic valve-gear (1713) was the device of a boy named Humphrey Potter; this was improved in 1718 by Henry Beighton. For the invention and description of locomotive engines, see Railways and Locomotive.

The unit for measuring the performance of steam-engines is the "horse-power," which was determined first by James Watt. The horse-power consists of 33,000 foot-pounds moved in one minute, and is a standard unit wherever the English foot and pound prevail. The horse-power in countries which employ the metric system is slightly less (32,549 foot-pounds). The performance of steam-engines is measured either on the revolving shaft of the engine by a measuring apparatus or dynamometer, or it is determined by the effort of the expansive force of the steam, measured in pounds of pressure exerted upon a known area in the cylinder of the engine, which product when multiplied by feet of distance, through which that pressure is exerted, will give a final product in foot-pounds, and measure the performance. That is: If $P$ = the mean effective pressure per square inch of area in the organ receiving the expansive force of the steam, and $A$ = the area, in square inches, of a disk, or piston, fitting steam-tight in a cylinder, then $P \times A$ = a total number of pounds. Furthermore, if $L$ = the length of the traverse of the above movable piston expressed in feet, then $P \times A \times L$ will denote the foot-pounds in one traverse of the piston in the cylinder. If the piston makes a number, $N$, of traverses in a minute, the product $PALN$ will give the foot-pounds of performance per minute; $N$ will usually be equal to twice the number of revolutions per minute. Finally, the horse-power of a steam-engine will be $PALN \div 33{,}000$.

It will appear from the above that two great types of engine can be designed of equal capacity in horse-power. The product $LN$ is called piston-speed of an engine, and with a constant value for this product the length of the stroke may be long, and the number of strokes per minute small, or a greater number of strokes per minute may be made with a short length for each stroke. It is further clear that by making the product $LN$ large we can correspondingly diminish the factor $A$, and by making $N$ large both the diameter and length of the engine will be diminished. When both high rotative speed and high piston-speed are combined the engine becomes compact, is easily regulated, and is light. Such an engine, however, is not ordinarily so economical in the use of steam as a more moderate application of these principles permits, by reason of the large clearance volumes in the cylinder, and by the necessity of a copious lubrication.

The usual engine-cylinder has a circular piston traversing a cylinder whose length varies from the diameter of the piston up to twice its diameter. Steam is admitted alternately on each side of this circular disk or piston, and causes it to move first in one direction and then in the other. This most common form of a cylinder is shown in Fig. 11, which represents a longitudinal section of a cylinder, with its piston and piston-rod. Fig. 1 represents a section of the cylinder of the Corliss engine. It shows a different arrangement of openings for the entrance and exhaust of steam. Fig. 2 represents the piston with its packing-

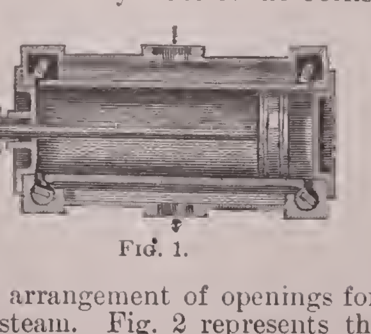

Fig. 1.

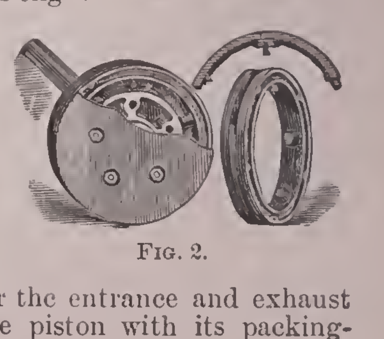

Fig. 2.

rings. These rings serve to prevent the escape of steam past the piston. The steam which has done its work of driving the piston in one direction is permitted to escape from the cylinder, and is called exhaust steam. The motion of the piston is carried outside by a piston-rod through

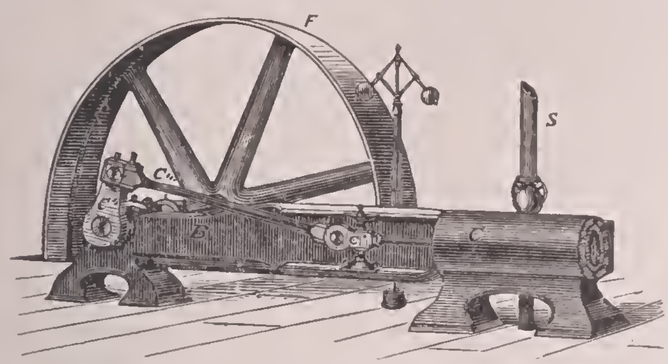

FIG. 3.—Horizontal stationary engine.

a device in the head of the cylinder so constructed as to permit the rod to slide in and out steam-tight. This apparatus is called a stuffing-box, and is arranged so that a fibrous and elastic material is forced against the rod by being compressed by a gland in an annular cavity. The end of the piston-rod which protrudes from the stuffing-box is guided by a cross-head which compels it to move in the axis of the cylinder by sliding between guides. In certain engines this rectilinear movement of the cross-head is secured by a linkage without the use of guides. Such linkage is called a parallel motion. The cross-head carries a pin called the cross-head pin on which vibrates the connecting-rod, by which the motion of the cross-head in a straight line is converted into the continuous rotation of the crank, by whose means the main shaft of the engine is caused to rotate continuously in one direction by the alternating traverse or reciprocation of the piston in the cylinder. The type above described is much the most widely extended, and is considered the most efficient and economical.

Fig. 3 exhibits the mechanism of such a stationary steam-engine, by which the reciprocating rectilinear motion of the piston and piston-rod is converted into continuous rotary motion. In this illustration C represents the cylinder, C′ the cross-head moving in guides, C″ the crank, C‴ the connecting-rod, F the fly or band-wheel, S the steam-pipe. Fig. 4 represents generally the corresponding features of the Corliss engine.

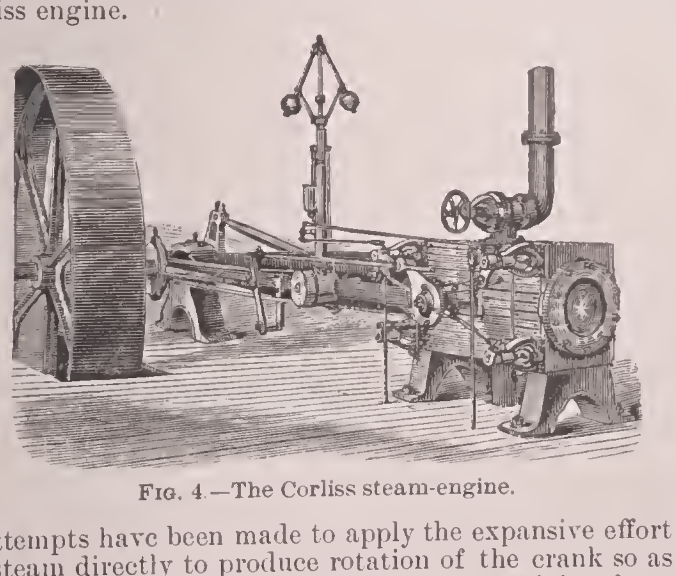

FIG. 4.—The Corliss steam-engine.

Attempts have been made to apply the expansive effort of the steam directly to produce rotation of the crank so as to get rid of the reciprocating motion and the weight of mechanism required for conversion of reciprocating into rotary motion. While the rotary engines offer considerable advantages from their compactness, the direct application of power, the ease with which they are reversed, etc., they are not usually an economical type in consumption of steam by reason of leakage and the difficulty of using steam expansively.

FIG. 5.

Figs. 5 and 6 are sketches illustrating the rotary forms of engine as invented by Watt and Bramah respectively. In these engines the cylinders are truly cylindrical, but the pistons revolve about the axes of the cylinders. Of many hundreds of devices of rotary engines these are the principal types.

If the connecting-rod of a reciprocating engine be thrown out from its mechanism and the free end of the piston-rod attached to the crank, then the piston-rod must have an angular motion to provide for the play of the crank, and this compels the cylinder to have a motion of oscillation. The engine is then called an *oscillating engine*, the cylinder being mounted upon trunnions on which it oscillates, the trunnions being hollow so that steam may enter through one of them and be discharged to the other. While some large engines have been built of this design, the difficulties from leakage when wear has begun are objections to this type. The *trunk-engine* is a mechanism in which the connecting-rod is attached directly to the piston which slides in the cylinder in a straight line. To enable the angular motion of the connecting-rod to pass out of the cylinder steam-tight, it is arranged to swing within a hollow cylinder or trunk whose diameter permits this angular motion without striking the sides and which passes out of the cylinder through a stuffing-box. As this arrangement makes the piston offer only an annular area to the steam on the trunk side, the trunk is often duplicated on the side opposite the crank to equalize the effort on the two strokes. Many illustrations of these trunk-engines are presented by the compact designs of monitors and other small naval vessels. A third type of engine results when the connecting-rod from the cross-head is brought backward at the side of the cylinder or part way to it to a crank at its back head or between the cylinder and cross-head. This type of engine is called a *back-acting engine*.

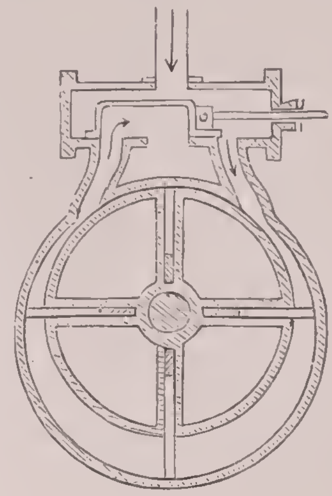

FIG. 6.

Engines may be grouped, according to the direction of the axis of the cylinder, as horizontal, upright, and inclined. The horizontal engine is much the most common because of the easy accessibility of all its parts, the ease with which its foundation can be made, and because all its parts lie close to the foundation. The vertical or upright engine has the advantage of having the piston bear equally over the entire bore of the cylinder without a tendency for the weight of the piston to wear the cylinder out of round. On the other hand, the weight of the reciprocating parts would make the effort on the up and down stroke unequal unless care be taken by special arrangements to neutralize this inequality. The upright engine appears in two forms: with the cylinder above the shaft, known as the inverted vertical, and with the cylinder below the shaft, which may be called the direct vertical. The inverted vertical is much the most usual because the revolving parts are close to the foundation, and the parts which are remote from it are those which have no motion. This is the prevalent type for the marine engine of screw-vessels where the revolving shaft must necessarily be close to the keel (Fig. 10). The direct vertical engine is not much used in the U. S.

In *beam-engines* a vibrating beam is introduced between the reciprocating piston and the revolving shaft. As distinguished from these, other engines are called *direct-acting*. In its most usual form the beam-engine is arranged to have a vertical cylinder from the top of which the piston-rod protrudes. The cross-head is connected by the short connecting-rods to one end of the oscillating beam, which is supported usually at its middle point upon a massive bearing. At the other end of the beam a long connecting-rod passes to the crank-pin, so that the alternating motion of the piston is converted by this means into the rotary motion of the shaft. By reason of the fact that in early engines of the beam type the long connecting-rod from the outer end of the beam was attached to the pump-rods of a mine or pit, this long rod in beam-engines is often called the pitman. Fig. 7 shows the mechanism of the American beam-engine as designed for large steamships and river-boats. In this sketch C represents the cylinder, C″ the condenser, B the working- (or "walking") beam, C″ the connecting-rod, C‴ the crank, A the air-pump, V valve-gearing. The beam-engine as used for pumping gives great convenience of attachment for the rods of the pumping-barrels, and its flexibility in a vertical plane has made it a very favored design for side-wheel vessels, particularly where the condition of shallow water prevented the attainment of vertical stiffness in the hull. Triangular beams have been used to enable a horizontal steam-cylinder to operate vertical pumps at a considerable distance below the level of the engine-room. The beam-engine also is convenient where more than one

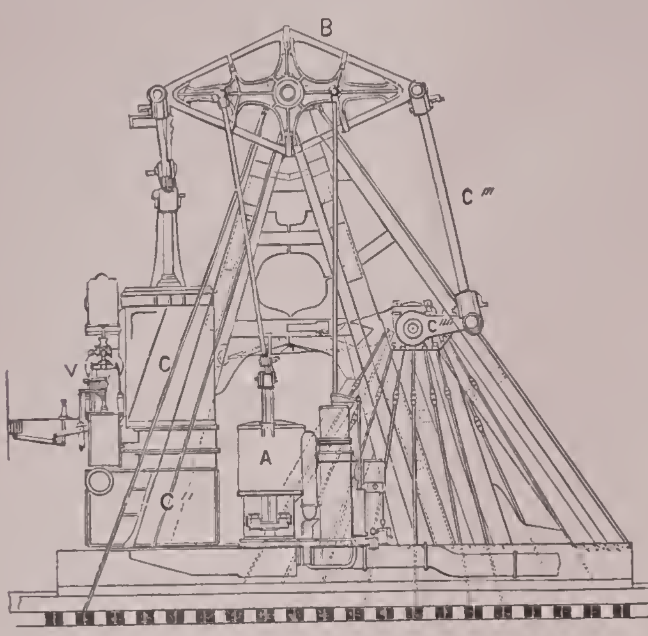

FIG. 7.

cylinder is to be used to produce motion upon one crank-pin. The *side-lever* engine is one in which the beam is placed below or at the side of the cylinder so as to bring the center of gravity low down in the hull of a side-wheel steamer and below a protective deck.

All reciprocating steam-engines may be classified according to the way in which the steam is employed in their cylinders. The steam may be permitted to flow from the boiler into the cylinder throughout the full length of the stroke of the piston. It must then escape as exhaust from the cylinder at the full pressure at which it entered and carrying with it all the heat which corresponds to that pressure. Such an engine is said to take steam at full stroke and to work without expansion in the cylinder or without cut-off. A second class of engine allows the steam to flow from the boiler into the cylinder at full boiler pressure for but a part of the stroke only. The admission of steam is then cut off by the proper valve mechanism, and the steam inclosed in the cylinder expands in the increase in volume as the piston moves under its action toward the end of its stroke. This increase in volume is accompanied by a fall in pressure and a reduction in temperature, so that upon exhaust a less weight of steam and a less number of units of heat are rejected from the cylinder than in the first case. Such an engine is called an expansive-working engine or a cut-off engine. The degree of expansion is the reciprocal of the point of cut-off expressed in terms of the length of the piston-stroke.

Again, the steam may be rejected from the cylinder at the pressure of the atmosphere, escaping as the vapor of water at 212° F., or slightly over. Such an engine is called a non-condensing-engine, because although the steam rejected passes back to water in the atmosphere at large, it is not condensed to water in connection with the engine itself. In the other type the steam is exhausted from the cylinder into a vessel, where it comes immediately into contact with a cool medium, and is thereby reduced back to warm water with the very great reduction of volume which follows such condensation, so that if the condensed water is continuously removed from the condenser a more or less complete vacuum can be maintained therein. Such an engine is called a condensing-engine, and has the advantage over the non-condensing-engine of a greater mean pressure in the cylinder for a given boiler-pressure and point of cut-off, from which results a smaller engine for a given power, or more power from an engine of given proportions. The heat in the steam is also utilized more completely, as the hot water which is caught in the condenser is pumped back again to the boiler at a higher temperature than the feed-water would otherwise have. An air-pump is used for draining the condensed water from the condenser. This, in many types of condensing-engine, is operated from the beam or cross-head of the main cylinder (Fig. 7). In recent practice it has been preferred to operate the air-pump independently with its own steam-cylinder. It can then be run at higher speed than the main engine, the vacuum in the condenser can be created before the main engine is started, and the air-pump can be located where it may be found most convenient. The advantage of the attached air-pump is that the large engine-cylinder is usually more economical than the small detached one. By putting the condenser at a height over 32 feet in the air, with a pipe running down into a reservoir or well, in which it is at all times sealed, it will be apparent that gravity acting upon the water in the condenser and its descending pipe will compel the water to stand in the pipe at a height at which the barometric pressure of the atmosphere will just balance the column. In other words, a Torricellian vacuum prevails in the condenser. By causing the water to meet the exhaust steam at this height condensation is continuous, and all that is necessary is to provide by the principle of induced currents or otherwise for the removal of air which will enter the condenser by leakage and from the steam and water. Such condensers are called gravity-condensers. Two great types of condensers are used. In the first the steam meets the condensing water directly and cools it by contact; the cold water or injection enters the condenser in a jet by atmospheric pressure, which gives to this type of condenser

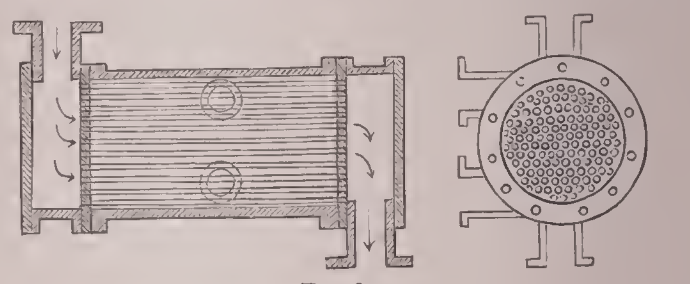

FIG. 8.

the name of jet-condenser. In the other type the steam is condensed by contact with a surface of brass tubes which are kept cold by the circulation through them of the condensing water (Fig. 8). The condensing water enters the tubes at one end, as shown by the arrows, and is discharged at the other, while the steam is admitted around the tubes. A mode of packing the ends of the tubes by ferrules of compressed pine wood is shown in Fig. 9. This device, the invention of Horatio Allen, and others like it have contributed to render the surface-condenser more perfect in its operations. In the jet-condenser a less quantity of water is required and the air-pump handles it all. The steam and condensing water are intimately mixed. In the surface-condenser arrangement the condensed steam is pure distilled water and does not become mixed with the condensing water, which can be impure and unsuitable for use in the boilers. The air-pump handles only the water condensed from the steam, and special pumps, called circulating-pumps, are required to circulate the cooling water around the tubes. In sea-going vessels surface-condensation is almost universal, the salt water from out-

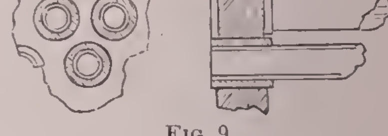

FIG. 9.

side of the hull being circulated through the condenser and overboard, while the pure distilled water from the air-pumps is used over and over again in the boiler.

Another difference which can serve as a basis for classification of steam-engines is brought about by the way in which the alternating traverse of the piston is affected by the pressure of steam. If both strokes forward and back, or upward and downward, of the piston are produced by the pressure of steam upon its area, the engine is said to be double-acting. Where steam drives in one direction only the engine is called single-acting. By far the greatest number of engines are double-acting. What is called the Cornish engine is one of the best known of the single-acting engines. In this design, which is mainly used, and is at its best, for pumping, the steam enters the cylinder from the boiler, and by its direct pressure and after cut-off by its expansion the piston is driven in one direction. When this stroke is completed a valve is opened by which an equilibrium of pressure is established through a side pipe between the top and bottom of the cylinder around the piston. The piston then yields to the action of gravity and returns to its initial position without the use of fresh steam, so that one stroke forward and back is accomplished by a single admission of steam. The Cornish engine appears in two forms: In the first, the piston is connected to the massive pump-rods of a mine-shaft, or to the heavy plungers of a water-works pumping-engine, by means of a beam, so that the working stroke which lifts the weight of the rods or plungers is the down-stroke of the piston, and the piston-rod passes out of the top of the cylinder. In the second type, which is known as the Bull Cornish engine, the piston-rod is attached directly to the rods or plungers, over which the cylinder is placed, so that the piston-rod goes down to the lower head, and the working stroke is the upward traverse of the piston. The Cornish engine has no fly-wheel, and the rapidity of its stroke is controlled by the flow of steam or of water through the valves. It is this peculiarity, which permits the mass of a long column of moving water to be the controlling feature of the velocity of the piston, that made this type of pump a popular form in early days. The objections to the system are the great bulk of the cylinder with comparatively small power, the massive foundations required, and the danger from accident to the engine if the pump-barrels should fail to fill, whereby the engine would make an over-stroke, since there is no crank to regulate the length of the stroke. The Cornish engine is usually designed to have its steam-valve operated by a cataract. The cataract consists of a small cylinder fitted with a plunger. The pump-rods on their working stroke lift the plunger in the cataract-cylinder, and the latter is filled with water. A weight upon the cataract-plunger tends to make it descend, but the speed of its descent is controlled by a valve upon an outlet-pipe whose position, by impeding the outflow of water, controls the time in which the cylinder will empty. The descent of the plunger, when near the bottom, opens the admission-valve of the main engine, and thus causes a stroke to be made. The plunger of the cataract-cylinder thus moving independent of the main engine will cause the latter to make strokes intermitting with periods of rest. For rotative types of engines two single-acting cylinders can be attached to the shaft with cranks at opposite phases, the two producing the same effect as a double-acting engine, with the gain that the pressure is always in one direction, and there should be no lost motion.

Another great principle of classification of engines is determined by the fact that the expansion of the steam in the cylinder may take place in a single cylinder, or be made continuous in two or more cylinders. This difference divides engines into simple, compound, and multiple expansion. In the simple engine the steam does its work upon one stroke of the engine, and then escapes as exhaust either into the atmosphere (non-condensing) or into a condenser, where it is reduced to water and causes a vacuum (condensing). A simple engine may have more than one cylinder, but if each cylinder takes steam direct from the boiler, and that steam is rejected at exhaust without doing additional work in another cylinder, such engine is not a compound engine. In the compound engine the steam enters a cylinder of a certain volume from the boiler and works in it as in a simple engine. The exhaust steam from this cylinder passes into a second cylinder of larger volume (usually three or four times that of the first), where it acts as a driving pressure, and from which it is exhausted when the stroke is completed. It will appear, therefore, that the driving steam for the second cylinder is a back-pressure on the exhaust side of the first cylinder, but as the areas are different the net effort is positive to produce motion of the larger cylinder. If the first cylinder has no cut-off, but takes steam full stroke from the boiler and without expansion, it is obvious that the final volume of the steam is as many times greater than its initial volume as the capacity of the larger cylinder is greater than the smaller, so that an expansive working of the steam is secured, although the first cylinder has a constant propelling effort from the beginning to the end. In a simple engine this expansive effect could be produced only by cutting off admission early in the stroke, whereby the propelling effect would have to be in excess at the beginning of the stroke in order that at the end, when the pressure had fallen, there might still be sufficient propelling effort to overcome a constant resistance. The compound engine, moreover, by distributing the range of temperature between the initial and final pressures of the steam, when the number of expansions is considerable, in more than one cylinder, causes a diminished loss of heat, both by radiation and contact of the walls of the cylinder with the steam. The transfer of heat by both these processes is greatest and most rapid when the difference of temperature is greatest. By keeping this difference of temperature less by having it distributed in two cylinders, the total loss is less than it would have been in the larger cylinder if the latter had been used alone in a single engine. The principle of the compound engine was first proposed by Jonathan Hornblower for the single-acting engine in 1781. It was reintroduced by Arthur Woolf for the double-acting engine in 1804. It was applied, to some considerable extent, to beam-engines by McNaught about 1845, but really secured its modern development by the application of the principle to marine practice by John Elder, of Glasgow, in 1854.

When the expansion is made continuous, as in the compound engine, through three cylinders, the engine is called triple expansion (or tri-compound); when the expansion is continuous in four cylinders the engine is called a quadruple expansion, or the general name of multiple expansion is given to an engine having the expansion continuous in more than two cylinders. It is the continuity of expansion and not merely the number of cylinders which gives the engine its name. It is often inconvenient in engines of great power to construct a single large cylinder of volume sufficient to secure a sufficient increase of volume to attain the desired range of pressures and the ultimate low temperature. It is usual to call the cylinder which receives the steam directly from the boiler the high-pressure cylinder; the last one in the series, from which the exhaust steam escapes, is called the low-pressure cylinder: if the expansion is continuous in three cylinders the middle one between the high and low pressure cylinders is called the intermediate cylinder. If the steam passes through four cylinders continuously there will be two intermediate cylinders, called respectively the high-pressure intermediate and the low-pressure intermediate. In a multiple-cylinder engine, in which the steam exhausts from one cylinder into two others, and acts in each at the same pressure, such two cylinders of equal pressure are designated as the first and second intermediate, or the first and second low-pressure, as the case may be. When two pistons of unequal diameter, working with steam of continuous expansion, are arranged upon the same piston-rod, the engine is called a tandem-engine; when the small cylinder is vertically over the larger in an inverted vertical engine, the name steeple-engine has been given to it. The cranks of a two-cylinder compound engine (sometimes called a bi-compound) can be arranged so as to be parallel to each other, so as to be 180 degrees apart, or so as to be 90 degrees apart. In the first two arrangements the steam can pass directly from one end of the smaller cylinder to the same or opposite end of the larger; in the third case, when the cranks are quartering, a receiver must be provided into which the steam from the high-pressure cylinder shall pass while the low-pressure piston at its dead point at the end of its cylinder offers no volume to receive the steam discharged from the preceding one. Such engines are therefore called receiver-compound engines, and when arranged, as they usually are in stationary practice, so that their two cranks are on opposite ends of the driving-shaft, compelling the steam to cross over a short passage between the cylinders, the engine is called a cross-compound engine. This receiver type and the cross-compound form offer the advantages possible from introducing into the receiver a device called a reheater, reheating or regenerating the steam in its passage from one cylinder to the other. The advantages of economy and from securing ability to use high pressure for the entering steam have been the great reasons for the wide increase in the development of the multiple-expansion engine, both condensing and non-condensing.

A classification of the steam-engine finally, with respect to the uses to which its developed power is to be applied, would be almost an enumeration of all the foregoing types in their different forms. A rough classification might be first into engines for propulsion and engines for stationary uses. The engines for propulsion on land are the locomotive and the traction engine, and on the water the type of marine engine of transatlantic and naval practice, and the type of beam-engine used more for coastwise traffic and in shallow waters where the paddle-wheel is the means of propulsion.

The locomotive and the traction engine consist of an internally fired boiler (see STEAM-BOILER) supported upon wheels, and carried by a frame to which the effort of the cylinders through the wheels gives the desired motion. The wheels receiving the effort of the steam are called driving-wheels, and are four, six, eight, or ten in number, dependent upon the desired traction or hauling power of the machine; this latter is, under ordinary circumstances, one-fourth of the weight borne on such driving-wheels, and the diameter of the cylinder and its stroke is usually proportioned so that the power of the cylinders shall be able to cause the driving-wheels to slip. Ability to start heavy trains is secured by giving a relatively small diameter to the driving-wheel, while very high speed requires a relatively larger diameter of the wheel, inasmuch as the circumference of the driver measures the space through which the engine will move forward in one revolution, which corresponds to two traverses of the piston. If the driver is too small for a high speed the number of revolutions per minute will become excessive.

In the traction-engine for hauling upon common roads, where the speed is relatively low, it is usual to reduce the speed of the driving-wheels from that of the engine-shaft by intermediate gearing. The driving-wheel also needs to have a tire of great breadth to distribute the weight of the boiler and engine over a large area of yielding roadway. The tires are also usually corrugated or roughened to give adhesion. The traction-engine must have a very efficient means for steering it to enable it to make the sharp turns required in ordinary roads, and it is furthermore usually so designed that by throwing out the intermediate gearing from connection with the traction-wheels, the steam-engine proper can be used as an agricultural engine for threshing, milling, and other similar purposes.

The marine engine of transatlantic practice is usually an inverted vertical compound or triple-expansion, double-acting reciprocating engine. The cylinders are supported on massive cast-iron or cast-steel frames shaped something like a letter A, while the revolving shaft is below the cylinder and between the frames so as to secure immersion for the

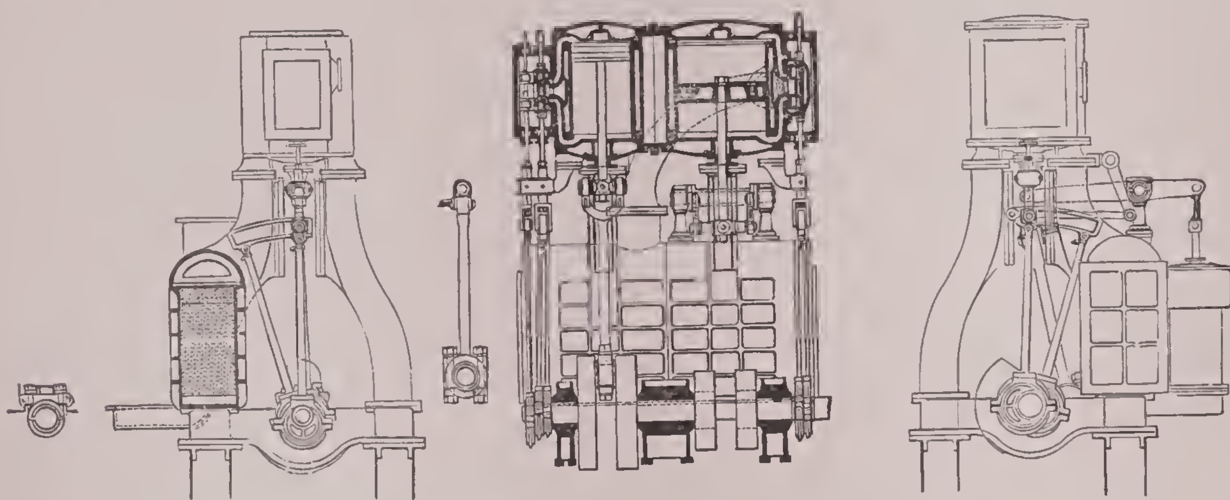

Fig. 10.

screw or propeller at the stern (Fig. 10). In the triple engine the cranks stand at angles of 120 degrees from each other, securing a good distribution of the turning effort upon the shaft. The cross-heads of the first and last cylinders usually operate the air-pump, by which the surface-condenser is freed from the condensed steam, while detached circulating pumps force the water of the ocean through the tubes to cool them. Injury to the valves by which the ocean water for condensation enters the engine has been the occasion of some noteworthy disasters to transatlantic vessels. The turning effort of the engine-shaft is transmitted from the engine to the propeller through a long shaft provided with the necessary bearings, and, in particular, a massive thrust-bearing, upon which is imposed the resistance to endwise motion which the reaction of the screw exerts as the vessel is forced forward. The thrust-bearing accommodates a series of collars, or enlargements of the shaft, whose area and number are proportioned so as to keep the pressure per inch of surface below that at which lubrication becomes difficult or impossible.

For the side-wheel vessel the necessity for having the center of the water-wheel shaft elevated above the water a distance nearly equal to the radius of the wheel has made the beam-engine and the inclined direct-acting engine the type most frequently met. Oscillating cylinders have been used in the past, but are not likely to be selected for large designs in the future. The inclined engine in the earlier practice was a simple condensing-engine; it has been made more recently compound and triple expansion. The advantage of the inclined type is that the center of gravity of the engine is low; the advantage of the beam type has been the flexibility which that construction permits, and that it secures a high piston-speed with a relatively small number of revolutions imposed by the large paddle-wheel, and allows a long stroke and a long connecting-rod without taking up valuable deck-room desired for cargo space in vessels of little depth of hull. On the other hand, when conditions necessitated such exceeding shallowness of hull, due to very light draught of water, that the concentrated weight of the vertical cylinder and the overhead beam became impracticable, there was developed a type of horizontal engine with long stroke and small diameter of cylinder, so that the weight of the engine might be distributed over a long length of the hull. The rapid current and tortuous channel of Western rivers suggested also the advisability of making the paddle-wheels on the two sides operate by separate cylinders, with a further advantage in distributing the weight of the engine. Furthermore, for towing on such rivers a type of steamer with the water-wheel at the stern has been developed, the wheel driven by cranks at each end of the shaft which are operated by long connecting-rods, one at each side. Great advantage has followed, where absence of ice makes the practice possible, from arranging the floats of paddle-wheels so that they will enter the water and leave it perpendicularly. The radial float tends to lift the vessel as it strikes, and to lift the water as it leaves; the perpendicular or feathering paddle produces all its effect in propulsion, without wasting a lifting effort. Feathering is secured by connecting the floats by a system of linkage which appears in several different forms.

For land engines and stationary practice probably the five most widely extended uses which involve the largest units are for pumping, for electric lighting and power, for mill and manufacturing purposes, for hoisting and air-compressing in mining, and for driving the roll-trains of iron and steel works.

For pumping, in addition to the Cornish engine, mentioned above, the two great types most usual are the beam-engine and the direct-acting pumping-engine. The older form of beam-engine was a single cylinder condensing-engine with overhead beam. The beam gives most convenient attachment for connecting-rods and plungers. More recently the compound and triple-expansion types have come forward, with either the beam below the cylinders or employing a beam of angular type, to various points of which are attached the rods to the fly-wheel shaft and to the pumps. An objection to the use of the fly-wheel in massive pumping-engines is its tendency alternately to accelerate and retard the flow of water in the main as the varying crank angle permits the piston to change its velocity. The direct-acting pumping-engine has no fly-wheel, but is so constructed that it can not stop when its stroke is completed by the expedient of having the valve which distributes the steam in the cylinder operated by another or an auxiliary engine, which latter receives its steam by the action of the piston of the main engine. This arrangement makes it impossible for the engine to stop with both steam passages covered by the valve. If this second or auxiliary steam-engine is made also to be a pumping cylinder, the type of direct-acting pump known as the duplex pumping-engine results. This type prevails very largely, and besides the advantage of having no fly-wheel and no dead centers, it offers the advantage of keeping the column of water always in motion, while a moment's pause at the end of the stroke of each cylinder permits the valves in that cylinder to seat themselves quietly before the return stroke begins. In some recent designs the horizontal type has been selected with fly-wheel and vertical beams.

For electric-light and power stations, and for electric railways, the type of horizontal engine, simple or compound, has been much used, the power being distributed among a large number of small units. In more recent practice, with larger units, the inverted vertical type, compound and triple expansion, has been extensively introduced, in many cases the revolving armature for the dynamos being continuous with the revolving shaft of the engine.

For both mill and manufacturing purposes the horizontal engine in tandem, cross-compound, or triple-expansion form has been by far the most widely distributed. The fly-wheel of such engines is usually made with a broad face, so as to be used as a belt or band wheel from which the power could be taken off to different driven shafts as required. The engines for cable-railway practice are usually of this type, but instead of flat belts, round ropes bearing in grooved pulleys are much more generally applied.

For hoisting-engines in mines and for elevator service it is usual to reduce the speed of the engine-shaft to that of the shaft which carries the hoisting-drum by means of toothed wheels or gearing; this permits the use of cylinders of smaller diameter operating at a high speed with the corresponding advantages. In air-compressing and blowing engines the horizontal and vertical type are very usual, the steam and air pistons being upon the same rod, and two connecting-rods from a cross-head between the two cylinders being coupled to crank-pins on the fly-wheel shaft. These air-compressing and blowing engines require a heavy fly-wheel by reason of the fact that the resistance is least at the beginning of each stroke, so that energy must be stored in them if the engine is working expansively, to be given out at the end of the stroke when the effort of the expanding steam is the least. For rolling-mill engines both horizontal and inverted vertical engines are used, in most cases connected directly to the train of rolls. The great variation in the resistance met by the rolls requires a very massive fly-wheel construction.

The requirement that the piston in the engine cylinder shall admit steam alternately upon its one side and the other, and shall at the same time discharge exhaust steam from one end while receiving live steam from the boiler at the other end, has given rise to a great many different types of mechanism for this purpose. The simplest type is a single valve, sliding upon a flat surface made at a convenient place on the side of the cylinder. The valve is caused to slide by means of a crank or eccentric, usually upon the revolving shaft, and so important is this function in the operation of an engine that space must be taken for a full description of the fundamental forms.

Fig. 11 represents a section of an engine-cylinder by which the action of the common D slide-valve (so called from

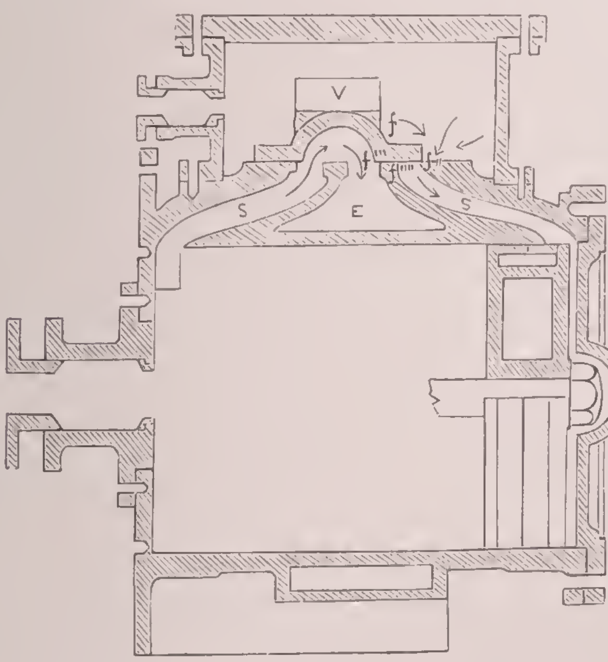

Fig. 11.

the shape of its section) may be explained. In this section V represents the valve, situated in a rectangular box or casing, which is in full communication with the boiler when the engine is running. This box, called the *steam-chest*, situated on the side of the cylinder and forming part of it, is constantly full of steam at nearly the boiler-pressure when the engine is in motion. S S are passages called steam-passages leading from this chest to the ends of the cylinder; E, a passage called the exhaust-port leading to the open air or to the condenser. The ports are long rectangular openings in a plane surface on the side of the cylinder. The valve V has such form and dimensions that it covers all these ports when in its neutral or middle position, and is caused to slide back and forth just enough to uncover alternately the steam-ports S S, the amount of this sliding, even in the largest engines, in which the valve may have a superficial area of several square feet, being only 3 or 4 inches. In small engines the extent of sliding in one direction may be only a fraction of an inch. This movement of the valve to the right and left is produced by means of an eccentric or small crank and a special connected rod attached to the valve, by which its motions are made to correspond in point of time with the motions of the piston; but the eccentric and main crank being keyed to the shaft in different positions, these motions, although taking place in the same times, will not at each moment correspond in direction or velocity.

It will be seen from the figure that the piston is at the end of its stroke, and its return to the opposite end depends on its receiving the impulse of steam admitted from the steam-chest just at this moment to drive it back. It will be observed, also, that the valve has been moved from its central position, covering all the ports, already sufficiently far to open the steam-port on the right a small amount, and steam is already admitted and fills the narrow space to the right of the piston. Thus the full boiler-pressure, or nearly so, is already acting on the right of the piston to drive it back. The condition of things on the left of the piston at this moment is quite different. The steam which has been confined in that part of the cylinder to the left, and which by its expansive action has driven the piston toward the right, is free to pass from this space into the atmosphere back through the steam-port S through which it came, but not into the steam-chest—the port S leading through the hollow of the valve to the exhaust-port; and this opening is by the movement of the valve already larger than the opening for admission on the right. The phenomena which take place while the piston moves from the right to the left are as follows: The valve completes its excursion to the left, and returns, so as to shut off the supply of steam on the right of the cylinder, while the piston is still in motion to the left. After the supply is cut off, the confined steam continues to act by its expansion alone, no more being admitted. The fraction of the stroke at which this occurs depends on the dimensions of the valve and the arrangement of the mechanism by which it is moved. It may happen, also, that by the same movement of the valve on its return to the right, and while the piston is still moving to the left, the exhaust-passage is closed so as to confine a portion of the steam in the left-hand part of the chamber, to act as a sort of cushion. This will occur at the moment the inner edge of the hollow part of the valve on the left reaches the inner edge of the steam-port. As the valve continues to move to the right, the outer edge of the valve on the left approaches the edge of the steam-port, and at a certain instant opens that port, letting new or "live" steam from the boiler into this end of the cylinder, which mingles with the exhaust steam already confined there as a cushion. This phenomenon usually takes place but an instant before the piston reaches the end of its stroke, in order that it may meet not only a cushion of exhausted steam, but of steam at full pressure from the boiler.

Fig. 12 represents on a larger scale a section of a simple

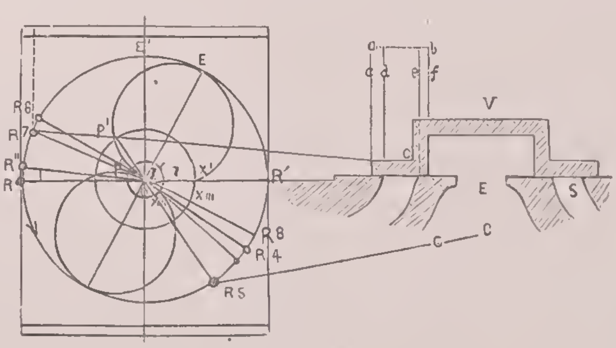

Fig. 12.

slide-valve and the cylinder ports, the valve being in its middle or neutral position, covering all the ports. The projection of the outer edges of the valve beyond the edges of the steam-ports, so that the ports are more than covered by the valve, is called the outside lap. It exercises an important influence on the distribution of the steam. The projection of the inside edges of the hollow part of the valve over the inner edges of the steam-ports is called the inside lap; it is always relatively small, and often does not exist to an appreciable amount.

The adjustment of the single slide-valve with a single eccentric, when once made, can not be easily changed while the engine is running. Where this is desirable in order to change the degree of expansion, and by that means the power of the engine, the link-motion is generally used. This is a device shown in Fig. 13, by means of which the

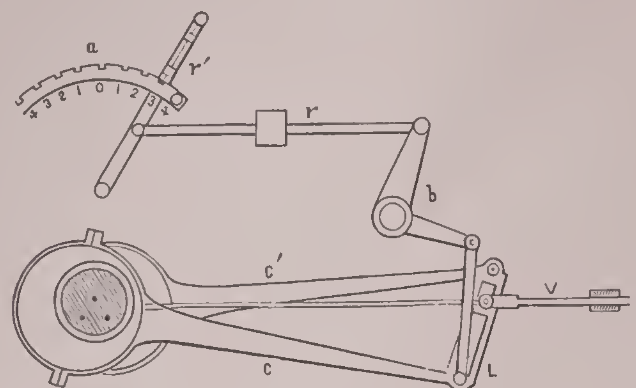

Fig. 13.

angle of advance and the eccentricity are simultaneously altered; and it is accomplished by means of two eccentrics, $C\ C'$, and a link, L, the effect of the two, with the link, being to make one virtual eccentric. The arrangement shown in Fig. 13 is that commonly used in locomotives, and is known as Stephenson's link-motion. It is arranged with a reversing lever, $r'$, by which either the eccentrics C and $C'$ can be caused to move the valve independently of each other, but one giving a forward motion and the other a backward motion to the engine. At positions of the link intermediate between these the virtual eccentric, which is the resultant of the two, controls the movements of the valve, and varies the degree of expansion. The notches in the arc ($a$) determine certain positions of the link with reference to the valve-stem, V. Applying Zeuner's valve-circle diagram to the Stephenson link with open rods, as in Fig. 14, O E is the

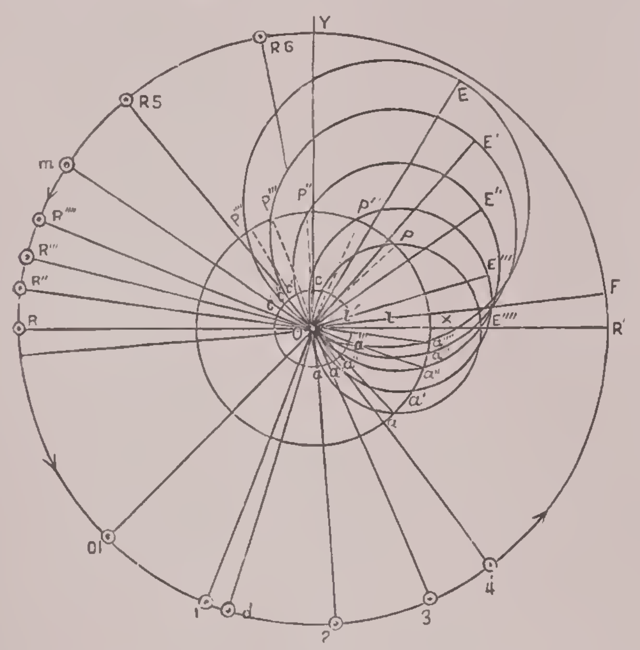

Fig 14.

eccentric and Y O E angle of advance for full forward gear (notch 4). For the third notch, O $E'$ gives the corresponding eccentric and angle of advance, and so on to mid-gear (notch 0), in which the eccentricity is O $E''''$ and the angle of advance 90°. The points of admission $a\ a'\ a''\ a'''$ on the left, from mid-gear to full-gear, the corresponding angles of lead, the points of cut-off $p\ p'\ p''\ p'''\ p''''$, the points of release $d\ d'\ d''\ d'''$ on the right of the piston, and the points of compression $c\ c'\ c''\ c'''$ on the right, are all shown for different grades of expansion; and the study of the diagram will also show the variations of lead, $l\ x$, for these different grades.

The extent of sliding movement of the valve is a consideration of importance, since the hurtful work of its friction depends directly on the extent of its motion. When slide-valves are very large, this useless work becomes an important item of expense. There are two means of reducing it: first, by reducing the travel or space passed over at each stroke; and, second, by relieving the back of the valve from a portion of the pressure of the steam in the valve-chest. Fig. 15 represents a valve in which both these methods are used. P is a plan of half of the valve, and S a section. There are two steam-ports, $s\ s$, on each side of the exhaust-port. When the valve moves from left to right, for instance, both ports $s\ s$ on the left are uncovered simultaneously; steam enters the *outer* port directly from the steam-chest, and the *inner* port indirectly through the arched opening in the valve O, the exhaust taking place on the opposite side, into the hollow of the valve and into the exhaust-port E. A partial vacuum is maintained on the back of the valve by means of a packing-ring, $r\ r$, which slides against the lower surface of the steam-chest cover, the space inclosed between this and the valve being connected with the condenser. This kind of valve is called an equilibrium double-ported slide-valve. The valve of which this is a representation had a total length of over 5 feet and a width of over 4 feet, the diameter of the packing-ring being about 4 feet; the extreme travel of the valve in one direction was only 5 inches, the outside laps less than 3 inches, and the inside laps only $\frac{1}{32}$d of an inch. It formed a part of the mechanism of a large marine engine.

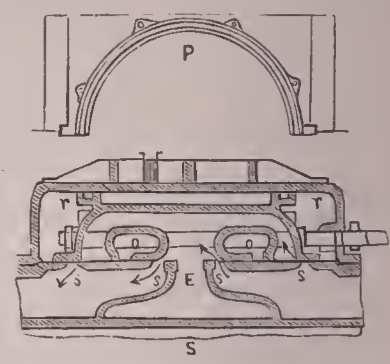

Fig. 15.—Double-ported equilibrium slide-valve.

To avoid long steam-passages, which are disadvantageous, two slide-valves are often connected by a bar and attached to the same valve-stem within the chest, these separate valves being then placed near the ends of the cylinder and having a common exhaust.

*Expansion-valves* and *cut-offs* designate special combinations of valve-mechanism by means of which the steam may be suddenly cut off at any point of the stroke independently of any other phenomena of the distribution of steam. The simple slide-valve, moved by a single eccentric, can not be arranged to cut off the steam at less than one-half the stroke advantageously, because, as will be evident from the inspection of the valve-diagrams for the link-motion, where the higher grades of expansion are used, the compression and release begin so much earlier that the power of the engine exerted in each stroke is diminished, and the efficiency—i. e. the economy—of the power is also diminished. To preserve the efficiency of the steam undiminished, and to place in the hands of the engine-driver the means of adapting the power of the engine to the work to be performed, two systems of construction are employed—one in which the variation in the expansion may be adjusted or controlled by the engine-driver by hand; for instance, when for a considerable period of time the engine is not required to perform its full amount of work, and a single adjustment for the given time is all that is required; and second, when a momentary variation of power may be advisable, so that the speed of the engine may remain invariable. The first system is an arrangement of expansion-valves, operated as required by the engine-driver; and the second system the "cut-off" system, in which the degree of expansion or the supply of steam at each stroke is regulated by the governor.

A great variety of expansion-valves, as well as variable cut-offs, are employed in practice. The most common, and perhaps the most simple and perfect, expansion-valve is exhibited in Fig. 16. In this figure the upper surface of the D-valve is made plane, and it is extended some distance beyond the outside laps, a mortise or rectangular aperture, nearly equal in area to the steam-port, being made in the ends. The valve is in other respects precisely like all other D slide-valves, and is moved by an eccentric, sometimes by two eccentrics, with a link for reversing the engine. The expansion-valve consists of two plates E sliding on the top of the D-valve (which is called in this combination the *distribution-valve*). These two plates are on the same valve-stem, S, which passes through both, and is supplied with screw-threads, right and left hand, so that when the stem is turned on its axis the two plates will approach or recede from each other. On their distance apart depends the period of cut-off, and a device may be attached to the valve-stem outside of the steam-chest by means of which this distance can be made greater or less by turning a hand-wheel even while the engine is running. The degree of expansion is thus controllable by hand. The expansion-valve is moved by a separate eccentric.

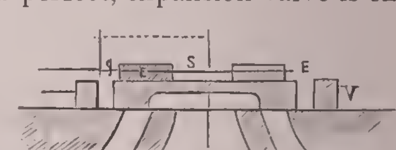

Fig. 16.

*Governor Cut-offs.*—Devices for cut-offs adjustable by the governor are very numerous. The old combination of the governor and throttle-valve is not a cut-off. Its action is to diminish or increase the pressure in the cylinder as the speed of the engine is increased or lessened, and thus diminish or increase the work per stroke; but a diminution of the initial pressure in the cylinder and the pressure throughout the stroke entails waste of heat and power, and is therefore only admissible where these considerations are not regarded as important. In stationary engines employed for many purposes it is not only important in point of economy that this waste should be avoided, but the character of the work may be such that variations of speed, to any considerable degree, are to be avoided. The action of the governor in causing a complete cut-off of the steam at any point of the stroke depends primarily upon the speed of the engine by which it is moved (see GOVERNORS), and secondarily upon its connection with the valves which close the steam-ports. The power of the governor is not sufficient, generally, to move these valves directly, and hence its action consists in nearly all cases in throwing into or out of gear mechanism driven by the engine itself; by which the requisite movement of the valve is produced. One mode consists in a sudden disconnection of the mechanism which moves the valve, which is then driven back so as to cover the steam-port by means of a weight or spring. The closing of the valve is thus almost instantaneous—a matter of importance both in the opening and closing of the valves. The Corliss engine furnishes an instance of this kind of cut-off. Fig. 17 repre-

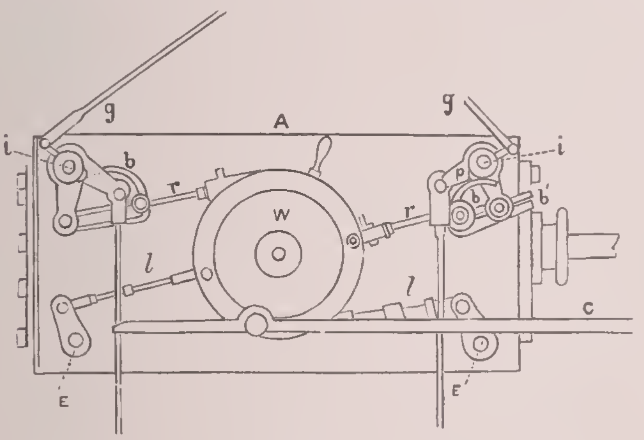

FIG. 17.

sents a section of the cylinder of a Corliss engine, with its four valves—the exhaust-valves and the steam induction-valves. The cut-off mechanism is exhibited in this figure, in which A represents a side elevation of the cylinder. The steam-valves move about axes projecting at *i i*, the exhaust-valves about axes at E E. W is a plate mounted on an axis projecting from the side of the cylinder. It performs the part of a "rocker" simply, being moved backward and forward by the eccentric-rod, *c*. The lever-arms of the lower or exhaust valves are connected with this "wrist-plate" by two links, *l l*, which are permanently adjusted, so as to cause the exhaust to take place at the proper moment. The upper corresponding lever-arms for the induction-valves have the form of bell-cranks, to one arm of which a weight is attached by a long vertical rod, shown in the drawing. The links, *r r*, attached to the wrist-plate are not permanently jointed to the bell-cranks, but the ends of these links or bars slide along the ends of the bell-crank; a notch in the sliding end catches the arm on the return motion and draws it back, opening the valve. The disengagement of this notch is effected by a bent piece, shown at *b*, which, as the link, *r*, is drawn back, strikes a small protuberance, *p*. The position of this small protuberance depends only on the governor. The governor-rods, *g g*, are attached to the ends of levers which move plates or rings embracing the axes, *i i*, and on these plates the protuberances are made. When the hook or bent piece strikes the protuberance, the notch is disengaged, and the weight, acting on the valve, closes it. The cutting off of the steam is thus instantaneously effected.

Another example may be given to illustrate the use of a cam-motion controlled by the governor. Fig. 18 represents a section of the cylinder of such an engine; V V the valves, which are balanced *poppet-valves*. These valves are double—that is, they have two conical seats—and when they are closed, the steam-pressure acting on both sides of the valve, it is nearly balanced. The stems of these valves extend to a position near the middle of the cylinder, and are there actuated by a cam, C, being alternately opened by the cam. When the cam in its revolution releases either valve, it is carried back promptly by a spring. The cam slides vertically on a rod, the vertical motion bringing a new arc of

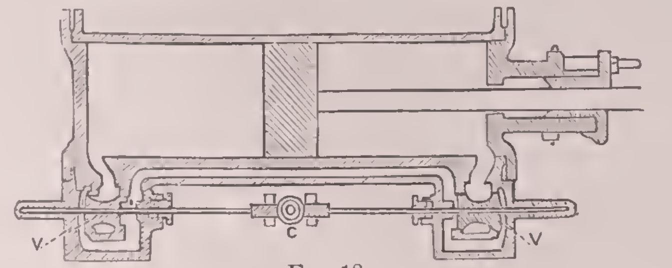

FIG. 18.

the cam into action. This vertical motion is controlled by the governor. Other efficient devices might be mentioned which are deservedly popular, but these are sufficient to illustrate the principle. The Stevens cut-off, so common on U. S. river-steamers, has poppet-valves, the vertical valve-stems having strong toes or projections attached to them which are lifted by corresponding toes or arms attached to the rock-shaft. This cut-off is not controlled by the governor, but is adjustable by the engine-driver. The Ryder cut-off is one in which by an ingenious device the governor performs the work of moving the expansion-valve unassisted by the engine.

*Fly-wheel.*—The fly-wheel is an important and essential appendage to the steam-engine under many conditions.

A stationary engine with a single cylinder requires a moving mass between the piston and the working-point, which by its alternate accelerations and retardations will store up and give out energy in such a manner as to keep the power, reduced to or at the working-point, nearly constant. As an example, the rolling-mill is perhaps the most striking. The useful work to be performed is in this case the driving of a heavy plastic bar or plate of iron or other metal between rolls—an operation not continuous, but occurring only at intervals. With a single-cylinder engine of the ordinary type the pressure of the steam on the piston at any instant is not usually sufficient to overcome the great resistance offered; by the interposition of a heavy fly-wheel, however, the action of the engine produces gradually a high velocity of revolution in the fly-wheel, causing an accumulation of energy. When the metal enters the rolls, this accumulated energy is given out; and even if the steam were suddenly shut off, the fly-wheel would carry the metal through the rolls. This is accomplished, however, only at the cost of a loss of velocity in the fly-wheel, which loss must again be restored by the engine. Again, when the resistance is sensibly constant, as when an engine is driving a shop or factory, the power of the engine is nothing at the dead-points, and is a maximum at nearly mid-stroke. If there were no moving mass to store up and give out energy, the engine must cease working at the first dead-point; for at that point the piston, which is the working-point, comes to a stop and begins to return on its course. When, in addition to the above considerations, the action of the steam on the piston is not constant, but diminishes gradually from the time it is cut off, the necessity for the fly-wheel to keep up a uniform or nearly uniform motion in the shaft is still greater; or, rather, the conditions on which its dimensions depend become more complicated. In cases where the energy of the fly-wheel is required for a short period of time to perform nearly the whole useful work, as in the case of a rolling-mill, its dimensions can not be theoretically estimated with certainty. Precedents and experience must then be the chief guides to the engineer. The dimensions suitable for a given engine, in which the resistances are supposed constant, may, however, be determined from theoretical considerations, at least with the aid of experiments made to determine certain constants which enter the formulas. It is impossible to establish a perfect uniformity of motion in the crank-shaft of an engine, because the mass, which by alternately gaining and losing energy preserves a uniform velocity during certain periods of motion, can only act by itself gaining or losing velocity momentarily at intervals of those periods; but under given conditions the variations of velocity may be made as small as is desirable.

The space available permits only a brief discussion of the theory of the action of steam in the steam-engine.

A certain quantity of steam enters the cylinder at each stroke of the piston, depending on the cut-off or degree of expansion. During this period the piston is actuated by the full pressure of the steam in the cylinder, generally a little less than that in the boiler, and performs a quantity of work represented in foot-pounds by the product of the pressure multiplied by the volume traversed during the period of full pressure, or $p_1 V_1$. After the steam is cut off it continues to act on the piston by its expansive force, but with a constantly diminishing pressure, to the end of the stroke. It is usually assumed in practice that the diminution of pressure takes place during this part of the stroke, according to the law that the pressure is inversely proportional to the volume; and on this supposition the mean pressure throughout the whole stroke is determined by the formula—

$$p_m = p_1 \frac{(1 + \log. r)}{r},$$

$p_m$ being the mean pressure, $r$ the ratio of expansion; the logarithms being taken in the Napierian system. As the piston returns, a certain back or negative pressure is unavoidable, due to the resistance offered by the steam that is being expelled from the cylinder. That pressure can not be determined from theoretical considerations, but it is approximately known from experience.

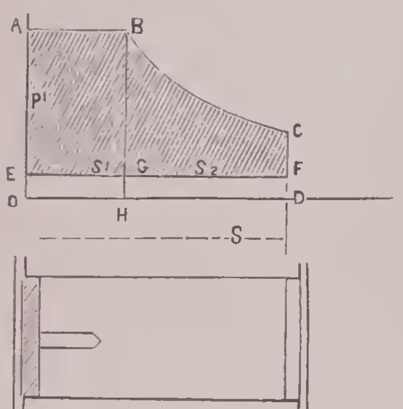

Fig. 19.

In engines in which the grade of expansion may be varied at will, the power of the engine will correspondingly vary. The engine making $n$ revolutions per minute, the distance passed over by the piston per minute will be $2nS$, which varies in practice from 200 to 800 feet. The formula is evidently a purely mechanical one—i. e. the force of the steam is treated as though it were any other force subjected to like variations, and acting upon the area of the piston. Questions of the quantities of heat do not enter. The action of this force is usually illustrated by a diagram as follows (Fig. 19): Let $OD = S$ represent the length of stroke of the piston; $AB = S_1$ the distance passed over by the piston before the steam is cut off. The ratio of expansion will be $\frac{S}{S_1} = r$, and that will be equal to the ratio of the volumes $\frac{V}{V_1}$ of the steam at point of cut-off and at the end of the stroke. Let $OA = p_1$ represent the initial pressure of the steam in pounds per square inch; then $p_1 A \times 144$ will represent the total force on the piston $= P$. The work performed during the travel from $O$ to $H$ or $A$ to $B$ will be represented by $PS_1$ or $A \times p_1 S_1 \times 144$. The area of the rectangle $OABH$ will then represent this work. The work performed during the travel from $H$ to $D$ will in the same manner be represented by the area $HBCD$, on the assumption that the curve $BC$ is an equilateral hyperbola. This area will be equivalent to $PS_1 \log. r$, and the sum of these two areas representing the whole work of the steam during one stroke,

$$PS_1(1 + \log. r).$$

It is assumed, further, that on the return of the piston the steam that filled the cylinder is discharged at a constant pressure, and that the fall of pressure at the end of the stroke, as well as the rise of pressure on the entrance of the steam, takes place suddenly while the piston is at rest. The area of the rectangle $OEDF$, subtracted from the sum of the areas given above, will then give an area, $EABCF$, which represents the work performed. The area $EOFD$ is represented by $p_2 V_2$, the value of $p_2$ being assumed.

The "efficiency" of a machine is a term used to designate the ratio of the disposable or theoretical work to the useful work. This is the usual mode of estimating the loss of effect in employing any machine. If the disposable work is estimated in the cylinder of the steam-engine in the theoretical manner above indicated, calling $W$ the disposable work and $W'$ the real work, the efficiency will be $\frac{W}{W'}$, a fraction always less than unity, because, on account of friction, there is always in any machine a certain amount of useless or ineffective work. There are generally also other causes of loss, so that the efficiency of a machine becomes still less. The efficiency of machines can be determined, therefore, only when the disposable work $W$ and also the useful work $W'$ can be determined.

In estimating theoretically the power of an engine furnished with a steam-jacket, it is impossible to assume with certainty the actual conditions of the problem. It is not known, for instance, precisely what quantity of heat will be furnished by the steam-jacket, nor what relative quantities of vapor and water will be found in the cylinder at the beginning of the expansion. It is usually assumed that enough heat enters the cylinder from the jacket during the expansion to prevent the condensation which would occur if no heat were added—i. e. if there were no steam-jacket; that the curve of expansion is the curve of quantity of vapor constant, and that the steam is saturated and dry at the beginning of the expansion. The curve of expansion is then represented by Rankine by the formula

$$PV^{1\cdot06} = P_1 V_1^{1\cdot06} \text{ or } P = C_1 \frac{1}{V^{1\cdot06}} = C\frac{1}{V^{1\frac{1}{16}}},$$

and the mean forward pressure is given by the formula

$$p_m = p_1\left(17\frac{1}{r} - 16\frac{1}{r^{1\frac{1}{16}}}\right),$$

$r$ being the ratio of expansion. The mean effective pressure $(p_m - p_2)$ is then known when $p_2$ is assumed.

The application of purely theoretical rules to the expansion is complicated by an important secondary phenomenon which can not well be submitted to analytical investigation. The cylinders of ordinary engines are made of cast iron, which takes up and gives out heat as a sponge takes up and gives out water. On this account, the expansion line of actual engines differs so much from any theoretical line that can be drawn that it is only from experiments with the indicator that the effect of this interchange of temperature between the iron cylinder and the mixed steam and water can be determined.

The use of the steam-jacket, or annular casing enveloping the cylinder with hot steam from the boiler, is an economizer of heat, not because condensation during expansion by the adiabatic curve is in itself a loss of heat, but because the presence of liquid water in the form of cloud, or in any other form, in the cylinder facilitates and renders more rapid the interchanges of heat with the metal of the cylinder and the hot steam entering from the boiler. Thus the initial pressure is diminished and the final pressure is increased in a way that can not be estimated theoretically. As nearly all engines work expansively, it is therefore generally impracticable to ascertain theoretically, except as a mere approximation, the quantity of work which an engine under given conditions is actually exerting. The only true resource is the indicator.

The following table gives the quantity of vapor required per horse-power per hour for an ideal engine:

| Pressures in atmospheres. | Pounds of water or vapor per horse-power per hour. | |
|---|---|---|
| | Non-condensing-engines. | Condensing-engines. |
| $1\frac{1}{2}$ | 73·9 | 15·6 |
| 3 | 33·3 | 12·9 |
| 4 | 26·7 | 12·0 |
| 5 | 23·2 | 11·5 |
| 6 | 21·0 | 11·0 |
| 8 | 18·3 | 10·4 |
| 10 | 16·7 | 10·0 |

The efficiency of a steam-engine in actual use may be ascertained by comparing the quantity of steam actually used to give one horse-power per hour with the quantity given by the above table for the same initial and terminal pressures of the steam. For instance, a non-condensing-engine may give a horse-power per hour with a consumption of 35 lb. of water or steam at a pressure of 6 atmospheres—a common performance. The theoretical quantity required in a perfect engine, according to the preceding table, for the same initial pressure is 21 lb. The efficiency of the engine under these circumstances, measured by the standard of steam required, is $\frac{21}{35} = 0·6$. Ordinary boilers of the best type may evaporate 9 lb. of water for 1 lb. of coal burned, the maximum of evaporation of the boiler being about 13·5 lb. of water per pound of coal. The efficiency of the boiler is then $\frac{9}{13·5} = \frac{2}{3}$. Multiplying these efficiencies together, we have the efficiency of the boiler and engine equal to $0·6 \times \frac{2}{3} = 0·4$.

The efficiency of the apparatus, measured by the ratio of the work in foot-pounds accomplished to the number of foot-pounds of work, which are equivalent to the heat evolved in the combustion of fuel, gives a different result. A non-condensing-engine that requires 35 lb. of water per horse-power per hour will require a consumption of about 4 lb. of coal per horse-power per hour, of which only about six-tenths are available, the other four-tenths being waste heat of the boiler, heat required to produce the draught, etc. One horse-power per hour is equivalent to 1,980,000 foot-pounds per hour of actual work. The available heat of combustion of 4 lb. of coal is about 24,000,000 foot-pounds. The efficiency of the whole apparatus on the basis of the heat which is imparted to the water by the combustion of the fuel will be $\frac{1,980,000}{24,000,000} = \cdot 08$, approximately. In condensing-engines a corresponding calculation will give an efficiency of ·17, a horse-power per hour being produced by 1·3 lb. of coal in some instances. The efficiencies of the non-condensing and condensing engines approach each other as the initial pressure increases.

It may be stated, as general conclusions, that the use of a steam-jacket with a single cylinder under ordinary circumstances results in an important saving of fuel, especially for high degrees of expansion; that in the compound engine, with the larger cylinder jacketed, there is a saving in economy over a single cylinder jacketed, even with the same steam-pressures and degree of expansion in both. This last conclusion, although derived from what appear to be conclusive and satisfactory experiments, is perhaps not universally accepted by engineers, the subject being one about which there is still considerable discussion. Large cylinders are more economical in expenditure of fuel for a unit of power than small ones, and slow-speed engines generally less economical than high-speed engines. An engine using steam at high pressures, other things being equal, is more economical than one using steam at low pressure. In regard to the degree of expansion to be allowed in designing an engine, it is to be observed that the point of cut-off with a given pressure determines the mean pressure in the cylinder; and if the speed of the piston be fixed the size of the cylinder is determined.

There is still a want of precise and definite rules for ascertaining the most economical degree of expansion in every given case; and hence a theoretical calculation of the dimensions of the cylinder of an engine to be constructed is a problem which involves some degree of uncertainty as to maximum economy. In a paper presented to the American Society of Civil Engineers by Dr. C. E. Emery, M. E., in 1874, giving an account of experiments made by him for the U. S. Navy Department, the following formula is given, based on the experimental data for the most economical ratio of expansion in a single cylinder:

$$r = \frac{p+37}{22},$$

in which $r$ is the ratio of expansion, $p$ the initial pressure above the atmosphere. For example, taking $p$ equal to 5, 10, 25, 40, 60, 80, 100, the values of $r$ will be 1·9, 2·1, 2·8, 3·5, 4·4, 5·3, 6·2, respectively. Dr. Emery states that these ratios are "nearly correct for single engines of large size, with details of good design, too small for single engines of ordinary construction, and too small for the better class of compound engines." The final performance of an engine can only be satisfactorily tested by the use of the indicator and dynamometer, with condensation of the steam and measurement of the consumption.

**Steamer-duck**: See Duck.

**Steam-hammers**: hammers which are raised by the direct action of steam on a piston in a steam-cylinder, as distinguished from hammers which are raised by other mechanical means, receiving their power from a steam-engine through the intervention of belts and pulleys or gearing. A heavy mass of iron constitutes the hammer, or "tup," as it is called. This tup slides freely in guides or ways in the frame or upright of the hammer. On top of this framer is placed a cylinder fitted with piston, piston-rod, and valve, after the manner of a steam-engine. The piston-rod, extending downward through a stuffing-box in the bottom cylinder-head, terminates in its attachment to the tup or hammer. Steam admitted under the piston raises it, and thus lifts the hammer; upon the opening of the exhaust and escape of the steam the hammer falls with a force due to its weight, less the friction of the piston, piston-rod, and escaping steam. This form of hammer was at first made single-acting only, that is, the steam is used only beneath the piston, but hammers are now commonly made double-acting, the pressure of the steam above the piston in the down stroke assisting the action of gravity, thus causing the hammer to strike a more rapid and more powerful blow.

The first practical steam-hammer, it is generally stated in English treatises, was invented and constructed by James Nasmyth, of the Bridgewater foundry, Patricroft, near Manchester, England. He had proposed the construction of such a hammer for forging the paddle-wheel shafts of ocean-going steamers in 1837. It is also claimed that the steam-hammer was invented by François Bourdon, in France, in 1839; and one was built from his designs by the Creusot iron-works in 1841. Earlier patents upon steam-hammers were taken out in England, by James Watt, in 1784, and by William Deverell in 1806, but there is no reason to believe that these patents were ever worked.

Nasmyth's first hammers—single-acting only—were worked by hand, but his engineering manager, Robert Wilson, hit upon a plan of operating the valve automatically; and he also, it is believed, first applied the balance principle of valve to the steam-hammer.

Steam-hammers have more cause to deteriorate in use than almost any other machine tool, inasmuch as the severe shocks to which they are submitted while in use tend to destroy their parts. In the earlier hammers the piston-rod seems to have been the part which gave the greatest trouble, and many inventions were made to remedy the defect.

Robert Morrison, of Newcastle-on-Tyne, in 1853 patented a steam-hammer in which the piston-rod was the hammer, and the blow was imparted by the end of the piston-rod properly protected by a shoe or hammer-face. He made the piston-rod very large and of wrought iron, welding the piston to the middle of this long rod, and guiding it by stuffing-boxes in the upper and lower cylinder-heads. To prevent the bar from turning, he cut a flat on the rod above the piston-head, and guided it by a corresponding shape in the top cylinder-head. Hammers for heavy forgings are constructed with double uprights, large-sized hammers, with a long stroke, having a wide spread of base between the legs of the upright to give room for the workmen to handle the iron being forged. The anvil-face is usually set at 18 inches above the floor-level. Fig. 2 shows a double upright hammer of the Morrison type. These large hammers are not made self-acting, as it is found to be more

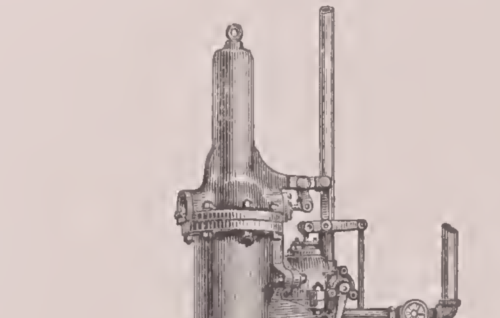

Fig. 1.

advantageous to work them by hand. In light work, such as drawing out bars of steel, an automatic valve-motion is of the utmost importance. Fig. 1 shows the form of a single upright hammer as used for light forging. A hammer weighing 300 lb.—i. e. the hammer-bar, or part which strikes the blow, weighing 300 lb.—should make at least 300 blows per minute to work economically in light forging. An important feature in these rapid-running steam-hammers is the separation of the exhaust-passages in the slide-valve, so that the exhaust from the space below the piston escapes through a passage which does not communicate with the exhaust-

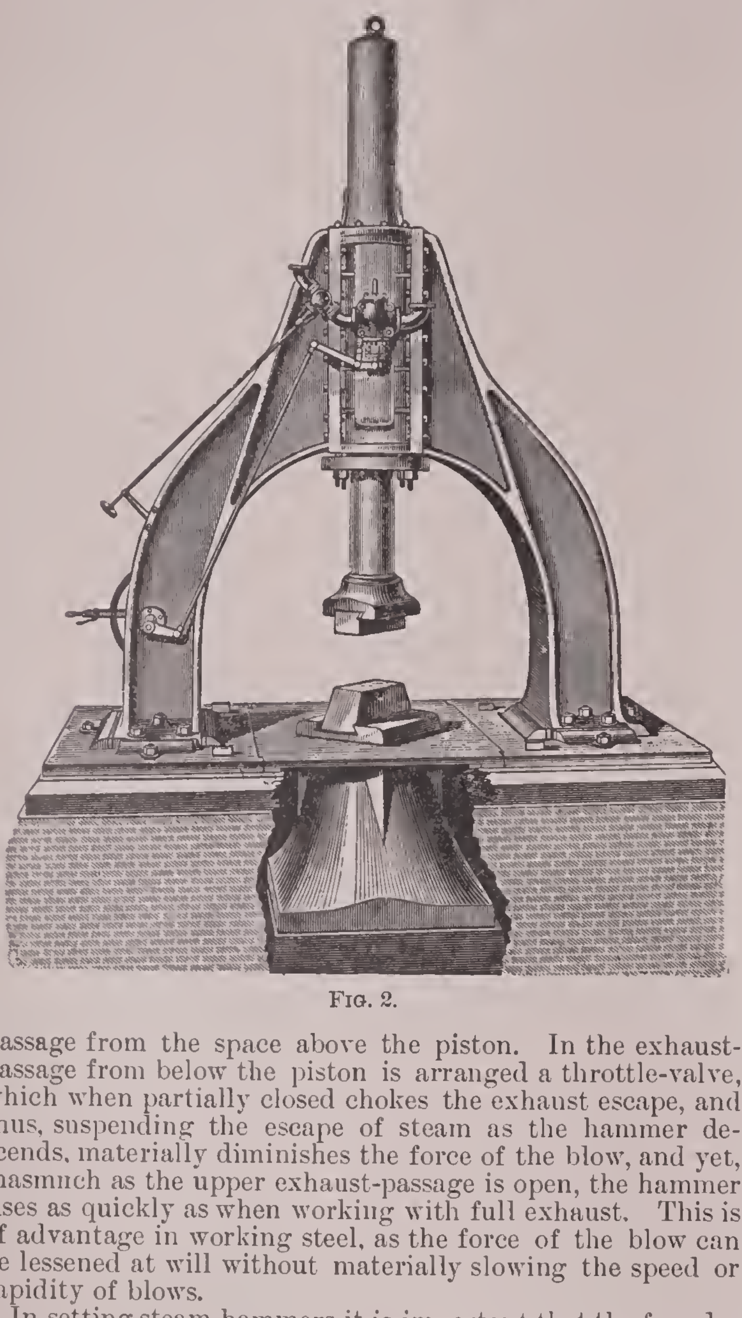

Fig. 2.

passage from the space above the piston. In the exhaust-passage from below the piston is arranged a throttle-valve, which when partially closed chokes the exhaust escape, and thus, suspending the escape of steam as the hammer descends, materially diminishes the force of the blow, and yet, inasmuch as the upper exhaust-passage is open, the hammer rises as quickly as when working with full exhaust. This is of advantage in working steel, as the force of the blow can be lessened at will without materially slowing the speed or rapidity of blows.

In setting steam-hammers it is important that the foundations should be of the most substantial character. It is usual to make the anvil-block separate from the hammer, and to place it on a separate foundation which is underlaid with some thicknesses of wood, say with two layers of closely fitted timbers at least 24 inches in thickness. This gives a degree of elasticity to the anvil and preserves the foundation. The anvil for iron-forging hammers should not be less than five times, and for steel-forging ten times, the weight of the hammer. The direct-acting steam-hammer has numerous rivals in iron making and shaping, such as helve and other power-driven hammers, which are found useful in many lines of manufacture; drop-presses, used for drop-forging; driven rolls; and, finally, hydraulic forging-presses. The steam-hammer forges the metal into the required shape with repeated blows and well-directed skill on the part of the workman. In hydraulic forging the red-hot metal may be made to flow in a solid state into metal moulds, and driven into them by plungers operated by hydraulic presses; but the hydraulic press may also be used to compress metal between a flat movable block and an anvil, thus becoming a direct competitor with the steam-hammer. The first cost of hydraulic apparatus, however, limits the extent of its introduction, and the steam-hammer will probably long continue to be one of the most extensively used forms of apparatus for forging iron and steel.

The largest steam-hammer in the world was built in 1891 at the Bethlehem, Pa., steel-works. The weight of tup, piston-rod, and piston aggregates 125 tons. The cylinder is 76 inches in diameter, and the stroke is 16½ feet. The anvil-foundation contains twenty-two blocks of cast iron, averaging 70 tons each, resting upon steel slabs supported by white-oak timbers. The mass of iron and steel in the foundation weighs 1,800 tons. Revised by William Kent.

**Steam-heating**: See Warming and Ventilation.

**Steam-vessels**: ships propelled by steam. The possibility of using steam for the propulsion of ships seems to have occurred to Roger Bacon in the thirteenth century. It has been stated that Blasco de Garay, of Spain, in 1543, propelled a vessel by steam, but La Fuente, the Spanish historian, having investigated the matter, found that de Garay made (1540–43) trials at Barcelona with paddles on ships furnished by Charles V., but in every case the paddles were moved by men. Suggestions as to the use of steam, none of which were carried out, were made by Salomon de Caus (1615) and the Marquis of Worcester (*Century of Inventions*, London, 1663). The earliest practical effort appears to be that of Papin, who in 1707 applied his steam-engine to the propulsion of a model on the Fulda river at Cassel. Newcomen had in the meantime brought the steam-engine itself to a working condition; and in 1736 Jonathan Hulls patented a marine steam-engine which he proposed to employ in a vessel to be used as a tugboat. About 1763 William Henry, of Pennsylvania, built a small model steamboat, which he tried with success on the Conestoga river; the experiment is notable as having furnished the hint to the efforts made later by Robert Fulton. During the last quarter of the eighteenth century the problem of steam-navigation had begun to engage many minds in Europe and the U. S. In France the Count d'Auxiron and M. Perier made experiments in 1774–75, and the Marquis de Jouffroy, upon a larger scale and with better success, in 1776–83. In the U. S. James Rumsey, of Maryland, was similarly engaged, and in 1786 built a boat which was propelled upon the Potomac by steam at the rate of 4 miles an hour by means of a jet of water forced out at the stern. He built a boat in London with which a successful experiment was made on the Thames in 1792. Meanwhile John Fitch experimented on the Delaware river. His first boat, built in 1786, was propelled by paddles moved by a steam-engine; at first a speed of only 3 miles an hour was attained, but improvements increased that speed to 8 miles. It is noticeable that in his boat he employed side-wheels, with a screw-propeller at the stern. In 1788 Miller, Taylor, and Symington built a boat which consisted of two connected hulls driven by a single paddle-wheel between them, which obtained a speed of 5 miles an hour on Dalswinton Loch. They built a larger vessel in 1789 with a steam-engine of 12 horse-power, which attained a speed of 7 miles. In 1801 Symington built a boat for towing, which drew vessels of 140 tons at the rate of 3½ miles an hour. About 1790 Robert Fulton left the U. S. for England, where he turned his attention to mechanics, and especially to steam-navigation. He made experiments in France, which were only partially successful, but he secured the confidence and aid of Robert R. Livingston, the U. S. ambassador, and in 1806 returned to New York, bringing with him a Boulton & Watt steam-engine, for which a hull was built. This vessel, named the Clermont, made a trial trip to Albany, Aug. 7–9, 1807, returning on the two following days, her average running speed being 5 miles an hour. The Clermont was 130 feet long, 18 feet beam, 7 feet deep, with a burden of 160 tons. She soon began making regular trips between New York and Albany, and for all practical purposes must be considered the first steamboat adapted for the conveyance of passengers and freight. Fulton and Livingston obtained from New York the monopoly for using steam-vessels in the waters of the State. John Stevens, of New York, was even earlier than Fulton an experimenter in steam-navigation. In 1789 he had perfected his plans for a steam-vessel, and in 1804 and 1805 built small vessels which showed that his plans were sound. The Phœnix, his first steamboat, completed in 1807, followed hard upon Fulton's Clermont. Prevented by the monopoly of Fulton and Livingston from navigating the Hudson, he sent his boat by sea to the Delaware, upon which she was afterward employed, and in this voyage demonstrated the problem of the possibility of the use of steam-vessels upon the ocean. Steam-vessels in the U. S. were thus an assured success. Fulton and his coadjutors soon placed a fleet of them upon the

Hudson river and Long Island Sound, while Stevens and his sons placed their steamers upon the Delaware and the Connecticut, and upon the Hudson after Fulton's monopoly had expired. The first steamboat in Great Britain was the Comet, 40 feet long, built in 1812 for the navigation of the Clyde; but before this time Fulton and Livingston had begun to build steamers at Pittsburg, Pa. Upon all navigable rivers and smooth waters of the civilized world steamboats were rapidly introduced, and their use upon the ocean followed. As early as 1819 the steamer Savannah made the voyage from Savannah, Ga., to Liverpool, England, in twenty-two days, and thence to Russia. From that time the development in ocean steamships has been steadily toward larger steamers, including the famous Great Eastern. The Lucania, of the Cunard Line, a screw steamship of steel, 620 feet long and having a gross tonnage of 13,000 tons, crossed the Atlantic from Queenstown to New York in 5 days 7 hours and 23 minutes (Oct. 21–26, 1894).

Revised by Marcus Benjamin.

**Stear'ic Acid** [*stearic* is from Gr. στέαρ, tallow]: the most abundant of the solid fat-acids; obtained in the saponification of all the fats containing stearin, and especially of beef's tallow, mutton suet, hog's lard, etc. The so-called stearic acid (or stearin) of commerce is a mixture of stearic and palmitic acids. This commercial stearic acid is produced by the treatment of neutral fats by superheated steam or by alkalies. See Soap.

*Saponification of fats by water alone*, at a high temperature, was patented by R. A. Tilghman, of Philadelphia, Jan. 9, 1854, and about the same time (Apr., 1854) by Berthelot, who announced that he had resolved the neutral fats with water in closed vessels at a temperature of 428° F. Tilghman specified the preferred temperature of melting lead, 625° F., but names also the melting of bismuth, 518° F., and to promote the reaction caused the mixture of water and fat to traverse small tubes of wrought iron heated in a fire to a pressure of 90 or 100 atmospheres. Tilghman's process, as originally set forth in his patent, was never introduced in practice. The very high temperature employed destroyed the glycerin and contaminated the stearic acid. As subsequently modified, it has been used with success, but, as the courts have decided, not within the limits of the patent. Melsens, of Brussels, almost at the same time with Tilghman took out in Belgium a patent for the use of water slightly acidified by sulphuric acid to act on fats under pressure at a temperature of 356° to 392° F. The presence of a small quantity of sulphuric acid—1 to 10 per cent. of the fat used—favors in a remarkable degree the evolution of the fatty acids. Melsens's method was put into successful operation at Antwerp almost immediately, using a peculiar form of digester, lined with lead, holding a ton of tallow, to which was added 50 per cent. of water, and in six hours the decomposition was complete at a temperature of 356° F. (ten atmospheres), and the fatty acids obtained were very satisfactory.

The possibility of decomposing the fats by water under high pressure was distinctly recognized by Chevreul, who pointed out the perfect analogy between the fats and the compound ethers, which are decomposed when heated in close vessels in contact with water.

George Wilson in 1852 revived the method of decomposing fats at a high temperature, and subsequently distilling off the acids and glycerin separately by a current of superheated steam, originally conceived by Chevreul and attempted by Bussy and Le Canu in 1825, and more successfully by Dubrunfaut in 1841. In 1855 Wilson exhibited to the jury of the Paris Exposition of that year the results of his method on palm oil by means of water and heat alone, distilling off both glycerin and fatty acids in a way to obtain all the products in a state of chemical purity. To this end the oil is heated in a still to the temperature of 550° to 600° F., and then a stream of subdivided, superheated steam passes through it of a temperature of 600° F. Below 550° F. the saponification and distillation of the products is slight; at about 600° F. the distillation is more rapid, but is then accompanied with the production of acroleins. It is by this process that Price's glycerin is produced. This process works well only on palm oil, and is in fact only a slight modification of the previous process of Dubrunfaut. The complete success of the hot-water process was achieved only in 1857 by Wright and Fouché—French patent of 1857, American in 1859. This requires particular mention.

*Wright and Fouché's apparatus by hot water alone* produces complete decomposition of fats into fat-acids and glycerin by a continuous and automatic commingling of water and steam with the fat at a pressure and temperature of ten to twenty atmospheres for a period of twelve to twenty hours. No lime is used; water at the temperature named is the sole chemical agent; and the glycerin produced is of excellent quality; the stearic and palmitic acids (after expressing the oleic acid) are white, fine-grained, hard, and free of odor.

Revised by Ira Remsen.

**Ste'arin** [from Gr. στέαρ, tallow] ($C_3H_5(C_{18}H_{35}O_2)_3 = C_{57}H_{110}O_6$): a glyceride or ether of glycerin, as shown by the formula *tristearin*. In commercial parlance, *stearin* is a term applied to the impure stearic acid obtained by the saponification of fats in the preparation of star candles. Tristearin is the natural form of stearin in hard fats.

**Stearns**, John William: See the Appendix.

**Stearns**, Lewis French, D. D.: theologian; b. at Newburyport, Mass., Mar. 10, 1847; nephew of President William A. Stearns; graduated at Princeton College 1867; studied theology at Princeton, in Berlin, and Leipzig, also in the Union Theological Seminary, New York, where he graduated in 1872. He was pastor of a Presbyterian church at Norwood, N. J., 1873–76, and Professor of History and Belles-Lettres at Albion College, Michigan, 1876–79; Professor of Systematic Theology in the Congregational Seminary at Bangor, Me., 1880, until his death. His inaugural discourse at Bangor (June 1, 1881) attracted much attention for its marked ability. In July, 1891, he read before the Congregational International Council in London a paper of very high merit on the *Present Doctrinal Tendencies of American Congregationalism*. His principal works were the *Lectures on the Evidence of Christian Experience*, delivered at the Union Theological Seminary, New York, in 1890, and subsequently published, and a posthumous volume, *Present Day Theology*. D. Feb. 1, 1892.

George P. Fisher.

**Stearns**, William Augustus, D. D., LL. D.: fourth president of Amherst College; b. at Bedford, Mass., Mar. 17, 1805, the son and grandson of Congregational clergymen; graduated at Harvard College 1827; studied theology at Andover, and after teaching a short time at Duxbury was ordained to the ministry, and installed pastor of the Congregational church at Cambridgeport Dec. 14, 1831. In 1854 he accepted the presidency of Amherst College, which he held till his death June 8, 1876. Besides valuable addresses given during his connection with the college he published several sermons, with papers in the *Bibliotheca Sacra*, *Biblical Repository*, and *New Englander*, a work on *Infant Church Membership* (Boston, 1844), and *Life and Select Discourses of Samuel H. Stearns* (1846).

**Ste'atite**, or **Soapstone** [*steatite* is from Gr. στέαρ, στέατος, tallow, fat]: a kind of stone which receives both its names from its unctuous quality. It is a compact form of talc, and is an impure hydrated silicate of magnesia. It has some use in the porcelain manufacture. A soft white sort is the French chalk of the toilet and of the tailors' shops. Powdered steatite is employed as a lubricant, and is an ingredient in several kinds of steam-packing. Steatite is easily cut into figures, which are then hardened by fire and colored to imitate more costly stones. Steatite is employed in making stoves and foot-stoves for use in cold weather, since it retains heat for a long time. It is abundant in many parts of the U. S. and other countries.

**Stebbins**, Horatio, D. D.: pulpit orator; b. at Hampden, Mass., Aug. 8, 1821; educated at Exeter Academy and Harvard College; graduated at the latter in 1848, and from Harvard Divinity School in 1851; received degree of D. D. from Bowdoin College in 1856; pastor of Unitarian churches at Fitchburg, Mass., and at Portland, Me., where during the civil war he made a civic reputation which led to his call in 1864 to the Unitarian church in San Francisco (where he has since remained) as the successor of Thomas Starr King, who had done the Union cause great service with his voice and pen. He has been actively engaged in educational work and in social reforms; has published sermons and addresses and several orations.

John W. Chadwick.

**Steckel**, Louis Joseph René: engineer; b. at Wintzenheim, Alsace, in 1844; studied engineering and architecture at Quebec; engaged 1861–62 on Gaspé and St. Lawrence road surveys; appointed in 1863 draughtsman of public buildings Ottawa; in 1870 on permanent engineering staff, Public Works Department, Canada; in 1873 assistant engineer on canal, harbor, and river works, Dominion of Canada, and in 1880 was appointed chief clerk engineering branch, Public Works Department. He is author of *Geometrical Solutions of Difficult Problems in Land Surveying* (1866); *An Essay on the Liquid Contracted Vein*; and various technical reports. NEIL MACDONALD.

**Stedman**, EDMUND CLARENCE, LL. D., L. H. D.: poet and critic; b. at Hartford, Conn., Oct. 8, 1833; studied at Yale College; became in 1852 editor of *The Norwich Tribune*, in 1853 of *The Winsted Herald*; settled in New York in 1855; in 1860 was employed upon *The New York Tribune*; was an editor and war correspondent of *The New York World* 1861–63; contributed to *The Atlantic Monthly* and other magazines; was in 1863 in the attorney-general's office at Washington, and has been since 1865 a stockbroker in New York. He is the author of *Poems Lyric and Idyllic* (1860); *Alice of Monmouth, and other Poems* (1864); *The Blameless Prince, and other Poems* (1869); and *Hawthorne, and other Poems* (1877). His *Poems* were collected in a single volume in 1873. He delivered his narrative poem, *Gettysburg*, in 1872 at a meeting of the Army of the Potomac, and his *Ode* at Dartmouth College 1873. Since 1873 he has devoted himself largely to critical work; *Victorian Poets* (1875; 13th ed. with supplementary chapter in 1887) was followed by *Poets of America* (1885), and by *The Nature and Elements of Poetry* (1892), originally delivered in 1891 at Johns Hopkins University as a lecture series on the Percy Turnbull memorial foundation. In 1891 he succeeded James Russell Lowell as president of the American Copyright League. In 1888–90 he edited, with Ellen Mackay Hutchinson, a *Library of American Literature*, in 1897 published another volume of *Poems*, in 1895 brought out *A Victorian Anthology*, and in 1900 *An American Anthology*.

**Steel** [O. Eng. *stēle*: O. H. Germ. *stahal* (> Mod. Germ. *stahl*): Icel. *stāl*; cf. O. Pruss. *stakla*. Russ. *stalĭ* is loanword from Germ.]: a term comprising several modifications of iron. It is necessary to define the term "steel" at some length, since the old classification very inadequately describes the modern cast, malleable compounds of iron, carbon, and metalloids used for structural purposes, and constituting at least three-fourths of the metal now made by steel processes. The old term "steel" referred to the cast malleable product of iron and so much carbon (from $\frac{3}{4}$ to $1\frac{1}{2}$ per cent.) that the metal would harden when heated to redness and quenched in water; it is used almost exclusively for cutting tools. The homogeneity of this metal is, however, an equally distinguishing quality, and is due to its having been poured into a mould while in a fluid state, so that the slag might separate by gravity, and the metal might become solid and crystalline. Wrought iron, on the contrary, while having similar chemical properties, and sometimes as much carbon, consists of pasty masses from which the slag is rarely quite expelled by the pressure that sticks them together; it is therefore laminated in structure. As the soft compounds and those largely varying in chemical constituents came gradually to be produced by casting processes, it was natural and convenient to enlarge the term "steel" to cover them; and the use of the term was at the same time rendered legitimate and scientific by basing the classification on one of the grand characteristics—structure due to casting—rather than on ingredients, as heretofore, especially since structural qualities were constantly increasing in importance. It is found practically convenient to distinguish between all the cast malleable compounds, whether hard or soft, by affixing the name of the metalloid chiefly incorporated, such as chrome steel, manganese steel, and the like, or the percentage of carbon, or both. It is important to know the amount of carbon in structural steels, and this may be readily determined. The general usage of commerce, as well as of works, is rapidly fixing this enlarged definition. As this article is intended to refer to those compounds of iron which are generally known and sold as steel, such as Bessemer rails and open-hearth boiler-plate, as well as tool-steel and spring steel, the definition must for these purposes be as follows: Steel is a compound of iron which has been cast from a fluid state into a malleable mass. The terms "pot" or "crucible" steel, "open-hearth steel," and "Bessemer steel" are convenient for distinguishing processes of manufacture, but they do not necessarily distinguish between steels which differ either chemically or mechanically.

*Nature and Composition of Steel.*—From the preceding definition it will be observed that the grand structural characteristic of steel, to which it largely owes its value for all uses, is homogeneity due to fusion; also, that its chemical constituents and the characters due to them are very various. The important chemical qualities of tool-steel are: (1) The tempering quality, which is due, first, to the presence of say $\frac{3}{4}$ to $1\frac{1}{4}$ per cent. of carbon; second, to the mechanical mixture of this carbon with the metal by means of slow cooling from a red heat, which makes the metal comparatively soft, so that it can be cut with the ordinary tools; third, the extreme hardening of the metal, when, by means of sudden cooling, the carbon is chemically dissolved in the iron. (2) An important condition of tool-steel is its freedom from ingredients, such as phosphorus, which induce brittleness. Excepting some modern steels, in the manufacture of which nickel, manganese, tungsten, chromium, titanium, and some other metalloids are employed, the best tool-steels have but a few hundredths of 1 per cent. of any ingredient except carbon, silicon, and iron.

The more important qualities of structural steels vary with their precise uses. In general, great resistance to statical strains, or to those gradually applied, is accompanied by comparative brittleness and unfitness to resist strains suddenly applied. High resistance, resilience, hardness, and brittleness increase, up to certain limits, with the amount of impurities, chiefly carbon, contained in the metal. Low resistance, softness, ductility, and toughness become more marked, within certain limits, as the impurities become less; but too little as well as too much impurity makes steel weak and unsuitable for structural purposes. It requires what is called body to give it resistance to either statical or sudden strains. This body is imparted by carbon, manganese, silicon, phosphorus, and by other ingredients; but too much of either of them, or of certain compounds of them, weakens the metal. While it is known, generally, that the substances mentioned may to a certain extent replace one another as body-giving elements, and that some of them appear to neutralize others (for instance, that manganese restores the ductility of steel made brittle by phosphorus), comparatively little progress has yet been made in definite and formulated knowledge regarding the mechanical effects of chemical mixture in iron and steel.

*The Manufacture of Steel.*—(1) *The Crucible Steel Process.*—This is the oldest and simplest. It at first consisted in melting wrought iron with carbon in clay crucibles. Thus Indian "wootz" is made, containing as much as $1\frac{1}{2}$ per cent. of carbon, so that it requires decarburization before it can be forged. In the present manufacture other ingredients besides carbon, chiefly manganese, are added. Sometimes substances intended to combine with and remove the impurities in the wrought iron are introduced, but generally these impurities remain in the steel. The finest steel must therefore be made from wrought iron which has been purified by reworking with pure fuel, and which was originally made from pure ores. The melting-point of wrought iron is so high that it has been usual to carburize it by cementation (see FURNACE) in order to fuse it at a convenient temperature in crucibles. This cemented or blistered bar was the steel of commerce until Huntsman melted it in a crucible in 1770, producing a true cast steel. The use of the Siemens furnace and the modern improvement of crucibles render the melting of wrought iron practicable and cheap. The cheaper grades of crucible steel are largely made from Bessemer steel rail-ends, crop-ends, and other scrap. This material, being made directly from cast iron, without that purification from silicon and phosphorus to which wrought iron could have been subjected in puddling, produces an inferior steel to that made from the purest wrought iron for purposes, like tool-steel, requiring both hardness and toughness. By melting wrought iron and a little cast iron together, especially cast iron containing manganese, the cheaper grades of steel are produced. The impurities of the cast iron remain in the steel. Although crucible steel has been cheapened by using the materials mentioned, and by means of the gas-furnace, the less refined grades of steel are made at so much less cost and with so much greater uniformity by the open-hearth process, and within certain limits by the Bessemer process, that the crucible process is becoming gradually confined to the finer grades of tool-steel; and here it must probably long retain its superiority, chiefly because it can begin with a highly refined iron, from which especially phosphorus, silicon, and sulphur have been more or less completely eliminated.

The quantity of steel made by the crucible process is relatively small. The two processes which produce the bulk of the metal for rails, structural material, wire, nails, plates, hoops, tin plates, etc., are the open-hearth or Siemens-Martin process and the Bessemer process. Until the invention of Thomas and Gilchrist the only raw material available for these processes was such as contained only a small quantity of phosphorus, 0·10 per cent. being the limit for pig iron. Since all of the phosphorus in ore enters the pig iron produced in the blast furnace, this restricted the steel-maker in his selection of ores and pig iron. Thomas and Gilchrist ascertained that if there is substituted for the usual silica or "acid" lining of the Bessemer converter or open-hearth furnace a refractory lining consisting of a mixture of calcined dolomite and tar, or of magnesia, a high phosphorus charge can be used. These latter linings are called "basic," in contrast with the older "acid" linings. Since their introduction it is the usual practice to distinguish between the "acid" and the "basic" open-hearth process and the "acid" and "basic" Bessemer process. The principal distinction in the two lies in the use of raw material, which must be low in phosphorus in the case of the acid process, and may or must be high in phosphorus in the case of the basic process. In the open-hearth furnace appliances are practically the same in either, the only difference being that the lime additions lead to the handling of a larger quantity of slag. In the basic Bessemer process the pig iron used must conform to certain specifications as to chemical contents. Silicon must be low, so that the life of the lining is not abridged by fluxing away in contact with the silica formed. From 1½ to 2 per cent. of phosphorus is necessary in the basic Bessemer pig, so that its combustion during the blowing may furnish the necessary heat. Lime additions must be made, and the charging capacity of the vessel is reduced through the room occupied by the greater amount of slag made. This slag is ground to an impalpable powder, and as such is used in agriculture as a substitute for phosphates, an important industry having been thus established.

(2) *The Open-hearth* (*or Siemens-Martin*) *Process.*—The melting of the ingredients of cast steel in large quantities and cheaply on the open hearth of a reverberatory furnace, rather than in small quantities and expensively in crucibles, having been often unsuccessfully attempted, was patented in a more scientific form by the eminent metallurgist Heath in 1845, and was then experimentally carried out with limited success. The Siemens regenerative gas-furnace, by means of the intensity and uniformity of its heat, first furnished practical conditions to the open-hearth process about 1862. It was also demonstrated by Messrs. Martin that the addition of manganese at a certain stage was necessary to the production of sound and practically malleable steel. The Siemens open-hearth steel furnace and its operation are fully exhibited and described under FURNACE. The hearth or bed of the furnace consists of a shallow iron tank, ventilated below to prevent the concentrated heat of the hearth and the regenerators from endangering the structure, and lined with a very refractory material, usually silica, nearly pure, and just fusible enough to set into a solid mass. The red-hot air and gas, entering and burning at, say, the right-hand end of the furnace, play upon the materials placed on the hearth, and pass down into the regenerators at the left end, where they give off their heat to a checkerwork of fire-bricks. The current being reversed after some thirty minutes, the air and gas enter at the left end through the newly heated regenerators and pass out at the right end.

The design of furnaces undergoes some modifications when natural gas is used as a fuel, the Lash furnace being the type most widely adopted in the U. S. An important modification of the ordinary open-hearth furnace has been introduced by H. H. Campbell, of Steelton, Pa., who has placed the entire hearth on rockers, which permit of tilting the furnace. This presents important advantages in charging and in tapping the charge. A plant of six of these furnaces, working 50-ton charges, is in operation at the works of the Pennsylvania Steel Company, three being basic and three acid furnaces.

The materials employed are various, and consequently the process varies, although the decarburization of pig iron is always a part of it. In order to obtain a sufficiently intense combustion there must be a slight excess of air; the flame is therefore oxidizing, and would seriously waste wrought iron or the ingredients usually melted in crucibles. A bath of cast iron, which on account of its carbon can be melted without serious loss, is first necessary; in this are immersed and protected the more readily oxidizable materials for the production of steel. The amount of cast iron varies from 10 to 33 per cent. of the total charge. For fine steels it should be as small as possible, so as to introduce the least amount of phosphorus, silicon, etc.

The more common process is known as the scrap process, and this again is divided into (1) the fusion of pig and scrap wrought iron or steel charged together, the former melting while the latter is heated preparatory to melting; (2) the dissolving of either hot or cold scrap in a bath of pig previously melted; (3) the dissolving of wrought-iron sponge in a cast-iron bath. The operation in all these cases is chiefly the melting of the decarburized iron forming the bulk of the charge, and the oxidation of the greater part of the carbon and silicon in the crude cast iron, and also in the basic process of the phosphorus. A portion of the iron is also oxidized, and this oxide of iron makes the product unmalleable or red-short. To remove the oxygen something must be added which has a greater affinity for it than iron has; for instance, manganese. The latter is easily and cheaply introduced in the form of pig iron called spiegeleisen, which contains 10 to 20 per cent. of manganese, or of an artificial ferro-manganese containing as high as 80 per cent. By using an excess of manganese any desired proportion of it remains in the steel. If the decarburization of the cast iron and the dilution of the carburized and uncarburized portions of the charge are carried only to such an extent that a highly carburized product remains, less manganese is needed to make it malleable, and this may be supplied by melting a manganiferous pig iron with the charge. Dissolving scrap in the bath is the more common process; the scrap is fed in a little at a time, so as not to chill the charge and cause it to set on the bottom of the furnace, and also to maintain uniformity in the temperature and working of the furnace. To save part of the stress on the steel furnace, an auxiliary furnace is employed in some works to heat the scrap and spiegeleisen before charging them into the bath.

In the production of boiler-plate and of steels to be subjected to blows and vibration while in tension, for which the open-hearth process is largely used and well adapted, about 20 per cent. of the best Bessemer pig, containing less than 0·10 per cent. of phosphorus, and preferably not over 1 per cent. of silicon, is employed, the remainder of the charge being charcoal blooms made from Bessemer ores, or puddle-bar made by the boiling process, so as to free it as much as possible from phosphorus. For cheap steels, especially those in which hardness without great resistance to impact are required, a less pure pig and any wrought-iron scrap, such as old rails, may be employed. The phosphorus imparted by the latter may be rendered harmless by employing a rich ferro-manganese at the close of the process, thus adding a large amount (¾ to 1 per cent.) of manganese and only 0·10 to 0·15 per cent. of carbon.

To ascertain when the charge is so far completed as to be ready for the manganese, samples are dipped out of the bath and tested from time to time. The decarburization is accurately denoted by the toughness of the sample and by the appearance of its fracture. As soon as the manganese is thoroughly diffused through the bath the charge is tapped out and cast. In many cases the manganese is added to the charge after it has been tapped into the ladle. The open-hearth furnace is made to hold from 10 to 50 tons, the more usual capacity being from 20 to 25 tons. The time of the operation is from eight to eleven hours.

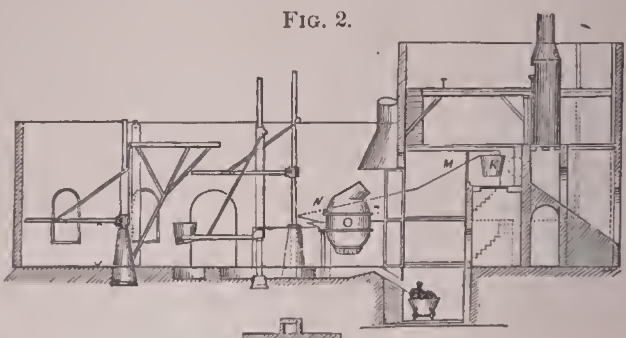
The pig-and-ore process, as developed by Siemens, consists in decarburizing a bath of pig iron by iron ore, and then adding ferro-manganese in the usual manner. The iron in the ore is added to the bath and a little limestone is thrown in to facilitate its separation. The theory is to use ore enough to make good the waste of the iron by oxidation. Although pig and ore may be employed alone with success, there is usually 10 or 15 per cent. of scrap made in rolling and forging, and this scrap is returned to the steel furnace. Sometimes 25 per cent. of scrap is added. The process thus partially takes the character of the pig-and-scrap process, although the use of ore as a rapid decarburizer of the large amount of pig employed gives it a distinctive character. The pig and scrap are first melted, the time being four or five hours. During this period an inch or more of slag forms over the bath. Then the ore, in lumps up to 3 or 4 inches in diameter, is charged a little at a time until the bath is nearly ready for the manganese, when it is allowed to stand so that the iron may work out of the ore and slag. After the charging of the ore begins there are two distinct periods: First, the rising of the slag. This increases in weight, but much more in volume, and is covered with large and heavily moving blotches or bubbles. Second, the boiling of the metal, when the slag settles and becomes thinner and the whole surface of the bath is covered with a lively spouting of the metal and slag, sometimes of the metal through the slag. These periods represent the following operations: (1) The silicon in the pig, having at this temperature a higher affinity for oxygen than the carbon has, is burned out first, partly by the flame, which is somewhat oxidizing, and partly by the oxygen in the ore. Thus slag is rapidly formed and also thickened by the release of the silica and other impurities in the ore. (2) When the silicon of the pig is nearly consumed its carbon begins to burn freely and to throw off carbonic oxide, which makes the now hotter and thinner slag boil violently.

(3) *Bessemer Process.*—The chemical part of the Bessemer process may be generally stated as the oxidation by means of air-blasts of the carbon and silicon (in the acid) or of the carbon and phosphorus (in the basic) in melted crude cast iron so as to make it malleable. During this reaction a certain quantity of iron is also oxidized. This is reduced by adding manganiferous pig iron, which reintroduces the necessary amount of carbon and also adds manganese, whose presence is useful in the subsequent rolling of the steel.

The Bessemer process as first performed, and as still practiced to a very limited extent abroad with irons rich in manganese, consists in applying the blast until all but one-fourth to one-half of 1 per cent. of the carbon is burned out, and then casting the product. Stopping the blast at this point, however, is very uncertain; hardly any irons contain the right amount of manganese for this treatment and the process has certain mechanical objections. Hence the nearly universal practice is to blow the iron until all the carbon is exhausted—a point readily determined; but the product now, as in the open-hearth process before described, contains so much oxide of iron that it is red-short and crumbles in working. To reduce this oxide of iron, manganese, which has a stronger affinity for the oxygen than the iron has, is added by running into the converter melted spiegeleisen, which is a pig iron containing 10 to 20 per cent. of manganese, or by otherwise adding ferro-manganese to the charge. Any desired amounts of carbon and manganese are also thus added to the product. No phosphorus is removed from the iron in the acid Bessemer process. Only the carbon and the silicon are oxidized. It is therefore important to start with pig irons having a little less phosphorus, sulphur, and copper than the steel may safely contain; but it is not usually practicable to use irons low in silicon, for the oxidation of this element produces the high temperature necessary to keep the mass fluid. Manganese is to a certain extent a substitute for silicon in this respect, and always a valuable ingredient, but the greater part of the irons of the world do not contain it in important quantities. Usually a pig containing from 1½ to 2½ per cent. of silicon is required. This will heat the charge to such a degree that 10 to 15 per cent. of scrap may be worked with the pig-iron charge. If there is more silicon than this the charge becomes too hot. One reason why silicon has greater heating power than carbon (it is stated by Akerman to have nine times as much) is because the product of its combustion, slag, remains in the converter, while the product of the combustion of carbon goes out in gaseous form, and carries much heat with it.

A standard American Bessemer plant of a type to which many existing works belong consists (1) of a melting department. The furnace and working-floor are shown in plan by Fig. 1; sections of these floors and the furnaces are shown by Fig. 2. There are hoists at *a* for coal, etc., and at *b* for iron; four cupola furnaces and their platforms and blowing machinery; two ladles, K, standing on scales, for weighing the melted iron; and spouts, M, N, Fig. 2, for conducting it to the vessels or converters; two reverberatory furnaces for spiegeleisen, and their spouts. (2) The converting department, shown in ground plan by Fig. 1 and in cross-section by Fig. 2. It contains two 5-ton to 7-ton vessels, N, in which the melted iron is treated by air-blasts. Such a vessel is illustrated by Fig. 3. Also a ladle and a hydraulic ladle-crane at E, Fig. 1, by means of which the steel is received from the vessels and poured into the ingot-moulds, which stand upon a depressed part of the floor called the pit. Three other hydraulic cranes swing over the pit to set the ingot-moulds and remove and load the ingots. Two of them swing over the vessels to assist in their daily repairs. The water and air pressure reservoirs are surmounted by a platform *d*, Fig. 1, standing upon which boys, by turning valves, admit water to the cranes and air to the vessels by means of underground pipes. All the constant operations of hoisting, lowering, and blowing are conducted from this platform, which overlooks the entire converting department. (3) The engine department, which is not illustrated. It

Fig. 2.



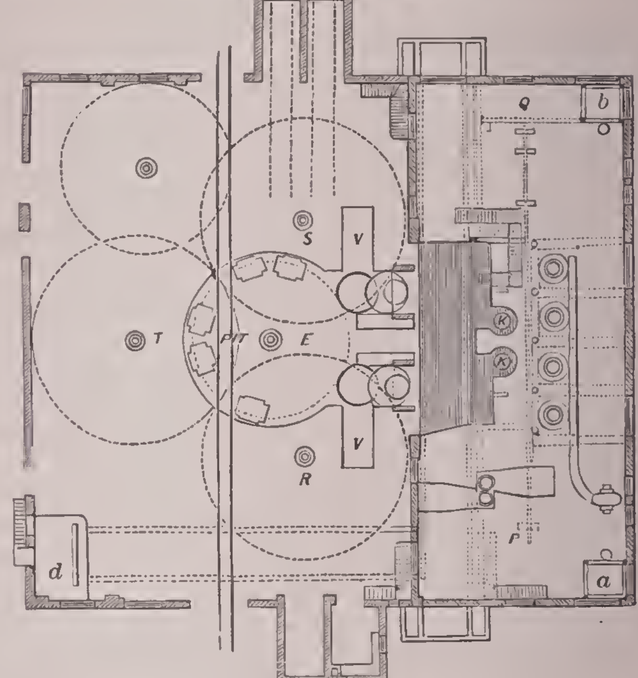


Fig. 1.

contains a blowing-engine, usually a double engine, capable of delivering air at 25 lb. pressure per square inch. The water-pressure machinery for actuating the hydraulic machinery consists of a pair of duplex pumps.

The recent tendency in the U. S. has been to do away with the troublesome casting-pit. In one conspicuous case this is accomplished by pouring the steel into a ladle suspended from an overhead traveling crane. The steel is poured into moulds standing on cars, constituting a train, so that the whole charge can be hauled out of the converting-house by a locomotive soon after it is cast.

A growing practice in Europe and in the U. S. is to dispense entirely with the remelting of the pig iron in cupolas. The molten pig iron as it is tapped from the blast furnace is run into ladles mounted on cars. It is cast into a large vessel holding 100 to 150 tons of molten metal, called the mixer. From this mixer the iron is tapped whenever required, and in the quantities needed, into ladle-cars, from which it is poured into the converters direct. This is called the direct process.

In the older process, the pig iron, having been hoisted to the charging platform, is put, with, say, 10 per cent. of coal, into one of the cupolas and melted. When some 18,000 to 30,000 lb. (whatever charge is determined on) have run into one of the ladles, K, the latter is turned over by means of a worm-wheel, thus pouring the iron into the spout, which leads it to one of the vessels, the simplest form of which is shown in Fig. 3. A vessel that will convert a 6-ton charge is 8½ feet in external diameter and 15 feet high. It is made chiefly of ½-inch to ¾-inch iron plates, and lined nearly a foot thick with refractory material. At one end it has an 18-inch opening, called the nose; at the other a tuyere-box, communicating with the blowing-engine. From the tuyere-box 12 fire-brick tuyeres, each perforated with 12 ⅜-inch holes, project through and are imbedded in the lining. A tuyere is shown in section by A. These tuyeres last but 10 or 15 heats, and are arranged in such a manner as to be readily renewed. The vessel is mounted on trunnions, and turned by a hydraulic cylinder by means of a rack and pinion. When the charge enters for the process the tuyeres are turned up as at C, so that the iron will not run into them. The blast is then admitted, and the tuyeres turned down so that the metal will flow over them, and be pierced by the entering columns of air. The cubical contents of the vessel is eight to twelve times that of the charge of iron,

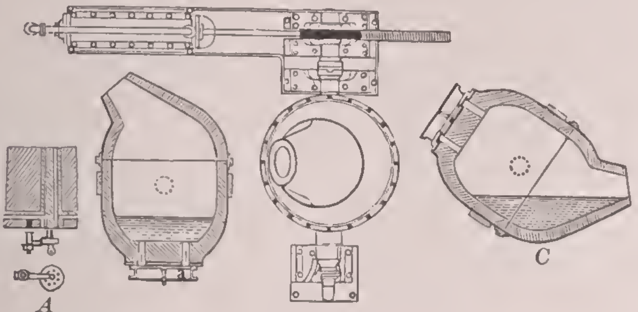

FIG. 3.

in order to give room for ebullition. The vessel lining is heated red hot and the fuel discharged before the iron is turned in. The iron is now subjected to 144 streams of air, three-eighths of an inch in diameter, at 15 to 25 lb. pressure, for about twenty minutes. Most of the silicon is first burned out, the result being slag, and a comparatively dull flame at the converter-mouth. When the carbon begins to burn freely the volume and brilliancy of the flame increase; and as the surging mass grows hotter, and boils over in splashes of fluid slag, the discharge is a thick, white, roaring blaze, and the massive vessel and its iron foundations tremble under the violent ebullition. Toward the close of the operation the flame becomes thinner, and it suddenly contracts and loses illuminating power when decarburization is complete. The determination of this period is the critical point of the process. Ten seconds too much or too little blowing injures or spoils the product. At the proper instant, as determined best by the spectroscope or by colored glasses, but usually by the naked eye, the foreman turns down the vessel and shuts off the blast. The charge of spiegeleisen is then run in, when another flaming reaction occurs. The vessel being still further depressed, the steel runs into the ladle, pure, white, and shining, from under its coating of red-hot slag. A blanket of slag, most useful in preserving its temperature, follows it into the ladle. The metal is then let into the ingot-moulds and, after the exterior surface of the steel has crystallized, the mould is removed, and the ingot is ready for reheating and rolling.

For the basic process the converter is lined with a mixture of highly calcined dolomite (magnesian limestone) and tar, either by ramming it into place or building it up of brick made from the mixture. A certain amount of calcined lime is charged with the iron, further additions being made as required. When the carbon has been blown out, the slag is poured off and a brief period of blowing, called the after-blow, follows, during which the last portions of the phosphorus in the metal are eliminated, passing into the slag.

The ladle-crane (Fig. 4) is a radical departure from the nearest kindred practice. The ladle, instead of swinging from a crane-chain, as in a foundry, is rigidly held in a fixed orbit. This feature was original with Bessemer, and to it he added the old ladle with a pouring-nozzle in its bottom, regulated by a movable stopper (1 and 2). This consists of a loam-coated rod, *a*, armed at its lower end with a round-ended fire-brick or plumbago stopper fitted to the concave top of a fire-brick nozzle. The stopper is raised and lowered by a lever, *o*, in the hand of the workman. Thus the heavy steel is discharged pure, while the lighter slag and impurities are left at the top. Pouring steel into moulds over the rim of a ladle, as in foundries, would make excessive scrap from spilling and chilling, and is wholly impracticable. The vertical motion of the crane is necessary in pouring from the vessel, to keep the ladle close under the nose, thus preventing too great a fall of the stream, and consequent slopping. The ladle is also tipped by a worm and worm-wheel, *h*, to regulate the position of the nozzle over the moulds and to turn over the ladle for heating and repairs. The hydraulic crane generally used in works in the U. S. is also illustrated by Fig. 4, and consists of a cylinder open at the top only, and requiring chiefly vertical support from the solid pier on which it rests. The ram passes through an upper stuffing-box and through a top support in the roof of the building. The jib is placed between these supports, so that the lateral strain on the ram is comparatively small. The ram is stepped upon a column of water which is substantially frictionless.

When the steel is intended for rails—and sometimes 33 per cent. of that made in the U. S. is so used—the charges are so regulated as to cast either five or six ingots, and a little over as a margin for chilling and spilling. Each ingot

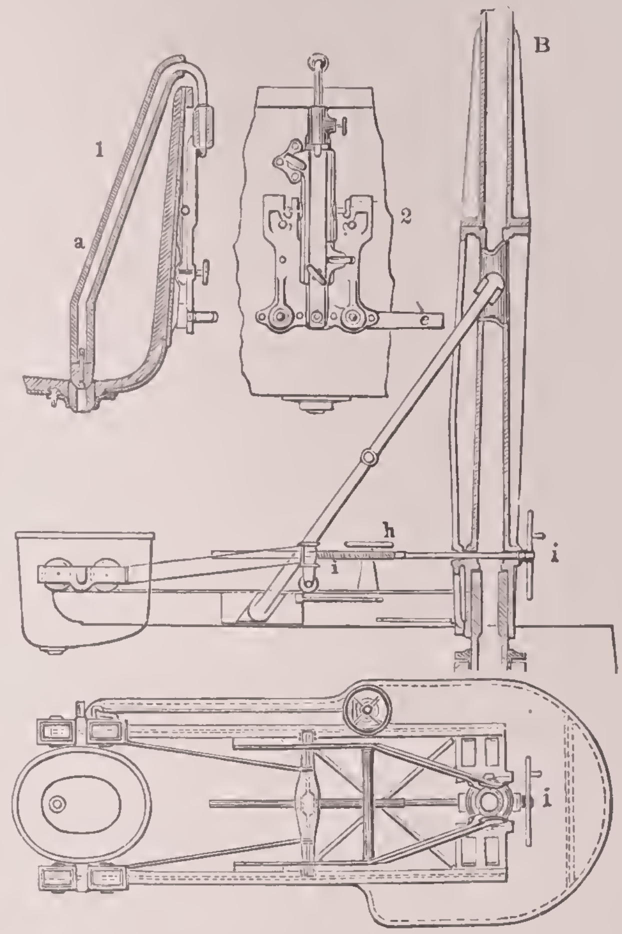

FIG. 4.

makes three or six rails. The ingots are removed hot to the blooming-mill, and if any heating-furnace is ready, they are charged into it directly, thus saving much heat. They must be allowed to crystallize, however, before rolling. If the interior of an ingot is still pasty from the heat of conversion, it will go to pieces in the rolls. Ingots for three to six rails each are used, instead of ingots for single rails—first, to save a repetition of manipulations in working. This must be done by machinery to be done cheaply, and a machine can handle a big ingot as quickly as a little one. Second, the extreme top of an ingot is unsound, and must be cut off and reconverted; the number of scrap ends is reduced to two for three to six rails. The practice is growing in the direction of large ingots and large reductions for all purposes; and the counterpart of this—to cheapen cost—is handling by steam and reducing rapidly by heavier rolls and hammers. See also ROLLING-MILLS.

Since about 1870 open-hearth and Bessemer steel have practically displaced puddled iron in the manufacture of rails, wire, plates, structural shapes, tin plate, and cut nails, and has made heavy inroads into its field, in bars and other shapes.

The production of crucible steel in the U. S. was 84,709 long tons in 1892, 63,613 long tons in 1893, and 101,213 long tons in 1899. The production of open-hearth steel was 669,889 tons in 1892, 737,890 tons in 1893, and 2,947,316 tons in 1899. The production of Bessemer steel was 4,168,435 tons in 1892, 3,215,686 tons in 1893, 3,579,101 tons in 1894, and 7,586,354 tons in 1899.

The total production of basic steel in the world was 3,638,556 tons in 1893, Germany contributing thereto 2,344,754 tons. Of the total productions of basic steel in the world in 1893, 2,808,241 tons was Bessemer and 830,315 tons was open-hearth steel.

Great Britain produced in 1893 1,493,354 gross tons of Bessemer steel ingots and 1,456,309 tons of open-hearth steel ingots. Germany made 2,171,138 metric tons of manufactured steel in 1893. Belgium produced 273,058 metric tons of steel ingots in 1893: France produced 814,977 metric tons of ingots in the same year: Sweden has a record of 82,422 tons of Bessemer and 76,556 tons of open-hearth steel ingots in 1892; and Austria reports 509,734 metric tons of Bessemer and open-hearth ingots in the same year. The production of Russia in 1892 was 365,484 metric tons. Spain made

78,413 metric tons in 1891, and Italy 56,543 metric tons in 1892. A small quantity of steel is also produced in Canada.

See *The Metallurgy of Steel*, by Henry M. Howe (New York, 1890); Bauerman's *Treatise on the Metallurgy of Iron* (London); Percy's *Metallurgy of Iron and Steel* (London); and Wedding's *Eisenhüttenkunde* (Brunswick).

**Steele**, DANIEL, A. M., D. D.: minister and educator; b. at Windham, N. Y., Oct. 5, 1824; educated at Wesleyan Academy and Wesleyan University, where he graduated 1848; joined the New England Conference of the Methodist Episcopal Church 1849; was pastor until 1862; Professor of Ancient Languages 1862–69 and acting president of Genesee College 1869–71; and vice-president of Syracuse University 1871–72; since then has taught in school of theology of Boston University, and served in several pastorates. He has published *Commentary on Joshua* (1872); *Binney's Theological Compend Improved* (1874); *Love Enthroned* (1875); *Milestone Papers* (1878); *Antinomianism Revived, or a Refutation of the Doctrines of the Plymouth Brethren* (1885); *Commentary on Leviticus and Numbers* (1891); *Bible Readings* (1892); *Sermons and Essays* (1892). ALBERT OSBORN.

**Steele**, DAVID, D. D.: clergyman and professor; b. near Londonderry, Ireland, Oct. 20, 1827; educated at Miami University and the Theological Seminary of the Reformed Presbyterian Church, Philadelphia; principal of Cynthia Academy, Kentucky, 1857–58; Professor of Hebrew and Greek in Miami University 1858–59; pastor of the Fourth Reformed church, Philadelphia, since 1861; Professor of Hebrew, Greek, and Pastoral Theology 1863–75, and since 1875 of Doctrinal Theology in the Reformed Presbyterian Seminary, Philadelphia; was moderator of the General Synod 1868; delegate to the Pan-Presbyterian Council at Philadelphia 1880; president of the board of foreign missions in the Reformed Presbyterian church since 1883. Dr. Steele edited *The Reformed Presbyterian Advocate* 1867–77; and has published *The Times in which we live and the Ministry which they require* (1872); *Biographical Sketch of Rev. J. N. McLeod, D. D.* (1875); *The Apologetics of History* (1886); and discourses. C. K. HOYT.

**Steele**, FREDERICK: soldier; b. at Delhi, N. Y., Jan. 14, 1819; graduated at the U. S. Military Academy July 1, 1843, and was assigned to the Second Infantry; fought in the war with Mexico, gaining the brevets of first lieutenant and captain for Contreras and Chapultepec; served in California 1849–55, and on the Western frontier from 1855 until the outbreak of the civil war, when, as major of the Eleventh Infantry, he was engaged in Missouri, commanding a brigade in the actions at Dug Spring, Wilson's Creek, and retreat to Rolla. Appointed colonel Eighth Iowa Volunteers in Sept., 1861, and commissioned brigadier-general of volunteers Jan. 29, 1862, he commanded a division in the army of the Southwest until November, when promoted to be major-general of volunteers and assigned to the Thirteenth Army-corps, which he led in the Yazoo expedition and capture of Arkansas Post (Dec., 1862–Jan., 1863); transferred to the Fifteenth Corps, he was engaged in the Vicksburg campaign, when his division was sent to Helena, Ark., and captured Little Rock Sept. 10; in 1864 commanded the department of Arkansas, and on Nov. 29, 1864, went to the aid of Gen. Canby in the reduction of Mobile; was mustered out of volunteer service in Mar., 1867. For the capture of Little Rock he was breveted brigadier-general, and for meritorious services major-general U. S. army. In July, 1866, he was assigned to the coloneley of the Twentieth Infantry, which he held at the time of his death, at San Mateo, Cal., Jan. 12, 1868.

Revised by JAMES MERCUR.

**Steele**, Sir RICHARD: author; b. in Dublin, Mar., 1672; educated at the Charterhouse, London, and at Oxford. In 1695 he enlisted as a private in the Life Guards, and in the same year published *The Procession*, a poem on Queen Mary's funeral. This was dedicated to Lord Cutts, who gave Steele a captaincy in his regiment, the Coldstream Guards. In 1701 he published *The Christian Hero*, a short manual of religious ethics, and in November or December of the same year brought out at Drury Lane his first comedy, *The Funeral*. This was followed by *The Lying Lover* (1703) and *The Tender Husband* (1705). About this time he became a member of the famous Kit-Cat Club, and married a widow, a Mrs. Margaret Stretch, who seems to have died in 1706. In May, 1707, through the influence of Arthur Maynwaring, he was appointed to the Government office of gazetteer. In Sept., 1707, he married Miss Mary Scurlock, of Llangunnor, Carmarthenshire, Wales. His letters to this lady were first printed in 1787. He was always in pecuniary difficulties; but such was his amiability that he always found friends to assist him, and was successively appointed to lucrative offices, among which were commissioner of the stamp office, surveyor of the royal stables, governor of the royal comedians, justice of the peace for Middlesex, and commissioner of forfeited estates in Scotland. In politics he was an ardent Whig. In 1713 he was returned to Parliament for Stockbridge, and was expelled in the following year on account of political articles written by him, but was knighted by the king, and returned to Parliament for Boroughbridge in 1715. In 1720 his patent as governor of the royal comedians was revoked, by which, according to his own statement, he suffered a loss of £10,000, and in the following year he brought out his successful comedy of *The Conscious Lovers*, which was dedicated to the king, who sent him a present of £500. His first wife, who died soon after their marriage, brought him a plantation in the West Indies, and his second wife was a Welsh heiress, but he squandered his large income in dissipation and unprofitable speculations, and being attacked with a paralytic stroke, which disabled him from literary work, he retired to his estate at Llangunnor, where he died Sept. 1, 1729. He was buried in St. Peter's church, Carmarthen. Several of Steele's political essays and pamphlets had a high reputation in their day, and his comedies were well received upon the stage. His chief fame rests upon his connection with *The Tatler* and *The Spectator*, almost the earliest of that long series of periodical works which occupy so prominent a place in English literature, although in these his part was much inferior to that of Addison, who had been his schoolfellow at the Charterhouse. *The Tatler* (1709–11) contained 271 numbers; 188 were by Steele, 42 by Addison, and 36 by both conjointly. This was succeeded by *The Spectator* (1711–12), containing 555 numbers, of which 236 were by Steele and 274 by Addison. After the discontinuance of *The Spectator*, Steele, with the co-operation of Addison, started *The Guardian*, but Addison soon withdrew, and the work was brought to a close with the 176th number, of which 82 were by Steele. Steele started other papers, *The Englishman*, *The Lover*, *The Reader*, *The Theater*, and *The Spinster*, which were comparative failures; and he left two unfinished comedies, *The School of Action* and *The Gentleman*. His *Poetical Miscellanies*, original and translated (1714), possesses little merit. See *Memoirs of the Life and Writings of Sir Richard Steele*, by H. R. Montgomery (London, 1865), and the *Life of Steele*, by Geo. A. Aitken, (2 vols., Boston, 1889). Also *Richard Steele*, by Austin Dobson (1886), who published his *Selected Works* in 1885.

**Steel-engraving**: See ENGRAVING.

**Steell**, Sir JOHN, R. S. A.: sculptor; b. at Aberdeen, Scotland, in 1804; studied art at Edinburgh and sculpture at Rome; made the seated statue of Sir Walter Scott which forms part of the monument in Edinburgh; produced the colossal statue of Queen Victoria placed above the Royal Institution, Edinburgh, and the bronze equestrian statue of the Duke of Wellington erected in 1850 in front of the Register House, Edinburgh. Others of his statues are of the Marquis of Dalhousie, and Hon. James Wilson at Calcutta; of Prof. John Wilson, erected at Edinburgh 1865; the Scottish National Memorial to Prince Albert; colossal bronze statues of Sir Walter Scott and of Burns for Central Park, New York; colossal statues of Allan Ramsay and Dr. Chalmers for Edinburgh; and monuments to the Forty-second and Ninety-third Highlanders in the cathedrals at Dunkeld and Glasgow. D. Sept. 15, 1891.

Revised by RUSSELL STURGIS.

**Steelton**: borough; Dauphin co., Pa.; on the Susquehanna river, the Pennsylvania Canal, and the Penn. and the Phila. and Reading railways; 3 miles E. of Harrisburg, the State capital (for location, see map of Pennsylvania, ref. 5–G). It was laid out under the name of Baldwin in 1866, subsequently was known as Steel-Works P. O., and was incorporated under its present name in 1880. It contains the great plant of the Pennsylvania Steel Company, comprising several blast furnaces, rail and blooming mills, and bridge and construction works; several flour, saw, and planing mills; electric railways connecting the borough with Harrisburg; a model public-school building, erected by the steel company; a national bank with capital of $75,000; and a daily and three weekly newspapers. Pop. (1880) 2,447;

(1890) 9,250; (1900) 12,086, not including the suburbs of Highland, Oberlin, New Cumberland, and New Market.

EDITOR OF "ADVOCATE."

**Steelyard**, or **Roman Balance**: See WEIGHING-MACHINES.

**Steen**, stān, JAN: painter; b. at Leyden about 1626; a pupil of Nicolas Knupfer at Utrecht, and afterward, at The Hague, of Jan van Goyen, whose daughter became his wife. In 1648 Jan Steen entered the corporation of painters at Leyden. He was absent from his native city for ten years, following, it is said, the trade of a brewer at Delft; returned to Leyden in 1658 and combined the work of painter with that of tavern-keeper. He died at Leyden in 1679, and was buried Feb. 3. His work shows the influence of Frans Hals and Adrian van Ostade. His works are chiefly to be seen in the public and private collections in Holland. One example of his art, *The Music-master*, is in the National Gallery, London. W. J. STILLMAN.

**Steenstrup**, stān'stro͝op, JOHANNES JAPETUS SMITH: zoölogist; b. at Vang, Norway, Mar. 8, 1813; Professor of Zoölogy at the University of Copenhagen until 1885. His principal works, which are characterized by elegance of style as well as originality of thought, are *Om Forplantning og Udvikling, gjennem vexlende Generationsrækker* (Copenhagen, 1842), translated from the German version as *On the Alternations of Generations* (1845); *Undersögelser over Hermaphroditismens Tilværelse i Naturen* (Investigations in the Presence of Hermaphroditism in Nature, Copenhagen, 1846); and *Et Blik paa Natur- og Oldforskningens Forestudier* (A Glance at Previous Studies of Nature and Archæology, 1862). D. at Copenhagen, July, 1897. D. K. DODGE.

**Steenwyck**, stān'vīk, HENDRICK: architectural painter; b. at Steenwyck, in the province of Overyssel, Netherlands, about 1550; studied under Hans Vredeman de Bries; also at Antwerp in 1577, and then went in 1580 to Frankfort-on-the-Main, where he died in 1603. His son, named Hendrick, also an architectural painter, was born at Frankfort in 1580. Both painted interiors of churches, halls, and rooms. The younger Steenwyck worked in Antwerp, but went in 1629 to London, where Vandyke employed him to paint architectural backgrounds to some of his portraits. D. in London about 1649. The Louvre, the Belvedere at Vienna, and the National Gallery at London contain examples of the art of father and son. Herman Steenwyck, of Delft, and his brother Pieter are not to be confounded with the above mentioned—these were painters of still life. W. J. S.

**Steeple-chase**: See HORSE-RACING.

**Steevens**, GEORGE: Shakspeare scholar; b. at Stepney, London, May 10, 1736; was educated at King's College, Cambridge; devoted himself to Shakspearean studies, and in 1766 published, in 4 vols. 8vo, *Twenty of the Plays of Shakespeare, being the whole number printed in Quarto during his Lifetime*, etc., which led to his association with Dr. Johnson in an annotated edition published in 1773 under their joint names. Afterward, in conjunction with Isaac Reed, he prepared two new editions (1785 and 1793). His editions remained the standard for the text for almost fifty years. He also assisted in the preparation of the *Biographia Dramatica*, and furnished contributions to Nichols's *Biographical Anecdotes of Hogarth*. D. at Hampstead, Jan. 22, 1800. Revised by H. A. BEERS.

**Steffens**, HENRIK: philosopher; b. at Stavanger, Norway, May 2, 1773; educated in Denmark 1779–94, and studied theology and natural science at the University of Copenhagen; went in 1794 to Germany, and became, through the study of Schelling's writings and through personal intercourse with the author, a zealous adept of the new sensational science, the so-called philosophy of nature. He returned to Denmark (1802), where he exercised a decisive influence on his contemporaries. His principal works from this period are *Recension von Scheltings naturphilosophischen Schriften* (1800); *Grundzüge der philosophischen Naturwissenschaft* (1806); *Anthropologie* (2 vols., 1822); and *Polemische Blätter zur Beförderung der speculativen Physik* (1829–35). He continued his study of mineralogy and geology at Freiberg under Werner (*Geognostischgeologische Aufsätze* (1810) and *Handbuch der Oryktognosie* (3 vols., 1811–19)); was appointed Professor of Natural Science in 1804 at Halle, in 1811 at Breslau, and in 1831 at Berlin. D. in Berlin, Feb. 13, 1845. In religion he first turned from the stiff orthodoxy in which he was educated to the pietism of Spener, which he found at Halle; then he became an ardent preacher among the Old Lutherans at Breslau; and finally, at Berlin, he adopted Schleiermacher's religion of the feeling (*Von der falschen Theologie und dem wahren Glauben* (1824); *Wie ich wieder Lutheraner wurde und was mir das Lutherthum ist* (1831)). He was also the author of several novels of a marked didactic character. His autobiography, *Was ich erlebte* (10 vols., 1840–45), was translated into English by William L. Gage under the title *The Story of my Career as Student at Freiberg and Jena* (Boston, 1863), and republished under the title *German University Life* (Philadelphia, 1874); *Nachgelassene Schriften* (1846, with a preface by Schelling). Revised by D. K. DODGE.

**Steganop'odes** [Mod. Lat. pl. of *steganopus* < Gr. στεγανόπους, web-footed]: an order of birds containing those which have all four toes connected with a web; synonymous with *Totipalmatæ*. It contains the gannets (*Sulidæ*), pelicans (*Pelecanidæ*), cormorants (*Phalacrocoracidæ*), darters (*Plotidæ*), frigate-birds (*Tachypetidæ*), and tropic-birds (*Phaëthontidæ*). It is the equivalent of Huxley's *Dysporomorphæ*. See the articles on the various genera. F. A. L.

**Stegoceph'ala** [Mod. Lat., Gr. στέγειν, cover + κεφαλή, head]: a group of extinct batrachians, like the salamanders in general appearance, but differing from all recent forms in the well-developed armor of bony plates which covered the skull and which usually extended over the lower surface of the body, and sometimes also covered the back. They first appeared in the Carboniferous and died out with the Triassic age. Some were small, others were veritable giants. The group is interesting to the naturalist since its affinities are apparently with the ganoids, and at the same time it is the ancestor of the batrachians of to-day. J. S. K.

**Stein**, stīn, HEINRICH FRIEDRICH KARL, Baron von: statesman; b. at Nassau-on-the-Lahn, Oct. 26, 1757; studied jurisprudence at Göttingen 1773–77; entered the civil service of the Prussian Government in 1780, and was made chief of the department of commerce, manufactures, and indirect taxation in 1804. Strongly opposed to the policy adopted by the president of the cabinet, Count Haugwitz, and by the king himself, he was dismissed Jan. 4, 1807, but recalled immediately after the Peace of Tilsit (July 20, 1807), and made president of the cabinet. In this position he developed an astonishing energy. His internal reforms were a complete reorganization of the Prussian state. Serfdom was abolished, and universal obligation of military service introduced; the manorial estates of the nobility were taxed, all citizens made equal before the law, a liberal municipal system established, and on the crown lands the system of peasant proprietorship was introduced. His final aim was to elevate the peasant class and to create a powerful and intelligent middle class, and, with the nation reorganized on this basis, to renew the contest with Napoleon. He had also a clear idea of what a united Germany meant, and was averse to that division of the country into petty states which had given the history of the nation such a chaotic and anarchical aspect. But his career was suddenly stopped An incautious letter, in which he criticised the policy of Napoleon and spoke of his own hopes and plans, fell into the hands of the French police, and was published in the *Moniteur* Sept. 8, 1808. On Nov. 24 Stein was compelled to resign, and on Dec. 16 Napoleon sent a decree from Madrid which outlawed him and confiscated his property. He went to Austria, thence to Russia, but once again he was at the head of the political affairs of Germany during the period between Napoleon's disaster in Russia and the Peace of Paris, when he actually was the leader of the diplomatic coalition against France. After peace had been concluded, his influence soon became comparatively small. The German princes hated him for his ideas of a German unity; the absolutists hated him for his ideas of a representative form of government; and he himself was unwilling to adopt the impracticable views of the radicals. He retired to his estates, and died at Kappenberg, Westphalia, June 29, 1831. Monuments have been erected to him in Nassau and in Berlin. See the biography by Pertz, and Seeley's *Life and Times of Stein* (1879, 3 vols.). See also the *Erinnerungen* of von Boyen (1891). Collections of his letters have been published, and are of great importance for the history of that time.

Revised by F. M. COLBY.

**Stein'bok** [from Dutch *steenbok*, and Germ. *steinbock*; *stein*, stone + *bock*, antelope]: any one of several species of the family *Bovidæ*. (1) The German designation *Steinbock* (and hence the Dutch *steenbok*) was originally conferred on the ibex or bouquetin of Europe, a species of goat, and to that animal the name properly belongs. (See BOUQUETIN.)

(2) The Dutch settlers of Southern Africa applied the name to a species of antelope peculiar to and not uncommon in that region, and it is now incorporated in the English vocabulary of animals in connection with it. The species is the *Nanatragus tragulus* (*Pediotragus campestris* of Gray). The steinbok is an animal of graceful and symmetrical form, with the head well proportioned, having a bovine nose and large muffle; the horns, developed only in the male and over the orbit, erect, elongate, and subulate; the legs long and slender; the feet destitute of side-hooflets; and the tail very short. The color is a fulvous ash above and on the sides, and white beneath. The length is generally rather less than 3½ feet, and the height at the shoulder somewhat more than 1½ feet. The species is most abundant on stony plains and in valleys, and especially on open flats, where large stones and clumps of trees are found. It is very swift, and progresses by great bounds. It is also very timid, and readily alarmed. It is much esteemed for its flesh.

THEODORE GILL.

**Steinen**, KARL, von den: ethnologist and traveler; b. at Mülheim-on-the-Ruhr, Prussia, Mar. 7, 1855. He studied medicine at Zurich, Bonn, and Strassburg, and ethnology at Berlin and Vienna; made a voyage round the world 1879–81, and was artist and naturalist attached to the German expedition to the Antarctic island of South Georgia 1882–83. In 1884–85, with two companions and a detail of Brazilian soldiers, he penetrated the unknown regions of Northern Matto Grosso, Brazil, discovered the head waters of the river Xingú, and descended it to the Amazon. A second journey to the upper Xingú was made in 1887–88. Dr. von den Steinen's works include *Durch Central-Brasilien* (1886), describing the first Xingú exploration; *Unter den Naturvölkern Central-Brasiliens* (1894); and many scientific papers. HERBERT H. SMITH.

**Steinheil**, LOUIS CHARLES AUGUSTE: genre, still-life, and portrait painter; b. in Strassburg, June 26, 1814; d. in Paris May 17, 1885; pupil of Decaisne; third-class medals, Salons, 1847 and 1851; second-class 1848; Legion of Honor 1860. His *Mother* (1847) is in the museum at Nantes.

**Steinmetz**, KARL FRIEDRICH, von: b. at Eisenach, Saxe-Weimar, Dec. 27, 1796; entered the Prussian army in 1813 as a lieutenant; fought against the French; became a captain in the regiment of Kaiser Franz in 1829; fought at the head of two battalions of the Second Infantry Regiment in Mar., 1848, in the streets of Berlin; was subsequently made governor of the academy of cadets at Berlin, and made his name illustrious as commander-in-chief of the Fifth Army-corps in the campaign against Austria in 1866. On June 27, 28, and 29, 1866, he made a stand at Nachod, Skalitz, and Schweinschädel with his corps and one brigade against three corps of the enemy, defeated them, drove them back, and took eleven guns and 6,000 prisoners. By this victory he made it possible for the second army to debouch, on which manœuver the success of the Prussian battle-plan depended. He received immediately the highest order, that of the Black Eagle, and the Diet voted him a national dotation. In the war against France in 1870 he was appointed commander-in-chief of the First Army, consisting of the First, Seventh, and Eighth Army-corps, but he held this position only for a short time, as he came in conflict with the supreme command—in what manner is not exactly known, but it seems as if the advance of the First Army on Aug. 6, and the measures taken by the general during the advance toward and around Metz on Aug. 14, 15, and 16, did not agree with the plans of von Moltke. In reality, the general now lost his independent command, his army being united to that of Prince Friedrich Charles, and the supreme command given to the prince. Nominally, however, Steinmetz remained a commander, subject only to the orders of the king, and thereby, as well as from the stubbornness of his character, arose disagreements between him and the prince. The result was that in Sept., 1870, Steinmetz was appointed governor-general of Posen and Silesia, and removed from the theater of war. He handed in his resignation, which, however, the king did not accept. He was made a general-field-marshal Apr. 8, 1871, and placed *à la suite*. D. at Landeck, Prussian Silesia, Aug. 4, 1877.

**Stein'schneider**, MORITZ: bibliographer; b. at Prossnitz, Moravia, Mar. 30, 1816; studied in Prossnitz, Nikolsburg, Prague, Vienna, Leipzig, and Berlin; teacher in Prague 1842; teacher in Berlin 1845; since 1859 director of the Veitel-Heine-Ephraimsche Stiftung in that city, and from 1869 to 1890 head of the Israelitische Töchter-Schule. He received the degree of LL. D. from Columbia College 1887; the title of professor 1894. He has devoted himself especially to the non-theological literature of the Jews and Arabs during the Middle Ages. As a bibliographer and historian of Hebrew literature he is unsurpassed. Among his numerous works are *Catal. libr. hebr. in bibl. Bodleiana* (Berlin, 1852–60); catalogues of the Hebrew MSS. in the libraries of Leyden (1858), Munich (1875), Hamburg (1878), and Berlin (1878); *Jewish Literature* (London, 1857; *Index*, Frankfort, 1893); *Zur Pseudepigraph. Lit.* (Berlin, 1869); *Alfarabi* (Petersburg, 1869); *Polem. und Apologet. Lit.* (Leipzig, 1877); *Bibliograph. Handbuch* (Leipzig, 1859); and *Hebräische Uebersetz. des Mittelalters* (2 vols., Berlin, 1893). See Berliner *Die Schriften des Dr. M. Steinschneider* (Berlin, 1886). RICHARD GOTTHEIL.

**Steinthal**: See OBERLIN, JOHANN FRIEDRICH.

**Stejneger**, LEONHARD: See the Appendix.

**Stel'larton**, formerly ALBION MINES: town of Pictou County, Nova Scotia; 3 miles from New Glasgow and 39 miles N. E. of Truro, on the Intercolonial Railway (see map of Quebec, etc., ref. 2–C). It is a thriving but dingy town which has grown up about the Albion coal and iron mines, the center of the chief mining district of the province. Petroleum is obtained in the vicinity. The town is the chief destination of the French immigrants to the province. Pop. (1881) 2,297; (1891) 2,410. M. W. H.

**Steller'ida**: a group of echinoderms, including the STARFISH (*Asteroidea*) and OPHIUROIDEA (*qq. v.*), in which the body is star-shaped.

**Stellhorn**, FREDERICK WILLIAM: theologian; b. in the kingdom of Hanover, Germany, Oct. 2, 1841. Emigrated to the U. S. in 1854; graduated at the institutions at Fort Wayne, Ind., and St. Louis, Mo.; pastor in St. Louis and DeKalb co., Ind., 1865–69; Professor of Hebrew, Greek, and Latin, Northwestern University, Watertown, Wis., 1869–74, and in Concordia College, Fort Wayne, 1874–81; since 1881 has been Professor of Theology, Capitol University, Columbus, O. In the Predestination controversy he parted from the Missourians and entered the Joint Synod of Ohio. He has been active as editor of the *Theologische Zeitblätter* and *Lutherische Kirchenzeitung*, as well as a contributor to *The Theological Magazine*. He has published a *Lexicon of New Testament Greek* (Leipzig, 1886), and begun a commentary on the New Testament, of which the volume on the Gospels has appeared. H. E. JACOBS.

**Stel'lio** [Lat. *stel'lio*, a newt with starlike spots on its back, deriv. of *stella*, star]: a genus of lizards of the family *Agamidæ*. The best-known species is *S. cordylina* of the Levant. Strict Mohammedans kill it because they conceive that by the frequent bowing of the head it intends to insult their religion, mocking their own gestures at prayer. The Turks use its flesh and excrement in preparing a cosmetic.

**Stem** [O. Eng. *stemn*: Germ. *stamm*, a deriv. of Indo-Europ. root *stā-*, stand, and originally denoting the trunk of a tree]: a term of historical grammar denoting that part of a word which is left when the inflexional ending is removed. The stem may therefore be identical with the root; e. g. in Lat. *vōx*, Gr. ὄψ, or in the Gr. verb εἶ-μι, but the stem is more commonly formed by adding to the root a formative element called a suffix. Thus in Indo-Europ. *klutós* < Sanskr. *çrutás*: Gr. κλυτός: Lat. *in-clutus*, *s* is inflexional ending, *kluto-* is stem, *klu-* is root, and *-to-* is suffix. Similarly we divide φηγ-ό-s, *fāg-u-s*; γόν-ο-s, τόμ-ο-s, *unc-u-s*, *dol-u-s*; ἅγ-ιο-s, *stud-iu-m*; τέκ-νο-ν, *grā-nu-m*; πίσ-τι-s, *cu-ti-s*; αὐχ-έν-α, *hom-in-em*; Sanskr. *ján-as-as*, Gr. γέν-ε(σ)-os, Lat. *gen-er-is*, etc. The relation of stem to root in the verb is evidently parallel to that in the noun—an inheritance from a period prior to the development of a grammatical distinction between noun and verb; thus the φερε-, φερο- of φέρε-ται, φέρονται is to the ἐσ- of ἐσ-τι, or the εἰ- of εἶ-σί-, as the λογο- of λόγο-s is to the φλεβ- of φλέψ. Though the purposes of grammatical analysis are well served by this division of stem into root and suffix, it by no means follows that in every case the suffix was an originally independent word or element. The form of the stem is in many cases due to the influence of analogy, and in others to the retention of the fuller original form of the primitive word which has elsewhere suffered reduction by the loss of a vowel. (See ROOT.) The word stem as thus used in grammar is a translation or transfer of the German word *stamm*, meaning the trunk (of a tree) in distinction to the *wurzel* or root. BENJ. IDE WHEELER.

**Stembel**, ROGER N.: See the Appendix.

**Sten'dal**: town and railway junction; in the province of Saxony, Prussia; on the Uchte; 36 miles by rail N. by E. of Magdeburg (see map of German Empire, ref. 3-F). It has a Gothic cathedral, manufactures leather, tobacco, woolen, linen, and cotton stuffs, and trades in corn and cattle. Pop. (1895) 20,666.

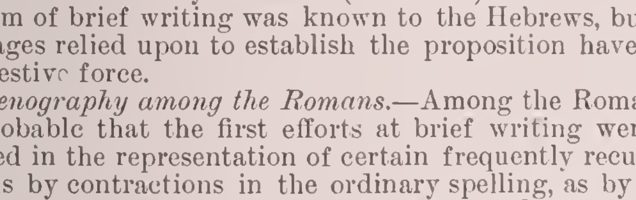
**Stenoglossa** [from Gr. στενός, slender + γλῶσσα, tongue]: a group of mollusks, embracing the *Rhachiglossa* and *Toxiglossa* of the *Gasteropoda*, in which the lingual ribbon is narrow.

**Stenog'raphy** [from Gr. στενός, narrow, close + γράφειν, write]: a generic term which embraces every system of shorthand writing, whether upon alphabetic, phonetic, or hieroglyphic principles. To those systems which are based upon the phonetic principle is given the name *phonography*, which therefore indicates a species of stenography. Some of the other names under which new stenographic systems have been introduced are *tachygraphy* (swift writing), *brachygraphy* (short writing), *semigraphy* (sign writing—that is, writing with signs), *cryptography* (secret writing), *hodiography*, *zeiglography*, *polygraphy* (writing much—that is, voluminous writing), *radiography* (easy writing), and *thoögraphy* (swift writing).

*Stenography among the Greeks.*—The great need of some method of representing in legible characters spoken words as fast as uttered was appreciated in the earliest times, and traces of shorthand writing may be found among the Greeks not many centuries later than the introduction and diffusion of the art of writing. The conclusion has been arrived at that among the Greeks Xenophon was the inventor of stenography, some method of which he employed in recording the *Memorabilia* of Socrates. Many references show that some style of writing briefer than that in common use was known at this time, though it is not clear that use was made of characters not found in the common alphabet. It has been suggested that certain references in the Bible to "ready writers" (Ps. xlv. 1) show that some system of brief writing was known to the Hebrews, but the passages relied upon to establish the proposition have only suggestive force.

*Stenography among the Romans.*—Among the Romans it is probable that the first efforts at brief writing were reflected in the representation of certain frequently recurring words by contractions in the ordinary spelling, as by their initial letters; thus: R. P. for *Res Publicæ*, P. R. for *Populus Romanus*, S. P. Q. R. for *Senatus Populusque Romanus.* The next step was the representation of certain frequently recurring terminations of words by arbitrary contractions or signs; and the next, the representation by arbitrary characters of words and phrases. Ennius the poet is said to have invented and used (239–169 B.C.) a series of 1,100 arbitrary characters for the ready representation of words. The first attempt at any system of stenographic writing is variously attributed to Cicero and to his freedman Tiro. Certain it is that Tiro, by the use of a system which he had mastered if not invented (and which is said to have been improved by Mæcenas), took down and thus secured the preservation of Cato's great oration against the proceedings of Cæsar respecting the Catilinarian conspiracy, as well as Cicero's own orations respecting the same. Julius Cæsar, Augustus, and Titus Vespasian are said to have been proficient in the art of shorthand writing; and this is clearly shown by many references in Horace, Ovid, and other writers. The following is an illustration of the Tironian system:

*Tironian Notes.*



*Translation.*

Cum petitionibus sacerdotum justis & rationabilibus divini cultus amore favemus, & eas cum Dei adjutorio

*Stenography among the French.*—There are said to be still extant, in the characters of the Tironian system, an inventory and fifty-four charters of Louis the Pious, successor of Charlemagne, copies of which were republished at Paris in 1747; but, whatever use was made of stenography during the Middle Ages, few traces are found of it previous to the end of the eighteenth century. The first work of importance to herald the revival of the art was an adaptation of Taylor's (English) system (1792) by Théodore Pierre Bertin. Since then half a dozen systems have been published, among which is that of Fayet, *Nouvelle Écriture et Sténographie* (1832), but those in use by most of the practical reporters (1895) are the systems of Duployé, de Prépean, Aimé-Paris, and Guénin.

*Stenography among the Germans.*—The credit of the first introduction of shorthand into Germany (1666) is given to one Marshof. His system was rapidly followed by others. The systems generally in use are those of Gabelsberger (1831) and Stolze, which have the merit of preserving to a great degree the slant of ordinary writing and the inclusion of many sharp angles, giving easy joinings, and distinguishing often by light and shaded characters.

*Stenography in Great Britain.*—Probably in no other nation have so many systems of shorthand been put forth as in England. The earliest of any prominence was that of Timothy Bright (London, 1588)—*Characterie, an Art of Short, Swift, and Secret Writing by Character.* Two years later appeared the system of Peter Bales, under the curious title *The Writing Schoolmaster, in three parts.* The more prominent of the succeeding systems were those of Willis (1602), Rich (1654–69), Mason (1672; republished with improvements by Gurney in 1753). Byrom published his first work in 1739, and his universal English shorthand in 1767. Taylor's book appeared in 1786, Lewis's in 1815, and Harding's in 1823. Harding's system was an adaptation of Taylor, and Isaac Pitman was induced to take up shorthand by seeing this book. Between the publication of Bright's work in 1588 and Selwyn's in 1847, about eighty different text-books appeared, nearly all of them of unphonetic systems. Isaac Pitman's system appeared in 1837. It was based upon phonetic principles; and, by reason of the simplicity of its consonants, and its copyright protection, made rapid strides in public use. He made use of Harding's pairing of the consonants and Good's use of hooks. Notwithstanding the general popularity of Pitman in England, the larger number of the legal and parliamentary official writers use (1895), with more or less modifications, the older systems, especially Gurney, Taylor, and Lewis. For his long and devoted service in advancing the phonographic art, Isaac Pitman was knighted in 1894.

*Stenography in the United States.*—About 1819 Phineas Bailey published *A Pronouncing Stenography*, a second edition in 1833, and a sixth, styled *Phonography*, in 1852. Keyes A. Bailey brought out his *Reporter's Guide* in 1845, and *A Practical Exposition of Phonography or Writing by Sound* in 1848. Several American editions of Isaac Pitman's (English) system, by Andrews and Boyle, Booth, Paterson, and Benn Pitman, also appeared, the latter in 1853. Day and Stetson brought out an unphonetic system in 1836, Thomas Towndrow a phonetic one in 1837, and Charles Saxton an unphonetic one in 1842. Lindsey's tachygraphy (which is slow, and has the feature of writing in the vowels, and the merit of lineality) was introduced 1864. Andrew J. Graham's adaptation was introduced in 1858, and rapidly found favor. The author undertook to provide a means of securing greater brevity by omissions, combinations, extended word and phrase signs, half-lengths, ticks, and other devices; and while many of his modifications and innovations were regarded as exceedingly valuable as time-savers, numerous practical writers believed that he had carried his ideas of abbreviation too far, and that a strict application of his system would result in the sacrifice of legibility to brevity. From the date of his first *Handbook of Standard Phonography* till his death in 1894 he published a large number of text-books and readers. Munson's system (introduced in 1866) is founded on that of Isaac Pitman, and has received a considerable degree of support. Its distinguishing features are the inversion of the original Pitman vowel scale and the use of small initial hooks on curved strokes for R and large ones for L, thereby avoiding the turning of a curved stroke for L and R hook, as in Fr, Vr, Thr, etc. Bishop (1887) employs a system of connectible, well-distinguished stroke vowels, treated in analogy with the treatment of the consonants, and claimed to give greater exactness and facility in representing any sound whatever used in speech, and to simplify the science by leaving less to mere memorizing and more to the application of fundamental principles. Other systems in the U. S. are Osgoodby's and Burnz's, both of which are adaptations from Pitman with considerable variations, the former exceedingly brief, and the latter being successfully practiced and taught by its author; and Longley's, a phonetic system. It is believed that Graham's modifications are used by more official court stenographers in the U. S. than all other adaptations of Pitman. The Benn Pitman, Graham, and Munson systems are probably more generally taught than any others, and each has a comprehensive dictionary.

Shorthand writers are employed as official reporters in both branches of Congress, in all the State Legislatures, and in nearly every important court in the country. Few newspapers now employ them for shorthand work alone, usually hiring an expert writer whenever a verbatim report of a lecture, sermon, trial, or other proceeding is wanted. The art of shorthand writing has become an invaluable promoter of general business activity, and has opened up a pleasant field of work for young men and young women. There is a constant demand for those possessing a knowledge of shorthand writing and a facility with the typewriter.

The more prominent systems in use in Germany, France, Great Britain, and the U. S. have proved equal, in the hands of experts, to the task of keeping pace with the most fervid oratory; but it must be acknowledged that the requirements of the art are so arduous that only those who have devoted years to the practice, and are, withal, specially adapted for the work, can ever hope to make themselves equal to the highest exactions of the profession. See PHONOGRAPHY.

Revised by THEO. C. ROSE.

**Steph'anus**, or **Stephens** (Fr. *Estienne* or *Étienne*): a family of French printers, several of whom were also noted as scholars. HENRY STEPHENS, the founder of the house (b. about 1460; d. in 1520), established himself in 1502 as a printer in Paris, where his works became famous for the accuracy and beauty of their typography. He was aided, and afterward succeeded in business, by his three sons, the most distinguished of whom was his second son ROBERT (b. in Paris, 1503), who was eminent as a scholar, and in 1531 began the publication of his great *Dictionarium, seu Thesaurus Linguæ Latinæ*, of which he put forth three editions, the last in 1545, and which has been several times republished. He also published editions of the Bible, with notes which were censured by the Sorbonne because of their Protestantism, and indeed Stephens was a Protestant, but he was protected by Francis I., who had made him royal printer. After the death of the king the Sorbonne prohibited the sale of his Bibles, and he was obliged to take refuge in Geneva, 1551, where he continued printing and died Sept. 7, 1559. He published nearly a dozen complete editions of the Bible in Hebrew, Greek, Latin, and French, and numerous separate editions of the New Testament in various languages, besides many other very important works. The present division of the New Testament into verses was made by him and first introduced in his Greek-Latin Testament published at Geneva 1551. After he had taken refuge in Geneva, the business in Paris was conducted by his brother CHARLES (b. 1504; d. 1564), who was appointed printer to Henry II., and put forth numerous classical and scientific works.—HENRY, son of Robert (b. 1528; d. Mar., 1598), was especially eminent as a Greek scholar, and carried on his business at first in Paris, and afterward in Geneva. He almost ruined himself financially by the publication of his *Plato* (1578) and his immense *Thesaurus Linguæ Græcæ* (1572, 5 vols. fol., reprinted with additions, London (by Valpy), 1815–28, and again, Paris (by Didot), 9 vols. fol., 1831–65), for at that time Greek students were too few in number to afford purchasers for an edition. He subsequently traveled from place to place, visiting all the principal libraries, for the purpose of collecting materials for various works, which he procured to be printed by others. Among these works is his *La Précellence du Langage françois* (1579).—PAUL, the son of Henry (b. 1566; d. 1627), carried on the printing business at Geneva for many years.—ANTHONY, the son of Paul (b. 1592; d. 1674), removed from Geneva to Paris, where for nearly half a century he conducted a printing-house, but with ultimate ill success. He died at the Hôtel-Dieu in Paris in utter destitution, and with him was extinguished this line of famous scholars and printers. Revised by S. M. JACKSON.

**Stephen**, SAINT [*Stephen* is from Lat. *Ste'phanus* = Gr. Στέφανος, liter., crown]: the first of all Christian martyrs. He was one of the seven deacons in the Christian congregation of Jerusalem. Charged by the Jews with speaking against the law and against God, he was stoned to death by order of the Sanhedrin. His history is given in chapters vi. and vii. of the Acts of the Apostles. His festival is held on Dec. 26, both in the Eastern and Western Churches.

**Stephen I.**, SAINT: King of Hungary. See HUNGARY (*History*).

**Stephen**: the name of ten popes. Some historians, however, count but nine, from the circumstance that Stephen II. died three days after his election, Mar. 27, 752, before he had been consecrated. The following bearers of the name are the most noteworthy: STEPHEN I., Saint: pope from about 254 to 257 A. D.; is noted for his controversy with Cyprian as to the necessity of rebaptizing converted heretics. The councils of Carthage (255 and 256) having decided against the Roman practice of recognizing baptism by heretics as valid, Stephen broke off communion with the African Church.—STEPHEN III. (II.): pope from 752 to 757; suffered severely from the aggressions of the Lombards. After asking in vain for help against them from the Byzantine emperor, Constantine Copronymus, he went in person to Pepin le Bref, chief of the Franks, whom he crowned king on the condition that he should expel Aistulf, the Lombard king, from the exarchate of Ravenna and the Pentapolis and bestow these territories on the see of St. Peter. Pepin made two campaigns in Italy, but succeeded at last in forcing the Lombards to retreat from the above territories, which he then gave to the papal see, in spite of the protest of the Byzantine emperor, thereby laying the foundation of the temporal power of the pope.—STEPHEN VII. (VI.) (896–897) is most noticeable for his violence in respect to his predecessor Formosus, whose corpse he caused to be exhumed, stripped of the papal insignia, mutilated, and thrown into the Tiber, at the same time annulling all his ordinances, and even his consecrations.—STEPHEN X. (IX.) (1057–58) was a son of the Duke Gotelon of Lower Lorraine, and was elected pope through the influence of Cardinal Hildebrand, afterward Pope Gregory VII., who was the real master of the Church.

**Stephen**: King of England; b. in Normandy about 1100; son of Stephen, Count of Blois, by Adela, daughter of William the Conqueror. William, the only son of Henry I., was drowned in 1120, and the heir-presumptive to the crown was his daughter Matilda, who was married to Henry V., Emperor of Germany; but before the death of her father the emperor died, and she married Geoffrey Plantagenet, Earl of Anjou, without the royal sanction, which was held to invalidate her right to the succession. Upon the death of Henry I. (in 1135), Stephen claimed the succession, although he was not next in the line, even if Matilda was set aside, for he had an elder brother, Theobald, Count of Blois; he was, however, chosen by a party of the prelates and nobles, and his election was sanctioned by the pope. At first his government was fairly successful. He ingratiated the English by issuing a charter confirming the favorable laws of Henry I.'s reign. He made peace with the Scots, whose king, David, paid him homage, and when the war broke out again the English were victorious in the battle of the Standard. The entire reign, however, was filled with revolts and civil war. The cause of Matilda was taken up by a party in England, headed by her natural brother, Robert, Earl of Gloucester, and after a contest of several years Stephen was defeated and made prisoner at Lincoln Feb. 2, 1141. The rule of the empress was so unpopular that a revolt broke out, and her brother, the Earl of Gloucester, was defeated and captured, but was afterward exchanged for Stephen. The civil war now raged with varying fortunes for ten years. In 1153 Prince Henry Plantagenet, son of Matilda, arrived in England at the head of a considerable force; but before a decisive action took place, the barons on both sides entered upon an armistice, and finally concluded the treaty of Wallingford by which Stephen should retain the crown during his life, and that after his death Henry should succeed him. Stephen survived this treaty only a few months, and with him ended the line of Anglo-Norman kings of England. D. Oct. 25, 1154.

**Stephen**, Henry John: jurist; cousin of Sir James and Sir George Stephen; b. in England in 1787; was called to the bar at the Inner Temple 1815; became commissioner of bankruptcy; was a distinguished practitioner at the London bar, and became sergeant-at-law 1827. D. at Clifton, Nov. 28, 1864. Author of a *Treatise on the Principles of Pleading in Civil Actions* (1824; 8th American ed. Philadelphia, 1859); of a *Summary of the Criminal Law in its present State* (1834); and of *New Commentaries on the Laws of England* (4 vols., London, 1841–45). In the preparation of three subsequent editions of this great work the author enjoyed the assistance of his son, James Stephen, LL. D.; b. in England in 1820; called to the bar at the Middle Temple 1846; became Professor of English Law and jurisprudence at King's College, London; recorder of Poole, registrar of bankruptcy at Leeds, and circuit judge at Lincoln. He issued revised editions of his father's *Commentaries*, also *Questions* for the editions, and was author of treatises on *Bar Etiquette* (1851) and *The Common-law Procedure Act* (1860).

**Stephen**, Sir Herbert: See the Appendix.

**Stephen**, Sir James Fitzjames: jurist; b. at Kensington, London, Mar. 3, 1829; educated at Trinity College, Cambridge (B. A. 1852), and was called to the bar at the Inner Temple in 1854; traveled circuit, and became recorder of Newark-on-Trent 1859–68; succeeded Sir Henry J. S. Maine as legal member of the legislative council of India 1869; with the assistance of two others he drew up and passed through the council a code of criminal procedure, which, with considerable modifications, was re-enacted as the code of 1882; prepared, and finally passed, the Indian Evidence Act of 1872. He returned to England in 1872, where he undertook the codification of the English law of evidence (which he never completed), and of English substantive criminal law, the resulting code being reported too late for the code of 1879, and subsequently dropped from the Government measures; in Dec., 1875, was appointed Professor of Common Law by the Inns of Court, and a member of the council of legal education and law reporting; was made Knight Commander of the Star of India in 1877, and appointed a judge of the Queen's bench division, which office he retained until he was stricken with insanity in 1891. D. in London Mar. 11, 1894. He wrote besides his great work, *History of the Criminal Law of England* (which is far more than a mere legal treatise; 3 vols. 8vo, 1863), a *Digest of the Law of Evidence* (1876); *Essays of a Barrister* (1862); *Liberty, Equality, and Fraternity* (1873); *Digest of the Criminal Law* (1877); and many monographs on legal subjects. See *Law Times* (Mar., 1894). F. Sturges Allen.

**Stephen**, Leslie, LL. D.: author; b. at Kensington, London, Nov. 28, 1832; son of Sir James Stephen and brother of Sir James Fitzjames Stephen. He was educated at Eton, King's College, London, and Trinity Hall, Cambridge (B. A. 1854), of which last he was a fellow. In 1864 he went to London and engaged in literary pursuits; edited *The Cornhill Magazine* 1871–72, resigning to take charge of the important *Dictionary of National Biography*. The first twenty-six volumes of this (1885–91) were issued under his supervision, and he was then succeeded in the editorship by his collaborator, Sidney Lee. In 1883 he held the Clark lectureship on English Literature at Cambridge. He married Harriet Marian, younger daughter of William M. Thackeray. Among his writings are *The Playground of Europe* (1871); *Free Thinking and Plain Speaking* (1873); *Hours in a Library* (1874–79); *History of English Thought in the Eighteenth Century* (1876); *The Science of Ethics* (1882); *An Agnostic's Apology* (1893); besides biographies of Pope, Swift, Johnson, and Henry Fawcett, and an edition of Fielding in ten volumes (1882). H. A. Beers.

**Stephen Báthori**, -baa'tō-rē: King of Poland; b. in 1532, of a celebrated Hungarian family; was Prince of Transylvania, and in 1575, after Henry of Anjou's abandonment of the Polish throne, was elected King of Poland. He put the Jesuits at the head of the new university which he founded at Wilna, and gave them many other preferments, but their efforts to induce him to put down the Reformation in Poland were in vain. In military respects he was successful, and humiliated the Russians several times, forcing them out of Livonia, which was then reannexed to Poland. D. at Grodno, Dec. 12, 1586.

**Stephens**: a family of French printers. See Stephanus.

**Stephens**, Alexander Hamilton, LL. D.: statesman; b. near Crawfordsville, Ga., Feb. 11, 1812; graduated at the University of Georgia 1832; admitted to the bar 1834; entered upon political life 1836 as member for Taliaferro of the State House of Representatives; was successively re-elected to the same office until 1840; declined an election 1841; the next year was chosen State Senator by the same constituency. In 1843 he was elected member of the House of Representatives of the U. S. That office he occupied until 1859, when he voluntarily retired to private life. The compromise measure passed by the Congress of 1850 had no bolder, abler, or more eloquent champion than Stephens. He was chosen a delegate to the State convention of that year—the convention which established the celebrated "Georgia platform." In 1855 he united with the Democrats to defeat the Know-nothing party. In the presidential campagin of 1860 he was placed at the head of the Douglas-Johnson electoral ticket. He was a delegate to the State convention of 1861 which passed the ordinance of secession. That measure he earnestly opposed by speech and vote, but, while he advised against the policy of secession for existing grievances, he maintained the right of a State to secede peaceably from the Federal Union for sufficient cause. When a majority of the convention passed the ordinance of secession, he readily acquiesced in their decision. He was a member of the Confederate provisional congress; was chosen vice-president of the provisional government of the Confederate States; was appointed commissioner to the convention between their government and the State of Virginia; was elected by the people, without opposition, to the vice-presidency of the Confederacy under the permanent constitution, as it was styled; and, when in Feb., 1865, the fortunes of the Confederacy were desperate beyond the reach of hope, he was placed at the head of the commission on the part of the Confederate States government in the famous Hampton Roads conference. After the downfall of the Confederacy he was arrested and confined a prisoner of state in Fort Warren for five months; he was released on his own parole in Oct., 1865. In Feb., 1866, the General Assembly elected him, by a large majority, against his wishes, to the office of U. S. Senator, but Congress ignored the restoration of Georgia to the Union under the presidential proclamation of Andrew Johnson, and he was not allowed to take his seat in the Senate. He was elected to the 43d, 44th, 45th, 46th, and 47th Congresses, in each case without more than nominal opposition; inaugurated Governor of Georgia Nov. 4, 1882. He belonged to the Jeffersonian school of American politics, and among the cardinal articles of his political creed were State rights, State sovereignty, local self-government; he always advocated the largest liberty of the citizen compatible with the attainment of the two prime objects of government—viz., protection to property and preservation of order. He wrote a *Constitutional View of the War between the States* (2 vols., 1867–70); a *School History of the United States* (1870–71); and a *Compendium of the History of the United States* (New York, 1883). D. at Atlanta, Ga., Mar, 4, 1883.

Revised by C. K. Adams.

**Stephens**, Ann Sophia (*Winterbotham*): novelist; b. at Derby, Conn., in 1813; became the wife of Edward Stephens in 1831; soon after they went to Portland, Me., where in 1835–37 she edited *The Portland Magazine*, and in 1836 compiled *The Portland Sketch-book*, a volume composed of the writings of natives or residents of that city. In 1837 they removed to New York, her husband subsequently receiving an appointment in the custom-house. She edited and contributed to various periodicals, and wrote many tales and novels, and some fugitive poems. A uniform edition of her works has been issued (new ed. 23 vols., Philadelphia, 1886). Among her most successful novels are *Fashion and Famine* (New York, 1854); *The Old Homestead* (1855; 2 vols., Philadelphia, 1860); *Mary Derwent* (1860); *The Rejected Wife* (1863); *Silent Struggles* (1865); *Mabel's Mistake* (1868); *Wives and Widows* (1869); *Married in Haste* (1870); *The Reigning Belle* (1872); *Bellehood and Bondage* (1873); and *Phemie's Experience* (1874). D. at Newport, R. I., Aug. 20, 1886. Revised by H. A. Beers.

**Stephens**, George: archæologist; b. in Liverpool, England, Dec. 13, 1813. After spending several years in Stockholm he was in 1851 appointed acting Professor of the English Language and Literature at the University of Copenhagen, and four years later permanent professor; resigned in 1893. He was an honorary member of a number of scientific societies, and was decorated several times. His chief work is *The Old Northern Runic Monuments of Scandinavia and England* (London and Copenhagen, 3 vols. fol., 1866-84). As a collection of plates and transcriptions, this work is invaluable, but many of the readings and criticisms have since been effectually disproved by Wimmer and others. He has also published a number of monographs and texts, English and Scandinavian, a translation of Tegnér's *Frithiof's Saga*, and a melodrama, *Revenge, or Woman's Love*. D. in Copenhagen, Aug. 9, 1895. D. K. DODGE.

**Stephens**, JOHN LLOYD: jurist, traveler, and author; b. at Shrewsbury, N. J., Nov. 28, 1805; graduated at Columbia College 1822; studied law and practiced in New York. In 1834-36 he traveled in Europe and the East; published *Egypt, Arabia Petræa, and the Holy Land* (2 vols., 1837), and *Greece, Turkey, Russia, and Poland* (2 vols., 1838). In 1839 President Van Buren appointed him special commissioner to negotiate a treaty with Central America. The civil war in that country prevented him from accomplishing his purpose; but in company with an English artist, Frederick Catherwood, he traveled in Central America and Southern Mexico, making a special study of the ancient ruined cities. Returning to New York he published *Incidents of Travel in Central America, Chiapas, and Yucatan* (2 vols., with fine illustrations by Catherwood, 1841). The results of a second journey, also with Mr. Catherwood, were embodied in *Incidents of Travel in Yucatan* (2 vols., 1843). These two works attained a wide circulation, and gave for the first time good popular descriptions of the wonderful Central American cities. Mr. Stephens was a delegate to the convention for revising the constitution of New York, 1846. In 1847 he took an active part in the organization of the first Atlantic steam-navigation company. After the discovery of gold in California he entered, with characteristic energy, into the scheme for a rail route across the Isthmus of Panama; was one of the first presidents of the Panama Railway Company, and personally superintended the construction. From exposure on the isthmus he contracted a disease of which he died in New York, Oct. 10, 1852.
HERBERT H. SMITH.

**Stephens**, WILLIAM: president of the colony of Georgia; b. on the Isle of Wight, England, Jan. 28, 1671, son of Sir William Stephens, lieutenant-governor of that island; graduated at Cambridge; studied law at the Middle Temple; sat in Parliament 1696-1722; settled at Charleston, S. C., about 1730; was appointed secretary of the colony of Georgia 1737; became president of the county of Savannah 1741, and governor of Georgia 1743-50. D. in Georgia in Aug., 1753. He was the author of *A Journal of the Proceedings in Georgia* (London, 3 vols., 1742). His biography was written by a son under the title of *The Castle-builder, or the History of William Stephens of the Isle of Wight* (2d ed. London, 1759).

**Stephenson**, GEORGE: engineer; b. at Wylam, Northumberland, England, June 9, 1781, the son of a poor colliery laborer. He was in childhood an engine-boy; became a fireman, and in time was placed in charge of an engine, which he studied until he had mastered its construction so as to be able to take it apart and put it together again. Accident gave him an opportunity of putting in motion a steam-engine which needed repairs, and in 1812 he was made engine-wright at Killingworth Colliery. The problem of constructing a locomotive steam-engine was then engaging many minds, and he was in 1814 the first to construct one which proved satisfactorily operative. He originated the steam-blast, which was introduced into his second locomotive, built in 1815, and in that year devised a miner's safety-lamp, for which a large prize had been offered by colliery-owners; but Sir Humphry Davy having simultaneously invented his safety-lamp, this prize, valued at £2,000, was awarded to him, £100 being awarded to Stephenson by the committee; a separate subscription of £1,000 was raised in 1817, which was presented to Stephenson, and his lamp is still in use in some English collieries. Stephenson then turned his attention to improvements in railways as well as engines. The first railway built by him, opened in 1822, 8 miles long, was so successful that in the next year he was appointed engineer of the railway authorized to be constructed between Stockton and Darlington, and in 1825 of the Liverpool and Manchester line, which was begun in 1826. He had in the meantime set up an establishment at Newcastle-upon-Tyne for the manufacture of locomotives, and on Oct. 6, 1829, his engine, named the Rocket, attained an average speed of 14 miles an hour, and for a short distance was driven at the rate of 29 miles. (See RAILWAYS.) During the next fifteen years he was actively engaged as a railway engineer and contractor in England and on the Continent, still carrying on his great locomotive-factory at Newcastle, and also engaging in coal-mining and lime-works. He passed the closing years of his life at his seat, Tapton Park, Derbyshire. D. Aug. 12, 1848. He retained during all his life, in speech and manners, much of the rustic simplicity belonging to his early life, and declined the honor of knighthood. By common consent he has received the title of the father of railways, and in 1862 a colossal bronze statue was erected in his honor at Newcastle-upon-Tyne. See Smiles's *Life of George Stephenson* (1857; new ed. 1874). Revised by R. H. THURSTON.

**Stephenson**, ROBERT: engineer; son of George Stephenson, engineer; b. at Willington Quay, near Newcastle-upon-Tyne, Oct. 16, 1803. He had little opportunity to obtain an education when a boy, and in 1819 he was apprenticed to a coal-viewer; but as his father's circumstances improved he gave his son the best education within his means, and in 1822 sent him to the University of Edinburgh, where he remained six months studying chemistry, mathematics, and geology, after which he assisted his father in railway surveying and in the locomotive-works at Newcastle. In 1824 he went to South America, where for three years he superintended the working of the Columbian Mining Association. He then returned to England, where he aided his father, partly in laying down the line of the Liverpool and Manchester Railway, but more especially in the locomotive-works; and to him chiefly belongs the honor of the practical development of the details of the locomotive and the railway. He was appointed engineer of the London and Birmingham Railway, which, built almost wholly under his direction, was opened in 1838, and from this time he was employed in similar undertakings at home and broad. He constructed several of the most stupendous iron railway bridges in the world, including the high-level bridge crossing the Tyne at Newcastle, the viaduct over the valley of the Tweed at Berwick, the Conway tubular bridge, the Britannia tubular bridge crossing the Menai Straits, the Victoria tubular bridge over the St. Lawrence in Canada, and those crossing the Nile at Damietta, Egypt. In 1847 he was returned to Parliament for Whitby. He received the great gold medal of honor from the French Industrial Exposition of 1855, and was president of the Institute of Civil Engineers from 1855 to 1858. He published a *Description of the Locomotive Steam-engine* (1838); *Report on the Atmospheric Railway System* (1844); and *The Great Exhibition, its Palace and Contents* (1851). D. Oct. 12, 1859. He was buried in Westminster Abbey, where a memorial window has been placed to his memory. See Smiles's *Life of George Stephenson* (new ed. 1874), and *Life of Robert Stephenson*, by J. C. Jeaffreson and W. Pole (2 vols., 1864). Revised by R. H. THURSTON.

**Step'niak**, SERGIUS MICHAEL DRAGOMANOFF: author; b. at Gadjatch, government of Poltava, Russia, 1841; member of a semi-noble family descended from the Cossacks of Little Russia; studied at Kieff 1859-63; published in that time in the Little Russian dialect some works which were prohibited by the Government in 1862; became docent in ancient history in the University of Kieff 1865; professor 1870; removed from his chair 1873 by the Government; exiled in 1876 on account of his criticisms on the system pursued by Count Tolstoi, one of the Ministers of Justice; settled in Geneva 1877, and published a review, *Gromada*, in the Ukraine dialect; settled in London 1885. He labored to establish equal political rights for all people in Russia, but was opposed to both socialism and absolutism. Among his principal works are the *Turks Within and Without* (Geneva, 1876); *La Russia Sotterranea* (Milan, 1881; Eng. trans. *Underground Russia*, 1883); *Russia under the Tzars* (Eng. trans. 1885); *Tyrannicide in Russia* (1881); *Historical Poland and the Muscovite Democracy* (1881); and *The Career of a Nihilist*, a novel (1889). He was a frequent contributor to the magazines and reviews. Killed at a railway crossing near London, Dec. 23, 1895. C. H. THURBER.

**Steppe**: the name given by the Tartars to the plains of Central Asia. They are usually covered with grass, and correspond in their aspects and relations to the prairies of the U. S. and the llanos and pampas of South America. See PLAIN.

**Steppe-murrain**: See RINDERPEST.

**Sterculia'ceæ** [Mod. Lat., named from *Stercu'lia*, the typical genus, from Lat. *Stercu'lius*, the patron deity of manuring, deriv. of *ster'cus*, dung]: a family of exogenous trees, shrubs, and herbs, mostly tropical. Many of the trees are of prodigious size, such as the baobabs and those of the genera *Bombax* and *Ceiba*. Many produce abundantly a substance called silk-cotton, which resembles true cotton, but will not spin well. The wood is often very light and soft. The family contains medicinal plants, and produces some excellent fruits, some gums, a few valuable bark-fibers, and a number of useful timber-trees; but its most important product is chocolate, from the oily seeds of *Theobroma cacao*. The flowers or fruits of certain species are putrid, whence the botanical name. Revised by L. H. Bailey.

**Stere**: See Metric System.

**Sterelmin'tha** [Mod. Lat., Gr. στερεός, solid + ἕλμινς, ἕλμινθος, a worm]: a name given to some of the Plathelminthes (*q. v.*), in allusion to the absence of all cavities in the body.

**Stereo-chemistry**: a branch of chemistry that has to deal with the relations which the atoms bear to one another in space. The ordinary methods of investigation of chemical compounds lead to certain conclusions in regard to the connections existing between the atoms in a molecule. Thus when water is expressed by the formula H–O–H, no attempt is made to tell anything about the arrangement in space of the two atoms of hydrogen and the atom of oxygen. The formula expresses the view that each of the two atoms of hydrogen is linked to the atom of oxygen, but the question whether they are on the same side or on opposite sides, above or below, is not touched. Yet it is certain that if these atoms exist and are united in the molecule they must be arranged in space, and a formula that does not take into consideration the three dimensions of space is certainly incomplete. Up to within a comparatively short time no facts were known that justified any speculation concerning the space-relations of atoms, but it appears that the time has come when such speculation is profitable, and facts are constantly being brought to light that can not be explained without its aid.

The investigations of Pasteur on the different varieties of tartaric acid form the basis of stereo-chemistry. Pasteur found that racemic acid, which can easily be made, can be converted into ordinary tartaric acid and a new variety of tartaric acid, and when these two varieties of tartaric acid are mixed in solution they form racemic acid. Ordinary tartaric acid, when examined with the aid of a polarizing apparatus (see Polarization), is found to turn the plane of polarization to the right, while the new variety obtained by Pasteur turns the plane to the left, and racemic acid is optically inactive—that is to say, it has no effect on polarized light. No explanation of these facts was offered until many years later. Meanwhile other cases similar to that studied by Pasteur were discovered, and chemists came to see more and more clearly that their theory of chemical constitution required an extension in order to accommodate it to the facts. At about the same time, and independently, Van't Hoff and Le Bel made a suggestion with reference to these cases that has proved to be of great value. The main idea is this: The atom of carbon, which, as is well known, has the power to unite with four univalent atoms or groups, is supposed to exert its four affinities from a center toward the angles of a tetrahedron—that is, symmetrically in space. Suppose all four atoms or groups that are in combination with the carbon atom to be of one kind, then but one arrangement of them in space is possible. So also if three are of one kind and one different, or two of one kind and two of another, they can be arranged in but one way around the central carbon atom. When, however, all four atoms or groups are different, then two arrangements in space are possible. The difference between the two arrangements is that which is observed between either one and its reflection in a mirror. Imperfectly the two arrangements are shown in the accompanying figures, in which C represents the carbon atom and R, $R_1$, $R_2$, and $R_3$ represent four different radicals or atoms.

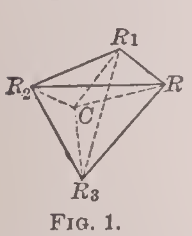

FIG. 1.

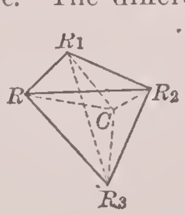

FIG. 2.

A carbon atom which is thus in combination with four different atoms or radicals is called an *asymmetrical carbon atom*. The proposition of Van't Hoff and Le Bel is that the presence of such an atom in a compound makes possible a kind of isomerism that is due to the arrangement of the constituents in space. In the case of the tartaric acids there are in fact two asymmetrical carbon atoms present. The constitution of these acids is represented by the formula

$$\begin{array}{l} CH(OH).CO_2H \\ | \\ CH(OH).CO_2H. \end{array}$$

It will be seen that each of the two carbon atoms that are represented as being in combination with each other is asymmetrical, a fact that is more clearly brought out by writing the formula thus:

$$\begin{array}{lll} & H & \\ & | & \\ (HO)- & C & -CO_2H \\ & | & \\ & CH(OH).CO_2H. & \end{array}$$

Accordingly, this compound presents the conditions necessary for the two arrangements in space—one right-handed, the other left-handed, corresponding to the action of the two varieties of tartaric acid on polarized light.

The same general statements hold true for the lactic acids, which are represented by the formula

$$\begin{array}{lll} & H & \\ & | & \\ (HO)- & C & -CO_2H \\ & | & \\ & CH_3. & \end{array}$$

There are two varieties of ordinary lactic acid which are apparently analogous to the two optically active varieties of tartaric acid, and, further, there is a third variety corresponding to racemic acid, and formed by the union of the two active varieties. The relations between the inactive racemic acid and the active tartaric acids, and between the inactive lactic acid and the two active varieties are not understood. It can only be said that in each case the molecule of the inactive substance must consist of at least one molecule of each of the two active varieties.

Investigation has shown that the asymmetrical carbon atom gives to the compounds in which it is present the property of optical activity and the power to form peculiar isomeric varieties which can not be accounted for by the ordinary theory of constitution. Much progress has been made of late years in the study of the phenomena of stereo-chemistry. Perhaps these phenomena are best illustrated in the field of the sugars, the remarkable studies of Emil Fischer in this field having led to the discovery of a large number of new sugars, the existence of which it appears to be impossible to explain without the aid of the principles of stereo-chemistry.

Werner and Hantzsch have extended the ideas of stereo-chemistry to some classes of compounds containing nitrogen, with interesting results. Ira Remsen.

**Stereornithes**: See the Appendix.

**Ste'reoscope** [from Gr. στερεός, solid + σκοπεῖν, to view]: an instrument to aid the eyes in obtaining binocular combination of two similar, or nearly similar, pictures. As long ago as the time of Euclid (B. C. 300) it was known that when a near object is regarded with both eyes the aspect is different to each eye separately. No practical application of this was made to the study of binocular vision until 1838, when Sir Charles Wheatstone constructed perspective drawings of a geometric solid as seen by each eye separately when held at a fixed distance in front of the face. The width of each drawing was made a little less than the distance between the pupils of the two eyes. In order that one of them should be seen only by the right eye and the other only by the left, Wheatstone looked through a pair of tubes; and the visual effect was found to be that of an apparently solid body in space. In order to obtain this effect more conveniently and to use larger pictures he constructed the first reflecting stereoscope. A pair of plane mirrors, *m p* and *m q* (Fig. 1), were fixed upon a frame at right angles to each other, one pair of edges being in contact at *m*. Light from the pictures, *a b* and *a' b'*, was reflected into the eyes, R and L, so that the combination appeared to be at A B.

Wheatstone's invention did not become popularized because of the difficulty of constructing accurate perspective drawings to use with it. If two such conjugate drawings be placed beside each other in the same plane, the corresponding edges, *a* and *a'* (Fig. 2), being on the right and representing one of the remoter points of the object pictured, while $c$ and $c'$ represent one of the nearer points, it can be easily proved geometrically or ascertained by careful measurement that the interval between $c$ and $c'$ is and must be less than that between $a$ and $a'$. The rays from $c$ and $c'$ after reflection appear to the eyes to have come from some point, C, nearer than A or B if the arrangement is such as to produce the least discomfort to the eyes. It was natural for Wheatstone to conclude that the localization of each point in the binocular field of view is determined by the intersection of the visual lines reflected into the eyes. This theory of binocular perspective was long held and is still frequently expressed or implied.

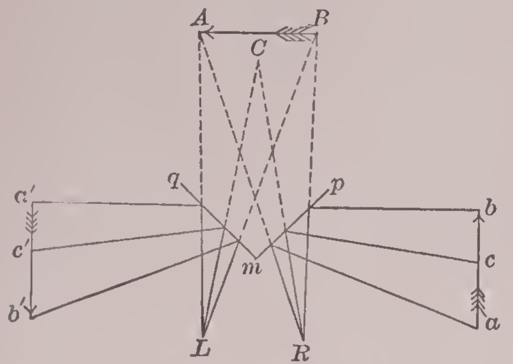

FIG. 1—Diagram of Wheatstone's stereoscope.

Prior to the invention of Wheatstone's stereoscope, James Eliot, of Edinburgh, constructed a pair of conjugate perspectives of a landscape, but not until 1839 did he construct an instrument for viewing it. This was merely a small box open at the two ends, with a partition along the middle, equivalent to a pair of tubes. About the same time the art of photography was introduced by Talbot and Daguerre. In 1849 Sir David Brewster improved upon Eliot's form of box stereoscope by putting at the eye end a pair of semi-lenses of glass with thin edges opposed. In connection with this he devised the double camera for taking photographically the pair of pictures composing the stereograph. The stereoscope and camera were carried by him to Paris during the following year. Here the stereoscope was popularized by Duboscq, who made these instruments and stereographs for it in great number and with various modifications.

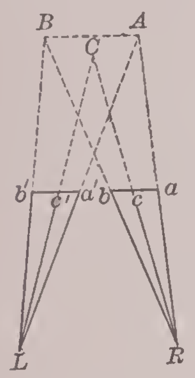

FIG. 2.

The form of open stereoscope commonly in use in the U. S. was devised in 1861 by Dr. Oliver Wendell Holmes. In this the box is discarded, but the pair of semi-lenses is retained, being fixed at one end of a shaft on which slides the stereograph-holder.

If the pair of conjugate pictures be transposed, that originally intended for the right eye being put on the left, the effect is reversion of relief, foreground points appearing in the background. Without such transposition or use of the stereoscope the same result may be attained by muscular crossing of the visual lines. By relaxing the muscles of the eyeball the right eye may be directed to the right picture and the left eye to the left. The visual lines then may often become divergent, but the localization in the field of view is perfect. This fact disproves the theory of stereoscopic perspective held by Wheatstone and Brewster. The apparent distance and size of the binocular image are much affected by the degree of strain imposed upon the muscles which control the eyeballs and the crystalline lens. The object of the stereoscope is to attain the binocular image with the least possible disturbance of the conditions of natural binocular vision.

The bibliography of this subject is included in that of VISION. W. LE CONTE STEVENS.

**Stereotyping and Electrotyping** [*stereotyping* is deriv. of *stereotype*, from Gr. *στερεός*, fixed + *τύπος*, impression, type]: the art or process of making metal plates, reproducing in facsimile the surface of engravings or type set up as for direct printing. Stereotypes are plates of type-metal of the same composition throughout; electrotypes have a facing, usually of copper, deposited by electricity.

I. STEREOTYPING.—Before the invention of stereotypes a work to be printed at intervals, as occasion demanded, had to be kept continually in type (at considerable risk of error creeping in) or else reset for each edition. About 1725 the plaster process of stereotyping was invented by William Ged, a goldsmith (b. in Edinburgh, 1690; d. 1749). In 1731 a company formed by Ged contracted with the University of Cambridge to print Bibles and prayer-books by stereotype, but after the printing of two prayer-books the contract was abandoned, owing partly to the hostility of pressmen to the innovation. Ged returned to Edinburgh, and in 1736 completed an edition of Sallust, which was printed in 1744. Few other attempts at stereotyping were made till 1793, when William Carey, the missionary, devised the method of letting the form of type fall face downward on a surface of hot lead at the point of solidifying, and then repeating this process with the matrix so formed, the result being a true reproduction of the original form in stereotype. Firmin Didot, of Paris, modified this plan by using types of a harder alloy, (30 parts of lead, 30 antimony, 30 tin, and 10 copper); a form of such type was pressed into a surface of pure lead, and the matrix thus obtained was attached to the hammer of a stamping-press and brought down upon a roll of type-metal about to solidify, thus flattening it out and forming a stereotype plate suitable for printing.

The method of Herhan, another French printer, was to set up the form in copper matrices in intaglio and take a cast in type-metal therefrom, thus procuring a cameo impression at one operation.

Stereotyping was introduced into the U. S. by David Bruce, of New York, in 1813. The first work stereotyped in America was the New Testament in 1814. The process of curving stereotype plates to adapt them to a cylinder printing-press was patented in England by Cowper in 1815, but was not very successful till applied to the Hoe perfecting-press. There are three leading methods of stereotyping—plaster, clay, and papier-maché; but only the last-named is now much employed. The metal used approaches type-metal in composition, and the plates after being used may be remelted and the metal used again.

*Plaster Process.*—For this the type is set up with shoulder-high spaces and quadrats. The surface is thinly and evenly oiled with a brush and the form is then inclosed in a rectangular frame termed a flask. Plaster-of-Paris mixed with water is poured upon it, forming a mould corresponding to the face of the form. When this has sufficiently hardened it is withdrawn and dried in an oven until all the moisture is driven off. The mould, laid face downward upon a casting-plate (floating-plate), is then placed within a casting-tray, which has a lid with openings at the corners. The whole is heated to about 400° F. while suspended by a crane over a pot of molten metal, and then gently lowered into the bath until the metal just flows into the corner openings, forming a thin plate which fills up all the cavities in the face of the mould. After being immersed eight or ten minutes the tray is lifted out and lowered upon a stone so arranged that the face of the plate is cooled first, and as shrinkage takes place more metal is added. The pan is then opened and the cast is separated from the mould and fitted to a block so as to make it type-high for printing.

*The Clay Process* (*or Clay-and-Plaster Process*).—For this the form is locked up with high furniture and slugs and placed on the bed of a special press, the face of the type being brushed over with benzine or naphtha and covered with a cloth. A plate covered evenly to the depth of ¼ inch with a mixture of equal parts of ground French clay and plaster-of-Paris moistened to the consistency of mortar is turned down over the type, and a partial impression taken; then, after opening the press to remove the cloth and any surplus clay, a complete impression is taken, imbedding the type in the plastic material to the desired extent. The mould is then removed and hardened by drying, and after being heated to the temperature of molten metal is inclosed on three sides by an iron wire, to which, over the face of the mould, a sheet of metal is clamped, as in a moulder's flask. The metal is poured into the open edge, and after cooling the mould is removed from the cast by washing. Curved plates for the Hoe press were cast from moulds made by using on the press a sheet of steel of the desired curvature spread flat and carrying the clay on what was its concave side. After the impression was taken the sheet was released and resumed its normal curvature, bending the plastic mould with it. The finished stereotype appeared as if taken from a type a little more condensed one way than that actually employed.

*The papier-maché process* was invented by Genoux in 1829 and introduced into Great Britain by Wilson, of Scotland, in 1832. It is far more expeditious than any other (by Hoe machines in 1895 plates could be made in six minutes), the type used suffers no perceptible injury, curved plates can be made with the same facility as flat, and a large number of plates can be cast from the same matrix; this process has therefore been adopted by all large daily papers. The material for a papier-maché matrix is formed by spreading paste over a sheet of moderately thick unsized paper and covering it with successive sheets of tissue-paper, each carefully rolled down smooth by means of a heavy iron roller. The whole is usually saturated with water, although some prefer using the matrix softened only by what moisture there is in the paste. The type matter is imposed in an ordinary chase and inclosed with type-high bearers, these having the inside top edge grooved out, making a bolster for the sheet of papier-maché which is then laid upon it, tissue side next the type. The face of the type is sometimes slightly oiled, and the surface of the sheet treated with powdered French chalk, but this is found to be unnecessary on most kinds of newspaper work. If the work is done by hand in the old way a linen cloth is moistened and laid on the back of the sheet, which is then thoroughly beaten into the form with a stiff brush. Much better and quicker work is done by machinery, however. In this method the form, covered by the sheet and a blanket, travels backward and forward under a large roller, and is then conveyed to a drying-press, where it receives strong pressure while resting on a large chest filled with steam under pressure. The matrix thus becomes dry and hard very quickly, and as it is held under pressure during the process, there is none of the roughness or distortion often produced in one taken from the form in a partially soft condition. After being taken from the drying-press and removed from the form, the matrix is exposed for half a minute to a strong heat, either in an oven or the flame of a gas-jet, to expel any remaining moisture. The edges of the matrix are then trimmed, and it is placed face up on the bottom of a casting-box, flat or cylindrical according to the shape of the plates to be made. It is inclosed on three edges by the sides of the box, which are as high as the stereotype plate is to be thick, and the fourth edge, over which the metal is to be poured, is covered by a thin sheet of steel or old matrix to prevent metal running under the matrix; the lid of the box is then fastened down and molten metal is poured in at the upturned open side, a two-handled ladle being usually employed in conveying it from the furnace. The plate is made considerably longer than the matrix at the open end in order to allow for the shrinkage as the metal cools. On being removed from the box this end is cut off, and the plate is trimmed and shaved down on the reverse side in order to bring it to the exact thickness required, all being very rapidly done by machinery.

*The chalk-plate process* is a method of producing drawings on plates to be used in a printing-press, and is similar in principle to stereotyping proper. A sheet of steel is covered thinly with a soft material, like chalk, about $\frac{1}{32}$d of an inch thick, and the drawing is transferred to this surface, after which the chalk is scraped away where the lines show, leaving the steel bare. The plate is then put in an ordinary casting-box, and used as a matrix. The cast is trimmed square, and made exactly type-high; it may then be locked in its place in the form, and treated just as an engraving, a papier-maché matrix being made from the whole.

II. Electrotyping.—The method of producing casts by means of electricity, as explained in the article Electrotype (*q. v.*), is much employed in making plates for printing, especially from engravings and for bookwork, as electrotype plates give a clearer impression and are more durable than stereotypes proper. A wax mould is first made from the engraving or type (set with shoulder-high spaces) and powdered graphite is spread over its surface so as to make it a conductor of electricity; copper may then be deposited on it by the ordinary process of electroplating. The first plates successfully used for printing were made by Joseph A. Adams, a wood-engraver of New York, who made casts from wood-cuts in 1839–41, some engravings being printed from his electrotype plates in the latter year. In his process finely pulverized tin was added to the graphite for facing the moulds. The effect of this in the sulphate of copper solution was to cause a rapid precipitation of the copper by the substitution of copper for the tin, the latter being seized by the oxygen of the solution while the copper was deposited upon the graphite. The film was afterward increased by the electric current. In Silas B. Knight's modification of this process, now in universal use, fine iron filings are dusted upon the wet graphite surface of the mould, and then a solution of sulphate of copper is poured upon it and gently stirred in with a brush. A film of copper is formed immediately over the entire surface, the acid leaving the copper and combining with the iron, forming a sulphate of iron, which floats away as copper solution is poured on. Machinery has been devised for increasing greatly the rapidity and accuracy with which electrotype plates can be made. The process in detail is as follows: Pure wax is melted in a kettle surrounded by a steam-chamber, and is then poured into a shallow moulding-case which has been previously heated so as to make the wax firmly adhere to it. As soon as the wax is firmly set it is run through a shaving-machine, which reduces it to a uniform thickness, and leaves a smooth surface, into which graphite dust is thoroughly rubbed in order to prevent it from sticking to the type or engraving. The impression is made by forcing the latter (also covered with graphite) into the wax to the required depth—an operation which was long performed on a hand-press, but which may now be done with great speed and perfect accuracy by power. The mould is taken from the press, the surplus wax removed with a sharp knife, and then with a hot iron new wax is melted and dropped on the surfaces between the lines and where there are large blank spaces. This avoids the necessity of later deepening the corresponding places on the cast plates, so as to prevent all possibility of their soiling the paper in printing. A piece of sheet-copper or lead is imbedded in the edge of the sheet of wax to facilitate electrical connection. The mould then receives a coating of graphite, and it is of the utmost importance that it should be thoroughly covered, and that the graphite should have a very high polish. The best work is done by a machine, which also obviates the great inconvenience of scattering the dust. The machine is entirely automatic. After washing the mould iron filings are sifted on, and a quantity of a weak solution of sulphate of copper is stirred in by means of a brush, a thin coating of copper being deposited upon the surface of the mould, as explained above. This operation is repeated, to make sure that every point is covered. The mould is then for one or two hours suspended as a cathode in a bath of sulphate of copper solution, and the coating is increased by the action of the electric current until it is about ·003 of an inch thick. After being detached from the mould and washed in boiling water, it is brushed on the back with a solution of chloride of zinc, and sheets of tinfoil are laid over it and melted, the face of the cast resting on a perfectly smooth surface. Molten metal is then slowly poured on, enough to give the plate the required thickness (about $\frac{1}{8}$ inch). It is cooled by an air-blast so diffused as to cause the entire plate to solidify at once, and is then subjected to pressure until quite cool and firm; if this is not done the plate is apt to become distorted, and needs to be straightened by skillful hammering. The plate is then finished to the exact size and thickness desired. Any blank spaces which are so high as to soil the paper in press are deepened, as also in stereotype plates, by a routing-machine. Plates to be used on a Hoe perfecting-press are passed through a machine which gives them the proper cylindrical curvature at one revolution. A special routing-machine is provided for such plates.

Electrotypes are sometimes faced with nickel by first placing the mould in a nickel solution and plating on a coating of the metal, and then removing to the copper solution and finishing in the regular way. Although these plates are attractive in appearance, and will not tarnish, the nickel is so liable to strip and the coating is so very thin that it is of little practical value.

Iron can be deposited by the electric current in the same manner as copper; electrotypes of iron have been made by Klein, of St. Petersburg, and the highest success is attributed to him in their application to the printing of bank-notes. The deposit is hard as steel and exceedingly durable.

*Glyphography*, another useful application of the art of electrotyping, is the invention of Palmer. A piece of ordinary copper plate is stained black on one side, and very thinly covered by a substance resembling white wax. The artist makes his sketch or drawing through this thin film, which wherever scraped away by his pencil exposes the black surface of the plate. The sketch when completed shows exactly what the print from an electrotype made from the plate will be. When the artist has finished his work the remaining wax is carefully built up in the regular way, and the plate is electrotyped in the same manner as a wax mould.

By what is known as electro-etching this process can also be reversed, and instead of making an electrotype from the prepared plate the plate can be immersed in the solution and connected with the positive pole of the dynamo, and the plate dissolved away where the lines expose it to the action of the solution. As the wax withstands the solution, the plate where covered by it will remain unchanged. When the lines are deepened by the action of the electric current and solution to the required depth, the plate is taken from the solution, and after the wax is cleaned off is mounted for printing. The drawing or sketch will appear in white lines on a black ground. O. B. BEACH.

**Sterility** [from Lat. *steri'litas*, deriv. of *ste'rilis*, barren, sterile]: an incapacity for procreation, whether in the male or female. A knowledge of the causes of sterility depends on an understanding of the laws of conception. (See EMBRYOLOGY, OVARIES, etc.) Sterility in the male is due either to impotency or to the absence of zoösperms (spermatozoa) in the semen, or to their lack of vitality when present. If by cause of old age, malformations of the genitals, or other influences, a man is incapable of performing the part allotted by the laws of nature, he is said to be impotent, and is therefore sterile. The male may be able, however, to perform the sexual act, and yet be incapable of procreation, because the semen may not possess zoösperms, without which fructification is impossible. This deficiency may be natural or acquired; it is normal only in extreme youth and in advanced old age. If a man is born with but one testis (monorchid), as a rule it does not secrete zoösperms; and if the testes are so imperfectly developed as to remain always in the cavity of the abdomen, as in the fœtus, then also the seminal fluid is deficient in the all-important property necessary for fecundation. Whatever produces an inflammation of the testes (orchitis) may bring about such a change in the secretory apparatus of these organs as to destroy the vitalizing power of the semen. A fall or a blow on these glands may do this, but the most common cause is inflammation communicated to them by continuity of surface from the urethra, neck of the bladder, and vesiculæ seminales, sequels of urethritis (gonorrhœa). Not unfrequently this happens as a consequence of parotitis (mumps), where from cold or other cause the inflammation is suddenly transferred from the parotid (salivary) gland to the testes. The seminal fluid may be emitted in a normal manner and may contain zoösperms or spermatic particles, but these may be dead or very feeble and incapable of surviving long enough to meet the ovule deep within the genital canal. This condition may be the result of some constitutional vice, drunkenness, syphilis, or excessive venery. It is estimated that 20 per cent. of sterile marriages are due to faults in the male. A man may be sterile or incapable of procreation at one time, and by appropriate treatment under favorable circumstances he may possibly regain the lost power; but the removal of incapacity in the male is not generally so successful as the removal of the obstructive causes in the female.

In the female, if competent for the married relation, and if the ovaries are functionally active, the cause of sterility is generally some obstruction to the entrance of zoösperms into the cervical canal (neck of the uterus), or a diseased condition of the mucous secretion of that canal, or some obstruction either to the exit of ovules from the ovary (periovaritis), or to the passage of zoösperms or ovules along the Fallopian tube or oviduct. If menstruation is normal, it may be taken for granted that ovulation is normal—that the ovum is at the regular time discharged from the ovary and starts on its way to the cavity of the womb; but some previous pelvic inflammation may have obstructed the Fallopian tubes or bound down their fimbriated extremities, so as to prevent them from fulfilling their functions in conducting the ovum to the cavity of the uterus. This state of things can usually be diagnosed with accuracy, but can not usually be relieved as far as sterility is concerned. Any marked and permanent deviation of the uterus from its normal position, whether anteriorly, posteriorly, laterally, or by descent, may interfere with conception. When the body of the uterus falls far forward, on the bladder, toward the pubes, it may so displace the os tincæ (outer orifice of the cervical canal) or produce such a degree of congestion in the whole organ as to prevent the zoösperm from reaching the cavity of the uterus; and if the uterus is bent on itself in this form of displacement (anteflexion), the obstruction is practically insuperable. When the body of the uterus falls far back under the hollow of the sacrum, pressing upon and obstructing the rectum, it may easily be restored to its normal position and kept there in a great majority of cases. Lateral malpositions and descent may require the same attention. A more frequent cause of the sterile condition, however, is found in the neck and cavity of the uterus. The cavity of the uterus may contain a tumor or polypus, which must be removed, or it may be in a state of inflammation (endometritis), which must be cured. Again, the mouth of the uterus (os tincæ) may be so small that the semen can not enter it; then it must be enlarged by forcible dilatation. Abnormal angulation of that portion of the womb just above the neck (lower uterine segment) is a frequent cause of sterility. It is often bent to an acute angle instead of being comparatively straight, but when this is not complicated with the presence of a fibroid tumor or other adventitious growth, it may be remedied, and is often easily and promptly cured, by surgical means. Another frequent cause of sterility is an abnormal condition of the secretions found in the utero-cervical canal. The mucus of the cervical canal from the third to the tenth day after the end of menstruation should be translucent, clear as the white of a new-laid egg, without any opaque or milky-looking spots. A drop of mucus taken from the cervical canal a few hours after sexual intercourse should be examined under the microscope. If living zoösperms are found in abundance twenty-four hours or more after coition conception is possible; but if the zoösperms are all dead or in a dying state, then there is some abnormal condition of the utero-cervical canal which gives rise to an abnormal secretion. The diseased condition of the utero-cervical canal (called endometritis) is often found in women whose general health is perfect, and is generally curable. See also the article HYBRIDISM.

Revised by B. C. HIRST.

**Sterilization**: See DISINFECTION.

**Sterlet** [= Fr. = Germ., from Russ. *sterlyadĭ*, sterlet]: the *Acipenser ruthenus*, a small species of sturgeon found in various Russian rivers and the Caspian and Black Seas, into which they empty, and esteemed for its flesh. It is characterized by a narrow, pointed snout, and the slightly fringed barbels; the dorsal shields, 11 to 17, are moderately developed, the lateral ones, 60 to 70, small, and the abdominal, 13 to 15, moderate; the skin is densely covered with minute denticulated ossifications of subequal size. It rarely or never attains a length of 3 feet, and a common size is 2 feet in length and 3 lb. in weight. It leaves the sea in May and June, and ascends the rivers, sometimes very high up, for the purpose of spawning. It has not only a superior reputation as a table-fish, but from its roes is made the best caviare, which constitutes a noteworthy article of trade in Russia. Its introduction into rivers of the U. S. has been strongly recommended, and it has been claimed that the Mississippi and Ohio rivers would be especially suitable for it. The Russian Government has introduced it into waters about St. Petersburg, and in 1870 a number of the fry were introduced into the waters of Sutherlandshire, Scotland, in apparently good condition. Their embryonic life is so short that it is difficult to transport the eggs with success. Revised by F. A. LUCAS.

**Sterling**: city; Whiteside co., Ill.; on the Rock river, and the Burlington Route and the Chi. and N. W. railways; 52 miles E. N. E. of Rock Island, 110 miles W. of Chicago (for location, see map of Illinois, ref. 2-D). It has excellent water-power; manufactures agricultural machinery, common and barbed wire, hearses, coffins, school furniture, gas-engines, and paper; and is in an agricultural region. There are 14 churches, 3 public schools, hospital, 2 national banks with combined capital of $175,000, a private bank, and a monthly, 2 daily, and 4 weekly periodicals. Pop. (1880) 5,087; (1890) 5,824; (1900) 6,309.

EDITOR OF "GAZETTE."

**Sterling**: city (founded in 1872); Rice co., Kan.; on the Atch., Top. and S. Fé and the Mo. Pac. railways; 252 miles W. of Kansas City, Mo. (for location, see map of Kansas, ref. 6-F). It is in an agricultural and stock-raising region; is principally engaged in farming, salt-mining, and milling; and contains 13 churches, 3 public-school buildings, Cooper Memorial College, a national bank (capital $50,000), a State bank (capital $50,000), a private bank, and 2 weekly papers. Pop. (1880) 1,014; (1890) 1,641; (1900) 2,002.

EDITOR OF "BULLETIN AND GAZETTE."

**Sterling, JOHN**: author; b. at Kames Castle, Isle of Bute, July 20, 1806, son of Edward Sterling, editor of the London *Times*; was educated at Glasgow and Cambridge; went to London in 1827; was a short time on the editorial staff of *The Athenæum*, and during a part of 1831-32 resided for his health in the West Indies. Returning to England, he took deacon's orders in 1834; was a curate at Hurstmonceaux, Sussex, but soon gave himself wholly to literary studies and pursuits. Among his works are *Arthur Coningsby*, a novel (1833); *Minor Poems* (1839); *The Election*, a poem (1841); and *Strafford*, a drama (1843). Two volumes of his *Essays and Tales* were edited, with a *Memoir*, by Julius C. Hare (1848), and Thomas Carlyle has written *The Life of John Sterling* (1851). D. in Ventnor, Isle of Wight, Sept. 18, 1843.

**Stern**, Daniel: See Agoult.

**Sternberg**, Constantine: See the Appendix.

**Sternberg**, George Miller: See the Appendix.

**Sterne**, Laurence: humorist; b. at Clonmel, Ireland, Nov. 24, 1713; son of a lieutenant in the British army; educated at Jesus College, Cambridge; graduated in 1740; entered into holy orders, and was presented by his uncle with the valuable benefice of Sutton, Yorkshire, to which that of Stillington, 1½ miles distant, was soon after added. Here he lived for nearly twenty years. In 1759 he published the first two volumes of *Tristram Shandy*, which became popular at once, and gained for him from Lord Falconbridge the additional curacy of Cotswold. He had been married nearly twenty years, and now, leaving his wife and daughter at York, he went to London, where or upon the Continent most of the remainder of his life was spent. He published several occasional sermons, and at intervals seven volumes entitled *The Sermons of Mr. Yorick, or Sermons by Laurence Sterne, A. M., Prebendary of York*, etc. (1760–69). His *Life and Opinions of Tristram Shandy, Gent.*, in all nine volumes, was published at intervals (1759–67). The *Sentimental Journey*, his best work, was written in France, but published in London, 1767. D. in London, Mar. 18, 1768. In 1775 appeared three volumes of his letters to his friends, edited by his daughter, and his *Letters to Eliza*. *Seven Letters by Sterne and his Friends*, edited by W. Durrant Cooper, was privately printed in 1844. Sterne was a subtle delineator of character, and a delicate artist of the pathetic and comic. His chosen province was the whimsical, and his great model in this kind was Rabelais. He was the cleverest of English sentimentalists. He was a minute philosopher, his philosophy is kindly, and he had the art of making much out of little; but his writings are morally corrupt, and his sentiment has a taint of insincerity. He was the most unclerical of clergymen, though his sermons were both witty and affecting. In character he was selfish, worldly, and vain. See the *Life of Sterne*, by Percy Fitzgerald (1864), and Thackeray's *English Humorists*.

Revised by H. A. Beers.

**Sterne**, Simon: lawyer and economic writer; b. in Philadelphia, Pa., July 23, 1839; graduated at the law school, University of Pennsylvania, 1860; removed to New York 1860; appointed in 1875 member of the commission to devise a plan for the government of cities in the State of New York, a report of which was presented to the Legislature, Feb. 24, 1887. He is the author of *Representative Government and Personal Representation* (Philadelphia, 1871); *Constitutional History and Political Development of the United States* (New York, 2d ed. 1888); and contributions to Lalor's *Cyclopædia of Political Science*. C. H. T.

**Sternhold**, Thomas: hymnologist; b. near Blakeney, Gloucestershire, England, about 1500; was educated at Oxford, but did not take a degree, and became groom of the robes to Henry VIII. and Edward VI.; with John Hopkins (d. Oct., 1570 (?); little is certainly known of him) was joint author of the first version of the Psalms into English meter. D. Aug., 1549. His first edition appeared in London in 1548, and contained nineteen Psalms; the second, *All such Psalmes of David as Thomas Sterneholde, late groome of the Kynge's Maiestie's roobes did in his lyfe tyme drawe into English metre* (1549), contained thirty-seven Psalms translated by Sternhold. A 3d ed., 1551, contains seven Psalms translated by John Hopkins. Other editions followed until 1562, when *The Whole Booke of Psalms collected into English Metre by T. Sternhold, J. Hopkins, and others, conferred with the Ebrue, with apt Notes to Sing them withal*, was annexed to the Book of Common Prayer. Of the entire number of Psalms, 40 were versified by Sternhold and 59 by Hopkins. Cf. art. *Old Version*, Julian's *Dictionary of Hymnology*. Revised by S. M. Jackson.

**Sternum**, or **Breast-bone** [*sternum* is Mod. Lat., from Gr. *στέρνον*, breast, chest]: a bony or semi-cartilaginous plate which serves as the anterior (or inferior) point of union of many of the ribs. It represents the blended hæmal spines of the dorsal vertebræ. In fishes, batrachians, and serpents it is absent. In tortoises it becomes the lower shell or plastron, and is much widened. In most birds it is strongly keeled in front, the keel serving as a point of attachment for the strong wing-muscles. In man it consists of three pieces, of which the uppermost is the *manubrium*; the next, the *gladiolus*; and the lowest, the ensiform or xiphoid cartilage. The sternum may be rendered very prominent in certain bone-diseases, as rickets, by the sinking in of the ribs, which thus push the sternum forward. The chicken-breast thorax results from such deformity. Contrariwise, the sternum is sometimes sunk below the rest of the front of the chest, especially in ill-formed phthisical persons.

**Sternutation**: See Sneezing.

**Sterrett**, John Robert Sitlington, Ph. D.: professor of Greek; b. at Rockbridge Baths, Va., Mar. 4, 1851; educated at University of Virginia, University of Leipzig, Polytechnic of Aix-la-Chapelle, and Universities of Berlin, Athens, and Munich (Ph. D.); secretary American School of Classical Studies at Athens; leader of various archæological expeditions to Asia Minor; member of the Wolfe expedition to Assyria and Babylonia; Professor of Greek in Miami University, Oxford, O., 1886–88, in the University of Texas, Austin, Tex., 1888–92, and at Amherst College, Amherst, Mass., since 1892; author of *Qua in re Hymni Homerici quinque majores inter se differunt* (Boston, 1881); *Inscriptions of Sebaste* (*Amer. Jour. Philol.*, 1883); *Inscriptions of Assos*, *Inscriptions of Tralleis*, *Preliminary Report of a Journey in Asia Minor* (all three Boston, 1885); *An Epigraphical Journey in Asia Minor*, *The Wolfe Expedition to Asia Minor* (both Boston, 1888); and numerous articles in *The Nation*, *The Independent*, *Classical Review*, etc. C. H. Thurber.

**Stesich'orus** [= Lat. = Gr. Στησίχορος; ἱστάναι (aorist, ἔστησα), station, establish + χορός, chorus]: Greek lyric poet of Himera, in Sicily; b. about 640; d. about 555 B. C.; of great reputation in antiquity, especially as an inventor of poetical forms. His true name was Teisias, but he was called Stesichorus, "arranger of choruses," from his choral odes, consisting of strophe, antistrophe, and epode, though this triple form is doubtless older. His themes were epic, and the Fourth Pythian of Pindar is supposed to give some notion of the way in which, according to Quintilian, "he sustained the weight of the epos with the lyre." On account of the poem in which he charged Helen with the woes of Troy he was fabled to have been smitten with blindness, which was removed when he withdrew his slanders in a *palinodia* or recantation. Stesichorus was also a fabulist, and to him is attributed the famous fable of the horse, the stag, and the man (Arist., *Rhet.*, ii., c. 20). Of this Homer of the lyric poets we have only scant fragments, to be found in Bergk's *Poetæ Lyrici Græci* (vol. iii., 4th ed., pp. 205–234).

B. L. Gildersleeve.

**Steth'oscope** [from Gr. *στῆθος*, chest + *σκοπεῖν*, view, examine]: an instrument employed by physicians for the physical exploration of the chest. (See Auscultation.) Laennec, the founder of methodical auscultation, introduced the solid stethoscope, a tube made from a single piece of wood (Fig. 1). It is from 10 to 12 inches long, has a flanging chest-piece to receive sound, an open canal to convey sound, the solid structure also serving to conduct it, and a broad flat ear-piece for apposition to the ear and the exclusion of extraneous sounds. The medical profession is indebted to Dr. Camman, of New York, for originating the "binaural" or "double stethoscope" (Fig. 2). For purposes of careful diagnosis, by concentrating local sound, conducting it to the exclusion of surrounding noise, and conveying a separate but similar and simultaneous impression to each ear, the stethoscope is invaluable. It is further valuable in hospital and other public service, preventing contact of the listener's head with unhealthy and uncleanly patients. It is particularly serviceable in

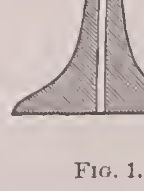

Fig. 1.

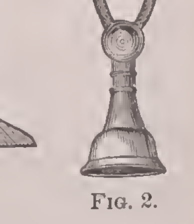

Fig. 2.

localizing the origin of sounds, as of small cavities in the lungs, valvular diseases of the heart, and in aneurism. The best auscultators prefer the unaided ear for habitual chest examination, reserving the stethoscope to aid in special and obscure cases. Revised by W. PEPPER.

**Stetson University**: See the Appendix.

**Stettin**, stet-teen′: town and railway center of Pomerania, Prussia; on the left bank of the Oder, at its entrance into the Stettiner-Haff, 83 miles N. E. of Berlin (see map of German Empire, ref. 2–G). Across the river, which is here from 12 to 16 feet deep, lies the suburb of Lastadie, connected with Stettin proper by three bridges. Outside and on the line of the old fortifications, removed in 1874, are the suburbs of Bredow, Grabow, and Züllchow. The site it occupies is hilly, and its streets are consequently uneven, but the houses are neat and substantial, and many buildings, such as the royal palace, the citadel and barracks, and the town-hall, are very handsome. Its sugar-refineries, oil-mills, glass-works, breweries, distilleries, and manufactures of anchors, sailcloth, rope, tobacco, soap, candles, hats, etc., are very important, and as a place of commerce Stettin is one of the leading ports of Germany. Only small vessels can reach it, however; its port on the Baltic is Swinemünde. It is the ancient *Sedinum*, afterward *Stettinum*, and is of Slavic origin. In the Middle Ages it was the residence of the Duke of Pomerania, and, having joined the Hansa, it soon became a flourishing commercial town. It forms the outlet for the rich products of Silesian industry. Pop. (1900) 210,-680. Revised by M. W. HARRINGTON.

**Steuart**, Sir JAMES DENHAM: political economist; b. in Edinburgh in 1712; was educated at the University of Edinburgh, and became an advocate. While traveling on the Continent he entered into relations with the Pretender, and when the rebellion of 1745 broke out he was forced to go into exile. He returned to Scotland in 1763, and was subsequently pardoned for any share he might have had in the rebellion. He published, among other works, *Apologie du Sentiment de Monsieur le Chevalier Newton sur l'ancienne Chronologie des Grecs* (1757) and *An Inquiry into the Principles of Political Economy* (1770), which preceded by several years Adam Smith's *Inquiry into the Nature and Causes of the Wealth of Nations*. Smith's work completely superseded Steuart's *Inquiry*, but the latter contains many valuable suggestions, and in some respects anticipates the ideas of later economists. Though he must be classed with the mercantilists, Steuart was free from many of the errors of that school of economists. D. in 1780.

**Steuben**, Germ. pron. stoi′ben, FRIEDRICH WILHELM AUGUST HEINRICH FERDINAND, Baron von: soldier; b. Nov. 15, 1730, in the fortress of Magdeburg, Prussia, where his father was an officer; entered the Prussian army as a cadet 1747; distinguished himself at the battle of Rossbach 1757; became adjutant-general 1758; was aide to Gen. Knoblauch in his brilliant march into Poland 1761; was taken prisoner and carried to St. Petersburg; won the favor of the Grand Duke Peter; was soon exchanged; was made captain (1762), and placed on the staff of Frederick the Great, from whom he received, with a few other selected officers, special instruction in tactics; was appointed in 1764 grand marshal to the court of the Prince of Hohenzollern-Hechingen, but resigned that post about 1775. In 1777 he was induced by Saint-Germain to offer his services to the American insurgents through the agency of Silas Deane, and was appointed inspector-general, with the rank of major-general, in the spring of 1778; took part as a volunteer in the battle of Monmouth in the following June; rendered memorable services in drilling the officers and men of the Continental army into efficiency; prepared a manual of instruction for the army, adopted by Congress and printed 1779; was a member of the court martial on Maj. André; took command of the forces in Virginia 1780, and rendered good services at the siege of Yorktown 1781. His greatest exploit, however, was his Virginian campaign. He had been left in Virginia by Gen. Greene to gather up and discipline the levies voted for the Southern army by that State when it was invaded by Arnold. On the appearance of this new danger the militia flocked to Steuben's standard. Arnold succeeded in burning Richmond, and then went down the James river on a marauding expedition; but when pursued and overtaken by Steuben with the militia, he fled up the Elizabeth river. Remaining as a citizen of the U. S. after the war, Steuben procured with difficulty an adjustment of his claims upon Congress. He was ultimately assigned a pension of $2,500 and received grants of land from several States. On the tract given him by New York, in Oneida County (the township of Steuben), he settled, accompanied by North, Popham, Walker, and others of his former aides, to whom he gave a large portion of his lands. D. at Steuben, Nov. 28, 1794. He was a man of great kindness and generosity, of ready wit and highly polished manners. A *Life* by Francis Bowen appeared in Sparks's series; another, containing much new material, was published by Friedrich Kapp (1860), and an epitome of the latter may be found in Greene's *German Element in the War of Independence* (1876).

**Steubenville**: city (site of a fort built in 1786, laid out as a town in 1798, incorporated as a city in 1851); capital of Jefferson co., O.; on the Ohio river, and the Cleveland and Pittsburg Div. of the Penn., the Pitts., Cin., Chi. and St. L., and the Wheeling and Lake Erie (Wabash) railways; 22 miles N. of Wheeling, and 43 miles W. of Pittsburg (for location, see map of Ohio, ref. 4–J). It is in a rich agricultural and mining region; is laid out on the second terrace of the Ohio, above danger from the floods for which the river is noted, and is nearly surrounded by hills from 300 to 500 feet high, which protect it from destructive winds. The city has excellent surface drainage, good sewerage, and a water-supply obtained from the river 2 miles above the city, with a system of high-pressure mains for fire and manufacturing purposes and one of low-pressure for domestic uses. The principal streets are paved with vitrified brick, and in the residence portions shaded by fine trees.

*Churches and Schools.*—Steubenville has 5 Methodist Episcopal churches, 3 Presbyterian, 2 Roman Catholic, 2 Lutheran, 2 Protestant Episcopal, and 1 each African Methodist Episcopal, Baptist, Congregational, Christian, Methodist Protestant, and United Presbyterian. The public-school system comprises 6 school buildings, 54 teachers, and over 2,200 pupils, and cost for maintenance $40,000 per annum. There are 2 Roman Catholic parochial schools, with over 500 pupils. There are several libraries and 3 daily and 4 weekly newspapers.

*Finances and Banking.*—In 1900 the receipts for municipal purposes were $167,216.95; expenditures, $95,185.13; the net debt was $34,875; assessed property valuation, $5,000,000. In 1900 there were 3 national banks with combined capital of $325,000, 2 private banks, and 2 building and loan associations.

*Business Interests.*—In the surrounding hills and underlying the city are extensive supplies of excellent coal. The seam beneath the city limits is worked by means of several shafts. Natural gas is abundant at distances of from 5 to 50 miles, and is piped into the city; petroleum-wells have been opened within 5 miles; and economic clays are easily mined in the hills. The principal manufactories are 3 blast furnaces, 2 rolling-mills, nail-factories, and tube-works, 2 foundries, 2 machine-shops, steel plant, boiler-works, 3 glass-factories, 2 flour-mills, glass-melting pot-works, paper-mill, white-ware pottery, and ice plant. Extensive fire-brick, paving-brick, and sewer-pipe works, N. of the city, form a part of the local industries, as do also numerous coal mines and quarries of building-stone in the vicinity, operated by local capital. The greater part of the coal product is shipped to the lakes. The city is the distributing point for a large area of country. Pop. (1880) 12,093; (1890) 13,394; (1900) 14,349.

JOSEPH B. DOYLE, EDITOR "HERALD-STAR."

**Stevens**, ABEL, LL. D.: minister and author; b. in Philadelphia, Pa., Jan. 19, 1815; studied at the Wesleyan University, Middletown, Conn.; joined the New England Conference of the Methodist Episcopal Church in 1834, was agent for the Wesleyan University one year, and in 1835 was stationed at Boston; in 1837 made a European tour, and after his return was stationed at Providence, R. I.; in 1840 became editor of *Zion's Herald* at Boston, and in 1852 of *The National Magazine*, an illustrated monthly, at New York, which was discontinued after two or three years. In 1856 he was elected by the general conference as editor of the New York *Christian Advocate and Journal*. From 1860 to 1874 he was joint editor of *The Methodist*, an independent journal published in New York. He published numerous books, including *Memorials of the Introduction of Methodism into New England* (1848); *Memorials of the Progress of Methodism in the Eastern States* (1852); *Church Polity*; *History of the Religious Movement called Methodism* (3 vols., 1858–61); *Life and Times of Nathan Bangs, D. D.* (1863); *History of the Methodist Episcopal Church*

*in the United States of America* (4 vols., 1864–67); *The Centenary of American Methodism* (1866); *The Women of Methodism* (1866); *Life and Times of Madame de Staël* (2 vols., 1882); *Character Sketches* (1882); and *Christian Work and Consolation* (1885). D. at San José, Cal., Sept. 11, 1897.
Revised by A. OSBORN.

**Stevens**, ALFRED: genre-painter; b. in Brussels, May 11, 1828; studied at the École des Beaux-Arts and under Roqueplan, Paris; third-class medal, Salon, 1853; second-class, Paris Exposition, 1855; first-class, Paris Exposition, 1867 and 1878; medal of honor, Paris Exposition, 1889; commander Legion of Honor 1878; commander in the Orders of Leopold of Belgium, Francis Joseph of Austria, and St. Michael of Bavaria. He is one of the ablest and most charming painters of modern life in the French school, to which, by residence and affinities, he belongs, and his works are especially fine in color quality. An excellent example of his style is *Five o'clock Tea*, in the collection of Mrs. W. H. Vanderbilt, New York. Studio in Paris.—His brother JOSEPH, born in Brussels, 1822, is distinguished as a painter of dogs and other animals. Among his works are *Taureau flamand poursuivi par un Chien* (1853) and *Chien regardant une Mouche* (1878). WILLIAM A. COFFIN.

**Stevens**, ALFRED GEORGE: sculptor; b. at Blandford, Dorsetshire, England, in 1817. He was the son of a house-painter and decorator, and was sent to Italy at the expense of a wealthy gentleman to study painting. He returned to England about 1842, and was made a teacher in the Government School of Design, then established at Somerset House, London, in which he remained about four years. During this time he made many designs for ornamental work of various kinds, such as the doorway of the Jermyn Street School of Mines, the doors themselves having been designed also by him but never carried further than the fine drawing in South Kensington Museum. As designer for the Green Lane works at Sheffield he made, about 1851, some remarkable fire-places and stoves, anticipating by many years the work of 1885–95 in modern adaptation of classical ornament. Of the years from 1850 to 1860 are some remarkable designs for pottery, daggers, and other small objects, and then, or at a later time, he designed the decorations of many very costly houses. He made designs, in competition, for the painted decorations of some of the halls of the new Houses of Parliament, for the decorations of the new Foreign Office, and for a memorial of the Exhibition of 1851. In 1857 he competed for a monument to the Duke of Wellington, and, among eighty-two competitors, was so far successful as to receive one of the minor prizes, and at a later time to be employed as designer of the work. His design was partly carried out, and the monument in a small chapel of St. Paul's Cathedral is what exists of it. The architectural design of the monument is fine and worthy of the occasion, but not very original. The sculpture is of very great merit. This was to consist of the equestrian statue on the summit, which, however, was never finished, and the following, which is all in place: A recumbent figure on a sarcophagus, a group of *Valor and Cowardice*, and one of *Truth and Falsehood*, besides decorative panels. D. in London, Apr. 30, 1875. RUSSELL STURGIS.

**Stevens**, CHARLES ELLIS, Ph. D., LL. D., D. C. L.: clergyman; b. in Boston, Mass., July 5, 1853; studied at Wooster University, Ohio, University of Pennsylvania, Yale College, Berkeley Divinity School, Middletown, Conn., Nashotah, Wis., and in Europe; ordained priest in the Protestant Episcopal Church 1875; assistant minister of Grace church, Brooklyn, N. Y., 1876; rector Church of the Ascension, Brooklyn, 1877; for many years from 1878 secretary of an auxiliary of the board of missions of the Protestant Episcopal Church and chairman of numerous committees of the diocese of Long Island; examining chaplain diocese of Long Island; archdeacon of Brooklyn 1888–91; president of League for Moral Instruction in Public Schools of New York 1890; rector Christ church, Philadelphia, 1891; lecturer on English and American constitutional law, Wooster University, 1888, at the University of the City of New York 1891, and at the University of Pennsylvania 1892; lecturer on constitutional law and English literature at St. Stephen's College, Annandale, N. Y., since 1890; received honorary degrees from Wooster University and King's College, Nova Scotia; fellow of Society of Antiquaries, Edinburgh, the Royal Geographical Society, and other learned societies; has in preparation a work entitled *Sources of the Constitution of the United States.*

**Stevens**, EBENEZER: soldier; b. in Boston, Mass., Aug. 22, 1751; was a member of Paddock's Company of Boston Artillery, and one of the famous "Boston tea-party" Dec., 1773; removed soon afterward to Rhode Island; raised two companies of artillery and one of artificers for the expedition against Quebec, in which he served as lieutenant, having been commissioned May 8, 1775; became captain of Knox's regiment Jan. 11, and brevet-major Nov. 9, 1776; commanded the artillery at Ticonderoga and at Stillwater; was appointed lieutenant-colonel Apr. 30, 1778; was assigned to Lamb's regiment; served under Lafayette in Virginia; was, alternately with Lamb and Carrington, in command of the artillery during the siege of Yorktown; was one of the founders of the Society of the Cincinnati, and became after the war a leading merchant of New York in the West India and Mediterranean trade; agent of the War Department, and a major-general of militia. D. at Rockaway, L. I., Sept. 2, 1823.

**Stevens**, EDWIN AUGUSTUS: inventor; b. at Hoboken, N. J., in 1795; son of John and brother of Robert L. Stevens; took part in their steamboat experiments and enterprises, and in conjunction with his brothers established passenger and tow boats on the Hudson and other rivers; also aided in the introduction of railways, and invented many appliances for use thereon. At the breaking out of the civil war he urged the Government to put in service the ironclad floating battery of which his brother had long before undertaken the construction, offering to complete it at his own risk, and to receive payment only in case it should prove successful; this offer being declined, he expended considerable sums on the vessel, and upon his death bequeathed it to the State of New Jersey, together with $1,000,000 for its completion; this, however, proved insufficient, and the battery was never finished, and was finally sold to dealers in old iron. He inherited a large fortune from his father and brothers, endowed the Hoboken High School, and bequeathed nearly $1,000,000 to establish at Hoboken the Stevens Institute of Technology. D. in Paris, Aug. 7, 1868. Revised by R. H. THURSTON.

**Stevens**, GEORGE BARKER, D. D.: clergyman and educator; b. at Spencer, N. Y., July 13, 1854; graduated at the University of Rochester, New York, 1877, and at the Yale Divinity School 1880; pastor of the First Congregational church, Buffalo, N. Y., 1880–83, of the First Presbyterian church, Watertown, N. Y., from 1883 to 1886, when he was appointed Professor of Criticism and Interpretation in Yale Divinity School. Besides reviews, essays, etc., he has edited Chrysostom's *Homilies on the Acts and the Romans* (1889), and published a *Commentary on the Epistle to the Galatians* (1890), *The Pauline Theology* (1892), and *The Johannine Theology* (1894). GEORGE P. FISHER.

**Stevens**, HENRY: bibliographer: son of Henry Stevens, antiquary; b. at Barnet, Vt., Aug. 24, 1819; studied at Middlebury College 1838–39; graduated at Yale College 1843, and at Cambridge Law School 1844; established himself in London 1845 (where he resided till his death) as agent for the British Museum in the purchase of North and South American books of all kinds, and was thus instrumental in placing in the British Museum a very complete collection of Americana. He also purchased for the Smithsonian Institution, the Library of Congress, and the chief libraries of the U. S., and for many private individuals. He published several valuable bibliographical treatises and catalogues, among which are *A Catalogue Raisonné of English Bibles* (1854); *A Catalogue of the American Books in the Library of the British Museum* (1856); a *Catalogue of the Crowninshield Library* (1860), and of the library of Baron Humboldt (1861), which latter collection he had purchased; *Bibliotheca Americana* (1861); *Historical Nuggets* (1862); *Bibliotheca geographica et historica* (1870), the latter book being the catalogue of the library of his father, of whom it contains a biographical sketch; *The Bibles in the Caxton Exhibition* (1878); *Historical Collections* (2 vols., 1881–86); and *Recollections of James Lenox* (1886). He also prepared indexes to the State papers in London relating to New Jersey (1858), Maryland (10 vols.), Rhode Island (6 vols.), and Virginia (1858), the three latter being in MS.; published a work on *The Tehuantepec Railway* (1869), and two small volumes of *Historical and Geographical Notes* (1869), relating to early explorations in America. He frequently wrote after his name the initials G. M. B. (= Green Mountain Boy). D. in London, Feb. 28, 1886.
Revised by S. M. JACKSON.

**Stevens,** Isaac Ingalls: soldier; b. at Andover, Mass., Mar. 28, 1818; graduated at the U. S. Military Academy July 1, 1839; promoted second lieutenant of engineers; was engaged upon construction and repairs of fortifications 1839–46; served in the war with Mexico as adjutant of engineers, participating in all the battles from Vera Cruz to the city of Mexico, and for gallantry at Contreras and Churubusco and at Chapultepec was breveted captain and major, and was severely wounded in the San Cosme suburb. From 1849 to 1853 he was principal assistant and in charge of the office of the U. S. Coast Survey at Washington; in Mar., 1853, resigned from the army to accept the governorship of Washington Territory; conducted the pioneer survey of the route for the Northern Pacific Railroad, an account of which he published; delegate to Congress from Washington Territory 1857–61; on the outbreak of the civil war was made colonel of the Seventy-ninth (Highlanders) New York Volunteers. Moving his command to Washington, he was made a brigadier-general of volunteers Sept. 28, and attached to the Port Royal expedition, which left Hampton roads a month later. He commanded the land forces in the actions at Port Royal Ferry, Coosaw river, and a division in the actions on Stono river and the assault on Secessionville. On July 4, 1862, he was made a major-general of volunteers, and a week later transferred to Newport News in command of a division; at the second battle of Bull Run his division (Ninth Corps) was hotly engaged. Near Chantilly, on the morning of Sept. 1, 1862, his division encountered the enemy, when Stevens, ordering a charge, placed himself at the head of his command, where he was shot through the head and instantly killed.

**Stevens,** James Gray: See the Appendix.

**Stevens,** John: inventor; b. in New York in 1749; graduated at King's (Columbia) College in 1768, and was admitted to the bar, but did not practice; became interested in the question of navigation by means of steam, and as early as 1789 presented a memorial to the New York Legislature stating that he had perfected his plans, and in 1804 launched a small vessel worked by steam with screws, and in 1807 built a steamboat which he called the Phœnix. Fulton had in the meantime built his steamboat, the Clermont, and obtained the exclusive right of navigating the Hudson by steam, and Stevens sent his vessel to the Delaware river. In 1812 he planned a revolving steam-battery, to be plated with iron, and involving essentially the principles afterward embodied in the monitors, and in the same year put forth an essay on railways, indicating the methods of operating them by steam, and suggested the construction of a railway from Albany to Lake Erie. The Camden and Amboy Railroad was planned by him. He once owned the entire site of Hoboken, N. J., and through profits in real estate and other enterprises amassed an immense fortune. D. at Hoboken, Mar. 6, 1838. Revised by R. H. Thurston.

**Stevens,** John Leavitt, LL. D.: writer and diplomat; b. at Mt. Vernon, Me., in 1820. He was educated in the schools and seminaries of his native State. In 1855 he became partner and coeditor with James G. Blaine of *The Kennebec Journal*, of which he subsequently was chief editor for many years; member of the Legislature 1865–70; U. S. minister to Uruguay and Paraguay 1870–73. In 1877 he was appointed minister to Sweden and Norway. During his official residence of six years in Stockholm he wrote the *History of Gustavus Adolphus*. In 1883 Tufts College conferred on him the degree of LL. D. In 1889 he was appointed minister resident to the Hawaiian islands, a title soon after changed, by act of Congress, to that of minister plenipotentiary and envoy extraordinary. He was recalled in 1893, his attitude during the revolution in the islands being condemned by President Cleveland as compromising the neutrality of the U. S. D. at Augusta, Me., Feb. 8, 1895.

**Stevens,** Robert Livingston: inventor; b. at Hoboken, N. J., Oct. 18, 1787; son of John Stevens, inventor; became early interested in the ideas of his father regarding steam navigation, and made many improvements in the construction of vessels, among which was that of giving concave water-lines to the hull. He subsequently engaged largely in the building of steamboats, improving the marine engine, and introducing the beam engine. In 1813 he invented and made for the Government elongated percussion shells for smooth-bore guns, and in 1822 used anthracite coal in a furnace, and soon after in his steamers; in 1836 introduced the T-rail on the Camden and Amboy Railroad, of which he was president, and in 1842 was commissioned to build for the U. S. Government an iron-plated floating battery, which remained uncompleted at his death. D. at Hoboken, Apr. 20, 1856. Revised by R. H. Thurston.

**Stevens,** Thaddeus: statesman; b. at Peacham, Vt., Apr. 4, 1792; graduated at Dartmouth College in 1814; went to Gettysburg, Pa., where he taught in an academy, at the same time studying law; was admitted to the bar in 1816, and soon acquired an extensive practice. In the presidential canvass of 1828 he was a strong opponent of the election of Gen. Jackson; in 1833 and several times subsequently he was a member of the State Legislature, in 1836 a member of the convention to revise the State constitution, and in 1838 canal commissioner. He was active in introducing the public-school system in Pennsylvania. In 1842 he removed to Lancaster; in 1848 was elected Representative in Congress; was re-elected in 1850, 1858, 1862, and thereafter to each Congress until his death, serving at various times as chairman of important committees, being one of the acknowledged leaders of the Republican party, and distinguishing himself for his earnest advocacy of measures in opposition to slavery, for the emancipation and enfranchisement of the colored race, and after the war for stringent proceedings against the seceding States. He was one of the most active managers in the impeachment trial of President Johnson. The degree of LL. D. was conferred upon him by Middlebury College in 1867. D. at Washington, Aug. 11, 1868.

**Stevens,** Walter Le Conte, Ph. D.: physicist; b. in Gordon co., Ga., June 17, 1847; graduated at the University of South Carolina 1868; instructor in chemistry, Oglethorpe College, Atlanta, Ga., 1870–72; teacher of physical science, Chatham Academy, Savannah, Ga., 1873–76. After a year at the University of Virginia he taught in New York until 1882, at the same time writing on physiological optics and acoustics in *The American Journal of Science*, *London Philosophical Magazine*, and other journals. He was Professor of Mathematics and Physics in the Packer Collegiate Institute, Brooklyn, N. Y., 1882–90; studied physics at Strassburg, Berlin, and Zurich from 1890 to 1892, when he became Professor of Physics in the Rensselaer Polytechnic Institute, Troy, N. Y. Besides contributions to various periodicals he wrote a large part of *Appletons' Physical Geography* (New York, 1887) and revised Steele's *Physics* (1888).

**Stevens Institute of Technology**: a school of mechanical engineering at Hoboken, N. J., founded in 1870 by a bequest from Edwin A. Stevens, and further assisted by donations by its president, Henry Morton. It prepares young men for employment in manufacturing establishments, on railways, and the like, where machinery is designed, constructed, and operated. Its course of studies comprises departments of mathematics, mechanical drawing, physics, general chemistry, analytical chemistry, mechanical engineering, experimental mechanics and shop-work, applied electricity, languages, belles-lettres, and engineering practice. Its course has been especially characterized by its large admixture of practical work in the line of workshop practice, in the handling of machine tools, and particularly in dealing with experimental problems, such as the operation of steam, gas, and hot-air engines, pumps, injectors, etc., with accompanying measurements of their efficiency by the use of indicators, dynamometers, calorimeters, etc. A department of applied electricity was established in 1883 and a chair of engineering practice was founded in 1888. The buildings include, besides lecture-rooms and drafting-rooms, chemical and physical laboratories, machine-shops, foundries, and other provisions for practical mechanical and electrical work. The faculty numbers thirty, many of whom are leaders in their departments as original investigators and authors. The students number upward of 250, and on graduation receive the degree of mechanical engineer.

Henry Morton.

**Stevenson,** Alan: engineer; son of Robert Stevenson (1772–1850); b. in Edinburgh, Scotland, 1807; educated at the University of Edinburgh; subsequently studied natural philosophy under Sir John Leslie, and for the profession of a civil engineer in the office of his father, with whom he entered into partnership. In 1843 he succeeded his father as engineer to the commissioners of northern lighthouses, to which his subsequent practice was confined. Among many other important improvements in lighthouse apparatus, he introduced the dioptric system in 1836. Of the many lighthouses designed and constructed by him, the Skerryvore was his chief work, an *Account* of which he published; also a *Treatise on Lighthouse Illumination*; contributed articles *Harbors, Lighthouses*, etc., to the *Encyclopædia Britannica*, and various scientific articles to the Edinburgh *Philosophical Journal*, etc. The Emperor of Russia and the Kings of Prussia and Holland bestowed medals upon him in recognition of his services as a lighthouse engineer. He was a fellow of the Royal Society of Edinburgh, member of the British Institution of Civil Engineers, etc. D. at Portobello, near Edinburgh, Dec. 23, 1865.

**Stevenson**, ROBERT LOUIS BALFOUR: author; b. in Edinburgh, Scotland, Nov. 13, 1850. He was grandson of Robert Stevenson, a distinguished engineer, and son of Thomas Stevenson, author of *Lighthouse Optics*. (See *Thomas Stevenson* in *Memories and Portraits*.) His ancestors for three generations had been civil engineers in the service of the board of northern lighthouses, and Robert, who was educated at the University of Edinburgh, was at first intended for the same profession. He was also admitted to the Scottish bar, but did not engage in practice. He first attracted attention as an author by two charmingly sketchy and vagabondish little volumes, *An Inland Voyage* (1878) and *Travels with a Donkey* (1879). These were followed by a series of romances, *New Arabian Nights* (1882); *Treasure Island* (1883), a tale of buccaneers and buried treasure and one of the best boys' books; *Prince Otto* (1885), a love story; *The Strange Case of Dr. Jekyll and Mr. Hyde* (1885), a psychological romance, and the most popular of Stevenson's fictions; *Kidnapped* (1886), a novel with historical elements and studies of Scottish character-types quite equal to Sir Walter Scott's; *The Merry Men and other Tales* (1887), a volume of short stories in a variety of keys; *The Master of Ballantrae* (1888); *The Wrecker* (1892, with Lloyd Osbourne); *David Balfour* (1893), a sequel to *Kidnapped*, etc. Stevenson's versatility is shown in his *A Child's Garden of Verses* (1885), a very imaginative, poetic representation of the world from the childish point of view, and in various volumes of travel, criticism, miscellaneous essays, and sketches, such as *Virginibus Puerisque* (1881); *Across the Plains* (1892); *The Silverado Squatters* (1883); and *Memories and Portraits*. He traveled much in search of health, and many of his books were written in a sick-bed, on railway journeys, or at sea. For a number of years he resided at Samoa and elsewhere in the South Sea islands, reporting his observations in *A Footnote of History* (1892), *Island Nights Entertainments* (1893), and other volumes. In an age of realism Stevenson brilliantly advocated the claims of romance both by practice and by theory. D. at Vailima, Samoa islands, Dec. 3, 1894. H. A. BEERS.

**Stevens Point**: city; capital of Portage co., Wis.; on the Wisconsin river, and the Gr. Bay, Winona and St. P. and the Wis. Cent. railways; 21 miles N. E. of Grand Rapids, 71 miles N. of Portage (for location, see map of Wisconsin, ref. 5–D). It is at the base of one of the most valuable pine districts of the West; has large lumbering interests and abundant water-power; and contains water, gas, and electric-light plants, numerous saw, shingle, and planing mills, foundries, railway machine and repair shops, flour-mills, 2 national banks with combined capital of $150,000, a State bank with capital of $60,000, and 4 weekly newspapers. Pop. (1880) 4,449; (1890) 7,896; (1900) 9,524.

**Stewardship of the Chiltern Hundreds**: See CHILTERN HUNDREDS.

**Stewart**, ALEXANDER TURNEY: merchant; b. near Belfast, Ireland, Oct. 27, 1802; distinguished himself at school, and was entered at Trinity College, Dublin, where he did not graduate. He emigrated to New York in 1823, bringing with him a few hundred pounds, a part of a small estate which he inherited, and for a time taught mathematics and the classics in a private school. Having invested his ready money in a small mercantile venture, he found himself unexpectedly left alone in the business with the rent of the shop on his hands and was forced to become a trader. Returning to Ireland, he sold his other property, invested the proceeds in Irish laces and similar goods, and in 1825 opened a small store in Broadway, and began the business which afterward grew to be the most extensive dry-goods establishment in the world, with branches in England, Scotland, Ireland, France, and Germany, besides large manufactories of woolens, carpets, and hosiery in the U. S. and Great Britain, the whole employing about 8,000 persons. At the time of his death it was said that only two men in the U. S. were more wealthy than he. Among his enterprises was the establishment of a town called Garden City, on Long Island, a few miles from Brooklyn. During the civil war he was an earnest upholder of the national Government, and in 1869 accepted from President Grant the nomination as Secretary of the Treasury. The nomination was withdrawn, it being found that he was rendered legally ineligible for that position on account of his being engaged in the importation of foreign merchandise. He was president of the honorary commission sent by the U. S. Government to the Paris Exposition of 1867. D. in New York Apr. 10, 1876, leaving no children. By his will his entire estate, with the exception of certain legacies, was devised to his wife. To Mr. Hilton, his legal adviser, was left a legacy of $1,000,000.

**Stewart**, BALFOUR, F. R. S.: physicist; b. in Edinburgh, Scotland, Nov. 1, 1828; educated at the Universities of St. Andrews and Edinburgh; settled in Australia, where he was engaged in business in Melbourne 1852–54; returned to Great Britain 1855; was for three years assistant to Prof. Forbes in Edinburgh in his lectures and experiments upon mechanics; was appointed director at Kew, July 1, 1859, and Professor of Natural Philosophy at Owens College, Manchester, 1870. He was the discoverer of the law of equality between the absorptive and radiative powers of bodies, for which he received the Rumford medal of the Royal Society, 1868; was author, jointly with Messrs. De la Rue and Loewy, of *Researches in Solar Physics*, and, with Prof. P. G. Tait, of papers giving the results of experiments on *Heating produced by Rotation in Vacuo*, and of a religio-scientific treatise, *The Unseen Universe* (1875); contributed numerous papers, chiefly on meteorology and terrestrial magnetism, to the *Transactions* of the Royal Society, and published *Elementary Lessons in Physics* (1870); *Elementary Treatise on Heat* (1871); the *Physics Primer* (1872); and the *Conservation of Energy* (1873) in the International Scientific Series. D. at Drogheda, Ireland, Dec. 19, 1887.

**Stewart**, CHARLES: rear-admiral U. S. navy; b. in Philadelphia, Pa., July 28, 1778; went to sea at the age of thirteen as cabin-boy in a merchant vessel, and before he was twenty had become captain of an Indiaman. In 1798 he entered the U. S. navy as lieutenant, and in July, 1800, was appointed to the command of the Experiment, a schooner of 12 guns, with which, Sept. 1, he captured the French privateer Deux Amis, 8 guns, and soon after the Diana, 14 guns, also recapturing several U. S. vessels which had been taken by the French. In 1804, in command of the brig Siren, he took part in the naval operations against Tripoli, aiding Decatur in the destruction of the U. S. frigate Philadelphia, which had fallen into the hands of the Dey of Tripoli. He was made captain in 1806; in the summer of 1813 took command of the frigate Constitution, 52 guns, and in December sailed from Boston for the West Indies, making several captures of British vessels. In Dec., 1814, he sailed on a second cruise, and on Feb. 20, 1815, captured the British ship Cyane, 34 guns, and the Levant, 21 guns. The action was fought at night, and lasted forty minutes; the Levant was, however, recaptured by a British squadron. In 1816–20 Stewart commanded the Mediterranean squadron, in 1821–23 that of the Pacific, subsequently serving on the board of navy commissioners, as commander of the home squadron, and of the naval station at Philadelphia. He was placed on the retired list in 1857, but resumed service in 1859, and was placed in command of the Philadelphia navy-yard with the rank of senior flag officer, and in 1862 was made rear-admiral on the retired list. D. at Bordentown, N. J., Nov. 7, 1869. Revised by C. BELKNAP.

**Stewart**, DAVID, Duke of Rothesay and Earl of Carrick: son of Robert III., King of Scotland; b. about 1377; became lieutenant of Scotland, subject, however, to the advice of his council, of which his uncle, the Duke of Albany, was a member. He defended Edinburgh against Henry IV. of England 1400, but was soon after seized by the opposite party and imprisoned in Falkland Castle, where he died by starvation 1401.

**Stewart**, DUGALD: philosopher; b. in Edinburgh, Nov. 22, 1753; son of Matthew Stewart, Professor of Mathematics in the University of Edinburgh; studied there and at Glasgow; was in 1774 appointed assistant professor to his father, whom he succeeded in 1785, in the same year receiving the chair of Moral Philosophy. In 1810 he resigned his chair on account of failing health, and passed the remainder of his life in literary labor at his seat on the Firth of Forth, the sinecure office of gazette-writer for Scotland having been created for him. The following are his principal works: *Elements of the Philosophy of the Human Mind* (1792); *Outlines of Moral Philosophy* (1793); *General View of the*

*Progress of Metaphysical, Ethical, and Political Philosophy*, prefixed to the supplement to the *Encyclopædia Britannica* (1816); *The Philosophy of the Active and Moral Powers of Man* (1828). He also wrote biographies of Adam Smith, Thomas Reid, and Dr. Robertson. The best edition of his collected works is that prepared by Sir William Hamilton (1856). D. in Edinburgh, June 11, 1828.

Revised by J. MARK BALDWIN.

**Stewart**, ESME: Lord of Aubigny, Earl and Duke of Lennox; b. in France about 1555; grandson of John, third Earl of Lennox; derived his French title from Sir John Stewart of Darnley, constable to the Scots army in France in the wars of Charles VII.; arrived in Scotland in Sept., 1579, and immediately became a favorite of his cousin, King James VI., who created him Earl of Lennox Mar. 5, 1580, Duke of Lennox and Earl of Darnley Aug. 5, 1581; took an active part in the political intrigues of the time, instituting legal proceedings against the ex-regent Morton, and secured his condemnation and execution for the murder of Darnley; quarreled with the Church, and was accused of treason, and expelled from Scotland Dec., 1582. D. in Paris, May 26, 1583.

**Stewart**, MATTHEW: Earl of Lennox, regent of Scotland; b. in Scotland about 1510; married Lady Margaret Douglas, and had by this marriage two sons, of whom the elder, Earl Darnley, married Mary Queen of Scots. He was prominent in the movement which resulted in the seizure and imprisonment of the queen at Lochleven Castle, June 15, 1570; was the next day declared lieutenant-governor of Scotland in behalf of his grandson, the infant Prince James VI.; was elected regent July 12; conducted the war against the partisans of Mary; took Dumbarton Castle Apr., 1571, but was unable to secure that of Edinburgh; held a Parliament at Leith May 9, 1571, and when on his way to hold a Parliament at Stirling was attacked and mortally wounded by a party of the queen's friends. D. at Stirling, Sept. 4, 1571.

**Stewart**, ROBERT: See CASTLEREAGH, VISCOUNT.

**Stewart**, WILLIAM, D. D.: minister and professor; b. at Annan, Dumfriesshire, Scotland, Aug. 15, 1835; educated at the University of Glasgow; minister in the parish of St. George's-in-the-Fields, Glasgow, 1868–75; in the University of Glasgow examiner in mental philosophy for degrees 1867–70, and since 1873 Professor of Divinity and Biblical Criticism. Dr. Stewart has published *The Divinely Established Connection between the Old Testament and the New* (1873); *The Plan of St. Luke's Gospel* (1873); a revised and edited translation of vols. xi. and xiv. of Meyer's *Commentary on the New Testament* (1879–80); *The Church of the Fourth Century* (1883); and *The University of Glasgow, Old and New, Illustrated* (1891). C. K. HOYT.

**Stewart Island**, also called **New Leinster**: the southernmost and smallest of the three chief islands of New Zealand. It is of triangular form, about 100 miles in circumference, with an area of 665 sq. miles; consists largely of hills, of which there are three ranges; the highest summit is Mt. Anglem in the northern part, 3,200 feet; is separated from New Zealand by Foveaux Strait, 20 miles wide, and forms a part of the province of Southland. It is well wooded and watered, has much mineral wealth, and some fertile valleys, and the waters surrounding it abound in fish and oysters. The population is sparse, mostly Maoris or half-castes.

Revised by M. W. HARRINGTON.

**Stewartry**: the name which was given in Scotland to a district governed by a steward, which officer was appointed by the king with jurisdiction over crown lands and powers similar to those of a lord of regality. While the civil jurisdiction of a steward was equivalent to that of a sheriff, his criminal jurisdiction was much more extensive. The only remaining trace of that jurisdiction exists in the term stewartry, which, in place of county, is applied to the district of Kirkcudbright. The reorganization of the office took place in 1747, but the name was continued until 1 Vict., c. 39, substituted the name sheriff for it.

**Stib'ium**: the Latin name of ANTIMONY (*q. v.*).

**Sticking-plaster**, or **Adhesive Plaster**: an article for surgeons' use, made of resin, lead plaster, and soap, melted together and spread by machinery upon stout muslin. It is of great value in practical surgery, but requires rather frequent renewal, as it loses its adhesive qualities. It has to be warmed before application, but is not loosened by wetting. Light adhesive plasters, court-plasters, and the like, are made of silk or goldbeater's skin, covered on the adhesive side with a solution containing isinglass and gum-benzoin, while the back of the plaster receives a varnish of Chian turpentine and benzoin. These plasters are wetted before application.

Revised by H. A. HARE.

**Stickleback** [M. Eng. *stickle*, prickle, spine + *back*]: a hemibranchiate fish of the family *Gasterosteidæ*, having the back armed with stout spines, whence the popular name. (See HEMIBRANCHII.) The form is more or less elongated; the body naked or covered with lateral plates; head compressed, more or less pointed; dorsal fin represented by a variable number of free stout spines (2–15) and an oblong fin with articulated rays; ventral fins represented by enlarged spines with an axillar ray each, and inserted more or

The stickleback (*Gasterosteus aculeatus*).

less behind the basis of the pectorals. The species with two or three free dorsal spines belong to the genus *Gasterosteus*, those with four to *Eucalia*, those with from seven to nine to *Pygosteus*, those without a bony cuirass between the ventrals to *Apeltes*, and the elongated salt-water species with fifteen spines to *Spinachia*. The species rarely exceed 6 inches, and are generally very much less. Although so small, they are nevertheless extremely pugnacious and voracious, and attack without hesitation animals many times larger than themselves. In the breeding season the males assume resplendent hues, which are very changeable. The males construct nests of particles of grass, roots, sticks, or leaves, which are united together by a viscid mucus or silk-like thread exuded from the body and wound round the material collected. The male seeks out a gravid female, conducts her to the nest, and she deposits a few eggs, and then escapes by an aperture already made or which she herself makes opposite to the one she entered by. This is repeated day after day until a considerable number of eggs is accumulated. Each time the male rubs himself against the female and passes over the eggs. For a month, while the eggs are maturing, the male watches over them with jealous care, and only leaves when the young are hatched and ready to care for themselves. The eggs are large in proportion to the size of the fish, and few in number, not much, if at all, exceeding 100 in the common two-spined sticklebacks.

**Stigma**: See PISTIL.

**Stigmatiza'tion** [from Lat. *stigmatiza'tio*, deriv. of *stigmatiza're*, from Gr. στιγματίζειν, to mark, brand, deriv. of στίγμα, στίγματος, puncture, brand, mark, deriv. of στίζειν, to prick, brand, mark]: a term employed in the literature of the Roman Catholic Church to denote the miraculous impression upon certain saints of marks similar to the five wounds of Christ (*stigmata*) or of the crown of thorns. Remarkable instances are those of St. Francis of Assisi (Sept. 15, 1224) and Veronica Giuliani (1694). Many persons, among whom was St. Catharine of Siena, are said to have felt at regular intervals the pain of such wounds, but without any external mark. See Görres, *Die Christliche Mystik* (1854), and Imbert-Gourbeyre, *Les Stigmatisées* (Paris, 1873). Revised by J. J. KEANE.

**Stiles**, EZRA, D. D., LL. D.: clergyman and author; b. at North Haven, Conn., Dec. 15, 1727; son of Rev. Isaac Stiles, minister at North Haven; graduated at Yale College 1746; studied theology; was ordained a Congregational minister June, 1749; was tutor at Yale College 1749–55; engaged in a series of researches with an electrical apparatus sent to the college by Dr. Franklin, and made the first electrical experiments in New England; preached for a short time to the Stockbridge Indians 1750; studied law; was admitted to the bar 1753, and practiced two years in New Haven; pronounced a Latin oration in honor of Franklin on the occasion of his visit to New Haven, Feb., 1755; was pastor of a church at Newport, R. I., 1755–77; was inaugurated president of Yale College June 23, 1778; acted also as Professor of Ecclesiastical History after 1780; delivered lectures on scientific subjects; was author of a *History of Three of the Judges of King Charles I.* (Hartford, 1794) and *An Account of the Settlement of Bristol, R. I.* (Providence, 1785), and an unfinished ecclesiastical *History of New England.* D. at New Haven, May 12, 1795. His daughter married Dr. Abiel Holmes, who published his *Life* (1798) and edited *The Family Tablet* (1796), containing poems by members of the Stiles family. Revised by G. P. FISHER.

**Stilicho**, stil'i-kō: general; son of a Vandal in the Roman service. He was born about 359; grew up in the camp, and developed such eminent talents that the Emperor Theodosius gave him his niece Serena in marriage, made him commander-in-chief of the whole military force of the Western empire, and appointed him guardian to the young Honorius. After the death of Theodosius in 395 A. D., Stilicho was the actual ruler of the Western Roman empire; he married his son to Placidia, the daughter of Theodosius, and his daughter, Maria, to the Emperor Honorius. The earlier part of his career was mostly occupied by rivalries with Rufinus, guardian of Arcadius, who had received the Eastern Roman empire, and the feuds ended with the assassination of Rufinus. In 403, when Alaric invaded Northern Italy, Stilicho brought together in haste the legions which were stationed in Britain, Gaul, and all along the northern frontier of the empire; defeated Alaric first at Pollentia, then at Verona, and drove him out of Italy. But on the withdrawal of the legions from the frontiers immense swarms of barbarians gathered under Radagaisus, invaded Italy in 406, and besieged Florence. Stilicho attacked them and routed them completely; Radagaisus was put to death and his troops were sold as slaves. At the court, Olympius, a eunuch, succeeded in turning the mind of the young emperor from his guardian. While Stilicho was encamped at Bologna, a number of his friends were put to death at Pavia. In the camp Stilicho's friends demanded that he should march immediately against Pavia and punish Olympius; and when he hesitated they rebelled against him. He fled from the camp and took refuge at Ravenna, where he was murdered Aug. 23, 408. The principal events of his life have been celebrated in verse by the poet Claudian.

**Still**, JOHN, D. D.: bishop; b. at Grantham, Lincolnshire, England, about 1543; educated at Christ's College, Cambridge; took orders in the Church of England; became Lady Margaret Professor of Divinity at Cambridge 1570; held livings in Suffolk and Yorkshire; became prebendary of Westminster 1573, master of St. John's College, Cambridge, 1574 and of Trinity College 1577; archdeacon of Sudbury 1577, prolocutor of the convocation 1588, and Bishop of Bath and Wells 1592. D. at Wells, Feb. 26, 1607. He was the author of *A Ryght Pithy, Pleasant, and Merie Comedie, intytuled Gammer Gurton's Nedle, played on the Stage not longe ago in Christe's Colledge in Cambridge. Made by Mr. S., Master of Arts*, etc. (London, 1575). This piece, abounding in low humor, supposed to have been written as early as 1565, was long considered the first extant English comedy, but that rank is now assigned to Udall's *Ralph Royster Doyster.*

**Stillingfleet**, EDWARD, D. D.: bishop and controversial writer; b. at Cranbourne, Dorsetshire, England, Apr. 17, 1635; educated at Cambridge; took a fellowship 1653; entered holy orders; became rector of Sutton in 1657; preacher at the Rolls, London, 1664; rector of St. Andrew's, Holborn, London, and lecturer at the Temple 1665; prebendary of St. Paul's 1667 and of Canterbury 1669; chaplain to Charles II. 1670; dean of St. Paul's 1677, and Bishop of Worcester 1689, holding also several other ecclesiastical preferments. He ranks among the foremost of English polemics, his life having been an almost uninterrupted controversy with Roman Catholics, Nonconformists, and Socinians. He was characterized by unrivaled learning and a sincere love of truth. Many of his works have been frequently republished in different forms. The most important are *Irenicum, a Weapon-salve for the Churches Wounds, or the Divine Right of Particular Forms of Church Government, Discussed and Examined* (1661); *Origines Sacræ, or a Rational Account of the Christian Faith as to the Truth and Divine Authority of the Scriptures and the Matters therein contained* (1663; 9th ed. 1797); *A Rational Account of the Grounds of the Protestant Religion* (1665); *Discourse Concerning the True Reason of the Sufferings of Christ* (1669); *Discourse Concerning the Idolatry Practiced in the Church of Rome* (1671); *Unreasonableness of Separation from the Church of England* (1681); *Origines Britannicæ, or Antiquities of the British Church* (1685); *The Doctrines and Practices of the Church of Rome Truly Represented* (1686; new ed. by W. Cunningham, Edinburgh, 1837; 3d ed. 1851—a standard work); and *Discourse in Vindication of the Doctrine of the Trinity* (1697). He was so handsome that he was wittily called the "beauty of holiness." D. at Westminster, Mar. 27, 1699. See memoir in his *Collected Works* (6 vols. fol., 1710). Revised by S. M. JACKSON.

**Stillin'gia** [Mod. Lat., named in honor of the English botanist Dr. Benjamin Stillingfleet (1702–71)]: a genus of euphorbiaceous trees, shrubs, and herbs. The U. S. has several species. *Stillingia sylvatica*, queen's-delight or queen's-root, is an herb of the Southern States whose root has a good reputation as an antisyphilitic remedy. The tallow-tree of China (*S. sebifera*) is naturalized in the southern parts of the U. S. It is a beautiful tree, and from its seeds the Chinese extract large amounts of a white tallow-like fat, very useful for candles. The wood is hard, and is a good substitute for box. The leaves give a black dye.
Revised by L. H. BAILEY.

**Stillman**, WILLIAM JAMES: painter, journalist, and critic; b. at Schenectady, N. Y., June 1, 1828; graduated at Union College, New York, 1848. He studied landscape-painting under Frederick E. Church and in France, exhibiting at the National Academy of Design in New York 1851–59. His most noted picture is the *Procession of the Pines*, painted in 1858. (See Emerson's *The Adirondacks.*) He was art editor of the New York *Evening Post* in 1853–54, and again thirty years later. In 1855 he founded, in connection with John Durand, *The Crayon*, a monthly art journal in sympathy with the views of Ruskin and the Pre-Raphaelite Brotherhood. In 1852 he visited Austria on a secret political mission for Kossuth. He was U. S. consul at Rome 1861–65, and in Crete 1865–69. Since then he has lived mainly abroad as correspondent of *The Times* in Greece and in Italy. He has given much attention to and has written controversially about Greek art and archæology, particularly the cyclopean (Pelasgic) constructions, which he has extensively explored. His principal works are *The Cretan Insurrection of 1866–68* (New York, 1874); *The Herzegovina and the Late Uprising* (London, 1877); *On the Track of Ulysses*, embodying also an essay on the so-called Venus of Melos (Boston, 1888); also *The Acropolis of Athens*, a valuable collection of photographs (London, 1870), and his autobiography (1901). D. July 6, 1901.

**Stills**: See DISTILLATION.

**Stillwater**: city (settled in 1843); capital of Washington co., Minn.; on the St. Croix river, at the head of Lake St. Croix, and on the Chi. and N. W., the Chi., Mil. and St. P., the Chi., St. P., Minn. and Om., the St. P. and Duluth, and the Wis. Cent. railways; 18 miles N. E. of St. Paul, 25 miles E. N. E. of Minneapolis (for location, see map of Minnesota, ref. 9–F). Originally the settlement was on a small plain, slightly above the level of the lake, and surrounded by graceful bluffs; but with the growth of the city the plain has been surrendered to business houses and manufactories, and the bluffs are adorned with handsome residences. The city is 30 miles above the junction of the St. Croix and the Mississippi rivers, and, with regular lines of steamers communicating with Dubuque and St. Louis, claims to be at the head of Mississippi river navigation. Stillwater is the business center of the great St. Croix lumber region, which extends north over large portions of Minnesota and Wisconsin. It contains many large sawmills, with an aggregate daily capacity of over 500,000 feet, and a capital of $3,000,000. During the summer several hundred million feet of logs are here formed into rafts to be towed by steamers to sawmills on the Mississippi. Although lumbering has always been the principal business, other industries have sprung up, and there are several flour-mills and feed-mills, grain elevators, foundries and machine-shops, carriage and wagon factories, and agricultural-implement works. There are 18 churches, 14 public schools, public library, 2 Roman Catholic convents, a hospital, 2 national banks with combined capital of $500,000, 2 savings-banks, 1 daily, 6 weekly, and 3 monthly periodicals, and the State penitentiary. Pop. (1880) 9,055; (1890) 11,260; (1900) 12,318. HARRY R. DANNER.

**Stilo**: See ÆLIUS STILO.

**Stilt**: any bird of the genus *Himantopus* (family *Recurvirostridæ*). They are related to the avocets, and are distinguished by the excessively long legs, the straight, slender bill, which is slightly compressed, the feet with the middle and outer toes connected by a small web and destitute of a hind toe, and projection of the tail beyond the wings. There are some half dozen species, inhabitants of various parts of the world. One is found in America, and ranges from the northern parts of the U. S. to Paraguay. Its total length is about 14 inches, of which the bill forms 3 inches, and the tail also 3 inches; the tarsi are about 4 inches in length, and rather longer than the tibiæ; the color is a glossy black on the head above, the neck behind, the back, and the wings; white on the head in front of and behind the eyes, and beneath; the bill is black, and the legs red. It not only dwells by the seacoast, but is found far inland, at least on the lakes and rivers of the western parts of the U. S. The stilts generally associate together in flocks of twenty or thirty. They prefer muddy flats with reedy margins. They breed in the U. S., and make nests of grasses, etc. They lay generally four eggs; these are relatively large and of a yellowish or ochraceous color, with dark-brownish blotches and lines. According to Coues, on the ground, whether walking or wading, they move gracefully and with measured steps; the long legs are much bent at each step (but only at the joint), and planted firmly and perfectly straight. When feeding, the legs are bent backward at an acute angle at the heel-joint, to bring the body lower. They feed mostly on aquatic insects, as well as the eggs and young of fishes, and small fishes. Revised by F. A. LUCAS.

**Stilton Cheese**: See CHEESE.

**Stimpson**, WILLIAM, M. D.: naturalist; b. at Cambridge, Mass., Feb. 14, 1830. He devoted himself principally to the description of invertebrates. He was naturalist of the Ringold and Rodgers expedition to the North Pacific Ocean, later was curator of the Chicago Academy of Science, and lost all his collections, MSS., etc., in the great fire of 1871. Later he superintended the dredgings of the U. S. Coast Survey in the Strait of Florida. Among his works are *Testaceous Molluscs of New England* (1851); *Marine Invertebrates of Grand Manan* (1854); *Prodromus Descriptionis Animalium Evertebratorum* (1857–61, containing a part of the invertebrates collected on the Ringold and Rodgers expedition); *Notes on North American Crustacea* (1859–71); *Crustacea and Echinodermata of the Pacific Shore* (1857); and *Crustacea Dredged in the Gulf Stream* (1871). D. at Ilchester Mills, Md., May 26, 1872. J. S. K.

**Stimson**, FREDERIC JESUP: novelist; b. at Dedham, Mass., July 20, 1855; graduated at Harvard in 1876; was admitted to the bar, and in 1882, under the pseudonym *J. S. of Dale*, published *Guerndale*, a novel of college life. In 1884–85 he was assistant attorney-general of Massachusetts. Other novels are *The Crime of Henry Vane* (1884) and *The Residuary Legatee* (1888). He has also published a number of law-books, the most important of which is perhaps *American Statute Law* (1886). H. A. B.

**Stimulants** [from Lat. *stimulans*, *stimulan'tis*, pres. partic. of *stimula're*, urge, goad on, deriv. of *sti'mulus*, a goad]: those agents which increase functional activity of the various organs of the body, more particularly in connection with the respiration, circulation, and nervous system. Such are, pre-eminently, strongly nourishing hot food if it can be digested; if it can not, then alcoholic or ethereal potions, ammoniacal solutions, heat, strychnine, etc.

**Stimulus**: that which excites or stimulates; used in physiology and psychology for any influence from outside which causes a reaction of the muscles in movement or of the attention.

**Sting-fish**: the greater weever (*Trachinus draco*). See TRACHINIDÆ.

**Sting-ray**: any ray of the genus *Trygon* (family *Trygonidæ*), a group of elasmobranchs belonging to the order *Raiiæ*. These fish have the body rhombic and moderately broad, the skin smooth and without tubercles, the nasal valves coalescent into quadrangular flaps, the teeth flattened, and the tail long, tapering, destitute of a true fin, and armed with an elongated spine (sometimes with two) compressed from before backward, and with teeth or serratures at each side directed downward. These spines are the "stings" which have insured the popular name to the forms in question. There are about thirty species found in almost all tropical and temperate seas, and much dreaded on account of the wounds which they inflict with their spine-bearing tail. They can whip the tail around with great ease and transfix the incautious intruder with the spines. Tetanus is sometimes the result, but the wound is a physical injury solely and not the result of poison. One species (*Trygon centrura*) is quite common along the eastern coast of the U. S. See also TRYGONIDÆ. Revised by F. A. LUCAS.

**Stinkhorn Fungi**: the *Phallaceæ*, a family of fetid gasteromycetous fungi numbering ninety-two species, most of which are tropical. The plants are filamentous saprophytes, growing in soil which is rich in decaying organic matter. The spore-fruits are roundish or egg-shaped bodies resembling PUFF-BALLS (*q. v.*), which develop at or beneath the surface of the ground and whose spore-bearing tissue (*gleba*) emerges from the peridium by the elongation of the sterile base (see figure). The fetid odor attracts flies and other insects, to which the spores adhere, thus securing their distribution. Several species occur in the U. S., one of the most common being the *Ithyphallus impudicus* (see figure), which is from 5 to 10 inches high, with a white or pinkish base (*volva*), a white, hollow, loosely cellular stalk, and a conical, reticulated pileus bearing black spores. Species of *Dictyophora*, *Mutinus*, and *Simblum* are common in the U. S. CHARLES E. BESSEY.

Stinkhorn (*Ithyphallus impudicus*) reduced one-half, with a young spore-fruit at the side.

**Stinkstone**: any one of certain marbles or limestones which on being struck emit the smell of sulphuretted hydrogen. The British islands abound in stones of this character and of various geological ages, some of them useful building-stones.

**Stinkwood**: the hard, durable wood of the *Ocotea bullata* (family *Lauraceæ*) and related plants, found in South Africa. The wood is handsome and valuable, but has a disagreeable smell even when seasoned. *O. fœtens*, a tree of the Canaries, has wood of a vile odor, but other members of this widespread genus are of pleasing fragrance. The name is also applied to a species of *Cassia*.

Revised by L. H. BAILEY.

**Stipple-engraving**: See ENGRAVING.

**Stirling**: town of Scotland; capital of Stirlingshire; on the Forth; 35 miles N. W. of Edinburgh (see map of Scotland, ref. 11–G). It contains a fine old castle, situated on a basaltic hill, with steep precipitous sides toward the W. and rising to a height of 340 feet above the plain. The town and its vicinity are rich in historic associations, and contain many objects of interest. Tartans, shawls, rope, soap, leather, and malt are extensively manufactured, and an important trade both on the river and by rail is carried on. Stirling unites with Dunfermline, Culross, Inverkeithing, and Queensferry in sending one member to Parliament. Pop. (1891) 16,974.

**Stirling**, JAMES HUTCHISON, M. D., LL. D.: philosopher; b. in Glasgow, Scotland, June 22, 1820; took the course in arts and medicine at Glasgow University; for a short time practiced as a surgeon in New South Wales; abandoned practice in 1851 and went to Germany to continue philosophical studies; is the author of *The Secret of Hegel, being the Hegelian System in Origin, Principle, Form, and Matter* (2 vols., 1865); *Sir William Hamilton, being the Philosophy of Perception* (1865); *Jerrold, Tennyson, Macaulay, and other Essays* (1868); *As Regards Protoplasm* (1869); *Philosophy and Theology*, Gifford lectures (1890); *Darwinianism: Workmen and Work* (1894); and the translator of Dr. Albert Schwegler's *Handbook of the History of Philosophy* (1867). Dr. Stirling is an opponent of Haeckel and Huxley on biological theories.

**Stirling**, Sir THOMAS, of Ardoch: soldier; b. in Scotland about 1735; became a captain in the Royal Highlanders July, 1757; served under Abercrombie at Lake George 1758, and Amherst at Lake Champlain 1759, at the siege of Niagara, and the invasion of Lower Canada 1760; was stationed in 1765 at Fort Chartres, Ill., whence he marched to Philadelphia 1766; became lieutenant-colonel 1771, colonel 1779, and major-general Nov., 1782; served throughout the war of the Revolution; took part in the battles of Long Island, Fort Washington, Red Bank, Brandywine, and Springfield; was made a baronet and lieutenant-general 1796, and full general Jan. 1, 1801. D. May 9, 1808.

**Stirling**, Sir WILLIAM: See MAXWELL.

**Stirlingshire**: a county of Scotland; bounded by the counties of Perth, Clackmannan, Linlithgow, Lanark, and Dumbarton, and forming the border-land between the Highlands and the Lowlands; area, 447 sq. miles, of which about two-fifths is under cultivation. The western part of the county is mountainous, and rich in iron, coal, and freestone. The highest peak is Ben Lomond, 3,192 feet above the level of the sea, near the foot of which lies the beautiful Loch Lomond. Agriculture, cattle-breeding, mining, and the manufacture of cotton and woolen goods, chemicals, etc., are pursued with success. The iron-works at Carron in this county are among the largest in the country. There are also extensive iron-works at Falkirk, where also three annual fairs, called trysts, the largest in Scotland, are held for the sale of horses, cattle, sheep, and wool. Stirlingshire is rich in historic associations, and boasts of many battle-fields, the chief of which are Stirling Bridge, Falkirk, Bannockburn, and Kilsyth. Pop. (1901) 141,894. The county sends one member to Parliament. County-town, STIRLING (*q. v.*).

**Stith**, WILLIAM: clergyman, educator, and author; b. in Virginia in 1689; educated in England, where he studied theology and took orders in the Church of England 1731; became in that year master of the grammar school of William and Mary College; chaplain of the Virginia House of Burgesses 1738, and president of William and Mary College and rector of Henrico parish from 1752 to his death at Williamsburg, Sept. 27, 1755. He was a brother-in-law of Peyton Randolph, and author of a *History of the First Discovery and Settlement of Virginia* (Williamsburg, 1747; 2d ed. 1753; new ed. New York, 1866). It traces the history only to 1624, has been by some critics censured as inelegant in style, but is admitted to be accurate and faithful, and the work is of the greater value since the materials on which it was based were destroyed by fire.

**Stjernhjelm**, styern'yelm, GEORG: statesman, scholar, and poet; b. in Dalarne, Sweden, in 1598. He was the son of a poor miner named Marqvardson, but on entering school assumed the name of Göran Lilje. His early education was obtained at Vesterås. After filling various Government positions he was appointed by Gustavus Adolphus lector in the school at Vesterås. Afterward he was ennobled by the king, and assumed the name by which he is known in literature. He was court poet to Queen Christina and high in favor, but afterward fell under suspicion and was disgraced. D. in poverty 1672. His principal works are the didactic poem *Hercules*, written in hexameters; *Bröllops besvärs ihugkommelse* (Remembrances of Wedding Vexations), a humorous lyric poem, also in hexameters; and three so-called ballets—*Parnassus triumphans*, *Den fångne Cupido* (The Captive Cupid), and *Freds Afl*—the first of which is like a modern opera, the others like the contemporary English masques. He is called the father of Swedish poetry. Before him there is a condition of absolute confusion in form. By his use of new meters, and particularly of the alexandrine, which he introduced into Swedish literature, he established a standard for his successors, who regarded him in form and language a model of artistic perfection. His poetical works were published at Upsala, 1856. See SWEDISH LITERATURE.

WILLIAM H. CARPENTER.

**Stoat**: See ERMINE.

**Stobæ'us**, JOANNES [so called from his birthplace, Stobi, in Macedonia]: an author assigned to the end of the fifth century of our era. For the instruction of his son, Septimius, he made a collection of sayings on various subjects from about 500 Greek authors, and these quotations have become of great interest, as in most cases the works from which they were taken have perished. They are arranged in two separate works—*Anthologion* and *Eclogæ*—both edited by Meineke, the former in 4 vols. (1855–57), the latter in 2 vols. (1860–62). There is a new critical edition of both, under the common title *Anthologion*, by Wachsmuth and Hense (Berlin, 1884), of which the third volume appeared in 1894.

Revised by B. L. GILDERSLEEVE.

**Stockbridge**: town; Berkshire co., Mass.; on the Housatonic river, and the N. Y., N. H. and Hart. Railroad; 8 miles N. of Great Barrington, 17 miles S. by W. of Pittsfield (for location, see map of Massachusetts, ref. 2–C). It is noted for picturesque mountain scenery, includes the beautiful Lake Mahkeenac, and has numerous villas, chiefly occupied during the summer by citizens of New York. Originally called Housatonic, the place was the chief residence of the tribe of Indians of the same name, also called Stockbridge Indians, who were Christianized in the eighteenth century by the labors of John Sargent, Timothy Woodbridge, and the celebrated Jonathan Edwards, to whose memory a monument has been erected here. The tribe, numbering 400, removed after the Revolution to Madison co., N. Y., afterward to the vicinity of Green Bay, Wis., and subsequently resided near Fort Leavenworth, Kan. Stockbridge was the native place of several eminent persons, including Catherine M. Sedgwick, Mark Hopkins, Cyrus W. Field, Henry M. Field, D. D., and Judge Henry R. Brown, of the U. S. Supreme Court. It contains the villages of Stockbridge, West Stockbridge Center, Curtisville, and Glendale, eight public schools, a public library (founded in 1862), an academy, woolen-mills, paper-mills, pulp-mills, grist-mills, and sawmills, and a national bank with capital of $200,000 and surplus of $150,000. It was incorporated in 1739, and in 1894 had an assessed valuation of $2,940,495. Pop. (1880) 2,357; (1890) 2,132; (1900) 2,081.

HENRY M. FIELD, EDITOR OF THE "EVANGELIST."

**Stockbridge**, HENRY: lawyer; b. at North Hadley, Mass., Aug. 31, 1822; graduated at Amherst College in 1845; studied law in Baltimore, and was admitted to the Maryland bar in 1848. During the civil war he took an earnest part in favor of the Union; in 1864 was a member of the Legislature, and drafted the act by which a constitutional convention was convened for the abolition of slavery in Maryland; was a member of that convention, took an active part in its proceedings, exerted himself to secure the adoption of the constitution framed by it, and defended it before the court of last resort. He instituted and conducted to a successful issue in the Federal courts proceedings by which were annulled the indentures of apprenticeship by means of which the effect of the emancipation clause was sought to be evaded, and thus secured the enfranchisement of more than 10,000 colored children in the State. He edited for years the Fund publications of the Maryland Historical Society, of which he was vice-president. D. Mar. 11, 1895.

**Stock-dove**: a European wild pigeon, *Columba œnas*, named from its habit of nesting in hollow stocks or tree-stumps, although it often builds in rabbit-burrows, etc. It is gray, with a purplish breast, scarlet eyes, orange bill, and red toes and legs. It is some 14 inches long. The young birds are prized as food.

**Stock Exchange**: an association of brokers in shares, bonds, or other securities of corporations, nations, states, counties, or municipalities, and in negotiable certificates representing commodities of trade. Until the decade 1880–90 the last-mentioned instruments were not regularly dealt in by stock exchanges. The Petroleum and Mining Exchange of New York city was, however, in 1885, expanded into an exchange for stocks, oil, and mining shares, and the older New York Stock Exchange shortly afterward admitted to regular trading on its board the so-called "pipe-line certificates" of the petroleum market, and later certificates of deposited silver bullion, through which the price of silver might be made a convenient speculation. Grain contracts for future delivery have also been dealt in regularly in the Consolidated Stock and Petroleum Exchange, but neither these nor the pipe-line certificates on the New York Stock Exchange became in any degree important features of the institutions.

*Membership Regulations.*—Membership in a stock exchange is usually limited, and as, in a number of exchanges, a "seat" is the property, not only of an active broker, but also of his heirs or assignees, the privilege represented by it possesses a marketable value. Memberships in the New York Stock Exchange have sold as high as $60,000 (price reached in 1901), and as low as $15,250, the record of 1893. Sales were made in the first quarter of 1895 at $18,000. The purchase of a seat from a previous incumbent does not of itself entitle the buyer to the privilege of trading on the floor. He becomes a member only after formal application, and by the approval of the committee on admissions. On the London Stock Exchange the applicant for membership must be recommended by three members of at least four years' standing, who severally bind themselves to pay £500 to the applicant's creditors, in case he be declared a defaulter within four years after his admission. No foreigner is eligible unless he shall have been naturalized for two years. In the Paris Stock Exchange the *agent de change* (see below) is ineligible unless a Frenchman. He must be proposed by his predecessor in membership (or that predecessor's heirs or proxies), and must be formally approved by the governing body of the exchange and the Minister of Finance.

Most stock exchanges place a limit on the number of members. On the New York Stock Exchange the limit is 1,100, a number reached after a considerable increase in 1869, when a successful rival, the Open Board of Brokers, was absorbed by consolidation of membership. In New York the Stock Exchange member frequently acts as solicitor of investment business—advertising extensively—as general banker and promoter, and as executor of orders on the floor. These functions are separated in London, where a customer usually gives his order to a broker in the exchange membership, through whom the "jobber," also a member of the exchange, is employed; the Stock Exchange forbids all its members to advertise. By the constitution of the Paris Bourse, its members, the *agents de change*, number only sixty; but stock-exchange business in Paris fell largely from the first into the hands of *coulissiers* or outside brokers, who frequented the outer corridors of the Bourse and traded as though members of a regular exchange. The strife between the *coulissiers* and the *agents de change* is bitter and historic. The *coulisse* was repeatedly suppressed by the courts and the police, and was driven at times to other quarters of the city. In 1859 individual *coulissiers* were heavily fined, but their business, under the generic name of the Petite Bourse, flourishes to this day. Trading on the larger Bourse in recent years has been also carried on by the head clerks of the *agents de change*, each agent being allowed two such clerks with privileges of the exchange.

*Discipline and Rules.*—Stock exchanges are invariably governed by strictly enforced by-laws, covering rules for general management, mutual arrangement and enforcement of contracts, and requirement of personal business honesty and good behavior. On the New York Stock Exchange an insolvent member is suspended until he has settled with his creditors, and may be readmitted only on proof of such settlement and on the formal vote of the committee on admissions or, if rejected by them, on appeal to the general governing committee. Suspension or expulsion is also fixed as penalty for (1) the making of fictitious sales; (2) the making of fictitious or trifling bids or offers; (3) the buying or selling of securities for a less commission than that fixed in the by-laws; (4) "obvious fraud"; (5) refusal to comply with any other regular provision of the by-laws. The London Stock Exchange's by-laws impose suspension or expulsion as penalty for violation of any Stock Exchange rules or regulations; for failure to comply with the committee's decisions; and for "dishonorable or disgraceful conduct." A declared insolvent also ceases to be a member. The *agent de change* in Paris is subject to discipline, under the institution's by-laws, whenever he "does not confine himself strictly to his duties," or if he "introduces into his operations or into the collection of his dues any innovations that may be injurious to the public weal or to the interests of the company." The penalty is left wholly discretionary with the governing board or "syndical chamber." It may fine, censure, or suspend a member, but for expulsion may only submit its recommendation to the Minister of Finance. This recommendation is, however, usually final.

"*Listing*" *of Securities.*—In nearly all stock exchanges no security can be dealt in on the floor unless it has been officially admitted by the committee appointed for the purpose. Securities may also be expressly excluded from trading by vote of this committee. The only exception to this privilege of exclusion, in European stock exchanges, is the public stock of the nation to which the exchange belongs. In London an explicit Stock Exchange rule forbids trading in public loans raised by nations at war with Great Britain. For the "listing" of new securities on the New York Stock Exchange certain formalities are prescribed. The applicant company must show to the committee on stock list that the shares or bonds in question were regularly issued, and that they have been actually marketed. A general financial statement at a date not too far distant must accompany the application. In the case of shares, the securities must be registered with a trust company satisfactory to the stock exchange. In the case of bonds, evidence must be submitted that the mortgage was properly drawn and properly recorded in every county touched by the enterprise. These stringent provisions were the result of numerous frauds and "over-issues" of securities in the earlier history of American stock speculation.

The competition of the Consolidated Exchange after 1885 led to some change in sentiment among the New York Stock Exchange authorities. A few years after that date the New York Exchange governors established a so-called "unlisted department," in which securities were admitted without the stringent provisions as to financial statement, registry of shares, etc. As a result, securities to an enormous aggregate value were admitted to official trading, when the investing public was left in total ignorance of the financial status of the enterprises. These securities soon became the chief center of active and reckless speculation. Although the Stock Exchange generally repudiates responsibility for the character and good faith of securities dealt in upon its floor, it has lately been generally admitted that the influence of these "unlisted securities" was demoralizing and harmful. Retroactive legislation against such securities was impracticable, but in Feb., 1895, the governing committee of the exchange adopted a resolution which marked an important change of policy. A very great amount of securities of insolvent companies were certain, later on, to be subject to reorganization. In such cases the new securities issued in the adjustment of the corporation's debt must apply for admission to the Stock Exchange. The governing committee's resolution stipulated that all such applications must be accompanied by a full and complete income report for the year preceding, by a detailed balance sheet, and by a civil engineer's report on the physical condition of the property. The resolution also went much further, and officially "recommended" to all corporations, whose securities were already admitted to trading, the publication, at least fifteen days prior to an annual meeting, of a faithful and detailed income account and balance sheet for the year. Although not mandatory, this declaration of general policy was regarded as highly important in the struggle of investors to obtain complete and frequent financial statements from corporation directors.

*Method of Business.*—All stock exchanges provide an open hall where brokers may personally buy from or sell to one another, for their own account or that of customers, such securities as are admitted to trading. A regular commission, which is a fixed percentage usually on the par value of securities bought or sold, is established for all such trading. Members are forbidden under penalty to accept a less commission. On the New York Stock Exchange the regular minimum commission is one-eighth of 1 per cent. on outside orders, one thirty-second of 1 per cent. on orders given by fellow members, and one-fiftieth of 1 per cent. where a member has merely employed a fellow member to make the bargain, delivery being made to or by the real purchaser or seller. All commissions are reckoned on a security's par value. In London the official Stock Exchange commissions vary according to the nature and face value of the security dealt in. On the stock of British and colonial corporations they range from 1*s.* to 5*s.* per cent.; on shares and bonds issued in the U. S. the commission is 1*s.* per $100; on British and foreign government funds it is 2*s.* 6*d.* per cent. In Paris the official commission of an *agent de change* is one-quarter of 1 per cent.

The bids and offers made on the floor of the exchange, though made only personally, become official. A broker is forbidden under penalty to sell stock at a price lower than the best bid made in his hearing for the amount in question, or to buy at a price higher than the lowest offer. This is to prevent unfair "manipulation." On the New York Stock Exchange the broker must deliver stock sold, and must pay for stock bought, by 2.15 P. M. on the day following the transaction. Since 1892 most of these transactions are settled through the Stock Exchange Clearing-house. (See below.) On the London Stock Exchange, and in the majority of exchanges in Europe, as well as some in the U. S., "settlements" between buyers or sellers are made at longer intervals. In London a contract made for purchase or sale of securities is settled by delivery of the securities and payment of the price at the next official settling day. These days occur at fortnightly intervals, or nominally twice a month, for general securities, and once a month for Government stocks. By mutual agreement, commonly on payment of a fixed percentage charge, the contract may be deferred or "carried over" to the next settlement. The Paris Stock Exchange and most other stock exchanges on the Continent deal "for the account" similarly to London. In all these exchanges cash transactions, closed on the spot, are admissible, though rare outside of British consols. In such cases, as may be seen by the daily quotations of British consols, the price for the "account" is usually higher than the price for "money" by a margin sufficient to cover the interest charge between the date of cash sale and the date of the next fortnightly or monthly settlement.

In all stock exchanges actual delivery of securities sold is required, the one apparent exception being in cases where mutually balanced contracts are canceled through the stock exchange clearing-house. The courts have in this case, however, decided that the cancelation in no respect affected the intent to deliver, the enforceability of delivery, and the actual delivery of stocks, so far as customers are concerned. The common assumption that trading on stock exchanges involves no real sale, purchase, or transfer, but is merely a species of gambling on differences, is wholly erroneous. This species of gambling is confined to the so-called "bucket-shops," private concerns with no stock exchange membership, and which neither receive nor deliver actual securities, merely paying to customers or receiving from them the money balance due between the stock exchange price at the time of the fictitious sale or purchase and at the time the contract is closed. In the U. S. these institutions are illegal by the statutes of most States, and are at intervals raided by the police as common gambling-houses.

*Stock-exchange Clearing-houses.*—The clearing-house for stocks is the most recent development in the machinery of stock exchanges. It is a natural outgrowth of the bank CLEARING-HOUSE (*q. v.*), and serves a similar purpose. Its fundamental principle is to offset contracts by one broker, to deliver securities, with contracts entered upon by the same broker to receive the same securities. If A has purchased 1,000 shares of stock from B, and has sold 1,000 shares of the same stock to C, the stock exchange clearing-house returns a balanced sheet to A, who thereupon neither receives nor delivers any of the stock, the double transaction being settled by the delivery of the 1,000 shares by B to C. Or if A has bought 1,000 shares from B and sold 600 to C, the clearing-house so arranges that B shall deliver 400 shares to A and 600 to C, no deliveries being made by A. By an ingenious book-keeping system, this principle is extended to the entire membership of the exchange, and as each active broker is apt to trade daily on both sides of the account in many securities, the economy in expense and labor is enormous. This system was first introduced in the Handelskammer at Frankfort in 1867. It was found that through its employment the necessary transfers of securities were reduced more than 90 per cent. The Berlin Exchange adopted the system in 1869, Hamburg in 1870, Vienna in 1873, London in 1876, some of the U. S. exchanges between 1880 and 1887, and the New York Stock Exchange in 1892. The last-named institution, following and perfecting the plan of the Consolidated Stock Exchange of New York, added a system of money clearings, through which the checks due by brokers in settlement were mutually offset, so far as the two sides of any broker's account balanced, at the clearing-house. It is estimated by officers of this clearing-house that the saving in checks drawn for brokers' settlements, under this system, has in the New York Stock Exchange alone averaged $400,000,000 per month. The system of money clearings has not been adopted in Europe, except, in a modified form, by the London Stock Exchange. The stock exchange clearing-house has received more full and complete discussion in *The Political Science Quarterly* for June, 1893.

*History.*—The trade of brokers, in the sense of professional buyers, sellers, and lenders on security, using for the purpose their own money or that of customers, is very ancient. Such trade was carried on in the Roman Forum during the days of the republic. The use for this purpose of the porticoes of the adjacent temples of Minerva and Mars Ultor is mentioned frequently by Martial, Juvenal, and other Latin writers, and their references assume a long-established institution. The brokers of that period, however, were hardly distinguishable from the bankers and money-lenders of the Middle Ages. The money-broker or money-changer, transacting much the same business as the money-brokers do to-day, was older as representative of a distinct profession, and indeed followed early international commerce as a necessary accompaniment. In the later Middle Ages exchanges for the transaction of general business were established, usually by national or municipal governments, and took the place of the temple porticoes and public markets commonly used at the beginning of the Christian era. The Royal Exchange in London, founded under Elizabeth by Sir Thomas Gresham, was of this character, and was suggested by similar institutions already established in some of the German commercial cities. But these were not stock exchanges, and were never used as such except when, in the infancy of stock-trading, a part of the general market space was used by brokers in securities.

The term broker is used in English statutory law as early as 1285, but apparently refers there to a species of pawn-broking business only. In 1604 an act of Parliament defines brokers only as dealers in "merchandise and wares." There is no evidence that the stock-broker in the modern sense became a factor in trade until the great movement for the creation of funded Government debts at the close of the seventeenth century, followed a few decades later by the incorporation of the East India Company and the South Sea Company in London, and of the Mississippi Company in Paris. The shares of these corporations were offered for public purchase, and advanced enormously in value. Before the South Sea Bubble burst in 1720 the stock-jobber had become a feature in English society, and both he and his peculiar professional slang occur frequently in the literature of the period.

The stock-broker's business was long conducted either in the Royal Exchange in London or, later, in the coffee-houses of the adjacent 'Change Alley. In 1801 the London Stock Exchange was founded in Capel Court, where it has continued ever since. A public exchange for brokers was established in Paris as early as 1304, but stock-jobbing began only with John Law's Mississippi Bubble of 1720. It was suppressed by governmental edict in 1720 and in 1793, both actions being provoked by the great demoralization in values caused by currency inflation. The present Bourse was founded early in the nineteenth century, and was first occupied in 1826. Contrary to usage elsewhere, the expense of its construction was paid by the city. As an organized body of brokers, the New York Stock Exchange seems to have originated as early as 1792, solely "for the purchase and sale of public stock." Its meetings, however, were held only in coffee-houses, or in rooms of private buildings; first in an office at No. 47 Wall Street, and later in the old *Courier and Enquirer* buildings. In 1827 an upper room was chartered in the Merchants' Exchange, Wall and William Streets; from 1854 to 1857 a room over the Corn Exchange Bank was used, then a hall in a building on Beaver Street, the present exchange being completed and first occupied in Dec., 1865. The list of celebrated names among the speculators in the membership of the New York Stock Exchange includes Jacob Little, Samuel Ward, Cornelius Vanderbilt, William R. Travers, Charles Woerishoffer, Daniel Drew, James Fisk, Jr., William H. Vanderbilt, and Jay Gould. Of these only the first mentioned, who flourished in the decade 1825–35, antedated the days of railway-share speculation. The Philadelphia Stock Exchange was founded at the opening of the century, and was for some time a more important institution than its New York rival. It has not kept pace with the New York Exchange, however, and, though trading actively in many of the securities dealt in at New York, devotes itself largely to specialties, notably, since 1890, to stocks and bonds of street-railways in various quarters of the Union. Philadelphia is the headquarters for the so-called traction stocks of New York, Baltimore, Philadelphia, and other cities. The Boston Stock Exchange—a much more recently founded institution—deals especially in securities of railways in New England. The Chicago Stock Exchange is dwarfed by the much larger concentration of grain-dealing in that city. Its dealings are chiefly restricted to shares and bonds of the elevated and surface railways of Chicago. Baltimore, New Orleans, and other cities possess also stock exchanges doing a still more limited business in securities of local enterprises. There are stock exchanges in all the principal commercial cities of Europe, and in many of the smaller municipalities. The most important institutions, outside of those already mentioned, are the stock exchanges of Berlin, Hamburg, Frankfort, and Vienna.

*Stock-exchange Phraseology.*—Trading in stocks has for nearly two centuries been characterized by a set of terms and phraseology peculiar to itself. Of these the most familiar are the following: A "bear" is a market operator working to cause lower prices. A "bull," conversely, is working for higher prices. Both of these terms occur in colloquial literature at least as old as England's South Sea speculation of 1720. The bear is usually said to be "short" of stocks. The origin of this more modern term is plain, and signifies that the operator has sold stocks which he does not yet own, for delivery at a fixed future date. The price may or may not be lower than previous recorded quotations. Usually he receives his payment, at current prices, on the spot, and in modern stock exchanges he also makes his delivery of stocks on the spot. But the stock thus delivered is borrowed from real holders, to be repaid when the "short" seller "covers"—that is to say, when he buys outright in the market to close his contracts. The bull is commonly "long" of stocks in a speculative way. This term signifies that he buys the stock and pays for it in money on the spot, but borrows the money for payment. When he sells his stock, at a profit or otherwise, he repays the loan. It often happens, therefore, that when the bear is borrowing stocks and the bull borrowing money, the one is simply lending to the other. Sales by the bulls are currently called liquidation. Stocks are said to be "carried" when a banker advances money to the bull speculator, retaining the stocks as security for the loan. The "carrying rate" naturally varies, therefore, with the rate of money and the demand for stocks. "Pools" are combinations of operators devoting their joint resources to the manipulation of a single security or group of securities. The manipulation is usually directed by one member of the pool. Contracts for such purpose have in some cases been recognized as legal by the courts, but appeal to law is rarely made, and bad faith, such as the "selling out on his associates" by one member of a "bull pool," is not easily proved against the offender. A "put" is a contract drawn by a capitalist or broker and sold at a specified sum to a speculator, in virtue of which the speculator may, within a fixed period, deliver the stock to the issuer of the put and be paid for it at a stipulated price. The buyer of a put is of course usually a bull, and buys the put to guard himself against losses on a possible decline. A "call" is the converse of a put. Its issuer contracts to sell to the buyer of the call, at or before a stipulated date, a certain amount of a certain stock at a fixed price. The bear buys this to guard against unexpected advances. A "spread" or "straddle" combines the features of both put and call, contracting at the option of its buyer to deliver to him or receive from him a fixed amount of securities named, the limits of price being set as many points apart as the situation, in the view of the issuer, will justify. All of the contracts described are generally classed as "options" or "privileges." A "wash sale" is a transaction in stocks wherein buyer and seller do not permanently transfer the securities at all, but work in a common interest to create semblance of activity and affect prices. In most stock exchanges "wash sales" are forbidden under heavy penalty, but they are difficult of detection and undoubtedly play a large part in current stock transactions. Two expressions in stock-exchange dialect, frequently used in cable dispatches, are peculiar to London. "Contango," a word probably derived from the continental expression for "contingent," refers to the rate or percentage charged an operator long of stocks for carrying over his account to the next fortnightly settling day. (See above, under *Methods of Business.*) "Backwardation" is an etymological barbarism describing the premium, if any, charged to a short operator for permitting him to defer delivery from one settling day to the next. Its equivalent on the New York Stock Exchange is the premium charged in the "loan crowd," where actual owners of stocks are lending the shares to bear operators desirous of making present deliveries.

*Statistics.*—Transactions on the New York Stock Exchange are more carefully recorded and tabulated than in any other similar institution. The statistics of its business will therefore give a fair idea of the trading which passes annually on a great stock exchange. For the calendar year 1894 the following figures of actual sales have been compiled:

| STOCKS AND SHARES. | Par value. | Market value. |
|---|---|---|
| Shares* | $4,821,876,020 | $3,094,942,769 |
| Railway bonds | 339,950,250 | 248,987,506 |
| U. S. Government bonds | 4,345,400 | 5,220,460 |
| State bonds | 10,929,900 | 4,441,015 |
| Bank stocks | 527,985 | 924,507 |

* Total number of shares sold, 49,075,032.

The year 1894, however, being a period of great financial depression, is not a fair year to select as representative of investment and speculation. Even in 1893 the shares sold on the New York Exchange aggregated 80,977,839, of a par value of $7,550,440,205, and a market value of $4,550,260,916. The maximum year's record of the Stock Exchange in the several kinds of securities is as follows: Shares (number), 116,307,271 in 1882; railway bonds, $660,659,400 in 1885; Government bonds, $112,571,850 in 1879; State bonds, $26,571,260 in 1882. It is generally estimated by brokers that sales of 200,000 to 300,000 shares a day are a fair average in active times. In a period of market excitement trading runs far beyond this average. The extreme high point was touched in the summer of 1887, when one day's total ran above 1,000,000 shares, the volume of business being so great that the Stock Exchange authorities were never able to compile its figures, even approximately.

LITERATURE.—The literature of this subject is not rich. The most complete legal and historical discussion will be found in J. R. Dos Passos's *Treatise on the Law of Stockbrokers and Stock Exchanges* (New York, 1882). The *Report* of the British Royal Commission on the origin and methods of the Stock Exchange (London, 1878) is full of valuable data. G. R. Gibson, of New York, has written several light but readable monographs on the various European exchanges. Various memoirs, chiefly of little value, have been published to narrate episodes of stock-exchange adventure. The most thorough and philosophical discussion of the financial questions involved in the subject is that of Robert Giffen, statistician of the British Board of Trade, in his *Stock Exchange Securities* (London, 1877). The numerous books and pamphlets on *How to Avoid Losses in Wall Street*, etc., are worthless and mischievous. Annual reports of the exchanges are usually limited to lists of officers, committees, and members. Valuable information as to the functions of stock exchange trading at earlier periods may be obtained from Walter Bagehot's *Lombard Street* (London and New York) and Clement Juglar's *Crises commerciales* (Paris).

ALEXANDER D. NOYES.

**Stockfish** (from the German *stockfisch*): a name for codfish and related species salted and dried. The fishes are split from head to tail, and the vertebral column in part taken out; they are then thoroughly washed and rid of the blood; after the water has been drained off, they are put in large vats, salted, and heavy weights are imposed; they are next washed and brushed, and laid out on the sandy shore and rocks. Finally, they are combined in small heaps, and become ready for the market, this stage being indicated by the assumption of a floury whitish appearance, technically designated as the "bloom." Revised by F. A. LUCAS.

**Stock'holm**: the capital of the kingdom of Sweden; beautifully situated at the outlet of Lake Mälar in the Baltic (see map of Norway and Sweden, ref. 11–G). It is divided into (1) Staden, the inner city, consisting of the islands of Stadsholmen, Riddarholmen, and Helgeåndsholmen; (2) Norrmalm, the northern part, connected with the inner city by a magnificent bridge of granite; (3) Ladugårdslandet, now Östermalm, communicating W. with Norrmalm; (4) Kungsholmen, communicating E. with Norrmalm; (5) Södermalm, the southern suburb, connected with the inner city by two drawbridges; and (6) Saltsjö-öarne, comprising the islands of Skeppsholmen, Djurgården, Kastellholmen, and Beckholmen, which complete the picture of an island city cut up and traversed in all directions by water. In Staden, the most prominent building is the royal palace, one of the most beautiful in Europe (built 1697–1754), containing a rich library, the palace of the stadtholder, the mint, the townhouse, the church of St. Gertrude, Storkyrkan, the Finnish church. In the island of Riddarholmen stand the Riddarholm church, containing the royal tombs, among which are those of Gustavus Adolphus and Charles XII.; the new house of deputies, and the statue of Birger Jarl. The bridge which leads from the inner city across the Helgeåndsholmen to Norrmalm is 380 feet long and 64 feet broad; on its eastern side extend the most beautiful promenades of the city, Strömparterren. This part of the city contains the Brunkeberg Place, the Hay Market, and the Place of Charles XIII., surrounded on three sides by rows of linden-trees, on the fourth by the sea, and ornamented by the statue of Charles XIII.; the palace of the princes, the royal theater, the Hammer museum, the academy of fine arts, the academy of science with rich collections, the observatory, the national museum, and the Fersen Terrace, which offers a magnificent prospect. Ladugårdslandet contains the arsenal, the barracks, the veterinary school, the academy of arboriculture, and the Hedwig Eleonora church; the Kungsholmen, the Seraphim hospital the Carolinian institute, the garrison hospital; and close by are Mariaberg, the military high school, and Carlberg, the cadet school. In Södermalm are Mosebakken, which presents the finest view of the city, and the Catharine and Maria Magdalene churches. Södermalm and Norrmalm are connected by a railway which for boldness in construction hardly has any equal in the world. The central dépôt in Norrmalm is a fine building, and, next to the royal palace, the largest in the city. Djurgården is a very fine park of considerable size, the general resort for amusement and recreation of the city, occupying a peninsula—2 miles long and 1 mile broad—whose natural beauty has been much improved by art. Communication between the various parts of the city is generally carried on by small steamboats which traverse the waters in all directions, with fixed routes and a cheap fare. The surroundings are rich in beautiful points, palaces, and villas, of which the royal summer palace, Drottningholm, is the most noticeable. The city possesses excellent water-works. The industry is considerable, especially in manufactures of tobacco, leather, linen, and cotton fabrics, iron, sugar-refining, etc. Commerce is also considerable, though navigation is closed each year for about five months, during which the harbor is covered with ice.

The town was founded toward the end of the twelfth century by King Knut Erikson, and given the rank of city in 1255 by Birger Jarl. In 1389 it was taken by Margrethe, Queen of Denmark. On Oct. 14, 1471, the Swedes under Sten Sture defeated the Danes at Brunkeberg, close by Stockholm, and drove them out of the country; but in 1520 they again took the city under Christian II., and the Stockholm massacre took place; by the general rising which the massacre caused throughout the kingdom Gustavus Vasa succeeded in establishing himself on the throne. During the peaceful times of the nineteenth century the prosperity of the city, like that of all Sweden, has much increased. Pop. (1896) 279,860. Revised by M. W. HARRINGTON.

**Stock'mar**, CHRISTIAN FRIEDRICH: diplomatist; b. at Coburg, Aug. 22, 1787; studied medicine, and became physician and confidential adviser to Prince Leopold of Coburg, and was very active in various diplomatic negotiations. He was the intimate friend of Prince Albert and Queen Victoria; received the title of baron. D. at Coburg, July 9, 1863. The *Denkwürdigkeiten aus den Papieren des Freiherrn Christian Friedrich von Stockmar,* edited by his son (Brunswick, 1872), was translated into English, with the title *Notabilia from the Papers of Stockmar*, and contains many interesting illustrations of the interior working of English politics in its relations with the court. See Juste, *Le Baron Stockmar* (Brussels, 1873), and Catherine von Bauer's *Memoirs* (Eng. trans., 1884).

**Stockport**: town; in Cheshire, England; at the confluence of the Mersey and the Tame; 6 miles S. S. E. of Manchester (see map of England, ref. 7–G). It is irregularly built on rugged and uneven ground across a gorge spanned by a viaduct of the London and Northwestern Railway; has a number of fine modern buildings, including a market-hall and a technical school, etc. It is an important seat of the cotton industry, and has also breweries, brass-foundries, iron-foundries, machine-shops, etc. Stockport was the site of a Roman station, and afterward of a Norman castle which was destroyed during the parliamentary war. It returns two members to Parliament. Pop. (1901) 78,871.

**Stocks**: a wooden apparatus formerly much used in different parts of continental Europe and Great Britain for punishing petty offenders and vagrants. It consisted of two heavy timbers placed one above the other, with corresponding notches made in each, and so arranged that when the upper timber, which was movable, was shut down in place and fastened, holes were formed in which the ankles of the offender were secured. There were sometimes other holes for the hands, and in some cases a hole for the neck. Stocks were first introduced into England probably about the time of the Statute of Laborers, 23 Edw. III. (1350), which provided that they be erected in every town, and by subsequent statutes this punishment was inflicted for minor offenses of various kinds down to very recent times. In the U. S. they were used to punish slaves. Stocks may still be seen in some villages in England.

F. STURGES ALLEN.

**Stocks and Stock Certificates**: in the U. S., the collective name for the shares or a number of shares of a concern (usually a corporation), or the fund employed in the carrying on of its business or enterprise. In Great Britain the aggregate amount of the capital invested in a concern is called stock when it is not divided into shares, but, with certain limitations, into any such amount as a purchaser desires. In Great Britain the term stock is also applied to money lent to a government, or the fund or obligation consisting of a capital debt by the Government to individual holders who receive interest at a fixed rate. This latter kind of stock, however, is a variety of public bonds.

*Method of issuing Stock.*—A concern, to issue stock, need not necessarily be a corporation, but most of the stock in existence is issued by corporations. The capital stock of business corporations is usually divided into equal parts, called shares, the ownership of which confers a proportional right in the management of the company and to its profits, and in its assets upon dissolution. The amount of the capital itself, the number of its shares, and the par value of each are entirely arbitrary, and are fixed by the charter. The par value of shares is usually fixed at $100, and otherwise, with very few exceptions, either at $25, $50, $500, or $1,000. This matter is often regulated by statute. The ownership of shares is usually evidenced by a stock certificate issued to each stockholder, certifying in substance that he is the holder of a designated number of shares. These stock certificates are not essential to the ownership of the shares or to their transfer, but they are merely the tangible evidences of the ownership of the shares and of the rights and duties attaching to the ownership. They are repleviable, as are other physical chattels.

*Kinds of Stock or Shares.*—The stock of a corporation is frequently divided into two or more classes, with different rights and liabilities. The most common kinds are *common stock*, which is stock which entitles the owners to an equal proportionate dividend of the corporate profits and assets, with one shareholder or class of shareholders having no advantage, priority, or preference over another; and *preferred stock*, which is stock which entitles the owners to dividends out of the net profits before, or in preference to, the holders of common stock.

Other less common forms of stock are *deferred stock*, the payment of interest upon which is expressly postponed until some other class of shareholders are paid a dividend; and (under Massachusetts law) *special stock*, which is a legal statutory kind limited to two-fifths of the actual capital of the corporation, subject to redemption at par after a fixed time, and upon which the corporation is bound to pay a fixed half-yearly sum or dividend as a debt. The holders of this stock are in no event liable for debts beyond the amount of their stock.

The term *watered stock* does not designate any special class of stock issued, but is used to designate any stock issued as fully paid up when any amount less than the whole amount has been paid; that is, it is stock which purports to represent, but does not represent in good faith, money paid into the treasury of the corporation or money's worth actually contributed.

In Great Britain and France there is frequently issued a class of stock called *founders' shares*, the ownership of which entitles the holders to take the profits after certain other dividends are paid. They are a sort of deferred stock, and sometimes acquire great value. The term *scrip* is there in common use to designate a written acknowledgment by a corporation that the holder will be entitled to certain shares of stock and a certificate thereof when unpaid installments are paid. Another kind of stock issued in Great Britain and unknown in the U. S. is *debenture stock*, the issue of which is provided in the Companies Act, and which is a charge on the net earnings and profits of the corporation.

*Issue of Stock.*—It is not essential to the existence and continuance of a stock corporation that any stock certificates should be issued, but when the right is exercised it must generally be exercised for the benefit of all. The two general methods of issuing stock are (*a*) in pursuance to an agreement of subscription, and (*b*) by way of disposing of a surplus, or, as it is commonly called, by way of a stock dividend. A subscriber need not necessarily pay his subscription before he becomes entitled to his stock certificates. The issue of stock, the amount of the shares, the terms upon which it may be issued, the capitalization of the corporation, etc., are generally regulated by statute. Stock must be issued in strict conformity to the provisions of the corporation charter, and the unanimous consent of the stockholders will not validate either an over-issue of stock or reduction of the capital stock, except in strict compliance with the provisions of statutes.

*The Legal Nature of Stock as Property.*—With few exceptions, the English courts and the courts of the U. S. have held shares of stock to be personalty, and in the nature of a chose in action. Shares of stock at the common law are therefore not subject to attachment or execution; and under the English doctrine they are held not to be goods, wares, and merchandise, within the meaning of the clause of the Statute of Frauds, which requires delivery, payment, or a memorandum in writing to make valid a contract for the sale thereof. The contrary doctrine is held in the U. S.

*Transfer of Stock.*—The right of transferring stock is incidental to its ownership; and, although the officers of a corporation can not take away the right of reasonable transfer, they may make reasonable regulations governing it. The mode in general use, and often prescribed by statute, is as follows: A book is kept by some designated officer, in which is registered each certificate of shares, and the name of the person to whom it is issued. In order to complete a legal transfer, the holder of the certificate must surrender it up to this officer, who thereupon issues a new one for a like amount to the assignee, and registers it in the transfer-book, and cancels the old record. To obviate the necessity of the personal appearance of the assignor to surrender his certificate, it is the universal practice to print upon the back of the certificate a power of attorney to be signed by the assignor, constituting the assignee an agent to make the surrender, and perform such other acts as may be necessary to procure the cancellation and receive a new certificate. This power of attorney is often made out with a blank left for the name of the agent, and the instrument signed or indorsed in this form is passed from hand to hand through many successive owners, until some one inserts his own name, surrenders the certificate, and takes a new one.

Most corporations require, either in their charters or by-laws, that stock shall be transferable only on the books of the company. It is generally settled that a transfer otherwise regular but not registered as required is valid, and passes the interest of the transferrer as between the parties. Where the rights of third parties are involved, the decisions vary as to the effect of the transfer. Except in a few cases, as where the transferrer is indebted to the corporation and holds stock which is subject to a lien, or where no surrender has been made of the certificate, a corporation can not refuse to register a transfer of the stock upon the demand of the proper party; and in case of refusal, the registration of transfer may be enforced by either of several remedies—an action in equity; according to the same authorities, mandamus to compel registration; and an action at law for damages.

In the case of forged transfers, a corporation is liable to the real owner, and must make good any loss which he has suffered, and the same is true in various other cases, where the facts of the case are such as to charge the corporation with notice of the equity of the real owner.

*Negotiability of Stock Certificates.*—Stock certificates are not, strictly speaking, negotiable instruments; but they are practically treated in great financial centers as though they possessed the quality of negotiability. They are pledged as well as sold, and are thus used to a very great extent as collateral security for loans. Although the by-laws of a corporation may require a surrender, cancellation, and re-issue to complete a transfer and to create a perfect legal title, in the U. S. the doctrine of estoppel is applied to such an extent as to protect a *bona-fide* purchaser of stock, in almost every instance, where he would be protected if he were purchasing a promissory note or other negotiable instrument; and the courts are constantly extending this application of the law of estoppel.

In Great Britain an entirely different rule prevails, and certificates of stock there are mere evidences of ownership of stock, and are not negotiable or quasi-negotiable. The purchaser is not protected against equities involved in the title of prior owners of the certificate, and can shut them off only by a transfer on the books of the company; and this rule is applied to certificates of stock issued by U. S. corporations and held by British subjects.

In the U. S., if the holder of a certificate signs a power of attorney in blank, then delivers the certificate into the possession of some person for a specific purpose, as for safe-keeping, and this person in violation of his duties fills up the blank and fraudulently surrenders the certificate, and procures another one to be issued to a *bona-fide* purchaser, it is very generally held that the real owner would be estopped by his act of indorsing in blank from setting up a claim against a *bona-fide* purchaser. In this way the substantial benefits of negotiability are secured.

For further information, see Cook on *Stocks and Stockholders.* F. STURGES ALLEN.

**Stockton**: city; capital of San Joaquin co., Cal.; at the head of Stockton channel, which connects it with the San Joaquin river, and on the Southern Pac. Railroad; 50 miles S. by E. of Sacramento, the State capital, and 100 E. by N. of San Francisco (for location, see map of California, ref. 7–D). The entire San Joaquin valley, the richest and most prolific section of country in the world, 300 miles long and 100 miles wide, with its numerous cities and towns, is tributary to the city as a commercial and shipping point. Stockton is well laid out; has paved streets, four public squares, embellished with semi-tropical plants and flowers, excellent transportation facilities by rail and water, electric street-railway, gas and electric lights, thorough sewerage, and a water-supply from artesian wells; and contains 20 natural gas-wells, with a daily flow of over 500,000 cubic feet. The average temperature is 40° in winter and 75° in summer, and the death-rate is the lowest in the State. The public buildings include a granite court-house, which cost $300,000; the Hazleton Public Library, of marble, cost $65,000; the State Insane Asylum, which cost $600,000; and the county jail.

*Churches and Schools.*—The principal religious denominations are represented by substantial church edifices. The public-school system has a high school and 12 grammar-school buildings, property valued at about $270,000, enrollment about 3,000, and annual expenses over $67,000. St. Agnes's convent and St. Joseph's Primary School, under the Sisters of St. Dominic, are model institutions, with buildings and grounds covering an area of three blocks. There are also a business college and normal institute and several private schools of high grade.

*Finances and Banking.*—The annual revenue is about $245,000; tax-rate, $1.75 per 100; bonded indebtedness, $370,000. There are 5 banks: the First National, with capital and surplus of $436,000; Farmers' and Merchants', $400,000; Stockton Savings, capital and reserve $475,000; Stockton Savings and Loan Society, capital $500,000, deposits $1,600,000; and San Joaquin Valley, capital and surplus $250,000.

*Business Interests.*—Stockton is an important manufacturing city, containing extensive flour, woolen, lumber, and paper mills, agricultural-implement works, foundries, shipyards, machine-shops, and terra-cotta works. It is the wheat center of the State and one of the principal wheat-markets on the Pacific coast.

*History.*—The city was laid out in 1849 by Charles M. Weber, who owned a large tract of land under a Mexican grant; first became important as a point of departure for gold-mining parties, and has since prospered as a commercial and wheat-distributing center. Pop. (1880) 10,282; (1890) 14,424; (1900) 17,506. J. M. REUCK.

**Stockton**, ALFRED AUGUSTUS, Q. C., LL. D.: Canadian publicist; b. at Stockholm, King's County, New Brunswick, Nov. 2, 1842; graduated at Mt. Allison College in 1864; admitted to the bar in 1868. He is an examiner in arts in Mt. Allison College, an examiner in law at Victoria University, president of the New Brunswick Historical Society, and registrar of the court of vice-admiralty of New Brunswick. He has been a member of the New Brunswick House of Assembly since Aug. 23, 1883. He has edited, with copious notes, Berton's *Reports of the Supreme Court of New Brunswick.* NEIL MACDONALD.

**Stockton**, FRANCIS RICHARD: humorist; b. in Philadelphia, Apr. 5, 1834. After graduating from the Philadelphia high school, he applied himself to wood-engraving and to literature, contributing illustrations to *Vanity Fair* and other periodicals, and issuing a number of stories for children, such as *The Ting-a-Ling Stories* (1869); *Tales Out of School* (1875), etc. He was employed successively upon the Philadelphia *Post*, the New York *Hearth and Home* (1872), *Scribner's Monthly* (afterward *The Century Magazine*), and *St. Nicholas* (1873). The first of his books to attract general notice to him, as a humorist of a new and original vein, was *Rudder Grange* (1879). This was followed by *The Lady or the Tiger?* (1884); *The Late Mrs. Null* (1886); *The Casting Away of Mrs. Lecks and Mrs. Aleshine* (1886); *The Dusantes* (1888); *The Merry Chanter* (1890); and many others. H. A. BEERS.

**Stockton**, RICHARD: jurist; b. near Princeton, N. J., Oct. 1, 1730; graduated at the College of New Jersey in 1748; admitted to the bar in 1754; became member of the executive council in 1768, and judge of the Supreme Court of the province of New Jersey in 1774. He attempted to effect a reconciliation between the colonies and Great Britain, and to this end submitted to Lord Dartmouth in 1774 "an expedient for the Settlement of the American Disputes," in which he proposed a plan of self-government for the colonies; but in 1776 he was chosen a delegate to the Continental Congress, and was one of the signers of the Declaration of Independence. In Nov., 1776, he was captured by a party of royalists, who threw him into prison in New York, where he was treated with great severity; his library was destroyed, and his lands laid waste; he was finally exchanged, but never fully recovered from the effects of the ill usage which he had received. D. at his home near Princeton, Feb. 28, 1781. In 1888 his statue was placed by the State of New Jersey in the Capitol at Washington.

**Stockton**, Robert Field: naval officer; son of Richard (1764–1828), jurist and U. S. Senator; b. at Princeton, N. J., Aug. 20, 1795; studied at the College of New Jersey, but left to enter the navy as a midshipman Sept. 1, 1811; became a lieutenant 1814; negotiated in 1821 the purchase from African native chiefs of the territory constituting the republic of Liberia; took part in the extermination of piracy in the West Indies; surveyed the Atlantic coast of the Southern States 1823–24; became commander 1830 and post-captain Dec. 8, 1838; was flag-officer of the Ohio in the Mediterranean 1838–39; declined the secretaryship of the navy 1841; was an early advocate of a steam navy; superintended the construction of the sloop Princeton, the first successful war-steamship, 1842; was chosen to carry to Texas the resolution of annexation 1845; proceeded to the Pacific as commodore of the U. S. squadron on the coast of California Oct., 1845; took possession of California for the U. S. Government, and formed a provisional government 1846; resigned from the navy May 28, 1850; was U. S. Senator 1851–53; was nominated in 1856 for the presidency by the newly formed "American party," but the ticket was withdrawn before the day of election. D. at Princeton, Oct. 7, 1866. See his *Life, Speeches, and Letters* (1856).

**Stockton-on-Tees**: town; in the county of Durham, England; on the left bank of the Tees, 4 miles from its mouth, 11 miles E. N. E. of Darlington (see map of England, ref. 5–H). A new town which has sprung up on the right bank of the river is known as South Stockton, the two being connected by an iron bridge of three arches built in 1887. The Tees is navigable for vessels of large tonnage up to the town, and the navigation of the river has been much improved. The town is well built, and has flour-mills and spinning-mills, breweries, blast furnaces, foundries, engine-works, and building-yards for iron ships, and carries on a considerable trade in wheat, coal, iron, and timber. The Stockton and Darlington Railway, opened Sept. 27, 1825, was the first railway to begin passenger traffic. Pop. of the parliamentary borough, returning one member, (1891) 68,895.

**Stoddard**, Charles Augustus, D. D.: editor; b. in Boston, Mass., May 28, 1833; educated at Williams College, New Church College, Edinburgh, Scotland, and Union Theological Seminary; pastor of Washington Heights church, New York, 1859–83; and since 1883 editor of *The New York Observer*. Dr. Stoddard has published *Across Russia* (New York, 1891); *Spanish Cities* (1892); *Beyond the Rockies* (1894); and many sermons and pamphlets. C. K. H.

**Stoddard**, Charles Warren: poet and traveler; b. at Rochester, N. Y., Aug. 7, 1843; educated at New York and California. In 1864 he visited the Hawaiian archipelago, where he has since resided at various times, and to which his writings largely relate. These include *Poems* (1867); *South Sea Idyls* (1873); *Mashallah: a Flight into Egypt* (1881); and *The Lepers of Molokai* (1885). In 1873–78 he traveled extensively as foreign correspondent of *The San Francisco Chronicle*. In 1885–86 he was Professor of English Literature at the University of Notre Dame, Indiana, and subsequently lecturer on English literature at the Catholic University of Washington, D. C. H. A. Beers.

**Stoddard**, Richard Henry: journalist and poet; b. at Hingham, Mass., July 2, 1825; was taken to New York when a child; attended the public schools of that city; became a mechanic in an iron-foundry; contributed poems to various periodicals, and in 1849 privately printed *Footprints*, a small volume of poems, followed in 1852 by a larger volume. From 1853 to 1873 he held appointments in the New York custom-house and dock department; was literary editor of *The New York World* in 1860–70, and in 1880 became literary editor of the New York *Mail and Express*. Besides numerous contributions in prose and verse to periodicals, he has published *Adventures in Fairy Land* (1853); *Songs of Summer* (1856); *Town and Country* (1857); *Life, Travels, and Books of Alexander von Humboldt* (1860); *The King's Bell* (1862); *Little Red Riding Hood*, in verse (1865); *The Children in the Wood*, in verse (1865); *Abraham Lincoln, a Horatian Ode* (1865); *Putnam the Brave* (1869); *The Book of the East* (1871); *Poems* (1880); and *The Lion's Cub*, poems (1890). He has also edited many volumes. See Stedman's *Poets of America*, pp. 57–59.

**Stoddard**, William Osborn: See the Appendix.

**Stoeckel**, Gustav J.: See the Appendix.

**Stoe'ver**, Martin Luther, Ph. D., LL. D.: educator and editor; b. at Germantown, Pa., Feb. 17, 1820; graduated at Pennsylvania College, Gettysburg, 1838; was tutor in Pennsylvania College 1839–40, afterward principal of its preparatory department, and Professor of Latin, History, and Political Economy until his death July 22, 1870. He was for many years secretary of the General Synod of the Lutheran Church and editor of *The Evangelical Quarterly Review*, in which he published an interesting series of *Reminiscences of Lutheran Ministers*; edited *The Literary Record* (1847–48); wrote biographies of Dr. Henry M. Muhlenberg (1856) and of Dr. Philip F. Mayer (1859), and a *Brief Sketch of the Lutheran Church in the United States* (1860), and had made extensive preparations for a fuller history of the same subject. Revised by H. E. Jacobs.

**Sto'ics** [from Lat. *Sto'icus* = Gr. Στωικός, liter., belonging to the Porch, deriv. of Στοά Ποικίλη, the Painted Porch at Athens in which the Stoics were wont to gather]: an ancient philosophic school founded about 310 B. C. by Zeno of Citium in Cyprus (flourished about 350–258). He numbered among his immediate disciples Persæus of Citium, Ariston of Chios, Herillus of Carthage, and Cleanthes of Assos, who succeeded his master. Cleanthes was succeeded by Chrysippus of Soloi, who reduced the Stoic doctrines to something like a system, and he by Zeno of Tarsus. Other celebrated Greek Stoics were Diogenes of Babylon, Antipatrus of Tarsus, Panætius of Rhodes, and Posidonius of Apamea. Owing mainly to Panætius, Stoicism found numerous disciples among the Roman nobility, and for centuries exercised a great and good influence upon the stronger minds of the empire. Among the Roman Stoics may be mentioned Q. Mucius Scævola, L. Annæus Cornutus, A. Persius Flaccus, L. Annæus Seneca, C. Musonius Rufus, Epictetus, and the Emperor Marcus Aurelius.

Stoicism was an offshoot from Cynicism, Zeno having been at first a disciple of Crates the Cynic; but it dropped some of the most objectionable elements of Cynicism, and became a civilized philosophy. It was divided by its adherents into three parts—logic, ethics, physics—of which the last was held to be most important, although the second received by far the most attention. Indeed Stoicism, like all the post-Aristotelian philosophies of antiquity, was essentially ethical.

(A) Under *logic* the Stoics included dialectic and rhetoric, the former of which was in reality a theory of cognition. They attached great importance to what they called a criterion of truth, although they were never able to fix upon any that would satisfy them as absolute. Their theory of sense-perception was essentially the same as that of Locke, the sentient soul being considered as a *tabula rasa*, impressed or otherwise affected by external objects. Perception was followed by memory and conception. Their highest concepts (τὰ γενικώτατα), by which they replaced Aristotle's ten categories, were (Trendelenburg, *Kategorienlehre*, p. 220, *seq.*)—

1. Ὑποκείμενα....................substrata.
2. " ποιά.................... " qualified (essentially).
3. " " πως ἔχοντα....... " " accidentally.
4. " " " " πρός τι. " " " thro' relation.

The Stoics, in the matter of general terms, were nominalists, or, more strictly, conceptualists. Under *dialectic* they included grammar, in the development of which they did some very good work. See Lersch, *Die Sprachphilosophie der Alten*, pt. ii., pp. 25, *seq.*; Steinthal, *Gesch. der Sprachw. bei den Griechen u. Römern*, pp. 277–363.

(B) Under *physics* the Stoics included theology. They replaced Aristotle's quaternity of cause by a duality, viz., force and matter, inseparable, and conceived very much as they are by modern physicists. Everything, even God, contains both. Their physical theory was in the main that of Heraclitus (*q. v.*), even down to the notion of a periodical ἐκπύρωσις or return of the universe to primeval fire. At the base of all lies necessity or providence—a tenet perhaps borrowed from Empedocles (περὶ φύσεως, line 1). With periodical conflagration, individual immortality (resurrection of the body) was of course incompatible. The individual, a mere temporary emanation, returns at last to his source.

(C) In their *ethics* the Stoics, if not what is now called altruistic, were essentially unselfish—that is, they rigidly maintained that the end of life was virtue for virtue's sake. What virtue was they found it difficult to define, their "living agreeably to nature" being very vague, not to say that they sometimes made nature mean human nature, sometimes universal nature. Man exists for society, for only in that is virtue possible. Virtue is sufficient for happiness; and pleasure, which naturally accompanies activity, is not to be sought for its own sake. The cardinal virtues are practical wisdom, courage, self-restraint, and justice (φρόνησις, ἀνδρία, σωφροσύνη, δικαιοσύνη), and it requires the possession of them all to constitute the truly wise man, who is free and the equal of Jupiter himself. The Stoics drew a broad distinction between acts and motives, and made the moral quality of acts depend entirely upon motives. Man shall do that which is good independently of surrounding influences and circumstances, and, having done that which is good, he shall feel happy independently of the sufferings and misery which may result from his acts. Of the works of the Stoics only fragments remain, the most important of which is Cleanthes's splendid *Hymn to Zeus*, of which there is an English rendering in Francis Newman's *The Soul, its Sorrows and Aspirations*, and another in *The Radical* (Boston, 1867). The best and most complete presentation of the Stoic philosophy is in Zeller's *Philosophie der Griechen* (vol. iv., pp. 26–340). English translation, *The Stoics, Epicureans, and Skeptics* (London, 1869). See also Ravaisson, *Essai sur le Stoicisme* (Paris, 1856); W. W. Capes, *Stoicism* (London, 1880); H. W. Benn, *The Great Philosophers* (2 vols., London, 1882).

Thomas Davidson.

**Stokes**, Sir George Gabriel, F. R. S.: mathematician and physicist; b. at Skreen, Sligo, Ireland, Aug. 13, 1819; educated at Bristol College; graduated 1841 as senior wrangler at Cambridge, and was elected to a fellowship in Pembroke College; and in 1849 was elected Lucasian Professor of Mathematics in that university; was elected to the Royal Society in 1851, and was awarded the Rumford medal of that society 1852; was secretary 1854–85, and was president 1885–90. From 1886 to 1893 he was member of Parliament for Cambridge, and in 1889 he was made a baronet. He contributed a report on hydrodynamics to the British Association in 1846, and several memoirs to the *Philosophical Transactions* on the dynamical theory of diffraction and the theory of fluorescence and phosphorescence, and has written papers in several scientific journals. In 1884–86 he delivered popular lectures on light at Aberdeen, which were published in 3 vols. (1887). His mathematical and physical papers have been reprinted (2 vols., 1880–83).

**Stokes**, Henry Newlin: See the Appendix.

**Stokes**, Whitley: Celtic scholar; b. in Dublin, Ireland, Feb. 28, 1830; educated at Trinity College, Dublin; barrister in London; barrister in Madras 1862; connected with the law department of the Government of India 1864–82, rendering important service in the codification of the Anglo-Indian laws. His chief activity has been in the field of Celtic philology, where he is a scholar of great accuracy and wide acquaintance with the materials involved. He is the author of *Irish Glosses* (1860); *The Play of the Sacrament, a Middle English Drama* (1862); *Three Irish Glossaries* (1862); *Gwreans an Bys, the Creation of the World, a Cornish Mystery, with a Translation and Notes* (1864); *The Indian Succession Act* (1865); *Hindu Law-books, edited with Notes and an Index* (Madras, 1865); *A Cornish Glossary* (1870); *Goidelica* (2d ed. 1872); *The Old Welsh Glosses on Martianus Capella* (1872); *Life of St. Meriasek, a Cornish Drama* (1872); *Three Middle Irish Homilies* (1877); *On the Calendar of Oengus* (1880); *Togail Troy* (1881); *The Anglo-Indian Codes*, editor (2 vols., 1887–88); *Urkeltischer Sprachschatz*, in vol. ii. of Fick's *Vergl. Wörterb.* (1894).

Revised by Benj. Ide Wheeler.

**Stokes' Law**: See Fluorescence.

**Stoke-upon-Trent**: town; in Staffordshire, England; on the Trent; 16 miles N. of Stafford (see map of England, ref. 8–G). It is the capital of the Potteries district, producing earthenware, porcelain, encaustic tiles and pavements. Coal-mining and brick-making are also carried on, and engines, machinery, etc., are manufactured. Pop. of the parliamentary borough, returning one member, (1891) 75,352.

**Stolz**, stōlts, Friedrich: philologist; b. at Hall, in the Austrian Tyrol, July 29, 1850; studied at the gymnasiums of Hall and Innsbruck, and at the Universities of Innsbruck and Leipzig; teacher successively in the gymnasiums of Görz, Klagenfurt, and Innsbruck; since 1887 professor in the University of Innsbruck. He is the author of *Die zusammengesetzten Nomina in den homerischen und hesiodischen Gedichten* (1874); *Die lateinische Nominalcomposition in formaler Hinsicht* (1877); *Beiträge zur Declination der griech. Nomina* (1880); *Studien zur lateinischen Verbalflexion* (1882); *Lateinische Laut- und Formenlehre* in Müller's *Handbuch der Alterthumswissenschaft* (1885; 2d ed. 1889); *Die Urbevölkerung von Tirol* (1886; 2d ed. 1892); *Historische Grammatik der lateinischen Sprache*, vol. i., *Einleitung, Lautlehre, und Stammbildungslehre* (1894).

Benj. Ide Wheeler.

**Stomach** [from Lat. *sto'machus* = Gr. στόμαχος, throat, gullet, stomach, deriv. of στόμα, mouth]: the chief organ of digestion; the expansion of the anterior portion of the alimentary canal for the reception of food, its disintegration and solution, and the digestion of albuminoid matter. The stomach is situated on the left side of the body, below the diaphragm, behind and beneath the free ribs. Its lower extremity extends across the median line. It is a membranous bag or sac, capable of great distension by food and gas, but often flaccid and collapsed when empty. When full it is 12 inches long and 4 high. The stomach receives food from the œsophagus through its upper or cardiac (Gr. καρδία, the heart) orifice, so termed because adjacent to the heart. The body of the stomach is beneath the ribs on the left side, and is termed the *fundus, cul de sac*, or *great pouch*. The *greater curvature* of the stomach is the lower, convex surface; the *lesser curvature* is concave and above. Food leaves the stomach through its lower orifice, the *pylorus* (Gr. πυλωρός, from πύλη, a gate), and enters the duodenum, the first section of the small intestine. The stomach has four coats: (1) The external serous layer, a reflection of the peritoneum, covering it at all points except the entrance of the nutrient vessels and nerves in the great and small curves. (2) The muscular layer, which has three separate sets of fibers—the longitudinal, the circular, and the oblique. These muscular bands, acting in different directions, propel the contained food from side to side of the cavity, aiding in its chemical disintegration by thorough admixture with gastric juice. This spiral movement is termed *vermicular* (worm-like), and also *peristaltic* (Gr. περιστέλλειν, to surround or wrap up). (3) The cellular coat, consisting of loose areolar tissue, connects the muscular to the internal mucous coat. It is called also the sub-mucous coat and the vascular coat, as it contains the blood-vessels which supply the elaborate capillaries beneath the secreting glands of the mucous membrane. (4) The mucous coat is thick, especially at the lower or pyloric end, presents large longitudinal folds when the stomach is but partially filled or empty, which disappear when it is distended. Closely inspected, the mucous surface is found to

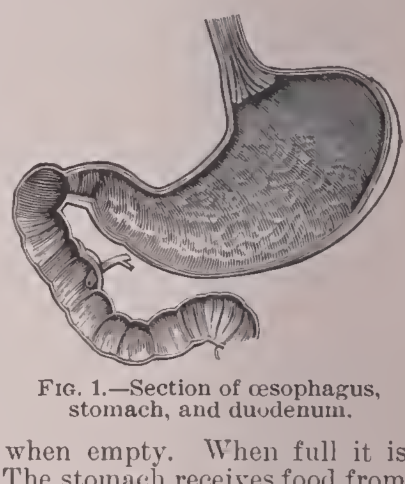

Fig. 1.—Section of œsophagus, stomach, and duodenum.

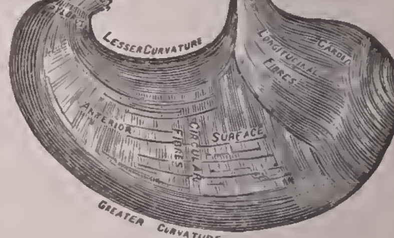

Fig. 2.—The muscular coat of the stomach.

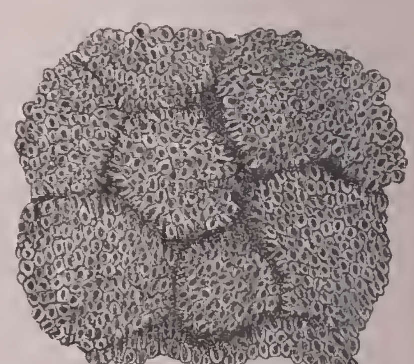

Fig. 3.—The mucous membrane of the stomach, orifices of the glands; magnified 20 diameters (*Sappey*).

be perforated by innumerable closely aggregated orifices of the gastric tubules. These are of two kinds: (1) the peptic glands situated in the cardiac and central parts of the organ, and (2) the pyloric situated at the pyloric end. The stomach is constantly lubricated by secreted mucus, which may become excessive in digestive disorders. Gastric juice is chiefly secreted after the ingestion of food. (See DIGESTION.) The stomach is intimately related to important adjacent viscera by both vascular and nerve connections. Its main artery, the gastric, springs from a common root with the hepatic and splenic arteries, and it also receives two branches of each of them. By branches of the sympathetic nervous system its functional activity is influenced by the health of each organ and part of the body; it receives the terminal branches of the pneumogastric nerve, which gives off branches controlling the action of the heart, lungs, and in a measure the larynx and pharynx. It is by these connections that gastric indigestion may cause palpitation of the heart, difficult and sighing breathing, irritability of the larynx, and hoarseness, and by reflex influence many morbid sensations in various parts of the body.

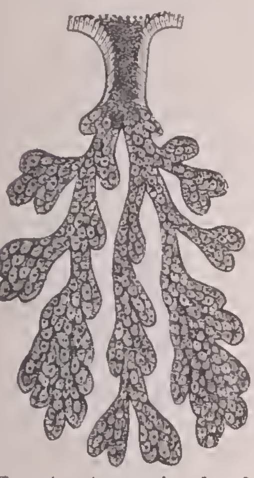

FIG. 4.—A peptic gland, magnified 100 diameters (*Sappey*).

The most frequent diseases of the stomach are its functional disorders. (See DYSPEPSIA.) In addition to these milder and chronic conditions, the stomach is liable to acute and organic disease. Acute inflammation or gastritis is of rare occurrence, the result of violent mechanical or chemical irritation, swallowing corrosive poisons or putrid and acrid food. It is characterized by violent ejection of all food, gastric mucus, traces of blood and bile, by sense of local burning pain, feeble pulse, cold extremities, and collapse. Perforating ulcer of the stomach is a not infrequent disease in young women of anæmic character. The symptoms are pain in the stomach upon reception of food, its rejection, and occasional hæmorrhage when the ulcerative process has eroded a blood-vessel. Hæmorrhage from the stomach is termed *hæmatemesis*, and must be carefully discriminated from *hæmoptysis*, the spitting of blood from the lungs. Cancer of the stomach is a relatively common affection of old persons, particularly of the male sex. It often occurs in persons of cancerous family history, in others with no hereditary taint. When at the pylorus, food is detained in the stomach, and after a time is ejected in great quantity, mixed with mucus, blood, and many fungous products of fermentation. There is a local darting pain, and often a local indurated tumor felt at the epigastrium through the emaciated abdominal wall; the face is cachectic, the body wasted, strength fails, death comes by exhaustion. Extreme neuralgia of the stomach—gastralgia or gastro-dynia—may occur, dependent on deranged nerve-centers or rheumatic or gouty vice of the blood.

Revised by W. PEPPER.

**Stomach-pump**: a form of syringe which has a flexible tube, designed to be passed down the œsophagus into the stomach, after which water is injected through it into the stomach and then withdrawn by reversing the action of the syringe. The operation may be repeated until the stomach is thoroughly washed clear of its contents. The instrument is especially useful in removing poisons from the stomach. In case of insane persons, or where some disease of the mouth or œsophagus exists, artificial feeding is required, and is usually accomplished with a simple rubber tube. The same is used in the treatment of diseases of the stomach for the purpose of washing out that organ.

Revised by W. PEPPER.

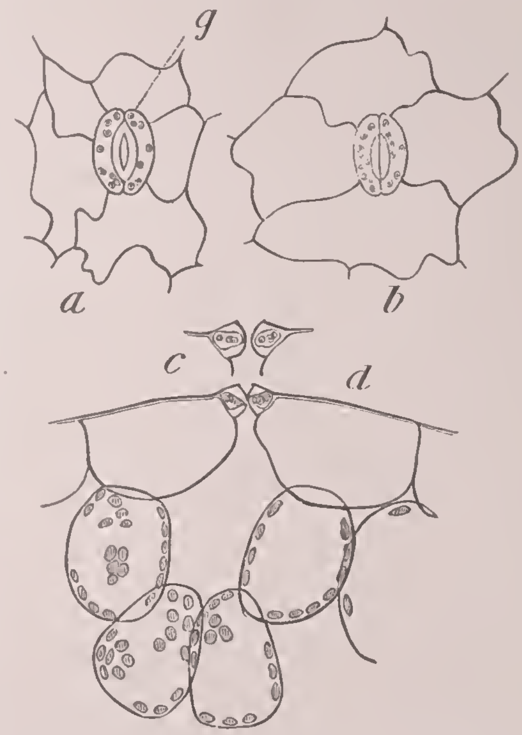
**Stomap'oda, Stom'apod**, or **Stomatop'oda** [Mod. Lat.; Gr. στόμα, στόματος, mouth + πούς, ποδός, foot]: a group of malacostracous crustaceans, embracing about sixty species of marine forms with elongate loose-jointed bodies. The carapax is small, having the last three thoracic rings free; the stalked eyes have a distinct ring; five pairs of feet are modified for maxillipeds, the second of these forming a strong pincer; and three pairs of thoracic feet, each of which is two-branched. The gills are borne on the abdominal feet. These characters mark the group off strongly from all other forms. They further differ from most crustaceans in that they deposit the eggs in their burrows. The young, though large, are thin and transparent, and were long regarded as

Mantis shrimp.

belonging to different forms. The species, which are known as Mantis shrimps, and which belong to the single family *Squillidæ*, are all inhabitants of the warmer seas, a single species occurring as far north as Massachusetts. See Miers, *Ann. and Mag. Nat. Hist.* (1880); Brooks, *Challenger Expedition.*

J. S. KINGSLEY.

**Sto'mate** [from Gr. στόμα, mouth]: a breathing-pore in the epidermis of plants, consisting of two elongated, somewhat curved cells, the guard-cells (*g* in figure), between which is a definite opening. When the guard-cells curve away from one another, as they do when the atmosphere is moist, the slit between them is opened, permitting the free ingress and egress of gases. The stomates are always placed over intercellular spaces of the underlying tissues, an arrangement which permits an interchange of gases throughout the plant.



Stomates of beet: *a*, top view, open; *g*, guard-cell; *b*, same closed; *c*, vertical transverse section, open; *d*, same closed, highly magnified.

Stomates are found in some liverworts, where they are curious chimney-like structures, but in the nearly related mosses (where they are confined to the capsules) they have essentially the same structure as in the flowering plants. In the fernworts they occur on the leaves and stems, and do not differ in any essential respect from those in the flowering plants. They rarely occur on submerged parts of plants, and in leaves which lie upon the surface of the water they are confined to the upper side. In ordinary leaves they are usually more abundant upon the lower side. In some, as in the compass-plants, they are about equally abundant upon both sides. The number of stomates on leaves varies very greatly. Weiss determined the number per square millimeter for the leaves of many species, and published the results in Pringsheim's *Jahrbücher für wissenschaftliche Botanik* (1865). A few of these are given below:

Olive (*Olea europea*), 625; hackberry (*Celtis occidentalis*), 616; black walnut (*Juglans nigra*), 461; lilac (*Syringa vulgaris*), 330; barberry (*Berberis vulgaris*), 229; golden currant (*Ribes aureum*), 145. In the foregoing, stomates occur on the upper side only; in the following they occur on both sides: sunflower (*Helianthus annuus*), upper, 175, lower, 325; cabbage (*Brassica oleracea*), u. 219, l. 301; pea (*Pisum sativum*), u. 101, l. 216; Indian corn (*Zea mays*), u. 94, l. 158; cottonwood (*Populus monilifera*), u. 89, l. 131; oats (*Avena sativa*), u. 48, l. 27.

In the development of stomates an epidermal cell undergoes division, usually into two unequal portions, and the smaller part is again divided in like manner. This may occur a third or even fourth time, when a last division into two equal parts (the guard-cells) takes place. These soon become somewhat rounded and separate at the center by the splitting of the partition between them.

CHARLES E. BESSEY.

**Stomati'tis**: See MOUTH, DISEASES OF THE.

**Stomatopoda**: See STOMAPODA.

**Stomiat'idæ** [Mod. Lat., named from *Sto'mias*, the typical genus, from Gr. στομίας, having a large mouth, deriv. of στόμα, mouth]: a family of isospondylous fishes. The species are elongated and of a club-shaped form, tapering from before backward; the skin is naked, or covered with very thin and readily deciduous scales; opercular apparatus imperfectly developed and very oblique; mouth with a very deep lateral cleft; upper jaw with its margin formed by the supramaxillary as well as intermaxillary bones; teeth on the jaws acute, and often barbed; gill openings very deep and continuous below; branchiostegal rays numerous (twelve to seventeen); anal fin very far behind and small; caudal distinct; pectoral fins low down on the scapular arch, and narrow; ventral fins inserted far backward. The ovaries have oviducts, and consequently the eggs are discharged directly through them into the water. The family is composed of a few species, which are rather small (all being considerably less than a foot in length), and inhabitants of the open sea and deep water.

**Stone** [O. Eng. *stān*: O. H. Germ. *stein* (> Mod. Germ. *stein*): Goth. *stains*; cf. O. Bulg. *stěna*, wall, and Gr. στία, στῖον, pebble]: in engineering, either natural or artificial rock suitable for use in foundations, walls, and piers. The natural sandstones, limestones, and granites furnish the greater part of all stone used in architecture and engineering. The essential qualities of a rock which renders it a good building-stone are strength and durability, while beauty and cheapness are desirable. The Egyptians quarried many very large stones for obelisks and for use in their temples, while from the earliest times stone-cutting has been a well-understood art. The cutting of dimension stones in the quarry by means of channeling-machines, introduced about 1870, has materially lowered the cost of many varieties of natural stone. See BUILDING-STONE for an account of the properties and methods of testing natural stone, and MASONRY for a description of the manner in which stones are laid together in buildings and engineering constructions.

Artificial stone consists of blocks or monolithic masses formed of materials which cement together. It is a combination of hydraulic cement, sand, crushed stone, pebbles, etc. Some varieties are of great value in districts where durable and cheap building-stone is not supplied by nature. The strength and durability of all varieties of artificial stone vary directly with the ultimate strength and hardness attainable by the hydraulic ingredients employed. An obvious means of improving their quality, therefore, is the employment of the highest grades of cement. Artificial stone may be made into blocks to be used as cut stone, or it may be built up into immense masses of any desired shape by moulding the different parts in place. The more important artificial stones are briefly described below. Most of these bear the names of their inventors.

CONCRETE (*q. v.*) is composed of hydraulic cement, sand, and broken stone or pebbles, and is much used in engineering construction. *Granolithic* is a trade-name for a combination of hydraulic cement and crushed granite (a granitic concrete), frequently employed for sidewalks and curbs, and for floors in stables, cellars, breweries, etc. *Béton-Coignet* is a combination of hydraulic cement, hydraulic lime, and sand, much used in France. The peculiarities are the substitution of hydraulic lime instead of part of the more expensive and stronger cement, and the small quantity of water used, and the thoroughness of the mixing. *Portland stone* is a name frequently given to a mixture of Portland cement and sand. The term Portland as applied to the stone, and also as applied to the cement of which it is made, was derived from the similarity of the artificial stone to the natural stone derived from the island of Portland, off the south coast of England. *McMurtrie stone* consists essentially of the Portland stone described above, in the pores of which are formed compounds of alumina with the fatty acids by the double decomposition of alum and a potash soap. The peculiar merit of this stone is that its power of absorbing water is decreased by the use of the alum and the soap. Absorbed water dissolves the salts of magnesia, lime, soda, and potash (of all of which there is always more or less in cement), and on evaporating leaves a white efflorescence on the surface which injures the appearance of the wall. For this reason the ordinary artificial stones are in disfavor for architectural purposes. The McMurtrie stone has been used in Washington, D. C., to a limited extent, the window-trimmings of the National Museum and also the fronts of a few stores and dwellings being of this stone. *Frear stone* is composed of sand and Portland cement, to which gum shell-lac is added. The shell-lac adds to the early strength of the stone, but it is not certain that it adds to the ultimate strength. It was for a time much used in architectural work in the western parts of the U. S., but did not give satisfaction. *Ransome stone* is made by forming in the interstices of sand, gravel, or any pulverized stone a hard and insoluble cementing substance, by the natural decomposition of two compounds in solution. Sand and the silicate of soda are mixed in the proportion of a gallon of the latter to a bushel of the former and rammed into moulds. At this stage of the process the blocks or slabs may be easily cut into any desired form. They are then immersed, under pressure, in a hot solution of chloride of calcium, after which they are thoroughly drenched with cold water to wash out the chloride of sodium formed during the operation. In Great Britain grind-stones are frequently made by this process. *Sorel stone* has as its basis a cement formed by adding a solution of chloride of magnesium to the oxide of magnesium. The strength of this stone as well as its hardness exceeds that of any other artificial stone yet produced. This process was formerly used in making emery-wheels. Owing to the great strength of the cement only a comparatively small proportion is required. *Medusaline* is an artificial stone combining the peculiarities of the McMurtrie and Sorel processes. In one variety the inert material is sawdust and the product is used as fire-proofing.

IRA O. BAKER.

**Stone**: in Great Britain, legally a weight of 14 lb. avoirdupois; but other stones are in use, such as 24 lb. of wool and 8 of butcher's meat. In other European countries there are weights called stone differing in pounds avoirdupois, and chiefly employed for weighing wool, hemp, flax, and feathers, the stone for flax containing twice as many pounds as the one used for wool or feathers. In all the principal commercial states of Germany the stone (of flax) is the fifth of a hundredweight (centner = 100 or 112 lb.)—i. e. 20 lb. in Prussia and the Zollverein, Hamburg, Lübeck, and Bremen, 22 lb. in Austria, while in Sweden it is equivalent to 32 lb. The origin of this peculiar method of weight-measuring is rather obscure, and still more so is that of the different forms into which it has branched.

**Stone** (in pathology): See CALCULUS.

**Stone**, CHARLES POMEROY: soldier; b. at Greenfield, Mass., Sept. 30, 1824; graduated at the U. S. Military Academy in 1845; appointed a brevet second lieutenant of ordnance; served in the war with Mexico, and was breveted captain; constructed the arsenal at Benicia, Cal., and performed the duties of chief of ordnance of the division of the Pacific 1851–56; engaged in the banking business for a year in San Francisco; in 1857 was appointed by the Mexican Government chief of a commission to survey and explore its lands in Sonora and Lower California; was appointed Jan. 1, 1861, to organize and drill the District of Columbia militia for defense of the capital. Appointed colonel of the Fourteenth U. S. Infantry May 14, and a brigadier-general of volunteers May 17, he served under Gen. Patterson during the latter's operations in the Shenandoah in July. In Feb., 1862, he was placed in confinement in Fort Lafayette, New York harbor, and held until Aug. 9, when released, not only without charges being preferred against him, but without explanation of the cause of his arrest. In 1863 he served in the department of the Gulf; in 1863–64 was chief of staff to Gen. Banks; mustered out of volunteer service Apr. 4, 1864. He commanded a brigade of the Fifth Corps before Petersburg from Aug. 21 to Sept. 13, 1864, when he resigned from the army. He was in the military service of the Khedive of Egypt 1870–82; brigadier-general and chief of staff 1870: Ferik-Pasha 1873–83, a grade next below field-marshal; received numerous decorations and orders, and filled various confidential positions under the khedive. He was chief engineer for the erection of the Bartholdi statue of Liberty, New York. D. in New York, Jan. 24, 1887.

**Stone**, DAVID MARVIN: journalist and author; b. at Oxford, Conn., Dec. 23, 1817; was a merchant in Philadelphia 1842–49; obtained his earliest reputation as an author of poetry and light literature contributed to newspapers and magazines; became commercial editor of *The Journal of*

*Commerce*, New York, 1849; with William C. Prime purchased the paper in 1861, and later was its editor-in-chief until 1893; author of *Frank Forrest*, which passed through more than thirty editions. D. in Brooklyn, N. Y., Apr. 2, 1895.

**Stone,** Frederick Dawson: See the Appendix.

**Stone,** John Seely, D. D.: clergyman; b. at West Stockbridge, Mass., in 1795; graduated at Union College in 1823; studied at the General Theological Seminary, New York, and took orders in the Episcopal Church 1826: was rector of churches at Litchfield, Conn., Frederick, Md., New Haven, Conn., Brooklyn, N. Y., Brookline, Mass., and of St. Paul's, Boston; lecturer in the Philadelphia Divinity School 1862–67; dean of the faculty of the Massachusetts Theological Seminary 1867–75. Besides several sermons and articles in periodicals, he published *Life of Bishop Griswold* (Philadelphia, 1844); *The Mysteries Opened* (New York, 1844; republished with title *The Christian Sacraments*, 1866); *The Church Universal* (1846; revised and enlarged as the *Living Temple*, 1868); *Life of James Milnor* (1848); *The Contrast, or the Evangelical and Tractarian Systems Compared* (1853); *Lectures on the Christian Sabbath* (1867). D. at Cambridge, Jan. 12, 1882.—His son, James Kent Stone, b. in Boston in 1840, graduated at Harvard in 1861; was ordained deacon and priest in the American Episcopal Church; professor (1863–67) and president (1867) of Kenyon College, Gambier, O., from which he received the degree of D. D. He was president of Hobart College, Geneva, 1868–69, but in 1870 entered the Church of Rome, becoming a Paulist Father. Revised by W. S. Perry.

**Stone,** Lucy: reformer; b. at West Brookfield, Mass., Aug. 13, 1818; graduated at Oberlin College 1847; began to speak on woman's rights and anti-slavery in the same year; lectured through the U. S. and Canada to large audiences; helped organize the first national woman's rights convention at Worcester, Mass., in 1850; married Henry B. Blackwell in 1855; helped organize the New England Woman Suffrage Association in 1868 and the American Woman Suffrage Association in 1869, and was chairman of the executive committee of the latter for twenty years; established *The Woman's Journal* in Boston in 1870, and was its editor till her death, which occurred at Dorchester, Mass., Oct. 18, 1893.

**Stone,** Thomas: a signer of the Declaration of Independence; b. at Pointon Manor, Charles co., Md., in 1743; was educated by a private tutor; studied law at Annapolis, and in 1764 began practice at Frederickton. He was a member of the Continental Congress 1775–79, and advocated the establishment of an independent government, although at first instructed by the Legislature of Maryland to oppose it; the State receding from its opposition, he was one of the signers of the Declaration of Independence; was again elected to Congress in 1783, and was a member of the committee to draft a plan of confederation, and was appointed a delegate to the convention of 1787, but was unable to attend. D. at Port Tobacco, Md., Oct. 5, 1787.

**Stone, Age of**: an archæological term denoting the stage of development in which people used tools and weapons made of stone. It does not refer to general chronology, but to a period in the development of each race. Thus certain races of the South Sea islands and extreme north have belonged to the stone age in the nineteenth century. It seems probable that in all parts of the world men have passed through this stage before making use of metals. (See Bronze, Age of.) In Europe the Stone Age is divided into two periods—the Palæolithic and the Neolithic. The remains of the former consist exclusively of flint, and roughly shaped by chipping into rude forms. The Neolithic implements include axes, hammers, knives, etc. These are made of various stones, some finer specimens being of jade, and are often highly polished. See Celt and Lake-dwellings. R. A. R.

**Stone, Artificial**: See Stone.

**Stone-borer**: any one of several bivalve molluscs belonging to several distinct families (*Pholadidæ*, *Gastrochænidæ*, *Saxicavidæ*, *Veneridæ*, *Petricolidæ*, and *Mytilidæ*) which have the faculty of perforating stone. The boring is accomplished by the shell and by the rubbing of the foot charged with sand. Besides these molluscs, species of worms and echinoids also excavate stone, and to that extent may be called stone-borers. E. A. B.

**Stone-chat**: a bird, the *Pratincola rubicola*. The male, in the breeding season, has the head, neck above, and back nearly black; the chin and throat black, and the neck on the sides white; breast chestnut in front and lighter backward; the wing-coverts of the tertials white, but partly hid by the other coverts, which are blackish brown, edged with lighter brown; upper tail-coverts white, and tail-feathers blackish; bill and legs black. (*Yarrell.*) The female is duller. The species is common in most parts of Middle Europe and Northern Africa. It is resident throughout the year in Great Britain, though mostly migratory in corresponding latitudes on the Continent. It feeds on insects.

**Stonecrop**: the wall-pepper (*Sedum acre*). See Wall-pepper.

**Stone-fly**: any plecopterous insect of the family *Perlidæ*. See Entomology (*Plecoptera*).

**Stone-fruits**: a popular name for those fruits which are known in botany as drupes. Most of them belong to the genus *Prunus*, which includes plums, prunes, apricots, peaches, nectarines, and cherries. See Drupe.

**Stoneham**: town (incorporated in 1725); Middlesex co., Mass.; on the Boston and Maine Railroad; 12 miles N. by W. of Boston (for location, see map of Massachusetts, ref. 2–H). It is noted for its manufactories of shoes and leather, and contains a national bank with capital of $50,000, a savings-bank, 6 churches, high school, 23 district schools, a public library, box-factory, machine-shop, and 2 weekly papers. Assessed valuation in 1894, $4,018,157. Pop. (1880) 4,890; (1890) 6,155; (1900) 6,197. Editor of "Independent."

**Stone'henge** [from Saxon *Stanhengist*, hanging stones]: a group of remains of rude stone structures, standing on Salisbury Plain, 2 miles from Amesbury, Wiltshire, England. It is at present much defaced, but was composed somewhat as follows: At the center was a large slab of blue limestone, 15 feet in length, supposed to be an altar. Around this were nineteen granite posts, over 20 feet in average height, set in an ellipse. Around this was another ellipse of sandstone posts, bearing a transom or lintel of sandstone across the top. There seem to have been six of these triliths. Outside this ellipse was a circle of thirty rough pillars of granite, some 6 feet high. Outside of this there was a circle, about 100 feet in diameter, of thirty sandstone posts, 4 feet apart and 13 feet high. A horizontal course of stone, dovetailed and mortised to the tops of the uprights and to each other, ran around this circle. Seventeen pillar-stones and six imposts retain their original positions. Without this circle there were a ditch and double mound of earth inclosing an area of about 120 yards in diameter. Many sepulchral barrows are found in the vicinity. It was first mentioned in the twelfth century by Henry of Huntingdon and Geoffrey of Monmouth, whose account may be considered as giving the earliest beliefs with regard to the origin of Stonehenge. Numerous theories have been propounded, and Stonehenge has been attributed to the Phœnicians, Druids, Saxons, and Danes; but it is mostly regarded by later archæologists as a burial-place of the people of the Bronze Age.

**Stone Implements**: See Stone, Age of; and Indians of North America.

**Stone-lily**: a crinoid having the form of a lily. See Encrinite.

**Stoneman,** George: soldier; b. at Busti, N. Y., Aug. 8, 1822; graduated at the U. S. Military Academy in 1846, and entered the First Dragoons, which he joined at Fort Leavenworth, whence he conducted a supply-train to Santa Fé, N. M., where he became acting quartermaster of the Mormon battalion, which he accompanied to California in 1847. In Mar., 1855, he became a captain in the Second Cavalry, and served until 1861 mainly in Texas; was in command at Fort Brown in February, when he was ordered by Gen. Twiggs to surrender to the State forces, but refused to do so, and evacuated the fort. He was promoted to be major First Cavalry, May, 1861; served on the staff of Gen. McClellan in West Virginia; Aug. 13 was appointed brigadier-general of volunteers and chief of cavalry of the Army of the Potomac, which he organized and commanded during the Virginia Peninsular campaign of 1862; succeeded to command of Kearny's (first) division, Third Corps, on the death of the latter, and of the Third Corps Nov. 15, 1862; was promoted major-general of volunteers Nov. 29, 1862, and led his corps at the battle of Fredericksburg; commanded cavalry raid to Richmond Apr.–May, 1863; was chief of cavalry bureau July, 1863–Jan., 1864; in command of Twenty-third Corps Jan.–Apr., 1864; of cavalry corps department of Ohio Apr.–July, 1864, participating in the Atlanta campaign May–July, 1864; conducted a raid for the capture of Macon and Andersonville and liberation of prisoners, but was compelled to surrender July 31, and held prisoner until Oct. 27; in temporary command of the department of Ohio Nov., 1864; in command of various districts and departments until mustered out of volunteer service Sept. 1, 1866; became colonel Twenty-first Infantry July 28, 1866; breveted colonel, brigadier, and major-general for gallant conduct; retired from active service Aug. 16, 1871. Resigned Sept. 15, 1882; Governor of California 1883–87. D. in Buffalo, N. Y., Sept. 5, 1894.

**Stone-pine, Swiss**: See CEMBRA PINE.

**Stone River, Battle of**: See MURFREESBORO.

**Stoneware**: See POTTERY AND PORCELAIN.

**Stoneworts**: the *Characeæ*, an order of lower plants, allied to the RED SEAWEEDS (*q. v.*) on the one hand and the

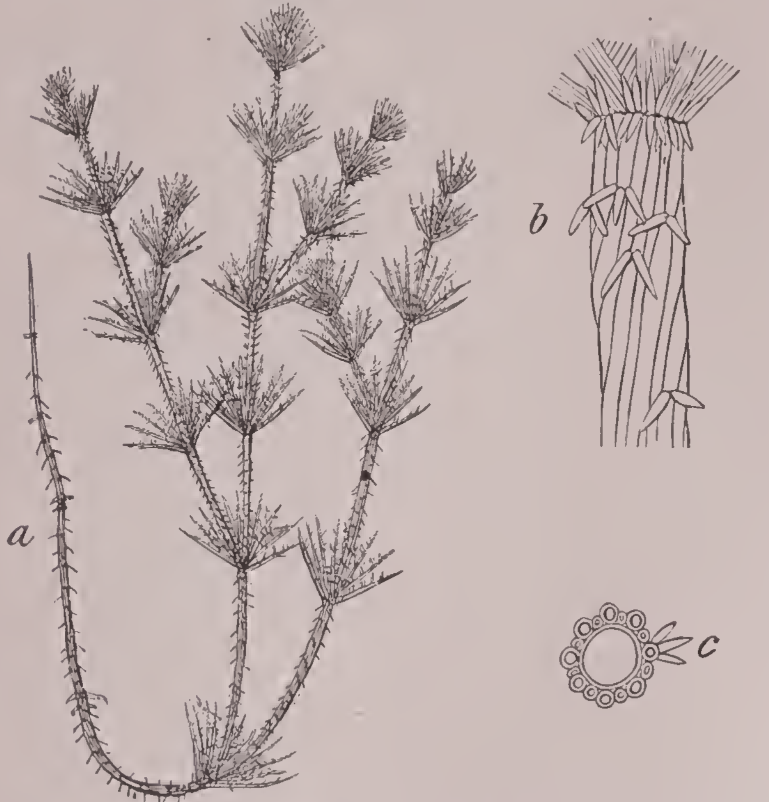


FIG. 1.—*a*, a stonewort (*Chara intermedia*), half the natural size; *b*, portion of stem, × 15; *c*, cross-section of stem, × 15.

MOSSWORTS (*q. v.*) on the other. They are small, green aquatic plants with jointed stems, bearing whorls of leaves

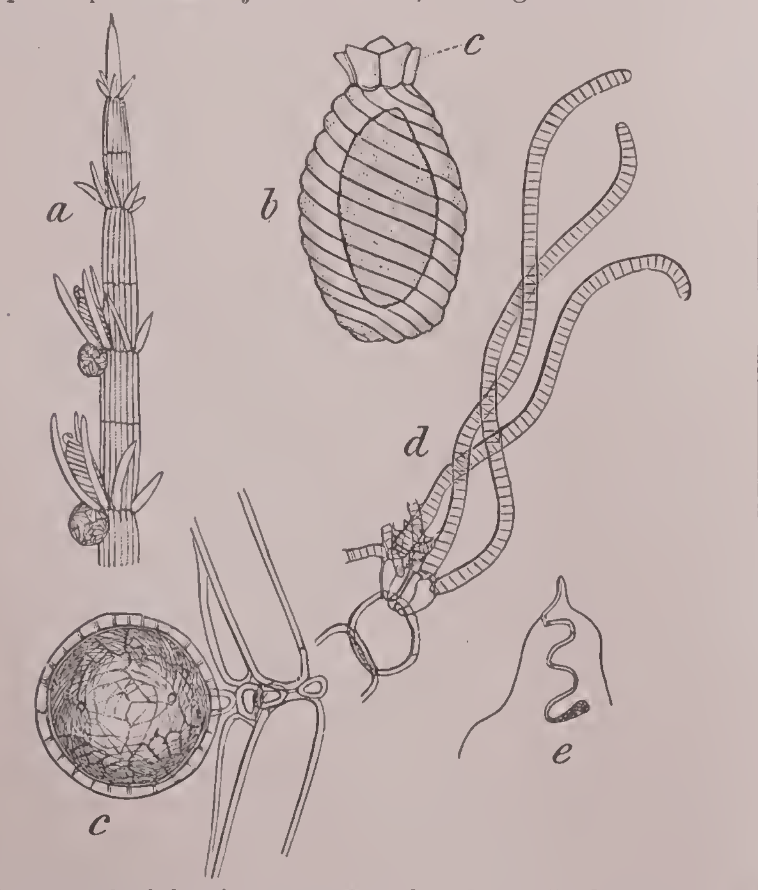

FIG. 2.—*a*, leaf, bearing young sexual organs, × 15; *b*, carpogone; *c*, coronula, × 30; *c*, antherid; *d*, threads from interior of antherid, × 200; *e*, antherozoid, × 600.

(Fig. 1). Both stems and leaves are very simple, being often no more than a row of cells, but sometimes a cylindrical mass of cells. The sexual organs, which occur upon the leaves, consist of antherids and carpogones. The former are globular bodies (Fig. 2), which at maturity are hollow and contain a number of short-celled threads. Each cell contains a spiral antherozoid, which, escaping into the water, swims actively with a rotating motion. The carpogone consists of a central cell, the oösphere, which soon becomes covered by a layer of spirally twisted cells, the pericarp, surmounted by one or two rows of short cells, the coronula (Fig. 2, *b*, *c*). Fertilization takes place by the entrance of the antherozoid through the opening in the coronula, and its fusion with the oösphere, which then acquires a thicker wall. This ripened spore-fruit soon falls to the bottom of the pond, and after a period of rest germinates by sending out a jointed filament, which eventually gives rise to a branching plant again.

The stoneworts number about 150 species, which are distributed among five genera and two families, viz., *Nitella* and *Tolypella*, constituting the family *Nitelleæ*, and *Lamprothamnus*, *Lychnothamnus* and *Chara*, constituting the family *Chareæ*. In North America there are about sixty-two species, widely distributed in ponds and slow streams.

The best works on the *Characeæ* are T. F. Allen's *Characeæ of America* (New York, 1888); W. Migula's *Die Characeen* in Rabenhorst's *Kryptogamen Flora von Deutschland, Oesterreich und der Schweiz* (Leipzig, 1890); and A. Braun's *Fragmenta einer Monographie der Characeen*, edited by O. Nordstedt (Berlin, 1882). CHARLES E. BESSEY.

**Stonington**: town (incorporated in 1658); port of entry; New London co., Conn.; on Long Island Sound, and the N. Y., N. H. and Hart. Railroad; 12 miles E. of New London, one of the county-seats (for location, see map of Connecticut, ref. 11–L). It includes the borough of Stonington, the villages of Old Mystic, Mystic, and Pawcatuck, and the farming region known as the Road district. The town has an excellent harbor, protected by a breakwater, and is in daily steamboat communication with New York. The principal industries are the manufacture of silk and cotton machinery, cotton and woolen goods, printing-presses, paper-cutters, spools for silk and thread, velvet and thread, boilers, and iron and brass goods. Stonington has a national bank with capital of $200,000, a savings-bank, and a weekly newspaper. In Aug., 1814, the town was bombarded by a British fleet, but the people successfully resisted occupation. Pop. (1880) 7,355; (1890) 7,184; (1900) 8,540, borough 2,278. EDITOR OF "MIRROR."

**Stony Point**: town; Rockland co., N. Y.; at the head of Haverstraw Bay; on the west side of the Hudson river, and on the N. J. and N. Y., the N. Y., Ont. and W., and the W. Shore railways; 42 miles N. of New York (for location, see map of New York, ref. 8–J). It is on a rocky promontory, which was fortified early in the Revolutionary war, was captured, strengthened, and garrisoned by the British, was retaken by the U. S. forces under Gen. Wayne in a night attack July 16, 1779, and soon afterward the fortifications were destroyed and the place abandoned. The summit contains a lighthouse and fog-bell tower. The house in which Benedict Arnold held his treasonable interviews was destroyed by fire in 1892. Remains of the fortifications are still preserved. Pop. (1880) 3,308; (1890) 4,614; (1900) 4,161.

**Stop**: in the organ, a series or set of pipes of similar tone and quality, tuned in regular gradation according to the order of the scale, and corresponding with the key-board either in the whole or a part only of its range. These stops are either simple or compound. A simple stop (as a diapason, flute, or trumpet) has only one pipe allotted to each key on the keyboard, but in a compound stop (as the sesquialtera or mixture) there are from two to five pipes for each key. The stops in a large organ are not only of various qualities of tone—soft, loud, delicate, bold, shrill, and the like—or imitations of the trumpet, violin, flute, etc., but are also distinguished by peculiarities of pitch, some stops giving the sound represented by the finger-keys to which they belong, others the octave or double octave below or above, while others are tuned in triple octaves above, and even in double and triple thirds and fifths, the whole combining and blending together with united effect, as if each key sounded only one richly toned pipe. The theoretical basis of this latter class of stops is explained in the article HARMONIC STOPS (*q. v.*). Organ-pipes are of two classes—flue-pipes and reed-pipes. The former are either metallic cylinders of various forms and proportions, with a mouth and lip resembling those of the ordinary pitch-pipe, or are square wooden tubes producing sound on the same principle. The latter are chiefly metallic tubes of tapering form, provided with flexible reeds of brass or other metal, the vibrations of which produce a sound richer and more penetrating than that of the flue-pipe. Among the flue-stops are the diapasons, principal, twelfth, fifteenth, tierce, and the compound stops; also the gamba, keraulophon, and the various flute-stops. In the class of reed-stops the most prominent are the trumpet, trombone, horn, bassoon, clarion, cremona, hautboy, and vox humana. See ORGAN and FOOT (in music).

Revised by DUDLEY BUCK.

**Stoppage in Tran'situ** [*in transitu* = Lat., in passage]: in law, stopping goods while they are in transit, and resuming possession of them by an unpaid seller, who has parted with their possession. The seller is allowed to exercise this right upon discovering the insolvency of the buyer, on the ground "that the goods of one man should not be applied in payment of another man's debts." The rule originated in chancery cases decided during the latter part of the seventeenth century, and was adopted by the common-law courts "for the benefit of trade." *Bohtlingk* vs. *Inglis*, 3 East 381.

*By whom Exercised.*—This right has been regarded with such favor by the courts that they have permitted not only sellers, but persons in the position of sellers to exercise it; for example, an agent of the seller to whom the bill of lading has been indorsed, or a consigner, or an agent of the buyer who has himself paid, or is directly responsible for, the price. (British Sale of Goods Act, 1893, § 38.) A seller is deemed unpaid when he has not been paid in full, or when he has received a negotiable instrument as conditional payment, which has been dishonored or has been discredited by the insolvency of the parties liable thereon to the seller. Nor does it matter that the buyer has negotiated such paper. A buyer upon credit is bound to keep his credit good, if he would prevent the unpaid seller from exercising his right of lien or of stoppage *in transitu.*

*Buyer's Insolvency.*—This is the basis of the right in question. If the seller knew of the buyer's insolvency when the sale was made on credit, there would be no equity in permitting him to stop the goods after deliberately parting with their possession in favor of the insolvent (*Fenkhausen* vs. *Fellows*, 20 Nev. 312); but the fact that the buyer was insolvent when the sale was made, if unknown to the seller, does not affect the latter's right. (*Benedict* vs. *Schaettle*, 12 Ohio St. 515.) A buyer who disputes the rightfulness of a particular stoppage of goods, by an unpaid seller, must prove that he was not insolvent when the goods reached their destination, and that he had not "afforded the ordinary apparent evidences of insolvency." A person is insolvent, within the meaning of the word in this connection, who has ceased to pay his debts in the ordinary course of business, or who is unable to pay his debts as they fall due, whether he has committed an act of bankruptcy, or become subject to insolvency proceedings or not.

*Transit.*—The rule upon this head was stated by Lord Esher, as follows: "When the goods have not been delivered to the purchaser or to any agent of his to hold for him otherwise than as a carrier, but are still in the hands of the carrier as such and for the purposes of the transit, then, although such carrier was the purchaser's agent to accept delivery so as to pass the property, nevertheless the goods are *in transitu* and may be stopped. There has been a difficulty in some cases where the question was whether the original transit was at an end, and a fresh transit had begun. The way in which that question has been dealt with is this: Where the transit is a transit which has been caused either by the terms of the contract or by the directions of the purchaser to the vendor, the right of stoppage *in transitu* exists; but if the goods are not in the hands of the carrier, by reason either of the terms of the contract or of the directions of the purchaser to the vendor, but are *in transitu* afterward in consequence of fresh directions given by the purchaser for a new transit, then such transit is no part of the original transit, and the right to stop is gone. So, also, if the purchaser gives orders that the goods shall be sent to a particular place, there to be kept till he gives fresh orders as to their destination to a new carrier, the original transit is at an end when they have reached that place, and any further transit is a fresh and independent transit." (*Bethell* vs. *Clark*, 20 Queen's Bench Division 615.) Whether the delivery of goods on board a ship, chartered by the buyer, puts them into the master's possession as carrier, or amounts to a final delivery at their place of destination, depends upon the intention of the parties, as disclosed by all the circumstances of the case. Goods are still subject to the right in question while in the carrier's or other custodian's possession, although they have reached the end of their transit, provided the buyer has not taken actual or constructive possession of them. For example, where the carrier retains or warehouses them subject to his lien for freight and charges; or where the buyer has rejected them; or where he has obtained delivery of a part only. If the delivery of part is made under such circumstances as to show an agreement to give up possession of the whole, or if the carrier wrongfully refuses to deliver the goods to the buyer, or if the carrier attorns to the buyer, that is, acknowledges that he holds the goods for the buyer, the transit is at end.

*Defeating the Right during Transit.*—The buyer may defeat it by obtaining delivery of the goods before their arrival at the appointed destination. In Great Britain it seems to be immaterial whether delivery is obtained rightfully or wrongfully (*Whitehead* vs. *Anderson*, 9 M. & W. 518; Sale of Goods Act, § 45 (2)); but there is authority in the U. S. for the view that this premature delivery must be obtained in good faith. (*Poole* vs. *Ry.*, 58 Tex. 134.) He may also defeat it by a sale of the goods accompanied by the delivery of actual or constructive possession, but a sale without delivery will not affect it. A creditor of the buyer can not defeat the right by levying an attachment or execution upon the goods while in transit. Such a levy gives him no greater claim to the property than the debtor had; and, besides, the object of the right—to prevent the application of one man's goods to the payment of another's debts—is decisive against such a creditor. Constructive possession of the goods may be given by the transfer of the bill of lading. It follows that a transfer of the bill of lading to a *bona-fide* purchaser of the goods for a valuable consideration will defeat the right of stoppage *in transitu*. It has even been held that such a transferee will get a clear title to the goods, although the right of stoppage had been exercised before the transfer, the goods being in transit still. (*Newhall* vs. *Ry.*, 51 Cal. 345.) If the bill of lading is transferred by way of pledge, instead of by way of sale, the right of stoppage is subject to the rights of the pledgee.

*How Exercised.*—Either by taking actual possession of the goods or by giving notice of his claim to the carrier or other bailee in possession of the goods. When it is given not to the person in actual possession, but to his principal, as a ship-owner or a transportation company, it must be given at such a time and under such circumstances that, by the exercise of reasonable diligence, it may be communicated to the one in actual possession in time to prevent delivery to the buyer.

*Consequences.*—The seller does not rescind the sale by stopping the goods *in transitu*, but restores his vendor's lien. Upon his giving due notice to the carrier or other person in possession, it becomes the duty of the latter to redeliver the goods in accordance with the seller's directions, but at the seller's expense. After the goods are stopped, the purchaser or his assignee may regain them by paying or tendering the price. Under the British statute (§ 48), if the goods are perishable, or if the seller notifies the purchaser of his intention to resell, and the latter does not within a reasonable time pay or tender the price, the goods may be resold, and the original seller may recover from the original buyer any loss thereby occasioned. This seems to be the common-law rule. (*Tuthill* vs. *Skidmore*, 124 N. Y. 148.) The right of the seller who has stopped goods *in transitu* is similar to that of a pledgee, with power to sell at private sale in case of default.

FRANCIS M. BURDICK.

**Storage Batteries:** See the Appendix.

**Storer**, DAVID HUMPHREYS, M. D.: naturalist; b. at Portland, Me., Mar. 26, 1804; graduated at Bowdoin College in 1825; devoted himself especially to natural history, and, besides contributions to scientific periodicals, published a translation from the French of Kiener's *Genera, Species, etc., of Recent Shells* (Boston, 1837); *Ichthyology, etc., of Massachusetts* (1839); *Fishes of North America* (Cambridge, 1846); and *History of the Fishes of Massachusetts* (Boston, 1853, and, with plates, 1866). D. in Boston, Sept. 10, 1891.

**Storer**, FRANCIS HUMPHREYS: b. in Boston, Mass., in 1832; graduated at the Lawrence Scientific School in 1855; was Professor in the Massachusetts Institute of Technology 1865–70; since 1870 Professor of Agricultural Chemistry in

Harvard University, and dean of the Bussey Institution; has contributed to scientific periodicals; was the American editor of Barreswill's *Répertoire de Chimie appliquée*, and has published *Alloys of Copper and Zinc* (1859); *Manufacture of Paraffin Oils* (1860); *First Outlines of a Dictionary of the Solubilities of Chemical Substances* (1863–64), and with Charles W. Eliot, *Manual of Inorganic Chemistry* (1869); *Manual of Qualitative Chemical Analysis* (1870); and *Agriculture in some of its Relations with Chemistry* (2 vols., New York, 1887).

**Storer**, Horatio Robinson, M. D.: surgeon; b. in Boston, Mass., Feb. 27, 1830; educated at Harvard, where he received A. B. 1850, and M. D. and A. M. in 1853; was Professor of Obstetrics and Medical Jurisprudence in the Berkshire Medical College; has contributed largely to medical literature, and has published *Why not? A Book for every Woman*, which received the gold medal of the American Medical Association (1866); *Is it I? A Book for every Man* (1867); *Decrease of the Rate of Increase of the Population in Europe and America* (1867); *Nurses and Nursing* (1868); with F. F. Heard, *Criminal Abortion, its Nature, its Evidence, and its Law* (1868) and *Volunteer Sanitary Organizations as an Aid to Official Boards of Health* (1890). He was coeditor of *The Journal of the Gynæcological Society* of Boston from 1869 to 1872. He is a high authority on medals, jetons, and tokens illustrative of the science of medicine. S. T. A.

**Stork** [O. Eng. *stork*: O. H. Germ. *storah* (> Mod. Germ. *storch*): Icel. *storker*. Cf. Gr. *τόργος*, vulture]: any bird of the genus *Ciconia* and of the family *Ciconiidæ*, which contains half a dozen species, all—save *Ciconia magnari*—inhabitants of the Old World. In general appearance they resemble the European stork (*Ciconia alba*). This is a large bird, about 3½ feet long; the head, neck, and body above, as well as below, are white, the wings partly black, and the bill and legs red. It is a migratory species, which in the warm season extends into Northern Europe, and in winter (as well as other seasons) is found in Northern Africa and Asia. It has no cry, but claps its bill together with a loud noise.

White or European stork.

Storks are great favorites with the people, who conceive that their presence brings good luck. They often build upon the roofs of houses. They devour offal, reptiles, and other vermin. The stork displays remarkable affection for its young, and is of old a popular emblem of filial piety and conjugal faithfulness. See also Shoebill and Shadow-bird.

Revised by F. A. Lucas.

**Stork**, Charles Augustus, D. D.: clergyman; b. at Jefferson, Md., Sept. 4, 1838; graduated at Williams College, Massachusetts, 1857; Professor of Greek Language and Literature, Newberry College, South Carolina, 1859–60; pastor Philadelphia, 1861–62, Baltimore, Md., 1862–81; Professor of Didactic Theology, Gettysburg, Pa., 1881–83. D. in Philadelphia, Dec. 17, 1883. After his death a selection from his writings was published, with the title *Light on the Pilgrim's Way* (Philadelphia, 1885), with a biographical sketch by his brother, T. B. Stork. See also *The Stork Family in the Lutheran Church* (Philadelphia, 1886).

H. E. Jacobs.

**Storm**: an intense atmospheric disturbance, which may be general or local, and may be characterized by high winds, when it is of especial importance to navigators, or by heavy precipitation of rain or snow, when it is most important inland, or by both wind and precipitation. General storms are areas of low pressure ("lows," or cyclones) of intense action, which travel eastward in temperate latitudes, but westward in the tropics. In summer very few of the "lows" are sufficiently intense to deserve the name of storm; in winter, perhaps, half of them are stormy, and in spring and autumn the ratio is still larger.

Stormy weather increases in frequency from the tropics toward the poles. The ocean in the vicinity of Cape Horn has the reputation of being the stormiest sea in the world, but the North Atlantic is the stormiest frequented ocean. The Pacific Ocean deserves its name only in lower latitudes. About the Aleutian islands and S. of Australasia it is very stormy. In the U. S. the storm frequency is greatest in New England and the region of the Great Lakes. Next come the extreme northwest, and the Atlantic coast. The most destructive general storms in the U. S. are of tropical origin (see Hurricanes), but they affect only the eastern part of the country, and occur only in late summer and autumn. The general storms which enter the U. S. from the western Gulf coast or Mexico in the colder seasons bring warmer weather with abundant precipitation, sometimes torrential rains. Most of the general storms which affect the eastern part of the U. S. appear first in sight on the plains E. of the Rocky Mountains, in Alberta or Assiniboia. The general storms from the Pacific come from the N. W., and enter on the coast of British Columbia, Washington, and Oregon. General storms are unknown on the Pacific coast from Lower California to Panama, but are more common over the West Indies, and occasionally pass far enough westward to affect Spanish Honduras, Yucatan, and, to a less degree, British Honduras. The western portion of the Gulf of Mexico is subject to severe winter gales from the N. The American storms which last long enough to cross the Atlantic usually pass northward of the British islands. A few pass over Great Britain, or sometimes pass farther S., over France, or even Spain. The most of the European storms, however, do not previously appear on the American weather-map. Manchuria and Central and Northern Japan are crossed by many storms, and the Sea of Japan, on which Russia has established her Pacific ports, is very stormy. The typhoons of the China Sea bring stormy weather to the Chinese coast S. of Shanghai, to the Philippine islands, Formosa, and Southern Japan. Similar typhoons occur about the Samoan and Fiji islands and about the Mascarenes, and Southern New Zealand and Tasmania have stormy coasts. The general storms of South America enter from the Pacific on the coasts about Chiloe, then pass northeastward, affecting Patagonia, Southern Argentina, Uruguay, and the coasts of Southern Brazil.

The approach of a general storm is heralded by a falling barometer, a rising thermometer (generally), and a sheet of clouds ascending from the W. and preceded by long filmy streaks of cirrhus. These signs usually give a day's notice, and the weather-map a notice of two or three days. The storm lasts from one to three days; the maximum of rainfall and wind usually precede by a few hours the minimum of air-pressure; and the retreat of the signs of the storm is more rapid than their advance with the approaching storm. The official forecasts of general storms can be made with more accuracy than those of moderate changes of weather, and their approach is heralded by storm-signals and warnings at the ports likely to be affected. (See Weather Signals.) A general storm occupies an area of about 500 miles in diameter on the average, and may live from three days to a fortnight.

While the advance of the general storm can be forecasted with fair accuracy a day or two beforehand, the same is unfortunately not true of local storms. They are small, are not of long duration, travel but short distances, occur usually in warm weather, and only in the hottest part of the day. The individual storms give but brief warning of their approach, and though the conditions under which they develop are known and can be predicted, yet the individual storms will be only sparsely scattered over the area in which these conditions exist. Tornadoes and squalls are forms of local storms especially characterized by high winds, and thunder-storms and cloudbursts those characterized by heavy precipitation. In the U. S. local storms usually occur in the warm season a few hundred miles to the southward of a large, moist, and warm "low;" especially when this is closely followed by a sharp fall of temperature. In the tropics they have no association with general areas of low pressure, but have a marked diurnal periodicity. For instance, at San José, Costa Rica, in the rainy season there is rain two days in three, and the rain is always after noon. Nine-tenths of the rain there falls between 2 P. M. and 7 P. M. See also Squalls, Cloudburst, Meteorology, and Ocean.

Mark W. Harrington.

**Storm**, Johan Frederik: philologist; b. at Lom, Norway, Nov. 24, 1836; educated at the University of Christiania; Professor of Romanic and English Philology in the University of Christiania since 1873; author, among other works, of *Practical Course in English* (1862, in Norwegian); *The Romance Nations and Languages* (1871, in Norwegian); *Selections of Phrases for Tourists Traveling in Norway* (4th ed. 1881); *English Philology* (1879, in Norwegian); *Englische Philologie, die lebende Sprache* (revised translation of preceding, 1881; 2d ed. 1892); *Det nynorski Landsmaal* (1888, concerning the attempt to create a new standard Norse on the basis of the Old Norse and the Norwegian dialects); *Romance Languages* (article in *Encycl. Britannica*, vol. xx.); *French Dialogues, a Systematic Introduction to the Grammar and Idiom of Spoken French* (Norwegian ed. 1887; Danish, 1887, 1889; Swedish, 1887, 1891; German, 1888; Dutch, 1888, 1892; Finnish, 1892; English, 1892); also many articles in scientific journals. B. I. W.

**Storm**, Theodor: poet and novelist: b. at Husum, Schleswig, Sept. 14, 1817; studied jurisprudence at Kiel and Berlin; practiced law in his native city and later in Prussia; was appointed judge at Husum in 1874; retired from his position in 1880. D. July 3, 1888. In 1843 he published with Theodor and Tycho Mommsen his first collection of poetry, mostly lyric poems of exquisite simplicity and great depth of feeling. His great popularity he gained, however, by his famous *Novellen* or short stories, of which he wrote a great many. The best known of these are: *Immensee*, *Im Sonnenschein*, *Ein grünes Blatt*, *Ein stiller Musikant*, *Viola tricolor*, *Pole Poppenspäler*, *Aquis submersus*, and *Der Schimmelreiter*. His *Erinnerungen an Mörike* (1882) show how deeply he was influenced by the latter poet, whose fine lyric talent and graceful humor he frequently attained in his own writings. See Jacob Bächtold, *Mörike-Storm Briefwechsel* (1891); Feodor Wehl, *Theodor Storm* (1888).

Julius Goebel.

**Storm-area**: an area on the weather-map over which the wind is high or the precipitation heavy, or both—a low of higher than average intensity. It can be at once distinguished by the crowding of the isobars and rain-symbols. The wind is the higher the closer the isobars are together. Heavy winds and torrential rains do not usually go together, though the former may follow the latter. The progress of a storm area is usually more uniform than that of gentler areas of low pressure. Western storm-areas usually increase in intensity as they pass eastward, but southern ones decrease in intensity and increase in size as they gain in northing. M. W. H.

**Storm Lake**: city; capital of Buena Vista co., Ia.; on Storm Lake, and the Ill. Cent. Railroad; 53 miles W. of Fort Dodge, 81 miles E. by N. of Sioux City (for location, see map of Iowa, ref. 3–E). It is in an agricultural and dairying region, and contains a national bank with capital of $50,000, 2 State banks with combined capital of $100,000, an incorporated bank, and 3 weekly newspapers. Pop. (1880) 1,034; (1890) 1,682; (1900) 2,169.

**Stormy Petrel**, or **Storm-petrel**: See Mother Carey's Chicken.

**Storrs**, Richard Salter, D. D.: clergyman; b. at Longmeadow, Mass., Feb. 6, 1787; descended from a long line of ministers, his father, who bore the same name, having been thirty-three years pastor at Longmeadow; studied at Yale and at Williams, where he graduated in 1807; was licensed to preach by the Suffolk, Long Island, presbytery in 1808; preached at Islip and Smithtown, Long Island, 1808–09; spent a year at Andover Seminary, graduating in 1810; was ordained pastor of the First Congregational church at Braintree, Mass., July 11, 1811, and, with the exception of a period of five years spent as agent of the Home Missionary Society, remained there until his death Aug. 11, 1873, after a pastorate of sixty-two years. He was the editor of *The Boston Recorder* (1817–25) and senior associate editor of *The Congregationalist* (1850–56): contributed to *Panoplist* and other periodicals; published a number of sermons.

**Storrs**, Richard Salter, D. D., LL. D., L. H. D.: clergyman; son of Rev. Richard S. Storrs (1787–1873); b. at Braintree, Mass., Aug. 21, 1821; graduated at Amherst College 1839; studied law and afterward theology at the Andover Seminary, where he graduated in 1845, and after serving for a year as pastor of a Congregational church in Brookline, Mass., became in 1846 pastor of the Church of the Pilgrims, Brooklyn, N. Y., a position which he still occupies. The completion of the fiftieth year of his pastorate was celebrated Nov. 18, 1896. Eminent as a preacher, he also contributed much to current literature, and was from 1848 to 1861 one of the editors of *The Independent*, a religious weekly. He had a part in the *Report on the History and Recent Collation of the English Version of the Bible*, undertaken by the American Bible Society, and the *Statement and Documents* in defense (1858); is the author of *The Graham Lectures on the Wisdom, Power, and Goodness of God, as manifested in the Constitution of the Human Soul* (1856); a series of lectures on *The Conditions of Success in Preaching without Notes* (1875); *The Divine Origin of Christianity indicated by its Historical Effects* (1884); *Bernard of Clairvaux* (1892); besides numerous historical and literary, as well as religious, discourses. He was president of the American Board of Commissioners for Foreign Missions 1887–97. D. June 5, 1900. Revised by G. P. Fisher.

**Story**, Joseph, LL. D.: jurist; b. at Marblehead, Mass., Sept. 18, 1779; graduated at Harvard College in 1798; studied law, and in 1801 began practice at Salem; was a member of the State Legislature 1805–08, and the acknowledged leader on the Republican side, defending Jefferson's proclamation of embargo as the only measure, short of war, by which American commerce could be protected from the restrictions of the belligerent European powers. In 1808 he was elected a representative in Congress, where he urged a repeal of the Embargo Act, on the ground that it was a temporary measure, the purpose of which had now been attained. Having declined a re-election to Congress, he was in 1810 again chosen a member of the State Legislature, of which he was elected speaker. In 1811 he was appointed associate justice of the Supreme Court of the U. S.; in 1820 was a member of the convention for the revision of the State constitution. In 1829 he was chosen Dane Professor of Law in Harvard College, a position created for him, and which he held for the remainder of his life. D. at Cambridge, Mass., Sept. 10, 1845. In 1804 he published a volume of poems entitled *The Power of Solitude* (most of the copies of which he bought up and destroyed), and in 1806 *Memorial of the Inhabitants of Salem*, a pamphlet addressed to President Jefferson relating to the infringements by foreign powers upon the neutral trade of the U. S. He also published many addresses, literary discourses, and reviews, etc., but his fame rests mainly upon his decisions, and especially upon his legal *Commentaries*, of which the following are the principal, all of which have passed through several editions, and most of which have been translated into German: *On the Law of Bailments* (1832); *On the Constitution of the United States* (1833); *On the Conflict of Laws, Foreign and Domestic* (1834); *On Equity Jurisprudence, as administered in England and America* (1835); *On Equity Pleadings* (1838); *On the Law of Agency* (1839); *On the Law of Partnership* (1841); *On the Law of Bills of Exchange* (1843); *On the Law of Promissory Notes* (1848). He also edited Chitty *On Bills of Exchange* and Abbott *On Shipping*, and left in MS. a *Digest of Laws*, supplementary to that of Comyns. As a constitutional lawyer he belonged to the school of Marshall, and supported the Federal authority. He was untiring in his work, and a great case lawyer. His commentaries and written decisions in his circuit comprise twenty-seven volumes, and his judgments in the Supreme Court an important part of thirty-four volumes more. A collection of his *Miscellaneous Writings* was published in 1852, and his *Life* has been written by his son, William W. Story (2 vols. 8vo, Boston, 1851).

Revised by F. Sturges Allen.

**Story**, Robert Herbert, D. D.: minister; b. at Rosneath, Dumbartonshire, Scotland, Jan. 28, 1835; educated at the Universities of Edinburgh, St. Andrews, and Heidelberg; assistant minister at St. Andrew's, Montreal, Canada, 1859–60; in Rosneath, as his father's successor, 1860–87; since 1887 Professor of Church History in the University of Glasgow, second clerk of the General Assembly of the Church of Scotland, and chaplain to the Queen; editor of *The Scottish Church* (a monthly magazine) since its foundation in 1885; the first lecturer on the Lee foundation, St. Giles, Edinburgh, 1886. Besides many contributions to various periodicals Dr. Story has published *Robert Story of Rosneath, a Memoir* (London, 1862); *Christ the Consoler, or Scriptures, Hymns, and Prayers for Times of Trouble and Sorrow, selected and arranged* (Edinburgh, 1865); *Life and Remains of Robert Lee, D. D.* (London, 1870); *William Carstares* (1874); *Creed and Conduct: Sermons* (1878); *Health Haunts in the Riviera* (Paisley, 1881); and *Nugæ Ecclesiasticæ* (Edinburgh, 1884). C. K. Hoyt.

**Story**, William Wetmore: sculptor; son of Joseph Story, LL. D.; b. at Salem, Mass., Feb. 19, 1819; studied law; was admitted to the bar, and published several legal books—*Report of Cases* (1842–47); *Treatise on the Law of Contracts* (1844); *The Law of Sale of Personal Property* (1847); edited the *Life and Letters of Joseph Story* (1851). About 1848 he abandoned law for sculpture, and from that time on he resided chiefly in Rome, where he died Oct. 7, 1895. Besides the practice of his art he was a somewhat prolific writer. He published *The American Question* (1862); *Roba di Roma* (1862); *Proportions of the Human Figure* (1866); *Graffiti d'Italia* (1869); *A Roman Lawyer in Jerusalem* (1870); *The Castle S. Angelo and the Evil Eye*, being a second volume of *Roba di Roma*, in 1877; and five volumes of poems. As a sculptor he is known chiefly by his large allegorical statues, *Medea, Cleopatra, The African Sibyl*; by the statue of George Peabody executed for the corporation of London; the statue of Edward Everett in the Boston Public Garden; the monument at San Francisco of Francis Scott Key; and busts of his father, James Russell Lowell, William Cullen Bryant, Josiah Quincy, and Theodore Parker. He was made Chevalier of the Legion of Honor at the Paris Exposition of 1878.

**Stothard**, Charles Alfred: painter and architectural draughtsman; son of Thomas Stothard, painter; b. in London in 1786; early distinguished himself by his skill as an artist. His best-known painting, *The Death of Richard II.*, was exhibited in 1810, and in the following year he began the publication of the *Monumental Effigies of Great Britain*, a series of etchings with descriptions, completed (1811–23) after his death by others, and valuable for its accuracy. He was selected by the Antiquarian Society to make drawings of the famous Bayeux tapestry, and in 1819 made sketches from the newly discovered old pictures on the walls of the Painted Chamber of the House of Lords. D. at Bere Friars, in Devonshire, England, May 27, 1821.—His widow, Anne Eliza (d. 1883), who assisted her brother, Mr. Kempe, in the completion of the *Monumental Effigies*, afterward married the Rev. Edward Bray. She was the author of several creditable novels and other works written during her second marriage. Revised by Russell Sturgis.

**Stothard**, Thomas, R. A.: painter and designer; b. in London, Aug. 17, 1755; was apprenticed to a designer of patterns for the silk trade, but soon became an illustrator of books, and finally a painter. He illustrated the set of *The Novelists' Library*, begun about 1780, and other popular works, and became known as a most prompt and useful workman, so that he was constantly employed. He was elected fellow of the Royal Academy in 1794, and its librarian in 1812. His illustrations for books number more than 4,000, among them being those for *Robinson Crusoe* and *The Pilgrim's Progress*, 1788, the *Rape of the Lock*, 1798, the works of the German poet Gessner, 1802, Cowper's *Poems*, 1825, and Rogers's *Italy* and *Poems*, of which he illustrated not only the splendid octavos of 1830 and 1834, but also the small 12mo editions with wood-cuts. His work as an illustrator of books is graceful and pure, not very realistic nor careful about costume and architecture or other matters where historical accuracy is thought necessary, but artistic in a very high degree. Among his best paintings are the *Canterbury Pilgrims*, the *Flitch of Bacon*, and *Four Periods in a Sailor's Life*. Besides his work in pure art he made many designs for goldsmiths and other decorative workers. D. in London, Apr. 27, 1834. See the *Life* by Mrs. Bray (1851). Revised by Russell Sturgis.

**Stoughton**, stō'tŭn: town; Norfolk co., Mass.: on the N. Y., N. H. and Hart. Railroad; 17 miles S. of Boston (for location, see map of Massachusetts, ref. 5–I). It contains the villages of Stoughton, North Stoughton, and West Stoughton; is principally engaged in the manufacture of boots, shoes, and rubber and woolen goods; and has 4 hotels, a public high school, 17 district schools, public library (founded in 1874), a co-operative bank, and 2 weekly newspapers. The assessed valuation in 1894 was $2,819,252. Pop. (1880) 4,875; (1890) 4,852; (1900) 5,442.

**Stoughton**: city (founded in 1847); Dane co., Wis.; on the Yohara river, and the Chi., Mil. and St. Paul Railway; 14 miles S. S. E. of Madison, the State capital (for location, see map of Wisconsin, ref. 7–D). It is in the center of the great tobacco belt; and contains 8 churches, high school, academy, 4 public-school buildings, water-works, electric lights, manufactories of carriages and wagons, cigars, harness, and flour and feed mills, 2 State banks with combined capital of $55,000, and 3 weekly newspapers. The city is an important tobacco-market. Pop. (1880) 1,353; (1890) 2,470; (1900) 3,431. Editor of "Courier."

**Stoughton**, John, D. D.: clergyman and author; b. at Norwich, England, Nov. 15, 1807; educated at Highbury College, Islington, and University College, London; pastor of Congregational churches at Windsor 1832–43, at Kensington, London, 1843–75; Professor of Historical Theology and Homiletics in New College, St. John's Wood, London, 1872–84. He was Congregational lecturer 1855, and chairman of the Congregational Union 1856. He edited for many years *The Evangelical Magazine*, and published many very popular as well as scholarly volumes, including *Lectures on Tractarian Theology* (London, 1843); *Windsor: a History and Description of the Castle and the Town* (1862); *Homes and Haunts of Luther* (1875); *Italian Reformers* (1881); *Spanish Reformers* (1883); but chiefly the series of Church histories of England from the opening of the Long Parliament (1640) to 1800, issued in revised form in 1881 under the title *History of Religion in England* (6 vols.); supplement carrying the story to 1850, 1884, 2 vols. He issued his autobiography, *Recollection of a Long Life*, in 1894. D. at Ealing, Oct. 25, 1897. Revised by G. P. Fisher.

**Stourbridge**, stėr'brij: town; in Worcestershire, England; on the Stour, 12 miles W. by S. of Birmingham (see map of England, ref. 9–G). It manufactures iron, glass, earthenware, and fire-bricks, the latter from a peculiar kind of clay called Stourbridge clay, on which fire has only a small effect. Pop. (1891) 9,386.

**Stout**: See Beer.

**Stove** [from Dutch *stoof*, foot-stove, drying-room: Germ. *stube* < O. H. Germ. *stuba*, room that can be heated, bathroom. The original meaning was "heated room." How the Romanic words: Fr. *étuve*, Ital. *stufa*, Span. *estufa*, cf. Fr. *étouffer* are related is still a question]: an apparatus for retaining and diffusing heat, as for warming and ventilating or cooking. In the Middle Ages stoves, constructed of brick or tiles and sometimes of slate or steatite, were used for warming dwellings. They were large, often filling the side of a room, and in Scandinavia their broad flat surfaces were sleeping-places. The fire was kindled at the bottom, and the heat and smoke passed through flues before making their exit into the chimney. Some of these stoves had ovens and flues for cooking, and when once thoroughly heated required feeding but once in twenty-four hours. An early attempt at making a stove or closed fireplace of iron was made by Cardinal Polignac in France. He published a description of this in *La Mécanique du Feu, ou l'Art d'en augmenter les Effets, et d'en diminuer la Dépense* (1709). The Polignac fireplaces were constructed with hollow backs, hearths, and jambs of iron to economize the heat. Des Aguliers translated Polignac's treatise (London, 1716), and modified his fireplaces so as to use them for coal. Neither these nor the Holland stoves, which were introduced soon after (plain box stoves with a small smoke-pipe or flue at the top, and a single door into which the wood or coal was thrown), became popular in England, owing to the prejudice of the people in favor of open fires. Dr. Franklin, writing of stoves after his invention in 1745, refers to a German stove recently introduced into England, consisting of an iron box made of five plates fastened together with screws, one side of which was left open, but when the stove was set, this open side, with the smoke-pipe, was in an ante-room, while the body of the stove projected through the partition to warm a larger room, the fire being fed and the smoke conducted off in the ante-room. Franklin's stove was a great advance. Although, in its ordinary use, a fireplace, it was capable of being closed, and had a downward draught, distributing the heat through the air-boxes in its sides, till at last the remainder of the heat escaped with the smoke through a flue leading into the base of the chimney. A register or "damper" of sheet-iron was introduced into the descending flue, which checked and controlled the fire. In 1771, and later, Franklin invented other stoves—one for burning bituminous coal which would consume its own smoke and had a downward draught, and another intended for the same purpose, having a basket grate or cage, with movable bars at the top and bottom, supported by pivots at its center. The latter, after being filled and kindled at the top, could be inverted and so made to burn from the base. Between 1785 and 1795 Benjamin Thompson, Count Rumford, devised several improvements in stoves, intended to economize fuel and heat.

In the U. S. before 1825 the use of stoves, generally of the box pattern and very rude, was confined to shops and offices, public rooms, and churches in cities and larger villages. In the country the churches were seldom warmed, but the women carried foot-stoves, and the men protected their feet by stout overshoes called "boxes." Among the wealthy in cities cannel and other English coal ("sea coal") was burned in imported grates or in the Rumford stove lined with fire-brick. A greater number in cities and larger villages used the Franklin stove, burning wood and making an open fire-place of it. The rest of the world used the old open capacious fireplace, burning wood logs. A huge brick oven adjoined the kitchen fireplace, and required a large quantity of wood to heat it. Until 1835 stoves in the U. S. were made almost exclusively at blast furnaces and directly from the ore, instead of being made in foundries by cupola furnaces from pig iron, as they were later, and they were consequently much heavier and ruder than now and had loose and imperfect joints. Most of them were made in New Jersey, Pennsylvania, and Ohio, though a few were cast quite early in the furnaces at Cold Spring and Warwick, N. Y., and at Salisbury and Canaan, Conn., and from 1820 to 1835 considerable stove-making was done in Rutland co., Vt. From 1795 to 1825 no material progress was made in the construction of stoves. Those for heating purposes were either box stoves made on the old German plan, an oven being sometimes added, placed directly over the fire, or portable and partly open fireplaces made on Franklin's plans. For cooking purposes Count Rumford's cooking-stoves or ranges lined with fire-brick or soapstone, and with a ventilating oven, which had been introduced in New York as early as 1798 and into Boston about 1800, were gradually coming into use. After the opening of the Erie and Champlain Canals, the introduction of steamboats on rivers, and the first beginnings in railway travel, the facilities for transportation for heavy goods were so increased that the manufacture of stoves, and especially of cooking-stoves, became an important industry. As yet these were universally wood stoves, but the anthracite coal was destined to create a revolution in stoves. Jordan L. Mott and James Wilson, both of New York, made self-feeding stoves between 1827 and 1831 that would burn the British coals, and were an improvement on previous inventions; but it was not until 1833, when Mr. Mott had demonstrated that an anthracite fire could be made successfully from nut and pea-sized coals, and that the depth of the column of coal in his self-feeders must be in direct proportion to its size, the largest coal requiring the highest column, that anthracite coal stoves became salable. Early in 1835 he built a small cupola furnace and cast his stove-plates from pig iron of the best quality, fluting them to prevent their cracking. This was among the first attempts to make stove-plates from pig iron and to make the plates light, even, and smooth. The first cooking-stoves made in Albany (1835) were of the old ten-plate oval pattern, with oven above the fire and a single hole on the top. These were followed by the saddle-bag pattern, having the oven in the middle over the fire and the stove-collar and pipe over it, while on either side was an oval projection with a boiler-hole on a level with the stove-top, these projections resembling very closely an inverted pair of saddle-bags. The next pattern was the horse-block (so called from the rear portion of the stove, which contained the oven, being a step higher than the front). The rotary stove, having a movable top revolved by means of a crank so as to bring any desired vessel directly over the fire, was a later invention. Then came the Buck stove, both for wood and coal, having the fire above the oven and reversible flues which carried the heat and flame around, behind, and below the oven before reaching the smoke-pipe, which was nearly on a plane with the oven-floor. There have been hundreds of modifications of this pattern, but in all of them the reversible flue has been the predominating feature. In heating-stoves there has been a great variety of forms and some new principles have been introduced, though many of these seem to have been anticipated by the inventions of Dr. Neil Arnott. The problem of adapting the heating-stove to the use of anthracite coal and utilizing its great heat-producing power economically was solved by President Nott, of Union College, who spent years and much money in perfecting his stove. The self-feeder had previously been made both in England and in France, but one of its applications was a device of Dr. Nott, which he applied to several stoves, and others were not slow to follow. Samuel Pierce, of Troy, and Anson Atwood, of Brooklyn, introduced the hot-air current to facilitate combustion and radiation of heat, or at least are believed to have improved upon that idea.

In cooking-stoves and fixed and portable ranges the number of inventors and manufacturers is large. One of the most ingenious inventors of cooking-stoves was P. P. Stewart, of Troy, N. Y., whose stoves were, and with some modifications still are, very popular. Dr. Nott also invented several excellent cooking-stoves. Albany, Troy, New York, Buffalo, Philadelphia, Pittsburg, Cleveland, Cincinnati, Chicago, Quincy, St. Louis, Milwaukee, Boston, Providence, Wheeling, and Detroit have each a number of manufactories engaged in the production of stoves, ranges, and heaters. The efforts of the stove-makers since 1850 have been directed rather toward completing the adaptation of the principles of base-burning, hot-air feeding, and the anti-clinker arrangement to stoves, and greater accuracy and perfection of the castings than to the discovery of any new principles. Portable and brick-set ranges in great variety are now produced, with similar arrangements for heating water as in the cooking-stoves. They are well constructed, have all the improved facilities for labor and fuel saving, and are particularly noteworthy for the perfection of their castings and finish. A few manufacturers make stoves entirely of steatite or soapstone. Such stoves retain the heat for a long time and require but a small amount of fuel, which they consume entirely.

While the use in the U. S. of cast iron has continued for heating-stoves and the majority of cooking-stoves, there has been a growing application of steel in the construction of cooking-ranges. Since 1885 an important development has been in the use of gasoline as a fuel—a practice that began in the West and has extended eastward. At first such stoves were made so as to burn the gasoline direct, but in the newer forms called process stoves the gasoline is first changed into gas. Kerosene has also been used as a fuel. The employment of illuminating gas as a fuel is steadily growing, and in cities improved burners and cheapened gas have led to the introduction of many forms of gas stoves for use in apartments. In Great Britain slot meters are employed by means of which a given amount of gas for a penny is turned on and automatically turned off when the amount has been consumed. The use of electricity as a heat-producer is recognized, and forms of heating apparatus for it were shown at the World's Columbian Exposition held in Chicago in 1893, but as yet its employment is slight. All the stoves used in the U. S. are of domestic manufacture. The National Association of Stove-manufacturers reported in May, 1894, that there were 274 firms engaged in that business in 1893, whose sales during that year amounted to $30,035,700. There is an export trade of gas and gasoline stoves to South America, Mexico, etc., and a slight exportation of anthracite stoves to Europe. Revised by MARCUS BENJAMIN.

**Stow**, BARON, D. D.: clergyman and author; b. at Croydon, N. H., June 16, 1801; graduated at Columbian College, District of Columbia, in 1825; edited *The Columbian Star* 1825–27; became pastor of the Baptist church at Portsmouth, N. H., in 1827, of the Baldwin Place church, Boston, in 1832, and of the Rowe Street (now Clarendon Avenue) church in 1848. He was prominent in the missionary enterprises of the denomination, and president of the trustees of Newton Theological Seminary. Besides numerous contributions to religious periodicals, he published *Memoir of Harriet Dow* (1832); *Helon's Pilgrimage* (1835); *History of the English Baptist Mission to India* (1835); *The Danish Mission on the Coast of Coromandel* (1837); *Question-book of Christian Doctrine* (1848); *Christian Brotherhood* (1859); *First Things* (1859); and, in conjunction with Rev. Samuel F. Smith, *The Psalmist*, a collection of hymns largely used by Baptists (1849). D. in Boston, Dec. 27, 1869. See *Life*, by R. H. Neale (1870). Revised by W. H. WHITSITT.

**Stowe**, CALVIN ELLIS, D. D.: clergyman, educator, and author; b. at Natick, Mass., Apr. 6, 1802; graduated at Bowdoin College in 1824, and in 1828 at Andover Theological Seminary; was Assistant Professor of Sacred Literature at Andover, and assistant editor of *The Boston Recorder* 1828–30; Professor of Languages in Dartmouth College 1830–33, of Biblical Literature in Lane Seminary, Walnut Hills, near Cincinnati, 1833–50, and of Natural and Revealed Religion in Bowdoin College 1850–52. In 1852 he became Professor of Sacred Literature in Andover Seminary, but resigned in 1864 and removed to Hartford, Conn. In 1836 he married Harriet Elizabeth Beecher. In the same year he was sent by the State of Ohio to examine the public-school systems of Germany. Upon his return he published a report on *Elementary Education in Europe*, which was distributed at the public expense to every school district in Ohio and was also adopted by the Legislatures of several other States. He translated from the German Jahn's *History of the Hebrew Commonwealth* (Andover, 1828; 2 vols., London, 1829); prepared from the *Prælectiones* of Lowth a volume of *Lectures on the Sacred Poetry of the Hebrews* (1829); began an *Introduction to the Criticism and Interpretation of the Bible*, of which only vol. i. was published (Cincinnati, 1835); and the *Origin and History of the Books of the Bible* (part i., containing the New Testament, Hartford, 1867). He also published several addresses and educational reports, and contributed largely to religious periodicals. D. at Hartford, Conn., Aug. 22, 1886.

**Stowe**, HARRIET ELIZABETH (*Beecher*): author; daughter of Lyman Beecher; b. at Litchfield, Conn., June 14, 1811. At the age of thirteen she was sent to the school kept by her sister Catherine at Hartford, where she studied and taught until 1832, when she removed with her father to Cincinnati; was married in 1836 to Rev. Calvin E. Stowe, then professor at Lane Seminary, Cincinnati. In 1849 she published *The Mayflower, or Sketches of the Descendants of the Pilgrims*, and in 1851 began in *The National Era* of Washington a serial story designed to illustrate the horrors of African slavery, which was published separately in 1852 under the title *Uncle Tom's Cabin*, and attained a rapid and almost unparalleled success at home and abroad. Within five years 500,000 copies were sold in the U. S.; within ten years there had been made from it two or three French versions and more than a dozen German ones. It was also translated into Danish, Swedish, Portuguese, Spanish, Italian, Welsh, Russian, Polish, Hungarian, Wendish, Wallachian, Armenian, Arabic, Romaic, Chinese, and Japanese. It did more than any other literary agency to rouse the public conscience against slavery, and has been repeatedly dramatized. In 1853 she put forth a *Key to Uncle Tom's Cabin*, in which were set forth the main facts upon which the story was based, together with many incidents in corroboration of its truthfulness. In 1850 Mrs. Stowe removed to Brunswick, Me., where her husband had been appointed to a professorship in Bowdoin College. In 1852 they went to Andover, Mass., where he had accepted a chair in the theological seminary. In 1853 she accompanied her husband and her brother to Europe, and upon her return published *Sunny Memories of Foreign Lands* (2 vols., 1854). Her subsequent writings, which were mostly inferior, usually first appeared in periodicals, especially in *The Atlantic Monthly* and in the *Hearth and Home*, of which she was for a time one of the editors. Among these, as published separately, are *Dred, a Tale of the Great Dismal Swamp*, subsequently published under the title *Nina Gordon* (1859); *The Minister's Wooing* (1859); *The Pearl of Orr's Island* (1862); *Agnes of Sorrento* (1863); *Oldtown Folks* (1869); *Pink and White Tyranny* (1871); *My Wife and I* (1872); *Bible Heroines* (1878); *Poganuc People* (1878); *A Dog's Mission* (1881); and a volume of religious poems. Her paper in *The Atlantic Monthly* in 1869, *The True Story of Lord Byron's Life*, started an unfortunate scandal, and she replied to her critics with *Lady Byron Vindicated, a History of the Byron Controversy* (1869). In 1864 Mrs. Stowe removed to Hartford, Conn., where she died July 1, 1896. See the *Life* by her son (Boston and New York, 1889). HENRY A. BEERS.

**Strabismus**: See SQUINTING.

**Stra'bo**: Greek geographer; b. at Amaseia, in Pontus, 63 B. C.; d. in the reign of Tiberius after 21 A. D. He received an excellent education under eminent masters in philosophy and in literature, went to Rome about 29 B. C., and undertook extensive travels in Asia Minor, Egypt, Greece, and Italy. At a mature age he wrote a history, which is lost, and a geography in seventeen books, which has come down to us, and is especially valuable for its historical notes, which are the more abundant as Strabo looks at geography from an historical point of view, and shows that he is a disciple of Polybius. His work is unequal, and it is a natural inference that where his descriptions are meager and incorrect his information is derived from books, and that where they are full and accurate we have before us the result of personal observation. His style is simple, and the grouping of the heterogeneous materials shows something of the Greek feeling for proportion. The first two books of his works form an introductory to geography; with the third the description begins. Eight books are devoted to Europe, six to Asia, and the seventeenth and last to Egypt and Libya. Editions by Kramer (3 vols., 1844–52) and Meineke (3 vols., 1852–53). English translation by Falconer and Hamilton (3 vols., 1854–57). The French translation, made by La Porte du Theil, Coray, and Gossellin, at the command of Napoleon I. (5 vols., 1805–19), is very rich in notes. There is a valuable German translation, with notes, by Groskurd, 1831–34. On Strabo, see Bunbury, *History of Ancient Geography*, vol. ii., 209, *seq.*; and also the introduction to Tozer's *Selections from Strabo* (1893).

Revised by B. L. GILDERSLEEVE.

**Strabo**, WALAHFRID (*Walafridus Strabus*, "the Squinter"): ecclesiastic and author; b. in Suabia about 809; educated in the Benedictine abbey school of Reichenau, on the island in Lake Constance; then at Fulda, 54 miles S. E. of Cassel, under Rabanus Maurus (826–829). From Fulda he went to Aix-la-Chapelle and became tutor to Charles, son of the Emperor Louis the Pious. The latter made him abbot of Reichenau 838. He was driven from his post by Louis the German 840, but restored 842. He died while crossing the Loire, Aug. 18, 849. He was a very prolific writer. His principal work, the so-called *Glossa ordinaria*, is a huge exegetical compilation, the oldest printed edition of which —without date and place, but about 1480—comprises four volumes in folio. It was for several centuries the principal source and the highest authority of biblical science in the Latin Church, being in use, indeed, to the seventeenth century. His *De exordiis et incrementis rerum ecclesiasticarum*, printed in Hittorp's *De officiis divinis* (Cologne, 1568), and in several later editions, best by A. Knoepfler (Munich, 1890), is an interesting handbook in ecclesiastical archæology. To him we owe the authentic lives of St. Gall (ed. R. Shute, St. Gall, 1890) and St. Othmar. He was a poet and not a mere monastic rhymer. The most curious of his poems is his *Vision of Wettin*, which relates his journey to hell, purgatory, and paradise. He has the hardihood to introduce Charlemagne in purgatory suffering for incontinence. Another poem is *Hortulus*, on the plants in the convent garden. See his works in Migne, *Pat. Lat.*, cxiii., cxiv., and his poems separately in Dümmler, *Poet. Lat. ævi Carolini II.*, 259–473.

**Strachey**, JOHN ST. LOE: See the Appendix.

**Strachey**, WILLIAM: historian; b. in England about 1585; was the first secretary to the colony of Virginia 1610–12, having been shipwrecked on the Bermudas 1609 with Gates, Somers, and Newport; wrote *A True Repertory of the Wracke and Redemption of Sir Thomas Gates, upon and from the Islands of the Bermudas*, in *Purchas's Pilgrims* (vol. iv., lib. ix., cap. vi.), upon which Shakespeare appears to have drawn in his description of a storm in the *Tempest*—an inference strengthened by the reference in the same drama to the "still-vexed Bermoothes"; compiled *For the Colony in Virginia Britannia, Lawes Divine, Morall, and Martiall* (London, 4to, 1612); and was author of *Historie of Travaile into Virginia Britannia*, written as early as 1618, and first published by the Hakluyt Society from an original MS. (No. 6, 1849)—a quaint and valuable work which supplies the means of correcting the false details of the early history of Jamestown (especially in relation to Pocahontas) which have been so often repeated upon the authority of Capt. John Smith. Strachey projected a larger work, of which this volume forms but "the first and second books of the first decade." The time and place of his death are unknown. See *A History of American Literature*, by Moses Coit Tyler (1878), vol. i., pp. 41–45.

**Strack**, HERMANN L.: See the Appendix.

**Stradiva'rius**, ANTONIO: maker of musical instruments; b. at Cremona, Italy, in 1644; learned the art of making violins and other string instruments from Nicolo Amati, under whom he worked for several years; in 1668 began to make violins marked with his own signature, and by degrees not only rivaled but even outshone his master. His best instruments were made in the period between 1700 and 1725, and command from $1,000 to $3,000. D. Dec. 17, 1737.

**Strafford**, THOMAS WENTWORTH, Earl of: minister of Charles I.; b. in London, Apr. 13, 1593; studied at Cambridge; traveled on the Continent; sat in Parliament, and was at first active in opposition to the court, though unwilling to go to radical lengths, and had no sympathy with the religious policy of the Parliament. In 1628 he went over to the king's side; was created Baron Wentworth, then viscount, lord president of the council of the North, a privy councilor in 1629, and lord deputy of Ireland in 1633. His rule in Ireland was harsh and despotic, aiming at the establishment of his system of "thorough" or the absolute power of the king, and he acquired the designation of "the wicked earl." In Jan., 1640, he was created Earl of Strafford, and soon afterward prepared an army in Ireland to aid against the Scots. Upon his return to England he supported the harshest measures of the crown. The famous Long Parliament convened Nov. 3, 1640, and within eight days Pym appeared before the bar of the House of Lord and in the name of the House of Commons impeached him of an attempt to overthrow the public liberties and subvert the public rights. He defended himself personally and with such ability that the Commons abandoned their original impeachment and passed a bill of attainder. The Peers were fairly overawed by the fierce attitude of the Commons and dared not refuse their assent to the bill, which was sent to Charles for his sanction. The king wished to save his minister, for whose safety he had pledged himself, but fearing a violent revolution he reluctantly gave his assent, and Strafford was brought to the block on Tower Hill, May 12, 1641. That he had been proved guilty of no crime which by the strict letter of the law was a capital one is certain, and the bill of attainder was in fact a retrospective law, justifiable only on grounds sufficient to warrant any other revolutionary proceeding. The act of attainder was reversed in 1662 after the restoration of Charles II., and the estates of Strafford were restored to his son. His *Letters and Dispatches*, edited by Dr. Knowles, were printed in 1739; his *Life* has been written by Elizabeth Cooper (1874) and by H. D. Traill (1889). The circumstances of his life have occasioned much controversy. Macaulay's account censures him most severely, while Gardiner takes a more favorable view of his political career. Revised by F. M. Colby.

**Straight University**: a coeducational institution at New Orleans, La.; founded by Seymour Straight and incorporated in 1869. It is for Negroes exclusively, and is under the care of the American Missionary Association. It has classical, normal, manual-training, theological, and four other departments, a faculty numbering 22, and 600 students.

**Strain**: the force applied to a rope or bar, or the amount of change of shape produced by the force, the word being generally used by practical engineers in the first sense and by scientific writers in the second. See Stresses.

**Straits**: See Physiography.

**Straits Settlements**: a British crown colony in the East Indies, including Malacca, Penang or Prince of Wales island, with the province of Wellesley on the continent, and Singapore. The Settlements were made a separate dependency of the British crown in 1853, and placed under the Governor-General of India. On Apr. 1, 1867, the connection with India ceased, the province became a crown colony, and is administered by a governor residing at Singapore. In 1887 the Cocos or Keeling islands were attached to the colony, and in 1889 Christmas island. The British possessions of 1,472½ sq. miles were inhabited (1891) by 512,342 persons, of whom 213,073 were Malays, 227,989 Chinese, and 53,927 natives of India. The protected Malay states of the peninsula (Perak, Selangor, Johor, Sungei Ujong, Negri Sembilan, and Pahang) comprise about 34,660 sq. miles. Pop. (1891) 418,-527, not including Johor, which has an estimated population of 300,000. The internal administration of these states is in the hands of the British residents. Mining is actively carried on, and large supplies of tin are exported from Perak and Selangor. Fifteen hundred British troops and a few vessels are sufficient in time of peace to maintain order and punish piracy. Revised by M. W. Harrington.

**Stralsund**, straal'sōōnt: town; in the province of Pomerania, Prussia; on the narrow strait which separates the island of Rügen from the mainland; has a good harbor and is strongly fortified (see map of German Empire, ref. 2–G). It is an old town (founded in 1209), and played a conspicuous part—first as a member of the Hanseatic League, then during the Thirty Years' war as a fortress. It has manufactures of paper, tobacco, oil, spirits, and mirrors, and an extensive export trade in grain, wool, cattle, and horses. Pop. (1895) 30,097. Revised by M. W. Harrington.

**Stramo'nium** [Mod. Lat., the thorn-apple, also the drug contained in its seeds and leaves]: a drug consisting of the seeds and leaves of *Datura stramonium*, an annual plant of the family *Solanaceæ*, growing rankly as a weed throughout almost all the temperate and warmer countries of the world. The herb, called thorn-apple, and in the U. S. also Jamestown weed, is a hardy plant, found mostly in rank soil near dwellings. Its average height is about 3 feet. It has an erect stem, with many branches beset with large triangular leaves, irregularly sinuate and dentate. The flower is large, white, solitary; the fruit a large, fleshy, four-celled capsule, thickly covered with sharp spines. The seeds are flat and of a dark-brown color. Both leaves and seeds contain an alkaloid, *daturine*, closely analogous both in chemical properties and poisonous character to *atropine*, the alkaloid of belladonna. Medicinally, stramonium is a duplicate of belladonna, and is used for similar purposes. One of its most frequent employments is for the relief of asthmatic attacks, for which purpose the dried leaves or powdered roots are smoked. Stramonium is a powerful poison, the effects being identical with those of belladonna.

**Stranahan**, James S. T.: See the Appendix.

**Strandberg**, Karl Vilhelm August (*Talis Qualis*): poet; b. in Södermanland, Sweden, Jan. 16, 1818. While a student at the University of Lund he wrote a number of songs, chiefly under the influence of the German political poetry of the period. From this he later freed himself entirely. His principal collection of poems is *Sångar i Panser* (Songs in Armor), which glow with patriotic fire. He was the author of a number of occasional poems and translated Byron and Molière. D. in Stockholm, Feb. 5, 1877. *Samlade Vitterhets Arbeten* (2 vols., Stockholm, 1877–78).

D. K. Dodge.

**Strange**, Sir Robert: engraver; b. on Pomona, one of the Orkney islands, July 14, 1721; studied painting, but in 1745, having joined the army of the Pretender, was obliged to conceal himself; afterward went to Paris, where he became a pupil of Le Bas, the famous engraver, and in 1751 established himself in London as an historical engraver, in which department of art he acquired great eminence. He was knighted in 1787. He published *A Descriptive Catalogue of Pictures, etc., collected and drawn by Sir Robert Strange* (1769) and *An Inquiry into the Rise and Establishment of the Royal Academy of Arts* (1775; new ed. 1850). A collection of fifty of his principal engravings has been issued in a magnificent atlas, and his *Memoirs*, by James Dennistoun, appeared in 1855. D. in London, July 5, 1792. Revised by Russell Sturgis.

**Strangles**: in the horse, an abscess which occurs between the branches of the lower jaw. If possible, the animal should be induced to eat. The throat should be thoroughly fomented, and as soon as the sore comes to a head it should be opened, whereupon recovery will generally follow. Sometimes, however, the lymphatic glands appear to be inflamed, and occasionally metastatic abscess appears in distant parts of the body. This disease is considered contagious, and there is a similar infectious disease, also called strangles, among swine.

**Strangulation** [from Lat. *strangula'tio*, deriv. of *strangula're* (whence Eng. *strangle*), from Gr. στραγγαλᾶν, strangle, deriv. of στραγγαλᾶν, strangle, deriv. of στραγγάλη, halter]: primarily, the mechanical closure of the air-passages of the neck, so as to prevent respiration. Death by strangulation is speedy, but there may be a chance of recovery for a considerable period. Artificial respiration, stimulant applications to the extremities and chest, and of ammonia to the nostrils, should be tried. When other means have failed the galvanic battery may be employed. After apparent recovery, death may speedily ensue from secondary causes. Revised by W. Pepper.

**Stran'gury** [from Lat. *strangu'ria* = Gr. στραγγουρία; στράγξ, στραγγός, drops + οὐρεῖν, make water]: a suppression of the urine. The name is especially applied to such suppression when it depends on the presence of spasm or tenesmus of the urethra. It may be caused by the too free use of Spanish-fly blisters or of oil of turpentine, or it may attend the presence of calculi in the bladder. The warm bath, hot fomentations, mucilaginous drinks, bland enemata, and the like will usually relieve the untoward symptom.

**Strassburg**, Germ. pron. straas'boorch (anc. *Argentoratum*; Fr. *Strasbourg*): important fortified town of Alsace, on the Ill, the Breusch, and the Rhine-Rhône and Rhine-Marne Canals; 2 miles W. of the Rhine; junction of the railways of Southern Germany and France (see map of German Empire, ref. 7–D). It is ill built, with narrow streets and high houses, but is improving. The most remarkable of its public buildings is the cathedral, with a tower 466 feet high, founded in 510 by Chlodwig, but the older structure was destroyed by lightning in 1007. In 1015 Bishop Werner, of Hapsburg, laid a new foundation, and in 1275 the main building was finished. The tower was begun in 1277 by Erwin von Steinbach, and completed in 1439 by J. Hültz, of Cologne. In this building is the famous clock (made 1547–80), representing our planetary system and its constellations. The Church of St. Thomas, founded in 1031, and containing a monument of Marshal Saxe, and the New

Church are also noticeable. A German university was opened May 1, 1872, and numerous educational and benevolent institutions exist. Commerce and industry flourish in consequence of the favorable situation on the river. Important tobacco-factories are in operation, numerous breweries, printing establishments, oil and saw mills, wool-spinning establishments, manufactures of oilcloth, straw hats, gloves, paper-hangings, chocolate, mustard, goose-liver pies, soap, candles, chemicals, musical instruments, furniture, jewelry, etc. The cultivation of vegetables, fruits, and flowers is considerable. Under French dominion the city had a strong bastioned circumvallation, but since it has become part of the German empire a new system of fortification has been applied, consisting of a number of large, strong forts surrounding the inner fortifications, so that an army can encamp between the city and the forts, while the city is entirely protected from the enemy's fire by the outer forts.

During the Middle Ages Strassburg was one of the most powerful free cities of the German empire, and during the period of the Reformation it played a prominent part as one of the centers of the Protestant movement. Sept. 30, 1681, Louis XIV. captured it, and by the Peace of Ryswick he retained it. It continued, however, a completely German city down to the time of the Revolution, when French gradually gained the ascendency. By the Peace of Frankfort (1871) it returned to Germany, and is the seat of the civil and military government of Alsace-Lorraine. Pop. (1900) 150,268. Revised by M. W. HARRINGTON.

**Strat'egy** [from Gr. *στρατηγία*, office of a general, deriv. of *στρατηγός*, general; *στρατός*, army + *ἄγειν*, lead]: that branch of the art of war which has for its object the initiation and conduct of wars, campaigns, and battles in such a manner as (1) to take advantage of all available means for securing success, and (2) to cause the greatest benefits to result from victory and the least injury from defeat. The scope of strategy was formerly considered as restricted to the movements of organized armies after they were placed in the field and before they came within cannon-range of the enemy. Modern wars, however, are conducted on so grand a scale and with such rapidity that they involve all the functions of a government, and definite plans for their conduct must be prepared in advance. Consequently questions of statesmanship and diplomacy are frequently the leading factors in planning campaigns and battles, and thus become strictly strategical considerations. The domain of strategy must therefore be extended to include the methods of organizing and stationing active armies and reserves so that without unintentionally threatening or irritating neighboring countries they can be immediately mobilized for campaign when necessary. Financial and commercial considerations have the greatest possible weight in this connection, and frequently fix the time for beginning hostilities and determine the plan of campaign. In a country with a popular government, in order to arouse enthusiasm and lead the people to make necessary sacrifices, strategy, as defined above, sometimes requires a plan of campaign which, under other circumstances, might not be desirable.

An army in campaign seeks to obtain possession of some point which is known as its objective, which is selected with a view to the injury inflicted upon the enemy by its loss, and the advantages resulting from its capture. The first may be material, moral, or political; the second generally consist in facilities for further advance, better communications, and greater ease in supplying the army. Hence objectives are frequently capitals, large commercial or manufacturing cities, arsenals, river crossings, or railway centers.

The base of operations is that part of a country from which an army draws its supplies. The portion of country between the army and its base which contains the railways, wagon-roads, and water-routes, by which the army advances and receives its supplies, is called its line of operations or its communications. Since the combatants of an army can not be expected to carry with them more ammunition, provisions, etc., than are needed for one battle, the necessity for securing its line of operations from being broken is manifest. Strategical movements very frequently are directed with a view to threatening the enemy's communications and protecting one's own.

A large army covering a very extended front may, by a skillful attack, have one wing destroyed before the other can come to its support. To accomplish or prevent this is another problem in strategy of frequent application. Similar problems arise when a small but concentrated army tries to beat in detail the parts of a larger one which attempts to concentrate upon a point at or near that occupied by the smaller force, and also in manœuvering to strike a hostile force in flank, in the larger or even in the smaller operations of war.

The guiding principles of strategy consist in so conducting the preliminary operations and movements as to force the enemy to fight at a disadvantage either in numbers, in position, or in the relative results which will follow victory or defeat. The best strategical combinations, however, will not secure victory unless supplemented by the proper handling of the troops in the battle, which is the climax of military operations and which is the field of TACTICS (*q. v.*).

The principles of strategy are best studied in the critical histories of the campaigns of great leaders. See also the *Commentaries* of Napoleon; Hamley's *Operations of War*; Jomini and Clausewitz on the *Art of War*, *La Stratégie Appliquée Fixe*, etc. JAMES MERCUR.

**Stratford**: town; in the county of Essex, England; on the Lea; 4 miles E. N. E. of London (see map of England, ref. 12–J). It has a fine town-hall (1869), several breweries, and manufactories of chemicals and carriages. Pop. (1891) 42,982. On the other side of the Lea is the parish of Stratford-le-Bow. Pop. (1891) 40,378.

**Stratford**: post-village; capital of Perth County, Ontario, Canada; on the river Avon, at the crossing of Grand Trunk Railway and its Buffalo and Goderich Division (see map of Ontario, ref. 4–C). It has extensive repair-shops, a fine railway-station, good water-power, extensive manufactures, and a town-hall. It is an inland port of entry. Pop. (1891) 9,501.

**Stratford de Redcliffe**, STRATFORD CANNING, Viscount: diplomatist; b. in London, Nov. 4, 1786: was educated at Eton and Cambridge; in 1807, while still an undergraduate, received diplomatic appointments and did not take his degree till 1812. In 1814 he was sent as minister to Switzerland, in 1820 on a special mission to the U. S., in 1824 to Russia, and in 1825 as ambassador to Turkey. Diplomatic intercourse having been interrupted by the naval battle of Navarino, he returned to England and subsequently sat in Parliament for Government boroughs until 1842, when he was again sent as ambassador to Turkey, retaining that position till 1858, during which time his influence at the Ottoman court was very great, and always exercised in favor of reforms, especially those involving the amelioration of the condition of the Christian population of Turkey. The most interesting point of his whole career was the contest between him and Prince Menchikoff, in 1853. The question was whether British or Russian influence should prevail in Constantinople—or, rather, whether Russia should be allowed to settle the future destinies of Turkey to her own advantage and without paying any regard to the views of the other European powers. The keenly contested diplomatic struggle between Lord Stratford and the Russian ambassador extraordinary—the result of which was the Crimean war—is narrated with dramatic power by Mr. Kinglake in his *Invasion of the Crimea*. Canning was raised to the peerage in 1852 by the title of Viscount Stratford de Redcliffe, and made Knight of the Garter in 1869. He published an essay, *Why am I a Christian?* (1873), and a drama, *Alfred the Great in Athelney* (1876). D. Aug. 15, 1880. See his *Life*, by Stanley Lane-Poole (1888).

**Stratford-on-Avon**: town; in Warwickshire, England; 8 miles S. W. of Warwick; on the Avon, which is here crossed by a bridge with fourteen arches built in the fifteenth century (see map of England, ref. 10–H). The house in which Shakspeare was born is still preserved; that in which he died has been razed. The former, which is a Shakspeare Museum, and Anne Hathaway's cottage, are national property. In the chancel, restored 1890–92, Shakspeare was buried. Pop. (1891) 8,318.

**Strathclyde'**: an independent kingdom formed in Southwestern Scotland at the dissolution of the ancient Britannic confederacy, and consisting chiefly, as its name imports, of the broad valley or dale of Clyde. The annals of its sovereigns are involved in deep obscurity, little more than their names being known. It fell to the crown of Scotland early in the twelfth century, was held for some years by Prince David as an independent kingdom, and was permanently united to Scotland on his accession to the throne in 1124.

**Strathcona and Mount Royal**, Sir DONALD A. SMITH, Earl of: See the Appendix.

**Strathmore′**, or **The Great Valley**: the most extensive plain in Scotland; stretches across the country from Dumbartonshire, in the S. W., to Stonehaven, in Kincardineshire, in the N. E. It is bounded N. by the great mountain rampart of the Highlands, and S. by the Lennox, the Ochil, and the Sidlaw Hills, and is drained for the most part by the Tay, the longest and largest river of Scotland. The whole tract, which is highly cultivated, is about 100 miles long, and from 5 to 10 miles broad. Perth stands near its center, and to this central part the name is more particularly applied.

**Strathnairn′**, Hugh Henry Rose, Baron: soldier; b. in Berlin, Mar. 8, 1803 (his father being British minister there), and entered the British army as ensign in 1820; served in the Syrian campaign 1840–41; was Queen's commissioner at the headquarters of the French army in the Crimean war, and was wounded before Sebastopol. Throughout the Indian mutiny (1857–58) he commanded the Central India field force. His rapid marches and successful actions in the field won for him the thanks of Parliament and promotion to the rank of lieutenant-general 1860. He subsequently succeeded Lord Clyde as commander-in-chief in India, and during his term the Queen's forces were united with those of the East India Company. He commanded the British forces in Ireland 1865–70; was raised to the peerage in 1866 as Baron Strathnairn of Strathnairn, in the county of Nairn, and of Jhansi, East Indies; was promoted to be general in 1867, and in 1869 was appointed to succeed Lord Gough in the command of the Royal Horse Guards. He became field-marshal in June, 1877. D. in London, Oct. 16, 1885. F. M. Colby.

**Strathpef′fer** (i. e. valley of the Peffery): village of Ross and Cromarty, Scotland; 20 miles by rail N. W. of Inverness. Here are cold sulphur and iron water springs, which are much frequented and are useful in gout, rheumatism, scrofula, and diseases of the skin, kidneys, stomach, and liver. The climate is very favorable for the latitude (57° 34′ N.), and the surrounding region is picturesque and interesting. See Fox, *Strathpeffer Spa* (1889). M. W. H.

**Strathroy′**: town of Middlesex County, Ontario, Canada; on the river Sydenham, and on Great Western Railway; 40 miles E. of Sarnia and 20 miles W. of London (see map of Ontario, ref. 5–B). It has manufactures of woolens, castings, steam-engines, agricultural tools, etc. Pop. (1891) 3,316.

**Stratig′raphy**: See Geology.

**Stratus**: See Clouds.

**Strauss**, strows: the name of a noted family of composers.—Johann, the elder, was born in Vienna, Mar. 14, 1804, and in early childhood showed great talent for the violin. After study and experience, became deputy conductor to Lanner. In 1826 he had his own orchestra, and then began writing the waltzes which have since made the name of Strauss known everywhere. It was in 1840 that he conducted for the first time in the Imperial Volksgarten, Vienna. D. Sept. 25, 1849. He had five children.—Johann, the eldest son, b. in Vienna, Oct. 25, 1825, succeeded his father as a conductor, and in 1863 became conductor of the court balls. He composed nearly 400 waltzes, and a number of operettas which have had great success. He retired from the conductorship in 1870 to devote himself wholly to composition. D. June 3, 1899.—Joseph, the next son, b. in Vienna, Aug. 22, 1827, became also a conductor and composer. His works number upward of 283. He died July 22, 1870.—Eduard, the third son, b. in Vienna, Feb. 14, 1835, made his first appearance as a conductor in 1862; in 1865 conducted at St. Petersburg, and in 1870 succeeded his brother Johann in Vienna. He has composed over 200 dance pieces. Both Johann and Eduard visited the U. S. and conducted concerts. D. E. Hervey.

**Strauss**, David Friedrich: theologian; b. in Ludwigsburg, Würtemberg, Jan. 27, 1808. His parents lived in moderate circumstances; his chief talent seems to have been inherited from his mother. As a child he was retiring and of weak constitution, but fond of study and thorough in his acquisitions. At an excellent school in Blaubeuren and at the University of Tübingen he pursued his classical and theological course with zeal and independence; Baur was one of his teachers in both places. In philosophy he was at first repelled by Kant, but attracted by Schelling, Jacobi, and the famous German mystic Jacob Böhme, following also with eagerness the new revelations of Kerner and others on "the dark side of nature" and in the sphere of the so-called animal magnetism. In the latter part of his course he was strongly influenced first by Schleiermacher, but chiefly by Hegel, whose severe and comprehensive system, sufficient, as was supposed, for all things, was just coming into general notice. Schleiermacher's lectures on the life of Jesus, which Strauss heard in Berlin in 1831, and Hegel's logic, were the preludes to the *Leben Jesu* of Strauss, which, published in 1835 and 1836, 2 vols., in Tübingen, made an epoch in the history of German theology. This work was written in the course of a year, while he was *Repetent* at Tübingen (since 1832), when the author was only twenty-seven years of age. In the learned world of Germany it brought matters to a crisis, both in respect to biblical criticism and the relations of faith to speculation (4th ed. 1840; translated from the 4th ed. into English by Mary Ann Evans (George Eliot), 3 vols., London, 1846; n. e., 1 vol., 1893; New York. 1850; into French, from the 3d ed., by Littré. 4 vols., Paris, 1840). Strauss lays down in the preface the general principle that nothing which is supernatural, neither prophecy nor miracle, can be historical. The force of his criticism of details rests on this assumption. He resolves all the supernatural elements of the gospel story into myths; his hypothesis is known as the "mythical theory"—that is, the transforming of popular religious beliefs into facts supposed to have been realized in the life of Christ. The work had the merit of bringing together all the scattered objections to the life of Christ, and shaping them into a theory. But unless the supernatural can not be manifested, the underlying theory falls to the ground. In his concluding essay he applies the Hegelian logic to the life of Christ in such a way that, though he denies the facts as historical, he yet admits that there are certain essential ideas at their basis. Historical Christianity is true, not as history, but as idea. The Hegelian philosophy is to be substituted for Christianity. The work was written in a clear and trenchant style, at once popular and scientific. It was replied to by some of the most eminent divines in Germany (such as Neander and Tholuck) and in other countries. In 1837–38 Strauss replied to his critics in several *Streitschriften*, and in *Zwei friedliche Blätter* (Altona, 1839). He lost his theological position at Tübingen (a full account of the ecclesiastical proceedings, including the letters of Strauss, is given by Weizsäcker in the *Jahrbücher f. deutsche Theologie*, 1875, 4th part), and became a teacher in Ludwigsburg and Stuttgart. He was called to be professor of dogmatics and church history in Zurich in 1839, but was deprived of his chair by a popular insurrection, though retaining for life half his salary. In 1839 he published in Leipzig a volume of *Charakteristiken und Kritiken*, embracing essays on Schleiermacher, Daub, and Kerner, on animal magnetism and modern possessions, etc. In 1841 he was married to a once-celebrated singer, Agnese Schebest, but their characters, says Zeller, were so incompatible and the marriage so unhappy that they separated by mutual consent after five years. The wife lived in Stuttgart until her decease Dec. 22, 1870. In 1840–41 Strauss attempted to do for theology what he supposed he had accomplished for the life of Christ. Under the title *Die christliche Glaubenslehre in ihrer geschichtlichen Entwickelung, und im Kampfe mit der modernen Wissenschaft dargestellt* (2 vols., Stuttgart, 1840–41) he tried to resolve the whole of theology into philosophy. But this work, though learned and acute, made a comparatively slight impression. Having thus, in his opinion, disposed of historical and dogmatic Christianity, he betook himself for twenty years to general literature, interspersed with political speeches and action, leading the life of a wanderer from city to city. In 1847, at Mannheim, he published a pamphlet, *Der Romantiker auf dem Throne der Cäsaren, oder Julius der Abtrünnige*, an ingenious parallel between Julian the Apostate and King Frederick William IV. of Prussia, made up chiefly of apt and sharp citations. In the revolutionary period of 1848 he failed in an attempt to be elected to the noted Frankfort Parliament, but he was chosen to represent his native town (Ludwigsburg) in the diet of Würtemberg, where, to the surprise of his adherents, he denounced democracy, and in his very latest work he takes special pains to disparage republican institutions. His political views are contained in *Sechs theologisch-politische Volksreden* (Stuttgart, 1848). In 1849 he published *C. F. D. Schubarts Leben in seinen Briefen* (2 vols.). In 1851, at Mannheim, appeared a memorial of one of his friends, Christian Märklin; in 1855, at Frankfort-on-the-

Main, the *Leben und Schriften des Dichters und Philologen Nikodemus Frischlin*, representing the German culture of the sixteenth century. In 1857 he produced at Leipzig in a more important work, the *Life of Ulrich von Hutten* (2 vols.; an abridged ed. 1871; Eng. trans., London, 1874), prepared for Böcking's edition of Hutten's works; and in 1860 a volume of Hutten's *Conversations*. It was here first that he so highly eulogized and vindicated the German nationality, which he afterward advocated in such a brilliant style in his correspondence with Renan, *Krieg und Friede* (1870). In 1862 he revived the memory of a German rationalist of high critical attainments—a forerunner of Lessing—Hermann Samuel Reimarus. These and other literary and biographical works, all wrought out with æsthetic care, added to his reputation for general scholarship. In 1864 he returned to theology in the attempt at writing another life of Christ under the title *Das Leben Jesu für das deutsche Volk bearbeitet* (Eng. trans., London, 1865). The school of Baur of Tübingen and the progress of historical criticism had effectually supplanted the mythical theory of Strauss's first *Leben Jesu*. His object in the second work is, in general, to show what remains of Christ for the people after German criticism has had its full course; and he still grants that "Christianity is a moral and spiritual power in the earth"; that "we can not do without it, nor can it be lost"; that Jesus "stands foremost among those who have given a higher ideal to humanity." In 1865 he reviewed Schleiermacher's *Life of Christ*, then first published, in a work entitled *Der Christus des Glaubens und der Jesus der Geschichte* (Berlin). In 1866, under the title *Die Halben und die Ganzen*, he criticises the semi-rationalistic theology of Schenkel even more severely than he does the unbending orthodoxy of Hengstenberg. His essays on *Voltaire* (Leipzig, 1870; 3d ed. 1872) were prepared for the Princess Alice, and are praised for their critical skill and elegant diction as standing by the side of Goethe's *Wahrheit und Dichtung*. His last work, *Der alte und der neue Glauben, ein Bekenntniss*, appeared in Oct., 1872. It is intended to give the result of his life's thought and work. It rapidly went through seven editions in Germany, was published in French, and in an English version by Mathilde Blind in London and in New York (1873).

Strauss founded no school, either in philosophy or theology. He was a critic, learned, sagacious, yet without any well-defined ultimate system. His life is a reflex of the most extreme anti-Christian theory of human life. He began as an idealist and ended as a materialist. He gave up his early Hegelian pantheism to the latest theory of atheistic evolution. D. at Ludwigsburg of cancer, after long and patient suffering, Feb. 8, 1874, and was buried, by his own direction, without any church service. His *Gesammelte Schriften*, edited by E. Zeller, appeared at Bonn (12 vols., 1876–78). See his *Life*, by E. Zeller (Bonn, 1874; Eng. trans., London, 1874), and by A. Hausrath (2 vols., Heidelberg, 1876–78). Revised by S. M. Jackson.

**Straw and its Manufactures** [*straw* is O. Eng. *strēaw*: O. H. Germ. *stroh*, > Mod. Germ. *stroh*, connected with *streuen*, Eng. *strew*]: The stalk or stem of certain grains, chiefly wheat, rye, oats, barley, and buckwheat, and sometimes of peas and beans, called straw, finds large use in the manufacture of textile fabrics, paper, and braid for hats and trimmings. Originally, the employment of straw was one of the primitive arts, and it is still practiced among the rudest tribes known. Mats for sleeping on are perhaps the earliest objects that were made from straw. Baskets and bags of braided straw are still common among many aboriginal peoples. Those made in the South Sea islands are so close in texture, though quite flexible, as to be impervious to water, and are used to carry liquids. A higher development of the art is shown in the so-called Panama hats and cigar-cases that are made in South and Central America from the straw of the *Carludovica palmata*. The leaves of this plant, which resemble a palm, are gathered before they unfold, and, after the ribs and coarser veins have been removed, are cut into shreds. These are exposed to the sun and then tied into a knot and immersed in boiling water until they become white, when they are hung up in the shade and afterward bleached. The finest of these Panama hats take several months to make, and come from Ecuador, while commoner kinds are made in a few days. In certain of the U. S., as Florida and Georgia, a domestic straw from some varieties of hair grass was formerly used in making women's hats. Other uses to which straw in its natural state is put include its employment as littering in stables; as fodder; as filling for mattresses; as thatching for roofs; as packing material for delicate articles, such as crockery, glass, etc.; as bottle-covers; as stuffing, as in saddles; as "straws" in fancy drinks; as sandals; for decoration and ornamentation, as in kindergarten work; or fancy straw frames and baskets. Its use as a fuel has been suggested in the event of the coal-supplies becoming exhausted. It is the fiber from the straw of the flax plant that is largely used in the making of linen. The most important application of straw is probably in paper-making. The crude straw is cut and put into vats with lime. It is then cooked and worked into pulp in a beating-machine. This pulp is run off in a web machine into straw-paper, used in wrapping, etc., or into straw-board, used in making boxes, etc. When bleached it is white. The tissue-paper used in the making of cigarettes is commonly made from straw. The rye straw yields the best qualities of paper. In the form of braid, straw is largely used in the making of hats, and as trimming in millinery. Straw hats were worn by the Romans, but the industry remained in a primitive condition until toward the end of the sixteenth century. It is said that Mary, Queen of Scots, engaged a company of Lorraine straw-plaiters to return with her to Scotland in order to instruct her countrywomen in their art; and thus "was the first straw-hat manufactory established in Scotland under the kind auspices of a female sovereign of eighteen." Notwithstanding her inability to care for the little colony she brought from France, they struggled on until her son James became King of England, and then they were transferred to Luton, Bedfordshire, England. In Italy the chief seat of the industry was in Tuscany, and the Leghorn hats have acquired a high reputation. A grand ducal decree of 1575 enumerates the dealers in straw hats among the Tuscan traders liable to a matriculation tax; but, according to a monumental inscription in the Church of San Miniato at Signa, near Florence, Sebastiano Michelacci di Bologna, who died in 1739, was the first to export straw hats to England, and he is hence regarded as the founder of this branch of national commerce. In Italy, as the making of straw plaits grew, certain straws, methods of treatment, and patterns gave rise to characteristic varieties of bonnets with special braids, as the Tuscan and Leghorn hats which were typical and fashionable. Foreign wars prevented their importation into England, and the Dunstable bonnet of home manufacture was the result. On the restoration of peace unplaited straws, imported from Tuscany, resulted in the Tuscan grass bonnet, one of which was publicly worn by Queen Adelaide. Thus the industry, originally that of the finished product, passed in England into one where various straws, both native and imported, were manufactured into the desired article. This result was somewhat due to the efforts of the British Society of Arts, which made great efforts to sustain the industry. In 1822 it awarded a silver medal and twenty guineas to Miss Sophia Woodhouse, of Connecticut, for a new material for fine plaits, the *Poa pratensis*, then supposed to be equal to the Italian straw for making fine straws. For some time the industry had been in existence in the U. S., and the first straw bonnet braided in the U. S. is said to have been made in 1798 by Miss Betsey Metcalf, of Providence, R. I., but the industry has followed the practice of Great Britain, and now the crude braid is chiefly imported and made up into the various finished products as hats (of which there are 103 factories in the U. S. and Canada). The principal sources of the straw imported into the U. S. are China, Italy, England, Switzerland, Germany, Japan, Belgium, and France. For braids wheat straw is preferred, but rye straw has longer stems and can be braided into more delicate and even tissues. It is, however, less durable, and does not wash as well as wheat. In Tuscany the preferred straw is from a variety of spring wheat, thickly sown, best on a sandy, hilly ground, in February or March, according to season and local climate, and harvested by pulling the bearded wheat while the ear is in a soft milky state. The straw is left spread upon clean ground or grass for some days for the sake of the action of the dew in bleaching it; it is then gathered into sheaves, from which the laborers draw out the stalks, breaking them at the joints and breaking off the heads. They are then sorted by a species of sieve composed generally of sixteen tin plates pierced with holes and briskly moved by a wheel. They are then plaited and, if for straw hats, are shipped in bales of 240 pieces of 50 meters each. English straws are made into lengths of 20-yard pieces, although sometimes 14 and 12 yard pieces are made. Originally, the "whole straw" was used in plaiting, but in England the splitting of the straw with a knife led to the production of a lighter variety, and, about 1815, machines were introduced for cutting. This invention is one of the causes of the great success that has attended the manufacture of straw plait in England. Originally, the varieties of straw plait were few, but in recent years an almost endless number of patterns have come into existence, many of which are colored. Notwithstanding the foreign competition, especially that from China, whence the so-called Canton plaits come, London continues to be the chief market of the world, and regular sales are held there. In the U. S. the crude braids are used chiefly for straw hats, and they are bleached and sewed into shape. The hats are then blocked and sized, after which they are finished by putting on bands, sweatbands, tips, etc. The fancy straw plaits are used in millinery, and are imported ready for use. According to the census returns of 1890 there were six manufactories of straw goods other than those of hats and caps in the U. S., with an aggregate capital of $106,750, and employing 433 hands. During the fiscal year 1899–1900 there were imported into the U. S. 5,495 tons of straw, valued at $15,750, also manufactures of straw not specially provided for, valued at $336,287. Materials for hats, bonnets, hoods, etc., including straw, chip, and other braids, amounting to $2,092,801, were imported during 1900.

MARCUS BENJAMIN.

**Strawberry** [O. Eng. *streawberige* < primitive Teutonic *strawa-* < Indo-Europ. *sraghwo-*; cf. Lat. *fragum*; Gr. ῥάξ. The association of the Eng. word with *straw* is false]: any species of the genus *Fragaria*, family *Rosaceæ*. The genus is a small one, comprising under a liberal estimate about a dozen species, and it is confined to temperate climates of both the northern and southern hemispheres. The species are all low herbs with thrice-divided leaves, propagating by runners, and bearing the flowers and fruits upon short scapes. Botanically considered, the strawberry fruit is a fleshy receptacle or stem, upon which the true fruits or akenes—generally called seeds—are borne. The strawberry is a fruit of comparatively recent cultivation, the first named garden variety having appeared in 1660. At the present time it is largely grown, and in North America it exceeds in importance any other of the small fruits. Commercial strawberry-culture began in the U. S. about 1830. The first important variety of American origin was the Hovey, which first fruited in 1836 or 1837 in the garden of the originator, Charles M. Hovey, Cambridge, Mass. This was followed in importance by Boston Pine. About twenty years after the Hovey appeared, the Wilson, or Wilson's Albany, was introduced from the garden of James Wilson, Albany, N. Y., and this variety is still the most popular market berry in many parts of the Northern States. These varieties, and all other commercial strawberries of North America, are offsprings of the old Pine strawberries, a class which sprung from the Chilian berry (*Fragaria chiloensis*). This species was first introduced into Europe about 1712, by Capt. Frazier. The evolution of the garden strawberries from this type has taken place mostly within the nineteenth century. The wild strawberry of the eastern parts of the U. S. (*Fragaria virginiana*) was early introduced into Europe, and it was once the leading type of garden strawberries, but it is now practically lost to cultivation. The Hautbois strawberry (*Fragaria moschata*), and the Alpine and Perpetual types (*F. vesca*), both of Europe, are occasionally cultivated by amateurs.

In the U. S. the strawberry succeeds in a great variety of soils, but, in the North at least, the best soil is thought to be a rich sandy loam, particularly one which resists the effects of drought. The methods of planting and cultivation are various, but all strawberry-growers agree that the plants are not profitable after they have born three crops. There is an increasing tendency to allow the plantation to bear but a single crop, for, if the ground is good and the treatment generous, the first crop is the best which can be obtained; and the frequent rotation prevents the land from becoming foul, and it effectually prevents serious mischief from the leaf-rust fungus and from various insects. Early spring is the time usually preferred for setting the plants, and the first crop is borne a year from that time. If the plants bloom to any extent the year they are set, the blossoms should be removed, in order to allow the plants to become thoroughly established for the following year's crop. Strawberries are commonly planted in rows from 3½ to 5 feet apart, and the plants are set from 1 foot to 2 feet apart in the row. It is customary to allow the plants to form a matted or continuous row a foot or 2 feet wide, although, in private gardens, hill-culture is sometimes practiced for the purpose of securing finer fruit. In the northern parts of the U. S. the plants are generally covered late in fall with a light mulch of straw or marsh hay, as a protection against frost. Most persons leave this mulch upon the ground until the crop is harvested, drawing it off the plants into the spaces between the rows as soon as growth begins in spring. Some varieties of strawberries have flowers without stamens, and these must be planted near pollen-bearing varieties to insure fruitfulness. The exact method of planting so as to insure perfect pollination, varies with the varieties and with the grower, but it is generally thought that at least one-third of the plants should be strong pollen-bearers. An average good yield of strawberries may be considered to be from 150 to 250 bush. per acre. There are various insect depredators and other troubles, for an account of which the reader should consult the bulletins of experiment stations. The varieties in favor change so frequently that no list of them can be recommended here. There are many good writings upon the strawberry. The fullest account of American varieties is to be found in Merrick's *Strawberry and its Culture* (1870). A philosophical discussion of the origin of the cultivated strawberries, by Bailey, occurs in *The American Naturalist* (xxviii. 293, Apr., 1894). The reader should consult Fuller's *Strawberry Culturist*, and Terry and Root's *How to Grow Strawberries*.

L. H. BAILEY.

**Strays**: See ESTRAY.

**Streator**: city (laid out in 1868, incorporated as a city in 1882); La Salle co., Ill.; on the Vermilion river, and the Atch., Top. and S. Fé, the Burl. Route, the Chi. and Alton, the Ind., Ill. and Ia., and the Wabash railways; 93 miles S. W. of Chicago (for location, see map of Illinois, ref. 3–E). It is built on the river bluffs, and has adequate sewerage, gas, electric-lighting, street-railway, water, and fire services, and an improved public park of 11 acres in the heart of the city. It is surrounded by a rich agricultural country, and is underlaid by several seams of coal, two of which are being worked, and also by valuable strata of shale, fire-clay, and other clays, which are used in making paving-brick, sewer-pipe, and other clay products. The city contains 23 churches, including a Greek Catholic church and the unique Church of Good Will toward Men, 17 public schools, a high-school building (the gift of a private citizen, cost $45,000), 2 kindergartens, 4 private and parochial schools, 2 convents, public library, Y. M. C. A. building with hall, gymnasium, and free reading-room, Plumb Opera-house, 3 national banks with combined capital of $250,000, 3 building and loan associations, 32 fraternal societies, and 3 daily and 8 weekly newspapers. In 1894 the estimated property valuation was $12,000,000. The industrial establishments include 8 clay-working factories, producing building and paving brick, sewer-pipe, and tile; several manufactories of glass bottles, window glass, rolled plate-glass, flint and Bohemian ware, and glass specialties; foundries and machine-shops, and flour and planing mills. Pop. (1880) 5,157; (1890) 11,414; (1900) 14,079.

J. E. WILLIAMS.

**Street**, GEORGE EDMUND, R. A., F. S. A.: architect; b. at Woodford, Essex, England, June 20, 1824; was educated at Camberwell, and afterward studied architecture under Gilbert Scott. In 1850 he was appointed architect for the diocese of Oxford, and subsequently for those of York, Ripon, and Winchester. His predilection was mainly for the Gothic style, and he was recognized as one of the leaders in the GOTHIC REVIVAL (*q. v.*). His architectural structures are very numerous and important: among them are SS. Philip and James, Oxford; the Crimean Memorial church, Constantinople; and the Synod House in Dublin. Among his restorations are Jesus College chapel, Cambridge, and the nave and choir of Christ Church Cathedral, Dublin. In 1847 he won one of the £100 prizes for a design for a new Foreign Office, and in 1868 was appointed architect of the buildings for the new courts of law, but his original design was afterward considerably modified. Besides numerous essays and lectures upon architecture, he published *The Brick and Marble Architecture of North Italy in the Middle Ages* (1855) and *Some Account of Gothic Architecture in Spain* (1865), which latter work is of peculiar value as being the only connected account of the interesting cathedrals and other churches of the Peninsula. D. Dec. 18, 1881.

Revised by RUSSELL STURGIS.

**Street-railways**: railways constructed wholly or chiefly in the streets of cities or towns, and designed especially for local passenger traffic. The first application of the railway to the facilitation of short-distance passenger traffic in towns was made by John Stephenson in New York in 1831. A track of flat iron bars spiked to timbers resting on stone blocks was laid on the Bowery and Fourth Avenue from Prince Street to the Harlem river. An omnibus car, with flanged wheels and built in three compartments entered from the side and each holding ten persons, and with seats on the roof for thirty more passengers, was drawn by horses. Commercially this enterprise was not successful, and was abandoned after four years, but was resumed in 1845 with cars of the form used at present, entered from the ends. In 1852, the Second, Third, Sixth, and Eighth Avenue lines in New York were begun. Boston began the construction of horse-car lines in 1856, Philadelphia in 1857, and New Orleans in 1861, using for the first time the one-horse small car usually known as the "bob-tail." In France a line was constructed in Paris in 1853. In Great Britain George Francis Train, after three years of earnest endeavor, succeeded in 1860 in building a road at Birkenhead and one in London, which was removed in a few months, and not until 1870 were horse-cars permitted in that city. In 1866 a number of horse-car lines were built in South America.

The passage of the General Tramways Act by Parliament in 1870 gave an impetus to street-railway construction in Great Britain, and during the following twelve years 671 miles of lines were laid.

In 1894 there were in operation in the U. S. 12,500 miles of street-railway track, in the United Kingdom 1,000 miles, and on the continent of Europe 1,200 miles. There were also lines in Africa, Japan, Australia, New Zealand and Ceylon, and South America.

Prior to 1873 all street-cars were drawn by horses. In that year Andrew Hallidie constructed a road in San Francisco, Cal., on which the motive power was provided by a stationary steam-engine which drove a drum, around which passed an endless wire cable which was carried in pulleys in a conduit underneath the surface of the street on which the rails were laid. Through a slot in the top of the conduit a flat bar passed from the car to the cable, fitted with apparatus for grasping the cable tightly or releasing it at will, which could be controlled from the car. After several years of successful operation of this mode of propulsion in San Francisco, it was introduced in Chicago in 1881, in Philadelphia in 1883, on the Brooklyn bridge in the same year, on Tenth Avenue and 125th Street in New York in 1886, and on Broadway and Third Avenue in 1894, and in Baltimore in 1893. A cable road was built in New Zealand in 1883 and one in London in 1884. In 1894 there were 662 miles of cable road in operation in the U. S., and 20 miles in England.

The first commercially successful application of electricity to the traction of street-cars was made at Lichterfelde, near Berlin, by Siemens and Halske in 1881. On July 27, 1884, the first operation of an electrically propelled line in direct competition with horse-cars was begun at Cleveland, O., on the Bentley-Knight system. In the same year the first practical system of conveying the electricity from wires overhead to a motor on the car by a trolley, or small grooved pulley on the end of a flexible pole extending above the roof of the car, was made in Kansas City, Mo. Improvements in the apparatus made by Sprague in 1888 led to the construction of the first installation on a large scale of an electrically propelled street-car system at Richmond, Va., in that year. The greater economy and efficiency of electric roads was quickly recognized, so that while in 1888 there were 89 miles of roads so operated, there were in 1894 9,008 miles in the U. S. and 195 miles in Europe. For description of the system, see ELECTRIC RAILWAYS.

In 1881 Mekarski applied compressed air with success as a motive power to street-cars at Nantes, France, and the same method has since been applied in Paris and in Berne, Switzerland.

The desire for more rapid transit between distant points in large towns than is safe in a street used by pedestrians and vehicles drawn by horses has led to the construction of lines of travel above and below the surface of the ground. The first effort in this direction was in London in Jan., 1863, when a 3-mile section of underground railway was opened for traffic. Its success led to the extensions of the line until 1884, when 15 miles of line were completed. In Dec., 1890, another underground road, the City and South London, 3 miles long and operated by electricity, was opened for travel. In Berlin a viaduct carrying railway tracks above the street-level for 7½ miles through the center of the city was opened in 1882. In New York an elevated railway, 4 miles long, supported on columns on the sidewalk of streets, was put in operation in June, 1869, operated by a cable. This was unsuccessful, and locomotive engines were substituted on Apr. 9, 1871. In 1877 additional lines were built, until in 1879 there were 32·4 miles in operation on Manhattan Island. Between 1886 and 1891 the system was extended 3·7 miles N. of the Harlem river, and introducing improved methods of construction and heavier rolling stock. In Brooklyn, in 1885, an elevated road was put in operation, and in 1895 there were 25 miles in operation. In 1893 an elevated railway, 5 miles long, was opened in Liverpool, England, operated by electricity. See UNDERGROUND RAILWAYS.

The relative cost of building and equipping each mile of double-track railway for the different methods of traction, the rate of speed attained, and the expense of running a car a mile, are approximately as follows:

| MOTIVE POWER. | Cost per mile. | Speed, miles per hour. | Operating expenses per car-mile. |
|---|---|---|---|
| Horses | $71,000 | 6 | 18 cents. |
| Cable | 300,000 | 10 | 14 " |
| Electric surface | 115,000 | 12 | 13 " |
| Steam elevated | 500,000 | 13 | 13 " |
| Underground | 1,500,000 | 13 | 15 " |

J. J. R. CROES.

**Streitberg**, strīt'bărch, WILHELM: comparative philologist; b. at Rüdesheim, Germany, Feb. 23, 1864; educated at the gymnasium in Wiesbaden and at the University of Leipzig; docent at Leipzig 1889, and in autumn of same year Professor of Indo-European Philology in the University of Freiburg in Switzerland. He is one of the most aggressive of the younger generation of comparative philologists. He is the author of *Die Abstufung der Suffixe io und ieu im Germanischen* (1888); *Perfective und imperf. Actionsart im Germ.* (1889); *Die germ. Komparativa auf -ōz* (1890); *Zur germ. Sprachgeschichte* (1892); *Entstehung der Dehnstufe* (1894); joint editor with K. Brugmann of *Indogermanische Forschungen* since 1891. BENJ. IDE WHEELER.

**Strength of Materials**: the resistance of materials to forces which tend to change their form; often called the elasticity and resistance of materials. The science of the strength of materials is sometimes called the mechanics of materials. The subject is partly experimental and partly theoretical, the experiments furnishing the fundamental facts, while the application of theory to these deduces the rules and formulas for practical use.

The materials used in engineering constructions are more or less elastic when the applied forces are not too great, that is, they spring back to their original form upon the removal of these forces. For elastic materials it is found that the change of form is proportional to the applied force; this law holds until a point called the elastic limit is reached, after which the change of form increases more rapidly than the force, and rupture finally occurs. It is a fundamental rule in engineering that materials should not be strained beyond the elastic limit, since then the elasticity is impaired and a permanent deformation results.

The molecular resistance which is developed by an applied force is called stress. Stresses are tensile when the forces tend to pull a body apart, compressive when they tend to crush it, and shearing when they tend to cut it across. In bending a beam stresses are produced often called flexural, but they can always be resolved into those of tension, compression, and shear; in twisting a shaft stresses are produced often called torsional, but they can also be resolved into the three kinds of simple stress.

*Tension.*—When two equal forces are applied at opposite ends of a bar or rod a tensile stress equal to one of the forces is produced at every cross-section of the bar. If $P$ be the intensity of each of the forces then the internal stress is also $P$. If $A$ be the area of the cross-section of the bar the unit-stress is $P \div A$, and this is represented by $S$. Unit-stresses are usually expressed in pounds per square inch or in kilogrammes per square centimeter. If the force $P$ be gradually applied the unit-stress $S$ also gradually increases, and is accompanied by an elongation of the bar. When $P$ is large enough to cause the rupture of the bar the unit-stress $S$ is called the ultimate tensile strength of the material. The elastic limit is reached for some materials when the unit-stress is about one-half the ultimate strength; when $S$ is less than this elastic limit the bar springs back to its original length upon the removal of the applied forces; when it is greater it does not entirely spring back, but a permanent set remains.

If $l$ be the original length of the bar and $\lambda$ the elongation produced at any stage of the test, $\lambda \div l$ is the unit-elongation. Within the elastic limit the ratio of the unit-stress to the unit-elongation is called the coefficient of elasticity, or sometimes the modulus of elasticity. Let $s$ be the unit-elongation, and $E$ the coefficient of elasticity; then

$$E = \frac{S}{s} = \frac{Pl}{A\lambda},$$

and the value of $E$ is sensibly a constant for any simultaneous values of $S$ and $s$, provided that $S$ is less than the elastic limit.

The following are average values of the tensile elastic limit, ultimate strength, coefficient of elasticity, as also the elongation at the elastic limit and the ultimate elongation, for four principal materials used in engineering:

| MATERIAL. | POUNDS PER SQUARE INCH. | | | ELONGATION, PER CENT. | |
|---|---|---|---|---|---|
| | Elastic limit. | Ultimate strength. | Coefficient of elasticity. | At elastic limit. | At rupture. |
| Timber | 3,000 | 10,000 | 1,500,000 | 0·20 | 1·5 |
| Cast iron | 6,000 | 20,000 | 15,000,000 | 0·04 | 0·5 |
| Wrought iron | 25,000 | 55,000 | 25,000,000 | 0·10 | 25·0 |
| Steel | 50,000 | 100,000 | 30,000,000 | 0·17 | 15·0 |

These values are subject to much variation, particularly for steel, which may range from 60,000 to 300,000 lb. per square inch in ultimate strength. Iron wire has an ultimate strength of nearly 100,000 lb. per square inch, and cast iron has been made with a tenacity of 46,000 lb. The strongest kinds of timber, as box, ash, and beech, reach nearly 20,000 lb., while weaker kinds, like poplar and white pine, may be only 4,000 or 5,000 lb. per square inch in ultimate strength.

The diagram in Fig. 1 gives graphical representations of the average tensile properties of these four materials. The stresses per square inch are laid off as ordinates and the percentages of elongation as abscissas, and for any point on one of the curves the approximate values of these two quantities are seen by inspection. The curve for each material is a

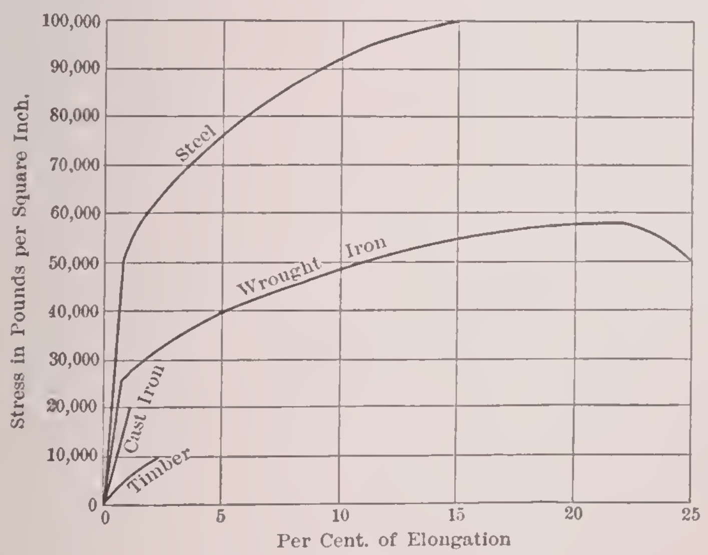

FIG. 1.

straight line from the origin until the elastic limit is reached, the unit-stresses being proportional to the elongations. At the elastic limit a sudden change in the curve is noted, and then the elongation increases more rapidly than the stress. The area between the curve and the base is a measure of the work required to rupture a cubic unit of the material.

As the elongation of a bar increases under tension a lateral contraction ensues, the unit-contraction being about one-third of the unit-elongation until the maximum strength is reached, and then, for ductile materials, the contraction increases very rapidly owing to the flow of the metal. The amount of ultimate contraction of area, which often amounts to 50 per cent. of the original area, is regarded as a valuable index of ductility and toughness.

*Compression.*—The phenomena of compression are similar to those of tension, provided that the elastic limit be not exceeded, and that the length of the bar does not exceed about five times its least diameter. Rupture usually occurs by cracking and shearing, or sometimes by lateral bulging. The following are average values of the compressive elastic limit, ultimate strength, and coefficient of elasticity for the six principal materials used in engineering constructions, all in pounds per square inch:

| MATERIAL. | Elastic limit. | Ultimate strength. | Coefficient of elasticity. |
|---|---|---|---|
| Timber | 3,000 | 8,000 | 1,500,000 |
| Brick | ...... | 4,000 | .......... |
| Stone | ...... | 6,000 | 6,000,000 |
| Cast iron | 6,000 | 90,000 | 15,000,000 |
| Wrought iron | 25,000 | 55,000 | 25,000,000 |
| Steel | 50,000 | 150,000 | 30,000,000 |

It should be noted that these average values are subject to much variation in different qualities of materials. For instance, the strength of some kinds of brick may be as low as 1,000 and of others as high as 15,000 lb. per square inch; that of some kinds of building-stones may be as high as 20,000 lb. Cast steel has been made with an ultimate compressive strength of nearly 400,000 lb. per square inch. The figures given hence should be used with caution in particular cases.

When the length of a bar or column is less than ten times its least diameter the compressive force $P$ may be regarded as uniformly distributed over the cross-section $A$, so that the unit-stress $S$ is simply $P \div A$; but for greater lengths a lateral flexure of the column occurs so that the compressive stress on the concave side is greater than that on the convex side. If $C$ denote the greatest unit-stress on the concave side, $l$ the length of the column, $r$ the least radius of gyration of the cross-section, then

$$C = \frac{S}{1 - \dfrac{nSl^2}{\pi^2 E r^2}},$$

in which $S$ is the mean unit-stress $P \div A$, and $n$ is a number depending on the arrangement of the ends of the column, being 1 when both ends are round, $\frac{4}{9}$ when one end is round and the other fixed, and $\frac{1}{4}$ when both ends are fixed.

*Shearing.*—A shearing stress occurs whenever two equal forces, acting like a pair of shears, tend to cut a body apart. When a hole is punched through a plate the ultimate shearing strength of the material must be overcome over the cylindrical surface of the hole. When a rivet connects two plates that are in tension the plates tend to shear the rivet across.

The ultimate shearing strength of timber is about 3,000 lb. per square inch across the grain and only about 500 lb. parallel with the grain; for cast iron it is about the same as the tensile strength; for wrought iron and steel perhaps one-fifth less than the tensile strength. Little is known regarding the elastic limit in shearing, but the coefficient of elasticity is between one-half and one-third of that for direct tension.

A shearing stress is always developed in an oblique section of a bar which is subject to direct tension or compression. If $S$ be the tensile or compressive unit-stress the maximum shearing unit-stress is $\frac{1}{2}S$, and this occurs in a direction making an angle of 45° degrees with the axis of the bar. Shearing stresses also occur in all cases of the bending of beams and the torsion of shafts.

*Working Stresses.*—The unit-stresses which should be used in the design of structures are much less than the ultimate strength of the material, and indeed less than the elastic limit. The ratio of the ultimate strength to the working unit-stress is called the factor of safety, and the following are average values of the factors of safety usually employed in cases of design:

| | Timber. | Brick and stone. | Cast iron. | Wrought iron. | Steel. |
|---|---|---|---|---|---|
| For steady stresses | 8 | 15 | 6 | 4 | 5 |
| For varying stresses | 10 | 25 | 15 | 6 | 7 |
| For shocks | 15 | 30 | 20 | 10 | 15 |

Steady stresses occur in buildings, varying stresses in bridges, while shocks are liable to occur in machinery and on railway wheels and rails. The injurious nature of shocks requires a high factor of safety, and hence a low working stress. A load suddenly applied theoretically produces twice the stress caused by the same load when applied gradually, and the elongation is also double. When a load drops upon a bar the resulting stresses and deformations are often more than double those caused by a gradually applied load. In all cases it is desirable that such a factor of safety should be used that the maximum working unit-stress may not exceed one-half the elastic limits of the material.

Repeated stresses beyond the elastic limit cause a change of molecular structure, or as commonly expressed, the material becomes fatigued. The greater the range of stress the less should be the working unit-stress used in the design. Stresses alternating from tension to compression require almost double the material that is necessary when the range is in tension alone, and nearly four times as much as for the case of steady stress.

*Testing-machines.*—The most common method of testing is by tension, the quantities determined being the elastic limit, maximum or ultimate strength, ultimate elongation, and contraction of area. Fig. 2 shows the form of specimen generally used, the heads being clamped in blocks to which the pulling force is applied. Marks are made at regular intervals along the specimen, and measurements made between these, both before and after the test, give the data for computing the elongation. The diameter of the specimen is usually about half an inch, and its length between the heads about 8 inches.

FIG. 2.

The numerous forms of testing apparatus may be classified as screw machines and hydraulic machines, the power being applied in the former by a screw and wheel, and in the latter by pressure transmitted through oil by means of a pump. Fig. 3 shows a machine of the latter class for testing wire and small rods. The wire clamped in position is seen in the foreground. The handle of the pump is worked by hand-power, and the pressure thus produced is transmitted through the oil by means of a small tube to the cylinder above the specimen, where it acts upon a piston which causes the cross-head to move up, and thus brings tension upon the specimen. A scale and weights are provided for reading the tensile stress applied. This machine is 4 feet high, nearly 4 feet long, weighs 890 lb., and can exert a tension of 10,000 lb.

Probably the best and most precise testing-machine in the world is that constructed for the U. S. Government by

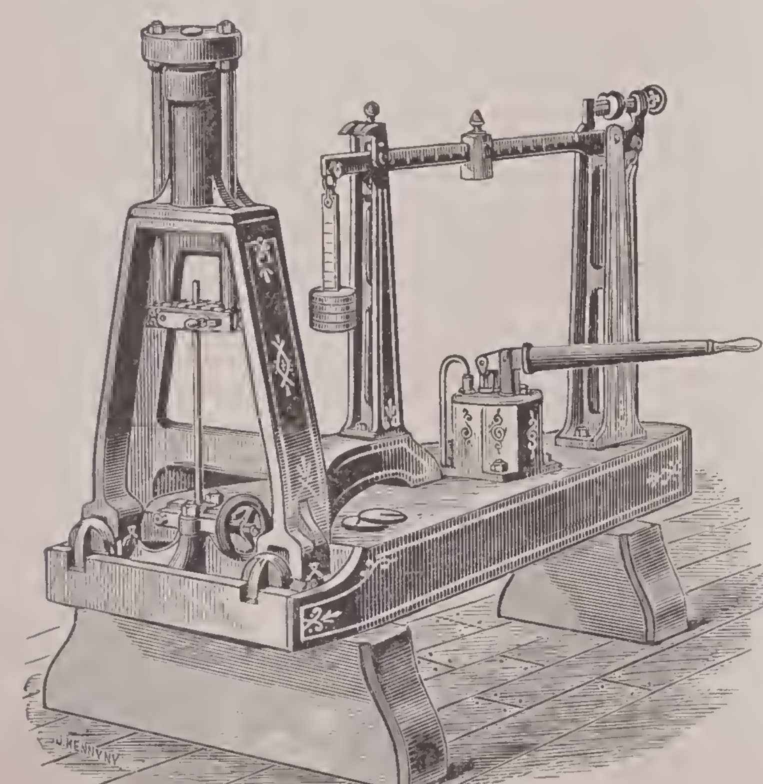

FIG. 3.

A. H. Emery, and now at the Watertown arsenal; it has a capacity of 1,000,000 lb., and can break a bar 30 feet long. Special machines of greater capacity have been constructed for testing eye-bars and other bridge members. The machine of the Union Bridge Company, at Athens, Pa., has a capacity of 1,224,000 lb., and it can break a bar 40 feet long. That of the Phœnix Bridge Company, at Phœnixville, Pa., built in 1893, has a capacity of 2,160,000 lb., and it can break a bar 45 feet long.

Compressive tests are more difficult to make than tensile ones, on account of the greater labor of preparing the specimens, and of insuring a uniform distribution of pressure over the surfaces. Even for a material like cement, which is always used in compression, the tensile test is preferred. Flexural tests of beams are often made to determine the modulus of rupture. (See FLEXURE.) Tests for the resistance of specimens to twisting are easily made by the machine devised by Thurston in 1873, which furnishes an autographic record of the stress and deformation, and thus renders possible a thorough study of the properties of materials under TORSION (*q. v.*).

*Resilience of Materials.*—When a body falls from a height upon a bar or beam it expends an amount of energy equal to the product of its weight and height of fall. This energy is resisted by the work of the internal stresses in the bar or beam. All the work of these internal stresses is called resilience, which is thus a measure of the capacity of the bar or beam to resist shock. Resilience is proportional to stress and deformation jointly. Elastic resilience is the work that can be resisted up to the elastic limit, and ultimate resilience is the total work up to the point of rupture, the latter being far greater than the former. The elastic resilience for different materials in tension can be compared by taking half the product of the elastic limits by the corresponding elongations; this quantity is often called the modulus of resilience. The ultimate resilience of materials can be roughly compared by the areas included between the curves in Fig. 1 and the base. The following mean-values of these quantities for tensile resilience are in inch-pounds per cubic inch of material:

| MATERIAL. | Elastic resilience. | Ultimate resilience. |
|---|---|---|
| Timber | 3 | 100 |
| Cast iron | 1 | 70 |
| Wrought iron | 13 | 13,000 |
| Steel | 42 | 12,000 |

The laws of elastic resilience show that the total resilience of a bar or beam is proportional to its volume, and independent of the form of cross-section, so that a beam resists shock with equal efficiency whether struck on the narrow or broad side; also the effect of a blow at the middle of a beam is no greater than at any other point. These conclusions are approximately true for ultimate resilience only in the case of cast iron; for other materials the laws are yet to be determined.

*History and Literature.*—The study of the strength of materials began with the announcement by Robert Hooke in 1678 of the law of proportionality between stress and elongation. Few experiments of value were made, however, until after the beginning of the nineteenth century. The work of Tredgold and Hodgkinson, prior to 1850, has since been extended by Kirkaldy, Bauschinger, Wöhler, Thurston, Howard, and others, so that volumes would be required to give even a fair summary of the properties of the numerous qualities of iron and steel. The strength of alloys of copper, zinc, and tin has been fully investigated by Thurston. Most valuable work was done by the British Government in 1848, and by a U. S. board in 1876. Numerous testing-laboratories have been established by manufacturers and by technical schools, and progress in the knowledge of materials is rapid and continuous.

The theory of the resistance of materials is intimately associated with that of beams, columns, and shafts. Beams were first discussed by Galileo in 1638, and during the nineteenth century the theory of all branches of the subject has been developed by Navier, Poncelet, Saint-Venant, Lamé, Weyrauch, Rankine, and many others. Todhunter and Pearson's *History of the Mathematical Theory of Elasticity and of the Strength of Materials* (London, 1893) gives a full account of these researches. Thurston's *Materials of Engineering* (3 vols., New York, 1884) and Burr's *Elasticity and Resistance of Materials* (New York, 1888) may be consulted for experimental results; Unwin's *Testing of Materials* (London, 1890) and Abbott's *Testing-machines* (New York, 1885) for the methods of conducting tests. Concerning beams and columns, reference is made to the article FLEXURE, and concerning shafts to the article TORSION. See also BRICK, BUILDING-STONE, CEMENT, CONCRETE, and FATIGUE OF MATERIALS. MANSFIELD MERRIMAN.

**Strepsip'tera** [Mod. Lat.; Gr. στρέψαι, aorist of στρέφειν, twist + πτερόν, wing]: a group of insects, formerly considered a separate order, but now classed with the *Coleoptera* as a family, called *Stylopidæ*. The elytra are very short, the wings of the male large and folded like a fan (whence the name); the females are wingless. The eyes are large; the tarsi two to four jointed. They are parasitic on various species of bees and wasps, and are found between the joints of the abdomen. The female never leaves the host, but the winged males become free when mature. E. A. BIRGE.

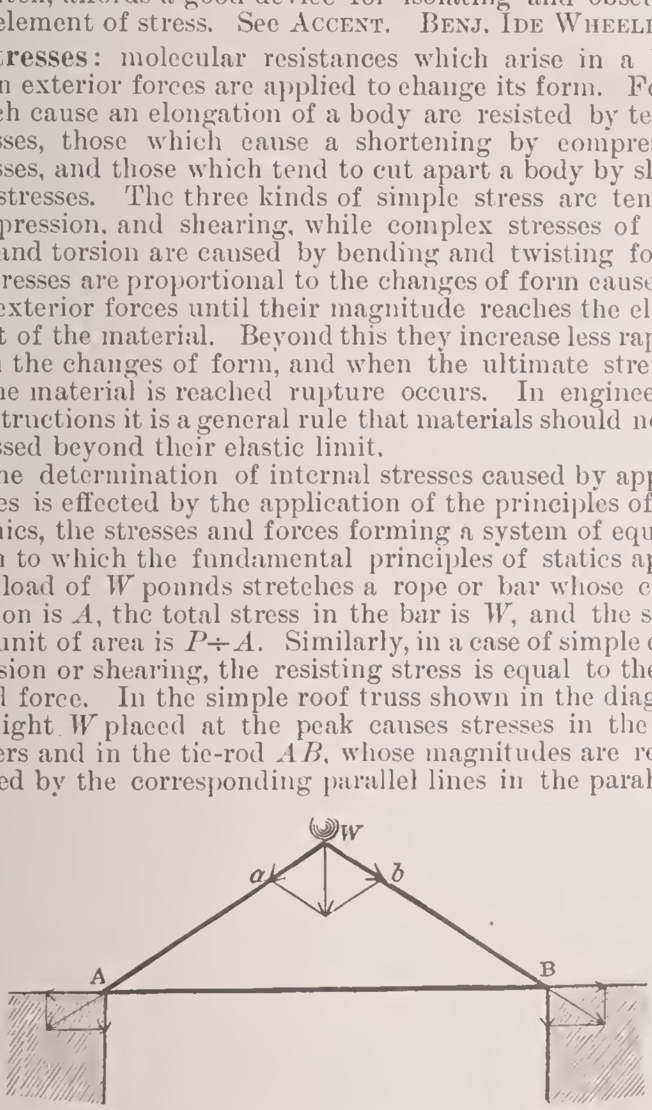
**Streptoneu'ra** [from Gr. στρεπτός, twisted + νεῦρον, nerve]: a term sometimes employed for a group of molluscs, including the *Prosobranchiata*, in which the pleurovisceral nerves have been crossed in the general twisting of the body. See GASTEROPODA.

**Stress** [M. Eng. *stresse*, probably abbrev. of M. Eng. *destresse* > Eng. *distress*]: a term of phonetics denoting the force in the outpush of breath accompanying the production of one syllable as compared with others; i. e. relative force. It is commonly attended in English by elevation of pitch, and these two features are often confused under the name accent. Whispering, inasmuch as it admits of no variation of pitch, affords a good device for isolating and observing the element of stress. See ACCENT. BENJ. IDE WHEELER.

**Stresses**: molecular resistances which arise in a body when exterior forces are applied to change its form. Forces which cause an elongation of a body are resisted by tensile stresses, those which cause a shortening by compressive stresses, and those which tend to cut apart a body by shearing stresses. The three kinds of simple stress are tension, compression, and shearing, while complex stresses of flexure and torsion are caused by bending and twisting forces.

Stresses are proportional to the changes of form caused by the exterior forces until their magnitude reaches the elastic limit of the material. Beyond this they increase less rapidly than the changes of form, and when the ultimate strength of the material is reached rupture occurs. In engineering constructions it is a general rule that materials should not be stressed beyond their elastic limit.

The determination of internal stresses caused by applied forces is effected by the application of the principles of mechanics, the stresses and forces forming a system of equilibrium to which the fundamental principles of statics apply. If a load of $W$ pounds stretches a rope or bar whose cross-section is $A$, the total stress in the bar is $W$, and the stress per unit of area is $P \div A$. Similarly, in a case of simple compression or shearing, the resisting stress is equal to the applied force. In the simple roof truss shown in the diagram a weight $W$ placed at the peak causes stresses in the two rafters and in the tie-rod $AB$, whose magnitudes are represented by the corresponding parallel lines in the parallelo-



grams of forces. The vertical reaction of each support is $\frac{1}{2}W$, and the moment of the stress in the tie-rod with respect to the peak is equal to the moment of the reaction with respect to the same point, or if $S$ be the stress, $l$ the length of $AB$, and $h$ the height of the peak, then $S \times h = \frac{1}{2}W \times \frac{1}{2}l$, whence $S = \frac{Wl}{4h}$, which is a tensile stress. The stress in each rafter is compressive, and its value is $\frac{W\sqrt{l^2 + 4h^2}}{4h}$. These expressions show that the stresses increase when $h$ decreases. See MECHANICS, MOMENT, STATICS, STRENGTH OF MATERIALS, and TRUSS. MANSFIELD MERRIMAN.

**Stretton**, HESBA: See SMITH, HANNAH.

**Strickland**, AGNES: biographer and historical novelist; b. at Reydon Hall, Suffolk, England, Aug. 19, 1806; with her four sisters was carefully educated under the care of her father, and commenced her career of authorship at an early age, in most of her works being assisted by one or the other of her sisters. Her first work, in conjunction with her sister Susannah, was a volume of *Patriotic Songs*, which was followed by *Worcester Field*, an historical poem. Her next work, also a poem, was *Demetrius: a Tale of Modern Greece* (1833), followed by *The Pilgrims of Walsingham*, an historical romance (1835), and at intervals by many other volumes of biography, poetry, and fiction, among which are *Queen Victoria, from her Birth to her Bridal* (1840); *Historic Scenes and Poetic Fancies* (1850); *Lives of the Bachelor Kings of England* (1861); *Lives of the Seven Bishops* (1866); and *Lives of the Tudor Princesses* (1868). Her most important works, both prepared in conjunction with her sister Elizabeth, whose name, at her own desire, did not appear as author, are *Lives of the Queens of England* (12 vols., 1840–48; new ed. 6 vols., 1864–65; abridged ed. 1867) and *Lives of the Queens of Scotland* (8 vols., 1850–59)—works based wholly upon original documents. She also put forth a collection of the *Letters of Mary, Queen of Scots*, with an historical introduction and notes (1842–43; new ed., with considerable additions, 5 vols., 1864). In 1870 she received a pension of £100 in consideration of her long and valuable literary services. D. at Reydon Hall, July 8, 1874. See *Life* by her sister Jane (1887).—Her sisters, SUSANNAH (Mrs. Moodie) and CATHARINE (Mrs. Traill), removed to Canada, and published works illustrative of life in the Dominion. Revised by H. A. BEERS.

**Stricture** [from Lat. *strictu'ra*, a compression, deriv. of *strin'gere*, *stric'tum*, draw tight, squeeze]: a constriction or compression of some tubular passage of the body, as the œsophagus, the larynx, the windpipe, the intestines, the anus, the urethra, the lachrymal ducts, and others. Strictures are produced either by new formations on the inside of the tubes, or by pathological changes in the walls and coatings of the same (cicatrization), or by the pressure of new formations or of atrophies outside. Examples of the first class are croup and diphtheria, which by deposition of fibrinous masses on the interior of the larynx and the windpipe narrow these organs sometimes to suffocation. A stricture of the third class is frequently produced in the œsophagus by a neighboring cancer, which may compress it to impermeability. The most frequent strictures are those of the urethra; they are generally produced by pathological changes in the coatings of the organ. Injuries of the perinæum and the penis, with or without rupture of the urethra, may originate them, but their most general cause is inflammation of the mucous lining of the urethra, gonorrhœa. Inflammation, if it spreads a little beyond the mucous lining, gives rise to new formation of connective tissue, which either directly compresses the urethra, forming a callous ring around it, or contracts it by atrophic cicatrization around the tube. The immediate consequences of urethral stricture are symptoms of impediment to free micturition. The urethra behind the stricture is dilated by the pressure of the accumulated urine. The bladder is not thoroughly emptied, and undergoes inflammatory irritation by chemical decomposition of its contents. The urine becomes alkaline, with a putrid and pungent smell of ammonia. The desire to urinate is very great, and never ceases. In more advanced stages the urine sometimes breaks through the wall of the urethra behind the stricture, and either makes a fistula by breaking also through the skin, or infiltrates the surrounding tissue, and so causes uræmia, and often death. In other cases, inflammation of the bladder extends to the kidneys, and there produces pyelitis and inflammation of the kidney proper. Strictures sometimes close up the urethra entirely, or become so narrow that the urine can be passed only in single drops by the strongest and most painful efforts. Speedy relief by operation is necessary in such cases to save the life of the patient. The treatment of stricture consists either in gradual dilatation or in external or internal urethrotomy. Gradual dilatation is effected by inserting bougies, or catheters, or sounds of increasing sizes. Every day or less frequently a larger instrument is passed through the stricture to the bladder, until the normal size of the urethra is attained. After this the last bougie is used occasionally for some time to prevent a relapse. The majority of authorities now consider dilatation with simultaneous division or incision of the constricting band the best, surest, and safest treatment of stricture. In cases where no instrument can be passed through the stricture, or where for other reasons the above method can not be resorted to, external urethrotomy is indicated. The operation is performed by cutting into the urethra from the perinæum, thereby opening the stricture lengthwise. It is kept open by regular catheterization, so that the healing wound leaves a canal of normal size. Internal urethrotomy is only applicable in cases where at least a small instrument can still be passed through the narrowed passage large enough to guide a small knife, which cuts and opens the stricture from inside. Revised by ROSWELL PARK.

**Stri'ges** [Lat. *strix*, *strigis*, a kind of owl; possibly akin to Gr. στρίξ, a screeching bird]: an order or other group of birds embracing the owls. The eyes are directed forward, and are surrounded by a more or less completely formed facial disk of radiating feathers; the plumage is very soft and lax and the feathers are without an aftershaft; the toes are four, the outer reversible; the claws are long, sharp, and decurved; the external ear is very large, often with a movable flap. The bones inclosing the cerebral cavity have a spongy diploë; the maxillo-palatines are spongy, the latter separated by an interval wide throughout or reduced to a cleft below, and basipterygoid processes are developed. This group has been placed with the *Raptores*, but recent authorities remove it from this association and place it near the *Caprimulgidæ* or goat-suckers. See STRIGIDÆ.

**Strig'idæ** [Mod. Lat., named from *Strix*, the typical genus, from Lat. *strix*, *strigis*; possibly akin to Gr. στρίξ, a screeching bird]: a family of birds variously limited and defined. In the restricted and generally accepted sense, the *Strigidæ* are owls having the breast-bone entire behind, with a central emargination, the furculum ankylosed, and the inner and middle toes of nearly equal length, the latter with its claw pectinate. It thus embraces the barn-owls, which are mostly of the Old World, though *Strix pratincola* is North American. The correlated *Bubonidæ* have the sternum notched behind, the furculum free, the inner toe shorter than the middle, and the middle claw not pectinate. The feathers on the sides of the head are often elongated into ear-tufts in this family, which includes the common owls of the U. S. When the *Strigidæ* are regarded as embracing all the species the groups above defined have sub-family rating. Revised by F. A. LUCAS.

**Strike** (in geology): See FAULTS.

**Strikes and Lockouts**: As defined by Carroll D. Wright, commissioner of labor for the U. S., a strike is the refusal of "the employees of an establishment to work unless the management complies with some demand." A lockout occurs when "the management refuses to allow employees to work except under some condition dictated by the management." Strikes and lockouts, therefore, are both warlike measures, and are declared to effect a specific object.

*Antiquity of Strikes.*—The first great strike of which we have record was that of the Hebrews in Egypt. There was a prolonged labor agitation, lasting many years, which the Egyptians endeavored to repress by imposing severer tasks upon the Hebrews. This was resisted, and many bloody encounters between serfs and masters occurred. Finally the labor forces were organized by Moses, with a general strike so thorough and well-arranged that the whole labor population marched out in a body and left their employers to their own devices. The employers were also said to be glad to get rid of their turbulent workmen. Ancient and mediæval history furnishes numerous examples of labor agitations of the nature of strikes, since inequalities of condition resulting from differences of ability in individuals keep a perpetual ferment in societies which issues in ill feeling and resentful strife between classes. Contention has characterized the history of all civilized nations, and where the industrial classes have been content to submit to unfavorable conditions the least advance has been made in civilization. The last half of the nineteenth century has seen the machinery and system of strikes brought to such perfection as to throw into the shade all previous movements of the same kind. The extension and generalization of trades-unions have led to such organization that strikes have become a recognized evil in social progress as much to be expected as changes of weather. They amount to a kind of inherent civil war.

*Objects of Strikes.*—A strike may be declared for one or more of the following objects: 1. To secure an advance or resist a reduction in wages. 2. To effect a reduction or oppose an increase of the hours of labor. 3. To resist the discharge of union men and hinder the employment of non-union men. 4. To regulate methods of work, materials used, number of apprentices, kind of work done by each branch of laborers, and the like. 5. To support a strike in some other industry or in some other branch of the same industry, as when pavers strike to help granite-cutters, or brakemen to help switchmen on a railway. These are known as sympathetic strikes. Strikes are wisely held by workmen to be the last resort of a contest, and never to be risked until it is clear that the desired object can not be reached without them. They are expensive, arduous, and uncertain, and if rashly undertaken end in disaster after much suffering.

*Boycotts.*—To the earlier weapons of strikers, modern ingenuity has added the boycott, by which all markets are closed against the goods of the employer against whom a strike is ordered. Even his household business is interfered with, so that his grocer and butcher are forbidden to supply his necessities under pain of being cut off from most other customers. This has proved a very effective weapon in the hands of laborers.

*Strikes in Great Britain.*—Philip Bevan gives the number of strikes in Great Britain from 1870 to 1880 as 2,352, or 235 per annum. In 1888 they had risen to 504 for that year; in 1889, 3,164; in 1890, 1,028, involving 4,382 establishments. Strikes would seem, therefore, to be on the increase.

*Strikes in the U. S.*—The first recorded strike in the U. S. was that of the journeymen bakers in 1741. The leaders were tried for conspiracy. Next came the shoemakers of Philadelphia in 1796, 1798, and 1799; then the sailors in Philadelphia in 1803, who struck for $14 against $10 a month. They were arrested, and the leaders imprisoned. In 1809 the New York cordwainers struck, and used the term "scab" to denote non-strikers of their association. Printers struck in 1821, using the word "rat" for non-union men against whom they struck. In 1834 the first women's strike took place at Lynn, Mass., in the shoe-trade It was unsuccessful. In 1848 the workmen of Allegheny city struck for ten hours, and carried their point after eight weeks of rioting, though with 16 per cent. reduction of wages. In 1850–51 1,300 workmen at Fall River were idle for six months at a loss of $140,000 in wages. A strike at Pittsburg in 1850, marked by violence, resulted in sentences of fines and imprisonment to many, afterward pardoned. In 1852 mill-hands in Salisbury, Mass., struck for fifteen minutes' recess at lunch. In 1868 Pennsylvania passed a law making eight hours a legal day; much striking resulted among the coal-miners, resulting in less hours of work and more wages. In 1877 occurred the great railway strikes on the Baltimore and Ohio, the Pennsylvania, and the Erie systems, resulting in the destruction on July 21–23 of 1,600 cars, 126 locomotives, and $5,000,000 worth of property, $2,000,000 of which loss fell on the railways. In 1880 there were 762 strikes and lockouts together, 617 of which related to wages. Up to 1881 1,491 strikes and lockouts had taken place. Of these 1,089 were about wages, and 583 failed. From 1880 to 1890 there were 7,114 strikes, which involved 2,268,272 persons.

According to statistics of Carroll D. Wright, the strikes of 1882 affected 2,105 establishments; those of 1883, 2,759; 1884, 2,367; 1885, 2,284; 1886, 9,861. The average duration of strikes was twenty-three days. Loss in wages is estimated at $51,814,723, and to employers over $30,000,000; 1,323,-203 employees were striking or involved, and 487,615 days were lost in all. Nearly four-fifths of these strikes were ordered by labor organizations. From 1881 to 1886 strikes affecting over 10,000 establishments succeeded, while strikes affecting about 9,000 failed. The trades represented were building, 6,075 establishments; tobacco, 2,959; mining, 2,060; clothing, 1,728; metallic goods, 1,570; transportation, 1,478. The lockouts were 2,214, of which 1,753 were ordered by organizations; 564 of these succeeded and 190 partially, and 1,339 failed. See *Third Annual Report of the Commissioner of Labor*, 1887.

In 1890 there were 798 strikes and 201,682 strikers. In the spring of 1892 occurred the granite-cutters' strike, which extended finally to pavers in New York, and arrested for a time the whole stone industry. This was, however, quite eclipsed by the famous strike in the Carnegie iron-works at Homestead, which was attended with such bloodshed and violence as to attract general attention. The Carnegie works were kept in a state of siege for several days, and the town presented the appearance of a military camp. Eight thousand soldiers were required to subdue the rioters, and though the strike apparently failed, yet it had a profound effect upon the industrial situation, and probably minimized the willingness of both laborers and capitalists to enter upon future battles. In the summer of 1894 a railway strike in Chicago and other Western cities, although a failure, threatened for a time the commercial interests of the whole country. It was ordered by E. V. Debs as president of the American Railway Union, in sympathy with striking employees of the Pullman Car Company, and resulted in the calling out of U. S. troops to protect the mails and restore order.

*Expenses of Strikes.*—The cost of strikes is often figured out by statisticians, and runs into enormous sums—enough to intimidate the boldest striker. Mr. Wright calculates that $60,000,000 was sunk in strikes and lockouts from 1881 to 1886. No doubt the funds of the unions—although now amounting to millions of dollars altogether—are often strained by the expenses of a great strike, and strikers and their families are subjected to extreme privations and distress before the contest is ended. Employers, also, are put to the greatest nervous strain, and their business is often imperiled to the verge of bankruptcy. One lockout on the Clyde, in Scotland, was reckoned to have cost the unions $750,000, while $1,560,000 was lost in wages. A strike in Manchester, England, cost the unions $400,000 and the employers $1,500,000. These figures convey a sharp warning. They indicate what the strike in Chicago (1894) and the disastrous street-railway strike in Brooklyn (1895) combine to teach—that strikes, like war, may easily cost more than they come to. It must be remembered, however, that, on the whole, strikes have seemed profitable to workmen; otherwise they must have ceased long ago.

*Why Strikes are believed Necessary.*—Strikes result largely from men's ignorance of their true interests and well-being. False economic theories are responsible for a large part of the enmity between capital and labor, out of which strikes and lockouts are born. The false notion that profits must fall as wages rise—a notion contradicted flatly by history, which shows high wages and large profits inseparably yoked together—is partly responsible for the striking spirit. Really the antagonism of capital and labor is an inheritance from an ignorant past. It is also an inference of short-sighted reasoning which regards wages as outgo and does not see that they immediately turn about and become income to the capitalist, since they are used to buy goods produced by labor, so that the higher the wages the larger the market becomes, and the greater the gross profits. On the other hand, also, the greater profits become the more capital stands ready to employ labor, and the stronger becomes the tendency in wages to rise in consequence. From the time when laborers were arrested and punished as conspirators, to the present day when they are regarded as disturbers of the peace and troublers of society, they and the upper classes have progressed together, often fighting but advancing most when co-operating rather than contending, and wages and profits have both risen greatly. The laborers get more wages, and their increased consumption increases the amount of goods needed, which enlarges the business of the capitalist and multiplies his profits. If this were not so, strikes would have ruined all parties long ago, impoverishing laborers and bankrupting capitalists.

*Increasing Magnitude of Strikes.*—The interests involved in strikes are constantly enlarging. The disturbances of 1892 at Homestead and New York and of 1894 and 1895 in Chicago and Brooklyn showed the whole nation to be, as it were, engaged in these industrial convulsions, and that nothing but a scientific adjustment of difficulties involved could bring about a condition of harmony and progress. A recognition of the economic principles involved alone will resolve the situation; and the main principle is the above law that wages and profits advance together, since profits are always largest in countries where wages are highest, and markets therefore largest. Lord Brassey, who has made a special investigation of the subject, has stated as a general truth that the higher-priced workmen are in reality the cheaper on account of the quantity and quality of the work done. Low-priced labor is found to be dearest. Of course it would be but a visionary business policy to favor increasing wages were it not that wage advance means larger demand, increased consumption, and ultimately larger profits, out of which, again, further advances of wages may be made, as they will certainly be demanded by strikes.

*Violence in Strikes.*—The Buffalo switchmen's strike of Aug., 1892, called out 785 men, affected twelve railways, and lasted two weeks. There was some violence, and many cars were burned. It was declared hastily by Grand-master McSweeny to secure ten instead of eleven hours' work, and 27 cents per hour instead of 25 cents. Eight thousand soldiers were sent to Buffalo to put it down, and it failed, as strikes generally do unless carefully prepared. This appeared especially clear in the Chicago strike of 1894 and the Brooklyn strike of 1895. Violence nearly always condemns the strikers in public regard and defeats their ends, while it cripples their resources. It is of no advantage to workmen striking for wages to destroy the property out of which wages come, and the impolicy of violence toward property is now becoming clear to strikers themselves; but toward workmen seeking to take the place of strikers there is still a very ready spirit of violence, which seriously threatens personal liberty and social order.

*Success and Failure.*—According to Carroll D. Wright's figures, about 60 per cent. of strikes succeed and about 60 per cent. of lockouts fail, as if the workmen were 20 per cent. wiser than the masters. This success, however, is rather apparent than real. As a matter of fact wages are seen to rise and fall from general causes just the same whether men strike or not.

*Arbitration.*—The great strike of the Shearers' Union in New South Wales in 1891, which finally involved so many industries, capitalists and workmen, skilled and unskilled, was made the subject of an elaborate examination by a parliamentary commission. The result was a recommendation of conciliation as a remedy, and if that failed arbitration without compulsory power. The same outcome resulted from a commission appointed to examine the Chicago strike and report. The idea is that such discussions and examinations as these measures necessitate tend to assuage ill feeling and promote reasonable conclusions sufficiently to carry force enough to settle disputes without other means. Doubtless there is truth in this position. Arbitration is also much valued as a means of preventing strikes and lockouts, by obviating the necessity for them. Doubtless as a temporary expedient it has value, as giving time for the adjustment of new departures before they are definitely formulated; but arbitration is at least a broken reed to lean upon, inasmuch as the causes of strikes are new desires and new demands, which the rules of the past can not satisfy. The elements of the problem are usually whether a given business can afford to pay its employees more, or give them shorter hours or more privileges than they have been having. Evidently this is a question which only the employer can answer. He is the only one who knows, and therefore what a board of outsiders may say about the matter is liable to be totally irrelevant. If he can grant the laborers' demands, he will finally be willing to do it, because it is the more profitable alternative. If, however, he can not grant these demands, owing to the fact of an already depleted margin of profit, he will no more be able to do so because advised by a board of arbitration than without such advice.

STARR HOYT NICHOLS.

**Strindberg**, AUGUST: writer; b. in Stockholm, Sweden, Jan. 22, 1849. In 1879 he went to Paris, where he remained ten years. His first important works were the powerful drama *Mästar Olof* and the social satire *Röda Rummet* (The Red Room), which was followed by dramas, novels, and tales, all displaying great originality and descriptive power. Among these may be mentioned *Gillets Hemlighet* (The Secret of the Club); *Hr. Bengts Hustru* (Mr. Bengt's Wife); *Fröken Julie* (1889); and *Himmelrikets Nycklar* (The Keys to the Kingdom of Heaven, 1892); and the novels *Utopier i Verkligheten* (Utopias in Real Life, 1885) and *I Hafsbandet* (In the Offing, 1891). Many of his works, especially the later ones, have aroused much controversy on account of the extreme social and moral views advanced in them. He is the leading apostle of naturalism in Sweden. D. K. DODGE.

**Stringy Bark**: See EUCALYPTUS.

**Strobilation** [= Gr. στρόβιλος, anything twisted, pine-cone, etc.]: a process of reproduction occurring among certain jellyfishes (*Discomedusæ*), in which the larva becomes transversely divided into a series of disks (*Ephyræ*), each of which later develops into a medusa. The partially divided larva was formerly regarded as an adult, and was called *Strobila*, in allusion to its appearance. A process akin to this occurs in the growth of the mushroom corals (*Fungia*) as well as in many tapeworms, in the latter resulting in the formation of the "joints" or proglottids. See TAPEWORM. J. S. K.

**Stro'boscope** [from Gr. στρόβος, rotation + σκοπεῖν, to view]: an instrument for examining the motion of a body by intermittent sight. It was invented in 1832, independently, by Plateau in Belgium and Stampfer in Germany. In its simplest form it consists of a disk perforated near the circumference with a series of equidistant radial openings, through which the body is viewed while the disk rotates uniformly. Suppose, for example, that the body is vibrating, and that the time of one complete vibration is equal to that required for the disk to rotate through the angular distance between two successive openings. The body will be seen in succession at the same phase of its motion, and will hence appear stationary. If the vibration period be slightly greater or less, the body will be seen successively in slightly different phases, and the visual impression is that of slow motion, the rate of which is calculable if the rate of rotation of the disk, the number of openings, and the period of the body be known. If the interval of time between the successive momentary views of the body be equal to or less than the duration of the retinal impression produced by it, the perception is uninterrupted. This duration decreases with increase of time of exposure of the retina and with increase in intensity of the light. The law determined experimentally by E. S. Ferry (see *American Journal of Science*, Sept., 1892, p. 204) is that retinal persistence varies inversely as the logarithm of the number which expresses the brightness. This means that if the intensity is increased by multiplying it by the second, third, or fourth power of some constant number, the corresponding duration will be one-half, one-third, or one-fourth of its original value. Under the conditions of ordinary daylight this duration varies from one-fiftieth to one-tenth of a second.

The principle of the stroboscope is applied in instruments to which a variety of names have been given, such as thaumatrope, phenakistoscope, vibroscope, zoetrope, zoöpraxiscope, kinetoscope, etc. If a succession of photographs of a rapidly moving body be taken at intervals of less than one-tenth of a second, and these be appropriately arranged for examination by the stroboscopic method, the resulting perception is that of the body in actual motion. With the development of instantaneous photography the preparation of such series of pictures has been brought to a high degree of perfection. See VITASCOPE. W. LE CONTE STEVENS.

**Strom'bidæ** [Mod. Lat., named from *Strom'bus*, the typical genus, from Lat. *strom'bus* = Gr. στρόμβος, a kind of spiral snail, also top, pine-cone, deriv. of στρέφειν, twist]: a family of gasteropod molluscs. The shells vary considerably in superficial character, but all have a more or less conic spire, and in most the outer lip is expanded and deeply notched anteriorly. Species are generally diffused in all tropical seas, and between seventy and eighty are known. They are distinguished by the peculiar form of the foot, which is fitted for leaping rather than the crawling progression common to most gasteropods, and by the pedicles bearing the eyes and tentacles. They are quite active, but are reputed to be chiefly carrion-feeders. The shells are often employed as ornaments, and especially is this the case with the *Strombus gigas*, often known as the fountain-shell. This is the largest of the family, and sometimes weighs 4 or 5 pounds. It is also largely employed for the manufacture of cameos. Revised by J. S. KINGSLEY.

**Strom'boli**: northernmost of the Lipari islands, in the Mediterranean, off the north coast of Sicily; area, 8 sq. miles. It is wholly of volcanic formation, and has a constantly active volcano 3,040 feet high with an extinct crater on top, but an active one on the side at the height of about 2,150 feet. Cotton, wine, and fruit of superior quality are produced, and sulphur and pumice-stone are largely exported. On the east side lies the small town of Stromboli. Pop. of island, 500. M. W. H.

**Strong**, AUGUSTUS HOPKINS, D. D., LL. D.: minister, educator, and author; b. at Rochester, N. Y., Aug. 3, 1836; graduated at Yale College 1857, and at Rochester Theological Seminary 1859; became Baptist pastor; pastor at Haverhill, Mass., 1861, Cleveland, O., 1865; president and Professor of Biblical Theology, Rochester Theological Seminary, 1872. He has published the following works: *Systematic Theology* (Rochester, 1886; 3d ed. New York, 1890); *Philosophy and Religion* (1888). W. H. W.

**Strong**, GEORGE CROCKETT: soldier; b. at Stockbridge, Vt., Oct. 16, 1832; graduated at the U. S. Military Academy in July, 1857; assigned to the ordnance, and in 1861 took temporary command of the Watervliet arsenal, West Troy. He was ordnance officer on Gen. McDowell's staff at Bull Run, and was then attached successively to the staffs of Gen. McClellan and of Gen. Benjamin F. Butler, whose chief of staff he became. He aided in the organization of the expedition for the capture of New Orleans 1861; in Apr., 1862, commanded the successful expedition from Ship island to Biloxi, Miss., and in September that to Ponchatoula, which destroyed a large amount of property belonging to the Confederates. In Nov., 1862, he was appointed a brigadier-general of volunteers, and in June, 1863, assigned to command of the brigade which, in the operations about Charleston, effected the landing on Morris island, July 10, 1863, Gen. Strong leading the successful assaulting column, as also the ineffectual assault on Fort Wagner the following morning. Again, a week later (July 18), his brigade led the second assault on that work, at the head of which Strong fell wounded. His commission as a major-general bore the date of the assault, July 18, and the name of Fort De Kalb, on the southern side of the Potomac, was changed to Fort Strong in his honor. D. of his wounds in New York, July 30, 1863.

**Strong**, JAMES, S. T. D., LL. D.: educator and author; b. in New York, Aug. 14, 1822; graduated at Wesleyan University in 1844; taught in Troy Conference Academy, Poultney, Vt., 1844–46; in 1847 removed to Flushing, Long Island; projected and built the Flushing Railroad, of which he was president; gave private lessons in Greek and Hebrew. In 1856, although not a clergyman, he received the degree of doctor of sacred theology from Wesleyan University, which institution also made him LL. D. in 1881; in 1858–61 was Professor of Biblical Literature and acting president of Troy University, and in 1868 became Professor of Exegetical Theology in Drew Theological Seminary at Madison, N. J. He was a member of the Anglo-American commission for the revision of the English version of the Bible. In 1873 he was chosen chairman of the archæological council of the Oriental Topographical Society, and in 1874 made an extended tour in the East; prepared for Lange's *Commentary* the English translation of the part on the book of Daniel, and published *Harmony and Exposition of the Gospels*, in English (New York, 1852), *Harmony of the Gospels*, in Greek (1854), and brief manuals of the Gospels and of Greek and Hebrew grammar. About 1853 he projected, in association with Rev. John McClintock, D. D., a *Cyclopædia of Biblical, Theological, and Ecclesiastical Literature* (10 vols., 1867–81, 2 supplementary vols., 1884, 1887, with later addenda, bringing the work down to 1891), Dr. Strong taking the department of biblical literature, including sacred geography, antiquities, and natural history. On Dr. McClintock's death, Mar. 4, 1870, Dr. Strong assumed the supervision of the whole work. He also published *Irenics* (1886); *The Tabernacle of Israel* (1888); *Sacred Idyls* (1889); *Future Life* (1891); *Jewish Life* (1891); *Our Lord's Life* (1892); *Commentary on Ecclesiastes* (1893); and an exhaustive *Concordance of the Bible* (1894), on which he labored more than thirty years. D. at Round Lake, N. Y., Aug. 7, 1894.

**Strong**, JOSIAH, D. D.: clergyman and author; b. at Naperville, O., Jan. 19, 1847; graduated at Western Reserve College, Hudson, O., 1869; studied theology at Lane Theological Seminary 1869–71. He was successively pastor of several Congregational churches (at Cheyenne, Wyo., 1871–73, at Hudson, O., 1873–76, at Sandusky, O., 1876–81); secretary of the Ohio Home Missionary Society 1881–84; pastor in Cincinnati 1884–86, when he became general agent of the Evangelical Alliance of the U. S. of America. He is the author of *Our Country* (1885, reissued in revised form 1891); *The New Era, or the Coming Kingdom* (1893). G. P. F.

**Strong**, Sir SAMUEL HENRY: See the Appendix.

**Strong**, WILLIAM, LL. D.: jurist; b. at Somers, Conn., May 6, 1808; graduated at Yale in 1828; admitted to the bar in 1832, and practiced at Reading, Pa.; Representative in Congress 1849–54; judge of the Supreme Court of Pennsylvania 1855–68, resumed practice, and in 1870 was appointed associate justice of the Supreme Court of the U. S. Retired 1880. D. at Lake Minnewaska, N. Y., Aug. 19, 1895.

**Strong**, WILLIAM L.: See the Appendix.

**Strongyl'idæ** [Mod. Lat., named from *Stron'gylus*, the typical genus, from Gr. στρογγύλος, round, spherical]: a family of parasitic round worms (nematodes) in which the mouth is usually surrounded by six papillæ or with a cup-like toothed expansion of these. Frequently in the male the end of the body has a bell-like expansion. Some species are parasitic in man, one, *Dochmius duodenalis*, causing the "tunnel disease" among the workers on the St. Gothard tunnel, or "Egyptian chlorosis" in Africa, a disease occasionally fatal. Other species live in domestic animals, the "gapes" of fowl being caused by the presence of *Syngamus trachealis* in the windpipe. J. S. KINGSLEY.

**Stron'tium** [Mod. Lat., deriv. of *Stron'tia*, from *Strontian*, in Argyleshire, Scotland, where strontia was first found]: the metallic basis of strontia, one of the alkaline earths, first obtained from native carbonate of strontium by Sir Humphry Davy in 1808. It is a pale yellow, burns with a crimson flame, emitting sparks, decomposes water, liberating hydrogen gas, is hard, ductile, and malleable, and is obtained from the anhydrous chloride by electrolysis. Specific gravity, 2·54; atomic weight, 87·5; symbol, Sr. Its most important compound is the oxide called strontia, a grayish-white, porous mass, which combines with water to form a white powder, the hydrate of strontium ($SrO.H_2O$). This compound has acquired considerable importance in Germany for its use in extracting sugar from beetroot molasses. The nitrate $Sr(NO_3)_2$ is much employed in the manufacture of the crimson lights in fireworks. The sulphate ($SrSO_4$) is found native, and is known as a crystalline mineral by the name of CELESTINE (*q. v.*). Revised by IRA REMSEN.

**Strophan'thus**: a genus of apocynaceous plants. From certain African climbing shrubs of this genus is prepared a poison locally known as kombo, inee, and onaye, and used for the purposes of the chase and war. It has been shown by Prof. T. R. Fraser to contain a crystalline principle, strophanthin, which has a powerful influence upon the muscular system, first stimulating, but if in sufficient dose finally causing a general paralysis, ending in death through failure of the respiration. It affects not only the voluntary muscles but also the muscle-fibers in the heart and in the walls of the blood-vessels; and since its first action, and indeed its entire action when in minute doses, is stimulating, it has become a very valuable remedy in the treatment of failure of the heart from any cause. It resembles digitalis in its use in disease, but differs from that drug in being much more prompt and fugacious in its action, and in affecting more powerfully the kidneys. Though less powerful than digitalis, it may be often substituted with advantage for that drug, especially when promptness of action is required, or when it is necessary to rapidly relieve dropsical exudations. The active principle, strophanthin, has been given in doses of 0·0002 to 0·0003 grammes, but the drug is chiefly used in the form of tincture, of which the dose is 5 to 10 drops. H. C. WOOD.

**Stro'phe** [viâ Lat. from Gr. στροφή, a turning]: unlike the Latin equivalent *versus*, a group of lyric cola, sometimes comprising several periods, combined into a symmetrical whole. In the Lesbian melic poetry it was a stanza (usually of four lines, some of which were alike) which was repeated *ad libitum* with the same music. In the choric poetry of the drama and the lyric poets the cola are more varied in form and usually more numerous, and the strophe was followed by another just like it, called the antistrophe, sung to the same music, the two being regarded as a complex unit, and the chorus executing a movement with the one and a counter-movement with the other, hence the names a "turning" and a "counter-turning." To this pair or syzygy was often (as always in Pindar) added another strophe without antistrophe, different in form, called epode (ἐπῳδός, sung after), the three constituting the lyric "triad." See PROSODY. MILTON W. HUMPHREYS.

**Stroud**: town; in Gloucestershire, England; on the Frome; 10 miles S. S. E. of Gloucester (see map of England, ref. 11–G). It is an important seat of woolen manufactures and dye-works, the water of the Frome being well adapted for dyeing. Pop. (1891) 9,818.

**Stroudsburg**: borough; capital of Monroe co., Pa.; on Broadhead creek, and the Del., Lack. and West. and the N. Y., Susq. and West. railways; 4 miles N. W. of the Delaware Water Gap, 24 miles N. of Easton (for location, see map of Pennsylvania, ref. 4–I). It is in an agricultural region, has excellent water-power, and is surrounded by attractive scenery. It contains 2 national banks with combined capital of $150,000, a building and loan association, local and serial, and 3 weekly newspapers. Pop. (1880) 1,860; (1890) 2,419; (1900) 3,450.

**Stru'ensee**, JOHANN FRIEDRICH, Count of: minister to Christian VII. of Denmark; b. at Halle, Prussian Saxony, Aug. 5, 1737; studied medicine; and was appointed personal physician to Christian VII., over whom he gained a complete ascendency. In 1771 he was made Minister of State, and a royal decree gave full authority to any orders he might issue, whether they were signed by the king or not. Struensee used his great influence to introduce sweeping reforms, some of which were beneficial to the people as tending to restrict the power of the nobles. Among other innovations he demanded the enfranchisement of the peasants, the introduction of examinations for public offices, the establishment of complete religious toleration and of liberty of the press. The suddenness of these reforms and their radical nature aroused violent opposition, which culminated in a conspiracy against him. The story of an intrigue between him and the young queen Caroline Matilda was employed by the queen dowager to induce the king to order his arrest, and Christian, whose enfeebled mind made him scarcely responsible for his actions, finally gave his consent. On Feb. 20, 1772, Struensee and the queen were arrested. No proof was advanced of his unfaithfulness as a minister, but the threat of applying the torture extorted from him a confession of guilty relations with the queen, and he was beheaded Apr. 28, 1772. See Wraxall, *Life and Times of Queen Caroline* (1864); Jenssen-Tusch, *Die Verschwörung gegen die Königin Karoline Mathilde und die Grafen Struensee und Brandt* (1864); and Wittich, *Struensee* (1878). F. M. COLBY.

**Struggle for Existence**: See EVOLUTION.

**Struma**: See SCROFULA.

**Strümpell**, GUSTAV ADOLF, M. D.: clinician; b. at Neu-Autz, Courland, Russia, June 28, 1853; educated in part at the University of Dorpat, where his father was Professor of Philosophy, and at the University of Leipzig, where he graduated M. D. in 1875; from 1876–82 assistant at the Leipzig clinic; in 1883 appointed Extraordinary Professor of Internal Medicine at Leipzig University and director of the polyclinic; in 1886 appointed to the chair of Special Pathology and Therapeutics at the University of Erlangen. His most important work is *Lehrbuch der speciellen Pathologie und Therapie der innern Krankheiten* (Leipzig), which has passed through seven editions and has been translated into French, Spanish, and English. S. T. ARMSTRONG.

**Struthiin**: See SAPONIN.

**Struthio'nes**: an order of birds characterized by the structure of the palate, in which the vomer does not articulate with the pterygoids. The sternum is devoid of a keel. The group contains the South American ostriches (*Rheidæ*), ostriches (STRUTHIONIDÆ, *q. v.*), cassowaries (*Casuriidæ*), and emus (*Dromaiidæ*). F. A. L.

**Struthion'idæ** [Mod. Lat., named from *Stru'thio*, the typical genus, from Lat. *stru'thio* = Gr. στρουθίων, ostrich]: a family of ratite birds. The bill is rather elongated, nearly straight, gradually depressed forward and narrowed toward the extremity, which is rounded, and the culmen is flattened; the nostrils are elongate-ovate, and in a broad membranous groove near the middle of the bill; the feathers are destitute of after-shafts; the wings are imperfect, and furnished with long curving soft plumes; the tail is moderate, and consists of curved pendent feathers; the tarsi are elongated, robust, and mostly covered with hexagonal scales, but in front toward the toes with transverse ones; the toes are two in number, with pad-like under surfaces, the inner (third) large, the outer (fourth) small; the claws short, curved, and blunt.

A number of osteological characters support the differentiation of the family from the others of the group, and have been formulated by Prof. Huxley—viz., the maxillo-palatines are thickened at their inner edges, and articulate with facets upon the sides of the vomer; the vomer is quite short, and does not articulate with either the palatines or pterygoids behind; the prefrontal processes of the primordial cranium are deficient in ossification; the sacral vertebræ are united by their bodies with the anterior ends of the pubes and ischia; the sternum has two shallow notches on each side at the posterior margin; the manus possesses the ordinary three digits, and of these the radial and middle have claws; there is a union of the pubes in a symphysis; the hallux is not only aborted, but also the distal end of the metatarsal bone and the phalanges of the second digit of the foot. See OSTRICH. Revised by F. A. LUCAS.

**Strutt**, JOHN WILLIAM, third Baron Rayleigh, F. R. S.: physicist; b. in England, Nov. 12, 1842. He was educated at Cambridge, and graduated 1865; became fellow of Trinity College 1866; succeeded to the title 1873; Professor of Experimental Physics in the University of Cambridge 1879–84; and Professor of Natural Philosophy in the Royal Institution of London since 1887. He is a member of numerous scientific societies and a correspondent of the Institute of France. He is the author of several memoirs relating to acoustics and electricity in the *Philosophical Transactions* of the Royal Society, of numerous papers in scientific journals, and of *The Theory of Sound* (2 vols., 1877–78; 2d ed., 1894). In 1894, in conjunction with Prof. Ramsay, he discovered, and has since prepared in quantity, a new element in the atmosphere, which he has called argon. For this discovery the trustees of Columbia College, New York, on the recommendation of the National Academy of Sciences, awarded Lord Rayleigh in 1895 "the Barnard medal for meritorious service to science." The discovery originated from the fact that the supposed nitrogen of the atmosphere was always found to be heavier than the nitrogen obtained by chemical means—from ammonia, for instance—the explanation being given by the admixture of the heavier gas, argon, with the former. The atomic weight of argon is 19·9, as compared with 14 of nitrogen, if it is assumed to be a single element. It would thus come between fluorine and sodium in the series of elements. It is believed that the gas was obtained in 1892 from the mineral uraninite by the American chemist W. F. Hillebrand, who by not applying sufficient tests concluded that it was nitrogen. Argon has since (1895) been found by Ramsay in the Norwegian mineral cleveite in conjunction with the solar element helium. (See SPECTRUM.) It differs in a remarkable way from all other known elements in its inertness or absence of chemical properties, whence its name (Gr. ἀργόν, neut. of ἀργός, lazy). Lord Rayleigh, however, believes that it has some affinity with certain of the hydrocarbons, and Prof. Berthelot, of Paris, has induced it to combine with the vapor of benzine, the product formed being a yellow resinous substance. In the course of his experiments in passing electric currents through argon mixed with benzine, Berthelot has obtained splendid displays of colors similar to those of the aurora borealis, which phenomenon, it is thus suggested, may be due to the action of electric currents upon the argon in the atmosphere. Its spectra have been studied by Crookes; they are of two kinds, with bright lines conveniently named red and blue, which are obtained under different conditions of pressure and electric current. The gas has been liquefied and solidified by Olszewski of Cracow. It dissolves in water under the ordinary pressure at 14° C. in the proportion of 4 volumes to 100, and is thus about three times as soluble as nitrogen. The critical temperature under 50 atmospheres is — 121. The density of liquid argon at its boiling-point is about 1·5. R. A. ROBERTS.

**Strutt**, JOSEPH: antiquary; b. at Springfield, Essex, England, Oct. 27, 1742; was apprenticed to an engraver, but early devoted himself specially to the study of British antiquities. His principal works in this department are *The Regal and Ecclesiastical Antiquities of England* (1773; new ed. by Planché, 1842); *Horda-Angel-Cynnan*, being a view of the customs, arms, etc., of the inhabitants of England from the arrival of the Saxons till the reign of Henry VIII. (1774–76); *The Chronicle of England*, completed only to the time of the Norman Conquest (1777–78); *Complete View of the Dress and Habits of the People of England from the Establishment of the Saxons to the Present Time* (1796–99; new ed. 1875); *The Sports and Pastimes of the People of England* (1801; often republished). He also published a *Biographical Dictionary of Engravers* (1785–86), and left several tales, one of which, *Queen Hoo Hall*, was edited after his death by Sir Walter Scott. D. in London, Oct. 16, 1802.

**Struve**, stroo've, FRIEDRICH GEORG WILHELM, von: astronomer; b. at Altona, Holstein, Apr. 15, 1793; studied first philology, and afterward astronomy, at the University of Dorpat; received an appointment at the observatory in 1813, and became its director in 1817. From 1834 to 1839 he planned and superintended the construction and erection of the observatory at Pulkowa, near St. Petersburg, which he has described in his *Description de l'Observatoire central de la Russie* (1845), and of which he was director to his death Nov. 23, 1864. This observatory became the most noted of the world. The earlier part of his career was mostly occupied by studies of double stars and of the construction of the Milky Way—*Observationes Dorpatenses* (8 vols., 1817–39); *Catalogus novus stellarum duplicium* (1827); *Stellarum duplicium mensuræ micrometricæ* (1837); *Stellarum fixarum, imprimis compositarum, positiones mediæ* (1852); and *Études d'astronomie stellaire* (1847). Subsequently he undertook several great geodetic works, such as the triangulation of Livonia (1816–19) and the measurement of a meridian arc in the Baltic provinces (1822–27), which he continued to the North Pole in connection with Hansteen, and to the Danube in connection with Gen. Tenner, and which he has described in his *Arc du méridien entre la Danube et la Mer Glaciale* (1861). Revised by S. NEWCOMB.

**Struve**, GEORG ADAM: jurist; b. at Magdeburg, in what is now Saxony in Prussia, Dec. 27, 1619; studied law at Jena and Helmstedt; held the offices of court assessor, privy councilor to the Duke of Weimar, and Professor of Law in the University at Jena; and in 1680 was appointed president of the regency of Weimar, the then duke being a minor. Of his numerous elaborate legal treatises the most important are *Syntagma Juris Feudalis* (1653); *Syntagmata Jurisprudentiæ Civilis* (1655); and *Jurisprudentia Romano-Germanica Forensis* (1670). D. at Weimar, Sept. 15, 1692.—His son, BURKHARD GOTTHELF STRUVE (b. at Weimar, May 26, 1671; d. at Jena, May 24, 1738), was a jurist and historian. He studied law, traveled, was appointed librarian of the University of Jena 1697, then Professor of History 1704 and of Jurisprudence 1730. He was historiographer to the house of Saxony. The most important of his many works are *Syntagma Historiæ Germanicæ* (1716); *Corpus Juris Gentium*; *Publici* (1717); and *Bibliotheca Historica* (11 vols., 1705). F. STURGES ALLEN.

**Struve**, OTTO WILHELM, von: astronomer: b. at Dorpat, Russia, May 7, 1819; son of Friedrich Georg Wilhelm von Struve, under whom he studied astronomy; succeeded him as director of the observatory of Pulkowa, and became known in the history of astronomy by many valuable researches. His *Determination of the Constant of Procession* is a classic, as is also his *Measurements of Double Stars*, a continuation of his father's work. He visited the U. S. in 1879 to order the object-glass of the proposed great telescope of his observatory from A. Clark & Sons, and again in 1883 to receive the glass. He resigned the directorship at Pulkova in 1890. SIMON NEWCOMB.

**Strychnine**, or **Strychnia**: See NUX VOMICA.

**Strych'nos** [Mod. Lat., from Gr. στρύχνος, a kind of nightshade]: a genus of trees and climbing woody vines of the family *Loganiaceæ*, found in the tropical parts of Asia and America. Most species are poisonous. *S. nux vomica* of India (see NUX VOMICA), a tree of moderate size, yields the alkaloids strychnine, brucine, and igasurine, all active poisons in overdoses. Equally poisonous are the *S. ignatia* of the Philippines and *S. tieute*, a climbing vine of Java. The East Indian *S. ligustrina* and *S. colubrina* are reputed to cure snake-bites. *S. pseudo-quina* of Brazil yields copalche-bark, a valued febrifuge; *S. potatorum* of India is the clearing-nut tree; and *S. toxifera* of South America probably affords the dreaded curare (or woorari) poison. Revised by L. H. BAILEY.

**Stryker**, MELANCTHON WOOLSEY, D. D., LL. D.: clergyman and educator; b. at Vernon, N. Y., Jan. 7, 1851; educated at Hamilton College and Auburn Theological Seminary; pastor of Calvary church, Auburn, N. Y., 1876–78; First Presbyterian church, Ithaca, N. Y., 1878–83; Congregational church, Holyoke, Mass., 1883–85; Fourth Presbyterian church, Chicago, 1885–92; since 1892 president of Hamilton College. He has published *The Alleluia* (1880); *Church Praise Book* (New York and Chicago, 1881); *Christian Chorals* (1885); *Church Song* (1890); *Choral Song* (1891); *Miriam and other Verse* (1888); *Essay on Dies Iræ* (1892); and *Inaugural Address, Hamilton College* (1893). C. K. HOYT.

**Strype**, JOHN, D. D.: ecclesiastical historian; b. at Stepney, England, Nov. 1, 1643; educated at St. Paul's School and at Cambridge; from about 1670 to about 1732 held the living of Low Leyton in Essex; later was settled at Tarring, Sussex. His important works are *Annals of the Reformation in England* (4 vols., 1709–31); lives of *Thomas Cranmer* (1694), *Sir Thomas Smith* (1698), *John Aylmer* (1701), *Sir John Cheke* (1705), *Edmund Grindall* (1710), *Matthew Parker* (1711), and *John Whitgift* (1718); and *Ecclesiastical Memorials* (3 vols., 1721). Editions of the *Historical and Biographical Works of John Strype* were issued from the Oxford Press in 27 vols. (1827–40). D. at Hackney, Dec. 11, 1737.

**Stuart**: town; Guthrie and Adair cos., Ia.; on the Chi., Rock. Is. and Pac. Railway: 41 miles W. of Des Moines, 105 miles E. of Omaha (for location, see map of Iowa, ref. 5–F). It is on a high rolling prairie, and contains 6 churches, 4 public-school buildings, electric lights, large locomotive and machine shops, a national bank with capital of $75,000, a State bank with capital of $50,000, and 2 weekly newspapers. Pop. (1880) 1,994; (1890) 2,052; (1900) 2,079. EDITOR OF "LOCOMOTIVE."

**Stuart**, or **Stewart**: a royal family which has given several sovereigns to Scotland and England. They trace their descent to a Norman baron, Alan, who accompanied William the Conqueror, and received large gifts of land in England. His second son went to Scotland, entered the service of King David I. (about 1130), by whom he was made steward of the kingdom, the dignity remaining hereditary in the family, who assumed the title as their family name. The sixth of these Stewards or Stewarts married in 1315 a daughter of Robert Bruce, and their son Robert in 1371 succeeded David Bruce on the throne of Scotland, under the title of Robert II. The following are the sovereigns of the Stuart line, with the dates of their accession: ROBERT II. (1371); ROBERT III. (1390); JAMES I. (1424); JAMES II. (1437); JAMES III. (1460); JAMES IV. (1488); JAMES V. (1513); MARY STUART, Queen of Scots (1542); JAMES VI., crowned King of Scotland in 1568, King of England under the title of JAMES I. (1603), and transmitted both thrones to his successors; CHARLES I. (1625); CHARLES II. (1649); and JAMES II. (1685). For an account of the reigns of these monarchs, see the respective titles. James II.'s son, JAMES EDWARD FRANCIS STUART (*q. v.*), assumed the title of James III. upon the death of his father, and is known in history as the Old Pretender. His eldest son, CHARLES EDWARD (*q. v.*), is known as the Young Pretender. Henry, the second son of the Old Pretender (see STUART, HENRY BENEDICT MARIA CLEMENT), died in 1807, and with him ceased the line of the Stuarts. The present royal family of England are descended only indirectly, and in the female line, from the Stuarts, through a granddaughter of James I. of England, upon whom the succession was bestowed by Parliament. F. M. COLBY.

**Stuart**, ARABELLA: member of the royal house of England and Scotland; b. at Chatsworth about 1575. Her father was Charles Stuart, Earl of Lennox, brother of Lord Darnley. She was in the direct line of descent to the English crown, standing in the same degree of relationship to Elizabeth as did her cousin James, and she became a subject of frequent intrigues. Upon the death of Elizabeth in 1603, an unsuccessful plot, in which it is said Sir Walter Raleigh was implicated, was formed to place her instead of James upon the throne; and from this moment she became an object of jealousy to her cousin; this was still more inflamed when in 1610 she was secretly married to William Seymour, grandson of the Earl of Hertford, who was also in the line of descent. Seymour was thrown into the Tower, and his wife was placed in the custody of the Bishop of Durham. She managed to escape, and made her way to the coast, where a French vessel was waiting for her and her husband, who had escaped from the Tower. He did not succeed in reaching the vessel, which sailed without him, but found another one, by which he reached France. The vessel in which was the Lady Arabella was captured by an English ship, and she was imprisoned in the Tower, where she became insane, and died Sept. 27, 1615. F. M. COLBY.

**Stuart**, GILBERT CHARLES: painter; b. at Narragansett, R. I., Dec. 3, 1755. His first instructor, Alexander, a Scotch artist, took him to Edinburgh in 1772, and soon died, but the youth worked his way back to Newport. Thence he removed to Boston. The stir of the Revolution drove him to New York, and thence in 1788 to London. There, after months of poverty, friendlessness, and ill success, he became acquainted with Benjamin West, who gave him encouragement and showed him every kindness. A full-length portrait of West, now in the National Gallery, gained for him reputation and opportunity. He soon rose to eminence in London, and painted people of rank—George III., the Prince of Wales, John Kemble, Joshua Reynolds (of whom he was held to be the peer). The Duke of Rutland invited him to Dublin, and there he lived in splendor as the artist of the nobility. In Paris he met with similar fortune, having as a sitter the king, Louis XVI. A desire to revisit his native country and to paint the portrait of Washington, whom he profoundly revered, led him to return to the U. S. in 1793. The first picture of the President was destroyed as unsatisfactory; the second, the original sketch whereof is in the Boston Athenæum, is the accepted portrait. Besides Washington, Stuart painted John Adams, Jefferson, Madison, Monroe, John Jay, and many other distinguished men and women of the day. The last painting was that of John Quincy Adams, which was finished by Sully. From 1806 till his death Stuart resided in Boston, and painted industriously. D. in Boston, Mass., July, 1828. No complete catalogue of his portraits exists. They are more than 750 in number, and are greatly prized. In the painting of heads he rivaled Copley, but the details are sketchy. Stuart was a brilliant man, eccentric, sensitive, proud, a wonderful talker, a penetrating observer, a genius in his art. In his early years he was an accomplished musician. His pictures are widely scattered, and are mostly in private hands.

**Stuart**, HENRY BENEDICT MARIA CLEMENT: last male descendant of the royal house of Stuart in the direct line; b. in Rome, Mar. 5, 1725; the son of the Pretender, James Francis Edward Stuart, by whom he was created Duke of York. He was preparing to join his brother in the rising of 1745 with a force of French troops when that prince was overthrown at Culloden; subsequently took orders in the Roman Catholic Church, and in 1747 was raised to the cardinalship by Pope Benedict XIV. as Cardinal York, taken from his ducal title. In 1788, on the death of his brother, the Young Pretender, he assumed the style of Henry IX., King of England—*gratia Dei, non voluntate hominum*, as expressed on a medal struck upon the occasion. When the French troops in 1798 took possession of the papal states he retired to Venice, but returned in 1801. During the later years of his life he was maintained by a pension from the British Government. D. at Frascati, July 13, 1807.

**Stuart**, JAMES: archæologist and architect; b. in London in 1713; until nearly thirty years of age was a decorator of fans and similar articles; made his way to Rome, where he studied Greek and Latin art and archæology; in 1752 accompanied the antiquarian Nicholas Revett to Athens, where he remained three years, making drawings from the remains of Greek architecture; in 1755 returned to London; became eminent as an architect; was appointed surveyor of Greenwich Hospital, and in conjunction with Revett began the great work, *The Antiquities of Athens, Measured and Delineated* (3 vols., 1762–94; supplementary volume, edited by Joseph Woods, 1816). This work may be said to have first made clear to Europe that there existed a Grecian architecture very different from the Græco-Roman of Italian and French ruins. A second supplementary volume was published in 1830 by Messrs. Cockerell, Kinnard, Donaldson, Jenkins, and Railton. He also published *Critical Observations on the Buildings and Improvements of London* (1771), and furnished the illustrations for a *Picturesque Tour through part of Europe, Asia, and Africa* (1793). D. Feb. 2, 1788. Revised by RUSSELL STURGIS.

**Stuart**, JAMES EWELL BROWN: soldier; b. in Patrick co., Va., Feb. 6, 1833; graduated at the U. S. Military Academy July 1, 1854, when appointed a brevet second lieutenant in the regiment of mounted rifles, receiving his full commission in October. In Mar., 1855, he was transferred to the newly organized First Cavalry, in which regiment he attained a first lieutenancy in the following December, and a captaincy Apr. 22, 1861. During the Kansas political troubles of 1855–58 he served with his regiment, and in 1859 was a volunteer aide to Col. Robert E. Lee during the John Brown insurrection at Harper's Ferry. On May 10, 1861, he was appointed lieutenant-colonel and July 16 colonel of a Virginia cavalry regiment, and was in chief command of the Confederate cavalry at the first battle of Bull Run. Promoted to be brigadier-general in the Confederate army in Sept., 1861, and major-general in July, 1862, he served thenceforth with the Army of Northern Virginia. Gen. Lee, assuming command of this army (June, 1862), and having reorganized it, determined upon a bold reconnoissance prior to resuming the offensive. Accordingly, on the morning of June 12, Stuart, with some 1,500 cavalry and four guns, left Richmond, and on the morning of the 13th reached Hanover Court-house, where he met and drove back two squadrons of the Fifth U. S. Cavalry; proceeding down the Pamunkey as far as Old Church, thence toward New Kent Court-house, striking the railway at Tunstall's Station and crossing the Chickahominy at Jones's Bridge the next morning, was safely back in Richmond that night, having made the circuit of McClellan's army with the loss of but one man. This cavalry raid, the first one of the war, caused much commotion in the Union army, and was the source of valuable information in the subsequent movements of Jackson, where Stuart led the advance. During Pope's campaign in Northern Virginia, Stuart surprised the headquarters' train of the former near Catlett's Station on the night of Aug. 22, 1862, capturing the personal baggage and official correspondence of Pope, and on the night of the 26th and morning of the 27th, in connection with two regiments of infantry, made a descent on Manassas Junction, capturing eight guns, several hundred prisoners, ten locomotives, and immense quantities of quartermaster and commissary stores. During the invasion of Maryland by Gen.

Lee in September, Stuart covered the Confederate rear, resisting the Union cavalry advance at South Mountain and holding the Confederate left at Antietam. During the subsequent period of inaction he crossed the Potomac above Williamsport with 1,500 cavalry Oct. 9, 1862, and passing through Maryland, he entered Pennsylvania and occupied Chambersburg on the 10th, and recrossed the Potomac below Harper's Ferry Oct. 12. In the battle of Fredericksburg his command formed the extreme right of the Confederate line. At Chancellorsville, after the fall of Stonewall Jackson and the disablement of Ambrose P. Hill, Stuart succeeded to the temporary command of Jackson's corps, which he led with ability in the severe fighting of Sunday, May 3. In anticipation of the proposed invasion of Pennsylvania, a large cavalry force had been accumulated at Culpeper under command of Stuart, against which Gen. Hooker dispatched two divisions of cavalry and two brigades of infantry, which, crossing at Beverley and Kelly's Fords (June 9), soon encountered Stuart advancing to cover the flank of the main movement. A fiercely fought but indecisive battle between the cavalry on both sides ensued, resulting in a loss to each of 500 or 600. During the subsequent campaign of Gettysburg he passed up through Eastern Maryland and Pennsylvania, and rejoined Lee at Gettysburg. In the campaign of 1864, Stuart by a wide detour succeeded in interposing himself between the Confederate capital and Sheridan's advancing column. Concentrating all his forces at Yellow Tavern, near Richmond, he was here attacked by his able rival. During the obstinate but ineffectual struggle Gen. Stuart was mortally wounded. D. May 12, 1864, soon after reaching Richmond. See *The Campaigns of Stuart's Cavalry*, by H. B. McClellan (Boston, 1885). Revised by JAMES MERCUR.

**Stuart**, JAMES FRANCIS EDWARD: See JAMES FRANCIS EDWARD STUART.

**Stuart**, JOHN, Earl of Bute: See BUTE.

**Stuart**, MOSES: biblical scholar and educator; b. at Wilton, Conn., Mar. 26, 1780; graduated at Yale College 1799; studied law, and was admitted to the bar in 1802, and for two years was tutor in Yale College; afterward studied theology with President Dwight, and in 1806 was ordained pastor of the First church (Congregational) in New Haven. In 1809 he became Professor of Sacred Literature in the Theological Seminary at Andover, Mass., and occupied the chair until 1848. By his stimulating influence as a teacher and author, he made an epoch in the study of biblical literature in the U. S. He was the teacher of more than 1,500 ministers. He held his professorship for thirty-eight years. He published several Hebrew and Greek grammars, commentaries on various books of the Bible, of which those on the epistles to the Romans and the Hebrews are among the most prominent, and *Elements of Interpretation* from the Latin of Ernesti (1822); *The Sabellian and Athanasian Modes of Representing the Doctrine of the Trinity*, from the German of Schleiermacher (1835); *Philological View of Modern Doctrines of Geology* (1836); *Hints on the Prophecies* (1842); *Critical History and Defense of the Old Testament Canon* (1845); *Conscience and the Constitution* (Boston, 1850); and other works. D. at Andover, Mass., Jan. 4, 1852.

**Stuart-Wortley**, CHARLES B.: See the Appendix.

**Stub**, stoob, AMBROSIUS: poet; b. on the island of Fünen, Denmark, May, 1705. The greater part of his life was spent in poverty, his genius failing to win recognition till long after his death. After serving as private tutor at various estates he finally established a private school in Ribe, where he spent the latter part of his life. He was the only great lyric poet of his time, and may be regarded as a worthy predecessor of Ewald and Wessel. All but one of his poems were published posthumously (1771). He is the original of the hero of C. K. F. Molbech's romantic drama *Ambrosius*. D. at Ribe, July 15, 1758. His collected poems were edited by Fr. Barfod (Copenhagen, 5th ed. 1879). D. K. DODGE.

**Stubbs**, WILLIAM, D. D., Bishop of Oxford: historian; b. at Knaresborough, England, June 21, 1825; was educated at the grammar school at Ripon and at Christ Church, Oxford, where he took a first class in the classics and a third class in mathematics, and was elected to a fellowship in Trinity College; took holy orders in 1848; became vicar of Navestock in 1852; librarian to the Archbishop of Canterbury at Lambeth in 1862, and was school inspector in the diocese of Rochester 1860–66, when he received the appointment of Regius Professor of Modern History at Oxford. In 1869 he became curator of the Bodleian Library; was chosen as a member of the hebdomadal council in 1872, and in 1875 received the presentation of the rectory of Cholderton, Wiltshire. He was appointed canon residentiary of St. Paul's in 1879, consecrated Bishop of Chester in 1884, and became Bishop of Oxford in 1889. He published *Hymnale secundum Usum Sarum* (1850); *Registrum Sacrum Anglicanum* (1858); *The Foundation of Waltham Abbey* (1861); *Chronicles and Memorials of Richard I.* (1864); the *Chronicle of Roger de Hoveden* (1868); *Select Charters, etc., of English Constitutional History* (1870); *Memorial of Walter of Coventry* (1872); *Memorials of St. Dunstan* (1874); *The Constitutional History of England* (3 vols., 1874, 1875, and 1878); and (with Haddam) *Councils and Ecclesiastical Documents relating to Great Britain and Ireland* (1869–78). His *Constitutional History of England* is one of the ablest and most authoritative works on the period of which it treats. D. Apr. 22, 1901.

**Stucco** [= Ital.: Fr. *stuc*, from O. H. Germ. *stucchi*, piece > Mod. Germ. *stück*]: plastic, adhesive composition applied to walls both internally and externally in order to give them a smooth and even surface, either decorative or plain in color or form. The cementing medium of the composition for inside work is common lime or calcined gypsum, or a combination of the two, generally mixed with a certain proportion of sand, depending on the special object to be secured. The word *stucco* technically applies to a mixture of lime-putty and white sand or powdered marble, and to a coating produced with this compound. The rudest example of the plasterer's art is the application of a single coat of mortar composed of lime-paste and common sand laid on the surface of a wall with the trowel, while the highest consists in imitating fine marbles and other beautiful building-stones by using pure calcined gypsum, mixed with gum, isinglass, and suitable coloring-matter, laid on in a variety of decorative forms in order to produce panels, pilasters, mouldings, cornices, etc. The implements used by the plasterer are of the simplest kind and few in number. They comprise a lathing-hammer, the hawk, the plastering or laying-on trowel, the float, a brush, and straight-edges and moulds of various kinds, together with a screen, shovel, rake, and hod for his attending laborer. The hawk is used by the plasterer for holding the mortar in his left hand while he applies it with the trowel held in his right hand. It is simply a piece of board about 10 to 11 inches square, held by a stout handle fixed on the under side in the center of the board and at right angles to it. The laying-on trowel is a thin plate of hardened steel or iron about 3 inches wide and 9 to 10 inches long, rounded slightly at the front end, square at the other end, and a little convex on the face. It is provided with a handle on the back parallel to the blade. The hand-float is of wood, shaped something like the laying-on trowel. It is used to rub down finished work and give it a hard, smooth, and even face. A cork float is sometimes used upon surfaces which are to receive a high degree of polish. A derby is a long, two-handed float, used principally in forming the floated coat of lime and hair. Jointing-trowels are of steel, the plate being triangular, with an acute angle at the front end, the handle being attached to the heel or base of the tool. They are used about cornices and mouldings in forming the miters where fine workmanship is desired. A corner-trowel is like a small laying-on trowel with its face bent lengthwise to a right angle; it is used at the intersections of walls and ceiling, etc. Moulds are pieces of hard wood cut to the form of the cornices or mouldings that are to be formed, to assist the workman in securing accuracy and uniformity in his work. They are sometimes made of copper plates inserted in a wooden stock. The plasterer's brush is broad and thin, and is used for keeping the material wet and plastic until it is finished to the required form. The plasterer's materials are lath-nails, laths, lime, calcined gypsum or plaster, hydraulic cement, and sand, together with various pigments for giving the requisite colors.

The mortars used for inside plastering are "coarse stuff," "fine stuff," "gauge stuff," called also "hard finish," and "bastard stucco." Coarse stuff is simply common lime-mortar, of the quality suitable for brick masonry, mixed with well-switched bullock's hair free from all animal and vegetable matter. Fine stuff is prepared by slaking pure lump-lime with a small quantity of water, and afterward adding water until the paste is diluted to the consistency of cream. It is then allowed to stiffen by evaporation to the proper condition for use. It is then sometimes called putty. It is used for the finishing coat, but always with some fine sand or calcined plaster, except for what is known as a slipped coat, and even for slipped work fine sand may be added in small quantities. Gauge stuff is composed of putty or fine stuff and calcined gypsum, in the proportion of 3 or 4 of the former to 1 of the latter. The mixture called stucco is prepared with lime-putty and white sand, and is used only for a finishing coat.

One coat of plastering on laths is said to be *laid*, and the coat is called a *laying* coat; and work in two coats is said to be *laid* and *set*, and the coats are styled a *laying* coat and a *set* coat. In three-coat work on laths the first is called the *pricked-up* or the *scratch* coat, the second is the *floated* coat, and the third the *set* coat. On masonry, plastering in one coat is styled *rendering*; two-coat work is said to be *rendered* and *set*; and three-coat work *rendered, floated*, and *set*. In good two-coat work upon laths, and also upon uneven masonry, the first coat should be a *screed* coat—that is, laid in *screeds* and "filling out." The screeds are strips or ledges of coarse stuff, 6 or 8 inches in width, applied at the angles of the room, and also in parallel strips 3 to 4 feet apart all over the walls and ceiling. They are carefully worked on, so that all those on the same wall or ceiling shall be accurately in the same plan, as determined by the frequent application of the straight-edge in all possible directions. When the screeds have become somewhat firm, the spaces between are filled in flush with the surfaces already established, so as to produce a continuous straight and even surface. In three-coat work the second is the screed coat. One-coat work on either laths or masonry—that is, either *laid* or *rendered*—although an inferior quality of work for walls and ceilings, is in common use for attics, kitchens, cellars, vaults, and places of like character. After the first coat of two-coat work has become partially dry, so that it will not break up under the trowel in the work which follows, it is in readiness for the *set* or finishing coat, which may be in *slipped work, stucco, bastard stucco*, or *hard finish*.

Hard finish is applied with a trowel to the depth of an eighth of an inch, and may be polished with the water-brush and trowel, but not hand-floated. Hard finish requires the least labor, and is extensively practiced in the U. S. In three-coat work on laths, the first coat—the *pricked-up*, the *scratch*, or *brown coat*—is applied in the same way as *laying*, with the exception that inasmuch as it is designed to form merely a good foundation for the *screed* coat, its thickness does not usually exceed one-quarter to three-eighths of an inch. After it has become partially dry, but while still soft, the mortar is *scratched* over nearly to its entire depth with a stick cut on the end into pointed teeth. The scratching is done in two sets of parallel scorings at right angles to each other, each running diagonally across the surface. The lines are about 2 inches apart, and are designed to assist the adhesion of the screed coat which follows. The second and finishing coats are applied as already described for a screed coat and set.

For *exterior plastering* a mortar composed of common lime and sand is not the most suitable, although frequently used upon the walls of common buildings well protected by projecting eaves. A cheap and useful surfacing of this kind is made by first cleaning off and roughing up the surface and raking out the joints to the depth of half an inch, and then rendering it with a not very thick coat of lime-paste and hair. When this has set, another coat of the same mixture is laid on evenly with the trowel without floating; and as soon as a few square yards are executed, a semi-fluid and thoroughly incorporated mixture of strong lime and fine clean gravel is firmly applied. This is at once, while soft, tinted to any desired color with an ocherous mixture put on with a brush. The whole dries and hardens into a compact mass.

Common lime forms the basis of some very good outside stuccoes, which, when properly applied, are very durable. Water holding coarse brown sugar or molasses in solution may be used for mixing the mortar, with beneficial effects on its subsequent induration. One lb. of sugar to 8 gal. of water will answer for all except the surface coat, which should contain four times this proportion of sugar. Powdered slaked lime, mixed with the scales from a smith's forge and tempered with bullock's blood, produces a moderately hydraulic and durable mortar, frequently used for exterior stucco. The wall should be previously coated over with boiled oil. In the U. S. hydraulic cement and clean, sharp sand, mixed up with fresh water to the consistency of plasterer's mortar, is most commonly used for the exterior coating of walls, more especially of brick walls. The mortar is usually applied in two coats in one operation; that is, the second coat is put on while the first is yet soft and plastic, so that the two become one. The workman never covers more than 2 or 3 superficial feet at one time, finishing it off with the second coat as he goes along. The aggregate thickness of both coats should be about half an inch. It should be protected from the direct rays of the sun for some days, and kept moist by sprinkling with a hose or brush. Sometimes the first coat is replaced by a wash of thick cream of pure cement, put on with a brush just in advance of the mortar. Faithful workmanship is most essential in this kind of plastering. The mortar must be put on under a firm pressure with the trowel, in order to secure intimate contact with the wall, and the surface must not be too dry. Deficient adhesion will result from neglect of these precautions. When a cement is too dark to give an agreeable shade of color, a judicious use of white sand, common lime, and ochers, singly or in combination, may generally be depended upon to greatly lessen if not entirely remove the objection.

Certain precautions are indispensable to the durability of stucco upon the exterior faces of walls. In the first place, the sand used must be perfectly clean, and should therefore be washed, repeatedly if necessary, until it will no longer discolor clean water. The most destructive agent to be guarded against is frost, when accompanied by the penetration of moisture between the stucco and the wall, which will inevitably result in throwing off the mortar. In well-troweled and hand-floated work all the vertical surfaces will shed the water with sufficient promptness to prevent that degree of saturation which would be likely to receive injury from frost. The points to be specially looked to are at the eaves and gables, the projecting portions of a wall, and the jambs of windows and doors. A projecting roof will afford sufficient protection to the upper edge of the stuccoed surface. Where the stucco abuts against a projection, like a sill or a lintel, the joint should be cleaned out to the depth of at least three-fourths of an inch, and the mortar firmly calked into it. At the jambs of openings extra care should be taken to secure close adhesion throughout, followed by a careful inspection by sounding and the renewal of all spots where the stucco has failed to unite with the wall. Revised by RUSSELL STURGIS.

**Stuhlweissenburg**, stool-vīs'en-boorch: town; in the county of Fehér, Hungary; on a marshy plain 16 miles N. E. of Lake Balatony (see map of Austria-Hungary, ref. 6–G). It has several fine buildings, a gymnasium, a military academy, a Magyar theater, manufactures of potash, leather, linen, and woolen fabrics, and an extensive trade in oil, wine, grain, cattle, and wool. In its magnificent cathedral the Kings of Hungary were crowned and buried from 1027 to 1527. Pop. (1890) 28,942.

**Stumpf**, CARL, Ph. D.: psychologist; b. in Wiesentheid, Bavaria, Apr. 21, 1848; educated at Würzburg and Göttingen Universities; became Professor of Philosophy at Würzburg in 1873, at Prague in 1879, at Munich in 1889, and at Berlin 1894; member of the Prussian Academy of Sciences 1895. His principal works are *Ueber den psychologischen Ursprung der Raumvorstellung* (1873) and *Tonpsychologie* (2 vols., 1885–90). J. M. B.

**Stupor** [= Lat., deriv. of *stupe're*, be struck senseless, whence (by deriv.) *stu'pidus*, senseless, dazed, stupid]: that condition in which, when fully developed, the functions of the brain, so far as the mind is concerned, are almost entirely suspended, the individual lying in an unconscious state, though he may still be aroused by vigorous shouting or shaking. When there is complete loss of consciousness the condition is properly spoken of as COMA (*q. v.*). It may be induced by pressure upon the brain, as from a depressed piece of bone of the skull or the entrance of some foreign body, as a bullet; by a blow or fall, causing concussion of the brain or compression from extravasated blood; by the rupture of a blood-vessel, causing cerebral hæmorrhage; by the circulation of poisoned blood through the cerebral vessels, as occurs, for instance, when an over-dose of opium or alcohol has been taken. Stupor and coma are to be distinguished from sleep by the fact that it is easy to awake a person from sleep, while it is difficult to arouse him from stupor and impossible in coma. In sleep the mind may be active; in stupor it is, as it were, dead. Stupor is a symptom of serious importance in various injuries and diseases to which the brain is liable. It may exist in all degrees of severity. There is a form of stupor, met with in certain diseases of the brain, in which the individual, though unconscious, is nevertheless not altogether deprived of the power to think and to move the limbs. There is, in fact, a marked degree of restlessness, though the movements are, as it were, automatic, and the speech is incoherent. This condition is known as "coma vigil." It generally only occurs in cases of great gravity, and it indicates a fatal termination.

Revised by W. PEPPER.

**Sturgeon** [from Fr. *esturgeon* : Ital. *storione* : Span. *esturión* from Teuton. *sturjo*, appearing in O. H. Germ. *sturio, sturo* > Germ. *stör* : O. Eng. *styrja*]: any ganoid fishes of the family *Acipenseridæ*. All the species have the body elongated and subcylindrical, or slightly compressed and tapering backward into a rather slender caudal peduncle; the skin is generally armed with minute bony plates, as well as five rows of larger keeled bucklers, one dorsal, one pair lateral, and one pair on the sides of the abdomen; there is no well-defined lateral line; the head is produced into a projecting snout, which is provided below with four barbels in a transverse row; the operculum proper well developed; the mouth is small, inferior, transverse, protractile, with fleshy lips; teeth entirely wanting in the adult; the dorsal fin far behind, and short; the anal still nearer the tail than the dorsal; the caudal with the upper lobe prolonged; ventral behind the center of gravity. The skeleton is cartilaginous. The stomach is not cæcal; the pyloric appendages are numerous; the rectum has a spiral valve; the air-bladder is large and simple, and communicates with the œsophagus; two accessory gills occur. Species are found in all the temperate portions of the northern hemisphere. All breed in the fresh water, but some are residents of the sea part of the year, while others are permanent denizens of the lakes and rivers. They nearly agree, in fact, in distribution with the salmonids, save that they are less generally found in streams, on account of their larger size. There are two primary types —(1) *Acipenser*, which embraces several subordinate subgenera or genera; and (2) *Scaphirhynchus*, of which only two species are known, one (*S. platyrhynchus*) confined to the Mississippi river and its tributaries, and another from Central Asia. The number of species of *Acipenser* is about twenty. The most common American species are *A. brevirostris*, or short-nosed sturgeon, and *A. oxyrhynchus*, or sharp-nosed sturgeon, which ascend the rivers of the Atlantic slope, and the fresh-water *A. rubicundus* of the Great Lakes and their tributary rivers. Their flesh is reddish, and is by some highly esteemed. Their eggs are often made into caviare; their air-bladders can yield a kind of isinglass. They are the largest of fresh-water fishes, the huso (*A. huso*) of the Caspian and Black Seas and Sea of Azov sometimes exceeding the length of 15 feet and the weight of 2,000 lb. See also FISHERIES and STERLET. For illustration, see FISHES.

Revised by J. S. KINGSLEY.

**Sturgeon Bay**: city; capital of Door co., Wis.; on Sturgeon Bay, about midway between Green Bay and Lake Michigan, and on the ship-canal connecting those bodies of water (for location, see map of Wisconsin, ref. 4–F). The bay is 8 miles long by 2 miles wide, and affords an excellent harbor for the largest vessels. The city is in an agricultural and lumbering region, has large shipping interests, and contains a State bank with capital of $25,000, a private bank, and a monthly and two weekly periodicals. Pop. (1880) 1,199; (1890) 2,195; (1900) 3,372.

**Sturges**, OCTAVIUS: physician; b. in London, England, 1833; educated at Addiscombe as a cadet in the service of the East India Company; served in India as a lieutenant in the Bombay Artillery; returned to England and entered Emmanuel College, Cambridge, taking the degrees A. B. and A. M. in 1862; entered St. George's Hospital, London; in 1862 became a member and in 1870 a fellow of the Royal College of Physicians; M. D., Cambridge, 1867; lecturer on forensic medicine 1868–71, on materia medica 1871–74, on medicine 1874–93 in Westminster Hospital. He was the author of *An Introduction to the Study of Clinical Medicine* (London, 1873); *The Natural History and Relations of Pneumonia* (London, 1876); *On Chorea and other Allied Movements* (London, 1881). D. Nov. 3, 1894. S. T. A.

**Sturgis**: village; St. Joseph co., Mich.; on the Gr. Rapids and Ind. and the Lake Sh. and Mich. S. railroads; 31 miles E. by N. of Elkhart, and 36 miles S. by E. of Kalamazoo (for location, see map of Michigan, ref. 8–H). It is in an agricultural region, and contains 9 churches, public, central, and ward schools, water-works, electric lights, fair-grounds, a mile race-track, several large manufactories, a national bank (capital $65,000), a State bank (capital $50,000), and a monthly and 3 weekly papers. Pop. (1900) 2,465.

**Sturgis**, JULIAN: See the Appendix.

**Sturgis**, RUSSELL: architect and writer on art; b. in Baltimore, Md., Oct. 16, 1836; studied architecture in a New York architect's office and in Europe, and practiced from 1865 to 1878. He then retired on account of feeble health and has since occupied himself with archæology and fine art, and the work of societies devoted to fine art in New York and elsewhere. Among the buildings designed by him are Battell Chapel, Farnam Hall, Durfee Hall, and Lawrance Hall of Yale College, the Homœopathic Medical College and Flower Hospital in New York, the Mechanics' and Farmers' Bank at Albany, and churches, business buildings, and residences in New York, Albany, Aurora, Tarrytown, Watertown, N. Y., New Haven, Farmington, and Litchfield, Conn., Minneapolis, and Louisville. Author of *European Architecture, an Historical Study* (New York, 1895), and editor of decorative art and mediæval archæology in *The Century Dictionary*, of fine art in general in *Webster's International Dictionary*, and of archæology and art in *Johnson's Universal Cyclopædia*. He has also published numerous magazine articles.

**Sturlason**, SNORRE: See SNORRI STURLUSON.

**Sturm**, stoorm, JOHANNES, von: educator; b. at Schleiden, Germany, Oct. 1, 1507; founded (1537) the gymnasium in Strassburg, which attained, under him, worldwide celebrity. He was generally regarded as the greatest educator connected with the Reformed Church, and received the title *Præceptor Germaniæ*. His work gave a great impulse to the establishment of classical schools. To read, write, and speak Ciceronian Latin was the great object of his instruction, and to this end a course of twenty-one years—six at home, ten at school, five at college or university—was thought about sufficient. D. at Strassburg, Mar. 3, 1589. See Joseph Payne, *Lectures on the History of Education*. C. H. T.

**Sturt**, Sir CHARLES: explorer; b. in England early in the nineteenth century; entered the army at an early age. In 1828 he was the leader of an expedition organized to explore the interior of Australia, during which he discovered the Macquarie, Castlereagh, and Darling rivers, and soon after led another expedition which explored the course of the Murrumbidgee river, and in June, 1830, discovered the great Murray river, which he followed to its mouth in Lake Alexandrina, returning early in 1831. In 1844 he penetrated to the great stony desert nearly in the center of the continent. He was made registrar-general and subsequently colonial secretary of South Australia. In consequence of his exposure in these expeditions he became totally blind, and returned to England, where he was knighted a short time before his death. He published *Two Expeditions into the Interior of Southern Australia in 1828–31* (1833) and *Narrative of an Expedition into Central Australia in 1844–46* (1849). D. at Cheltenham, England, June 16, 1869.

Revised by M. W. HARRINGTON.

**Sturzenbecker**, stoorts'en-bek-ker, OSKAR PATRICK (*Orvar Odd*): writer; b. in Stockholm, Sweden, 1811. He was from the first one of the warmest advocates of the union of Scandinavian countries, on behalf of which he began to write in 1830. His greatest success was achieved in the light feuilleton style imitated from the French, in which he has never been equaled in Sweden. His best sketches are collected in *Grupper och Personagen från igår* (Groups and Persons from Yesterday). He was also the author of lyrics that display patriotic warmth and a deep sympathy for human progress. D. near Helsingborg, Feb., 1869. Selected works were published at Stockholm in 1878. D. K. DODGE.

**Stuttering**: See STAMMERING.

**Stuttgart**, stoot'gaart: capital of the kingdom of Würtemberg, Germany; on the Nesenbach, an affluent of the Neckar; 38 miles E. S. E. of Carlsruhe (see map of German Empire, ref. 7–D). It lies in a charming valley among hills covered with forests and gardens, and is regularly and beautifully built. The Altstadt, occupying nearly the center, and grouped around the market-place, contains several small and narrow streets, but the new parts of the city, mostly erected during the nineteenth century, have broad and beautiful streets and symmetrical squares. The most prominent point is the palace square, ornamented with gardens and fountains, containing the jubilee column, over 50 feet high, and surrounded by magnificent buildings. Among these the new palace is the most remarkable—a very handsome structure, with two projecting wings, the central building containing 365 rooms rich in works of art by Dannecker, Gegenbaur, Thorwaldsen, and others. To the right of this edifice stands the old palace, built 1553–70, a gloomy castle with towers and pinnacles, but containing a beautifully painted chapel and large halls, the curious Reitschnecke, a spiral horse-path giving access to the third floor, and in the court the equestrian statue of Eberhard, the first Duke of Würtemberg. In the left wing of the new palace is the royal theater, finished in 1846, and opposite the palace is the Königsbau, a beautiful structure with an Ionian colonnade, built 1855–59, and containing numerous shops, elegant *cafés*, a concert-hall, and other assembly-rooms. In the rear of the old palace is the Schiller Square, containing the statue of the poet, the immense building of the palace of the princes, and the parish church, erected 1436–90, and restored in 1841. One of the most beautiful and most important streets is the Neckarstrasse, running from the palace square in a northeastern direction, and containing the museum of natural science with a rich collection of mammals; the national library, comprising 400,000 volumes, 3,600 manuscripts, 2,300 incunabula, and a collection of 8,700 Bibles in eighty-nine different languages; the museum of art, containing an art school and collections of paintings and statues, etc. Nearly parallel with the Neckarstrasse runs the Königsstrasse, traversing the palace square and dividing the city into two parts, a southeastern and northwestern; on this are the royal stables and the royal central hall for commerce and industry, with a good library and important collections. Other remarkable buildings are the museum for Wurtembergian antiquities, the polytechnic school, the new market-hall; and among the churches, the Leonhard's church, Johannis church, a Roman Catholic church, an English church, and the magnificent synagogue. The finest promenade is the palace garden, a park with lakes, fountains, statues, etc., stretching from the palace for the distance of about 2 miles. In the vicinity are the royal summer palaces, Solitude, Villa Rosenstein, Wilhelma, and the Villa, and the charming town of Cannstatt-on-the-Neckar, with 22,000 inhabitants, much frequented as a bathing-place, connected with the city by a railway. The industry in woolen manufactures is important; a wholesale cloth-fair is annually held in August. The manufactures of pianos, carriages, chocolate, sugar, and machinery are also considerable. The commerce of the city is extensive: the book and art trade is especially important. Pop. (1900) 176,318. The name *Stuttgart* first occurs in history in 1229, though the exact date of its foundation is not known. It became the residence of the Count of Würtemberg in 1320, and the capital of the country in 1482. The city was held by Austria from 1519 to 1534, and occupied by Alba in 1546 in the Smalkaldic war. In the period from 1634 to 1638 one-half (8,810) of the inhabitants died from the plague. In the wars of Louis XIV. it was taken by the enemy three times; also several times during the wars of Napoleon.

Revised by M. W. Harrington.

**Stuyvesant**, stī've-sănt, Peter: director-general of New Netherlands; b. in Holland in 1602: served in the West Indies; was director of the colony of Curaçoa; lost a leg in an attack upon the Spanish island of St. Martin; returned to Holland in 1644, and in 1647 was sent to the New Netherlands as director-general. Upon his arrival at New Amsterdam (now the city of New York) in May, 1647, he made peace with the Indians, and a few years later arranged the boundary-line between the Dutch and the English possessions in North America. In 1651 the Dutch built a fort on the site of the present Newcastle, Delaware river, which the Swedish governor Rising captured in 1654. In 1655 Stuyvesant sailed for the Delaware with seven vessels conveying 600 or 700 men, recaptured the fort, and took possession of the entire colony of New Sweden. In the meanwhile discontent had sprung up against the arbitrary administration of the Dutch West India Company, and in 1653 a convention of two delegates from each settlement in the colony assembled and demanded that obscure and obsolete laws should not be revived, and that no officer should be appointed except with the approbation of the people. Stuyvesant replied that the magistrates derived their authority from God and the Dutch West India Company, and not from a few ignorant subjects, and ordered the convention to disperse under pain of condign punishment. The discontent, however, still continued. The English colonies in New England, in spite of the repeated remonstrances of the governor, began to encroach upon the boundaries of New Netherlands. In 1664 Charles II. of England issued a charter to his brother, the Duke of York, afterward James II., bestowing upon him all the country between the Hudson and the Delaware, including New Netherlands, as well as some territory which had previously been granted to the New England provinces. In August of that year, although England and Holland were at peace, Col. Nicolls, with an English fleet, appeared in the bay and demanded the surrender of New Amsterdam. Stuyvesant at first refused, but the municipal officers, seeing little hope of successful resistance, and having no very warm attachment to their Dutch masters, insisted that he should yield, and the town was surrendered Sept. 3, 1664, and its name changed to New York—a designation soon extended to the whole province of New Netherlands. Stuyvesant went to Holland the next year, but returned soon after, and passed the remaining eighteen years of his life at his farm, called the *Bowerij*, which has given its name to the street called the Bowery. D. in Aug., 1682. Revised by F. M. Colby.

**Sty**, or **Horde'olum** [*sty* < O. Eng. *stigand*, swelling, adjec. sc. *ēage*, eye]: a small boil which occurs on the edge of the eyelid. It should be treated with a warm-water dressing or light wet poultice; after the discharge of a little pus and a slough, it usually gets well at once. If there be a long succession of sties, as sometimes happens, iron and quinia, with occasional mild laxatives, will be useful.

**Style**, or **Stylus**: See Pen.

**Style, Old and New**: See Calendar.

**Stylites**: See Pillar Saints.

**Stylites, St. Simeon**: See Simeon Stylites.

**Stylopidæ**: See Strepsiptera.

**Styptics**: See Bleeding.

**Styraca'ceæ** [named from the typical genus *Styrax*, from Lat. *styrax* = Gr. στύραξ, storax, or the tree yielding it]: a family of exogenous, gamopetalous trees and shrubs, with the stamens commonly monadelphous or polyadelphous, and adnate to the base of the corolla; the calyx more or less adnate, and the seeds few and large with a bony coat; the leaves alternate entire, serrate membranous, or coriaceous feather-veined. There are about 235 species distributed among seven genera, the most important of which are *Halesia* and *Styrax*. The former is the Snowdrop-tree (*q. v.*). *Styrax* contains over sixty species, restricted to the warmer parts of Asia, Europe, and America. Many of the species yield valuable gums, such as Benzoin (*q. v.*) and storax. The latter is a solid resin, resembling vanilla in odor, obtained from *S. officinalis*, a small tree of Asia Minor and Syria. Liquid storax is a balsam obtained from the inner bark of *Liquidambar orientalis*. It is used in making incense and perfumery. Its chief market is in the East.

**Styr'ia** (in Germ. *Steiermark*): province of Austria; bounded N. by Upper and Lower Austria, E. by Hungary, S. by Carniola and Croatia, and W. by Carinthia and Salzburg. Area, 8,670 sq. miles. In the southern part, on some of the plains, and in the valleys are raised wheat, maize, tobacco, flax, hemp, wine, and fruit; elsewhere the province is mountainous, and cattle-rearing, dairy-farming, mining, and manufactures of metallic wares are the principal branches of industry. The Noric Alps cover the surface between the Ens and the Mur; the Styrian Alps, between the Mur and the Drave; and the Carnic Alps, between the Drave and the Save. These mountains rise to a height of between 7,000 and 8,000 feet, and are rich in iron, copper, salt, alum, marble, and coal. Pop. (1890) 1,282,708, of whom over 710,000 are of German and the rest of Slovenian descent. Capital, Gratz. Revised by M. W. Harrington.

**Styrian Literature**: See Slovenian Literature.

**Styx** [Gr. Στύξ, the hateful]: in Greek mythology, a river of Hades which flowed from the tenth source of Oceanus. At the entrance to Hades was the abode of the nymph or goddess Styx, by whom the most solemn oaths of the gods were sworn, thus dedicating themselves to death in case of perjury.—Styx was also the name of the highest waterfall (not, as Herodotus says, a fountain) in Greece, near Nonacris in Arcadia. The ancients, like the modern residents of the vicinity, considered its waters fearfully poisonous, and it was believed that no vessel could hold any of it unless made of the hoof of an ass or horse. The ancients associated this waterfall with the mysterious Styx of the lower world. Revised by J. R. S. Sterrett.

**Suabia**: See SWABIA.

**Suakim**, swaa-keem′, or **Sawakin**: fortified town of Nubia and best port on the Red Sea; on an island a few hundred feet from shore; lat. 19° 7′ N. (see map of Africa, ref. 3–G). It has been in the possession of the British since 1882. Formerly the head of the caravan routes into the interior, it lost much of its importance as a result of the Mahdist rebellion, and this is not yet recovered, because of the insecurity of the interior. The influence of the British hardly extends beyond the reach of their cannon. Opposite Suakim on the mainland is the suburb of El-Kef, also fortified, connected with the city by a low bridge and short railway. The latter is all that was made of a railway projected to Berbera on the Nile in 1884, but prevented at that time by the Mahdists. Suakim is considered of great strategical and commercial importance, and is the most suitable terminus for a railway into Egyptian Sudan. The chief exports are gum arabic, silver, ivory, senna, and skins. Pop. (1897) 15,713. MARK W. HARRINGTON.

**Subcarbonif′erous Series**: in American geology, the lowest group of Carboniferous strata. It occupies the interval between the Devonian system and the coal-measures. Earlier designations of the same division are mountain limestone, Carboniferous limestone, and Lower Carboniferous, and a later proposed title, Mississippian series, has much to commend it. In the Mississippi valley it consists principally of limestones and shales, and includes, in an ascending order, the Kinderhook, Burlington, Keokuk, Warsaw, St. Louis, and Chester formations or groups. In Pennsylvania the equivalent series consists principally of sandstone and shale, having a maximum thickness of 5,000 feet. The series has also been recognized in Nova Scotia and New Brunswick, and has a great development in the Rocky Mountain region. The fossils are principally marine invertebrates, some of which, especially the brachiopods, are of worldwide distribution. Remains of fishes and of reptiles also occur. Rocks corresponding to the Mississippian series in time have a wide distribution in other countries, and especially in Europe. See CARBONIFEROUS PERIOD and DEVONIAN PERIOD. ISRAEL C. RUSSELL.

**Subconscious States**: states of mind which belong to us and which we can pay attention to, but which we may not be actually thinking of; such as our sense of the furniture in the room about us. Such states or elements are very common in our mental history, and are called subconscious as long as there is evidence that they have not sunk entirely out of the whole of our present state of mind. On the other hand, things which we may merely remember on occasion, and are in no sense conscious of at a particular moment, are then "unconscious." See UNCONSCIOUS STATE. J. M. B.

**Suber′ic Acid** [*suberic* is from Lat. *su′ber*, cork-tree, cork]: a homologue of oxalic and succinic acids. Its general characters are those of that family of dibasic acids, and its empirical formula is $C_8H_{14}O_4$. The name was originally due to the fact that this acid was first obtained by the action of nitric acid on cork. Fats generally, however, yield it by the same treatment, and it is by no means a characteristic product of cork. To obtain suberic acid free from the other acids produced by the action of nitric acid on fats, the mixed product is treated with cold ether, in which this acid is almost insoluble. It is necessary, however, to purify it further by recrystallization. It may be obtained in large needles, which sublime like oxalic acid. It is sparingly soluble in cold, but easily in boiling water, and soluble in alcohol.

Revised by IRA REMSEN.

**Suberine**: See CORK.

**Subiaco**, sōō-bēē-aa′kō (anc. *Sublaqueum*): town; in the province of Rome, Italy; on the right bank of the Teverone; 42 miles E. N. E. of the city of Rome (see map of Italy, ref. 6–E). It derived its name from its situation below a villa belonging to Nero, in the grounds of which were three lakes. In the monastery of Santa Scolastica, founded in the fifth and restored in the tenth century, the printing-press was first used in Italy, a Lactantius (1465) being the first issue. The monastery of St. Benedict, the first founded by the saint himself, was rebuilt in 817. Pop. 6,503.

**Subinfeudation**: See LANDLORD AND TENANT.

**Sublima′tion** [from Lat. *sublima′re*, raise, deriv. of *subli′mis*, lifted up, on high]: a chemical process of separation and purification, applicable only occasionally in cases in which a volatile substance condenses or crystallizes from the condition of vapor directly to the solid condition, and not to the usual liquid form. In such cases this method of obtaining bodies in pure and crystallized form is highly convenient and valuable. Among the more important substances to which this method is applicable are sulphur, iodine, vermilion, corrosive sublimate, calomel, salts of ammonia, arsenious oxide, oxalic, benzoic, succinic, and pyrogallic acids, camphor, caffeine, etc. As those substances which volatilize at low temperatures will readily pass through porous diaphragms like paper when in a vaporous state, it is often convenient to cover the lower vessel, containing the substance to be volatilized, with paper, which will prevent the crystals that condense in the head or upper inverted vessel from falling back and causing waste of time. In cases of bodies requiring high temperatures wire-gauze screens may be employed in the same way. Revised by IRA REMSEN.

**Sublime** [from Lat. *subli′mis*, lifted up, lofty, sublime]: Contradistinguished from the beautiful, which charms and attracts us, the sublime awes us, moves us with a feeling of pleasure mixed with fear. The sublime in nature is usually found in the boundless expanse of the ocean, in the resistless might of its waves when moved by a storm, or more frequently in the thunder-storm with its threatening look, its vivid and destructive lightnings, and its deafening crashes of thunder. Still more adequate is the manifestation of the sublime in instances of moral heroism—in deeds of daring and self-denial; the sublime in art has most frequently made use of this phase. Kant, in his *Critique of the Judgment* (§ 23–53), has given the first thorough and systematic treatment of the sublime. According to him, "while the beautiful in nature appertains to the form of an object—hence to its circumscribed limits—the sublime, on the contrary, is to be found also in formless objects: a want of limitation attaches to it. It is, however, represented as a whole, and not as something merely fragmentary. The beautiful may therefore be regarded as the portrayal of an idea of the understanding (not a mere concept), but the sublime is rather the portrayal of an idea of the reason, which, from its nature, can not be adequately represented by material things." "The pleasure of the beautiful appertains to the quality of an object, while the sublime is manifested chiefly in the quantitative aspect of it." "To the charm of the beautiful there is frequently joined a sportiveness, but the sublime is always earnest." "The sublime, in its proper form, is not presented in a sensuous manner, but concerns only ideas of the reason, whose very incommensurability with sensuous forms, being exhibited, stirs the heart." "The beautiful pleases us immediately, but in its presence we feel disinterested; the sublime pleases us, but through its hostility to our sensuous interests." Cousin (*On the True, Beautiful, and Good*, lecture vii.) says: "A beautiful object is something completed, circumscribed, limited, which all our faculties easily embrace, because the different parts are on a somewhat narrow scale. A sublime object is that which, by forms not in themselves disproportional, but less definite and more difficult to seize, awakens in us the sentiment of the infinite." Hegel (*Æsthetics*, 2d part, div. i., chap. ii.) makes the sublime a province of symbolic art, whose chief function is to portray the purification of spirit and its separation from the world of sense and all visible existence. "The highest principle is regarded as existing apart by itself, and as incapable from its very nature of finding adequate expression in the finite appearances of the real world." "The sublime arises in an attempt to express the infinite without finding in the domain of visible phenomena an object capable of representing it. The infinite elevates itself above particular existences, considered either in themselves or in their totality; they are as nothing before it; and the positive relation which sensuous objects have to the beautiful, in the sublime changes to a negative relation which is more in conformity to the divine nature. God is thus represented as purified of all contact and participation of visible appearance." "In the Orient, in India, the One, or Substance, is conceived as immanent in contingent existences created by it; they are portrayed as mere instruments of the divine power, or as mere ornaments for the display of the glory of the Absolute." In the *Bhagavat Gita* (ch. xi.) the vision of the Universal Form of Vishnu furnishes us the highest example of this phase of the sublime. The speech of the *Erdgeist* in Goethe's *Faust* is an example quite similar in form and content. In Hebrew poetry Hegel finds the highest realization of the sublime; "Jehovah is not 'immanent' in nature, but 'transcendent'

—lord over the universe—and in his presence the entire creation is devoid of power and sinks into nothingness. The grandeur of the Lord is revealed by the fact that the real world, with all its splendor, pomp, and magnificence, is a mere accident, an instrument, an ephemeral appearance in comparison with the eternal and immutable Being. In the 104th Psalm God is represented as covering himself with light as with a garment, and as stretching out the heavens like a tent. 'He layeth the beams of his chambers in the waters; he maketh the clouds his chariot; he walketh upon the wings of the wind; he looketh on the earth, and it trembleth; he toucheth the hills, and they smoke. He laid the foundations of the earth, that it should not be removed forever.' In the psalm of Moses (Ps. xc.) the finitude of man furnishes the contrast which makes the portrayal of the omnipotence of God sublime." For other but less adequate treatises on this subject, the reader is referred to the writings of Burke, Dugald Stewart, and Addison. The famous treatise of Longinus (Περὶ Ὕψους) should not be omitted. WILLIAM T. HARRIS.

**Sublime Porte**: See PORTE.

**Subluxation**: See SPRAIN.

**Submarine Navigation** [*submarine* is from Lat. *sub*, under + *marine*, from Lat. *mari'nus*, deriv. of *ma're*, sea]: the art of navigating a submerged vessel. In submarine navigation it is requisite that an operator should be able to move freely in any direction and at any depth, and with no communication with the surface except at long intervals. The accounts of early attempts to accomplish these results are exceedingly meager. William Bourne, of London, is mentioned as proposing a plan in 1578, and Cornelius Debbrel, in 1624, is said to have constructed a submarine boat to carry twelve rowers, besides passengers, and also to have discovered a liquid which had the property of restoring air when it became impure by breathing: but he died before his plans were perfected, and his secret died with him. Papin and Borelli are mentioned in 1672, and Stapleton in 1693; but little was apparently accomplished till 1771, when David Bushnell first suggested the idea of attacking a vessel underneath the water, and constructed a submarine boat capable of accomplishing the desired object. There is no drawing extant of this remarkable invention, but the accompanying figure corresponds with the descriptions, which are quite accurate, and will serve to illustrate an invention which, for the purpose for which it was designed, was the most perfect thing of its kind that has ever been invented. The boat was shaped like a turtle, and floated in the water with the tail down. It contained air enough to support life for half an hour, and air could be renewed at the end of that time through small ventilators by rising to the surface. The operator was seated in the middle, the seat forming a brace between the two sides, and in this position he had his eyes opposite one of the numerous glass plates in the cover or top of the boat. In front of him was the handle of a screw, by which the boat was propelled; another, by which it was raised or lowered; a compass marked with phosphorus; a water-gauge, to show the depth, marked with oil and phosphorus; and near him the handles or treadles of various small pumps and levers, by which water and foul air were expelled, the rudder moved, ballast let go, etc. The torpedo—or submarine magazine, as Bushnell called it—consisted of a block of oak containing a charge of about 150 lb. of powder. This block was on the upper after

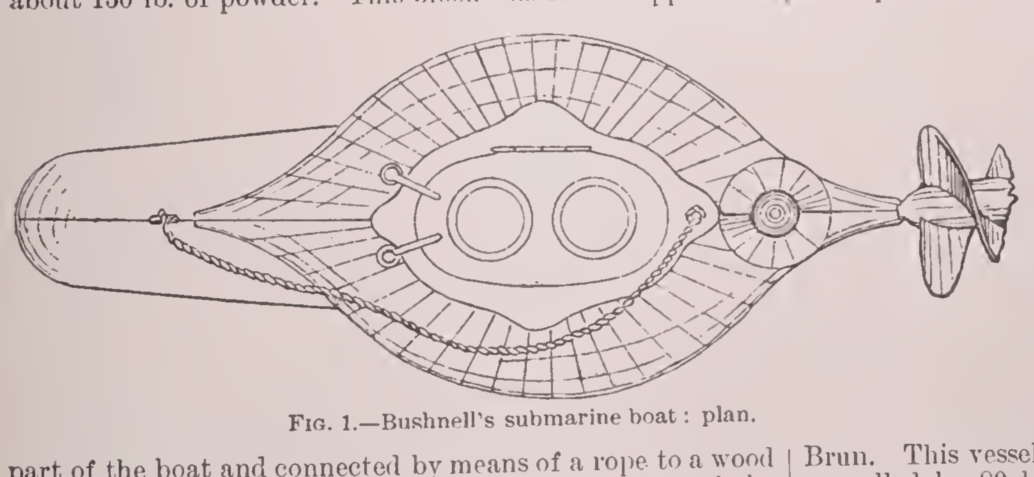

FIG. 1.—Bushnell's submarine boat: plan.

part of the boat and connected by means of a rope to a wood screw, the handle of which was directly in front of the operator. The mode of operation was to move slowly along the surface, with the top just awash, till within a short distance of a vessel at anchor, then to sink, and, coming up underneath the bottom, fasten the torpedo by means of the screw. The torpedo and screw were then detached from the

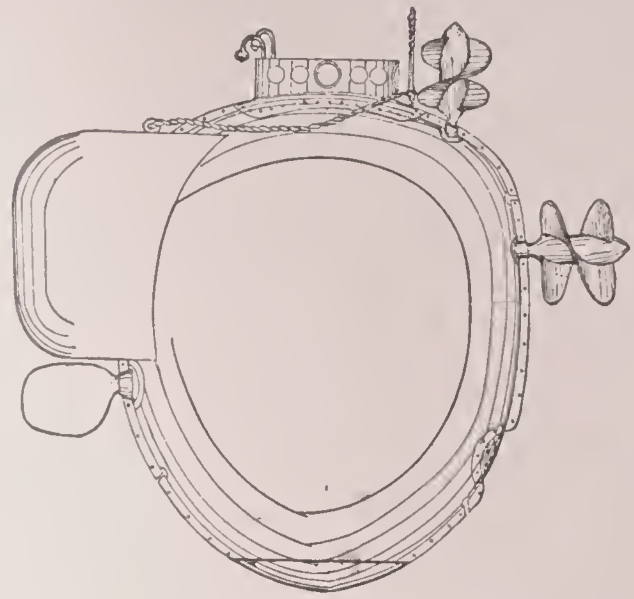

FIG. 2.—Bushnell's submarine boat: elevation.

operator's boat, a clock-work mechanism inside the torpedo being set going at the same time. This clock-work could be set for six, eight, or twelve hours' run, thus allowing the operator ample time to make his escape. See TORPEDOES.

In 1845 a shoemaker of Michigan City, Ind., named Phillips, devised a submarine boat in which he made frequent descents, sometimes taking his family. In 1864 occurred the only successful use of a submarine boat in warfare, when the U. S. S. Housatonic was sunk by a spar-torpedo carried by a Confederate "David," a cigar-shaped boat built of boiler-iron and having a crew of nine men, eight of whom worked the propeller. This boat is, however, supposed to have been only partially submerged when the attack was made. She was sunk with her entire crew by the explosion of her own torpedo. About the same time the French Government tried a boat called the Plongeur, designed by Admiral Bourgeois and M. Brun. This vessel was of about 200 tons displacement and propelled by 80 horse-power compressed-air engines. Her depth of immersion was to be regulated by the admission or expulsion of water, but horizontal rudders of large area were found a better means of attaining this end, and a vertical screw worked by hand was afterward added to assist in the depth regulation. Although since Bushnell's time many inventors, including Fulton, have turned their attention to submarine navigation, little real progress was made for over a century. The principal naval powers, however, have conducted experiments looking to the adoption of submarine boats for war purposes, and it has been shown that submarine navigation is feasible, though opinions differ greatly as to its value for actual service.

In Great Britain the Nordenfelt boats have attracted widespread attention. Their principal features are steam-propulsion on the surface, the use of the reserve heat stored in the water and superheated steam for propulsion under water, and submergence by vertical screws. The first boat, built in 1883 and sold to Greece, had a surface speed of 9 knots. The second and third boats were of 160 tons displacement, with 12 knots surface speed, and were built for the Turkish Government. The fourth boat embodies numerous improvements over her forerunners. Her displacement is 250 tons submerged and 160 tons when running on the surface. Engines of 1,000 horse-power give a speed of 15 knots on the surface, and the heat stored in her boilers, which contain 27 tons of hot water, furnishes power for a submerged run of about 20 knots at 5-knot speed. Submergence is effected by vertical screws, working in wells, one at each end of the boat, and actuated by separate engines, the boat being first brought awash by filling certain compartments with water. The reserve buoyancy is never less than half a ton, and can be increased by expelling the water by powerful pumps. In the conning-tower are placed the necessary connections for controlling the machinery for driving and steering the vessel, sinking or rising, and for discharging the Whitehead torpedoes with which she is equipped.

In France, where perhaps the greatest advance in the art of submarine navigation has been made, the Goubet boats, a number of which are said to have been bought by Russia, succeeded the Plongeur. These are very small boats and originally were driven by hand-power, though in the later ones an electric motor working from accumulators is used. The submerged displacement is 2 tons and the speed 5 knots. Trim is preserved by water-tanks at each end connected by a pump which transfers water from one to the other on being started by the automatic action of a pendulum. The crew of two men are provided with sufficient air, from a reservoir at 50 atmospheres pressure, for ten hours. The screw is fitted with a universal joint so that the propelling power can be applied to changing the course in any direction. The armament consists of a torpedo carried outside the boat and intended to be released at the proper moment so as to rise under the enemy's bottom and there be exploded by a wire leading to the boat after she has withdrawn to a safe distance. The utter impracticability of this method of attack is evident. A later French production is the Gymnote, of 30 tons displacement, spindle-shaped, and 56 feet long by 6 feet maximum diameter. This boat was so successful that a larger boat of the same general design, and named after the inventor, Gustave Zédé, was also ordered. The Gymnote is propelled by a 55 horse-power electric motor worked by accumulators, submergence being effected by filling water-compartments until she has only a slight buoyancy and then causing her to dive by means of horizontal rudders. She has a speed of 10 knots and is worked by a crew of three men. An electric gyroscope indicates angular movements in the horizontal plane, and enables her to maintain a fixed course beneath the surface.

In the U. S. two improved types of submarine boat, invented respectively by George C. Baker, of Detroit, and J. P. Holland, of New York, have been tried. The essential feature of the Baker boat is the use of two screws on a transverse shaft through the center of gravity of the boat, these screws being susceptible of movement so that the thrust developed by their rotation can be directed at will in a plane at right angles to the shaft. The motive power is electricity from storage-batteries, and submergence is effected and maintained by giving the screws a sufficient angle to overcome the buoyancy by the vertical thrust and at the same time propel her by the horizontal component. This plan renders it less important to preserve horizontality of the boat's axis than in a boat whose motive power is at the stern, but it has the disadvantages of being wasteful of power and of placing the screws in a greatly exposed position. The Holland boat, which has been, perhaps, as successful as any yet built, is shown in the drawing. She was 31 feet long by 6 feet in diameter, circular in cross-section, and weighed 18 tons when submerged. The motive power was obtained from a petroleum-engine which gave a surface speed of 8 knots and a submerged speed of about 6 knots. Reservoirs containing 240 cubic feet of air at 300 lb. per square inch supplied the air necessary for breathing purposes, for the engine, for the propelling charge of a gun fixed in the bow, and for expelling water from the water-ballast tanks if it became necessary to ascend quickly to the surface. The engine-compressor, drawing its air directly from the living space, gave sufficient ventilation. The essential feature of this boat was the use of diving-rudders on a horizontal shaft at the stern, to produce and maintain submergence, the boat being steered in a vertical direction just as an ordinary boat is in the horizontal plane. The practicability of this method was proved by numerous dives in water of various depths, and it was found possible to maintain a nearly constant depth either by hand-steering or by an automatic device similar to the depth-regulator of a Whitehead torpedo. A camera-lucida projecting above the water gave a clear view while the boat was running several feet below the surface.

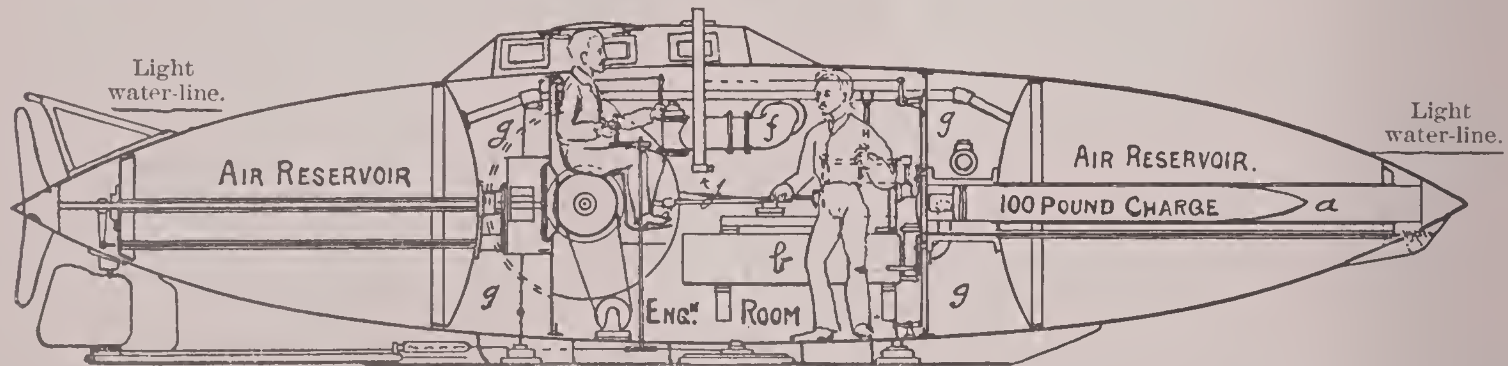

Fig. 4.—Vertical longitudinal section of Holland's submarine boat: *a*, submarine gun and projectile; *b*, firing-charge chamber; *f*, automatic air-pressure regulator; *g g*, water-ballast tanks; *j*, camera-lucida.

In 1892 an appropriation of $200,000 was made to enable the Navy Department to build and test a submarine boat, and Mr. Holland's plans for a boat of about 150 tons displacement were adopted. This boat differs from that above described in having a 70 horse-power electric motor, worked from storage-batteries, for under-water propulsion. Her surface speed was designed to be 15 knots, with 1,000 horse-power steam-engines actuating twin screws, and her submerged speed 8 knots for six hours. An automatic device controlling the vertical rudders enables a straight course to be held under water. The armament adopted consists of Whitehead torpedoes expelled from a pair of bow tubes. In addition to the diving-rudders this boat has a vertical screw at each end actuated by an 8 horse-power electric motor to maintain submergence when not moving. An important feature is an automatic safety device by means of which, when a dangerous depth is reached, air is admitted into a bow compartment, expelling a large quantity of water, and, by raising the bow, changing the course upward.

General requirements for submarine boats for war purposes—and this is their only practical use—stated in the order of their importance, are safety, facility of manœuver, speed, endurance, and offensive power. For safety the boat must have strength to resist the crushing force of the greatest depth to which she will descend, and must possess a reserve buoyancy, overcome during submergence by mechanical means but never destroyed. She must have stability enough to prevent capsizing or considerable change of trim under service conditions, and must carry an ample supply of air for the crew. Modern steel construction enables the necessary strength for a submergence of 150 feet, which is ample, to be obtained with a weight of hull of about one-half the displacement. Reserve buoyancy is a feature of all modern submarine boats, and additional safety is given by various devices whereby the pressure due to any stated depth will automatically impel the boat upward, either by expelling water from the tanks or by moving the horizontal rudders. Stability on the surface is obtained as in ordinary vessels, and below the surface by simply placing the center of gravity below the center of buoyancy. Compressed air in tanks gives a ready means of ventilation, but in a boat of ordinary size there is enough air to last the crew several hours, especially as the storage-batteries generally in use for propulsion under water give off a certain quantity of oxygen. Complicated means for purifying the air are found to be practically not necessary. Facility of manœuver in the vertical plane can probably be best obtained by diving-rudders, for with these a boat can most quickly come to the surface and again disappear. Any simple form of pressure-gauge will indicate the depth of submergence, and the variations of the water-pressure are easily made to control the diving-rudders automatically, the replacement of fuel, torpedoes, or other stores expended by an equal weight of water keeping the buoyancy and trim unchanged. Motion in the horizontal plane is controlled by ordinary rudders and twin screws add to the turning power. Surface speed is of great importance, since approach to an enemy must be on the surface, and escape may depend upon it. Steam propulsion is still the best for surface use, means being provided for rapidly housing the smoke-stack and sealing the furnace-doors preparatory to diving. Endurance depends only on the weight which can be allotted to fuel or other sources of power. Fuel for a run of 1,000 miles on the surface and electric power for a run of 50 miles under water can easily be carried in a boat of 150 tons. For purposes of offense the automobile torpedo is probably most effective, though the submarine gun, using either powder or compressed air as a propelling charge, promises well. Speed under water is best obtained by the use of the electric motor and storage-batteries, the feature of unchanging weights having manifest advantages. With a vessel of good form there should be no difficulty in attaining as great or greater speed than on the surface, but there is no probability that high speeds will ever be used in submarine navigation, the impossibility of seeing anything and the uncertainty of position and direction rendering it necessary to move slowly.

**Subpœ'na** [Lat. *sub*, under + *pœ'na*, penalty]: in law, a writ or process by which either parties or witnesses are compelled to appear in court or before a judicial officer and answer or testify, as the case may be, under a penalty for their disobedience. There are several different kinds of this writ. In the courts of chancery it was for a long time the ordinary process, issued upon filing a bill of complaint, for the purpose of procuring the defendants to appear and answer. This use, however, was abolished in England some time before the consolidation of the law and equity courts and procedure (see COURTS), and the defendant in a chancery suit was simply served with a copy of the bill, and with a notice or summons indorsed thereon or accompanying the same. The common species of subpœna now used in all the courts, civil and criminal, is the subpœna *ad testificandum*, for the purpose of ordering witnesses to attend upon a trial or other judicial examination, and to give their evidence thereat. It generally purports to be issued by the court, to be signed by its clerk, and sealed with its seal; but in the loose practice prevailing in many States of the U. S. it is issued by the attorney. It commands the person to whom it is addressed to lay aside all excuses and pretenses, and to appear before the court or officer at the time and place mentioned, and testify on behalf of the party issuing it, under a penalty in case of a neglect to comply with the order. A variety of this species is termed the *subpœna duces tecum*, and contains an additional clause directing the witness to bring with him into court certain books, papers, etc., in his possession which may be useful as evidence, and which must be designated with sufficient particularity to apprise the witness of the exact papers to be produced. Both these forms are compulsory; the witness must obey the mandate, and it is for the court alone to decide whether his evidence or the documents he is ordered to produce are material and proper. If the witness violates the command, an action for damages may be maintained against him by the party who is materially injured by his default. The subpœna is served by exhibiting the original to the witness and delivering to him a copy thereof, and paying him his lawful fees for travel and for attendance. Both the subpœna *ad testificandum* and the subpœna *duces tecum* may be used by committees of legislatures and other *quasi* judicial bodies lawfully constituted for the purpose of carrying on investigations, as well as by courts and magistrates. Revised by F. STURGES ALLEN.

**Subroga'tion** [from Lat. *subroga're*, put in another's place, substitute; *sub*, under + *roga're*, ask]: an equitable doctrine by which a person paying in proper circumstances a debt which as between himself and another should have been paid by the latter is given the rights and remedies of the original creditor. It may be stated as a general principle that whenever a person *secondarily* liable for a debt pays the same, the demand is not regarded in equity as discharged, but he at once and by operation of the equitable doctrine succeeds or becomes subrogated to all the rights, remedies, and securities which the creditor held against the debtor primarily liable, and may enforce the same as a creditor against such debtor in order to reimburse himself for the outlay which he has made on behalf of that party. The following are some of the most common and important instances which result from an application of this general principle to different facts and circumstances: (1) When a junior mortgagee pays the debt due to a prior mortgagee of the same land he becomes entitled to the prior mortgage, is regarded as its equitable assignee, and can compel its actual assignment to himself. The rule applies to all cases where a junior creditor pays the demand of a prior creditor; he succeeds to the latter's claim and is entitled to all the securities held for its enforcement. (2) When one of several joint debtors pays the entire demand he is entitled to a contribution from the others for their respective shares, and acquires the rights and securities of the creditor against them. (See CONTRIBUTION.) (3) The principle is most frequently applied in the case of the surety who pays the demand primarily owing by his principal debtor. He is entitled to recover their contributory shares from his cosureties, if any, and the entire amount which he has advanced from his principal. To aid him in enforcing these rights he is entitled to hold and use all the collateral securities given by the principal debtor to the creditor. For example, if as such surety he pays off a mortgage debt he is an equitable assignee of the mortgage itself. If the creditor has recovered a judgment against the principal and surety, or against the principal alone, and the surety pays the demand, he is not only entitled to hold this judgment, but he is permitted to enforce it by execution against the principal.

**Subsidies** [from Lat. *subsidium*, reserve-troops, support, relief; deriv. of *subsi'dere*, settle down, lie in wait]: (1) in English constitutional history, special taxes assessed upon persons and not directly upon property; (2) in the political history of Europe, payments to an ally, to aid in carrying on a war; (3) the usual application of the term since 1840, grants of money by the state in aid of individual enterprises. The most important subsidies of this kind have been granted in aid of transportation companies.

*Railway Subsidies.*—In Great Britain the Government granted no subsidies whatever except in Ireland. France defrayed about half the original cost of her railways, and left them to the companies to operate. This policy was followed in most of the other states of Southwestern Europe, as well as by Austria, Russia, and British India. (For the history of direct ownership of railways by the state, see TRANSPORTATION.) In the U. S. the subsidy system has been much more complicated. Railways have been assisted by State and municipal subscriptions to their stock and their bonds, even on an unwisely large scale. National aid to railways, with one important exception, has been in the form of grants of public land. From an early period there had been important grants of this kind in favor of roads and canals. In 1850 large grants of public land were made to the Illinois Central and the Mobile and Ohio railroads, through the medium of the States of Illinois, Alabama, and Mississippi, Congress for form's sake delivering the land to the States, to be in turn by them delivered to the railway companies. The example was rapidly followed in other parts of the U. S., the system being extended to Missouri in 1852, to Arkansas in 1853, and in 1856 to Michigan, Wisconsin, Iowa, Florida, and Louisiana, besides additional grants to Alabama and Mississippi. It was a game of sectional interests, each part of the republic being anxious to secure its share of the spoil. Some 27,000,000 acres were given to corporations in this way before the crisis of 1857 put a temporary stop to all schemes of the kind.

The civil war, though it stopped railway building, gave a new impulse to the policy of subsidies. California was at that time so far out of communication with the rest of the republic that its adherence to the Union was a matter of sentiment rather than of direct connection. To strengthen this sentiment on the one hand, and to secure the means of communication by land when it was no longer safe by sea, public attention was directed to the project of a Pacific railway, which seemed to be a political necessity, to be obtained at almost any price. The Pacific Railroad Bill, carried by Thaddeus Stevens in 1862, gave to the Union and the Central Pacific railroads a money subsidy amounting to over $25,000 a mile, and more than 30,000,000 acres of land in addition. The money subsidy took the form of a loan, but it was not expected that it would be repaid. It seemed for a time doubtful whether the road would be built at all; but the work proved unexpectedly easy, and the Crédit Mobilier, a construction company formed for the purpose of building the road, realized enormous profits, involving a public scandal, since many Congressmen were found to hold the stock of this construction company without having furnished any consideration therefor. The unexpected success of this enterprise made the company profitable, and it might have paid interest on the moneys advanced by the U. S., but, taking advantage of a technical defect in the remedies by which the lien of the U. S. could be enforced, the company evaded this obligation. The Thurman Act of 1878 attempted to settle the matter by providing for the payment to the U. S. of a portion of the earnings of the company, to form a sinking fund which should meet the amount of the debt at maturity; but these earnings proved much less than had been expected.

The Northern Pacific road did not succeed in getting a cash subsidy, like that of the Union Pacific, but its promoters secured a double grant of land per mile, amounting to about 47,000,000 acres in all. The two southern routes secured about 70,000,000 acres, so that there have been granted in aid of railways something like 160,000,000 acres of territorial land. In addition to this, Congress, in the years immediately following the war, renewed the policy of State land grants, renewing those which had been forfeited and adding new ones to the amount of some 30,000,000 acres. Besides these grants of U. S. land, certain swamp and timber lands, which under general laws had been made the property of the States themselves, were also devoted to the aid of railway construction. The nominal amount of land thus granted in aid of railways under various acts exceeds 200,000,000 acres, but only a little more than a fourth of this has been actually patented.

The method adopted in the granting of the lands was ingenious. The whole country being divided into quarter sections of 160 acres each, the U. S. reserved the alternate squares or quarter sections, like the black squares on a checker-board, and granted to the railways only the intermediate parts. On the lands thus reserved by the U. S. the price was at once doubled, so that the treasury was as well off as before, and even better off, since its land came into market more rapidly, owing to the construction of the roads. Meantime, it was ingeniously argued that a settler, so far from being burdened by the change, was better off than before, for he could better afford to pay $2.50 an acre for land that was near a railway than $1.25 an acre for land which was wholly out of reach. Thus it was thought that the help might be rendered to the railways without sacrifice of any other interests. Unfortunately, it proved that the system stimulated unsound railway schemes and caused railway building to be misdirected; that the provisions intended to protect the Government interests were disregarded; that the settler was induced to move too far West, where he was, for the time being, at the mercy of the railway; and that the real gainer by these schemes was usually either the land speculator or the financial operator of the worst sort. The best practical proof of these mistakes is seen in the reaction against land grants which made itself suddenly felt at the time of the granger movement. Since 1872 the policy has been abandoned, though it has been impossible always to enforce forfeitures, even in cases where such a procedure would be clearly just. The whole history of the land grant system, as well as that of municipal subscriptions to railway stock and bonds, gives force to the views of those who disbelieve in Government interference. It appears that business men, as a rule, can judge better than Congressmen of the necessities of the various sections of the U. S., and that the attempts to stimulate enterprise in particular directions, though well meant, have been apt to do harm rather than good. It is probable that the subsidy to the Union Pacific was justified by the result, and perhaps that to the Illinois Central also, but the number of mistakes is largely out of proportion to the number of successes.

A most important system of subsidies has been that of the Dominion Government to the Canadian Pacific Railway. The reasons in this case were a good deal like those for the Union Pacific route in the U. S., and the success of the enterprise seems to have justified the policy of its promoters.

*Steamship Subsidies.*—Ocean steam-navigation was proved possible as early as 1818, but it was not until many years afterward that the commercial success of any such enterprise was assured. The marine engines of that period were not economical in their construction, and sails furnished cheaper, though less sure, motive power. It was a political necessity, however, for Great Britain to have steamships sooner than any other nation, even if such steamships were for the time being unprofitable. Her colonial possessions were so scattered that every argument in favor of the Union Pacific Railway subsidy in the U. S. applied with vastly greater force to steamship subsidies for Great Britain. In 1838 proposals were asked for a line of Atlantic steamers, and in 1839 the contract was awarded to Samuel Cunard. In 1840 four ships were put on, with an annual subsidy of £81,000. The contract was gradually extended until 1858. It was not until about 1870 that it was gradually reduced. About the time of the establishment of the Cunard subsidy a contract was made with the Peninsular and Oriental Steamship Company for the carriage of the mails to Gibraltar, and this contract was afterward extended so as to secure the carriage of the mails by the same company to Alexandria, Calcutta, Bombay, and finally to Australia. In 1840 a contract was also made with the Royal Steam Packet Company for the carriage of mails to the West Indies, and afterward to South America. At the time when the subsidy system was most largely developed, the British Government was spending in round numbers £1,000,000 annually for the conveyance of the mails—a sum which has been reduced to about £700,000 annually.

To the Cunard Company and to the Royal Mail Company these contracts were unquestionably of great value. In the case of both these companies the price paid was sometimes much more than the service was commercially worth. If proof were needed, this is shown by the fact that the Inman line, established in 1850, has worked successfully without the aid of subsidies. Other unsubsidized companies of the same sort soon followed, and ultimately public sentiment forced the Government to reduce the payments to the Cunard line. The Peninsular and Oriental Company was not quite so liberally dealt with as the two other great subsidized lines. In many cases it would appear that the special requirements as to construction, sailing ports, and penalties for delay almost offset the advantage of a subsidy. Great Britain was paying not for mail contracts but for military strength, and she got what she paid for, and on the whole she got it cheaply. In one instance, at least, that of the Galway and the Anchor line, a subsidized line failed in the competition with an unsubsidized one.

The admiralty subsidies in Great Britain are at present £33,847 annually. Besides this, the payments for carrying the mails in the fiscal year 1893–94 were £710,585, which is about £450,000 in excess of the receipts for sea-postage.

The U. S. did not want Great Britain to get the start in ocean steam-navigation. In 1841, two years after the first Cunard contract, there was an agitation in favor of similar action on the part of the U. S. In 1845 the Postmaster-General was authorized to make contracts for the conveyance of foreign mails in steamships sailing under the U. S.

flag. A line to Bremen was established under this act in 1847. In the same year an act was passed requiring the Secretary of the Navy to arrange for U. S. steamships to carry the mail from New York to Liverpool, to the West Indies and Gulf ports, and from Panama up the Pacific coast. From these contracts arose the Collins line and the Pacific Mail Steamship Company, besides others less important. By act of 1851 provision was made for the Panama Railroad, and in 1852 the Collins line subsidy, originally $385,000, was increased to $858,000 annually. In 1852 the payments for U. S. foreign mail service amounted to about $2,000,000. The Collins line was the most important enterprise, and for the time being the most successful. It had the fastest and best steamships of their period, built of oak, and relying on paddle-wheels as their motive power. The subsidy was $33,000 a voyage, or $4.70 per mile run. The average speed attained was nearly half a day better than that of the Cunarders. In 1854 the Arctic was sunk in a collision, and the Pacific disappeared in 1856. Such was the effect of these accidents that, in spite of the subsidy, it was no longer possible to run the Collins line, and the field was left to the British steamers. At the outbreak of the civil war the U. S. lines to Europe were withdrawn. In 1864 arrangements were made for subsidizing a line to Cuba and Brazil. In 1865 the Pacific Mail Company was offered large inducements to extend its lines to China and Japan; $150,000 annually was spent for the Brazil line; $500,000 for the China and Japan line. In 1868 an attempt was made to establish a European line with a subsidy of from $400,000 to $600,000 a year, but it failed because the mail service provided under this act would have been inadequate. In 1872 an attempt was made to increase the subsidies to the Pacific Mail and Brazil companies. But the reaction was close at hand. An investigation into the history of the means by which these appropriations were secured brought such scandalous corruptions to light that no Congressman dared to vote for the continuance of a policy of this kind. Meantime the Pacific Mail Company had been unfortunate in every way. Prior to 1865 it had been a sound concern. When the subsidy was increased it fell into the hands of speculators. The stock fell from par to below 40. The money under the supplementary contract of 1872 was not earned by the company, owing to its failure to construct the vessels at the appointed time. In 1875 the Brazilian and Pacific mail subsidies expired, and hardly a voice was heard in favor of their renewal. In the year 1879 a strong effort was made to secure renewed subsidies for a Brazilian steamship line, but without success. It was not until 1891 that the efforts to secure profitable mail contracts for American lines met with anything like success. By an act of Mar. 3 of that year the Postmaster-General was directed to make arrangements with U. S. steamship companies, whose vessels were so constructed that they could serve as naval auxiliaries in time of war, to carry the U. S. mails at a rate not to exceed $4 a mile run with first-class vessels—i. e. vessels of not less than 8,000 tons register and 20 knots an hour ordinary sea speed. Vessels of lower classes in tonnage and speed were limited to $2, $1, and $0.66⅔ per mile for successive classes. Mail contracts for service between the U. S. and Great Britain were only to be made with vessels of the first class. A number of lines to South American ports took advantage of these contracts, and the Pacific Mail and Oceanic companies arranged for a considerable Pacific service on this basis; but it was not until the autumn of 1892 that the International Navigation Company made an arrangement for first-class European service (in connection with the admission of the Paris and New York to the U. S. register).

To U. S. steamships carrying mails without special contract an advantage is given by paying them $1.60 a pound for letters and post-cards and 8 cents a pound for other articles, instead of 44 cents and 4½ respectively, which are the rates paid foreign vessels. The total ocean mail payments of the U. S. in the year 1893–94 were as follows:

| SERVICE. | U. S. vessels. | Foreign vessels. |
|---|---|---|
| Transatlantic service | $188,722 | $422,160 |
| Transpacific service | 140,756 | 11,699 |
| Miscellaneous service | 381,966 | 28,098 |
| Totals | $711,444 | $461,957 |

The Dominion of Canada voted a subsidy of £15,000 to the Canadian Pacific Railway for its service to China and Japan, and a few years later (1893) it voted £150,000 for a transatlantic steamship line.

Germany has paid subsidies to mail-steamers amounting in 1893 to 4,990,000 marks, or $1,240,000—averaging about $1.25 per mile run—besides regular payments at low rates for mail carriage on ordinary routes.

France has adopted a much more comprehensive system of shipping bounties. It includes payments both for construction and navigation of steam-vessels, whether they carry mails or not. By the act of 1893 the construction bounties are as follows:

| | | |
|---|---|---|
| Iron and steel vessels | | 65 francs per gross ton. |
| Wooden vessels: | Over 150 tons | 40 " " " " |
| | Under 150 tons | 30 " " " " |
| Engines and boilers | | 15 francs per 100 kilos. |

In addition to this there are navigation bounties for vessels engaged in foreign trade. For those engaged in the "distant" trade (beyond Gibraltar or the Suez Canal) these bounties are as follows per 1,000 nautical miles run:

| VESSELS. | First year, francs per ton. | Decrease for each successive year. |
|---|---|---|
| Steel or iron, steam | 1·10 | 0·4 |
| Wooden, steam | 1·10 | 0·6 |
| Steel or iron, sail | 1·70 | 0·6 |
| Wooden, sail | 1·70 | 0·8 |

In order to earn this bounty these boats must be built in France and almost entirely manned by French sailors. The act of 1881 allowed one-half the regular rate of navigation bounty to foreign-built ships run under the French flag, but this was withdrawn by the act of 1893. Vessels in the short-distance foreign trade earn two-thirds of the amount above given. The average annual payments under the act of 1881 were: Construction bounties, $570,000; navigation bounties, $1,540,000. The act of 1881 was more successful in encouraging navigation than in encouraging construction.

Italy has a combined system of construction and navigation bounties. The construction bounties are nominally in the form of a tariff rebate on materials used; but as this rebate is purposely made larger than the tariff, it operates as a premium. The navigation bounties are at the rate of .65 lire (about 12½ cents) per net ton per 1,000 miles on all long distance voyages. The total amount paid averages about 4,000,000 lire a year. Most of the long mail routes are maintained under special contract rather than under the general act.

Austria has a combined system of mail contracts with navigation bounties. Norway and Sweden have no direct subsidies, and their postal contracts are trifling in amount.

A. T. HADLEY.

**Substance** [from Lat. *substan'tia* (*sub*, under + *stare*, stand), constructed first as translation of Gr. ὑπόστασις, support, real essence, substance; ὑπό, under + ἱστάναι, stand]: in philosophy, a term which appears first in Aristotle, who uses it in two senses, between which it has wavered ever since. Logically, it is the first of the categories as opposed to the other nine, which are its accidents (συμβεβηκότα). There are first and second essences, the first always designating singulars—e. g. *a man*, *a horse*; the second being general terms, as *man*, *horse* (*Categ. V.*). It is also used in the sense of εἶδος or constituting essence, in which acceptation it is sometimes rendered into Latin by *essentia* (*Metaph. IV.*, 8). The logical οὐσία is the first of induction (πρῶτον πρὸς ἡμᾶς); the metaphysical οὐσία, the first of deduction (πρῶτον φύσει). None of the post-Aristotelian philosophical schools had profundity enough to require the category of substance until the rise of the Neo-Platonists, who re-established it. Plotinus criticises Aristotle rather severely for not distinguishing between material and spiritual substance (*Enneads*, bk. vi.), as he himself did. Porphyry and Simplicius accepted the Aristotelian doctrine. In the Middle Ages the metaphysical view prevailed, and substance was identified variously with God, person, etc. The same is true of modern times, dating from Descartes. He regarded substance as that which can exist independently of anything else, and Spinoza (*Ethics*, i., def. iii.) as "that which is in itself and is conceived by itself"—a definition which, of course, identifies it with God. Leibnitz identified with substance the monads. Locke looked upon substance as a mere imagined substratum, holding attributes together, but did not altogether deny its validity, as did Hume (*Human Nature*, pt. i., § 6). Kant classed substance in his Transcendental Table of the Concepts of the Understanding along with Cause and Community under the head of Relation, and defined its scheme as the "permanence of the real in time" (*Critique of Pure Reason*, p. iii., Meiklejohn's translation). Hegel defines substance as the "absolute, as relation to itself" (*Logik*, pt. 2, p. 185, ed. 1834), and as "the unconditioned essence (*Wesen*) existing in and for itself as being immediate existence" (*Propädeutik*, p. 105). Mill and the English school mostly follow Locke. In the orthodox doctrine of the Trinity, substance is used of the essential unity of the Divine Being as distinct from the tripersonality.

THOMAS DAVIDSON.

**Substitutions, Theory of**: a recondite but most attractive branch of modern mathematics, which has placed the theory of algebraic equations on a new basis. A substitution is an operation which is conceived to interchange quantities or symbols among themselves, putting one in place of another, but taking none away, and adding no new ones. If we have an algebraic expression containing several symbols, say the roots of an algebraic equation, some substitutions may change the value of the expression and others may not. For example, in the expression $x + y - z$, an interchange of $x$ and $y$ makes no change of value, because $x + y = y + x$; but interchanging either of these quantities with $z$ changes the value. An excellent treatise on the subject is that of Netto, of which an English translation from the German original has been made by Prof. Cole, of the University of Michigan, and published at Ann Arbor. The most exhaustive treatise is that of Jordan, of Paris, published in 1870. S. NEWCOMB.

**Succession** [from Lat. *succes'sio*, deriv. of *succe'dere*, *succes'sum*, go under, follow after; *sub*, under + *ce'dere*, go]: in European law, a term which covers all cases where rights or obligations previously established are acquired or assumed by new parties. Where one acquires a right previously held by another, the jurist speaks of an active succession; where one takes the place of a debtor, they speak of the succession as passive. The ordinary transactions of life give rise only to special or "singular" successions. In case of death, however, the Roman law, and the majority of modern legislations provide that some person or persons shall step into the place of the deceased, acquiring, in principle, all his rights, and becoming answerable for all his obligations. These persons are the "heirs" (see HÆRES), and their succession is termed universal.

The heir or heirs may have been designated by the deceased. At Roman law this could be done only by testament. (See WILL.) Teutonic custom, however, permitted rights of inheritance to be created by contract also, and most of the modern German codes retain the Teutonic rule (so the Prussian and Saxon codes, the German draft code, and, with limitations, the Austrian code). In the French law, rights of inheritance can be created by antenuptial contracts, but by such contracts only.

In the absence of heirs designated by the deceased, the succession is determined by the law. Succession *ab intestato* may be based upon the family organization or upon consanguinity. The first principle would wholly exclude illegitimate children. The second would exclude succession between husband and wife, and between adoptive parents and children. The Roman law, in its latest development, represents a compromise between the two principles. The same is true of all modern European legislations. Illegitimate children have some rights of inheritance, not only from the mother and her relatives, but also (if "recognized") from the father. Husband and wife also have reciprocal rights of succession, but the exact position assigned to the surviving spouse differs in different legislations. The law of intestate succession is often modified in this point by the rules of matrimonial property. See MARRIED WOMEN.

In general, succession is determined by the degree of kinship, nearer relatives excluding the more remote. (For the different methods of reckoning degrees, see CONSANGUINITY.) It should be noted, however, that the degree of consanguinity is never wholly decisive. In every legal system direct descendants, though of remoter degree, are preferred to ascendants and collaterals; and even among collaterals the remoter relative may be preferred—e. g. a brother's grandchild will always take precedence of an uncle, although by either the Roman or the canonical computation the latter is one degree nearer. In other words, every legal system regards the *kind* of relationship as well as the degree, and divides the relatives into classes, so that any member of a prior class excludes all members of a posterior class. Such a classification becomes perfectly logical only when succession is avowedly based on the preference of the nearer *parentela*. This term designates the descendants of one ancestor. The *parentela* system divides all the relations of a deceased person into a series of such ancestral groups. The direct descendants of the deceased constitute the first *parentela*. His parents and their other descendants (i. e. his brothers, sisters, nephews, nieces, etc.) make up the second *parentela*. His grandparents and their descendants (not already included in the first or second group) are of the third *parentela*, and so on. As long as any member of a nearer *parentela* is in existence, all members of other *parentela* are shut out. This is claimed to be the Teutonic principle of succession. It lies at the basis of the English law of succession to real property. It is logically carried out in the Austrian code and in the codes of several Swiss cantons. It is adopted in the German draft code.

Whenever, under any system of succession, there are several heirs of the same class, those nearer in degree are preferred. This principle is modified, however, by the right of "representation," by which more remote relatives may be put into the place of their ancestor, and take the share to which he would be entitled if he had survived the intestate. In such a case succession within the class is said to be *per stirpes*, by lines. (See DESCENT.) In all modern legislation direct descendants take *per stirpes*; and the same system obtains, to some extent at least, among collaterals. Among remoter collaterals, however, the right of representation is frequently refused, because it tends to an undesirable subdivision of property.

Teutonic law never developed a "universal succession." It always recognized distinct succession to realty and to personalty. It often drew further distinctions. It exhibited, in particular, a tendency to consider the channel through which property had come to the deceased; to prefer the paternal relatives when the property had been inherited from the father, the maternal when it had come from the mother. Modern European codes generally reject this distinction.

*Special variations* in the law of succession, which have existed in past times and still exist sporadically, are the exclusion of females or of the descendants of females (older Roman law), or a preference of the male line (classical Roman law). Similar tendencies reveal themselves in the older Teutonic law of real property; and under the influence of feudalism the preference of males was associated with the preference of the eldest son. (See PRIMOGENITURE.) In the succession to German peasant estates, also, the system of primogeniture generally obtained through the Middle Ages, and still obtains in some territories. Sporadically, a preference of the youngest son has also existed.

At Roman law the estate of a deceased person did not devolve *ipso jure* upon the heir unless he was a child or slave of the deceased. All others had to "enter," and could refuse to enter. The Teutonic principle, on the contrary, is that death vests seizin (at least as regards real property)—i. e. the legal heir acquires *ipso jure*. This rule is recognized in the French code and in the German draft code (in the latter for testamentary as well as intestate heirs); but the heir may divest himself of the inheritance by an express renunciation.

Since the acquisition of an inheritance makes the heir personally liable for the debts of the deceased, the Roman law established the rule, first for the children and then for other heirs, that they might take with the "benefit of inventory," in which case their liability was limited to the amount of the assets. This rule obtains generally in modern Europe. Conversely, when the heir is insolvent, the creditors of the estate may demand a separation.

See Demolombe, *Des Successions* (Paris, 1880); Koeppen, *Erbrecht* (Würzburg, 1888), and *Motive zum deutschen bürgerlichen Gesetzbuch* (vol. v., Berlin, 1888).

MUNROE SMITH.

SUCCESSION, in the common-law system, is employed in a more limited sense than in the civil law. In England and the U. S. the term is used only to describe the transmission of property (*a*) from a person or group of persons composing a corporation to his or their successors; or (*b*) upon the death of a person to his heir, devisee, or next of kin. Technically, it is only in the former sense—as describing the persistence of the rights of a corporation through all changes in its membership—that the term has any footing in the common law. The power of perpetual *succession* is one of the peculiar properties of a corporation, and the term successor, applied to a person in his corporate capacity, is the legal equivalent of the term heir, applied to a person in his natural capacity.

In the other sense mentioned, however, the term succession is sometimes, by analogy with its signification in the civil law, employed to describe the acquisition of property rights upon and in consequence of the death of the former owner. Thus used it may comprehend the transmission of property by will or by descent, and it is under the description of those terms respectively that the devolution of property upon the death of the owner is treated by the common law. The subject of succession by testament is considered under the title WILL. "Descent," in its more general acceptation, includes the devolution, in case of intestacy, of personal as well as of real property. As only the latter is considered under that head, however (see DESCENT), the transmission of personal estate under those circumstances is considered here.

There was no such thing as a universal succession at the common law. This familiar principle of the civil law is not to be found in the early Teutonic customary law, nor did it ever find a place in the English system. The functions of the Roman *hæres* were from an early period divided up between the "heir," who took the real property, and the person or persons to whom the personal property descended; and it is not the English heir, but the personal representative—the executor or administrator—of a decedent, whose position bears the closest analogy to that of the Roman heir.

Although the right to dispose of personal property by will has always existed at common law, it was in the early history of English law much restricted by considerations of public policy, and of what were regarded as the rightful claims of the surviving members of the family. A rule of "reasonable partition," as it was called, prevailed, which provided that if a man left a wife and children surviving, one-third of his personal estate should go to the wife and one-third to the children, leaving only one-third of the whole to be disposed of by the will of the decedent. If the testator left a wife, but no children, or if he died a widower, but leaving children, he was entitled to dispose of one half of the estate, the other half to go to the surviving wife or children, as the case might be. Long before the time of Blackstone, however, this compulsory feature of the law of descent of personal property had disappeared, and the law was confined in its operation to cases where the owner of the estate died wholly or partially intestate.

There being no absolute right of succession to personal property recognized by the common law, except as above described, the title to all such property as a decedent might have disposed of by will, but which he failed so to dispose of, vested in the crown. By a series of early statutes this right of the crown was speedily reduced to a right of ADMINISTRATION (*q. v.*), the property being "distributed very justly to the wife and children and relations, to every one according to the degree that belongs to him." (Stat. Canute, cap. 71.) So a statute of William the Conqueror (cap. 34) provided that if a man died without a will, his children should divide the inheritance equally. In the course of time this right of administration became vested in the Church, and it continued to be exercised by the ecclesiastical tribunals in England from before the reign of Edward I. (A. D. 1272) down to the year 1857. It seems, from the authorities, to be clear that by an abuse of this right of administration the clergy claimed and for a considerable period exercised the right to appropriate the personal property which thus came into their hands in case of intestacy to "charitable and pious uses," but when they were constrained by statute (31 Edw. III., Stat. I., cap. 11) to grant administration to the next of kin of the intestate the just distribution to the nearest relations which the law contemplated was again made possible.

The distribution of intestate estates which now prevails dates back directly to a statute enacted in the year 1670 (22 and 23 Car. II., cap. 10) by which the respective rights of wife, children, and next of kin were fairly and, as the event has proved, permanently adjusted. By that statute one-third of the personal estate undisposed of by will, and remaining after the payment of debts and funeral expenses, was to go to the widow, and the residue to the children, to be equally divided among them. If there was no widow, the children took the whole of the surplus; if there was a widow but no children, the widow took one half and the next of kin (parents, brothers and sisters, grandparents, etc., "every one according to the degree that belongs to him") took the other half. If the intestate left no widow or children, the next of kin were entitled to the whole surplus. In case a person entitled was dead, his legal representatives would take his share. There was no discrimination (as there was in the rules regulating the descent of real property) against kin of the half-blood nor against female kin, but all of the same class or grade of kinship inherited equally. The rights of the husband in the personal estate of his wife were not altered by this statute, but remained as at common law. As a married woman could own no personal property during her life, she could of course leave none at her death, save only such claims against others (*choses in action*) as her husband had not previously reduced to possession. As to these, he was solely entitled to administration for the purpose of collecting them in and converting them to his own use. See MARRIED WOMEN (*Property Rights*).

The statutes of distribution now in force in Great Britain and the U. S. are substantially only re-enactments of the act of Charles II. above described. (See, for example, New York Revised Statutes, ii., 96, § 75, and Laws 1845, chap. 236.) In those States in which the common-law disabilities of the married woman have been removed and she has been rendered capable of holding property free from her husband's control, the rights of the latter with respect to the property left by the wife *ab intestato* have also generally been somewhat modified. Thus it is provided by statute in New York that the husband of a deceased married woman who leaves descendants her surviving, shall be entitled only to such distributive share in the personal estate of his wife as a widow is entitled to in the estate of her husband. (Laws 1867, chap. 782, § 11.) This statute does not, of course, affect the rights of her husband in case the wife dies leaving no descendants. He is not required to share the estate with her next of kin, but takes the whole surplus as at common law.

The meaning of the expression "next of kin" and the relative rank of such persons, and the order of their succession, are defined with precision in the several statutes of distribution to which reference has been made. The test usually applied is nearness in degree of blood, and the method employed to ascertain the degree is usually that of the civil law. (See CONSANGUINITY.) Persons born out of lawful wedlock have no part in the distribution of personal estate, whether they claim as children of the intestate or as next of kin. A bastard is *nullius filius* by the common law, and is wholly outside the pale of consanguinity. In some of the States, however, an illegitimate child has by statute been rendered capable of inheriting from his mother. Of course, if such a person marries, he or she thereby becomes capable of taking property by descent from the wife or husband, the capacity in that case being wholly independent of any relationship of blood.

See the articles on DESCENT and HEIR. Consult also Stephen's *Commentaries*; Kent's *Commentaries*; *The American and English Encyclopædia of Law*, title *Intestate Laws*; Williams on *Executors*; Woerner on *The American Law of Administration*; and the statutes of the several States.

GEORGE W. KIRCHWEY.

**Succession Wars**: in general, wars resulting from conflicting claims to the throne. The term is especially applied to the four wars of the eighteenth century that arose from the disputed succession to (1) the throne of Spain (1701–14); (2) that of Poland (1733–38); (3) that of Austria (1741–48); and (4) that of Bavaria (1778–79)—of which only the first and third are of sufficient importance to be treated within the limits of the present article.

*War of the Spanish Succession.*—The weak and imbecile King of Spain, Charles II. (1665–1700), had no children, and the succession accordingly devolved upon the collateral heirs. In the lifetime of Charles there were three principal claimants, first, Louis XIV., in right of his wife, Maria Theresa, daughter of Philip IV., who, however, had expressly renounced her right in the Treaty of the Pyrenees; second, Leopold I., Emperor of Germany, by virtue of his descent from Philip III. of Spain; and third, Joseph Ferdinand, the electoral Prince of Bavaria, grandson of Leopold and Margaret Theresa, the younger daughter of Philip IV. Neither Louis nor Leopold ventured to claim the throne for himself, but only for a member of his family, the former supporting the candidacy of his grandson, Philip, Duke of Anjou, the latter that of his second son, the Archduke Charles. Nevertheless, so great an accession of power to either the Bourbon or the Hapsburg dynasty was thought to endanger the independence of other nations, and it was finally agreed that the electoral prince should succeed to the Spanish throne

His death, however, in 1699, reopened the question, now further complicated by the fact that there was no third candidate on whom all could agree. In the intrigues which ensued Louis was successful, and Charles II., just before his death in Nov., 1700, made a will bequeathing all his possessions to Philip of Anjou. The latter was well received in Spain, and his title was generally recognized throughout Europe, but Louis took a course that was at once aggressive and impolitic. He alienated the other nations by declaring that Philip's succession to the Spanish throne had in nowise affected his right to the throne of France, and he angered England by pronouncing the Pretender the lawful heir to the English throne. In the winter of 1701–02 the Grand Alliance was concluded between England, the emperor, the Dutch, the King of Prussia, and the Grand Duke of Hesse, with the object of breaking the power of the Franco-Spanish monarchy. For ten years the war was actively carried on, the chief campaigns being in Spain, in Italy, in the Rhine countries, and in the Spanish Netherlands. In Spain the French were generally successful, and, first under Berwick and afterward under Vendôme, expelled the invaders and maintained Philip on the throne. In Northern Italy the Austrians, under Prince Eugene, conquered Milan and Mantua, and finally, after a victory at Turin, forced the French to withdraw altogether from Italy. In the meanwhile Marlborough and Prince Eugene had won the important victory of BLENHEIM (*q. v.*) in 1704. Marlborough's victory at Ramillies, two years later, drove the French out of the Netherlands, and their attempts to regain their lost footing were foiled by Marlborough and Prince Eugene at Oudenarde (1708) and Malplaquet (1709). Louis now sued for peace, but the terms imposed by the allies were so humiliating that he preferred to continue the war. Circumstances soon came to the rescue of France: the death of Leopold I. and of his son and successor, Joseph I., brought the Archduke Charles to the throne. To unite the thrones of Spain and the German empire seemed even more menacing to the balance of power than to maintain the Bourbon king in Spain. In England the Tories, who had supplanted the Whigs, desired peace, and in 1713 was signed the Treaty of Utrecht, stipulating that the two lines of the Bourbon house should renounce all claims of inheriting from each other, and the two crowns should never be held by the same person. In the following year the treaties of Rastadt and Baden settled the particular questions at issue between Austria and France.

*The War of the Austrian Succession.*—As the Emperor Charles VI. had no male heirs, he tried to obtain the accession of all the powers concerned to the Pragmatic Sanction, by which it was stipulated that after his death all the Austrian possessions should be transmitted undivided to his eldest daughter, Maria Theresa. The nearest claimant to the Austrian inheritance, the Elector of Bavaria, Charles Albert, never gave his consent to the Pragmatic Sanction, and when Charles VI. died (Oct. 20, 1740) a general desire was manifested among the other European powers to break up the Austrian state and divide its dominions. Claims were advanced by Spain, Augustus III. of Poland and Saxony, the King of Sardinia, and Frederick the Great of Prussia, to whom France was added by her traditional hatred of the Hapsburgs. Great Britain alone went to the aid of Austria. The Elector of Bavaria took possession of Bohemia in 1741, and in the following year was crowned emperor. Frederick the Great had in the meanwhile seized Silesia. Stripped of her provinces and threatened with an advance of the Bavarian and French troops upon her capital, Maria Theresa appealed to her Hungarian subjects for aid. It was granted, and a large army was soon in the field. A period of Austrian success followed, due in part to the purchase of Prussian neutrality by the surrender of Silesia to Frederick the Great; but the latter, alarmed by the continued success of the Austrians, again took the field in support of the emperor (1744). At the same time a reverse took place in the Austrian fortunes at other points of the contest. In Upper Italy a French army joined the Spanish, and fought with great success, and in the Netherlands Marshal Saxe began his brilliant campaign with the victory at Fontenoy May 11, 1745. Soon, however, events occurred which gradually prepared people's minds for peace. On Jan. 20, 1745, the emperor, Charles VII., died, and in September, Joseph, the husband of Maria Theresa, was elected Emperor of Germany under the name of Francis I. Frederick the Great had become thoroughly disgusted with his allies, the French, and in the death of Charles VII. he found an opportunity of retiring from the coalition; peace was concluded between Prussia and Austria on Dec. 25, 1745. The war with France continued. Marshal Saxe gained brilliant victories in the Netherlands (at Raucoux Oct. 11, 1746; at Laufeldt July 2, 1747) and penetrated into Holland, where he took Bergen-op-Zoom and Maestricht. The British, however, had nearly destroyed the French shipping and conquered many French colonies, and when Russia, in June, 1747, joined Austria and sent an auxiliary army to Germany, France was willing to make peace. Peace was concluded at Aix-la-Chapelle in Oct., 1748. Austria gave up Parma, Guastalla, and Piacenza to Don Philip, of the Spanish Bourbon line, several districts of Milan to Sardinia, and confirmed Frederick II. in the possession of Silesia.

F. M. COLBY.

**Succin'ic Acid** [*succinic* is from Lat. *suc'cinum*, *sucinum*, amber, deriv. of *suc'cus*, *su'cus*, juice]: one of the series of acids of which oxalic acid is the first member. Its composition is $C_4H_6O_4$. Succinic acid was known to the ancients as volatile salt of amber, from which it is obtainable by distillation. It is found ready formed in several plants, and even in animal bodies. It has been identified in the urine of dogs and rabbits. It is formed, with SUBERIC ACID (*q. v.*) and others of this homologous series, by the action of nitric acid on fatty substances. Pasteur found that it is an invariable product of the alcoholic fermentation of saccharine liquids. Many other organic transformations engender it. It is found in the watery part of the products of the distillation of amber, in solution, and crystallizes out by cooling. Warming with nitric acid will destroy the impurities, and enable pure succinic acid to be obtained by recrystallization. It is, however, obtainable much more cheaply from crude calcic malate, prepared from mountain-ash berries. This is fermented with yeast or rotten cheese, and the calcic succinate formed decomposed by sulphuric acid. Succinic acid crystallizes well, and is soluble in five parts of cold water. It melts at 356° F., and boils at 455° F., and is decomposed with formation of water and succinic anhydride, $C_4H_4O_3$. Revised by IRA REMSEN.

**Succory**: See CHICCORY.

**Suc'coth** (tents or booths): the Hebrew name of the second station in the Exodus itinerary (Ex. xii. 37, xiii. 20; Num. xxxiii. 5, 6). Excavations made by Naville in 1883, at Tell el-Maskhûta near the eastern end of the Wâdi Tûmîlât in the eastern Delta region of Egypt, and just westerly of the middle of the Isthmus of Suez, resulted in the discovery of a place which bore the civil or political name *Theku-t* (Succoth), the religious or sacred name *Pi-Tum* (PITHOM, *q. v.*), the Greek name HEROÖPOLIS (*q. v.*), and the Latin name Ero-Castra. The importance of the discovery was in the confirmation of the record of the building of Pithom as one of the "store cities" (Ex. i. 11) constructed for Ramses II., the Pharaoh of the oppression (thus approximately fixing the date of the Exodus), and in the determination of the starting-point and of the route followed by the Israelites when they left Egypt. See also MIGDOL. C. R. G.

**Suchet**, sü'shā', LOUIS GABRIEL, Duke of Albufera: soldier; b. in Lyons, France, Mar. 2, 1770. Entering the army in 1792, he served under Bonaparte, Brune, Masséna, Joubert, and Moreau in the campaigns in Italy and Switzerland, passing through the grades from *chef de bataillon* (major) to that of lieutenant-general before the age of thirty. Subsequently he distinguished himself at Ulm, Jena, and Austerlitz. Under orders of Lannes he served with the Fifth Corps at the siege of Saragossa, and was designated by him to Napoleon on his departure for the command in Aragon. A series of battles and sieges (of Lérida, Mequinenza, Tortosa, Tarragona) gained for him the marshal's baton (July 8, 1811), and after the battle of Albufera and the siege and capture of Valencia he was created Duc d'Albufera (Jan. 24, 1812). He immediately joined Napoleon on his return from Elba. Under the Restoration he lived for several years in retirement, but was again invited to the court in 1819. The *Mémoires du Maréchal Suchet sur ses Campagnes en Espagne* forms one of the classics of military literature. D. in Marseilles, Jan. 3, 1826.

**Suchow**, or **Soo-chow-foo**: a city of China, capital of a department of the same name, and of the province of Kiangsu; situated on the Grand Canal, 80 miles W. of Shanghai (see map of China, ref. 6–K). The city is rectangular in plan, with walls 30 feet high and 12 miles in circuit. Outside five of the six gates by which the walls are pierced are large suburbs. The original plan, engraved in stone, has been preserved since 1247 in the temple dedicated to Confucius. In 1861 the Taipings reduced the city almost to a heap of ruins, the only buildings which escaped destruction being the temples (300 in number) and pagodas, of which there are seven, one of them, the Great Pagoda, being the highest in China. Suchow is a great commercial and manufacturing city, thousands of looms turning out many varieties of silk and satin, and there are numerous workers in wood, iron, brass, tin, stone, silver, and gold. Its streets —7 or 8 feet wide—are too narrow for much traffic, but a great network of canals extends throughout the city and surrounding region, and along these all the heavy traffic passes. Though devoid of Western improvements, Suchow has, from an Eastern standpoint, many marks of culture and refinement, and the gaiety and elegance of life and manners entitle it to be called the Paris of China. With HANGCHOW (*q. v.*) it shares the distinction of being likened by the natives to an earthly paradise. Pop. 500,000. A history of Suchow in 150 vols. was written 1,000 years ago. See *The Chinese Recorder*, vol. xiv. On Sept. 26, 1896, Suchow was opened to foreign trade. THOMAS A. HEARN.

**Sucker**: any one of several fishes which have no resemblance to each other except that they "suck" in some way. 1. The CATOSTOMIDÆ (*q. v.*). 2. The ECHENEIDIDÆ (*q. v.*). 3. Representatives of the families *Cyclopteridæ*, *Liparididæ*, and *Gobiesocidæ*. These have ventral fins peculiarly modified and adapted for adhering to rocks and other bodies. The species are numerous, and each family is represented on the coast of the U. S. Revised by F. A. LUCAS.

**Suckling**, Sir JOHN: poet; b. at Whitton, Middlesex, England, in 1609; educated at Trinity College, Cambridge. In 1631–32 he served as a volunteer under Gustavus Adolphus, King of Sweden, who was waging war against the Emperor of Germany. Returning to England, he was attached to the court of Charles I., and in 1639 equipped a troop of horse for the royal service against the Scotch. In 1640 he was elected to the Long Parliament, but was obliged to flee to France in consequence of his complicity in a plot to rescue the Earl of Strafford from the Tower. His works, most of them first published after his death, include four plays, some letters, *An Account of Religion by Reason*, and a number of songs, of which *A Ballad upon a Wedding* and *Why so Pale and Wan, Fond Lover*, are still popular, and are admirable specimens of the gay and graceful poetry of the Cavaliers. A complete edition of his poems, plays, and remains was published in 1874. D. in Paris about 1642. Revised by H. A. BEERS.

**Sucre**, soo'krā, more commonly called **Chuquisaca**, choo-kee-saa'kaa, and formerly **La Plata**: the official capital of Bolivia and capital of the department of Chuquisaca; on a terrace of the Eastern Cordillera of the Andes, overlooking the valley of the upper Pilcomayo, and in the midst of magnificent mountain scenery, 8,840 feet above the sea (see map of South America, ref. 6–D). It was founded by order of Pizzaro in 1539, on the site of the Indian village of Chuquichaca (golden bridge), and during the colonial period was renowned for its riches, derived from the silver mines of the vicinity. Later, the Potosi mines attracted part of the population; but La Plata, as it was then called, remained the metropolis of the district. From 1559 it was the seat of the *audiencia* of Charcas, and hence the capital of Upper Peru, now Bolivia. After independence was won, in 1826, the name was changed to Sucre, in honor of the first president. It remained the official capital, but during the civil wars it became customary for congress to meet at La Paz, which is now virtually the capital of Bolivia. Remains of its former grandeur are seen in the fine cathedral and other public buildings. It has a university, the oldest in the republic, and is still the metropolis of the mining region and of a rich agricultural district. A railway to Oruro is projected. Pop. about 26,000. HERBERT H. SMITH.

**Sucre**, ANTONIO JOSÉ, de: general; b. at Cumaná, Venezuela, Feb. 3, 1793. He joined the revolutionary army in 1811, served with distinction under Miranda and Piar, was on the staff of Bolivar's army, and rose to be general of division. He commanded the advance in the movement on Guayaquil, and his victory at Pichincha, May 24, 1822, finally drove the Spaniards from Quito or Ecuador. In the Peruvian campaign he took a leading part. After the battle of Junin, Bolivar left him in command of the army, and the decisive and brilliant victory of Ayacucho, Dec. 9, 1824, practically ended the South American war for independence. In honor of this event he was created grand-marshal of Ayacucho. In 1825 he was elected first president of Bolivia, and he governed with wisdom and success; but in 1828 the faction opposed to Bolivar, having obtained power in Peru, demanded Sucre's removal. To prevent a civil war he resigned and went to Colombia, where Bolivar placed him in command of the army acting against Peru. He defeated the Peruvians at the battle of Giron, near Cuenca, Feb. 26, 1829, and forced them to sue for peace. The same year he was president of the congress of Colombia. While returning to his home at Quito he was assassinated near Pasto, June 4, 1830. HERBERT H. SMITH.

**Sucto'ria**: a group of *Protozoa*. See INFUSORIA.

**Sudan'**, **Soudan**, or **Soodan** (Arabic, *Belad es-Sudan*, or country of the blacks): geographic name for that part of Africa lying S. of and adjacent to the Sahara, and extending, roughly, from 5° N. lat. to 15° N. and from 10° W. lon. eastward to the Nile. This region is occupied by many peoples and many different states, and embraces the basins of the Niger, Lake Chad, and the Bahr-el-Ghazal branch of the Nile, representing, respectively, Western, Central, and Eastern or Egyptian Sudan. The upper part of the basin of the Senegal is sometimes distinguished as the French Sudan. This, with the Kong country on the upper Niger, is mountainous, with elevated plateaus. Central Sudan is less elevated and generally level, but contains some high mountains (as Alantika, 9,800 feet). French, Western, and Central Sudan are generally well wooded and watered, and of great agricultural capacity. The Egyptian Sudan is generally arid. The races occupying the Sudan are very varied, mostly Negroes (hence sometimes called Nigritia, or Negroland), but also including Fulas, Tuaregs, Arabs, and in the east Shoas. See SENEGAMBIA, NIGER, SOKOTO, CHAD, DARFUR, BAHR-EL-GHAZAL, NILE, SAHARA, etc. See also the *Travels* of Mungo Park, Vogel, Baikie, Barth, Rohlfs, Schweinfurth, Nachtigal, and Lenz. M. W. H.

**Sudbury**: town of Nipissing district, Ontario, Canada; junction of the Canadian Pacific Railway with its Sault Ste. Marie branch; 125 miles W. of Mattawa and 182 miles E. of the Sault (see map of Ontario, ref. 1–C). It is in the center of a rich copper and nickel mineral district. Branch lines of railway run out short distances to the more important mines. Pop. 800. M. W. H.

**Su'dermann**, HERMANN: dramatist and novelist; b. at Matziken, East Prussia, Sept. 30, 1857; was a private teacher and journalist until he suddenly became famous by his drama *Die Ehre* (1890), which, on account of the clever and sentimental treatment of the social question, achieved a remarkable success, and which has since been translated into several European languages. His subsequent plays, *Sodoms Ende* (1891), *Die Heimat* (1893), and *Die Schmetterlingsschlacht* (1894), were less successful, and established the fact that their author had been greatly overestimated. He also wrote a number of novels and short stories, of which *Der Katzensteg* (1890) is the best. JULIUS GOEBEL.

**Sudeten-Gebirge**, soo-dā'ten-gā-beer'ge: a range of mountains which separates Silesia from Moravia, and connects the Riesengebirge with the Carpathian Mountains. They are 2,000 or 3,000 feet high, covered with pine forests, rich in coal and metals, and form plateaus with single peaks, rather than continuous chains.

**Sue**, sü, MARIE JOSEPH EUGÈNE: novelist; b. in Paris, Dec. 10, 1804; studied medicine, and held a position as surgeon, first in the army, then in the navy, until 1829, when, having inherited a considerable fortune, he retired and devoted himself to literature. His first novels, *Kernock le Pirate*, *Plick et Plock*, *Atar-Gull*, *La Salamandre*, *La Coucaratcha*, *La Vigie de Koat-Ven*, which appeared between 1831 and 1835, were inspired by Cooper, and inaugurated in France the novel of naval adventure. In *Cécile*, *Arthur*, *Le Marquis de Létorière*, *Jean Cavalier* (4 vols.), *Thérèse Dunoyer*, *Latréaumont*, from 1835 to 1838, he worked the historic, melodramatic, and romantic vein. After 1840 he became frankly socialistic, and celebrated the proletariat in his most famous and exceedingly popular novels, *Mathilde* (6 vols., 1841); *Les Mystères de Paris* (12 vols., 1842–43); *Le Juif Errant* (10 vols., 1844–45); *Martin* (12 vols., 1847); *Les Sept Péchés capitaux* (16 vols., 1847–49); *Les Mystères du Peuple* (16 vols., 1849–57). Elected to the Legislative Assembly in 1850, he took his seat among the most extreme radicals. After the *coup d'état* he left France and settled at Annecy, in Savoy, where he died Aug. 3, 1857. He wrote about fifty volumes of novels not mentioned here. Revised by A. G. CANFIELD.

**Suetonius** (swē-tō'ni-ŭs) **Tranquil'lus**, Gaius: author; b. probably about the beginning of the reign of Vespasian, and employed for some time by the Emperor Hadrian as his *magister epistolarum*. The date of his death is unknown, perhaps about 160. His principal work, *Duodecim Cæsarum Vitæ*, has been preserved entire and in authentic form. It contains biographies of the first twelve Roman emperors, beginning with C. Julius Cæsar and ending with Domitian. The best editions are by Baumgarten-Crusius (Leipzig, 1816), C. B. Hase (Paris, 1828), and Roth (Leipzig, 1858). The other writings are best given by Reifferscheid (Leipzig, 1860). English translations of the *Vitæ*, by John Clark (London, 1732), and by Thomson and Forrester in Bohn's Classical Library (1855). Revised by M. Warren.

**Suevi**, swee'vī: originally a collective name, comprising several individual Germanic tribes which formed a kind of union. It is thus used by Cæsar and Tacitus. In the fourth century the name was applied to a single tribe, one branch of which settled in the regions along the Neckar, afterward called Suabia, while another branch broke into Gaul, and in 409 crossed the Pyrenees and penetrated into Spain, where they embraced Christianity, conquered Galicia, and formed a kingdom, which in 585 was united with the Visigothic empire.

**Suez**, soo-ez': town of Egypt; at the head of the Gulf of Suez, an inlet of the Red Sea, in lat. 29° 59′ N. and lon. 32° 31′ E., and 2 miles from the southern end of the Suez Canal (see map of Africa, ref. 2–G). The surrounding region is a desert, and provisions and water must be brought to the town from a distance. Since the opening of the railway from Cairo to Suez, and the opening of the Suez Canal, the city has grown rapidly. Pop. (1882) 10,913; estimated (1895) 12,500. Revised by M. W. Harrington.

**Suez Canal**: See Ship-canals.

**Suez, Gulf of**: the western and larger of the branches into which the Red Sea divides lying between Egypt and the peninsula of Sinai. Its extreme length is about 180 miles; its average breadth 20 miles. It was known to the ancients as the Gulf of Heroöpolis, and the generally received scene of the passage of the Red Sea by the Israelites is near the present head of the gulf.

**Suez, Isthmus of**: a neck of land connecting the continents of Asia and Africa, and separating the Mediterranean from the Red Sea. Its extreme breadth from the Gulf of Suez to that of Pelusium is about 72 miles in a straight line, but following the course of the canal the distance is 100 miles. The surface is low and sandy, having an average elevation of not more than 6 or 8 feet above the sea, but in places reaching to 50 or 60 feet. In general, the isthmus is almost a desert; where irrigation has been practiced, however, it is quite fertile. It is probable that the whole isthmus was once covered by the waters of the Mediterranean and Red Seas, which were then connected.

**Suffix**: See Stem and Root.

**Suffocation**: See Asphyxia.

**Suffolk**: county of England; bounded N. by the Ouse, S. by the Stour, and E. by the North Sea; area, 1,475 sq. miles. The surface is flat, and the soil for the most part productive and excellently cultivated. Wheat, barley, beans, oats, and hemp are raised, dairy-farming is extensively carried on, and butter is one of the principal products of the county. Five members are returned to the House of Commons. Pop. (1901) 306,688. Capital, Bury St. Edmunds.

**Suffolk**: town; capital of Nansemond co., Va.; on the Nansemond river, and the Atl. and Danv., the Norf. and Car., the Norf. and W., the Seaboard Air Line, and the Suf. and Car. railways; 18 miles S. W. of Norfolk (for location, see map of Virginia, ref. 7–I). It is in an agricultural region; is engaged in lumbering, oyster-packing, and the manufacture of iron, lime, and woolen goods; and contains a State bank with capital of $20,000, and a daily, a monthly, and 2 weekly newspapers. Pop. (1890) 3,354; (1900) 3,827.

**Suf'fragan** [from O. Fr. *suffragant* < Lat. *suf'fragans*, pres. partic. of *suffraga'ri*, vote for, assist; cf. also Late Lat. *suffraga'neus*, suffragan]: a bishop of a single diocese in an ecclesiastical province subject to the ecclesiastical authority of the metropolitan of that province. A coadjutor is sometimes said to be suffragan to his superior bishop. A bishop of a limited part of a diocese is a suffragan to the bishop of the diocese. For instance, the Bishop of Dover is a suffragan of the Archbishop of Canterbury, while all bishops of the province of Canterbury are suffragans of the same metropolitan in a different sense. In the Protestant Episcopal Church in the U. S. suffragan bishops are not allowed, the canons forbidding their creation. All attempts to remove this prohibition have failed.

Revised by W. S. Perry.

**Suffrage**: See Citizen and Privilege.

**Su'fis**, or **Soofees**: the mystics of Islam, deriving their name from a coarse woolen cloak, their principal garment. Rabia, a Mussulman woman who lived not long after the prophet Mohammed, taught as her central doctrine divine love, and is reckoned by them their founder. Abu Saïd, son of Abul Khaïr, in the ninth century, advanced further, and urged abandonment of the world and consecration to a contemplative life. The various doctrines developed by his adherents and followers embrace every possible phase of mysticism. Many are pantheists, and declare that God is all, but that all is not God. Some claim direct communication with the Deity, and a mysterious union or identification with him. They are numerous in Persia, and have furnished noted scholars and poets. See Dervishes. E. A. Grosvenor.

**Sugar** [M. Eng. *sugre*, from O. Fr. *sucre*, Ital. *zucchero*, from Arab. *sokkar*, from Sanskr. *çarkarā*, whence Gr. σάκχαρον, whence Lat. *sac'charon*, whence Eng. *saccharine*]: any compound of a carbohydrate nature which is soluble in water. In the common acceptation of the word, it is any such compound having a sweet taste, but the term usually includes only cane-sugar (sucrose, or saccharose), and possibly also sugars made from starch, known as glucose or grape-sugar, and consisting chiefly of dextrose, dextrin, and maltose. By some chemists beet-sugar is called betose.

The sugar of commerce is derived almost exclusively from sugar-beets and sugar-cane, the former supplying a little less than two-thirds and the latter a little more than one-third of the world's consumption; sugar from either of these sources is usually called cane-sugar, although the more correct term is sucrose. The other sources of sugar, such as maple, palm, sorghum, and starch, while of importance for special purposes and in limited localities, do not supply sufficient quantities to affect sensibly the commerce of the world.

*Occurrence.*—Sugar is a normal product of almost every kind of vegetable growth. It is the first and principal result of the biochemical activity of all green plants, and is an important component of many plants devoid of chlorophyll, such as the mushroom. Its formation is the result of the condensation in the living plant-cells of its elements pre-existing in the air. These elements are carbon dioxide and water. The sugar thus formed furnishes the principal food-supply for the growth of all the other tissues of the plant. From it are formed directly the wood-fiber, the digestible fiber, the pentosans and the starches, all of which have essentially the same centesimal chemical composition. Indirectly, it enters into the formation of the fats and oils and of the nitrogenous constituents of the plant organism.

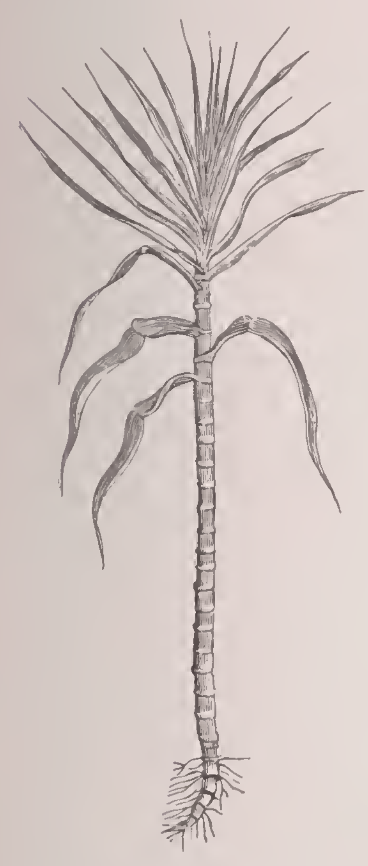
In many plants almost all the sugar produced is consumed in their further growth and development. In others the amount of sugar produced is far in excess of the demands of nutrition, and it is then stored as a waste or excess product in some part of the plant itself. In the sugar-cane, sorghum, and green Indian corn it is found in the stalks. In root-crops, such as beets and turnips, it is found in the fleshy roots. In trees, such as the maple and sugar-palm, it is dissolved by the first flowing sap of the spring. It exists in nearly all seeds, and of many, such as the coffee-bean, the peanut, and the cottonseed, it forms an important constituent. Sugar is also formed as a normal product of the functional activity of certain animal organs, such as the liver, and is an abnormal product of these in certain forms of disease, as diabetes mellitus. Many kinds of sugar have also been formed synthetically in the chemist's laboratory.

*History.*—(1) It is quite certain that the nations of remote antiquity were not acquainted with sugar as such, but honey was known to them all. The bees must be regarded as the first manufacturers of sugar. The sugar which is found in Honey (*q. v.*) is derived chiefly from the nectar of flowers, and this nectar consists of mixtures of cane-sugar and a sugar made by the inversion thereof, known as invert sugar or fruit-sugar. The sugar of the nectar of flowers in its fresh state consists largely of pure cane-sugar, but this, in passing through the organism of the bee, becomes inverted probably by some indirect biochemical action or under the influence of the formic acid which the bee secretes. The result is that the honey which is stored by bees, and which they obtain from the nectar of flowers, consists almost exclusively of invert sugar and water. The percentage of water varies largely, but the mean may be taken to be about 15 or 20.

The chief supply of sugar for consumption, for medicinal uses and as an article of luxury, was furnished by bees until probably the beginning of the fifteenth century.

(2) Sugar-cane, *Saccharum officinarum*, doubtless had its origin in India, and, from the best information which can be obtained, the original varieties contained only a very small quantity of sugar, probably not more than from 2 to 4 per cent. By constant cultivation and selection the content of sugar in the sugar-cane has been increased until it averages from 10 to 12 per cent. in Louisiana, 15 per cent. in Cuba, and 16 per cent. in the Hawaiian islands. It is believed that the original form no longer exists.

Cultivated sugar-cane will not return to the wild state, and it uniformly dies out when deprived of the care of man. Even the earlier travelers Cook (1773) and Forster (1777) found in the Hawaiian islands and other South Sea islands only the cultivated cane. The statements which have been made regarding the existence of the wild varieties in Africa have not been positively negatived, but it is more than likely that these were some of the varieties of sorghum which grow wild in all those localities and resemble in many respects true sugar-cane, as were those described by Humboldt on the Indus, the Euphrates, and the Persian Gulf. Hennepin, in 1690, declared that the banks of the mouths of the Mississippi were thickly covered with sugar-cane, which, under the heat of the sun, exuded sugar that dropped from the stalks like gum. This growth was doubtless the wild cane *Arundo donax or Arundinaria gigantea*, which, though also a grass, is very different from the sugar-cane.



Sugar-cane.

While the cultivated cane will not revert to a wild state, yet with proper care, in favorable climates, it will continue to grow from the same stubble for fifteen or twenty years. In some cases it has been known to grow for forty years.

The sugar-cane does not appear to have been known outside of Bengal at the time of the writing of the Rig-Veda (about the fourteenth century B. C.). In other Vedas the sugar-cane is mentioned, especially in the Atharva-Veda; but even at the time of Buddha the sugar-cane was not generally known in that part of India. At that period the stalk was either used directly or the expressed juice drunk without further preparation. The first use of fire for concentrating sugar-juices was doubtless also due to the inhabitants of India, about 600 or 700 years B. C. From there this art was spread among all nations of antiquity. Humboldt asserts that the Aztecs in Mexico were accustomed to make sugar from the stalks of maize before the Spanish invasion. At first only sirup or molasses was made, and after that the art of sugar-making was learned. Probably solid sugar was first made and used in India about the sixth century of the Christian era.

The existence of the sugar-cane was not known to the Grecian nations before the Christian era. Pliny (23–79 A. D.) says sugar came from Arabia, but the Indian product was preferable. It was a honey collected from canes, white like gum, breaking easily between the teeth, and was used only as a medicine. It was not until about 500 A. D. that the knowledge of the art of growing and refining sugar began to spread westward. In their wars of conquest toward the East the Mohammedans first learned of the manufacture of sugar. At the time of Harun-al-Raschid the tribute of some of the conquered provinces was paid partly in sugar. It was valued as a luxury and as a medicine.

In the eighth century the culture of the sugar-cane had spread over the greater part of the Nile delta. The sugar-cane grew so well in Egypt that it soon became an article of export from that country to the Mohammedan Asiatic provinces. Because it could not well be transported by water, it was always sent overland and many of these cargoes fell into the hands of the Christians during the crusades, and in this way the knowledge of sugar was diffused throughout Europe. When Sicily was conquered by the Arabs the culture of sugar was introduced into that island from Egypt, and thence also to Spain at the time of the Moorish conquest in the eighth century. Sugar-cane is still cultivated in the valleys along the southern Mediterranean shore of Spain. In the ninth and tenth centuries the culture of sugar-cane in Spain was carried on in all of the provinces of Andalusia. In the beginning of the fifteenth century the Spanish production amounted annually to over 2,000,000 cwt., and there were fifteen sugar-factories at the village of Motril, near Granada.

At the time of Marco Polo, about 1280, the sugar-cane industry had assumed considerable importance in China, whence it spread to Siam, Ceylon, and Japan. The first introduction into Western Europe was made by the returning crusaders, by whom it was used only as a medicine. The sugar brought from Syria soon came into use as a delicacy, and in parts of France as early as the twelfth century sugar became a regular article of commerce, being used for making cakes and preserving fruits. From France the use of sugar spread into Holland, Italy, and Germany. Venice, in the Middle Ages, became the headquarters of the industry, receiving the crude materials from the East, refining them, and delivering the products to the North and West.

Sugar is not mentioned in the oldest German literature, and it is first spoken of by the poets of the twelfth and thirteenth centuries. Later it became an article of commerce with the Venetian dealers and the German merchants at Constantinople. It was used in cakes and preserves and eaten only by the wealthy.

A considerable part of the sugar used in Europe in the fourteenth and fifteenth centuries came from Cyprus, where the culture of sugar-cane had been introduced by the Arabs in the seventh century. Perhaps the greatest quantity of sugar from any country among those mentioned was sent to Europe from Egypt.

The refining of sugar was probably first practiced at Venice; at least that is where the industry first assumed importance. In a directory of that city, published in 1473, refiners of sugar are mentioned. The art of refining, as at first practiced, consisted simply in melting the sugar in water and recrystallizing it by evaporation over an open fire. This was often repeated two or three times.

Columbus took sugar-cane from the Canary islands to San Domingo at the time of his second voyage, and his report to the Spanish king told of the wonderful growth of the cane in the New World. A new lot was sent in 1506. From San Domingo the culture of sugar-cane spread to Cuba and the neighboring islands and also to Mexico. As early as 1553 Mexico exported sugar to Spain. In 1532 sugar-cane was introduced into Brazil from Madeira. Within 100 years after the first introduction of sugar-cane into the New World the production of sugar therein was so great as to turn the dealers of Europe toward the West for their supply of this commodity.

In 1597 a sugar-refinery was erected in Dresden, and soon afterward Antwerp became a center for the sugar-trade. In the seventeenth and eighteenth centuries the production of sugar rapidly increased in the New World, especially in the British and French colonies in the tropics, San Domingo leading with a production of 80,000 tons annually. The revolution of 1791 in that island, however, almost destroyed the industry.

The processes of manufacture in all these countries were of the most primitive kind. The canes were crushed in crude mills driven by oxen, wind, or water; clay and lime were largely used in purifying the juices, the clay acting chiefly in a mechanical way in removing impurities. The boiling was accomplished in iron or copper kettles over the open fire. The raw brown sugar thus made was refined by melting and recrystallizing, the whitest product obtained in this way being known as "king's sugar." Europe continued to be the only market for American sugars, and in the competition thus produced the sugar industries of Sicily, Egypt, and Spain were ruined and practically ceased to exist. The desolation wrought by the Thirty Years' war in Germany put a stop to the consumption of sugar in that country, and the commercial downfall of Spain and Venice threw the trade of the world into the hands of Great Britain, France, and Holland. In Great Britain the consumption of sugar increased rapidly. In 1700 it was 10,000, in 1750 80,000, and in 1800 150,000 tons annually.

The first sugar made in Louisiana was in 1791 by Don Antonio Mendez, associated with a farmer named Solis. Étienne de Boré, about 1794, was the first to make sugar-culture a commercial success, and his first crop amounted to nearly 100,000 lb., for which he received about $12,000. His plantation is now a part of the city of New Orleans. In 1818 Joseph Coyron erected the first steam-engine ever used to grind sugar-cane in Louisiana. The variety of cane in cultivation at first was known as creole, and was a very tender plant, easily injured by frost. In 1820 the red-ribbon cane, a much hardier variety, was introduced from Georgia. The yield of sugar gradually increased in Louisiana until 1853, after which it slightly decreased until 1861, when the largest crop ever made in the State up to that time was secured, viz., 230,000 tons. The civil war almost paralyzed the sugar industry in Louisiana, and for three years no data of yields are recorded. In 1864 the crop amounted to only 5,000 tons. From this time on the production of sugar in Louisiana increased, but not with regularity on account of disasters from flood and frost, until the season of 1893–94, when it amounted to 320,000 tons.

Sugar-cane is also cultivated to a considerable extent in Texas and Florida, and in a smaller way in Georgia, Alabama, and Mississippi.

3. The sugar-beet, *Beta vulgaris*, originally came from the lowlands of Burgundy, and was carried by the Mennonite exiles into the Palatinate. From this locality it gradually spread to all parts of Germany, and was grown as cattle-food. In 1747 Marggraf (1709–82) discovered that sugar could be obtained from the common beet. Achard (1753–1821), in Kaullsdorf, near Berlin, was the first who undertook a systematic culture of the beet, and he largely increased its content of sugar. In France the sugar-beet appeared soon after its introduction into Germany and Holland, and was cultivated by Vilmorin in 1775, but its first systematic culture there was undertaken by Abbé Rozier in 1782. In 1786 it was introduced into England by Perkins and in 1830 into the U. S. by Vaughn and Ronaldson. In 1798 Achard, in Berlin, succeeded in preparing crystallized sugar from beets in considerable quantities, and as much as 16 cwt. was used in 1800 in the bakeries of Berlin.

The first real beet-sugar factory was erected by Achard, with royal aid, at Kunern, in Silesia, and put in operation in Mar., 1802. Many attempts were made to manufacture beet-sugar in Germany during the decade beginning in 1800, but in spite of the fact that the competition with cane-sugar was practically removed by the Napoleonic embargoes these attempts were generally unsuccessful. In France the Emperor Napoleon appointed a commission to investigate Achard's work, and as a result an imperial decree, in the early part of his reign, established the beet-sugar industry in France, and a considerable subvention from the imperial treasury was accorded it. Two factories were built at St.-Ouen and Chelles, but for lack of scientific supervision they failed of their purpose.

In 1808 Delessert undertook the culture of the sugar-beet at Passy, and by means of clarification with lime, sulphuric acid, and charcoal, succeeded in making a good merchantable sugar. In 1812 the Emperor Napoleon, as a result of a personal inspection at Passy, ordered that ten new factories be immediately constructed, and committed the work of construction to Delessert. In Great Britain, on account of her tropical colonies, the introduction of the beet-sugar industry was vigorously opposed, and its further development on the Continent discouraged.

In the U. S. attempts were made as early as 1830 by a Philadelphia company, of which John Vaughn and James Ronaldson were successively presidents, to introduce the culture of the sugar-beet. By reason of the absence of practical information little was accomplished. In 1839 a beet-sugar company was formed at Northampton, Mass., by David L. Child, and 1,300 lb. of sugar was made and the enterprise was then abandoned. The next company of which there is any account formed for the purpose of promoting the culture of the sugar-beet was in 1863, in Livingston co., Ill., but no practical results were obtained. In 1864 the Gennert Brothers established a beet-sugar factory at Chatsworth, Ill., but failed for lack of capital. The establishment was subsequently bought by a German company and removed to Freeport, Ill. All these attempts, however, ended in failure. The next beet-sugar factory in the U. S. was established in 1866 at Fond du Lac, Wis., and for two or three years a considerable quantity of sugar was made at that point. In 1870 the proprietors removed to California and organized the Alvarado Sugar Company, which, after various vicissitudes, finally succeeded in establishing itself on a firm basis, and is still in operation. Companies were also organized for the manufacture of sugar from the sugar-beet at Sacramento, San José, and Soquel, but none of them except the Alvarado company was finally successful. In 1878 a large factory built on modern principles was established at Portland, Me., and in the following year factories were also established at Wilmington, Del., and Franklin, Mass., and large sums of money were invested therein. After unsuccessful attempts at profitable manufacture all of these establishments were abandoned. For many years no further attempts were made to manufacture beet-sugar in the U. S., except at Alvarado, Cal. In 1888 a factory was built at Watsonville, Cal., and in rapid succession factories were established at Grand island and Norfolk, Neb., Chino, Cal., and Lehi, Utah. At present (1900) there are 31 fully established beet-sugar factories in the U.S. The total quantity of sugar manufactured at these localities during the season of 1899–1900 was valued at $7,323,857.

*Palm-tree Sugar.*—An old and, at one time, important sugar of commerce is the product of certain of the varieties of the palm-tree. It has been and is produced principally in India, where it is known as jaggery, a word which is of the same origin as the word sugar. The palms used for sugar-making are planted in rows in high and dry land, and can be used from five to thirty years. The trees are tapped in the same manner as the maple, but usually a small triangular hole is cut into the tree for the purpose of collecting the sap, which is removed by boring a hole into this receptacle from below and inserting therein a small bamboo cane, which conducts the sap into an earthenware receptacle. The sap flows principally during the night, and should be removed the following morning before the sun becomes very hot. After tapping, the tree will continue to afford a supply of sap for about three days, and must then be allowed a period of rest. The sugar season begins in November and lasts until the middle of February. The cooler and calmer the weather the better the harvest. The juice, with the addition of a little lime, is evaporated over the naked fire to a thick sirup. Part of it is sometimes further dried in the sun to a hard mass. This thick sirup is sometimes called date-tree honey, and was known as an article of commerce at the time of Herodotus and probably for many years before. The sugar of the palm as it comes from the tree is nearly pure sucrose, or cane-sugar, but much of it becomes inverted in the crude process of manufacture. Good palm-trees yield from 30 to 40 lb. of sugar in a season. The varieties cultivated are chiefly *Phœnix sylvestris*, *Cocos nucifera*, *Borassus flabelliformis*, *Caryota urens*, and *Arenga saccharifera*. A grove of from 600 to 800 palms is considered a valuable possession. The annual production in India is estimated at 1,000,000 metric centners (100,000 tons of 2,204·6 lb.).

*Maple-sugar.*—The maple-tree is the sugar-palm of temperate climates. Of the several varieties of this tree, only the *Acer barbatum* (also called *A. saccharinum*) is used to any extent for sugar-making. The principal centers of the maple-sugar industry are in Vermont, New York, and Ohio, but almost everywhere in the northeastern parts of the U. S., and also in parts of Canada, some sugar and molasses are made. Only the old trees are used for sugar-making, and, until within a few years, the natural forests. Within the past few decades there has been some planting of maple-trees for sugar-producing purposes, although a grove is not profitable for use until it is thirty or forty years old. The best groves for sugar-making are those in which the underbrush and small trees have been cut away, allowing the larger trees an opportunity to increase their leaf and twig growth. As a rule, the shorter trees with dense spreading overgrowth are better for sugar-production, both in the sweetness and quantity of sap. Woodpeckers are quick to discover the sweeter trees, which they fill with holes in the springtime for the purpose of drinking the sap. The excess of sap flowing over the bark darkens it, and the sweeter trees thus often have almost a black exterior.

The sugar season begins after the breaking up of the winter. In the more southern latitudes the sap will flow freely after the first thaw in winter, often in January. In

Southern Indiana and Ohio the manufacturing season usually begins in February and lasts until the end of March; in Vermont, in March, lasting until the end of April. A cold, steady winter is favorable to a good season, because it prevents the flow of sap until the sugar season fairly opens. The trees are tapped by boring with an auger, three-quarters of an inch in diameter, on the southern exposure of the tree. The holes are bored at a distance of from 2 to 4 feet from the ground. Spiles made of elder-bushes or of metal are fitted into the auger-holes, water-tight, so as to cause all the sap to flow out through the central orifice, where it is collected in appropriate vessels. Where little regard is had for the welfare of the tree a notch is cut in it as described for the date-palm. This is, however, very injurious, and trees thus treated during a series of years lose their vitality. From one boring the sap will continue to flow for a considerable time—usually for one season. Sometimes, however, a second boring is practiced to increase the flow. Usually two spiles are put into each tree; in small trees, sometimes only one; in very large ones, three or four. The flow of sap is most free during a warm, still day. It is checked by a frost at night and by high winds. In case of a thaw it will flow for twenty-four or even for forty-eight hours. It will then cease and begin again after another freeze. When the buds begin to swell later in the spring the flow ceases, and if started again by a subsequent freeze the sap is found to be less sweet and to have undergone a viscous fermentation which unfits it for sugar-making. The sap is nearly pure sugar and water, containing, however, certain organic aromatic compounds, which give the "maple flavor," and make both sugar and molasses so highly prized that they command double the price of similar sweets made from cane or other sources. The maple-sap also contains notable quantities of malic acid combined with lime. This is especially the case toward the end of the manufacturing season. In evaporating the sap the malate of lime is precipitated, and forms a scale or sandy deposit in the bottom of the pans which is known as sugar-sand. The sap of the maple contains varying quantities of sugar, depending on the year, the time of collection, and the position and peculiarities of the trees.

In the analyses of the sap from twelve trees from a maple-bush in Northwestern Indiana, taken on Mar. 21, the average content of sucrose was found to be 2·93 per cent. The highest content in any one tree was found to be 3·95 per cent.; the lowest, 1·95 per cent. At the same time the sap from a tree in Southern Indiana showed 4·30 per cent. The average content of sugar in the sap of fifteen trees near Lunenburg, Vt., examined daily from Apr. 7 to Apr. 28, was found to be 2·33, 2·72, 5·01, 3·66, 3·42, 3·15, 3·74, 2·98, 3·73, 3·53, 3·75, 3·55, 3·69, 4·36, and 3·18 per cent. respectively.

From a comparison of all the analyses made it is apparent that the average percentage of sugar in the sap is about 3·5. In one instance determined in Vermont in the mixed sap of 3,350 trees, taken at intervals from Apr. 9 to 22 inclusive, the average percentage of sucrose was found to be 3·25. The average yield of sugar from a tree is difficult to determine, inasmuch as the sap of the trees is mixed and no attempt made to keep the samples separate. In some few instances it is stated that trees have yielded as high as 40 lb., and yields of 20 lb. per tree are not uncommon. The average quantity of sap required to make a pound is 16 quarts. It is probable that the average yield of all the trees during one season and from one season to another is about 3 lb.

In the best orchards metallic spouts are used strong enough to hold a pail. Tin pails are preferred to wooden ones, the latter often imparting a bad taste to the sap. The sap is collected from the pails as often as possible, and when drawn to the small factory it should be strained before being placed in the storage-tanks. For boiling, the best sugar-makers use pans made of Russia iron, about 5 feet long, 2·5 feet wide, and 8 inches deep. They are set on arches of brick 20 inches in depth and provided with grate bars and other appliances to make the use of fuel economical. Open kettles are also often employed, but not by the best makers. In many factories the juice before entering the evaporator is passed through a heater, a copper box provided with tubes, through which the waste heat from the furnace passes. Many of the makers also use the continuous evaporating pans so largely employed in the manufacture of sorghum molasses. The fuel usually consists of the waste wood from the grove itself or adjoining forests. From 1 to 1·25 cords of wood are required for each 100 lb. of sugar produced. Sometimes the white of eggs is used for clarifying the sap, but as a rule this is not necessary. The scums which form during the boiling and which are usually of a very dark color, should be carefully removed. They contain large quantities of albuminous matters which if left in the sugars or sirups impair their keeping qualities. The sugar is either poured while hot into moulds, or, if a granular variety is desired, is vigorously stirred while cooling. This process is termed "sugaring off." The granular sugar thus made, especially while fresh, has a most delicious flavor and is highly prized. The refining of maple-sugar would deprive it of its characteristic flavor and thus reduce it in value to the level of ordinary sugar. It is therefore never practiced.

The quantity of maple-sugar made in the U. S. is not easily ascertained. Much of it goes into domestic use, while often large quantities which are placed on the market are adulterated. The total quantity varies probably between 15,000 and 20,000 tons per year. There is little evidence of either an increase or a decrease in the amount, but inasmuch as the maple-tree tends to grow naturally in rich soils, there is a disposition on the part of the farmers to clear the land and thus to diminish the output of sugar. The maple forests which are best preserved therefore are those which are found growing on places too hilly or rough for easy tillage.

Attempts were once made to introduce the growth of the maple-tree and the manufacture of sugar therefrom into Europe, but without any encouraging results. Maple-seeds were sent to Berlin from the U. S. in 1797 at the instance of a member of the Prussian cabinet, and encouragement was given to use also the sap of the silver maple, already growing in that country, for sugar-making purposes. Some little sugar was made in this way during the decade and a half beginning with the nineteenth century. The reopening of the West Indies to European commerce, however, which attended the downfall of Napoleon, caused all these efforts to cease, and the production of maple-sugar became confined to North America.

*Maize-stalks.*—The stalks of maize, *Zea Mays*, at the time of the formation of the starch in the grain are filled with a sap very rich both in sucrose and reducing sugars (sugars which reduce an alkaline copper solution with the formation of suboxide of copper). Humboldt reported in the account of his visit to Mexico that, before the arrival of the Europeans, the Mexicans as well as the Peruvians pressed out the sap of the maize-stalks, and by concentration thereof prepared sugar, and Cortés reported to Charles V. that the Mexicans had for sale honey, wax, sirup, and sugar from the maize-stalks, which were as sweet as sugar-canes. The maize used was doubtless sweet corn, the juice of which will sometimes yield as much as 16 per cent. of massecuite. From maize grown in Germany in 1766 Justi obtained a fairly good sugar, and in Italy, in 1784, Jacquin and Marabelli erected a mill for pressing the maize-stalks, and succeeded in making sugar therefrom.

Numerous analyses of the juice of maize-stalks were made in the U. S. Department of Agriculture from 1878 to 1882, and attempts were made on a small scale in the manufacture of sugar. Previous to this, in 1876, F. L. Stewart had announced in *The Public Ledger* of Philadelphia the result of some of his experiments in manufacturing sugar from maize-stalks. According to his analyses the juice of the maize-stalks contained 10·8 per cent. of sugar. In 1879, in the Department of Agriculture, samples of maize juices were analyzed showing 5·6 and 6·7 per cent. respectively of sucrose in the juices. In 1881 analyses of a large number of samples of maize juices showed a percentage of cane-sugar varying from 9 to 13, and in 1880 nearly 300 analyses were made showing a variation of cane-sugar in the juices from 9 to 15. The percentage of reducing sugars in the juices was also determined, showing a wide range in round numbers of from 1 to 4 per cent.

The attempts at making sugar, however, from these juices were attended with very little success, the sirups resulting from concentrating them crystallizing with great difficulty. Nevertheless a committee of the National Academy of Sciences reported that the experiments had shown that in successive years there was obtained from the stalks of common maize, after the ripened grain had been plucked, sugar at the rate of 900 lb. per acre.

Although the stalks of maize at the time the starch is in a milky state in the grains contain large quantities of sugar, there is no reason whatever to believe that maize can ever enter into competition with the sugar-cane and the sugar-beet as a source of commercial sugar. In a small way and for domestic consumption a fairly good sirup may be made therefrom, but all enthusiastic promoters of enterprises for making sugar from maize-stalks should be reminded that economically the task is a hopeless one so long as cheaper and better sources of raw material are available in practically inexhaustible supplies.

*Sorghum Sugar.*—The history and method of making sugar from sorghum are described in the article SORGHUM (*q. v.*).

*Culture of Sugar-cane.*—Since the sugar-cane and sugar-beet are practically the sources of all commercial sugar, a description of the methods of cultivation will be confined to these two plants. Sugar-cane is propagated by cuttings, and in rare instances from the seed. All parts of the cane having well-formed joints may be used for planting. In some localities it is customary to cut off the top, which is less rich in sugar, and use it for planting, while the rest is employed for sugar-making. The more common practice, however, is to use the whole cane, with the exception of that portion of the top devoid of well-formed joints. In the U. S. the time of planting extends from October to March. As a rule, autumnal planting is to be preferred. The soil is prepared by plowing and reducing with harrows and cultivators to a good tilth. Furrows are then opened by a double mould-board plow, at distances varying from 5 to 8 feet. The canes, cut into sections of about 2 feet in length, are laid in the bottom of the furrow and the soil thrown over them either by a hand-hoe or by a plow. Some planters prefer not to cut the canes unless they are crooked. When the seed is good, two canes alongside are enough to make a good stand. A third cutting is, however, often laid at the points of union of the canes, making, in the language of the planter, "two canes and a lap" in a row. The total quantity of seed required varies from 4 to 6 tons an acre. After planting it is best to either roll the top of the soil or to smooth the space over the furrows with a hand-hoe, removing all clods which might interfere with the exit of the young canes from the soil. The young canes grow from eyes held on the joints of the parent cane. When spring planting is practiced, the eyes of the cane are preserved from the injurious effects of frost by being preserved between the rows, the top of one cane being spread over the stalk of the one previously cut. This process is called windrowing. A light covering of earth, which can be thrown over the canes by running a plow on either side, is sufficient to protect the seed from all ordinary frosts and to prevent it from becoming too dry. If a better protection be desired the seed is preserved in mats, piles of cane carefully laid down and covered with cane-tops and earth. The preservation in windrows is usually preferred to that in mats, unless very cold weather be expected. Cane preserved for seed is subject to disasters due to drying up, frost, insects, and fungous diseases. For this reason the seed preserved for spring planting is often of poor quality, requiring a larger weight per acre.

Young canes are not seriously hurt by frost unless it comes very late in the spring. In the cane-growing districts of the U. S. frosts are not often experienced after Mar. 1. In fields which have long been under cultivation sugar-cane requires generous fertilizing. Superphosphates, potash salts, and cottonseed-meal are the fertilizing materials usually employed. The highest tonnage per acre has been obtained by using 350 lb. of cottonseed-meal, 430 lb. of acid phosphate, and 100 lb. of sulphate of potash.

The sugar lands of Louisiana consist almost wholly of alluvial deposits embracing two types, a light and a dark soil. The cultivation of the growing cane consists in keeping the ground well plowed and free from weeds. As the cultivation goes on it is the general custom to throw the soil toward the row, so that at the time of "laying by" the field is left in ridges, the canes growing on the summits. The cultivation usually lasts until the latter part of June. After the first crop of canes is harvested the stubbles will produce in the succeeding years a second crop and often a third or fourth. In the U. S. the replanting of the fields, however, usually takes place every second or third year, while in tropical countries the fields may run from ten to fifteen, and even a greater number of years, without replanting. The first crop from the fields is known as plant-cane, and subsequent crops as first and second year stubble, etc. The beginning of the cultivation of stubble-cane consists in barring off, that is, in throwing the soil from the stubble by means of a single mould-board plow. In addition to this the stubble is often shaved, that is, cut off smoothly just beneath the surface. At this time it is also customary to apply the fertilizers. After a few days the soil is thrown to the stubble and the middles broken out and reduced to good tilth, and the subsequent cultivation is the same as that for plant-cane already mentioned. The stubble crops from year to year become harder and contain more woody matter, but the juices are, as a rule, richer in sugar, so that the total amount of sugar per ton is about the same in both plant and stubble crops. In harvesting the canes are cut as near the surface of the soil or as little thereunder as may be with a broad steel knife furnished with a hook on the back, by means of which the laborer by a skillful stroke on either side of the cane relieves it of its leaves, after which the top is cut at the first immature joint and the canes thrown in a pile for subsequent removal to the factory by cart or portable railway. A good laborer will cut from 3 to 5 tons of cane per day.

*Culture of the Sugar-beet.*—Sugar-beets are grown to the best advantage for sugar-making purposes in northern temperate regions. In going southward, as a general rule, the beet becomes less sweet and more pithy and tends to grow to a larger size. A mean temperature of 70° F. is well suited to the growth of beets of high sugar content. The soil in which beets are planted should be plowed to the depth of about 10 inches and loosened by a subsoil plow to an additional depth of 6 inches. The plowing is often accomplished in the late autumn. In all cases before planting the surface should be reduced to perfect tilth. Any soil suited to the growth of good crops will produce beets, but they do not grow well in a stiff clay. The seeds are planted in rows about 18 inches apart, and covered to the depth of about 1 inch. Deep planting should be avoided, inasmuch as the tender shoots of the young plants are not able to emerge from a very deep covering of earth. From 12 to 20 lb. of seed are planted per acre. When the plants are grown until they show four well-developed leaves, the thinning process is commenced, leaving one vigorous shoot at about every 9 inches in the row. The number of plants per acre is determined in a large measure by the fertility of the soil and the degree of fertilization practiced; but in all cases they should be numerous enough to limit the average weight at harvest-time to a little more than 1 lb. The culture of the beet consists in keeping the soil well stirred and free of weeds. Deep culture is not admissible on account of the danger of disturbing the young plants in their position and of covering up the tops. At the time of laying by, which is about the middle of July, the surface of the soil should be left as smooth and level as possible. The planting in the chief beet-sugar countries extends from the last day of April till the end of May. In California, where are found exceptional climatic conditions, the planting begins as early as January and extends to June. As a rule, the earlier plantings produce the better crops. In Germany and France the harvest begins about Sept. 15, and is concluded by the middle or end of November. In California the harvest begins as early as August and continues until the end of the manufacturing season. The beets can be left without much danger until January, or until there is danger of second growth from the winter rains. In harvesting, the beets are loosened by a digger which passes under them, and are then removed from the soil by their tops and thrown into heaps. The tops with a portion of the neck of the beet are then removed by means of a large sharp knife, and the beets are then ready for preserving in silos or delivering to the factory. In siloing the beets they should be covered as lightly as possible, to preserve them from danger of freezing. If the temperature of the silo becomes too high the beets are apt to be injured.

The manufacturing season begins in California in August, and in other countries in September. The average duration of the manufacturing season is about three months, but in exceptional cases it lasts for four or five months. With the approach of spring, however, the beets rapidly deteriorate, and for this reason manufacturers try to close the season by the end of January.

The production of a beet rich in sugar has become a separate branch of the sugar industry. From an original content of from 4 to 6 per cent. of sugar, the development of the beet has continued until it now shows from 13 to 15 per cent., and in exceptional cases from 15 to 19 per cent.

At the time of harvest certain beets of typical shape and size and of apparently perfect nature are selected and preserved in silos over the winter without having their necks removed. In the following spring the silos are opened and each beet examined separately by taking out a core cut diagonally through it by an appropriate machine. The juice is expressed from this core and the content of sugar determined therein. The beets thus examined are classified according to their sugar content. The following table shows the number of beets of each variety placed in each class, as determined by analyses made at the experiment station of the Department of Agriculture in Schuyler, Neb., in 1893:

| VARIETIES. | No. 1 grade: sucrose 18 per cent. and upward. | No. 2 grade: sucrose 15 to 18 per cent. | No. 3 grade: sucrose 12 to 15 per cent. |
|---|---|---|---|
| Original Kleinwanzlebener.... | 36 | 465 | 448 |
| Dippe's Kleinwanzlebener..... | 6 | 483 | 1,176 |
| Vilmorin's improved.......... | 8 | 600 | 784 |
| Lemaire...................... | .. | ... | 476 |
| Desprez...................... | .. | ... | 168 |
| Élite Kleinwanzlebener........ | 7 | 210 | 224 |
| Totals.... .. ............ | 57 | 1,758 | 3,276 |

The beets are not materially injured by this boring, and after the examination is made they are carefully protected until all danger of frost is passed, when they are transplanted into a field devoted to this purpose and placed in rows at distances of about 3 feet. Each class is planted by itself, and thus three grades of seed are produced. The first grade is kept especially for the production of special beets of high content of sugar, while the second and third grades are used for the production of beets, which in their turn are planted in large quantities to furnish seed for commercial purposes. It is by the persistent application of this principle of scientific selection that the sugar-beet has been raised to its present high content of sugar, enabling it to compete successfully with sugar-cane, and even to exclude sugar made from the sugar-cane from the markets of Europe.

*Manufacture of Cane-sugar.*—The process of making sugar from sugar-cane is very simple. In its most primitive form it consists of crushing the canes between appropriate rollers, and evaporating the juice thus obtained to the crystallizing-point in open vessels. Commercially the process is as follows: The canes, harvested as previously described, are sent from the field to the factory, where they are crushed between powerful iron rollers. In many factories before entering the rolls the canes are passed through a shredder, which tears them into small pieces and thus puts them in a condition to be more evenly fed to the mill and to yield with a given pressure a higher percentage of juice. In the best factories the mills are erected in series of two or three. The first mill usually has three large rolls and the emerging canes, now called bagasse, are conducted by a carrier to a second mill, consisting usually of two rolls, but larger and heavier than those of the first mill. While in transit between the mills the bagasse is generally moistened with steam or hot water, whereby a better extraction of the saccharine matter is obtained, although the resulting juice is more dilute. Occasionally a third mill, similar in construction and operation to the second, is found. To avoid danger of breaking, the rolls are made adjustable to feeds of different magnitudes by means of rubber pads or springs or hydraulic regulators. With careful control, and with canes not too woody, from 75 to 86 per cent. of the saccharine matter contained in the canes may be obtained by milling. Taking into consideration all kinds of milling practiced in sugar-cane countries the world over, it may be said that only about two-thirds of the sugar produced in the canes is obtained by the crushing process.

The bagasse from good milling is conducted at once to a specially constructed furnace, and by its combustion renders the use of any other fuel in the factory unnecessary.

To a limited extent the diffusion process is used in the extraction of sugar-canes. This is described in the section on the manufacture of sugar from sugar-beets. The cutters used for canes to prepare them for the diffusion process are, however, different from those employed for beets. The canes are either cut into thin slices by being fed obliquely through hoppers against a revolving horizontal disk carrying radial knives, or else are torn into fine pieces by means of revolving, staggered, circular saws. From 90 to 95 per cent. of the saccharine matters in the cane are obtained by the diffusion process, but the juices are more dilute and the bagasse is left in a condition unsuited for fuel.

The juices obtained from the sugar-cane are treated with cream of lime to neutralize the free organic acids therein contained, heated to the boiling-point, and the blanket of scum thus produced removed. After standing for some time the sedimentary matters separate and the clarified juice is drawn off and sent to the evaporators. The scums and sediments are passed through a filter-press and the clear juice obtained thereby added to that secured as described above. The evaporation of the juice and its subsequent conversion into crystallized sugar are accomplished as in beet-sugar manufacture.

*Treatment of Sugar-beets.*—After the removal of the tops, together with a portion of the neck or collar, the beets are ready for the factory. The upper portion of the beet contains an excess of mineral matter, the introduction of which into the factory would prove injurious to the yield of sugar by preventing its crystallization. The beets are thrown into a trough and moved by a series of screw-paddles against a strong current of water. Adhering soil and sand, the presence of which would render the slicing of the beets difficult by reason of the dulling of the knives, are removed by this treatment. After washing, the beets are carried by an elevator to the slicing apparatus, situated above the center of the diffusion battery. In countries where a tax is laid upon the beets they are, after washing, carried into a weighing-machine, where their weight is noted by an agent of the inland revenue bureau. The best slicer consists of a revolving, horizontal disk carrying radial knives against which the beets are fed through a hopper. These knives are corrugated in such a way as to produce an irregular cutting, usually of a V-shape. The beet cuttings are known in France as *cosettes* and in Germany as *Schnitzel.* Their irregular form prevents the too close contact of their surfaces in the diffusion battery, and thus permits a freer circulation of the diffusion liquids throughout all parts of the system. The theory of the diffusion process rests upon the well-known principle of osmosis. If a crystallizable body in solution be separated from pure water by means of a pervious membrane there will be an interchange of such a nature that at the end of a certain time the crystallizable body will be found equally diffused within and without the membrane. The vegetable membranes which compose the cells of sugar-beets and sugar-cane easily permit this diffusion to go on. If, therefore, into a mass of finely sliced cane or beets warm water be introduced, it will soon become impregnated with sugar, and after a certain time, depending upon the temperature and the fineness of the cuttings, will contain the same percentage of sugar as the unbroken cells themselves. In practice the water thus impregnated with sugar is passed into another cell containing fresh cuttings, while fresh water is passed into the first cell, and this process is continued until all the cells of the battery, with two exceptions, are in operation. A diffusion battery usually consists of twelve cells. When in operation ten will thus be found under pressure, while one will be filling with the fresh cuttings and one will be emptying of the exhausted cuttings. The process once established goes on continuously.

*Treatment of Beet Juices.*—The saccharine juices extracted from beets require a more elaborate treatment than those expressed from sugar-canes. This arises from the fact that they contain foreign bodies more refractory to purifying treatment and more difficult to eliminate. The preliminary treatment of the beet juices preparatory to condensation is carried on as follows: The juices as they come from the diffusion battery are treated with lime in considerable excess of the quantity required to neutralize their natural acidity. From 2 to 3 lb. of lime are used for each 100 lb. of juice. Beet juices a few moments after expression or extraction become quite dark, and when in a large mass, as in the juice from a diffusion battery, the color is quite inky. The excess of lime precipitates this coloring-matter, as well as a part of the nitrogenous and other impurities present. To remove the excess of lime after the purification, carbonic acid is blown into the mixture, and the temperature is slowly raised until the boiling-point is reached, a little before the saturation is complete. The carbonic acid is obtained from a lime-kiln, which also furnishes the lime for the preliminary treatment. At the end of the saturation with carbonic acid the lime is found in the form of a carbonate of a fine granular texture, which is a great help in the following filtration, preventing the clogging of the filter-cloths. This treatment is technically called carbonatation or saturation. At the end of the operation the whole mass is passed through a filter-press, and the precipitated carbonate of lime and the other solid impurities are separated as press cakes. The emergent juice is of a bright amber color, transparent and apparently quite pure. In practice, however, it is found to be profitable to repeat the process just described. In the second saturation the quantity of lime used is much less than in the first, not exceeding from $\frac{1}{2}$ to 1 lb. to 100 lb. of juice. The second saturation is followed by a second filtration, and the bright juices thus obtained are ready for evaporation, although they still contain large quantities of soluble materials other than sugar, chief among which are salts of potassium.

The evaporation, concentration, and crystallization of the purified juices, both from beets and sugar-cane, are carried on in the same manner, and one description of the process is sufficient.

*Evaporation and Crystallization.*—The two chief points to be kept in view in securing the sugar from the saccharine juices, clarified as above described, are the removal of the water and the prevention of the inversion of the sugar during boiling. Evaporation in open kettles is largely practiced in making sugar in a small way. The heat is applied directly to kettles or pans by means of a fire of wood or bagasse, or indirectly by means of copper coils connected with a steam-boiler. As the concentration proceeds the condensed juices are carried to the finishing kettle or pan, fresh juices being added to the others. When the evaporation has proceeded to the crystallizing-point, which is determined by the temperature or the appearance of the boiling material, portions of the mass may also be removed, cooled, and tested. The sugar, still in a liquid state, is put into vessels, where it crystallizes. When the crystallization is complete, the molasses is removed by transferring the mass to hogsheads with perforated bottoms. Sugar-canes are often pushed into the crystalline mass to open up channels for the liquid portions. The sugar thus formed is of a more or less pronounced yellow color and quite moist. When made from cane it retains the natural aromatic flavoring matters of the original juices, and is highly prized, especially by bakers. The process, however, is not an economical one, both on account of the large amount of fuel required and by reason of the loss of sugar by inversion at the high temperature reached in the end process. Even in Louisiana, where this method was once the leading one, it has almost entirely given way to more modern processes.

All modern sugar-factories of a magnitude to be of any commercial importance conduct the evaporation of sugar juices in a partial vacuum. This not only secures great economy in the use of fuel, but also, by reason of the lower temperature which is maintained, avoids all loss by inversion. To avoid confusion, some of the technical terms in use in sugar-factories should be defined. The word juice or liquor is applied to all saccharine liquids of moderate density in the raw state after extraction from the cane or beets, or in the clarified state with its attendant concentration. The term sirup designates the saccharine liquid after its first evaporation but before it is finally boiled for sugar. The expression massecuite is used to designate the mass as it is finally boiled for sugar, and embraces not only the crystallized but also the liquid contents of the vacuum-pan at the end of the boiling. Molasses is a term applied to the separated portion of the massecuite, whether obtained by drainage or by centrifugal action. Multiple effect is the name given to the series of evaporators joined *en suite*, by means of which the juice is reduced to a sirup. When only two are *en suite* it is called double, and when three a triple or multiple effect. They are arranged in such a way as to require steam to be applied only to the first one. The vapors arising from the first pan become the source of heat for the second, those from the second of the third, and so on. This is accomplished by so arranging them as to have the lowest vacuum in the first of the series and the highest in the last. If three pans be used, the reading of the vacuum-scale on the first one will be, for example, 5 inches, on the middle one 15 inches, and on the last one 25 inches, 30 inches representing practically a perfect vacuum.

In point of fact, by this arrangement there is no economy of speed, four pans not evaporating any more than one would at the highest vacuum and with the same amount of steam. The amount of fuel required, however, for a given volume of evaporation is approximately only one-third that which would be required if only one pan were used plus the amount necessary to operate the vacuum-pump. Inasmuch, however, as the quantity of steam required for the pump is the same whether one or three pans be used, there is saved, approximately, two-thirds of the fuel. In practice it is found that no economy is secured by increasing the number of pans beyond three or four. The saccharine liquor is gradually transferred during the operation to the third pan, from which the finished sirup is removed from time to time or continuously by means of a pump which will create a higher vacuum than that existing in the pan. The process in a multiple-effect apparatus, when once started, is a continuous one, fresh juice entering the first pan and the finished sirup flowing from the last one.

The strike-pan is a boiling apparatus used with a high vacuum in which the sirup is concentrated to massecuite. Its size corresponds to the capacity of the factory, and for those houses which use from 200 to 400 tons of raw material a day the strike-pan will vary from 6 to 10 feet in diameter and from 10 to 20 feet in height, and with a capacity of from 20,000 to 70,000 lb. of massecuite at each strike. Heat is applied in the strike-pan by means of a series of copper coils, one above the other, beginning near the bottom and extending half way or more to the top. These coils of copper are of large diameter, in order to permit the free circulation of exhaust steam, at low pressure, from the engines and pumps of the factory. Live steam is not used in the pan except when the exhaust steam proves to be insufficient. For the manufacture of raw sugar the vacuum is maintained as high as possible. With a good pump and other apparatus, at sea-level, it can be kept at from 28 to 29 inches. In this vacuum the boiling will take place at a temperature of from 120° to 150° F., according to the density of the mass.

The operation is begun by taking into the pan a quantity of sirup large enough, when concentrated to the crystallizing-point, to cover the first coil. By means of the proof-stick the sugar-boiler determines when the sirup has a proper degree of consistence. At this point a considerable additional quantity of sirup is quickly drawn into the pan, whereby a crystallization is produced in the thickened sirup in the pan. The crystals formed at first are too small to be seen with the naked eye, but when some of the mass is put on a piece of glass it is seen to have a turbid appearance. The art of the sugar-boiler consists in feeding these crystals with fresh quantities of sirup, added in such a way as to avoid, on the one hand, the melting of the crystals already formed, and, on the other, the formation of a new crop of crystals known as false grain. When the operation is properly conducted, the pan is gradually filled with the growing mass of crystals, and coil after coil of the heating apparatus is brought into use until all are in operation. After this the boiling goes on with great activity until the pan is full. At the end the further supply of sirup is cut off, usually after the addition of a considerable quantity of sirup, for the purpose of washing the crystals, and the mass is thickened by further boiling until the minimum quantity of water consistent with the proper handling of the massecuite is secured, viz., from 6 to 10 per cent. The large valve at the bottom of the pan is then opened, after the vacuum has been broken, and the massecuite falls directly into a mixer or into wagons in which it is carried to a mixer. When the sirup is rich and pure the massecuite, as it drops from the pan, is already in appearance a solid body. In the mixer the massecuite is kept in motion by revolving paddles, and thus prevented from setting into solid masses, which would be difficult to break up and dry. From the mixer the massecuite passes directly into the centrifugal machines, where the sugar is separated from the molasses. So quickly is this accomplished that within a few minutes after leaving the strike-pan the dry sugar, still warm, may be found in packages ready for shipment to the consumer or the refiner.

The molasses secured by the above process is still rich in crystallizable sugar, and is reboiled for a second crop of crystals. When very rich it can be boiled to grain, as in the first instance, but if too poor for this it is boiled to string proof to the proper consistence, placed in cars in a warm room, and allowed to remain for a week or ten days. By this time the crystallization is completed, and the contents of the cars are thrown into the mixer, well broken up, and the sugar separated in the centrifugal in the manner already described.

The molasses obtained from this second crystallization is sometimes rich enough to be again reboiled, after which it is placed in wagons or large cisterns, and allowed to remain for several months, yielding a third crop of crystals, which when dried form a low-grade sugar. The residual molasses is finally either sold for culinary use or for mixing with glucose to make table sirups, or is sent to the distiller.

Beet-sugar molasses is unfit for table or culinary use on account of the large quantity of mineral salts which it contains. It is either sent to the distiller or the sugar it contains is recovered by combining it with strontium or lime, whereby an insoluble sucrate of the base used is obtained, which is separated from the soluble salts and other impurities by means of a filter-press. In this case it is the residue in the press cake which forms the valuable product. The sucrates therein contained are beaten to a cream with water, and the lime or strontium precipitated by means of carbonic acid. The carbonate of the base is separated by filtration, and the comparatively pure sugar juices obtained are concentrated and crystallized in the usual way.

*The Refining of Sugar.*—The sugar which is obtained by the above described processes is not white nor pure, and is prepared for table use by the refiner. In the historical sketch above given it was stated that the early processes of refining consisted at first in simply melting and reboiling the crude sugar. Each successive crystallization obtained in this way showed an improvement in color and purity, but the quantity of fairly white sugar finally obtained was a very small part of the raw material originally taken. The aid of clay, lime, and the white of eggs or blood was found to assist in the refining process, but without adding much to the total yield.

In India the term refined sugar includes sugars which have been purified by charcoal strainers and freed from all admixture of uncrystallized sirup, and also the raw native sugars prepared in the following way: The immediate product of the first boiling of the cane juice is known as gurh or rab, according as the sugar is boiled down to a hard mass, or allowed to remain in a semi-liquid condition. Both gurh and rab contain some uncrystallized sirup. Gurh, as a rule, is intended directly for home consumption, and is comparatively seldom used in the manufacture of refined sugar. Rab, on the other hand, is always intended for refining. In the process of refining the molasses known as shira is partially expressed from the rab by the primitive contrivance of a man standing on a pile of bags filled with rab, and working them backward and forward by the movement of his body. The rab partially refined in this way is called putri, and though it still contains a large percentage of shira it is far more compact, and shows more granulation than before pressing. The putri is thrown into a crate covered with a species of water-weed known as siwar (*Vallisneria spiralis*), and the remaining sirup slowly drains out at the bottom of the crate, and the putri gradually whitens into a mealy looking sugar called pachani, and it is then dried in the sun and broken up by being trampled on for some hours. When dried it is known as shakar.

These crude methods in sugar-refining have led to the modern processes, which are so perfect as to permit of the recovery in a state of purity of almost all the sugar in the crudest articles of commerce.

The process of refining is often carried on in connection with the manufacture of sugar from the raw materials. Various methods are employed. In one process the juices are subjected to the action of sulphur-fumes, whereby they become bleached. In the subsequent boiling the massecuite is left in a less dense state, so that the crystals are more readily separated from the molasses, and more easily washed. When the crystals are dried in the centrifugals they are washed with a little water, and also with a solution of chloride of tin, which give them a bright appearance. Sugar made in this way, especially from cane-juice, is quite pure, and has a white or delicate yellow tint, and is much prized by some consumers. The yield, however, as can be readily seen, is much less than that obtained by the dense boiling before described.

Instead of sulphur-fumes bone-black is also employed in making a white sugar directly in the factory. The bone-black is generally used on the sirups until they are practically decolorized. Sugar made with the use of bone-black is washed in the centrifugals with a little water, followed by a solution of ultramarine. The bluing thus practiced gives a whiter tint to the crystals.

These refining processes are profitable only where there is a good domestic demand for high-grade sugar, and in localities remote from refineries, where the freights attending the shipment of refined sugar materially increase the price.

From an economical point of view the refining of sugar is entirely distinct from its manufacture from the raw materials. It is carried on in the most economical way in large establishments kept in operation during the greater part of the year. In the U. S. there are in active operation less than a dozen refineries supplying nearly 2,000,000 tons a year.

Following is a brief description of the process of refining sugar on a large scale:

The raw sugar is dumped into vats, where it is stirred with warm water until melted. In this manner a sirup is obtained containing from 30 to 40 per cent. of sugar. The bags and other packages in which the sugar is shipped are washed, and the wash-water added to the saccharine mixture. The liquor thus formed is filtered through bags or filter-presses, to remove suspended matters. Sometimes the liquor is made thinner, and treated with lime and clarified in the manner described for cane juices. After filtration the limpid liquors are bleached with sulphur-fumes, or by passing over bone-black, which is the more usual way. Bone-black is prepared by subjecting bones to distillation in a retort practically excluded from the air. A large part of the organic matter in the bones is by this process converted into carbon, and left in a finely divided state distributed throughout the molecules of lime phosphate of which the mineral matter of bones is chiefly composed. This combination of animal char and lime phosphate has the property of rapidly oxidizing the coloring-matter of sugar solutions, and thus of bleaching them. The freshly burned char is contained in cylindrical vessels of steel or iron arranged in convenient series. The most highly colored solutions are passed first through those filters which have been in use some time, and thus have lost to a certain extent their decolorizing power. The process is continued in such a way that the less colored solutions are finally brought into contact with some fresh char, whereby they are rendered almost if not quite water-white. The more complete the decoloration the larger the percentage of white sugar which will be obtained. The bone-black, when it has once lost its decolorizing power by use, can have it restored by washing in a dilute acid, followed by water, and then burning in specially constructed retorts. These retorts are continuous in their operation, the spent black being fed in at the top and the revivified char being removed at the bottom. After repeated using, however, the char loses its virtue, and is then sold for fertilizing purposes.

The nearly white liquor finally obtained is ready without further preparation for treatment in the strike-pan. The general method of boiling is the same as that already described. The crystals are made large or small to meet the demands of the trade and at the will of the sugar-boiler. If a hard crystal be desired the boiling takes place at a lower vacuum, say 24 to 26 inches, while if a soft crystal be demanded the vacuum is made as high as possible, from 28 to 29 inches. After leaving the strike-pan the crystals are dried in the centrifugals in the manner already noted. The still slightly moist crystals, as they come from the centrifugal, may be moulded into cubes and dried (loaf-sugar), or dried in larger masses and cut or broken into approximately cubical pieces (cut or broken loaf), or dried and ground to a fine powder (powdered sugar). The hard crystals are also dried in revolving drums heated by steam, and form thus the granulated sugar of commerce, a form in which by far the larger part of refined sugar now reaches the consumer.

The molasses from the first granulation is reboiled and lower grades of nearly white sugar made therefrom. These sugars are sold under many names, such as coffee A, coffee C, brown sugar, etc. A third and even fourth crop of crystals is sometimes obtained, and finally nearly all the sugar originally present in the crude material is secured in a refined state. The art of the sugar-boiler is constantly brought into use to make grades of sugar which the trade demands, and also to use the material placed in his hands to the very best advantage. When his work has been properly conducted there is finally little waste material left to be sold to the mixers or distillers as "black strap."

In some countries, especially in Great Britain, sugar in the form of large yellow crystals is much in demand. These crystals were first made in Demerara, and hence the name which they bear. They are made by building a very large crystal in the strike-pan and then producing thereon a superficial coating of caramel to give a yellow color. This was formerly accomplished by introducing a quantity of sulphuric acid into the pan just before the strike was dropped. At present tin chloride is chiefly used for coloring the crystals. In making these large crystals, after the sirup in the pan has been reduced to a certain consistence, a large quantity of ordinary granulated sugar is put in the pan, and on these crystals the larger ones are built in the manner already described.

*Relative Sweetness of Beet and Cane Sugars.*—In chemical and physical character pure refined sugar made from beets is the same as that made from cane. In the raw sugars, however, and in the sugars made from molasses, there are marked differences. The beet contains a large quantity of alkaline salts, and these bodies are found to some extent in the raw beet-sugars and in beet-molasses. An unrefined beet-sugar has a higher percentage of ash than the same grade of cane-sugar. The aromatic organic ethers and essential oils that give an agreeable odor and flavor to cane-sugar are mostly absent from beet-sugar. A stranger entering a cane-sugar factory during the working season will at once notice the agreeable aromatic odor everywhere present. On the contrary, in a beet-sugar factory, especially if much molasses be in process of manufacture, the opposite will be noticed. Raw or unrefined cane-sugar may be used on the table or in the kitchen, and the old-fashioned open-kettle molasses is a luxury. Unrefined beet-sugar can not be used with comfort on the table, and beet-molasses as a culinary article is unknown. Beet-molasses contains a certain quantity of the sugar known as raffinose, which modifies both the physical and chemical characters of the sugars made therefrom. Even in the refined sugars a difference may be noticed between cane and beet sugars if the samples are kept well stoppered for some time. An air-tight package of granulated cane-sugar will have an agreeable aromatic odor when opened, while beet-sugar in the same condition gives an unpleasant sensation to the nostrils. In respect of the sweetening properties of pure cane and beet sugars there is no difference whatever between the two varieties.

*Chemistry.*—Until within recent years there has been much confusion in the classification of sugars and sugar-like bodies as made by different chemists. By many authors only those bodies were classed as carbohydrates which contain six atoms of carbon or some multiple thereof, together with oxygen and hydrogen in the proportion to form water. In 1882 von Lippmann published a work in which he took the view first proposed by Fittig, that the carbohydrates were all derived from a hypothetical, heptatomic alcohol having the composition $C_6H_7(OH_7)$. From this form by dehydration are produced the anhydrids, such as $C_6H_{12}O_6$ or $C_{12}H_{22}O_{11}$, representing glucose and saccharose respectively.

In 1888 a marked advance in the knowledge of carbohydrates was secured by the publication of Tollens's *Handbook*. Tollens defines carbohydrates as always or nearly always neutral bodies which form only loose compounds, especially with the bases, and consequently all bodies, such as methylhydroxyglutaric acid ($C_6H_{10}O_5$) and its lactone acid ($C_6H_8O_4$), as well as the saccharines which possess the general formula of carbohydrates but pass over easily into the form of acids, must be excluded from the list.

According to Tollens the carbohydrates have many common properties, and they possess these properties either in themselves, as, for instance, the glucoses, fruit sugars, and dextrose, or they are easily converted into bodies which do possess them, as, for instance, cane-sugar, cellulose, and starch. In some of the undoubted carbohydrates one of the general properties may be wanting, but there are other properties which are indispensable, and those bodies which do not possess them must be left out of the class even should they be indifferent chemically and have the general carbohydrate formula. According to this view the properties peculiar to the true carbohydrates are the following:

(*a*) The power of reducing alkaline metallic salt solutions and of forming a yellow color with alkalies.

(*b*) When in solution they must possess the ability to rotate the plane of polarized light.

(*c*) They must have the power of fermenting when treated with yeast, with the production of alcohol and carbon dioxide.

(*d*) When heated with hydrochloric or sulphuric acid they should produce levulinic and formic acids and humus substances.

(*e*) They should have the property of giving a yellow crystalline precipitate when treated with phenylhydrazin acetate.

(*f*) They should give characteristic color reactions when treated with acids and aromatic alcohols.

(*g*) They should be soluble in water either directly or after hydrolysis with an acid.

(*h*) When subjected to strong heat all carbohydrates are decomposed, turning brown at first and afterward black, with a production of many different substances.

Tollens, in accordance with his views, classifies the carbohydrates and nearly related bodies according to the number of carbon atoms which they contain, as monosaccharids having 6 atoms of carbon, disaccharids with 12 atoms, and polysaccharids with 18, 24, or 36 atoms, etc. By this classification the number of true carbohydrates is diminished until it is comparatively small, while the number of carbohydratoid bodies is large. The common sugars and carbohydrates, according to the above classification, are grouped as follows:

I. Monosaccharids or glucoses, type $C_6H_{12}O_6$.
 1. Dextrose.
 2. Levulose, invert sugar, mannitose.
 3. Galactose.
 4. Sorbin or sorbose.
 5. Different little-known glucoses.

II. Disaccharids or saccharoses, type $C_{12}H_{22}O_{11}$.
 1. Cane-sugar.
 2. Milk-sugar.
 3. Maltose.
 4. Trehalose.
 5. Melezitose.

III. Polysaccharids.
 (*a*) Crystallizable polysaccharids.
 1. Raffinose, $C_{36}H_{64}O_{32} + 10H_2O$.
 2. Lactosin, $C_{36}H_{62}O_{31}$.
 (*b*) Difficultly or non-crystallizable polysaccharids.
 1. Starch.
 2. Inulin.
 3. Saccharocolloids, gums, and slimes.
 4. Cellulose.
 5. Pectin and pectose bodies.

IV. Substances which resemble the glucoses, but do not have either the exact composition thereof or for other reasons are not to be classed therewith.

(*a*) Substances which contain oxygen and hydrogen in the proportion to form water.
 1. Arabinose, $C_5H_{10}O_5$.
 2. Cerasinose.
 3. Formose, $C_6H_{10}O_5$.
 4. Phenose, $C_6H_{12}O_6$.
 5. Inosit, $C_6H_{12}O_6$.
 6. Dambose, $C_6H_{12}O_6$.
 7. Scyllit, $C_6H_{12}O_6$.
 8. Quercin, $C_6H_{12}O_6$.
 9. Bergenin, $C_6H_8O_4$.

(*b*) Substances which contain more hydrogen than would be necessary to form water with the oxygen present.
 1. Isodulcit, $C_6H_{12}O_5$.
 2. Quercit, $C_6H_{12}O_5$.
 3. Pinit, $C_6H_{12}O_5$.
 4. Sennit, $C_6H_{12}O_5$.

(*c*) Mannit and its isomers.
 1. Mannit, $C_6H_{14}O_6$.
 2. Dulcit, $C_6H_{14}O_6$.
 3. Perseit, $C_6H_{14}O_6$.
 4. Sorbit, $C_6H_{14}O_6 + \frac{1}{2}(H_2O)$.

(*d*) Arabit, $C_5H_{12}O_5$.

Of the carbohydrates conforming to the above definition dextrose, levulose, galactose, and mannit are types. They respond to the reactions given, and have been found to possess the composition of ketones or aldehydes of the hexavalent alcohol $C_6H_{14}O_6$. On the other hand, there are carbohydrate bodies, such as arabinose, having the formula $C_5H_{10}O_5$, which are sugars having all the properties of a carbohydrate, and evidently should be classed with those bodies. There is another sugar, erythrose, having the formula $C_4H_8O_4$, which is an aldehyde of the tetratomic alcohol erythrite, and another sugar glycerose having the formula $C_3H_6O_3$, which also has valid claims to be classed with the other sugars. From the researches of Fischer on synthetic sugars it appears that the old classification is hardly a proper one, and a new one based on his work is preferable. It appears from these researches that there is a homologous series of aldehyde or ketone alcohols having the general formula $C_nH_{2n}O_n$ which have these common properties: 1, Sweet to the taste; 2, optically active; 3, reducing alkaline metallic solutions; 4, yielding with phenylhydrazin characteristic crystalline compounds. All these bodies therefore possess the essential characteristics of true carbohydrates and are as a consequence eligible to classification as such. According to Fischer, the classification of the substances which constitute this homologous series, so far as they have been made known, is as follows:

1. Trioses, type $C_3H_6O_3$, typical member glycerose.
2. Tetroses, type $C_4H_8O_4$, typical member erythrose.
3. Pentoses, type $C_5H_{10}O_5$, typical members arabinose, xylose.
4. Hexoses, type $C_6H_{12}O_6$, typical members dextrose, levulose, galactose, mannose.
5. Heptoses, type $C_7H_{14}O_7$, typical member heptose.
6. Octoses, type $C_8H_{16}O_8$, typical member octose.
7. Nonoses, type $C_9H_{18}O_9$, typical member nonose.

According to Fischer, every asymmetric carbon atom in a carbohydrate molecule makes two forms possible. There can therefore be at least eight hexoses, and each of these is optically paired, making sixteen in all. Of the sixteen possible forms, ten have already been discovered. Of the thirty-two possible heptoses only six have been discovered, and of the 128 possible nonoses only two are known. There is every reason to believe that the series will be extended by the discovery of new types, increasing very largely the number of possible sugars. In the sugars classified as above all those which contain three atoms of carbon or multiples of three are susceptible of fermentation, while the intervening members can not be fermented. Thus only the trioses, hexoses, and nonoses are fermentable.

Natural sugars all have the power of rotating a plane of polarized light, and this quality serves as a basis for optical SACCHARIMETRY (*q. v.*). Synthetic sugars, on the other hand, are devoid of rotatory power, and this is due to the fact that they are composed of twinned molecules having opposite rotatory powers of equal value. See STEREO-CHEMISTRY.

All sugars, natural or synthetical, containing three atoms of carbon or some multiple thereof in each molecule, are susceptible to fermentation when treated with yeast. The products of fermentation are chiefly alcohol and carbon dioxide, but a large number of secondary products are formed, such as glycerol and organic acids.

Cane-sugar, sucrose, or saccharose forms a molecule represented by the formula $C_{12}H_{22}O_{11}$. Cane-sugar belongs to the disaccharids, according to Tollens's classification, or to the hexoses according to that of Fischer. Under the influence of acids and certain ferments it undergoes hydrolysis, assimilating a molecule of water and forming equal quantities of two hexoses known as dextrose or glucose and levulose or fructose. The reaction which takes place is represented by the formula $C_{12}H_{22}O_{11} + H_2O = C_6H_{12}O_6 + C_6H_{12}O_6$. From the above it is seen that the two sugars formed are chemically identical, but optically and physically they have very different qualities, one being a right-handed sugar and easily crystallizable and the other a left-handed sugar and crystallizable with difficulty.

Cane-sugar forms compact, monoclinic crystals having a specific gravity of 1·58. Sugar is very soluble in water. At a temperature of 32° F. a saturated solution of sugar in water contains in each 100 parts sixty-five parts of sugar, and at 120° F. eighty-three parts. In pure aqueous solutions of sugar the density of the solution is directly proportional to the quantity of sugar present. Upon this fact is based a method of determining the percentage of sugar in a solution from its specific gravity. The instrument most commonly used is the Brix spindle. (See HYDROMETER.) For instance, a sugar solution which marks 5° Brix contains 5 per cent. of sugar and has a specific gravity of 1·0197, and one which marks 50° Brix contains 50 per cent. of sugar and has a specific gravity of 1·2328. Elaborate tables are found in works on sugar analysis, giving the percentages of sugar for varying degrees of density, and the specific gravities for each degree and half degree of the standard hydrometers in common use. It is only when sugar solutions are free of impurities that these tables can be used.

Cane-sugar does not possess the power of reducing an alkaline solution of copper, but the dextrose and levulose produced by the treatment of cane-sugar with an acid or inverting ferment possess this power. The process of converting cane-sugar into dextrose and levulose is known as inversion or hydrolysis. Upon the property of reducing alkaline copper solutions to suboxide is based the process of chemical saccharimetry.

When cane-sugar is subjected to a strong heat it suffers a partial decomposition, becomes brown, and forms caramel or burnt sugar.

Many oxidizing bodies act upon cane-sugar with great vigor. For instance, if a mixture of cane-sugar and potassium chlorate be touched with a drop of sulphuric acid the oxidation will be so rapid as to produce a brilliant deflagration. Hot nitric acid also oxidizes cane-sugar with the production of organic acids. A saturated solution of cane-sugar stirred with strongest sulphuric acid will lose its water of composition, and will give a porous mass of carbon and humus bodies. Cane-sugar unites with the bases, especially those of the alkaline earths, forming distinct chemical compounds known as sucrates. The sucrates of calcium and strontium play an important part in the separation of sugar from beet molasses.

*Statistics.*—The total production of cane and beet sugar in the world in 1893–94 was over 7,550,000 tons, and in 1899–1900 more than 8,500,000. The following table includes all the most important countries producing sugar-cane except China. Most of the sugar consumed in Japan (125,000 tons per annum) is imported.

CONSUMPTION OF SUGAR IN THE U. S. FROM 1887 TO 1899, IN TONS OF 2,240 LB., AND CONSUMPTION PER CAPITA IN POUNDS.

| YEAR. | Tons. | Pounds per capita. |
|---|---|---|
| 1887 | 1,392,909 | 53·11 |
| 1888 | 1,457,264 | 54·23 |
| 1889 | 1,439,701 | 52·64 |
| 1890 | 1,522,731 | 54·56 |
| 1891 | 1,872,400 | 67·46 |
| 1892 | 1,853,370 | 63·76 |
| 1893 | 1,905,862 | 63·83 |
| 1894 | 2,024,648 | 67·07 |
| 1895 | 1,949,744 | 62·6 |
| 1896 | 1,960,086 | 61·6 |
| 1897 | 2,070,978 | 63·7 |
| 1898 | 2,002,902 | 60·3 |
| 1899 | 2,094,610 | 61·7 |

The total consumption of foreign sugar in 1899 was 1,844,642 tons. The total consumption of domestic cane-sugar in 1899 was 160,400 tons (in 1898, 252,812 tons). The total consumption of domestic beet-sugar was 79,368 tons (in 1898, 34,453 tons). The total consumption of domestic maple-sugar was 5,000 tons (in 1890, 25,000 tons).

CONSUMPTION OF SUGAR IN EUROPE FOR THE YEAR 1894, IN TONS OF 2,240 LB., AND CONSUMPTION PER CAPITA IN POUNDS.

| COUNTRY. | Tons. | Pounds per capita. |
|---|---|---|
| Great Britain | 1,484,000 | 70 |
| Germany | 623,000 | 19 |
| France | 488,000 | 24·5 |
| Austria | 325,000 | 14 |
| Holland | 55,000 | 26 |
| Belgium | 75,000 | 26 |
| Russia | 450,000 | 10 |
| Italy | 55,000 | 4 |
| Spain | 40,000 | 6 |
| Sweden and Norway | 30,000 | 10 |

At present Canada consumes about 140,000 tons of sugar annually, amounting to approximately 56 lb. per capita, and Australia and New Zealand 175,000 tons annually, amounting approximately to 90 lb. per capita. From the above data it is seen that the English-speaking people of the world are the great consumers if not the great producers of sugar.

*Prices of Sugar.*—It is difficult to compare modern with ancient prices, not only on account of the change in the weights and names of coins, but especially because gold, which is the ultimate standard of value, has itself varied so much in its purchasing power in the last thousand years.

From the best authorities the prices of sugar in England at the dates mentioned below, calculated to the present value of gold, are as follows:

From 1259 to 1350, $156 per 100 lb.; from 1351 to 1400, $237 per 100 lb.; from 1401 to 1540, $150 per 100 lb.; from 1541 to 1582, $181 per 100 lb.; and from 1583 to 1702, $106 per 100 lb. From 1700 to 1800 the price varied through wide limits, but still remained pretty high, being in 1800 about $38 per 100 lb. From that time the price was much less, being $16 per 100 lb. in 1810 and $4 per 100 lb. in 1885.

In the U. S. from 1845 to 1895 the average price, duty free, for fair refining sugar, polarizing about 96 per cent., was $4.38 per 100 lb. The lowest price recorded for fair refining sugar was, Feb. 21, 1895, $1.94 per 100 lb. net cash, duty free. The selling price of refined granulated sugar, including the duty, was on Feb. 21, 1895, 4 cents a pound.

LITERATURE.—*Historical*: *History of Sugar*, by Dr. Edward O. von Lippmann.

*Cane-sugar*: *Sugar Growing and Refining*, by Lock and Newlands Brothers; Bulletins of the Louisiana Sugar Experiment Station; Bulletins 5, 11, 15, 17, 18, 21, 22, 23, Division of Chemistry, U. S. Department of Agriculture.

**Sugden**, EDWARD BURTENSHAW, Lord St. Leonards, LL. D., D. C. L.: jurist; b. in London, England, Feb. 12, 1781, his father being a wig-maker. He was largely self-educated, and was called to the bar at Lincoln's Inn in 1807. He almost immediately rose to the front rank of his profession by the publication of his *Practical Treatise of Powers*, previous to which he had published (Feb., 1805) his *Concise and Practical Treatise on the Law of Vendors and Purchasers*; was made king's counsel in 1822, and a bencher of Lincoln's Inn; was elected M. P. for Weymouth and Malcombe Regis as a Tory; and in 1829 appointed Solicitor-General and knighted; elected M. P. again in 1830, and sat in the Short Parliament which passed the first reform bill, of which he was one of the most persistent and shrewd opponents; was sworn member of the privy council 1834, Lord Chancellor of Ireland 1835, and again 1841–46; Lord High Chancellor of Great Britain from Mar. to Dec., 1852, being raised to the peerage. He was a deputy lieutenant for Sussex, a trustee of the British Museum, and lord high steward of the borough of Kingston-on-Thames. Although a Conservative he effected reforms in the law of contempt of courts, and in the laws relating to the conveyance of the property of infants, lunatics, mortgages, etc. He was recognized as the highest authority on the law of real property, and as the first practitioner of his time in the court of chancery. D. at Boyle Farm, near Thames Ditton, Jan. 29, 1875. Besides his treatise on *Powers*, and great work on the law of *Vendors and Purchasers* (which has gone through many editions), he published many technical works of lesser importance, including *A Handy Book on Real Property Law* (1858). See *Irish Law Times* and *Law Times* for Feb., 1875. F. STURGES ALLEN.

**Suggestio Falsi**: See FRAUD.

**Suggestion**: a great class of phenomena typified by the abrupt entrance from without into consciousness of an idea or image which becomes a part of the stream of thought and tends to produce the muscular and volitional effects which ordinarily follow upon its presence. I suggest a course of action to my friend—he may adopt it. Besides this fact of ideal suggestion there is what may be called physiological suggestion, covering the same class of phenomena in cases where the suggestion does not attain the standing of a conscious image, but remains subconscious. It is called physiological because the nervous process, as in all cases of very faint degrees of consciousness, is largely self-acting or reflex. By physiological suggestion, therefore, is meant the bringing about of a reaction subconsciously by means of an extra-organic stimulus.

The clearest examples of such suggestions occur in sleep. Words spoken to the sleeper are intelligently answered. Positions given to his limbs lead to others ordinarily associated with them; the sleeper defends himself, withdraws from dangers, etc. The early development of the child's consciousness proceeds largely by such suggestions. Before mental images are definitely formed and subject to association, we find many motor reactions stimulated by such physiological suggestions from the environment.

From physiological the child passes to sensori-motor suggestion, the type of reaction which illustrates most clearly the law of dynamogenesis. In this case it is a sensation, a clear state of consciousness, which liberates motor energy and produces movement. Besides the inherited sensori-motor couples, which are numerous and well marked, other reactions grow up early in life and become habitual. Of the latter the following may be mentioned in particular:

*Sleep-suggestions.*—The early surroundings and methods of inducing sleep become powerful re-enforcements of the child's drowsiness, or even substitutes for it.

*Food-suggestions and Clothing-suggestions.*—These represent the spheres of most frequent and highly spiced joys and sorrows, and their reactions soon take on the involuntary and yet highly purposive character which marks our adult attitudes toward dress and the table.

*Suggestions of Personality.*—The child shows preferences for individuals at a remarkably early age. He seems to learn and respond to a personal presence as a whole. Probably the voice is the first indication of his nurse's or mother's personality to which he responds, then touch, then the sight of the face.

*Imitative Suggestion.*—The simple imitation of movements and sounds, clearly manifested about the seventh month of life. See IMITATION.

In *ideo-motor* or *ideal* suggestion we pass to the motor aspects of images, reproductions; and here the motor accompaniments are largely associations and follow the laws of association. As soon, further, as reproductions come up, with their suggested trains, we find the rise of will; that is, they become stimuli to the voluntary consciousness. Yet there is a state of conflict and hindrance among presentations which is mechanical in its issue, the attention being drawn in a reflex way. So states of vexation, divided counsel, conflicting impulse, and hasty decision against one's desire for deliberate choice. We often find ourselves drawn violently apart, precipitated through a whirl of suggested courses into a course we feel unwilling to own as our own. This is the case in the disease called *aboulia*, or loss of will. The man is prey to conflicting impulses. This state, called by the writer deliberative suggestion, characterizes many actions of the young child before will is clearly exercised.

*Organic Stimuli to Movement.*—In general, any condition of the organism, be it active or passive, which is sufficient to reach consciousness, tends to muscular expression, either natural or acquired. Any derangement of the digestion, respiration, or circulation quickens or deadens muscular tone, and comes out, if not in the face, yet in the conduct of the man. The muscular feelings themselves, so large a portion of the general sensibility, reflect direct changes in the tendency and direction of motor reactions. Diseases of the nervous system find their diagnosis in their effects upon the muscular apparatus: paralysis means rigidity; epilepsy, convulsions; sleep, flabbiness of the muscles. The effect of organic stimulation upon the motor consciousness is best seen in conditions of pleasure and pain. Among direct or native reactions an important class are called expressive; they are differentiated muscular movements which reflect uniformly various affective states of consciousness.

*Pleasure-suggestion and Pain-suggestion.*—Perhaps the most direct and invariable stimulus to involuntary movement is pain; and its motor force is independent, as it seems, of the intrinsic experience of which it is the tone. The motor force of a sensation of light, for example, may be in direct antagonism to the motor force of the pain which the light causes to a diseased eye. Despair begets inaction, but the painfulness of it begets restlessness. This is only to say that the tone is an element of sensibility apart from the sensation it accompanies, and that both the one and the other have motor force.

Yet the fact that there are no experiences absolutely indifferent as respects pleasure or pain gives the motor aspect of them an universality and importance which must be acknowledged and provided for in any mental theory. It is a question answered often in the negative whether any course of conduct is ever pursued without primary reference to the pleasure it will bring or the pain it will avoid. However this question may be answered, it may be said at this point that no line of muscular reaction is possible in which an element of motor discharge due to pleasure or pain has not entered. This must be true if the fundamental position is true that every ingoing process alters the equilibrium of the central system and modifies the direction of its outward tendency. Pleasure and pain arising from bodily states may therefore be called the most general internal stimuli to the reactive consciousness.

*Motor Spontaneity.*—The observation of infants clearly tends to show that movement is no less original a fact than feeling. It is impossible to say whether all antenatal movements are in response to feeling conditions, as claimed by some, just as it is impossible to prove that the beginning of feeling is possible only after sufficient physical organization to make motor reaction possible, as claimed by others. It is altogether probable that the two kinds of phenomena are equally original, and depend upon each other. This is certainly the case, at any rate, at the dawn of independent life. Internal conditions of the organism itself are sufficient stimuli to an endless variety of movements. Such reactions, which are simply the discharges, the outbursts, of the organism, independent of definite external stimulation, are called spontaneous. So the incessant random movements of infants and the extraordinary rubber-like activity of the year-old child.

The movements of infants seem to indicate greater suggestibility than is found in adults. A child's extreme restlessness is due to a high feeling of potential or readiness of discharge; and fatigue is accompanied by a correspondingly complete collapse of muscular movements. This follows from the mobility of the infant's cerebral elements before they are pressed into definite connections and systems which give them greater inertia, on the one hand, and greater general capacities for continued expenditure on the other. Upon this superfluity of motor energy is built up the so-called play instinct, which is not definite enough in its channels to be classed properly as an instinct.

J. MARK BALDWIN.

**Suhm**, soom, PETER FREDERIK: historian; b. in Copenhagen, Denmark, Oct. 18, 1728; studied law and philology at the university of his native city; settled in 1751 in Trondhjem in Norway, where he lived till 1765, devoting himself to the study of Danish and Norwegian history and antiquities in preparation for his great works. D. in Copenhagen, Sept. 7, 1798. Among his many writings relating to the history of Denmark may be mentioned *Forsög til Forbedringer i den gamle danske og norske Historie* (1757); *Om de nordiske Folks ældste Oprindelse* (1770); *Kritisk Historie af Danmark i den hedenske Tid* (4 vols., 1774–81); *Danmarks Historie* (14 vols., 1782–1828). In spite of its many faults of style and arrangement this last still remains the greatest work of its kind in the Danish language, the chief authority from which later historians have borrowed. By his *Letter to the King* (1772), indorsing the conspiracy against Struensee and calling upon Christian VII. to restore the ancient liberties of Denmark, he became for the moment the most popular man in the North. Both as patron and author he devoted himself to the advancement of freedom and culture. His magnificent library, containing 100,000 volumes, he bequeathed to the Royal Library. Of *Scriptores Rerum Danicarum Medii Ævi* he edited vols. iv.–vii. (1776–92). Revised by D. K. DODGE.

**Suicide** [Lat. *sui*, of one's self + *cædere*, slay, kill]: intentional death by one's own hand. Among the ancients suicide was considered neither a crime nor dishonorable, Demosthenes, Themistocles, Mark Antony, Cleopatra, Hannibal, and many others having chosen this way of ending their days. The Scriptures and the Apocrypha furnish examples, as Samson, Eleazar, and Judas Iscariot. In modern times history furnishes numerous striking suicides. The famous suicides among the ancients followed various motives, the vindication of honor being a common object. Mithridates and Hannibal died in this way rather than be taken prisoners. Others have committed suicide through false pride or timidity: a striking case in point was the death of Cato; determined not to live under the despotism of Cæsar, he stabbed himself, but, having fainted, his wound was dressed. When he recovered he tore off the bandages, let out his entrails, and expired.

Many writers have defended this crime, the most able of whom were Madame de Staël, Gibbon, Hume, Schopenhauer, and von Hartmann. Suicide is rarely committed, however, except when the functions of the brain have been impaired and the action of the mind perverted and directed in improper channels.

Suicide has sometimes been epidemic in character. A remarkable epidemic prevailed in Versailles in 1793; the number of suicides in that year reached 1,300, which was greatly disproportionate to the population. Instances have been cited where children have followed the example of one of their number and have taken their own lives. An epidemic of suicide took place in the army of the First Napoleon, and it was only after a strong appeal made by the emperor to the pride and courage of the men in the ranks that it was finally stopped. One of these outbreaks followed the suicide of a convict, who hanged himself to the crossbar of his cell. Five others hanged themselves on the same bar within two weeks. The public prints probably have much to do with the increase of suicide. A morbid person who reads the account of such a case will very often have a train of thought started that will end in the commission of the act. Favorable opportunities for the accomplishment of self-murder will also produce a sudden irresistible impulse. People who have gone up into towers and monuments, or above precipices, have often refrained with difficulty from casting themselves down.

The consideration of suicide from the medical point of view has cleared up many mooted points, such as the degree of responsibility the person is under, the degree of prevention possible, etc. In certain forms of insanity the impulse to suicide is now a recognized symptom, notably in all the disorders which involve melancholia. Alcoholic mania is liable also to issue in this impulse. The peculiar liability of persons whose mental balance is at all weakened to the influence of suggestions of all kinds makes it a necessary part of competent medical treatment that any accounts of suicide, murder, or suggestions of death be kept from them. On the other hand, solitary confinement is found to increase the number of suicides; probably because by diminishing the number of the patient's interests his thought is brought home more forcibly to his own condition, grievances, etc.

*Statistics.*—Thorough and adequate statistics of suicide are not to be had. Those now given are current ones, and should be quoted only with reservation. In Roman Catholic countries the number of suicides is considerably less than in Protestant countries (about half), the figures in the aggregate for Protestant countries being about 175 to 200 for each million of the population. As to the difference between men and women, suicides are oftener men by about three to one.

From Table I. (from Morselli) and other sources we get the average annual number of suicides per million of inhabitants: Denmark, 258; Germany, 175; Norway and Sweden, 100; France, 150; to which may be added England and the U. S., each 70. Among uncivilized and barbarous tribes and peoples, suicide is practically unknown. It is therefore peculiarly a disease of civilization. In all countries it is more frequent among the mercantile than among the professional classes; and more frequent among the responsible heads of institutions, business houses, etc., than among the dependent classes represented by clerks. Indeed the fact of responsibility seems to be a prevailing cause of suicide. Those, on the contrary, who live a most precarious life, such as the day-laborers, who may be thrown out of employment at any moment, seem to take their chances with less brooding and personal violence. There is here a discrepancy between the tendency to murder and that to commit suicide; for the murderers are more common among the laboring class, or

still lower classes. Education also seems to increase the propensity to commit suicide. One of the defects of most statistics of suicide is that they do not take account of the unsuccessful attempts at self-destruction, in which the person is equally a suicide.

LITERATURE.—Morselli, *Suicide* (London and New York, 1882); Legoyt, *Le Suicide Ancien et Moderne* (Paris, 1881); statistics contained in successive *Census Reports* of the different governments; Lewis, *History, Literature, etc., of Suicide* (London, 1885); full list of titles in *Notes and Queries* (1890), p. 489; Tuke, article *Suicide* in *Dic. of Psych. Medicine* (London, 1892), where statistics are given down to 1888. J. MARK BALDWIN.

SUICIDE IN LAW.—The legal definition of suicide is intentional self-murder by a person of criminal responsibility, in point of age and mental condition. According to Bracton, the early English law treated suicide as a felony, punishable by the forfeiture of lands in case it was committed to escape conviction for a crime, by the forfeiture of goods in all other cases. (2 *De Legibus*, ch. 31.) Later English law imposed the forfeiture of goods and chattels real in all cases. The rule was evaded frequently by a finding of the coroner's jury that the suicide was insane, and was formally abolished in 1870. (33 and 34 Vict., ch. 23.) From an early day the practice prevailed of burying suicides at cross-roads with a stake through the body; but it is said to have been without warrant in the common law. (3 Stephen's *History of Criminal Law*, p. 105.) Its origin is doubtful, but has been ascribed to a Teutonic custom taken up into the canon law. (Guernsey, *Penal Laws against Suicide*.) The object of impaling the body appears to have been to keep the ghost from wandering about to the discomfort of the living. (Stranahan, *Suicide and Insanity*, London, 1893.) Parliament abolished the practice in 1823, and later statutes authorize the interment of suicides in churchyards or burial-grounds, with such funeral services as those in charge of the body may provide. (45 and 46 Vict., ch. 19.) The Roman law dealt very leniently with suicide, even to the extent of legalizing it in various circumstances. During the later empire and the Middle Ages the legal rules upon this subject underwent a radical change, produced not only by different ethical and religious views but by political considerations. It was argued that "there could be no patient endurance in the state unless there was patient endurance in the citizen. If the people resorted to suicide to escape trouble, so would the state, and all social order would be at an end."

In the U. S. suicide is not treated as a crime. It is deemed unlawful, however, and a person who unintentionally kills another while attempting to commit suicide is guilty of criminal homicide. (*Commonwealth* vs. *Mink*, 123 Mass. 422.) At common law a person who kills another at the latter's request, or who persuades another to kill himself, or who agrees to join another in committing suicide, is guilty of murder. Such is still the rule in England, although it is improbable that one who joined another in a common attempt at suicide, but who escaped, would be punished capitally. An unsuccessful attempt at suicide is a common-law misdemeanor. In some of the U. S. such an attempt is punishable as a statutory felony, as is the offense of aiding another to commit suicide, and that of abetting another to attempt suicide. (See New York Penal Code, §§ 172–178.) The Indian penal code provides a severer punishment for persons aiding minors or incompetents to destroy themselves than for those who abet the suicide of sane adults. (§§ 305 and 306.) Macaulay, in his report of the draft of this code, argues strongly against the common-law rule which places the abettor of suicide in the same category with the abettor of murder. (See Wharton, *On Homicide*, § 315, note.) The punishment of one who attempts suicide and fails has been criticised as putting a premium upon the successful completion of the suicidal act.

The law of Scotland does not treat suicide as a crime. It does provide for the escheat of the suicide's movables; but the proceeding leading to such escheat is civil and not criminal, and the next of kin to the deceased must be made parties. The proceeding is practically obsolete. (Erskine, *Principles of the Law of Scotland*, p. 559, § 20, Rankine's ed., Edinburgh, 1890.) There is no warrant in law or practice for the infliction of any punishment or indignity upon the body of a suicide in Scotland. 1 Hume, *Commentaries on the Criminal Law of Scotland*, p. 300; *Earl of Eglington* vs. *Campbell*; Maclaurin's *Criminal Cases*, 504–531.

The consequences of suicide in life-insurance cases are discussed in the article on LIFE-INSURANCE under the heading *Forfeiture*. See also Richards, *On Insurance*, § 184; *Smith* vs. *National Benefit Society*, 123 New York 85; and *Conn. Life-insurance Company* vs. *Akens*, 150 United States 468. FRANCIS M. BURDICK.

**Su'idæ** [Mod. Lat., named from *Sus*, the typical genus, from Lat. *sus*, hog]: a family of artiodactyl ungulate mammals, of the section *Omnivora* or *Non-ruminantia*, typified by the common hog. The form in all is essentially like that of the domesticated hog, but mostly less gross; the feet are unguligrade (i. e. with the hoofs only touching the ground), and the external toes and hooflets are reduced in size and do not assist in progression, the median (third and fourth of normal series) only being functional; the snout is disciform and provided with a cartilaginous ring, and in the disk the nostrils are open and forward; the mammæ are in considerable number (four to ten), ventral as well as inguinal; the back has no dorsal scent-gland; the tail is short or rudimentary; the tegumentary appendages are developed as stiff bristles; the orbits are directed outward and forward; the occipital bones have long deflected styliform paroccipital processes in front of the occipital condyles; the zygomatic processes overlie the malar bones; the articular surfaces for the lower jaw are transversely concave, antero-posteriorly convex, and limited by no post-glenoid processes; the pterygoid bones are twisted and reflected outward, the crest continued upward and backward into the temporal region; the malar bones are elongated, and have long inferior processes; the teeth are generally in full number, i. e. M $\frac{3}{3}$, P. M. $\frac{4}{4}$ $(\frac{3}{3})$, C. $\frac{1}{1}$, I. $\frac{3}{3}$ $(\frac{2}{3}) \times 2 = 44$; the molars have corrugated cusps, presenting, when worn, deeply sinuated insular areas; the canines of the upper jaw, in the males, are more or less twisted outward and upward, and parallel with the lower. In their anatomy the feet offer characters shared with the wart-hogs and peccaries, and differentiating from the hippopotamids. The living representatives of the family are aboriginally peculiar to the Old World, although in the Tertiary epoch species appeared to have existed in America. Exclusive of the domesticated forms, fifteen species have been recognized. Twelve of these belong to the genus *Sus*, and are all peculiar to Asia, except *S. scrofa* (the wild boar of Europe) and *S. sennaarensis* of Northern Africa; the genus *Potamochœrus* is confined to West Africa, the single species of *Babirussa* to Celebes and a few of the adjoining islands, and a single species in India and the Archipelago exemplifies the very strongly marked genus *Babirussa*. The domesticated swine are subject to great variation, and Gray even differentiated them into two peculiar genera—*Scrofa* for most of the breeds, and *Centuriosus* for a peculiar race of Japan and China, distinguished by the strongly defined concentric wrinkles of the face. See BABYROUSSA, BOSCHVARK, and SWINE. Revised by F. A. LUCAS.

**Su'idas** [= Lat. = Gr. Σουΐδας]: lexicographer. Of his life nothing is known; even the age in which he lived is uncertain, though it may be fixed not later than the twelfth century. His book contains explanations and notices of Greek words and names, illustrated by extracts from older Greek writers. It has evidently gone through many hands before reaching its present form, and it is generally of very little critical value; but as many of the works from which it quotes passages are lost, it has great historical interest. Editions by Gaisford (Oxford, 1834); Bernhardy (Halle, 1834); and Bekker (Berlin, 1854.)

**Suine**, or **Butterine**: See BUTTER, ARTIFICIAL.

**Sukhāvatī** [Sanskr., paradise of pleasures]: the heaven over which, according to the Mahā-yāna, or "Great Development" of Buddhist doctrine, a Dhyāni-Buddha (see DHYĀNI-BUDDHAS) called Amitābha presides, and where the saints, exempt from suffering, death, and sexual distinction (but not from rebirth), may live for countless ages in absolute bliss. Summer and winter are there unknown; the sun never scorches and cold winds never blow; sweet flowers shed their perfume around, and birds of the most beautiful plumage sing day and night of the five chief virtues, the five sources of moral power, and the seven steps in knowledge, and the listener is so affected by their music that he can think of nothing but of Buddha, His law, and his Order. Among the Chinese this paradise is called *Tsing-tu*, the Pure Land (in Japanese, *Jōdō*), because its inhabitants are free from the five impurities of this world. Rebirth in Sukhāvatī can be secured only by unswerving faith in Amitābha, by fervent prayer addressed to him, and by the practice of every virtue. Amitābha is not only the Buddha of "boundless light," but also of great mercy and sympathy. His worship is peculiar to the northern school of Buddhists, among whom it takes the place of NIRVĀNA (*q. v.*), which is too difficult of attainment. Sukhāvatī is situated in some universe in the far West, and hence is known as the "Paradise of the West."

**Sula Islands** (Dutch. *Soela*): a group of three islands and many islets in the Dutch Moluccas, E. of Celebes and N. W. of Buru, between lat. 1° 40′ S. and 2° 30′ S., and 124° and 127° E. lon. Area, 2,590 sq. miles. The largest and westernmost is Taliabu (70 miles long and 15 broad); immediately E. is Mangola, the second in size, and S. of the latter is Besi, the smallest but most thickly populated, and containing Senana, the capital. Pop. about 7,000, formerly six times as large, but depopulated by pirates and slave-merchants. The islands are prosperous under Dutch management. M. W. H.

**Suleïman′**: Ottoman prince. After the battle of Angora (1402) he, as the eldest surviving son of Bayezid I., ascended the throne at Adrianople, but was overthrown by his brother Musa (1410). The Ottoman historians do not consider him a sultan, inasmuch as he reigned only over a part of the empire. E. A. G.

**Suleïman**: the name of two Ottoman Sultans. SULEÏMAN I., EL KANOUNI, the Legislator, often called the Great, the Magnificent, the Sublime (1520–66); b. in 1495, son of Selim I. His reign is a series of generally successful wars, during which he conducted thirteen campaigns in person. In 1521 he crushed a rebellion in Syria, concluded a treaty with Venice, wherein she promised an annual tribute of 10,000 ducats, and captured Belgrade. In 1522 he subdued Rhodes, expelling the Knights of St. John of Jerusalem, whose stronghold it had been 214 years, who found an asylum at Malta. In 1526 he concluded a partial alliance with Francis I. of France against Charles V.; broke the Hungarian power at the battle of Mohacz, where King Louis and 25,000 Hungarians were slain, and brought to Constantinople 100,000 Christian captives, the royal jewels of Hungary, and the precious library of Mathias Corvinus. Besieging Vienna with 120,000 men and 400 cannon, he was repulsed (1529); concluded an offensive and defensive alliance with Francis I. (1535); and took Bagdad from Persia (1534). Meanwhile his admiral, Khaïreddin Pasha, terrorized the Mediterranean and subjected Northern Africa. Moldavia and the Khan of the Crimea made submission (1538). Venice, after a disastrous war, purchased peace by promising annual tribute of 300,000 ducats (1539), and Austria, by like tribute of 50,000 ducats (1547). He conquered Persian Kurdistan, captured Van and Tebriz, and partially subdued Georgia (1548). Austria fared better in the next war, defeating the Ottomans with fearful loss in their five months' siege of Erlau (1552). Though Suleïman formed an offensive and defensive alliance with Henry II. of France, dissensions prevented real benefit to either. Fruitless wars followed with Persia (1554–55) and with the Hungarians (1558). Instigated by his favorite, Roxelana, who sought the succession for her son, he put to death his oldest son, Mustapha (1553). Enraged with his son Bayezid, who fled to Persia, he paid the Shah Tahmasp 400,000 gold pieces to insure the murder of the fugitive and of his four sons (1561). To break the naval power of Spain and control the Mediterranean he attacked Malta, but was defeated with the loss of 20,000 men (1565). Carrying on a last war with Austria, he died at the siege of Szigeth (1566), which, after an heroic resistance, fell three weeks later. Meanwhile the death of Suleïman was kept secret, that his successor, Selim II., might have time to reach Constantinople from Kutahia. During his reign the Ottoman empire reached its acme and began its decline. The discipline of the janissaries was relaxed: the harem, in the person of Roxelana, first began to exert undue and hence pernicious influence, and expenditure was carried to its utmost extravagance. More fatal still, during the latter part of his life, Suleïman partially withdrew into Oriental seclusion, leaving affairs to his ministers. Yet this was the golden age of Ottoman jurisprudence, literature, and art. Suleïman remodeled and almost recreated the code, determined ecclesiastical procedure, introduced a less vicious system of taxation, and erected the mosques of Suleïman—the masterpiece of Ottoman architecture—of Selim, the Shahzadeh, Djeanghir, and the Hasseki. He had statesmen and generals of unusual ability in Ibrahim Pasha, Rustem Pasha, and Sokolli Pasha. His admirals, Khaïreddin Pasha, Dragut Pasha, and Piali Pasha, were the most skillful naval commanders Turkey has possessed. But Suleïman was the spoiled favorite of Ottoman fortune, and his successes were mainly won during the early years of his reign. Though he extended the boundaries of his empire, he left it at his death weakened and exhausted. —SULEÏMAN II. (1687–91), b. in 1642, the son of Sultan Ibrahim. Timid and incapable, he committed the administration of affairs to his vizier, Kuprnli Zadek Mustapha Pasha, the Virtuous, who was slain, with 28,000 Ottomans, at the terrible defeat of Selankemen (Aug. 19, 1691), two months after the death of his master. E. A. GROSVENOR.

**Suleïman Pasha**: Ottoman prince; son of Orkhan and grandson of Osman I. He captured Tzympe and Gallipoli (1357), the first territorial acquisition made in Europe by the Ottomans. He was killed by a fall from his horse in 1359, and his father died of grief in 1360. E. A. G.

**Su′lidæ** [Mod. Lat., named from *Sula*, the typical genus, from Icel. *sūla*, gannet]: a family of swimming birds of the order *Steganopodes*, limited to the gannets. The neck is moderately long, although shorter and stouter than in either the pelicans or cormorants; the bill about as long as the head, straight, but with the tip decurved, with the lateral grooves well defined, composite as in the other members of the group, and with the edges serrate; narial openings lacking; no gular pouch developed; wings moderately long and pointed; tail long and cuneate, and with twelve to fourteen feathers; tarsi moderately short; toes (four, as in all *Steganopodes*) well developed and connected by a full membrane. The skull is of the desmognathous type, and exhibits modifications co-ordinate with the external characteristics. The species are almost exclusively marine, and one or more may be found on the seacoast of every country. See GANNET. Revised by F. A. LUCAS.

**Suliman′ Mountains**: a chain of mountains forming the boundary between India and Afghanistan. They range from N. to S., and reach their greatest height, 11,300 feet, in Takht-i-Suliman, in lat. 31° 25′ N. They connect S. with the Kurlekhi Mountains of Kelat, and N. with the Sefid Koh, which is 15,622 feet high and ranges from E. to W. The descent toward India is steep, but gentle toward the Afghan plateaus; the valleys drain eastward to the Indus. The most convenient ascent to Kandahar is effected along the Gomal from Dera Ismael Khan on the Indus.
Revised by M. W. HARRINGTON.

**Suli′na**: the name of the central delta-branch of the Danube. The Danube, at 45 miles from the coast, divides into the Kilia and Toulcha branches, the former conveying more than half the entire discharge. The latter again divides into the Sulina and St. George branches. The Kilia and St. George mouths are 33 miles apart, and the Sulina mouth nearly half way between. The European Commission of the Danube, representing eight European states, was created by the treaty of Paris (1856), for the purpose of removing obstructions to navigation and deepening the channel, and its powers were prolonged until Apr., 1904, by the treaty of London (1883). This commission has so far succeeded that the Sulina branch is navigable by the largest vessels. (See HARBORS.) The town of Sulina, at the corner of the right bank and the Black Sea, originally a miserable fishing-village, has remarkable public works. Pop. (1889) 4,315. E. A. GROSVENOR.

**Su′liotes** [deriv. of *Suli*, in the Cassopeian Mountains, formerly their chief village]: a band of 1,500 Albanian Christian warriors who forced the Ottomans to acknowledge their independence about 1730. In 1788 and again in 1792 they successfully resisted Ali Pasha of Tepeleni, who undertook their subjection. From 1799 to 1803 they were blockaded and practically besieged in their mountain fastnesses by Ali Pasha; their strongholds were gradually captured, despite desperate resistance, and they finally surrendered on favorable terms. The conquerors violated their oath, and men, women, and children were indiscriminately massacred. Only a few escaped. The story of the twenty-two Suliote women, who, rather than fall into the hands of the Ottomans, hurled their children from a precipice and then leaped after them, is everywhere known. Marco Botzaris was a Suliote. They were avaricious and haughty, but loved their freedom above all. E. A. GROSVENOR.

**Sulla**, or **Sylla**, LUCIUS CORNELIUS, surnamed FELIX: dictator; b. 138 B. C.; was noted in youth for his vices, but distinguished himself under Marius as a cavalry leader in the Jugurthine war, and it was through his skill as a negotiator that Jugurtha was surrendered to the Roman general.

From this moment Marius feared and hated him as a rival. In the war against the Cimbri and Teutones (104–101), Sulla commanded with distinction, and in 92 he was sent as proprætor to Cilicia, where he defeated Gordius, the general of Mithridates, reinstated Ariobarzanes as King of Cappadocia, and received an embassy from Arsaces, King of Parthia. In the Social war both Sulla and Marius commanded with success, but it was Sulla who defeated Papius Mutilus, the chief of the Samnites, and took Bovianum, their capital. For the year 88 he was elected consul almost unanimously, and, to the deep mortification of Marius, appointed commander in the Mithridatic war, a war which Marius had in many ways instigated, in the hope of being chosen general. By means exceedingly violent, though in form legal, Marius succeeded in subverting the appointment of Sulla and getting himself appointed, but during the riot which took place in Rome Sulla escaped to Nola in Campania, where his army was stationed. Followed by the rank and file of his army, he now marched on Rome. Marius fled to Africa, and Sulla was perfect master of the situation; but realizing his dependence upon the army, which was eager for the spoils of an Eastern war, he soon left the city and proceeded with the army to Greece. He stayed away four years (87–83). Shortly after his departure he was declared a public enemy: his property was confiscated; his friends were persecuted or slain. Marius returned, and the Marian or popular party domineered in Rome and Italy. But of all this Sulla took no notice; he simply prosecuted the war. Sulla took Athens by storm in 86 and gave it up to plunder. Shortly after he routed one of the hostile armies at Chæronea; next year he totally destroyed another at Orchomenus, and having expelled Mithridates's troops from Greece and pacified the country, he crossed the Hellespont in 84. Pressed at the same time by another Roman army sent out by the Marian party under Flaccus and Fimbria, ill supported by his Greek subjects in Asia, who found him as unamiable as the Romans, and nearly exhausted by his enormous losses in Greece, Mithridates now sued for peace, and after a personal interview between him and Sulla a treaty was concluded, according to which he returned all his conquests in Asia, surrendered a fleet of seventy large vessels, and paid 2,000 talents. Sulla now turned against Fimbria, whose soldiers deserted him, and who committed suicide; he then regulated the affairs of the province of Asia, from whose cities he made enormous conscriptions, and finally set sail for Italy, where he landed at Brundisium in the spring of 83. His soldiers were now rich, and they knew that the final success of their general was a condition of the enjoyment of their riches; they clung firmly to him, and he acted cautiously. Marius was dead, but his son was consul and his party in power, strengthened by an alliance with the discontented Italian nations. The final battle was at the gates of Rome, where Sulla's veterans defeated a large body of the Samnites. Sulla was made dictator for life. It was not his purpose, however, to establish a monarchical constitution in Rome. The legislation which he enacted as dictator, the so-called *Leges Corneliæ*, aimed simply at the restoration of the old aristocratic constitution, the extension of the authority of the senate, the restriction of the power of the tribunes, etc. In order to establish this constitution firmly and safely, he first determined to extirpate its adversaries, the Marian party. Thousands of men fell under his *proscriptio*; that is, they were outlawed and slain, and their property was confiscated and given to somebody else. He then attempted to form a steady support for it by settling his veterans in military colonies on such Italian soil as had been confiscated in the Social war or afterward, and by organizing a bodyguard stationed at Rome. When he considered his work finished, he assembled the people, abdicated the dictatorship, retired to his villa at Puteoli, and returned to the lazy, voluptuous habits of his youth. His death, which occurred in 78 B. C., was hastened by his debaucheries.

Revised by F. M. COLBY.

**Sullivan**: city; capital of Moultrie co., Ill.; on the Chi. and E. Ill., the Peo., Dec. and Evansv., and the Wabash railways; 14 miles N. W. of Mattoon, 25 miles S. E. of Decatur (for location, see map of Illinois, ref. 7–F). It is in an agricultural and stock-raising region, and contains 2 State banks with combined capital of $55,000, and 3 weekly newspapers. Pop. (1880) 1,305; (1890) 1,468; (1900) 2,399.

**Sullivan**: town (laid out in 1843); capital of Sullivan co., Ind.; on the Evansv. and Terre Haute and the Ind. and Ill. S. railways; 26 miles S. of Terre Haute (for location, see map of Indiana, ref. 9–B). It is in a coal-mining region; manufactures lumber, flour, and tile; and contains 6 churches, graded public schools, electric lights, 2 State banks with combined capital of $24,000, and a semi-weekly and 2 weekly periodicals. Pop. (1880) 2,161; (1890) 2,222; (1900) 3,118.

EDITOR OF "DEMOCRAT."

**Sullivan**, ALEXANDER MARTIN: journalist and politician; b. at Castletown, Ireland, in 1830; was connected in 1855 with the Dublin *Nation*, of which he was editor and proprietor until 1876. In 1868 he was indicted for sedition in consequence of articles referring to the Manchester executions, and sentenced to four months' imprisonment. He was returned to Parliament in 1874 in the Home-rule interest, a movement with which he was especially identified. Mr. Sullivan represented the county of Louth till the general election of 1880, when he was elected for Meath. In 1882 he withdrew from Parliament in consequence of ill health. He published several works, among which are *A Visit to the Valley of Wyoming*, a pamphlet descriptive of a tour in America made in 1857, and *New Ireland* (1877). D. at Dalkey, Ireland, Oct. 17, 1884.

F. M. COLBY.

**Sullivan**, Sir ARTHUR SEYMOUR: composer; b. in London, May 13, 1842; the son of a teacher of music. He was early trained in the art, singing in the chapel royal when a mere child; at the age of fourteen gained the Mendelssohn scholarship, which enabled him to pursue his studies under the best masters at home and on the Continent. For *The Tempest* of Shakspeare he composed incidental music which was performed for the first time at the Crystal Palace in 1862. He was knighted May 15, 1883. His compositions include overtures, symphonies, songs, and piano music; the operettas *Box and Cox*, *Thespis*, and *Contrabandista*; the cantatas *The Bride of Neath Valley*, *Kenilworth*, and *On Sea and Land*; the oratorios *The Prodigal Son*, brought out at the Worcester musical festival in 1868, and *The Light of the World*, produced at the Birmingham festival in 1873; and an opera, the libretto by Chorley, entitled *The Sapphire Necklace*. Sullivan's greatest successes have been made with his comic operas, in which he had the invaluable collaboration of William S. Gilbert, the distinguished playwright. Beginning with *H. M. S. Pinafore* (1878), and followed by *The Pirates of Penzance* (1879), *Patience* (1881), *Iolanthe* (1882), *The Mikado* (1885), also *The Yeomen of the Guard*, *The Gondoliers*, etc., his popularity has been greater, perhaps, than that of any other English composer. He also wrote a grand opera called *Ivanhoe*, which did not prove a success. D. Nov. 21, 1900.

**Sullivan**, BARRY: actor; b. in Birmingham, England, in 1824; made a successful *début* on the stage at Cork in 1840, acting thereafter in the principal towns of Ireland, Scotland, and England, and making his first appearance at the Haymarket theater, London, in 1852, as Hamlet. He visited the U. S. in 1857; returned to Great Britain in 1860, and in 1861 made a profitable professional visit to Australia, returning to England in 1866. He subsequently became lessee of the Holborn theater, London, and in 1875 made a second and not very successful visit to the U. S. D. at Brighton, England, May 3, 1891.

Revised by B. B. VALLENTINE.

**Sullivan**, FRANCIS STOUGHTON, LL. D.: lawyer; b. probably in Ireland near the middle of the eighteenth century; became Professor of Common Law in the University of Dublin, and was the author of two legal works of great value, *Historical Treatise on the Feudal Law, and on the Constitution and Laws of England* (1772) and *Lectures on the Constitution and Laws of England* (1776).

F. S. A.

**Sullivan**, JAMES, LL. D.: jurist and statesman; b. at Berwick, Me., Apr. 22, 1744; studied law; practiced at Biddeford, and in 1770 was appointed king's attorney for York County. As the Revolution approached, he espoused the patriot cause; was a member of the provincial congress of Massachusetts, of which Maine was then a part, and was one of a commission of three who were in 1775 sent on a secret mission to Ticonderoga. In 1776 he was appointed a judge of the superior court, in 1779–80 a member of the State constitutional convention, and a delegate to Congress in 1784–85. He removed to Boston, for which he was repeatedly chosen representative in the Legislature; was a member of the executive council and judge of probate in 1787; attorney-general of the State 1790–1807; elected Governor in 1807, and again in 1808. He was the projector of the Middlesex Canal, a member of the American Academy of Arts and Sciences, and for many years president of the Massachusetts

Historical Society. Among his works are *Observations on the Government of the United States* (Boston, 1791); *History of Maine* (1795); *Review of the Causes of the French Revolution* (1798); and *History of Land Titles in Massachusetts* (1801). D. in Boston, Dec., 1808. See *Life*, with selections from his writings, by his grandson, Thomas C. Amory (2 vols., Boston, 1859).

**Sullivan**, JOHN, LL. D.: soldier; brother of James Sullivan, jurist; b. at Berwick, Me., Feb. 17, 1740; studied law and practiced successfully; was a member of the first general congress, and in Dec., 1774, led a company which captured a fort near Portsmouth, N. H. In June, 1775, Congress appointed him a brigadier-general, and during the siege of Boston he commanded the left wing under Gen. Lee. In 1776 he commanded the Northern army in Canada, attacked Three Rivers unsuccessfully, and retreating, joined at New York the army under Gen. Washington. On Aug. 10, 1776, he was made a major-general, and in the battle of Long Island commanded temporarily the division of Gen. Greene; was taken prisoner, but soon afterward exchanged; commanded at Trenton and Princeton the division of Gen. Lee, who had been captured; at the battle of Brandywine commanded the right wing of the army, and defeated the British left at Germantown. Transferred in the winter to command in Rhode Island, he laid siege to Newport in Aug., 1778, but the French fleet under d'Estaing failed to cooperate, and he was compelled to withdraw his forces from the island, after defeating the enemy at Butt's Hill, Aug. 29. In the summer of 1779 he marched against the Indians of the Six Nations, defeated them and their Tory allies, and laid waste the country to prevent their return. Shortly after, he resigned from the army, and in 1780 was again a member of Congress. Resuming the profession of law in New Hampshire, he was attorney-general 1782–86, and president of the State 1786–89; in 1788 his exertions secured the adoption of the Constitution. In Oct., 1789, he was appointed U. S. district judge of New Hampshire. D. at Durham, N. H., Jan. 23, 1795.

**Sullivan's Island**: a long, narrow island in Charleston co., S. C.; 6 miles from Charleston, and on the north side of the entrance to Charleston harbor. It is the site of FORT MOULTRIE (*q. v.*), and is a fashionable resort for sea-bathing. There are many summer residences. The island is connected with Charleston by steam-ferryboats, which convey some 200,000 passengers annually. The island is 6 miles long, and is separated from the mainland by a tidal channel.

**Sullivant**, WILLIAM STARLING, LL. D.: botanist; b. near Columbus, O., Jan 15, 1803; graduated at Yale College in 1823; took charge of the extensive landed estates left by his father, and devoted himself with great zeal to botany, making the mosses a special subject of study. He published *Catalogue of Plants Native or Naturalized in the Vicinity of Columbus, Ohio* (1840); *Musci Alleghanienses*, to produce which he made a journey from Maryland to Georgia (1845); *Musci and Hepaticæ of the United States East of the Mississippi River* (1856); *Mosses brought Home by Wilkes's Exploring Expedition* (1859); *Mosses and Hepaticæ, collected mostly in Japan* (1860); *Musci Cubenses* (1861); *Icones Muscorum* (vol. i., 1864; vol. ii. (posthumous), 1874); and in conjunction with L. Lesquereux, two series of *Musci Boreales Americani*. D. in Columbus, Apr. 30, 1873.

Revised by CHARLES E. BESSEY.

**Sul'ly**, JAMES, M. A., LL. D.: psychologist; b. in Bridgwater, Somersetshire, England, Mar. 3, 1842; educated at Taunton, London, and Göttingen; was lecturer in College of Preceptors, London, until 1892, when he became Professor of Philosophy in University College, London. His principal works are *Sensation and Intuition* (London, 1874); *Pessimism* (London, 1877); *Illusions* (London, 1881); *Outlines of Psychology* (London, 1884); *The Teacher's Handbook of Psychology* (London, 1886); *The Human Mind* (London, 1891).

J. MARK BALDWIN.

**Sully**, sü'lee', MAXIMILIEN DE BÉTHUNE, Baron of Rosny, Duke of: chief minister of Henry IV. of France; b. at Rosny, department of Seine-et-Oise, Dec. 13, 1560, of a Protestant family; was from his eleventh year educated with Henry of Navarre; accompanied him through his shifting fortunes at the court and in the camp, and became his Minister of Finance and chief adviser in all public and private affairs when he ascended the throne under the name of Henry IV. A skillful administrator rather than a statesman, he made no radical changes, but contented himself with improving the efficiency of the existing system. His chief work was the reform of the finances, which were in a disorganized condition, and managed in such a manner as to invite fraud and corruption. By enforcing a proper system of auditing accounts and by insisting that the levy of all sums should be authorized by the Government, he did away with illegal taxation, saved France more than 120,000,000 francs annually, and amassed a reserve of 30,000,000 livres. His economical views were characteristic of his time; he considered agriculture as the only productive source of the wealth of a nation, but his policy had the advantage of making France independent of foreign nations for the prime necessities of life, at a time when she was on the point of entering upon a long period of war. After the assassination of Henry IV., he resigned his offices and retired into private life. D. at Vielebon, Dec. 22, 1641. Of his *Mémoires*, two volumes were published by himself in 1634, and two more in 1662 by Jean le Laboureur; translated into English by Mrs. Lennox (1761).

F. M. COLBY.

**Sul'ly**, THOMAS: painter; b. at Horncastle, Lincolnshire, England, June 8, 1783; was taken to the U. S. by his parents, who were actors, in 1792; lived in Charleston, Richmond, New York, and finally in Philadelphia; painted Jefferson, La Fayette, *Washington crossing the Delaware*, Fanny Kemble, Charles Kemble, Mrs. Wood, Cooke the tragedian, and other actors of celebrity. In England he painted a portrait of Queen Victoria for the St. George's Society of Philadelphia. The *Jefferson* is at West Point, the *Washington* in Boston. Sully did not, like Stuart, confine himself to portraiture. D. in Philadelphia, Nov. 5, 1872.

**Sulphates**: See SULPHURIC ACID AND SULPHATES.

**Sulphides**, or **Sul'phurets** [derivs. of *sulphur*]: compounds of sulphur with metals and other elements more basylic or less electro-negative than itself. This class of compounds is probably quite as large in number as the oxides. Indeed, sulphur combines with one element, fluorine, which is not known to combine with oxygen at all. There seems a general strict analogy between sulphur and oxygen in combination, running through very extended ranges of compounds. The sulphides of the metals possessing practical importance will generally be found described under the head of the metal.

**Sulphites**: See SULPHUROUS ACID.

**Sulphocyan'ic Acid**, also called **Hydrosulphocyanic Acid** and **Sulphocyanhy'dric Acid** [(the names being various combinations of) *sulphur* + *cyanic* + *hydrogen*]: a compound of cyanogen, CNHS, analogous in composition to cyanic acid, CNHO, in which the atom of oxygen is replaced by one of sulphur. It occurs in saliva, and in some sulphuretted essential oils of plants, such as mustard and radish. It may be prepared from sulphocyanate of mercury, which is first made by precipitating a mercurous salt with sulphocyanate (sulphocyanide) of potassium, the material of the so-called "Pharaoh's serpents." *Potassium sulphocyanate* (CNKS) is a salt of much interest from being an important and delicate laboratory reagent for ferric compounds, with which all soluble sulphocyanates strike a deep and characteristic blood-red color. The potassium salt is prepared by fusing cyanide of potassium and sulphur and subsequently purifying.

Revised by IRA REMSEN.

**Sulphur**, or **Brimstone** [*sulphur* is from O. Fr. *soulfre* < Lat. *sulfur*, *sul'phur*; cf. Sanskr. *çulvāri*, sulphur; *brimstone* is M. Eng. *brimston*, *bremston*, *brenston*, *bernston*; *brennen*, *bernen*, burn + *ston*, stone]: one of the most important of the elements of matter, very abundantly and almost universally distributed throughout the earth and the sea. It occurs native as a mineral in many countries. It is also found in mineral form as GYPSUM (*q. v.*) and in a great variety of metallic SULPHIDES (*q. v.*); also dissolved in the ocean as sulphates. It is an important essential element of the blood, muscles, skin, hair, and other parts of animals, and exists also in some essential components of plants, though not in the woody substance thereof. It is evolved also from volcanoes, both as vapor of sulphur and as sulphuretted hydrogen and sulphurous dioxide, these gases being doubtless products of the action of oceanic water, that has penetrated to the volcanic focus, upon metallic sulphides it finds there. Indeed, it is more than probable that such action is itself one *vera causa* of vulcanicity.

Most commercial sulphur is merely the native mineral purified by fusion or further by distillation and sublimation. In Sicily, where the crude sulphur, mixed more or less with other minerals, is very abundant and fuel scarce, the method is often adopted of making a portion of the sulphur of the ore furnish the heat (not very great in amount) necessary to fuse out and separate the rest of the sulphur. The ore is piled in heaps, sometimes in kilns, so constructed that a portion of it can be set on fire and heat the whole mass throughout to the fusing-point of the sulphur. The latter then collects slowly in liquid form in cavities formed for the purpose, and may be ladled out and sold or refined. The Sicilian sulphur, being free from arsenic, which is the most objectionable impurity liable to occur, is highly prized for making SULPHURIC ACID (*q. v.*). Deposits of sulphur are reported in various parts of the U. S., but the chief source is from iron pyrite. In 1899 the product was 4,380 short tons (value $107,500) from Louisiana, Nevada, Texas, and Utah. The refined sulphur (brimstone) of commerce and the pulverulent material known as flowers of sulphur are products of distillation and sublimation—operations which are often conducted simultaneously, there being duplicate condensing-chambers, the first of which being hot condenses liquid sulphur, which is drawn off and cast into sticks or cylinders; while in the second, which is kept cool, the vapor precipitates in the form of "flowers," which are, when freshly prepared, composed of a special allotropic modification of sulphur.

Sulphur is one of those elements most liable to assume allotropic states when isolated. These are characterized by differences of crystalline form or by amorphous character, different relations to solvents, and different densities, but not so much by different colors as is the case of phosphorus-allotropes. Native sulphur often occurs in very beautiful and brilliant transparent yellow crystals, which are orthorhombic in form, with two imperfect cleavages. When molten sulphur cools it takes the crystalline form, the crystals belonging to the monoclinic system. Very beautiful crystals of this form are easily obtained by breaking the crust upon a cooling mass of melted sulphur and pouring out the liquid interior. On breaking the mass after cooling, the cavity will be found filled with slender brilliant prisms. Sulphur on heating passes through a succession of changes, melting at about 120° C. to a thin yellow liquid. If again cooled, it becomes a permanently transparent solid. Above 120° the sulphur becomes thick and viscid, losing its fluidity altogether and assuming a brown color at about 250° C. At 300° the mass again becomes liquefied. At 440° C. (822° F.) sulphur boils, forming an orange-yellow vapor. Some of the sulphur-allotropes, including the two crystalline forms above described, are soluble in several liquids, such as bisulphide of carbon, oil of turpentine, and others. The bisulphide-of-carbon solution on evaporation yields beautiful transparent crystals similar to those of native sulphur. Flowers of sulphur are composed of an amorphous soluble modification. Sulphur inflames in air at a remarkably low temperature, about 482° F., burning with blue flame and evolution of suffocating sulphurous oxide, $SO_2$.

MEDICINAL USES OF SULPHUR.—Taken internally, sulphur produces little effect beyond that of a mild and somewhat slow laxative. Externally, applied in the form of ointment, it is a powerful parasiticide, principally employed to kill the little insect that produces the itch disease. *Potassium sulphide* is a sharp irritant, and in large dose internally a corrosive poison. It may be used instead of the simple sulphur ointment as a local remedy in itch and in other skin diseases, and dissolved in water as a bath is used in skin disease and in lead-poisoning. In common with other sulphides it is sometimes used as a depilatory.

Revised by IRA REMSEN.

**Sulphurets**: See SULPHIDES.

**Sul'phuretted Hydrogen**, called also **Hydrosulphu'ric** [*hydrogen + sulphur*] **Acid**, etc.: a gas, $H_2S$, analogous to water, $H_2O$. It was first discovered by Rouelle the younger, but Scheele first ascertained its nature and properties. Sulphuretted hydrogen is emitted naturally by mineral springs and from volcanoes, and in combination with ammonia is evolved in the putrefaction of animal and vegetable matters. The smell of rotten eggs and that of a privy, generally attributed to sulphuretted hydrogen itself, are due chiefly to the compound it forms with ammonia or sulphide of ammonium. Artificially this gas is prepared by the action of a dilute mineral acid on certain metallic sulphides, of which ferrous sulphide of commerce is the one generally employed, though the native sulphide of antimony may also be used. If hydrogen gas be passed through melted sulphur this compound is formed, and a convenient way to evolve sulphuretted hydrogen for laboratory use is to melt together in a flask sulphur and paraffin. When pure, sulphuretted hydrogen is a colorless gas of an intense odor, somewhat recalling that of bitter almonds, which produces immediate vertigo in the case of some persons and acts as a deadly poison upon some animals even in very small proportion. Many persons will, however, inhale it in diluted form without much apparent effect for a considerable time, so that it can not be regarded as necessarily a dangerous poison in the case of mankind, though its unnecessary inhalation in quantity ought to be avoided. The density of the gas is 1·175, air being unity. Faraday reduced it by compression to a liquid whose density he gives as about ·9. The solubility of the gas in water is given by Bunsen as 4·37 per cent. of its volume at freezing, and about 3·2 per cent. at normal temperature. Alcohol takes up about three to four times as much as water. It is combustible, with a blue flame, burning to water and sulphurous dioxide. This gas is a very important reagent in the laboratory for precipitating metals from their solutions in processes of analysis and in many processes of preparation of organic compounds in pure state, particularly in cases of organic acids, which are first converted into lead salts, to be decomposed afterward by sulphuretted hydrogen.

Revised by IRA REMSEN.

**Sulphu'ric Acid and Sulphates**: a compound of sulphur, $H_2SO_4$, and its forms of combination with metals. Sulphuric acid is called also *oil of vitriol*, from its having been originally obtained by distillation from *vitriol*, or sulphate of iron. This acid was probably known to the Arabian protochemists. Basil Valentine, however, is the first known author who, writing in the fifteenth century, mentions the making of sulphuric acid by distilling iron sulphate. The manufacture by burning sulphur, as now practiced, was introduced in England by Dr. Roebuck about 1720. The general method is to burn sulphur, either as brimstone or in the form of metallic sulphides, as pyrites, in a draught of air, which is passed into very large chambers built of metallic lead, where the sulphurous oxide gas formed by the combustion is mixed with steam and a quantity of nitrous fumes evolved from a mixture of saltpeter or sodium nitrate with sulphuric acid. The oxides of nitrogen in the presence of water oxidize the sulphurous acid to sulphuric acid and are themselves reduced to lower forms which, in the presence of air, are converted into higher oxides, among which is nitrogen peroxide $NO_2$, and these again react with sulphurous acid, so that the operation of a limited amount of nitrous fumes is continuous, acting as a carrier of oxygen to the sulphurous dioxide without consumption of its own substance. The product precipitates with condensing steam upon the walls and floors of the leaden chambers as diluted sulphuric acid, which is then concentrated to oil of vitriol—first, in pans of lead, and when it has become strong enough to attack these, the boiling down is completed in large stills made of glass or platinum.

Sulphuric acid when fully concentrated has a density at 0° C. of 1·846. It is an oily, colorless, inodorous liquid, which boils at 620° F. and freezes at −31°. It absorbs water rapidly from the air, being one of the most useful agents in the laboratory for drying air and for absorbing moisture from other substances, which are for this purpose simply placed in a confined space with a quantity of oil of vitriol, which, through the medium of the air, will gradually abstract all the moisture from such substances. When mixed with water, great heat is developed.

*Nordhausen*, or *Fuming Sulphuric Acid*.—This is the acid obtained by distilling ferric sulphate. It has the composition $H_2S_2O_7$, and is considered by some chemists as containing sulphuric trioxide $SO_3$ or as $H_2SO_4.SO_3$, but this seems hardly in accordance with the fact that it crystallizes as a whole in transparent crystals at zero. When gently heated, however, it breaks up into sulphuric oxide, which distills over and condenses as a solid body, and ordinary oil of vitriol, which remains behind in the retort. Its name of *fuming* acid comes from the fact of its forming white fumes in the air, due apparently to the evolution of vapor of $SO_3$ even at ordinary temperatures. Fuming oil of vitriol is used in the laboratory for dissolving indigo and as a reagent in gas analysis, to absorb the illuminant hydrocarbons from ordinary coal-gas.

*Diluted Sulphuric Acid*.—It is very useful in chemical and technical operations to be able to determine the strength of a dilute acid from its density as taken with the hydrometer. The following figures are condensed from tabulated determinations of densities of dilute sulphuric acid by J. Kolb:

| DEGREES BAUMÉ. | Densities. | $SO_3$ in 100 parts. |
|---|---|---|
| 1 | 1·007 | 0·7 |
| 5 | 1·037 | 4·7 |
| 10 | 1·075 | 8·8 |
| 15 | 1·116 | 13·2 |
| 20 | 1·162 | 18·0 |
| 25 | 1·210 | 23·2 |
| 30 | 1·263 | 28·3 |
| 35 | 1·320 | 33·9 |
| 40 | 1·383 | 39·5 |
| 45 | 1·453 | 45·2 |
| 50 | 1·530 | 51·0 |
| 55 | 1·615 | 57·1 |
| 60 | 1·711 | 63·8 |
| 65 | 1·819 | 73·2 |
| 66 | 1·842 | 81·6 |

*Uses of Sulphuric Acid.*—Among those materials and products of science and art that constitute the main pillars of modern civilization sulphuric acid occupies incontestably a first rank. Probably none other except iron could be justly ranged with it in this regard. This will appear on a mere enumeration of some of the principal products necessary to human life, health, comfort, luxury, or necessity which are dependent, directly or indirectly, upon sulphuric acid as an essential agent in their production: *soda* from common salt, and through this, *glass, soap, sodium, aluminium, magnesium*; *nitric* and *hydrochloric acids*, upon which depend the arts of *refining gold and silver* for money and jewelry, with the *electroplater's* and *photographer's* arts; artificial *mineral waters*; all the *vegetable acids* and *alkaloids*; *alum*; *ammonia*; *ultramarine*; the *aniline colors*; *bleaching-powder*; *chrome compounds*; *chloroform* and *ether*; *phosphorus* and *matches*; *artificial fertilizers*; *kerosene*; and so on.

*Sulphates.*—Among the compounds of sulphuric acid with metals are many of commercial value and importance which are described under the heads of the different metals. The following is a more complete enumeration:

*Aluminium Sulphates.*—Of these there are several, some of which occur as native minerals. The normal sulphate is $Al_2(SO_4)_3.18H_2O$, constituting the mineral *alunogen.* The alums (see ALUM) are double salts of normal aluminium-sulphate with the sulphates of potash, ammonia, or soda, containing 24 equivalents of crystal-water.

*Ammonium Sulphate*, $(NH_4)_2SO_4$.—A commercial salt of great importance, anhydrous, not deliquescent, made largely from the ammoniacal liquor of gasworks, and used as a fertilizing agent.

*Barium Sulphate*, the mineral *barite*, *barytes*, or *heavy spar* ($BaSO_4$).—Insoluble in water, very heavy: densities, 4·123 and 4·554. The source of most commercial barium compounds. It is ground, purified, and sold largely as a pigment or inferior substitute for white lead.

*Calcium Sulphates*; the *anhydrite* mineral is $CaSO_4$.—It is orthorhombic. Minimum and maximum densities, 2·911 and 3·104. See GYPSUM and SELENITE.

*Cobalt Sulphate* ($CoSO_4.7H_2O$).—The mineral *bieberite.*

*Copper Sulphate* ($CuSO_4.5H_2O$).—*Blue vitriol*, an important commercial salt. Crystals triclinic.

*Iron Sulphates* ($FeSO_4.7H_2O$).—*Copperas* or *green vitriol.* A large article of commerce. Crystals monoclinic. This is *ferrous sulphate. Ferric sulphate* (normal) is $O_{12}S_3Fe_2.9H_2O$, as the mineral *coquimbite.* There are many basic ferric sulphates.

*Lead Sulphate* ($PbSO_4$).—The mineral *anglesite.* Splendid orthorhombic crystals. Minimum and maximum densities, 6·2 and 6·42.

*Magnesium Sulphate, Epsom Salt* ($MgSO_4.7H_2O$). See MAGNESIUM.

*Manganese Sulphate* ($MnSO_4.7H_2O$).—Monoclinic, like green vitriol.

*Mercury Sulphates.*—Mercurous sulphate is $Hg_2SO_4$, and mercuric sulphate is $HgSO_4$. The former is insoluble, like calomel or mercurous chloride; the latter soluble, like corrosive sublimate or mercuric chloride. The mercuric salt is obtained by boiling mercury with oil of vitriol.

*Nickel Sulphate* ($NiSO_4.7H_2O$).—Very beautiful green crystals, right rhombic and isomorphous with Epsom salt. This salt, of much commercial importance by reason of its large use in nickel-plating, is liable to contain iron and copper as impurities, both wholly destructive to its usefulness.

*Potassium Sulphate* ($K_2SO_4$).—A hard anhydrous salt, crystals trimetric; minimum and maximum densities, 2·423 and 2·888. Much less soluble than other potash-salts generally. Water at 0° C. dissolves but 8·36 per cent. It is a considerable article of commerce for fertilizing purposes, for which it has great power.

*Silver Sulphate* ($Ag_2SO_4$).—Trimetric crystals, turned green by light. Requires as much as 200 parts of cold water for solution.

*Soda Sulphate* or GLAUBER'S SALT (*q. v.*).

*Strontium Sulphate* ($SrSO_4$) forms the beautiful mineral *cœlestine*; trimetric. Densities, minimum and maximum, 3·589 and 3·992.

*Uranium Sulphate* ($U_2SO_6.3H_2O$).—Small lemon-yellow prisms.

*Zinc Sulphate* ($ZnSO_4.7H_2O$), *White Vitriol*, also the mineral species *goslarite.*—Orthorhombic and isomorphous with nickel-sulphate and Epsom salt.

Sulphur forms with oxygen two compounds: sulphur dioxide ($SO_2$), that combines with water to form SULPHUROUS ACID (*q. v.*), and sulphur trioxide ($SO_3$), that combines with water to form SULPHURIC ACID (*q. v.*). Salts of sulphurous acid are called sulphites, and salts of sulphuric acid are called sulphates. Also there is known in combination sulphur sesquioxide ($S_2O_3$), which is contained in hyposulphurous acid ($H_2S_2O_4$), whose salts are called hyposulphites, and sulphur heptoxide ($S_2O_7$), which is contained in persulphuric acid ($H_2S_2O_8$), whose salts are called persulphates. Thiosulphuric acid was formerly called hyposulphurous or hyposulphuric acid, and its salts hyposulphites or hyposulphates.

Revised by IRA REMSEN.

**Sulphuric Ether**: See ETHER.

**Sul'phurous Acid**: an acid formed when sulphurous dioxide gas is passed into water. A crystalline hydrate, $H_2SO_3.6H_2O$, was obtained by Schönfeld. Sulphurous acid is a strong reducing agent. It deoxidizes iodic, arsenic, chromic, and permanganic acids and gold chloride, precipitating metallic gold from the latter.

*Sulphites.*—Of these the sulphites of calcium and of sodium only are of much practical interest, they being prepared commercially to some extent for bleaching and for the prevention of fermentation of wines, sirups, and other organic liquids. There are two soda-salts—one neutral, $Na_2SO_3$, and one acid, $HNaSO_3$. The latter is obtained as a crystalline precipitate on cooling a warm solution of sodium carbonate which has been supersaturated with sulphurous oxide gas. This salt is used as a reagent. Sulphites that contain an additional atom of sulphur are called hyposulphites, as sodium hyposulphite ($Na_2S_2O_3$), which is used in medicine for febrile diseases and in dyspepsia. Revised by IRA REMSEN.

**Sulphurous Oxide, Sulphur Dioxide**, or **Sulphurous Anhydride**: the gaseous substance ($SO_2$), formed by the combustion of sulphur in the air. Even in pure oxygen the same compound is formed. It is emitted by volcanoes. It may be obtained artificially, in a pure state, by heating oil of vitriol with some metals, copper and mercury being among these. Sulphate of the metal and water are at the same time formed: $Hg + 2(H_2SO_4) = HgSO_4 + 2H_2O + SO_2$. It is also obtainable pure by heating together sulphur and sulphuric trioxide, $SO_3$, in one limb of a sealed U-tube. It then appears as a liquid, condensed by the pressure, in the other limb. Sulphurous oxide is colorless, with the well-known suffocating odor. Bunsen gives its density as 2·21122 (air being 1), and its solubility in water as about 69 per cent. of the volume of the latter at zero, and 41 per cent. at normal temperature. Alcohol at zero takes up nearly five times as much as water. A pressure of about three atmospheres, or the cold of snow and salt, condenses it to a liquid, which produces so much cold in its evaporation as to freeze water when poured upon it. Sulphurous oxide has strong bleaching power over most vegetable colors, and is therefore used for bleaching. See REFRIGERATING PROCESSES.

Revised by IRA REMSEN.

**Sulphur Springs**: city; capital of Hopkins co., Tex.; on the St. L. S. W. and the Sherman, Shreveport, and S. railways; 80 miles E. by N. of Dallas (for location, see map of Texas, ref. 2–J). It is in an agricultural region, and contains Central College (Methodist Episcopal South, opened in 1876), 2 national banks with combined capital of $200,000, and 4 weekly papers. Pop. (1890) 3,038; (1900) 3,635.

**Sulpic'ia**: (1) a Roman poetess, probably the daughter of Servius Sulpicius Rufus, and niece of Messalla, to whom are attributed a group of six charming elegies, describing

the love of Sulpicia and Cerinthus, which have been preserved among the poems of Tibullus (book iv., 7–12). (2) A poetess contemporary with Martial, and highly praised by him. Her poems were amatory, and in various measures. The extant poem known as *Sulpiciæ satira*, in seventy hexameters, supposed to refer to the banishment of the philosophers by Domitian, must belong to a much later period, and is by some scholars regarded as a modern forgery. See E. Baehrens, *De Sulpiciæ quæ vocatur satira* (Jena, 1873), who also gives the text, and J. G. Boot (same title, Amsterdam, 1868).
M. WARREN.

**Sulpic'ians**: a Roman Catholic congregation of priests founded in Paris in 1642 by Abbé J. J. Olier. They were confirmed in 1645. They have (1895) several houses in France, one in Rome, one in Canada, and three in the U. S. Their chief work is the training of young men for the priesthood. They are properly called the Society of St. Sulpice, from the parish where they were first organized.
Revised by J. J. KEANE.

**Sulpic'ius** (or **Sulpitius**) **Severus**: ecclesiastic and author; b. in Aquitania about 365 A. D., though the precise date is not known. He was descended from a noble family, and in his youth had a career of distinction at the bar and in public life open before him. The loss of his wife, to whom he was greatly attached, led him to abandon, about 392 A. D., the career on which he had entered, and to give himself up to solitude and religious meditation. He entered the Church; became a presbyter and a devoted admirer of St. Martin of Tours, whose life he wrote. The date of his death is not known, but it was probably about 425. His chief writings are *Chronica*, in two books, from the Creation to A. D. 400, *Vita S. Martini*, *Tres Epistolæ*, all relating to his patron St. Martin, and a sort of continuation of the *Life*; *Dialogi duo* (in some editions *tres*); to these are added *Epistolæ Septem*, though doubtfully ascribed to Sulpicius. The best editions of his collected works are that of de Prato (2 vols. 4to, Verona, 1741–54) and that of Halm (8vo, Vienna, 1866), in which the seven doubtful epistles are given as an appendix. His complete works were translated by Alexander Roberts in vol. xi., 2d series, *Nicene and Post-Nicene Fathers* (New York and Oxford, 1894).
Revised by M. WARREN.

**Sultan**: a title; first used by Mahmud of Ghazni (997–1030). It is assumed by many Mussulman sovereigns, as the rulers of Zanzibar, Borneo, etc., and is the common European appellation of the sovereign of the Ottoman empire, who is sultan of sultans, though commonly called by his Mussulman subjects *Padishah*. The feminine, sultana, is applied to the mother or daughter of a sultan. The masculine form precedes the name, as Sultan Mahmud; the feminine follows, as Nachshedil Sultana. E. A. GROSVENOR.

**Sulte**, BENJAMIN: See the Appendix.

**Sulu** or **Suluk Islands**: a group of 162 small, mountainous, fertile islands in the Indian Ocean, extending from Borneo to Mindanao; between lat. 4° 44′ and 6° 56′ N., and lon. 119° 30′ and 122° 30′ E. Area, 1,948 sq. miles. Pop. 75,000, mostly Malays, addicted to piracy and the taking of slaves till conquered by the Spaniards in 1876, and since then chiefly engaged in pearl-fishing and collecting edible birds' nests. The islands yield sandalwood, teak, sugar, rice, coffee, spices, metals, and fish. The largest island is Basilan (450 sq. miles), adjoining Mindanao on the N. Spain's claim to these islands was recognized by the powers in 1885, and they were ceded to the U. S. by the treaty of Dec. 10, 1898.

**Su'mach**, or **Sumac** [= Fr., from Arab. *summāq*]: any plant of the genus RHUS (*q. v.*), which includes about 120 species, mostly natives of warm or hot climates. In the U. S. there are about twelve species of sumachs, all of which are shrubs or small trees; of these the most common is the well-known smooth sumach (*Rhus glabra*), which is often found covering large tracts of barren ground, where it grows to a height of from 2 to 12 feet, with compound leaves a foot long. The yellowish-green flowers appear in June, and have a fragrant odor. The fruit is in dense crimson clusters with a velvety appearance and a pleasant acid flavor; the leaves are among the earliest to take on their autumn colors of yellow and scarlet. The stag's-horn sumach (*R. typhina*) sometimes reaches the height of 30 feet, and is readily distinguished by the soft down at the extremity of the branches. The dwarf sumach or mountain sumach (*R. copallina*) is rarely more than 6 or 8 feet high, with dark shining leaves, which in autumn become a rich purple. A still more diminutive species (*R. pumila*) is found in the pine-barrens from North Carolina southward. The fragrant sumach (*R. aromatica*) ranges from Vermont to Florida, and as far westward as the Rocky Mountains; its leaves are among those which are smoked by the Indians in lieu of tobacco under the name of killikinick. The *Toxicodendron* group of the sumach family includes two species, with white or dun berries and a very poisonous foliage, the poison-oak and the poison-ivy. (See RHUS.) The sumach of commerce formerly consisted of the leaves of the *R. coriaria*, closely resembling the North American stag's-horn sumach, which is largely cultivated in Sicily, and used in tanning, dyeing, and calico-printing; but it has been proved that the sumachs of the U. S. are quite as valuable, and the collection and preparation of the leaves has become an important industry in parts of the South. The Japan wax is yielded by the *R. succedanea*, being prepared from the white coating of the seeds within the capsules. The Japanese lacquer is prepared from the juice of *R. vernicifera*, a shrub closely resembling the poison-sumach of the U. S. The Chinese galls are the result of the deposition of the eggs of an insect on the leaf-stalks and young shoots of *R. semialata*, and are largely imported into England for dyeing and tanning. See SUMACH FAMILY and LEATHER.
Revised by CHARLES E. BESSEY.

**Sumach Family**: the *Anacardiaceæ*; a small group (430 species) of mostly tropical, dicotyledonous trees and shrubs, with a gummy or milky-resinous juice. The small flowers have three to seven sepals, three to seven petals, with as many or more stamens, and a superior, monocarpellary, one-ovuled ovary. The native species of the U. S. are all sumachs. Important tropical representatives are the cashew-nut of the West Indies, the pistachio-nut (*Pistacia vera*) of Syria, the mastic-tree (*P. lentiscus*) of Southern Europe, the mango-tree (*Mangifera indica*) of the East Indies, and a Peruvian tree (*Schinus molle*) very freely grown in California and other mild climates under the name of pepper-tree. See SUMACH and RHUS. CHARLES E. BESSEY.

**Sumaro'kov**, ALEKSANDR PETROVICH: author; b. in Moscow, Russia, Nov. 14, 1718; first attracted attention by his tragedy of *Khorev* (1747), followed by *Sinav i Truvor* and *Semira*, which increased his fame. From 1756 to 1761 he was director of the newly founded court theater in St. Petersburg, after which he devoted himself exclusively to literature, being the first Russian writer to have no other profession. D. Oct. 1, 1777. Sumarokov's place in the literary history of his country is far greater than his talent as an author would alone justify. Though his satires and his tragedies were little more than spiritless imitations of the French, his comedies of even less merit, his eighty or so odes, his sonnets, madrigals, epigrams, fables, etc. (produced in acknowledged rivalry with Voltaire's many-sidedness), of almost no value at all, he was still the father of the Russian drama. His style is clear, and on the whole unaffected; he was a pioneer who led the way for greater men than himself, and his influence as a critic was of value in forming the public taste. Second edition of complete works 1787; French translation of his tragedies by M. L. Pappadopoulo 1801.
A. C. COOLIDGE.

**Suma'tra**: island; extending from N. W. to S. E., between lat. 5° 45′ N. and 5° 55′ S., and between lon. 90° 40′ and 105° 5′ W., divided by the equator into two equal parts; extreme length, 1,115 miles; extreme breadth, 275 miles. Its area has been computed at 162,608 to (with coastal islands) 170,780 sq. miles (see map of East Indies).

*Physical Features and Climate.*—Through its whole length Sumatra is traversed by a mountain range, Bukit Barissan, which reaches its greatest height, 9,655 feet, in Ophir, in lat. 0° 4½′ N., lon. 100° 1′ E. The range runs as a narrow ridge nearer to the western than to the eastern coast; a true mountain region is formed only in the center of the island, where some ranges run transversely. The principal rocks are granite, syenite, gneiss, mica-slate, and red sandstone, none of which are found in Java, whose geological and chorographical formation is entirely different from that of Sumatra. Six volcanoes are known, situated near the equator. The southeastern part is rich in streams, navigable even for large vessels far into the interior. These streams carry large masses of mud and earth to the sea, the result of which is a considerable extension of the coast-line; at the same time the surface of the island, like that of Java and Borneo, appears to be rising slowly, but steadily. The several river systems are connected with each other by arms and canals, and on the banks, in the midst of a luxuriant vegetation, stand the towns and villages. The climate varies in the different parts of the island, but is generally healthful, with the exception of the low coast regions to the W. The heat varies on the coast between 82° and 86° F., at an elevation of from 2,500 to 3,000 feet between 64° and 73°; these highlands are known for their healthful climate. The monsoons are not so steady and regular as elsewhere. The dry season lasts N. of the equator from October to May, and S., from the end of April to the end of October.

*Natural Products.*—The natural productions are more varied and more abundant than in any of the other islands. Of metals, gold, iron, copper, and tin abound; brown coal occurs, but not anthracite. Petroleum abounds and is exported. Rice forms the principal food, then sago, beans, and roots (jolichos, batatas, and dioscoreas). The most palatable among the fruits are the mangosteen, durian, rambutan, rambei, pisang, pineapples, etc., many of which thrive only here, and can not be introduced into other countries. Of trees, the species of *Sideroxylon* (justly called *kayu* (wood) *besi* (iron), that is, iron-wood) yield the best wood for shipbuilding, it being so hard that it blunts the sharpest arrow; teak is not found. The most important plants entering into commerce are cotton, black pepper, caoutchouc, benzoin, gutta-percha, dyestuffs, and camphor, for which the island was celebrated among the ancients. The Dutch have introduced coffee, tobacco, and cacao. The fauna, Indian in its general character, corresponds nearer to that of Borneo than to that of Java. Of mammals there are eighty species, among which are the elephant, rhinoceros, tapir, tiger, panther, and bear; among the ruminants, the *Cervus equinus* is noticeable; among the many species of apes are the orang utan and two gibbons, the siamang (*Hylobates syndactylus*) and the wau-wau (*Hylobates variegatus*); the buffalo occurs both wild and domesticated; the horse is small, but vigorous, adapted to a mountainous country.

*Population.*—The population, which was 2,972,383 in 1892, is chiefly Malayan. There are about 25,000 Europeans, mostly Dutch, some Chinese, and other Asiatic races. Sumatra was the cradle of the Malays as a nation; in the interior they founded the empire of Manang-Kaban, once very powerful. Next to them the Battas are the most important division; they formerly inhabited the country N. of lat. 1° N., but the population of Achin has separated from them, and they themselves have decreased in number, and are crowded together in a small space. The Orang Koabos live in the forests; in physical respects they do not differ from the other inhabitants of the islands, but they are uncivilized, though harmless; they are agriculturists. The Malays are all Moslems. The Battas are fetich-worshipers and addicted to cannibalism—a custom which the Dutch have tried in vain to abolish.

*History.*—Ptolemy calls the island *Aurea Chersonesus*, the Arabs *Fantsaur*; the name *Sumatra* occurs in 1330, used of the city of Samatrah. The Arabs visited Sumatra about 860 A. D.; Islamism was introduced into Achin in 1205; the Venetian merchant Marco Polo landed here in 1290; the Portuguese under Alvaro Talesso in 1506, the Dutch in 1597; an English squadron appeared before Achin in 1602. The Dutch East Indian Company established settlements on the eastern coast in 1618. Great Britain tried to compete, but was compelled in 1783 to return all its possessions in Sumatra to Holland. In 1811 it once more occupied the island, but by the treaty of Mar. 17, 1824, it exchanged all its possessions in the archipelago for the Malayan peninsula, and thus Holland became the only European power holding dominion in Sumatra. Since then the Dutch have been occupied in gradually extending their conquests over the entire island. The last to hold out were some tribes of the Battas in the interior, and about 150,000 of them were yet practically independent in 1895.

Revised by M. W. HARRINGTON.

**Sumba'wa**: an island of the Sunda islands, Dutch East Indies, E. of Java, between Lombok and Flores. Area, 5,400 sq. miles. It is high, mountainous, and volcanic. The still active volcano Tambora, on the north coast, 8,940 feet high, caused a terrible destruction by its eruption in 1815; the ashes fell in Sumatra, 840 miles distant, and in a large part of the island itself all vegetation was completely destroyed. The sea also rose and swept away men and houses. More than 12,000 people are said to have lost their lives. Another eruption, less destructive, occurred in 1836. The principal products are gold, sulphur, saltpeter, rice, various kinds of wood, and a fine breed of horses. The inhabitants, 150,000 in number and closely allied in habits and manners to those of Celebes, live in four states which are under Dutch authority. Revised by M. W. HARRINGTON.

**Sum'bul** [from Pers. and Hind. *sumbul*, spikenard]: an umbelliferous plant, the *Ferula sumbul*, indigenous to certain parts of Central Asia. It was originally thought to possess the properties of musk, and to be a nervous stimulant, or, more properly, a drug to "steady" the nervous system. In reality it is of very little value, but is popular with some physicians, who give it to nervous women in association with more powerful remedies. H. A. HARE.

**Sume'rians**: the people who are believed by most Assyrian scholars to have occupied Babylonia before the Semites appeared in that region; to have invented the cuneiform script; and to have been the teachers of the Semites, by whom they were finally displaced or absorbed. It would seem that there were two branches of this people —the Sumerians and the Akkadians. To designate the whole people, sometimes one name, sometimes the other, and sometimes the compound name, is employed. In the Sumero-Akkadian language are written some of the oldest inscriptions from Babylonia, like those discovered by de Sarzec at Telloh. There are also many bilingual productions of a later date, notably from the library of Asshurbanipal. These are mainly grammatical, lexical, magical, ritual, or religious in content. The language seems to have become a sacred tongue, like the Latin of the Middle Ages. While this account represents the prevailing view, it must be added that several eminent scholars, in particular Joseph Halévy in France and Friedrich Delitzsch in Germany, deny *in toto* the existence of a Sumero-Akkadian people or language. (Cf. J. Halévy, *La prétendue langue d'Accad*, etc. (Paris, 1875); J. Halévy, *Recherche critique sur l'origine de la civilisation babylonienne* (Paris, 1876); F. Delitzsch, *Assyrische Grammatik* (Berlin, 1889), § 25. On the other hand, cf. E. Schrader, in *Zeitschrift der deutschen Morgenländischen Gesellschaft*, xxix., 1–52 (1875); P. Haupt, *Akkadische und Sumerische Keilschrifttexte* (Leipzig, 1881–82); P. Haupt, *Die Akkadische Sprache* (Berlin, 1883).) These scholars maintain that in the so-called Sumerian or Akkadian we have not a language different from Assyrian, but genuine Assyrian in archaic form, or written in a hieratic script. The question is not one of linguistics merely, but it involves the origin of the Babylonian culture. It can not be considered definitely settled so long as the lack of agreement among specialists prevails. The vast majority of Assyrian scholars, however, feel no doubt as to the reality of the Sumero-Akkadian language and people, as A. H. Sayce, in *Hibbert Lectures for 1887*, pp. 415–436, while others hold themselves neutral, as Tiele does in his *Babylonisch-Assyrische Geschichte*, pp. 58–71. D. G. LYON.

**Sumeru**: See MERU.

**Summary Proceedings**: in a general sense, any legal proceedings, or proceedings before a judicial tribunal, which are of a summary and peremptory nature, that is, those which are short and simple, and ordinarily dispense with the aid of a jury. Such proceedings, except perhaps in cases of contempt, can be instituted only under express authority of statutory laws, which, being in derogation of the common law, must be strictly construed.

The ordinary purposes for which summary proceedings are resorted to are: (*a*) Ejectment of a tenant for non-payment of rent, or for holding over his term. Authority to bring these proceedings was first granted in England by the Statute of Laborers, followed by others down to the Summary Act of 1879, which greatly extended the power, and in the U. S. it has been granted to a greater or less extent by the statutes of the various States. (*b*) For the recovery of debts due the state of the U. S. from a collector of taxes or revenue. (*c*) For the punishment of the contempt of court. (*d*) For the punishment of many minor offenses, violations of municipal ordinances, etc., which may be proceeded against without a jury; while in respect to others, the constitutional requirements as to due process of law are satisfied if a trial by jury in an appellate court is accorded the accused.

In the U. S. statutes authorizing summary proceedings are unconstitutional and invalid when they conflict with the constitutional provisions requiring that a trial by jury shall remain inviolate. Such provisions as to the right of trial by jury did not extend the right, but prevented its being abridged. The offense to be punishable by summary proceedings must be petty or trivial, and not of a serious character affecting the public at large; nor can the right of appeal be done away with. They are usually such offenses as are punished by fines, though in some cases by short terms of imprisonment. Violations of municipal ordinances are not strictly criminal in nature, but they are generally made summarily punishable.

The procedure is statutory, and the statutes must be strictly complied with.

See McAdam on *Landlord and Tenant*; Dillon's *Law of Municipal Corporations*; Stephen's *History of the Criminal Law of England*; Cooley's *Constitutional Limitations*.
F. STURGES ALLEN.

**Summer-duck**: See WOOD-DUCK.

**Summers**, THOMAS OSMOND, D. D., LL. D.: clergyman and author; b. near Corfe Castle, Isle of Purbeck, Dorsetshire, England, Oct. 11, 1812; removed to the U. S. 1830, and prepared for the ministry; was "admitted on trial" into the Baltimore Conference of the Methodist Episcopal Church in 1835; aided in organizing the Texas Conference Dec., 1840; was transferred to the Alabama Conference; became assistant editor of *The Southern Christian Advocate*, Charleston, S. C., 1846; was secretary of the Louisville convention in 1845, at which the Methodist Episcopal Church South was organized; compiled hymn-books for the connection; was the general book-editor of the Church from its organization; founded and edited for four years *The Sunday-school Visitor*; removed to Nashville in 1855, the publishing-house being there located; edited *The Quarterly Review of the Methodist Episcopal Church South*; revised and edited hundreds of books for the Church. Dr. Summers was the author of *Commentaries on the Gospels, the Acts, and the Ritual of the Methodist Episcopal Church South* (6 vols.); a *Treatise on Baptism*, one on *Holiness, The Sunday-school Teacher, or the Catechetical Office of the Church*: *Seasons, Months, and Days*; *Talks Pleasant and Profitable*; *Refutation of the Theological Works of Paine* (not answered in Bishop Watson's *Apology*); *The Golden Censer, an Essay on Prayer*, with a collection of forms for all occasions; and of minor works. He returned Feb., 1862, to Alabama; in 1866 was re-elected general editor, and editor of *The Sunday-school Visitor*; became also editor of *The Christian Advocate*; was Professor of Systematic Theology in Vanderbilt University and dean of the theological faculty, and *ex-officio* pastor of that institution. D. at Nashville, Tenn., May 6, 1882. See his *Life*, by O. P. Fitzgerald (Nashville, Tenn., 1884).
Revised by A. OSBORN.

**Summerside**: port of entry in Prince County, Prince Edward island (see map of Quebec, etc., ref. 1–B). It is the second town in size in the province, and has a good harbor, rather difficult of access, a large export trade, considerable ship-building, a public hall, and several manufactories. Pop. (1891) 2,882.

**Summers's** or **Somers's Islands**: See BERMUDA ISLANDS.

**Summerville**: town; Dorchester co., S. C.; on the S. C. and Ga. Railroad; 22 miles N. W. of Charleston (for location, see map of South Carolina, ref. 7–F). It is a noted winter resort for invalids, on a pine-clad ridge extending from the Cooper to the Ashley rivers, and contains several hotels and boarding-houses, brick-works, sawmills, and a weekly newspaper. Pop. (1890) 2,219; (1900) 2,420.

**Sumner**, CHARLES: scholar and Senator; b. in Boston, Mass., Jan. 6, 1811, educated at the Boston Public Latin School and at Harvard College, where he graduated in 1830. He was a recluse and studious boy, seldom joining in any amusement or athletic games; and this mood lasted through his college years. Though a diligent student, he gave more attention to general literature than to the special studies of the university. After his graduation he gave a year to science, belles-lettres, history, and art. In 1831 he joined the Harvard Law School, then under the charge of Judge Story, and entered on his studies with enthusiasm, renouncing all other subjects, and giving himself, without any relaxation, to a profound study of law. This devotion gained him the warm friendship of Story, who treated him as a son. Admitted to the bar in 1834, he visited Washington with such earnest letters of introduction from Story as secured him the friendship of Kent, Horace Binney, Judge Marshall, and others, who frankly expressed their wishes that before long he should find his place on the bench. Appointed by Story reporter to his circuit court, he published three volumes of Story's *Decisions*, and often supplied his place as lecturer at the law school, where he was himself lecturer from 1835 to 1837 and in 1843. In 1836 he edited Dunlap's *Admiralty Treatise*. In 1837 he went to Europe with numerous letters of introduction; was received with most flattering attention, and became personally acquainted with almost every leading man and woman in Europe. While his days were passed in society and galleries, his nights were spent in study, for he early showed that almost incredible power of working which distinguished him through life. Returning in 1840 from Europe, he again opened a law office, and, with J. C. Perkins, edited twenty volumes of Vesey's *Reports*. It was during this labor that his health broke down, and an illness followed which nearly proved fatal. He could have had, after Story's death (1845), his professorship at the law school, but declined it. In 1845 he was chosen by the city of Boston to pronounce the Fourth of July oration, and took for his subject the *True Grandeur of Nations*. This was a plea for peace, and was bitterly criticised at home, though welcomed abroad, and pronounced by Cobden "the most noble contribution made by any modern writer to the cause of peace." His protest against war he repeated frequently in later years.

Favorite as he had been, and great as was his promise at the bar, his decided anti-slavery position created a resolution to crush him socially and professionally. This hostility pervaded Boston society, her merchants, and the Suffolk bar till the civil war broke out. Sumner valued his social position very highly. He had not inherited it, but had himself achieved it. It is unspeakably to his credit that, when he saw this long-coveted and hardly earned distinction and all his professional prospects crumbling around him, though too fond perhaps of praise and keenly sensitive to blame, he never retreated an inch or remodeled a phrase to regain his place or conciliate opposition. From this moment, however, he was recognized as the leader of the young men of the Commonwealth, and hidden in their hearts. No matter that in after years the Legislature censured, the press abused, and politicians criticised him. He always had, to the day of his death, the hearty, entire, steadfast, and loving confidence of the young men of Massachusetts. This explains his strength and influence in years when, judging of public opinion by the ordinary signs, he seemed to have lost his hold and to be near defeat.

In 1849 he maintained before the Supreme Court of Massachusetts the unconstitutionality of separate schools for whites and blacks. The decision was against him. In 1851, by a coalition between Free-Soilers and Democrats, he was elected Senator of the U. S., the first civil office, and the only one, he ever held. There were twenty-six ballotings, and the struggle lasted three months. He took his seat Dec. 1, 1851. Once in the Senate, the force of his will, the almost entire devotion of his time to one cause, the aggressive attitude he took, and the vigor and ability of his incessant assaults, made him indisputably the leader of the political anti-slavery movement.

In Aug., 1852, he began his congressional assault on slavery by an argument for the repeal of the Fugitive Slave law, entitled *Freedom National—Slavery Sectional*. This phrase became the watchword of his party, and gives the key to most of his later arguments. In May, 1856, he made one of his ablest speeches, *The Crime against Kansas*, advocating the admission of that State to protect it from slavery. His comments on the conduct of several Senators who had taken a part in the debate, especially Butler of South Carolina, Douglas of Illinois, and Mason of Virginia, and his indignant reply to their personal attacks on himself, led to a scene which Sir George C. Lewis characterized as "the beginning of the civil war." On May 22, 1856, Preston S. Brooks, a nephew of Senator Butler, and one of the Representatives from South Carolina, approached Sumner while writing at his desk in the Senate chamber and struck him, without warning, repeatedly over the head with a heavy cane. Sumner, blinded by the blows, strove to rise and free himself from the restraint of the desk. He succeeded in wrenching it from the floor, to which it was screwed, but fell unconscious from the repeated blows. The indignation at the North was wide and hot, but while Massachusetts and the North generally thrilled with indignation, leading citizens of Boston refused to take part in meetings called to protest, and when Sumner returned to Boston, Nov. 3, 1856, though received by crowds in the streets and by the State authorities, the windows of every house in Beacon Street, through which he passed, except those of Prescott and Samuel Appleton, had their blinds closed to show indifference or contempt.

His injuries proved more serious than was at first supposed. Illness detained him nearly four years from Congress, with the exception of one brief attempt in the winter of 1857–58 to attend the Senate sessions, to which he found himself unequal. Two visits to Europe, rest, and the best medical skill of both hemispheres enabled him at last to resume his seat on Dec. 5, 1859. On Jan. 13, 1857, during his illness, he had been elected unanimously by the Senate, and almost unanimously by the House of Representatives of Massachusetts, to the senatorship. Again in Jan., 1863, and subsequently in 1869, he was re-elected, passing the last twenty-three years of his life in the Senate.

His attention was by no means given exclusively to slavery. His speeches cover all topics of national importance, and are always able. He took a leading part in all great debates. His speech in Jan., 1862, advocating the surrender of Mason and Slidell, taken from the British mail-steamer Trent, is a masterly exhibition of maritime law, and did much to reconcile the republic to that distasteful course. His speech on the Alabama claims in 1869, bitterly offensive to all his English friends and severely criticised by John Bright, was undoubtedly a fair representation of opinion in the U. S., and was the basis of final settlement. His addresses on the constitutional law respecting seceding States, on reconstruction, the war powers of the Government, international relations, internal improvements, etc., exhaust the subjects of which they treat. His sketches of Story, Allston, Granville Sharpe, Lincoln, and Lafayette show rare powers of portraiture. His articles on *White Slavery in the Barbary States*, *Prophetic Voices concerning America*, and other literary efforts, show good taste, ingenious research, and exact scholarship.

Worn down by the labor and excitement of the session, and by a return of the illness which Brooks's assault produced, he again sailed for Europe on Sept. 5, 1872, returning in November. In May, 1872, he had moved in the Senate that the names of victories in the civil war should not be inscribed on the regimental flags. On Dec. 2, 1872, the first day of the session, he again introduced a similar resolve to the Senate. For this he was censured by the Legislature of Massachusetts Dec. 18, 1872. This was rather a political trick than any real expression of Massachusetts feeling. The censure was rescinded the last month of his life. During this session of 1872–73, and the following one, he gave most of his time to his Civil Rights Bill, which puts the Negro on the exact level of the white in respect to inns, juries, schools, churches, public conveyances, and all civil privileges. His health was much broken, however, and an attack of his old malady, agony of the chest, in the Senate Mar. 10, 1874, proved fatal in his own house at Washington on Mar. 11, 1874. Almost his last words were addressed to Judge Hoar: "Take care of my Civil Rights Bill."

His natural powers were not of the highest order. "Industry was his talisman." He knew how to work, and had, as he said of Story, "the genius for labor." In mind he was more like Story, trained to exhaustive research and clear statement, than like Kent and Marshall, born lawyers. In preparing to write or speak he ransacked libraries, laying under contribution all ages and tongues. He had read everything and listened to everybody. His memory never lost a phrase or a fact he had once heard, and could always recall it at the right moment. His wealth of illustration was no effort, but the natural action of a full and ready mind. When first in the Senate his speeches were carefully prepared and written out. It took him five to seven years to acquire the power of extemporaneous debate; but to the last he usually wrote out his speeches. It has been generally supposed he was a mere scholar, fit only for investigation or debate. In truth, no man in Congress was more methodical, exact, painstaking, prompt, and efficient in attending to the details of business pertaining to his office. His eloquence belongs to the school of Burke, whom he liked to be thought to resemble, as indeed he did in features. His speeches had more learning than Burke cared to show, but in wealth of illustration, gorgeous rhetoric, lofty tone, and a "gigantic morality which treads all sophistry under foot," the resemblance was close. His real power lay in the sincerity and fiery enthusiasm of the speaker, whose whole soul freighted his words, and in the fact that there was "always a man behind the speech." He did not know what fear was. Alone in Baltimore on Apr. 18, 1861, he yielded nothing to that mob which the day after shot down the Massachusetts troops. For ten years he walked Washington streets, his life constantly threatened, and well knowing that if a fanatic's or drunkard's hand took his life the assassin would not only be sheltered by the power of ten States, but petted and applauded as a champion. When he entered the Senate, free speech could not be said to exist there. To him, as much as to any man, was due the breaking of that chain. Sumner was exact in all etiquette, careful in dress, fond of society, easy of access, and had always time for every comer, his hours of study running to midnight and long after. His manner was always courteous, but in his last years had a marked tenderness. To the very last day of his life he was a loving student of the classics of all languages; a "bite of the classics" being his preparation for bed somewhere about two or three o'clock in the morning. He cultivated art, and was a diligent collector of autographs, pictures, rare books, bronzes, and other objects of *virtu*, most of which he bequeathed to the Art Museum of Boston and to Harvard College. To the college library he also gave half of his estate. He was married Oct. 17, 1866, to Alice (Mason) Hooper, widow of W. S. Hooper, of Boston. They separated very soon, and he was divorced May 10, 1873. His complete works were published in 15 volumes (Boston, 1870–83). Eleven of the volumes, with copious notes, were published under his own supervision. For full details of his life, see Pierce's *Life of Charles Sumner* (4 vols., Boston, 1877).

Revised by C. K. Adams.

**Sumner**, Charles Richard, D. D.: bishop and author; b. at Kenilworth, Warwickshire, England, Nov. 22, 1790; educated at Eton and Cambridge (B. A. 1814): took holy orders; became curate of Highclere 1816; librarian and historiographer to George IV. and chaplain to his majesty's household at Carlton House, London, and rector of Abingdon—all in 1821; was made prebendary of Worcester in 1822 and of Canterbury in 1825; dean of St. Paul's and Bishop of Llandaff 1826; in 1827 was transferred to the more important see of Winchester, which he resigned in 1869 on account of the infirmities of age. He published *Prælectiones Academicæ Oxon. habitæ* (London) and the *Ministerial Character of Christ Practically Considered* (1824), besides several *Charges*, and edited in the original and translated the long-lost Latin manuscript of Milton, *De Doctrina Christiana* (1825), which gave occasion to Macaulay's brilliant essay on Milton. He was a brother of John Bird Sumner, Archbishop of Canterbury. D. at Farnham Castle, Surrey, Aug. 15, 1874. His *Life*, by G. H. Sumner, appeared in 1876 (London). Revised by S. M. Jackson.

**Sumner**, Increase, LL. D.: jurist; b. at Roxbury, Mass., Nov. 27, 1746; was admitted to the bar in 1770, and began practice in his native town; was representative in the Legislature 1776–80, State Senator 1780–82, associate judge of the Supreme Court 1782–97, Governor of Massachusetts 1797–99, and in 1789 member of the convention for the adoption of the U. S. Constitution. D. at Roxbury, June 7, 1799.

**Sumner**, William Graham, LL. D.: economist; b. at Paterson, N. J., Oct. 30, 1840; prepared for college at Hartford (Conn.) grammar school; graduated at Yale College 1863; traveled in Europe, residing at Geneva during winter of 1863–64; studied philosophy at the University of Göttingen 1864–66, and at Oxford, England; was tutor in Yale College 1866–69; took orders in the Protestant Episcopal Church Dec. 29, 1867; was for a time assistant minister of Calvary church, New York; appointed Professor of Political and Social Science at Yale College 1872. Among his works are a *History of American Currency* (1874); *Collected Essays in Political and Social Science* (1885); *Protectionism, the System which teaches that Waste makes Wealth* (1885); *The Financier and Finances of the American Revolution* (1891); and *Robert Morris* (1892).

**Sumptuary Laws** [from Lat. *sumptua'rius*, deriv. of *sumptus*, expense, extravagance]: laws which seek to restrict and regulate private expenditures, and generally are aimed at extravagant outlays for food, for clothing, or for funerals. Such laws were enforced, in past centuries, by every nation of the Old World, and have been indulged in, to some extent, even by the modern States of North America. For example, Massachusetts thought it necessary at one time to regulate by legislation the cost of funerals. These laws have flourished most abundantly in the periods of transition from semi-barbarism to civilization. Witness the legislation of Lycurgus and of Solon, in Greece, that of the Roman republic especially from the Twelve Tables to the second century before Christ, and that of modern European states during the thirteenth, fourteenth, and fifteenth centuries.

The reason for this is twofold: First, public opinion among the governing class does not keep pace with the rapidly increasing conveniences and refinements of life, but insists upon tabooing them as conducive to effeminacy. Second, the state has unlimited confidence in its strength and wisdom and undertakes to guard its subjects with paternal care. Some of the most interesting specimens of sumptuary legislation in modern Europe are found among the laws of Frederick II. in Italy, of Edward III. in England, and of Philip IV. in France. One of these statutes (10 Ed. III., st. 3), ordaining that no man should be served at dinner or supper with more than two courses, except upon certain great holidays, when he might be served with three, was not repealed until the nineteenth century.

This kind of legislation is condemned generally by modern political science. Adam Smith declares, "It is the highest impertinence and presumption in kings and ministers to pretend to watch over the economy of private people and to restrain their expense, either by sumptuary laws or by prohibiting the importation of foreign luxuries." Roscher, however, contends that while such laws are at present useless or harmful, they have proved salutary at times, citing in support of his views the laws of Florence in the fifteenth century against extravagant outlays upon personal pleasures, which, he believes, tended to promote indulgence in the nobler luxury of building churches and palaces, of collecting libraries, and of encouraging artists; and the laws of the Roman empire which drove the most odious forms of vice under cover.

During the sixteenth and seventeenth centuries the motive of sumptuary legislation underwent a change. It was enacted not so much from a benevolent regard for the spendthrift as from commercial and police considerations. English legislators, for example, prohibited the wearing of silk on garments, not with a view to limit personal expenditures, but to promote domestic manufactures of wool. In various countries laws wearing a sumptuary appearance were passed for the purpose of maintaining class distinctions. The latest piece of true sumptuary legislation in Great Britain is the Scotch luxury law of 1621. In our day the term sumptuary is often applied to laws curtailing or prohibiting the liquor traffic. They are dealt with by the courts, however, as police regulations. Under the Federal and State constitutions of the U. S., with their special guaranties of individual liberty, it is held that the habits, occupation, food and drink—the life of the individual—are severally matters for his own determination. They can be abridged by the majority of the people, speaking through the Legislature, only when the public safety, the public health, or the public protection requires it. The constitutional guaranty of life, liberty, and the pursuit of happiness can be limited only by the absolute necessities of the public. *Intoxicating Liquor Cases*, 25 Kan. 751, 765; *Mugler* vs. *Kansas*, 123 U. S. 623.

FRANCIS M. BURDICK.

**Sumter**: city; capital of Sumter co., S. C.; on the Atlantic Coast, the Cent. of S. C., and the Charleston, Sumter and N. railways; 43 miles E. by S. of Columbia; 93 miles N. by W. of Charleston (for location, see map of South Carolina, ref. 5–F). It is in an agricultural and a tobacco and truck raising region; ships annually 25,000 bales of cotton; and contains 6 churches for white people and 6 for colored, 5 public-school buildings, 2 academies for young ladies, 2 planing-mills, cotton, telephone, and sash and blind factories, improved system of water-works, electric lights, a national bank with capital of $75,000, a State bank with capital of $75,000, and 6 newspapers. Pop. (1880) 2,011; (1890) 3,865; (1900) 5,673.

EDITOR OF "HERALD."

**Sumter, THOMAS**: soldier; b. in Virginia in 1734; removed in early life to South Carolina; participated in the Cherokee war, and was a prominent actor in the events which preceded the Revolution: was appointed lieutenant-colonel of the Second Regiment of riflemen in Mar., 1776, of which he became colonel; served in the interior of the State until the fall of Charleston; went to North Carolina and raised a large force, with which he defeated (July 12, 1780) a force of British and Tories; made an unsuccessful attack on the post at Rocky Mount Aug. 1, but Aug. 6 defeated and routed the Prince of Wales regiment at Hanging Rock, and dispersed a large body of Tories; was defeated and routed by Tarleton on the 18th at Fishing Creek; gained a victory at Broad river Nov. 12, and on the 20th defeated Tarleton at Blackstocks, and was severely wounded; had previously been appointed brigadier-general of South Carolina militia in Jan., 1781; received a vote of thanks from Congress for his eminent services; having raised three regiments of rangers, co-operated with Marion, Pickens, and other partisan leaders; was member of the convention which adopted the Federal Constitution; was member of Congress 1789–93 and 1797–1801, U. S. Senator 1801–09, and U. S. minister to Brazil 1809–11. D. at South Mount, near Camden, S. C., June 1, 1832.

**Sumter, Fort**: See FORT SUMTER.

**Sun** [O. Eng. *sunne*: O. H. Germ. *sunna* (< Mod. Germ. *sonne*): Icel. *sunna*: Goth. *sunna*; cf. (with different suffix) O. Eng. *sōl*: Goth. *sauil*: Sanskr. *svar*: Gr. ἥλιος: Lat. *sōl*]: for us, the most important body in the universe. next to the earth on which we dwell. It is the great center around which all the planets of our system revolve, and without its vivifying influence the whole earth would speedily be enveloped in a mantle of ice. on which no living being could exist. Yet to the question what the sun is, science can not as yet return an entirely satisfactory answer. The ancients knew that it was a shining sphere, and it is now known to be a very hot body; what is known more than this consists rather of fragments than of a well-rounded body of knowledge. Numerous though the fragments are, it is true that modern science has raised more questions about the sun than it has conclusively answered.

Beginning with certain particulars on which there is exact knowledge, it may be stated that the mass and volume of the sun are enormous compared with those of the earth, and that nature there conducts her operations on a scale of which we can form no conception. In volume it is more than a million times that of our earth; in mass more than 300,000 times. Its density is about one-fourth that of the average of the materials which make up the earth, and therefore only about half as much again as that of water. Its mean distance from us is 93,000,000 miles; its diameter 866,000 miles. The force of gravity on its surface is twenty-seven times what it is on the earth. Under such circumstances a man attempting to stand up would be instantly crushed to death by his own weight. High mountains could scarcely exist, because they would be flattened out by the pressure, and vegetation of the sort familiar to us would not be possible.

Like the earth and planets, the sun rotates from W. toward E. on an axis nearly perpendicular to the ecliptic. It has therefore two poles, where the axis intersects its surface, and an equator of its own. The period of rotation is about 26 days. A curious circumstance is that the equatorial regions rotate in less time than those nearer to the poles, the range being perhaps from 25 to 26¼ days.

*Temperature and Physical Constitution.*—The flood of heat which the sun sends us at its enormous distance indicates that the matter composing it is intensely hot; but estimates of the actual temperature have differed widely. It appears higher than any that we have yet produced, even in the electric arc; probably more than 10,000° F. This statement applies to the photosphere, or visible surface of the sun; the great invisible interior must be at a much higher temperature. There must be a constant interchange of matter between the interior and the surface, else the latter would speedily cool off under the influence of its rapid rotation. Consequently the interior must be, at least in the great mass, either liquid or gaseous. The best sustained view at the present time is that at such a temperature as that within the sun no permanent chemical combination is possible. There can be only an indiscriminate mixture of elements; for example, a mixture of oxygen and hydrogen, instead of water. Moreover, the distinction between a liquid and a gas becomes obliterated under the combined effect of the temperature and the pressure. We must therefore regard the sun as a mass of gas, condensed nearly to the density of a liquid by the pressure of its own mass. The visible photosphere is, indeed, sometimes supposed to be wholly or partially solid. This is a point not yet settled. It may be that, under the influence of rapid cooling, the substances which rise to the surface are constantly condensing to solids, and then falling down again are once more melted by the heat of the interior; but it has also been pointed out that a purely gaseous envelope around the sun would increase so rapidly in density toward the interior, owing to the immense pressure of gravity, that it would present the same appearance that the sun actually does.

*Appearance of the Photosphere.*—Through a good telescope, under favorable conditions, the photosphere is seen to have a mottled or curdled appearance, looking much like a plate of rice soup. This appearance probably arises from a constant rising of currents of heated matter from the interior. Although attempts have been made to assign definite shapes to these seeming rice-grains, the writer believes that they are quite irregular, both in size and shape, and have no well-marked outline or distinctive features.

When the apparent center of the sun is compared with the edge of the disk, it is seen to be markedly brighter; this difference can be seen without a telescope, if the sun is examined through a very dark-green or blue glass, so as no longer to dazzle the eye. It is attributed to absorption of the rays by the solar atmosphere, a view which is confirmed by the fact that different rays of the spectrum are absorbed in very different degrees. The absorption is greatest of all in the case of the photographic rays, so that a photograph of the sun will ordinarily show very dark at the extreme limb unless over-exposed at the center. The absorption is less in the visual rays and still less in the heat rays, which shows that as we descend in the spectrum the transparency of the sun's atmosphere to the rays increases.

*Solar Spots.*—The most striking and peculiar feature of the photosphere is formed by the spots, which may nearly always be seen when the sun is examined with a telescope. They were seen by the earliest telescopes, and have formed a subject of constant study by astronomers ever since. When examined with a high power, and under favorable conditions, a sun-spot is found to possess marked peculiarities of structure. A general idea of the appearance may be formed from Fig. 1. We have in the center a dark portion called the nucleus, or *umbra*, which is commonly of irregular form. The word dark must, however, be interpreted in a relative sense; though apparently dark in contrast with the effulgence of the photosphere, the spot would be intensely bright if isolated. Around this dark center is a gray fringe intermediate in brightness between the nucleus and the photosphere, which is called the *penumbra*. To ordinary examination the penumbra appears to be nearly uniformly gray, but when best seen in a good telescope it is found to have a striated or fibrous appearance, being composed of an immense number of root-like filaments directed from the outside toward the center. Groups of minute specks, brighter than the general surface of the sun, are often seen in the neighborhood of spots or elsewhere and are called *faculæ*.

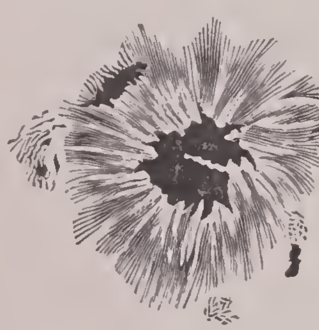

FIG. 1.

The spots vary in size from the smallest visible points to objects large enough to be seen with the naked eye, and therefore nearly 100,000 miles in diameter. A curious circumstance is that the spots are not seen all over the solar disk, but only near to what, in our globe, would correspond to the tropics. They are most numerous about twenty degrees on each side of the solar equator; they are rarely seen exactly at the equator, and scarcely ever in more than thirty-five or forty degrees of latitude. They frequently appear in groups comprising two or three, and sometimes many more. In consequence of the sun's rotation, each spot is seen to move slowly across its disk, occupying about thirteen days from the time it appears on one side until it disappears on the other, always supposing that it endures as long as this. The duration of a spot is very variable, ranging from a few days to several months.

A view very generally entertained is that the spots are cavities in the photosphere. This was believed because, as the spot approaches the edge of the sun, the umbra is supposed to appear wider on the side toward the sun's limb, which would be the case if it were a hollow cone at which we were looking obliquely. But the figure and size of the penumbra are so irregular that it is not easy to establish such a fact as this, and Schörer, of Potsdam, one of the industrious students of solar spots, denies that there is any such difference. According to his view, the penumbra is on the same level with the photosphere. Yet another view is that the spots are cooled portions of matter floating, as it were, upon the hotter photosphere. They have also been attributed to down-rushes of matter, carrying the cooler portions near the surface with them. Between these various views it is impossible at present to decide.

*Periodicity of the Spots.*—It has been well established by careful observation since about 1850, as well as by previous records, that the frequency of the sun-spots goes through a fairly regular period of about eleven years. In recent years the maxima have occurred about the years 1848, 1860, 1870, 1881, and 1892. The next maximum may therefore be expected about the year 1903 or 1904. During the years of maximum the sun is rarely seen without spots, and generally with a considerable number. During the intermediate years of minima the sun is seen without spots about half the time. The variation does not, however, go on with entire uniformity, the general rule being that the rise from minimum to maximum is more rapid than the fall from the maximum to the minimum. For instance, a maximum occurred about the year 1860, a minimum about 1867, and another maximum about 1870. Thus the number of spots took seven years to fall to a minimum, and only three to rise to a maximum. We also have here an illustration of the irregularity of the period. The interval is not always exactly eleven years, but sometimes a little more and sometimes a little less, varying in an irregular manner. Sufficient data have not yet been accumulated to determine accurately the law of change. It was formerly supposed that the maxima and minima might be associated with the revolutions of the planets, a view which was first suggested by the close approximation of the period of the sun-spots to that of Jupiter, the latter being somewhat less than twelve years; but careful investigation shows that the sun-spot period can not be as great as the period of Jupiter, so that the close approach to coincidence can be regarded only as an accident. The fact seems to be that the variation occurs in consequence of a cycle of changes going on within the body of the sun itself, but of the nature of those changes nothing is known.

*The Sun's Surroundings.*—The glare of the sun's rays in our atmosphere, even in the finest climates, is such that objects in its immediate neighborhood are ordinarily invisible. But from time to time there are a few rare minutes in which this glare is removed, in consequence of the moon passing over the sun's disk in a total eclipse. The opportunities thus offered for scrutinizing the immediate neighborhood of the sun have resulted in bringing to light a number of singular phenomena, many of which can be seen only during total eclipses. (See CORONA.) It is known that the photosphere is surrounded by a comparatively thin layer of vaporized or gaseous matter, known as the *chromosphere*. Continuous with this layer, and yet possibly having a different origin, are the protuberances, which appear to consist of vast masses of glowing gas ejected from the sun with inconceivable force, the velocity sometimes amounting to 200 miles a second. These protuberances exhibit a great variety of the most fantastic forms, sometimes appearing like immense flames, sometimes like clouds floating above the sun and remaining for hours, or even days, in the same region. It has been noticed that they are more frequently seen in the neighborhood of sun-spots than elsewhere, yet not necessarily over the spots. Some of the forms are shown in Fig. 2, on a scale on which the earth would be represented by a globe of perhaps one-eighth of an inch in diameter.

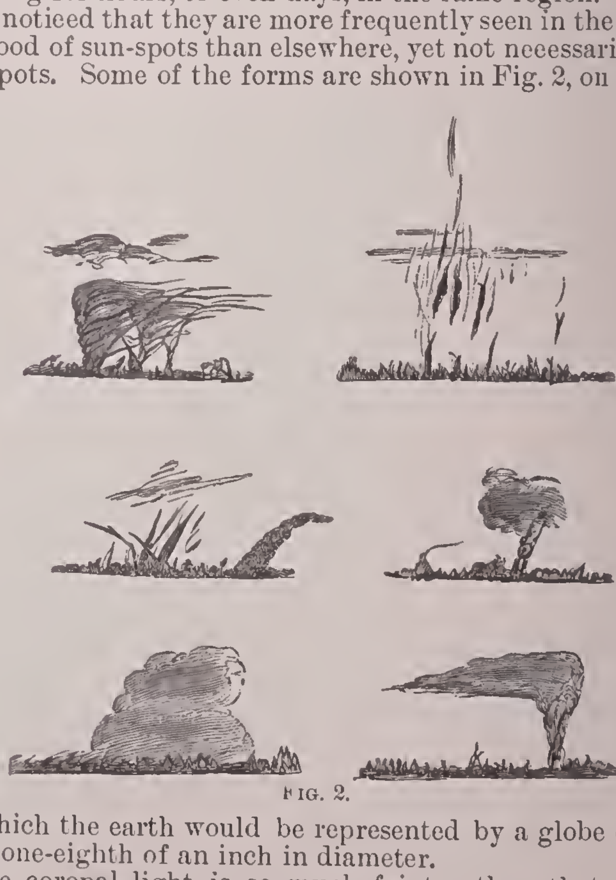

FIG. 2.

The coronal light is so much fainter than that of the protuberances that it can not be detected, even by the spectroscope, except during total eclipses. (See Eclipse.) It can be plainly seen extending to a distance from the sun nearly equal to its semi-diameter, but it also shows rays or streamers extending to much greater distances, sometimes a degree more, and therefore millions of miles in extent. The most remarkable feature of its spectrum is a bright line in the green, which was discovered independently by Young and Harkness during the total eclipse of 1869. This line has not certainly been identified as belonging to any substance known to exist on the earth, and the term *coronium* has been applied to the unknown element which causes it. Repeated study of the corona seems to show that it generally has the greatest extent about the middle latitudes of the sun, and that its structure is of a peculiar filamentous character like that of combed wool. A resemblance of these filaments to the lines of magnetic force has been brought out by Prof. F. H. Bigelow, who has constructed a magnetic or polar theory of the corona, ascribing it to the sun's magnetism. It can not be said, however, that any entirely satisfactory theory of this object has yet been established. Magnetic force may very well account for the structure and appearance, but the great difficulty is how substances of any sort can remain at rest so near the sun, under the enormous gravitating force of the latter. The corona has sometimes been described as a solar atmosphere, but it can not be such in the sense in which we use the term atmosphere. The fact that comets have passed through its substance with a speed of several hundred miles a second, without suffering, so far as could be seen, the slightest retardation or disturbance, shows that there can be in the corona no substances but such as are of the utmost tenuity—particles so light that the thinnest air would be as lead in comparison. It has been suggested that these particles may be held up by electrical repulsion, or that they may be in a state of projection, continually thrown up from the sun and falling back again upon its surface. All these hypotheses are possible, and some may be more or less probable, but no one is yet proved to the exclusion of the others.

*Elements which compose the Sun.*—A comparison of the solar spectrum with the spectra of the various elements found on the earth shows that the sun is composed very largely of the same substances as the earth. The most thorough comparison of this kind is that of Rowland, which is still in progress. He finds that thirty-six terrestrial elements may be detected in the sun. Of these, calcium, iron, and sodium are among those most strongly marked. The elements not yet detected are mostly those which are found on the earth in comparatively small quantities, such as antimony, arsenic, gold, mercury, etc. The most curious case among the doubtful elements is that of oxygen. It is not yet certainly decided whether the spectrum of the sun does or does not show the existence of oxygen in that body. It is to be remarked that the absence of the lines of an element in the solar spectrum does not prove the absence of that element. The solar spectrum shows only the lines of those elements which are vaporized at its surface; hence if any elements do not come to the surface at all, or do not form a vapor there, they will not show themselves in the solar spectrum. The general result has been summed up by Rowland in the remark that were the earth heated up to the temperature of the sun, its spectrum would probably resemble that of the sun very closely. It is also to be remarked that there are lines in the spectrum of the sun, or of its surrounding atmosphere, which have not yet been identified as belonging to any terrestrial element. Of these the most noteworthy is a line, $D_3$, found in the spectrum of the chromosphere and attributed to a non-terrestrial substance which has received the name *helium.* It has been announced by Ramsay (1895), however, that a gas obtained from *cleveite*, a rare mineral from Norway, shows this line, and therefore may be presumed to be helium. For an illustration of the solar spectrum see the article Spectrum.

The question whether the sun affects the earth otherwise than by its light, heat, and gravitation is one with which science is busy, but on which no positive conclusions are yet reached. A relation between the period of the aurora and that of the sun-spots seems to be not improbable, but the question whether auroras are themselves excited by actions going on in the sun is an open one. This whole class of questions can be settled only by long-continued observation and careful study.

*The Sun's Heat.*—The question of the permanence of the sun's heat is presented in a new light by those generalizations of modern science which relate to the conservation of energy. To our ancestors there was no apparent reason why the sun should not continue to light and warm the earth and planets forever; but modern science shows that the radiation of heat from the sun to the earth involves a continuous expenditure of an agent called energy, of which the supply is necessarily limited.

The quantity of heat which is received from the sun has been determined by several experimenters. The recent observations of Langley probably give the most accurate result, which may be expressed in the following way: Let us consider a cubic centimeter of water, that is, a cube about four-tenths of an inch on each side. We may realize this cube in the form of a thin metallic vessel, filled with water. Let this vessel be covered with lampblack, and one side of it be exposed perpendicularly to the rays of the sun. Langley's result is that if these rays reached the earth without being absorbed by our atmosphere, they would, when absorbed by the cube, heat it at a rate of 3·6° C., or $6\frac{1}{2}$° F. per minute. Taking as the unit of heat the quantity which would raise the temperature of 1 cubic cm. of water 1° C., we may say that the sun radiates upon each square centimeter of surface 3·6 heat units per minute. Imagine a spherical surface surrounding the sun, at a distance equal to that of the earth's orbit. Every square centimeter of that surface would receive this quantity of heat from the sun. We may state this result in another way. If the amount of heat falling on a square centimeter were transformed into a lifting force, without any loss whatever, it would raise a cubic centimeter of water against the force of gravity at the rate of about 4,800 feet per minute. A similar computation shows that the heat which the sun, when near the zenith, radiates upon the deck of a steamship would suffice, could it be turned into work without loss, to drive her at a fair rate of speed.

Considering the sun simply as a hot body, it would be cooled by the heat which it radiates, and calculation shows that the amount of heat radiated would result in a cooling of 5°, more or less, per year, according to the specific heat of the substances which compose it. It follows that, in such a case, the sun would cool off entirely in a very few thousand years. As no actual cooling seems to take place, the question arises how the heat is kept up.

Two theories on this subject have been maintained in recent times. One, known as the meteoric theory, is that the countless meteors which are known to be moving in all directions through the solar system are continually falling into the sun and supplying it with the heat generated by the impact. As to this theory it can only be said that it seems impossible that meteoric matter in sufficient quantity could be falling into the sun. The other theory, which is now universally accepted, at least provisionally, by the ablest physicists, is that the heat is kept up by the contraction of the sun's volume as it cools. A very curious result of this contraction was reached some years ago by an American investigator, J. Homer Lane, who showed that as the sun contracted it would actually become hotter, because although heat was lost by radiation, yet, so far as temperature was concerned, this loss would be more than made up by the resulting contraction, so long as the sun remained gaseous. This, however, does not mean that the heat would last indefinitely. After contracting to a certain point the matter composing the sun would necessarily begin to assume a solid or liquid form, and then would rapidly cool off. The available supply of energy would then be exhausted forever, and our system would be overtaken by eternal cold and darkness. Thus the physical conclusion to which we are led by a study of the laws of nature is that the sun, like a living being, must have had a birth and will have an end. From the known amount of heat which it radiates we can even, in a rude way, calculate the probable length of its life. From fifteen to twenty millions of years seems to be the limit of its age in the past, and it may exist a few millions of years, perhaps five or ten, in the future.

These computations have brought the conclusions of physics and astronomy into collision with those of geology. About the middle of the nineteenth century geologists were led by a study of the rocks composing the earth's surface in successive periods of their deposit to conclude that geological processes must have been going on for hundreds of millions of years. It can not be said that a complete reconciliation has yet been reached; but the writer believes that the general tendency of late years has been to shake the confidence formerly felt in the great length of the geological ages.

Connected with and yet apart from this is the question of the invariability of the supply of heat. Can we be sure that this supply has been every year the same during many ages past, and that it will remain unchanged for ages in the future? May it not be that the glacial epoch was due to a diminution of the sun's radiation? May this radiation not increase or diminish in the future to such an extent as to affect seriously the activities and destiny of the human race? These are questions to which the science of to-day can return no positive answer. All that can be said is that during the two or three centuries of accurate observations of temperature and climate there is no evidence of any permanent change. Adding to this the fact that a comparison of the ancient records of the magnitude of the stars with their present magnitudes does not show any evidence of change, and that the sun is undoubtedly a star which is brighter than others because we are so much nearer to it, the conclusion is that there is no reason to apprehend any sudden or rapid changes in the supply of solar heat.

BIBLIOGRAPHY.—*The Sun*, by C. A. Young, in the International Scientific Series, is the latest complete work in English on the subject. Proctor's *The Sun, Ruler, etc., of the Planetary System*, will also be found extremely interesting. A yet more voluminous work is that of Secchi, *Le Soleil* (2 vols., Paris, 1870), which is beautifully illustrated.

SIMON NEWCOMB.

**Sun Animalcules**: See HELIOZOA.

**Sun-bird**: any bird of the family *Nectariniidæ*, inhabiting a great part of Africa, Southern Asia, and Australasia. Although only distantly related, the sun-birds have a superficial resemblance to the humming-birds, with which they are generally confounded by colonists, in their smallness, slender build, brilliant, often metallic colors, and habits of feeding from flowers, but belong to a different order, the passerines. The tongue is practically tubular and suctorial, although their food consists mainly of insects. Their nests, which are roofed over, are swung from a slender twig or the tip of a leaf; the eggs, generally three in number, are white, plentifully sprinkled with grayish green. There are over 100 species, which have been described in a *Monograph of the Sun-birds*, by Capt. Shelley (London, 1876–80).

F. A. LUCAS.

**Sun-bittern**: a wading bird (*Eurypyga helias*) of somewhat uncertain affinities, but usually placed in a separate family (*Eurypygidæ*) near the cranes and rails. It is about 16 inches long. The head is black, with a white stripe above and beneath each eye; the balance of the plumage is curiously and elaborately mottled with black, white, chestnut, and various shades of buff and brown. The sun-bittern is found along the banks of rivers in the northern and eastern parts of South America, and feeds on fishes and insects. Its nearest relative is the KAGU (*q. v.*). F. A. LUCAS.

**Sunbury**: borough; capital of Northumberland co., Pa.; at the junction of the northern and western branches of the Susquehanna river; on the N. Cent., the Penn., and the Phila. and Reading railways; 54 miles N. of Harrisburg, the State capital (for location, see map of Pennsylvania, ref. 4–G). It is in a lumbering region; is an important shipping-point for coal; and contains the repair-shops of the Phila. and Erie Division of the Penn. Railroad, rolling-mill, organ-factory, saw and planing mills, nail-works, and coffin, table, and sash and door factories, a national bank with capital of $200,000, a trust and safe-deposit company with capital of $125,000, and a daily, a monthly, and two weekly periodicals. The borough was founded in 1772; was the site of the Indian village of Shamokin and of Fort Augusta, erected by the provincial government in 1756 as a defense against the French and Indians, the magazine of which is preserved in the Fifth Ward of the borough; and is separated from East Sunbury borough (incorporated in 1891) by a small stream. The interests of the two boroughs are identical. Pop. (1880) 4,077; (1890) 5,930; (1900) 9,810.

EDITOR OF "SUNBURY DAILY."

**Sunda Islands**: the chain of large islands belonging to the Malay Archipelago, which, beginning with Sumatra and ending with Timor, separates the Java Sea from the Indian Ocean. The name is derived from the indigenous name of the western part of Java, adjoining the Sunda Straits. See JAVA. M. W. H.

**Sun'darbans**, or **Sunderbunds**: the part of the delta of the Ganges which extends from the Hugli to the Megna. It has an area estimated at 7,550 sq. miles, and consists of a great number of smaller and larger islands covered with dense forests and infested by tigers and crocodiles. As this tract of land is in the highest degree pestiferous, the Government has taken measures to improve it, or at least make it innoxious, and in many places the forests have been cleared and the ground transformed into fields of rice and sugar.

Revised by M. W. HARRINGTON.

**Sunday** [O. Eng. *sunnandæg* (*sunne*, sun + *dæg*, day), transl. of Lat. *di'es so'lis*; *dies*, day + *solis*, genit. of *sol*, sun. See SUN]: the secular name of the first day of the week, which is held among Christians as a Sabbath, or rest-day, and in remembrance of Christ's resurrection. As soon as the Christian religion was recognized by the state, laws were enacted for the observance of Sunday. Constantine (321) prohibited all business except agricultural labor and all legal proceedings except the manumission of slaves. Subsequent emperors made similar enactments. Theodosius II. (425) forbade games and theatrical exhibitions on Sunday (*Cod. Theod.*, xv., tit. 7). The most strict of these laws is that of Leo and Anthemius (469, *Cod. Justin.*, iii., tit. 12). The laws of Theodoric the Great, several kings of France, and especially Charlemagne (813), prohibited servile work and secular business.

In England Sunday laws were of very early origin. The common law distinguished Sunday from other days by allowing no judicial acts on that day, according to the maxim, *Dies dominicus non est juridicus.* The code of Ina, King of the West Saxons (about 693), punished servile work by fine. Alfred the Great (876) forbade work, traffic, and legal proceedings on Sunday. Similar laws were in force through all the Saxon period, and were often enacted in subsequent reigns. The statute 27 Hen. IV., c. 5, enacts that all fairs and markets on Sundays, except in harvest, shall cease on pain of forfeiture of goods. The statute 5 and 6 Edw. VI., c. 3, makes Sundays, with Christmas, Easter, etc., holy days, but permits work in harvest and in other cases of need. The statute 1 Eliz., c. 2, punishes by fine persons absenting themselves from church without excuse. In 1618 James I. issued his *Book of Sports*, in which he declares certain games, sports, etc., lawful on Sundays after divine service. Charles I. in 1638 reissued the *Book of Sports.* The most important of the English statutes is 29 Chas. II., c. 7, which prohibits all worldly labor or business (works of necessity and charity only excepted), the sale of goods, traveling for purposes of trade, and the serving or executing of any process or warrant, except in case of treason, felony, or breach of peace. The dressing of meat in families and its sale in inns and eating-shops and the crying of milk before nine and after four are allowed. This statute, somewhat modified by subsequent laws, is the present Sunday law of Great Britain, and lies at the basis of the Sunday laws of the U. S.

In France, during the Revolution, when the Christian calendar was abolished and the decade substituted for the week, each tenth day was made a rest-day, and its observance was enforced by a law (17 Thermidor, An VI.) which required the public offices, schools, workshops, stores, etc., to be closed, and prohibited sales except of eatables and medicines, and public labor except in the country during seed-time and harvest. On the restoration of the Gregorian calendar, Sunday was recognized in the *Code Napoléon* (Art. 25, 260). A law of Nov. 18, 1814, prohibited ordinary labor, traffic, etc., and, though declared by the courts in 1838 and 1845 to be still in force, it has been for many years a dead letter. The International Sunday-rest Congress, in connection with the Paris Exposition of 1889, and the Berlin Labor Conference, convened by the German emperor in 1890, gave increased prominence to the question of the legal protection of Sunday rest which had been previously agitated by labor and other associations. Laws restricting Sunday labor and trade to a greater or less extent exist in Germany, Switzerland, Austria, Hungary, Belgium, Holland, Denmark, Sweden, and Norway.

The early English colonists of North America brought with them the observance of Sunday, both as a religious and as a civil institution, and both the religious and secular observance of the day was enforced by laws similar to the English statutes, though modified by the popular feelings and modes of life. The early laws of Massachusetts, Connecticut, Georgia, South Carolina, and Virginia compelled attendance at church, the Massachusetts law (1782) providing that such attendance was not required where there was no place of worship which the person could conscientiously attend. (The oft-quoted BLUE LAWS (*q. v.*) of Connecticut are a pure fiction, first published in London in 1781 by Samuel Peters, in revenge for being driven from the colony on account of his obnoxious royalism.) After the establishment of the Federal Government, as the separation between Church and state came to be more fully understood and carried out, the earlier Sunday laws were modified in conformity with this principle, and the legislatures and courts have been careful to distinguish between Sunday observance as a religious and as a civil institution, and to enforce only the latter. The existing Sunday laws rest chiefly upon the following grounds: The right of all classes, so far as practicable, to rest one day in seven; the right to undisturbed worship on the day set apart for this purpose by the great majority of the people; the decent respect which should be paid to the religious institutions of the people; the value to the state itself of the Sunday observance as a means of that popular intelligence and morality on which free institutions are conditioned. The Federal Constitution provides that Sunday shall not be reckoned in the ten days within which the President may return any bill; the Federal courts and the offices of the departments are closed; the service of the post-offices is restricted; no session of Congress is held, and provision is made by act of Congress for the observance of Sunday in the army and navy. Beyond this, Sunday legislation does not come within the sphere of the Federal Government. The constitutions of all but a very few of the States, like the Federal Constitution, except Sunday in reckoning the time within which the executive may return a bill to the Legislature. Sunday laws exist in all the States, with a single exception. The statutes of the States differ somewhat in details and strictness. Sunday is everywhere held as a *dies non.* Public affairs are suspended; the legislatures do not sit; courts are not held, except that in some cities police courts are open for an hour or two; legal processes are not served. In most of the States common labor and traffic are prohibited; contracts made or for service on Sunday are invalid; public amusements are restricted or forbidden. In many States partial exception is made for those who observe the seventh day of the week. The constitutionality of Sunday laws has been decided frequently by the highest State courts.

Allen, opinion in *Lindenmüller* vs. *The People*, 33 Barbour 548; *The Sunday Problem*, papers read at the Sunday-rest Congress at Chicago in 1893 (New York, 1894). See LORD'S DAY and SABBATH. W. W. ATTERBURY.

**Sunday Letter**: See DOMINICAL LETTER.

**Sunday-schools**: gatherings for religious instruction and worship, in which the learners are clustered in classes under separate teachers, all the classes being associated under a common head, and the form of instruction being interlocutory or catechetical. These characteristics include many schools which are held on Saturday, or which are known as First-day schools.

*Modern Sunday-schools.*—These had their origin in a movement begun by Robert Raikes, the proprietor of *The Gloucester Journal*, in Gloucester, England, in July, 1780. His purpose was to provide instruction in reading, and in the Church of England catechism, for the neglected children of a manufacturing district of that city. His first school was gathered on a Sunday in a private house under the charge of four women, who were employed at a shilling a day. Its forenoon session was from ten to twelve o'clock. In the afternoon, after a brief session, the children were conducted to the parish church for a part in worship, and were afterwards examined in the catechism. The Rev. Thomas Stock, a parish clergyman, assisted Mr. Raikes in this work, and gave an extra sixpence a day to the teachers.

Descriptions of this movement in *The Gloucester Journal* and other periodicals in 1783 called public attention to it, and it soon became widely popular. Volunteer teachers took the place of paid ones. The queen gave it her approval by sending for Mr. Raikes to tell her its story, and to congratulate him on what he was doing. Bishop Porteus was an early and earnest friend of the movement. John Wesley introduced its plan of work into his religious operations. A general Sunday-school society was organized with the aid of William Fox and Jonas Hanway, having its center in London. The success of the movement was quickly assured, although not without opposition from ecclesiastical authorities and timid religionists. A council of bishops was summoned by the Archbishop of Canterbury to consider the best means of checking the innovation; and the Presbyterians of Scotland and the Congregationalists of New England took stand against it as tending to the secularization of the Sabbath. Within four years from the public announcement of his work by Mr. Raikes, however, the membership of such schools in the United Kingdom numbered over a quarter of a million, and the increase of their numbers has been constant.

*Ancient Jewish Schools.*—Although this was the beginning of the modern Sunday-school movement, its idea was of ancient origin, and had found expression in various forms all along the ages. Religious instruction, apart from that which was given in the family, seems to have been practiced in the days of Abraham (Gen. xiv. 14). Home instruction was not deemed sufficient for the children under the Mosaic law (Deut. xxxi. 10–13). The Levites were traveling Bible-teachers in the days of the kings of Judah (2 Chron. xvii. 9). The synagogue seems to have included in its exercises from its beginning, during the Captivity, the study of the law by interlocutory methods. According to the Talmud and to Josephus, a system of religious schools in connection with the synagogues was organized in the century before Christ. This system included many of the features of the modern Sunday-school. The size of classes was limited to the capability of the teacher. Selected Bible lessons were arranged for a series of years. Attention was given to the fitness of instruction to the ability and needs of the pupils. Freeness in questions and answers was cultivated. Such schools were general in Palestine in the days of Jesus, and there is reason to suppose that he was a pupil in one of these in his Nazareth home.

*Early Christian Schools.*—The religious school was a prominent agency in the early Christian Church. "The apostolic Church," says Baron Bunsen, "made the school the connecting link between herself and the world." Catechising engaged the best efforts of the best Christian teachers. A compulsory system of Bible-schools for children in every city was in force in extensive fields as early as the fourth century, and charity schools in all country churches were ordered by a general council of the Church in A. D. 680. Such work was never wholly lost sight of even in the Dark Ages, although as the ecclesiastical spirit began to predominate over the evangelical less attention was given to it. In the Reformation of the sixteenth century the school idea gained new prominence. Said Luther: "For the Church's sake Christian schools must be established and maintained. . . . God maintains the Church through the schools." And he acted on this idea, as did also Calvin, Zwingli, Beza, Knox, Cranmer, Ridley, Usher, and others. Under Jesuit lead the Roman Catholic Church paid fresh attention to schools, and regained a measure of its lost ground through methods with children similar to those now in use in Sunday-schools generally. Two causes combined to check the progress of what might be called "the Sunday-school idea" after its revival in the sixteenth century. The unintelligent memorizing of set answers, in catechisms intended as a mere guide in teaching, gradually took the place of religious teaching; and the polemical spirit among Protestants lifted sermonizing into an undue prominence over Bible study. A marked religious decline was the result, and social and personal morals were at a very low point in the latter half of the eighteenth century, when the new movement in favor of Sunday-schools was begun by Robert Raikes.

*Modern Beginnings before Raikes.*—The plan of Raikes was only the new application of an old idea, but the circumstances of his beginning gave fresh importance to his work, and therefore its date marks a new era. Single schools much like his are claimed to have been started before that date, as follows: In Bath, England (by Rev. Joseph Alleine), in 1665–68; in Roxbury, Mass., in 1674; in Norwich, Conn., in 1676; in Plymouth, Mass., in 1680; in Newtown, Long Island (by Rev. Morgan Jones), in 1683; in England (by Bishop Frampton), in 1693; in Berks and Montgomery cos., Pa. (by the Schwenkfelders), in 1734; in Savannah, Ga. (by Rev. John Wesley), in 1737; in Ephratah, Pa. (by Ludwig Höcker), in 1740; in Bethlehem, Conn. (by Rev. Joseph Bellamy), in 1740; in Philadelphia, Pa. (by Mrs. Greening), in 1744; in Norham, Scotland (by Rev. Mr. Morrison), in 1757; in Brechin, Scotland (by Rev. David Blair), in 1760; in Catterick, England (by Rev. Theophilus Lindsey), in 1763; in Columbia, Conn. (by Rev. Eleazer Wheelock), in

1763; in Bedale, England (by Miss Harrison), in 1765; in High Wycombe, England (by Miss Hannah Ball), in 1769; in Doagh, County Antrim, Ireland (by William Galt), in 1770; in Bright, County Down, Ireland (by Rev. Dr. Kennedy), in 1774; in Little Lever, near Bolton, England (by James Heys), in 1775; in Mansfield, England (by Rev. David Simpson), in 1778; also about the same time in Asbury, England (by Rev. Thomas Stock), and in Dursley, England (by William King).
