ORANGES AND GRAPEFRUIT: WEIGHTED AUCTION PRICES AT NEW YORK, NORMAL SEASONAL TREND, AND 1940-41

* FLORIDA ORANGES, 90 POUNDS NET PER BOX; CALIFORNIA ORANGES, 70 POUNDS; FLORIDA GRAPEFRUIT, 80 POUNDS
▲ ARITHMETIC MEAN OF THE EIGHT MIDDLE PRICES FOR EACH WEEK OF THE 12-YEAR PERIOD, 1927-38

THE FRUIT SITUATION

Summary

Fruit growers, in general, will receive higher prices for their crops in 1943 than they received this year. Consumer ability to purchase fruits will be greater than in 1942. If supply and demand were to continue to govern fresh fruit prices, materially higher prices would be received by growers of those fruit crops which turn out to be in smaller supply in 1943 than in 1942. However, price controls probably will be an important factor in 1943. Prices received by growers of pears sold for fresh consumption averaged close to parity in the summer of 1942. If the parity price of apples in October were to be adjusted for seasonal variation it would then be only slightly higher than the actual price received by growers.

The fruit crop in 1943-44 probably will be slightly smaller than the bumper crop in 1942-43. Commercial apple production probably will be materially smaller than in 1942. Pear production may be slightly smaller, and grape production only a little larger. Since military and lend-lease requirements in 1943-44 will be substantially above those for the preceding year, considerably less fruit will be available for civilian consumers. The decrease from 1942-43 in the total supply of fruits marketed fresh probably will be greater than the decrease in total production. Although the amount of fruit canned may be smaller than a year earlier because of tin plate restrictions, the amount dried is likely to be substantially increased so that the total used for canning and drying will be larger than in 1942-43.

At this time it appears likely that the 1942-43 weighted average price received by growers for oranges and grapefruit (sold for fresh consumption

and for processing) will be at least 15 percent and 5 percent higher respectively than the weighted average in 1941-42. The orange and grapefruit crops that will be marketed from this fall to next may easily be the largest on record. However, the demand for both of these fruits for processing, as well as for fresh use, will be exceptionally great. Large quantities of concentrated orange juice are desired for lend-lease shipment, and it is probable that the grapefruit juice pack will be of record size.

The War Production Board, through a recent order, acted to prevent the depletion of canned fruit and juice stocks before the 1943 pack comes on the market. This order prohibits canners from shipping more than a specified percentage of their packs available for civilian consumption during certain periods. For instance, not more than 70 percent of their total civilian supply can be shipped prior to April 1, 1943. Since the civilian demand for canned fruits this season at ceiling prices is greater than the supply available, there would have been little or no stocks available toward the end of the current season if inventory controls had not been instituted.

-- October 30, 1942

CITRUS

BACKGROUND.-- The trend in orange production has been steadily upward during the past 20 years. This upward trend has been particularly marked in the production of Valencias in California and of all oranges in Florida. During the decade 1919 to 1929 grapefruit production followed a gradual upward trend. Since that period the increase has been more pronounced, with production in Texas increasing at a more rapid rate than production in other areas. The extremely low prices received for citrus fruits from 1930 to 1932 were largely a result of increasing production and decreasing consumer purchasing power. Since 1932 prices have averaged below pre-depression levels as a result of sharply increased production.

The orange and grapefruit crops that will be marketed from this fall to next may easily be the largest on record. On October 1 it was indicated that the production of oranges, excluding California Valencias, would total 58.6 million boxes compared with 53.8 million in 1941-42. The production of grapefruit, excluding California "other" varieties, was indicated to total 45.2 million boxes compared with 38.7 million in the preceding season.

The demand for both of these fruits for processing will be exceptionally great since large quantities of concentrated orange juice are desired for lend-lease shipment, and the pack of grapefruit juice may be of record size. Supplies of oranges and grapefruit for fresh sale will be large during the winter and spring of 1943, but consumer demand continues to increase.

Retail price ceilings have been established for fresh citrus, excluding grapefruit, at the highest price prevailing from September 28 to October 2. Retail price ceilings of fresh grapefruit have been fixed in such a manner that they will average roughly 10 cents per grapefruit, or the retailer's cost plus 2-1/2 cents, whichever is lower. The 10 cent price for grapefruit represents the average retail price for grapefruit in localities in which it was sold during the period September 28 to October 2. During this period California was the only State shipping oranges and grapefruit, and orange and grapefruit prices were close to their seasonal peaks.

It is likely that the 1942-43 weighted average price received by growers for oranges and grapefruit (sold for fresh consumption and for processing) will be at least 15 percent and 5 percent higher respectively than the weighted average in 1941-42.

APPLES

BACKGROUND.- Production of apples has fluctuated widely in volume in the past 30 years largely as a result of year-to-year changes in growing conditions. However, there has been a moderate downward trend in apple production since the peak year 1914. The number of apple trees has decreased greatly in the past 30 years. This decrease has been caused by the abandonment of farm orchards, normal mortality, the removal of low-yielding trees, and loss from droughts, storms, and freezes. Apple prices have recovered markedly from depression levels and in the 1941-42 season averaged 60 percent above the low reached in 1932-33.

The United States average price received by apple growers on October 15 was \$1.14 per bushel, 77 percent of parity. If the parity price in October were to be adjusted for seasonal variation it would then be only slightly higher than the actual price received by growers. Last season

the price increased more than the normal seasonal amount from September to June. The October 15 price this year was about 30 percent higher than that on October 15 a year ago. Auction prices of all leading varieties of Western apples at New York in the week ended October 16 averaged approximately 25 percent higher than in the comparable week in 1941. Apple growers in general probably will receive the highest average prices for their crop since 1929.

The commercial apple crop was estimated, as of October 1, to total 128.4 million bushels, about 5 percent more than in 1941. Production in the major producing areas is well above that of last year with the exception of Washington where the crop is expected to be only 1 percent greater. In 1943 the apple crop is likely to be materially smaller than in 1942.

PEARS

BACKGROUND.-- Pear production has about doubled in the last 20 years. The increase occurred largely in the Pacific Coast States, where during the 5-year period 1936-40 two thirds of the total United States pear crop was produced.

In 1934-38 approximately 18 percent of the total pear crop was marketed outside of this country. In this period about 30 percent of the canned pack and 76 percent of the dried pack were exported. Substantial quantities of fresh pears were also exported. In the 1942-43 season practically all of the dried pears will be shipped under lend-lease.

On October 1 it was estimated that the 1942 pear crop would total 30.5 million bushels, about 1 million bushels greater than in 1941. Bartlett production in the Pacific Coast States was indicated to total 15.4 million bushels compared with 15.6 million last year, and production of late variety pears was indicated to total 5.0 million bushels, slightly larger than a year ago. Production in 1943 may be slightly smaller than in 1942.

Prices of California Bartlett pears at the New York auction have averaged considerably higher this season than last. The crop is indicated to be slightly smaller, and the demand by canners and fresh fruit consumers has increased over last year.

The situation with regard to fall and winter pears is more favorable than last year even though production is slightly larger. The effect on prices of increased consumer demand this fall and winter will more than offset the adverse effects of a slightly larger production. Little difficulty should be encountered in marketing these pears as far as the demand situation is concerned. In September auction prices of Bosc and D'Anjou pears at New York averaged considerably above prices in September 1941.

GRAPES

BACKGROUND.-- Immediately after the enactment of prohibition, prices of grapes were high and large acreages were planted in California. As a result, grape production increased rapidly until 1928. From then until 1936 production declined because of a reduction in bearing acreage, relatively unfavorable weather, and in some years severe damage from insects. The large production of grapes in the last few years has been the result of adequate water supplies, favorable growing conditions, and a slight increase in bearing acreage.

Grape prices declined rapidly with the increase in production in the early 1920's and remained at fairly low levels throughout the 1930's. In 1941 the second largest grape crop on record sold at an average price of \$23.82 per ton, the highest since 1929. This relatively high price was the result of increases in demand from the Government and from the regular trade for raisin grapes for drying, crushing, and fresh table use.

On October 1 grape production was indicated to total 2.5 million tons compared with 2.7 million in 1941. The 1941 crop was the second largest on record. The 1942 crop in California was indicated to total 2.3 million tons, 8 percent less than last year. In 1941 a total of 836,000 tons of the raisin variety crop was dried, and the remainder went to wineries and for fresh table use.

This season the largest possible pack of raisins is needed to fill requirements of the United Nations. Government programs to support prices and restrict uses of raisin varieties (discussed in the August issue of this report) have been set up, and it is believed that they will insure a pack of raisins somewhere in line with the needs of the United Nations. Between 1,120,000 and 1,160,000 tons of raisin grape varieties may be dried this year. The raisin pack would then total between 280,000 and 290,000 tons compared with 209,000 tons in 1941.

The total supply of raisins (pack plus carry-over from the 1941-42 season) probably will be from 30 to 35 percent greater than the supply in 1941-42, but military and lend-lease needs will be such that the carry-over into the 1943-44 season probably will be little, if any, greater than the carry-over into the present season. The amount of raisins available for civilians probably will total considerably more than the average amount consumed by civilians in 1941. The utilization of 1,120,000 to 1,160,000 tons of grapes for drying would leave only approximately 1,147,000 tons to 1,187,000 tons of California grapes for other uses (wine and juice production, and fresh consumption), compared with 1,711,000 tons last year.

CIVILIAN DEMAND FOR CANNED FRUITS IN 1942-43

The establishment of price ceilings on canned fruits has increased the need for an economic analysis that can be used as a basis for estimating the civilian demand for canned fruits. Indications are that without ceilings, prices of canned fruits in general in the 1942-43 marketing season would have been about 15 percent higher than the average that will exist under price ceilings. When prices are artificially held below levels that would have resulted from the normal interplay of supply and demand an "economic" shortage of the commodity in question will arise. This does not necessarily mean that a shortage from the nutritional standpoint will exist. In the instance of canned fruits, the total supply is fixed at the beginning of the season and whenever prices to consumers are held artificially below the levels that would have resulted from the working out of supply and demand conditions, the demand for canned fruits then exceeds the supply. As a result, canned fruit stocks would be depleted before the start of the next season's pack unless some measures were taken to control inventories.

In order to determine the likelihood of an "economic" shortage, an analysis has been made of the average relationships existing between the per capita civilian consumption of canned fruits (excluding juices), prices quoted by canners for canned fruits, and an index of consumer purchasing power. Data for the 21-year period 1921 to 1941 were used. The consumption of canned fruit juices was not included inasmuch as juices are not generally used by civilian consumers for the same purposes as are canned fruits.

The per capita civilian consumption series for canned fruits is composed of 13 individual series derived from pack estimates, imports, exports, and shipments to and from territories, and canners' stock data where these latter were available. Published data on canners' stocks are available only for California packs and the total pack of red sour pitted cherries. Stock data are available on individual packs making up about 55 percent of the total pack of the 13 canned fruits in the 5-year period 1935-39. The lack of stock data for pineapple presents the most serious difficulty because of the importance of pineapple in the total fruit picture and the likelihood that for certain years there would be a considerable difference between beginning and ending stocks. Shipments of pineapple from territories to continental United States are used together with imports in deriving the pineapple series rather than estimates of total pack in territories. These shipments, however, do not necessarily constitute sales out of canners' hands since Hawaiian canners have storage facilities in continental United States. The lack of stock data on pineapple and less important fruits results in an indicated consumption which is larger than the amount actually consumed in years of small consumer demand, and which is smaller than the actual in the years immediately following.

The index of prices paid for canned fruits was based on canners' quoted prices for nine important canned fruits. There are no satisfactory series on retail and wholesale prices covering a period long enough to make them suitable for analytical purposes. The price series used does not include prices for four of the relatively minor fruits used in the consumption series. Even if price data were available for these four fruits, their weights in the index would be so small that the final index would have been little different from the one used in the analysis. It is probable that canners' quoted prices on canned fruits are in general higher than their actual sales prices.

An index of per capita national income payments was used as a measure of consumer ability to purchase canned fruits at given price levels. It is believed that aggregate purchases of canned fruits by farm families represents a fairly sizable portion of total canned fruit purchases. It was for this reason that per capita national income payments rather than per capita nonfarm income payments were used in the analysis.

The analysis indicates that in the 21-year period 1921 to 1941, changes in the quantity of canned fruits consumed per capita of the civilian population were on the average closely associated with changes in canners' quoted prices and the level of per capita national income payments. The square of the multiple correlation coefficient show that approximately 89 percent of the variation in the per capita consumption series is explainable by the two independent variables (price and per capita national income payments). The correlation between the independent variables was small.

Figure 1 shows the average relationship that would be expected between per capita civilian consumption of canned fruits and the index of canners' quoted prices at the estimated 1942-43 level of per capita national income payments.

The analysis indicates that if ceiling prices for canned fruits in 1942-43 had been placed at the average level of prices in the 1941-42 marketing season (P), civilian consumers would have purchased, if available, about .45 cases per capita (Q). However, prices were not held at the 1941-42 average level, but were advanced by the Price Administrator to allow for increases in canners' costs. It is estimated that canners' quoted prices in 1942-43, on a comparable basis with prices in previous years, will average 15 percent above the 1941-42 level. The index would then be at about 140 percent of the 1935-39 average. It is likely that canners' quoted prices under present price ceilings are much nearer to actual sales prices than were quotations in the years covered in the analysis. An adjustment for this apparent lack of comparability was made by increasing the estimated index in 1942-43 by 5 percent.

If the price index averaged 140 percent of the 1935-39 average (P_1) and with per capita national income payments at the estimated 1942-43 level, the analysis indicates that civilian consumers would take, if available, approximately .41 cases per capita (Q_2). Actually it is probable that only about .36 cases per capita will be available for purchase by civilian consumers. 1/ The broken lines D' and D'' in figure 1 indicate the upper and lower limits of the error of individual forecasts. 2/

It is likely that the analysis underestimates the quantity of canned fruits that would be desired by civilians at the estimated price level in 1942-43. That is, consumer demand for canned fruits probably has increased more than the increase in per capita national income payments would indicate. This is due to the fact that price ceilings in general and rationing of some commodities have increased the proportion of spendable income which can be used for the purchase of goods which are still available and are not rationed.

F. C. JONES

1/ The estimated .36 cases per capita is the summation of the total amount of canned fruits available to civilians from the 1942-43 packs, canners' stocks at the beginning of the season, and an estimate of that portion of distributors' stocks at the beginning of the season that would have remained in canners' hands in normal years.

2/ The band around the regression formed by lines D' and D'' has the following statistical meaning. If in every separate problem in forecasting such a band is constructed, the value that actually will occur will be contained in at least 95 percent of them.

1/ Estimates of the commercial crop refer to the production of apples in the commercial apple areas of each State and include fruit produced for sale to commercial processors as well as for sale for fresh consumption. 1934-41 revised. For some States in certain years, production includes some quantities unharvested on account of market conditions.

^{1/} Relates to crop from bloom of year shown. In California the picking season usually extends from about Oct. 1 to Dec. 31 of the following year. In other States the season begins about Sept. 1. For some States in certain years, production includes some quantities donated to charity and/or eliminated on account of market conditions.

^{2/} Short-time average.

^{3/} Net content of boxes varies. In California and Arizona the approximate average for oranges is 70 pounds net and grapefruit 60 pounds; in Florida and other States oranges 90 pounds and grapefruit 80 pounds; California lemons about 76 pounds net.

1/ 1930-41 revised. The estimates of utilization of prunes (right-hand portion of this table) include quantities sold and used on the farm for household consumption. 2/ For some States in certain years, production includes some quantities unharvested on account of market conditions. In 1941, estimate of such quantities were as follows (tons): Plums, California 5,000; prunes, eastern Oregon 500; in 1942, prunes, western Washington 1,800, western Oregon 10,000. 3/ Includes the following quantities harvested but not utilized due to excessive cullage (tons): Eastern Washington 500, western Oregon 2,800. 4/ In California the drying ratio is approximately 2-1/2 tons of fresh fruit to 1 ton of dried. In some years, in addition to the dried prunes produced, additional quantities of prunes remained unharvested on account of market conditions. In 1941, the equivalent of 11,000 tons of dried prunes was not harvested on account of market conditions. 5/ Includes small quantities for cold packing. 6/ The drying ratio in Washington and Oregon ranges from 3 to 4 tons of fresh fruit to 1 ton of dried.
