BRILL CONVERTIBLE CAR—CLOSED.

all times. In fact, the demand for an open car is hardly less imperative than the demand for a car which will meet all conditions of weather between seasons and out of seasons.

Almost every year since the first open car was built, there have been attempts to produce a car suitable for use all the year round, many of which were failures. Some were clumsy in appearance, difficult to operate, and many of them had no side entrance. The demand has increased notwithstanding the many failures.

There are two classes of convertible cars, those which contain their movable parts when not in use, and those from which the movable parts are detached. The limitations and defects urged against the latter class are the time required to make changes, the fact that changes are necessarily made at the place of storage, the breakage and injuries incident to changing, the space occupied in storage, and time of changing dependent upon guesses as to future weather conditions.

The design of self contained convertible cars was undertaken by Mr. John A. Brill, of the J. G. Brill Co., with the following requirements in view; the car when closed must be weather proof; the windows to be of regulation size; no unsightly parts associated with the storage arrangement to be left in evidence; in all, a box car of the usual type, including all the present-day features. The car when open must be easily accessible at the sides; the movable parts entirely concealed within the roof in such a manner as not to alter materially the roof's appearance; and, to include all the advantages of the best style of summer car. The convertible mechanism must be simple in character and easily operated.

The Brill convertible car has long passed the experimental stage, and the company states a large number having been in service for several years in different parts of this country. South America and Europe, they have been thoroughly tried under varying conditions, and in every case have fully answered expectations. At the Paris Exposition of 1900 this car was awarded the Grand Prix entirely upon the merits of its convertible system.

The Brill convertible car does not differ in appearance, externally, from the standard types of open or closed cars, except in a few insignificant details. Nor does it differ in strength of construction, no feature having been gained at the expense of strength and durability. The conversion from one type to the other, is accomplished in a few minutes, without stopping of car.

The distinctive features of the Brill convertible car consist of a set of posts carrying a complete set of sash, panels, and roller curtains; and a recess in the roof so constructed as to contain within very narrow limits these sash, panels, and roller curtains, completely hidden and securely held.

The panels are made of two sheets of metal, between which, at intervals, are horizontal slats. Being elastic, these panels conform to the curved outline of the posts. The sash are made in two parts, hinged together, the division being well above the line of

Sash and panels apparently slide in the same groove (one is within the other), and separate on entering the roof recess without the intervention of switches or mechanism of any kind. The Brill round-corner seat-end panels permit the roller curtains to be drawn to the floor.

The same classification made in the foregoing with reference to the method of disposing of the movable parts applies to the windows of the semi-convertible cars. The car is either self-contained or with detachable windows. The limitations and defects of the detachable system are of course the same as mentioned before. Another class should be added, namely, that in which the sash drop into pockets in the wall. The disadvantages of this method are said to be that it detracts from the interior width of the car, and adds to the height of the window rail, and the pocket affords a receptacle for newspapers and rubbish, which soon clog it up.

The chief difference between the convertible and the semi-convertible car lies in the fact that the former has side entrance like the ordinary open car, to permit of rapid loading and unloading. While this advantage is important on many roads, the semi-convertible car is considered by other managers to be the most satis-

INTERIOR OF BEAVER VALLEY CAR.

factory style of car for interurban service, as being safer where the speed is high, and in cases of accident.

The large windows and low window rail, together with the arrangement for storing the sash in the roof, are the chief features of the semi-convertible car. It does not otherwise differ in appearance from the usual type of closed car, having the monitor deck, drooped platforms, cross seats and centre aisle. Another point in the Brill semi convertible car on which stress is laid is the additional inside width obtained, actually 7 1/4 in. The comfort of

the passengers is thereby increased by wider aisles and longer seats, this extra width is secured without in any wise sacrificing structural strength. The system of roof pockets, windows, and roller curtains is practically the same as in the convertible car, the difference being that the roof pockets are narrower, and the windows larger and the sections not hinged together.

An admirer of this car has said that the astonishing facility with which the windows are raised and lowered produces a sensation

CONVERTIBLE CAR—OPEN.

akin to that experienced in assisting in a sleight-of-hand performance. It is accomplished before one's eyes, but just how is not apparent. Investigation reveals the fact that the sections of the window are separate and that the lower and larger, in being raised, slides up behind the smaller, and engaging it automatically without pausing carries it into the roof.

#### A NEW ELECTRIC RAILWAY TRUCK.

Within the past few months the Powell & Turner Truck Co., of 107 Washington St., Troy, N. Y., has brought out a new form of truck for electric cars, which has been termed the "New Century" truck.

In presenting the new type the company makes the following claims: The truck has an exceptionally long car carrying spring bearing; it has a right and left side spring with one end to the car sill, while the other end engages with a cross spring which supports the car at its ends, allowing but the platform and timbers to project beyond the spring bearing; it is non-oscillating while in motion; it will carry its load all on one end and not tip down, but will carry the car body straight; it has an equalizing bar which carries the weight from the end of the truck frame to the journal, it has a relief spring at one end of the equalizing bar, which takes all the jolts and jar off the wheels while passing over the joints, frogs and switches; it is constructed entirely of steel; its frame is made in a truss shape and warranted not to bend; all the prin-

POWELL & TURNER "NEW CENTURY" TRUCK USED IN ALBANY.

cipal parts are riveted together; it has a new three-lever wheel brake believed to be exceptionally powerful and reliable; its parts are simple, durable and strong.

The "New Century" truck has been running for the past eight months on the Albany division of the United Traction Co., of Albany, N. Y. Messrs. Charles Powell and James Turner, patentees of the truck are experienced railway men. Mr. Turner is foreman of the electrical department of the New Albany cars of the United Traction Co. Mr. Powell was for years connected with the Gilbert Car Manufacturing Co., of Troy, N. Y.

The Kansas City-Leavenworth Railway Co. will erect a new depot at its present terminus in Fort Leavenworth.

#### LIVERPOOL CORPORATION TRAMWAYS.

The first annual report of the general manager of the Liverpool Corporation Tramways has just been published, covering the year ending Dec. 31, 1901, this being the first complete year of electric traction in the city. The transfer of the lines was made from the Liverpool United Tramways & Omnibus Co. on the 31st of August, 1897, when the lease of the lines in the city, which were owned by the corporation, had over 17 years to run. The purchase price was fixed by agreement at £507,375. At that time the total length of single track was about 75 miles and the number of cars in service, 297. The changing and reconstruction of the lines was taken up immediately after this purchase and one route was equipped with the overhead trolley system as an experiment and was opened Nov. 16, 1898. The experience with this road was such as to do away with the objections which had been formerly raised against the overhead system, and it was eventually decided to reconstruct the whole of the existing system, putting in electric traction, and also to build about 46 miles of additional track for which Parliamentary powers were granted. The work of reconstruction was commenced in January, 1897, and by October, 1900, nearly 100 miles of line had been reconstructed. The last horse car in the city was taken off the road on Dec. 15, 1900. The track has been laid with 60-ft. girder rails, weighing 95 lb. per yard, having a tread of 2½ in. in width and a groove of 1 in. by 1 in.

Various joints have been used, including the Cooper patent rail joint, the Falk cast-welded joint and the ordinary fish plate joint. Where the latter has been used the bonding has been by means of two No. 0000 "Crown" flexible bonds.

The paving has all been laid upon a Portland cement foundation 6 in. in thickness, and is principally of granite sets. The exceptions to this are about four miles where Australian hard wood blocks have been used and a length of one mile laid with prismatic oak blocks. The construction of the roadbed was carried out by the corporation under the supervision of the city engineer. Some of the special work, which is very complicated, was supplied by the Lorain Steel Co.; one junction supplied by this company comprised 16 points. The overhead electric equipment was carried out by Messrs. R. W. Blackwell & Co., Ltd., London. On narrow streets span wire construction is used, and where arrangements could be made the spans were supported by rosettes attached to the buildings on either side of the street. Wherever the streets were sufficiently wide to permit it center poles were used.

The power for the road is supplied at 500 volts pressure from the power station of the corporation, which also supplies current for lighting and other power purposes. Two new stations are in the course of construction and when completed will each have a capacity of 15,000 h. p. The units adopted in these stations consist

of a Willans engine of 1,200 h. p. direct connected to a Siemens dynamo, giving an output of 1,450 amperes at 550 volts.

The gross profits for the year amounted to £147,057 and the net credit balance to £52,822, out of which is to be drawn a sum for both depreciation and renewals.

The company which has begun the construction of the proposed Nashville (Tenn.) & Gallatin and Nashville & Columbia Electric Rys. contemplates a third line which will connect Nashville and Huntsville by way of Murfreesboro, Shelbyville and Fayetteville. Charles W. Ruth, Frank Haskall and John H. McMillan, of Pittsburg, are reported to be the principal promoters. Construction work is in charge of J. H. Connors, Wilcox Building, Nashville.

## LONDON'S TUBES, TRAMS AND TRAINS.

An interesting paper on this subject was read by Mr. J. Clifton Robinson, before the Society of Arts, London, on March 19th. Within the past 12 months two pressing problems regarding rapid transit in London have come prominently before the public mind. One of these is how the "tangle of locomotion" in the Metropolis is to be straightened out and relieved, and the other is the question of the greatly extended use of electricity in locomotion. Mr. Robinson's address included a review of the past progress of electric traction, a statement of its present position, more especially as regards London, and a glance forward to its future development.

Nearly 20 years ago the author, at the request of the Royal Scottish Society of Arts, read a paper on tramway traction. At that time the cable had just come into vogue in America and was far in advance of any other form of mechanical power for surface lines. He then, however, expressed the view that we should do well to preserve an open mind for future developments, and since then his whole time has been devoted to the practical application of electric power at home and abroad. He was engaged to years ago to prepare the plans and carry forward to completion the construction and equipment at Bristol of the first electric tramway in Great Britain built under the existing stringent regulations of the Board of Trade.

In reviewing the past history of electric traction in England the insufficient and meagre advance made in that country in the direction of tramway extensions are considered largely due to the tramways act of 1870. The burdens and hindrances laid by that act upon the promoters of tramway enterprises have been so great that the record of tramways in the United Kingdom showed in 1890 only about 160 roads in existence, covering less than 1,000 miles of route. A few of these sections were operated by cable, locomotives were used on a few others, while all the rest of the lines in the kingdom used horse propulsion. In view of the obstacles put in the way of tramway building a determination seems to have been arrived at that cars should not be allowed to operate in London's most crowded and therefore most necessitous thoroughfares. Yet, in spite of this blunder the returns show that with about one-eighth of the mileage of the kingdom, suburban London supplied about one-third of the number of passengers. Notwithstanding this encouragement to provide more of such a manifestly popular means of urban travel, we see to-day in London on one side an obvious necessity for the speedy improvement of the means of locomotion to, in and through the metropolitan area, and on the other side a most bitter opposition on the part of nearly every man in power and an endeavor of local authorities to hamper and obstruct attempts to grapple boldly with the vast and pressing problem.

Previous to the issue of the Board of Trade regulations two successful efforts to work a tramway by the overhead trolley system had been made in England. The first electric tramway which followed the issue of the Board of Trade regulations in 1894 and which was established in conformity therewith was the one in Bristol previously mentioned. This line proved an instant success and has been operated without stoppage or accident in the six intervening years. This first example of an electric tramway in a city formed a standard for future guidance. It proved conclusively that a district could be opened up under electric traction which, with only horse power available, must, owing to its gradients, have remained without a tramway. So unequivocal was the conversion of the citizens of Bristol from doubt or opposition to enthusiastic approval that the Bristol Tramway Co. at once proceeded to convert all its existing lines and to extend its mileage in various directions under electric traction. A fine power house lately completed and capable of developing 7,000 h. p. is no more than sufficient to meet the demands entailed by the continuous growth of the company's traffic.

An important event in the development of electric traction was the passing of the Light Railways Act in 1895. When the act came into operation the use of electricity for traction had not advanced very far, but the effect of the act is seen in the difference in the application made under it for the first 18 months. The proposed projects submitted to the commission at the beginning of this time numbered for steam locomotion, 53, of 626 miles, and for electric traction, 32, of 324 miles. For the last year the applications for steam roads numbered 9, of 59½ miles, and for electricity, 54, of 595 miles.

The laws in regard to the tubes, trams and trains are rather

anomalous, as for each of these different styles of roads different laws and practices exist. If a tramway is to be constructed, the General Tramways Act of 1870 with its purchase clause and other difficulties blocks the way. Light railways come under a different law but with difficulties peculiarly their own. The railway stands on a still different footing and it possesses the distinct privilege of going before Parliament on its merits, an advantage hitherto denied tramway undertakings. It was especially recommended by a joint committee of Parliament which sat last year that the London problem should be largely met by means of underground lines within the more congested parts of the city and its immediate suburbs, joined up for the purpose of interchange of traffic with electric surface tramways, etc., in the suburban districts. It is here a curious anomaly is encountered. To follow these rules under existing arrangements the surface lines must be promoted as tramways while the tunnels, although designed to form integral portions of the through service, must be promoted as railways. In one case the two-thirds consent of the various local authorities concerned must be obtained by previous negotiations or the project will fail, while a railway whether it be a tube or shallow tunnel comes at once into court on its merits, and cannot be wrecked by interested opponents or obstructive municipalities. The author joins with everyone who has recently spoken or written on the subject, that one of the greatest obstacles to electric progress in Great Britain has been the discouragement presented on the one hand to scientific and manufacturing skill and on the other hand to financial enterprise, by the shackles and hindrances which legislation has imposed.

There has been evidence of some gradual change of public feeling as electric lines have been opened up to traffic and the real benefits of the service have become manifest. But the irreconcilable opponent of tramways in any shape still exists and the hardness of heart of local authorities in striving to impose impossible conditions is as yet little abated. Small wonder it is that Great Britain lags behind the world in electrical development and that even when the lighting and tramway project has succeeded in being authorized it is necessary to come to the United States for much of the plant and machinery special to such undertakings.

One point of government interference referred to by the speaker which threatens to give great trouble to electrical undertakings of all kinds is the determination of the postmaster-general to introduce clauses alleged to be required for the protection of the telegraph and telephone wires which would place in the hands of the post office the power of controlling every electrical undertaking in the country. These clauses are certainly harmful to tramway enterprises. Attention is also drawn to another sign of danger to electric traction as regards underground lines or shallow railways under the streets, parks, etc. A paper recently read at a meeting of the Auctioneers' Institute of the United Kingdom dealt with the "problem of the tubes." The paper dealt principally with the land owners' position in this matter, and it is pointed out that only such a depth of ground is vested in the road authority as is needful to enable sewers, etc., to be constructed and the road to be kept in repair, while all the soil below belongs to the adjoining land owners. Owing to the great value of the surface it is often customary to sink double basements under the sidewalks and in other cases to run connecting tunnels under the streets between two buildings of the same owner on either side of the street. As the tube railways are run at various levels their construction might render it impossible hereafter to carry out double basements or subways, and this point constitutes a danger signal to which promoters of underground lines would do well to take heed.

Having thus glanced at the earlier history of electric traction in London and indicated some of the difficulties which have hampered progress in the past and which still threaten in the future, the author proceeded to describe the outlook in the immediate future. Of electric tramways in London the leading place is occupied by the operations of the London United. It is generally known that the London County Council obtained control of the tramways in South London six years ago and that the actual progress there is limited so far as electricity is concerned, to a decision to begin to convert a portion of the existing horse car lines to underground conduit. The Middlesex County Council has, owing to the pressure of public opinion, abandoned its obstructive tactics so that it will in the future work in harmony with the enterprise in which the development of greater London is so largely concerned.

As regards "tube" electric railways, the position in London shows:

LINES IN OPERATION.

- The City & South London Railway, opened in 1800.
- Waterloo & City Railway, opened in 1868.
- Central London Railway, opened in 1900.

LINES UNDER CONSTRUCTION.

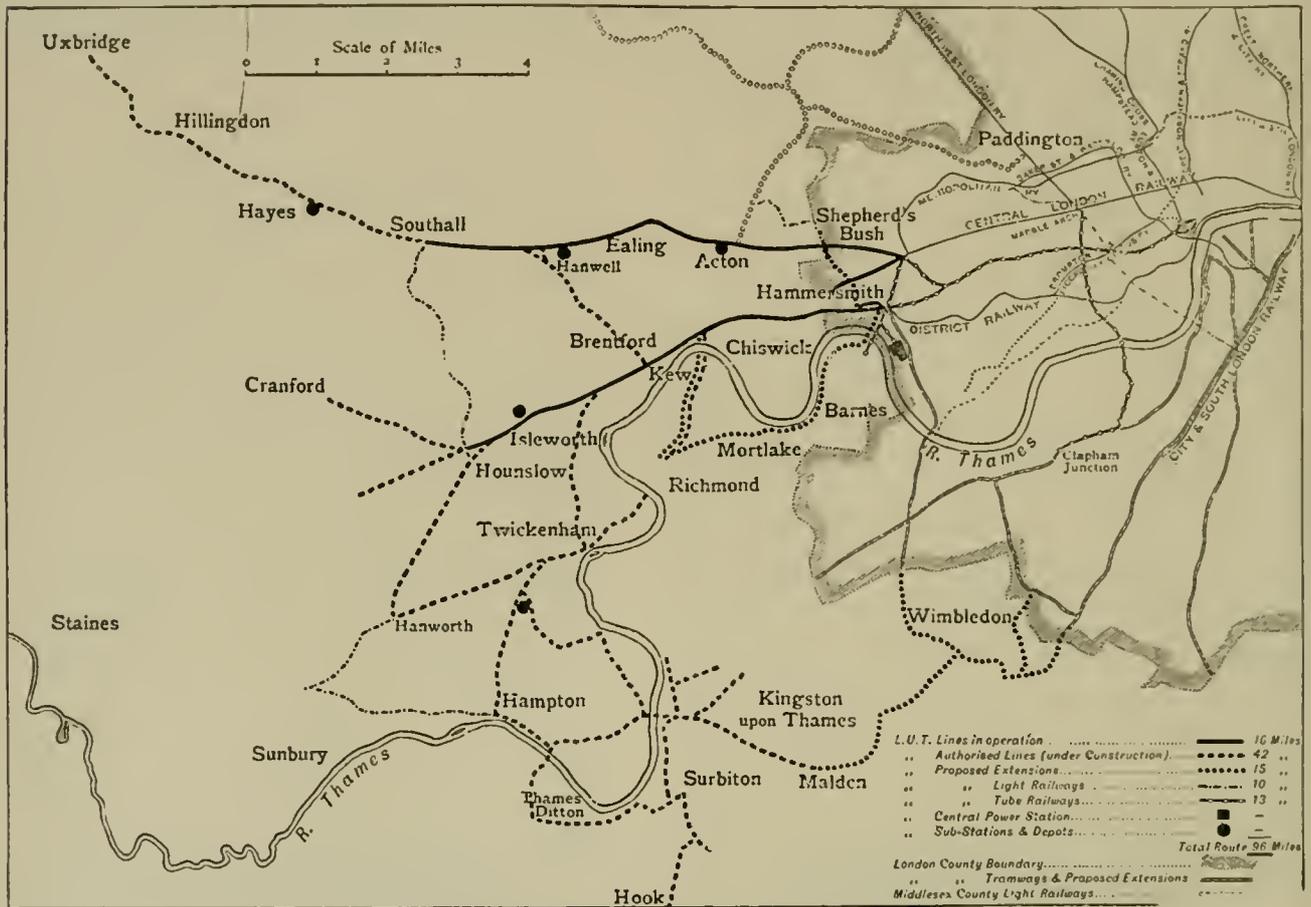

- Waterloo & Baker Street Railway.
- Great Northern & City Railway.

The last named differs from most of the other "tube" lines, in so far that it is constructed with tunnels of 16-ft. diameter, so as to allow ordinary railway stock to run over its rails.

LINES AUTHORIZED.

1. Brompton & Piccadilly Circus Railway.
2. Charing Cross, Euston & Hampstead Railway.

The lines in operation have served the double purpose of affording a great public convenience over a large suburban territory and of opening the eyes of London to the great possibilities in economy, efficiency, speed and comfort of a properly organized electric service. The lines under construction amounting to 42 miles of route are shown by the map to cover a large extent of the western and southwestern suburban district. The proposed extensions of the surface lines for which authority is now sought comprise 23½ miles of electric tramways and light railways. Here is an example of the tangle of tramway legislation. These lines are admittedly required and the assent of the local authorities to build them has been obtained, but the County Council in the position of a rival promoter has the power, as the other authority, to step in, and by refusing assent, prevent the promoters from presenting the case on its merits to Parliament. In several cases the promoters

MAP OF LONDON'S TUBES AND TRAMS.

3. City & Brixton Railway.
4. Great Northern & Strand Railway.
5. North West London Railway.

The above enumeration gives the following figures:

	Route miles.
In operation .....	15¾
Authorized and under construction.....	36½
	52¼

The accompanying map shows all the existing and proposed tramways as well as other railways, etc., in the district of the London United system. The following is a short tabular statement:

	Miles.
Electric tramways in operation.....	16
Electric tramways now under construction.....	42
Electric tramway extensions proposed .....	15
Electric tramways as light railways proposed.....	8½
Electric tube railways proposed.....	13
Total .....	24½

have concluded agreements where, in consideration of large outlays for street improvements they have secured franchises of 50 and 25 years respectively, with power of purchase, in some cases, as a going concern.

COMBINED SURFACE AND TUNNEL SYSTEM.

There is in British tramway practice a difficulty which does not present itself to the American or the Continental engineer, namely: the universality of outside seats on British tramway cars. Despite the austerity of the climate on occasions, there is a strong public desire for outside travel such as seems not to prevail anywhere else in the world. Hence there has always been the hard and fast line of demarcation between a railway carriage and a tram car, while in nomenclature the two have been one in America. But, except under special circumstances, it would be impracticable to adapt a shallow tunnel to accommodate top seat cars. The London United Ry. will make use of the Greathead shield method of constructing these tunnels and at the same time reduce to a minimum the inconvenience at the stations by means of special arrangements in the form of moving platforms, ventilating, etc.,

so as to attract the public by lessening the objections more or less inseparable from an underground line. Interchange of traffic and minimum fares will be made special features, carrying out even more fully than the joint committee suggested facilities for travel from the center of London to its vast western and south-western suburbs. Communications will be opened with all other tube railways whose course may be touched or crossed so that the very widest facility will be provided for expeditiously traversing the whole of the suburban and metropolitan areas with a maximum of ease and a minimum cost on the part of the passenger.

It is believed that from the principles of construction, installation and operation the same success in conducting the traffic will be attained as has been achieved on the electric surface tramways now under the same administration and management. The routes to be followed by the London United Electric Rys. are seen from the diagram. They consist of two principal lines, making in all about 13 miles. The first of these is the east and west railway extending from Charing Cross to Hammersmith where an extended loop will embrace both Shepherd's-bush and the Hammersmith-broadway with a tunnel under the river to the Richmond Mortlake Tramway terminus at Barnes. Second, the north and south line running from the Marble Arch via Sloan St. and Battersea Park to Clapham Junction. The importance of this project will be seen as providing full interchange of traffic east, west, north and south, and the cost of the works, lines and stations apart from power house and equipments is estimated at about 3¼ millions sterling, the total estimate including acquisition of properties, stations, etc., being £5,413,250. The capital represented by tubes, trams and trains in and about London alone will represent when completed an expenditure of not less than £50,000,000.

#### TUBE RAILWAYS IN LONDON.

The Northwest London line, running from the Marble Arch traversing the Edgware Road has a length of 4¼ miles. The Charing Cross, Euston & Hampstead Ry., the contract for the main part of which has been let, has been ordered by the Parliamentary joint committee to stand over till the present session. This line will effect a connection at Charing Cross with the London United as will the northwest London line at Marble Arch, thus affording to the public valuable transfer facilities.

The Baker Street & Waterloo Ry. is in the central position between these two and the original route of three miles is nearing completion. An extension to Paddington will undoubtedly be built in due course.

The Great Northern & Strand Ry. is 6¼ miles as at present laid out and though it offers no through connections with other tubes under the present plans this will doubtless soon be rectified. Arrangements can be made for an interchange between the London United and the Metropolitan District at Charing Cross. This would secure through connections with the northern suburbs and with the populous districts served by the system of the United Electric tramways.

The Great Northern & City Ry., now being completed, has tubes which are 16 ft. in diameter. The difference in diameter prevents any direct interchange of traffic with other underground lines, but it will have a joint station with the City & South London Ry., and in this way will bring north and south into direct communication.

While northwards is found great progress with the new style of underground railway, the southwest and west regions as yet present a blank. The City & South London as shown comes to Clapham Common and was the first electric railway in London. The Waterloo lines also touch an important point in South London, but these are the only lines yet constructed south of Oxford St. and west of Waterloo Bridge.

From Paddington to Kennington Oval, via Victoria is also the proposed West & South London Junction Ry. Covering more or less the same route as is intended to be served by the east and west line of the London United Electric Rys., previously described, there are three other proposals promoted by the Charing Cross, Hammersmith & District Ry., the Piccadilly & City Ry., and the Central London Ry. The two latter extend into the city.

#### CORPORATION VERSUS COMPANY.

The author from the earliest period has been a zealous advocate of railway enterprises being in the hands of incorporated com-

panies rather than in the hands of local authorities. Even in the largest provincial cities difficulties have already arisen in the extension of tramways beyond the civic boundaries. In London the argument in favor of a company undertaking such works is especially powerful and is the more emphasized in the face of a strong desire shown in many places that the tramways there should be in the hands and under the management of the London County Council. The Council does not govern the whole of the Metropolitan area and even within its own bounds it possesses only a joint authority with a multitude of municipalities. How could the initial 16 miles of the London United have been brought into existence and operated had it been left to any combination of local authorities to project, construct and operate them? The company has been at a great disadvantage from the multitude of authorities with which it has had to deal, but it had a unity of purpose and even negotiations with three County Councils and 30 District and Urban Councils did not daunt it. This multitude of councils might have projected and constructed each its own bit of line and they might even have operated these fragments as one system, but each section would have had its staff of Parliamentary agents, engineers and contractors and each one would have demanded its share of the profits, if any could arise from such a jumble of ownership and management. The accounts would be voluminous and their accuracy would be practically impossible, while the hosts of officials would be disastrous to the funds.

In what form shall the power be applied on surface tramways? To this question the author unhesitatingly answers on behalf of the overhead trolley. It has as yet no rival in economy of construction, in simplicity of operation, in safety and in economy as regards passengers. In expressing this opinion the author quoted from his article in the "Review" for January, 1901, on Electric Tramways, as follows:

"Is there any other adaptation of electricity that will probably outrival the overhead trolley for general use under all conditions within the next ten years? I confess I have seen nothing as yet that would suggest this. Every point of view must be looked at before one system can be pitted against another. Is it cheaper, more efficient in operation, as convenient in daily use, as trustworthy in all weathers, and as reliable under all conditions; can it cope with all and every development of the public demand, is it free from danger to passengers and the public? Thus examined I see nothing in any of the existing conduit or surface-contact systems to commend them either to the practical tramway man, or to the engineer. The aesthetic objection? Is that a sufficient reason? Edinburgh, or at least its Lord Provost thought so, for refusing the electric overhead wire, so economical in construction and communication to outlying districts. I think not, and shall probably continue to think so ten years hence."

There is, of course, a probability of startling discoveries in accumulators and some other discoveries in electricity which might upset all existing ideas and send generators, poles and trolleys to the scrap heap. These things are of course possible, but they are not at present "within the range of practical politics." And even if such a day should come the overhead trolley lines could be changed with less capital sacrifice than any other known system. The surface contact system is not favored by the author, largely on account of the rattle and noise of the skates. In Paris the lines on this system originally laid down are being superseded by the overhead trolley, although at Wolverhampton the corporation has entered on a bold scheme of allowing 11½ miles to be equipped in this way. In view of the many changes and improvements which are constantly occurring in this field the author is a little careful as to prophesying, but he expressly limits his opinion to the next ten years and believes that even at that time nothing better will probably be found for London than the plans established by last year's Parliamentary Committee in regard to the problem of intercommunication in the city.

---

An electric line from Batavia, N. Y., to Lake Ontario, via Medina, is projected and actual construction work will be begun before the end of the year.

---

The Newport (R. I.) & Bristol Ferry Railroad Co., which was incorporated in March to build an interurban in Rhode Island, has effected a temporary organization with James Anthony, of Middletown, as chairman.

MASSACHUSETTS REPORT.

The thirty-third annual report of the Board of Railroad Commissioners of the state of Massachusetts has just been issued, covering the fiscal year ending Sept. 30, 1901. Reports were received from 110 railroad companies. Eighteen new companies were organized during the fiscal year under the general law, and five companies were organized under special laws, while 20 companies have been consolidated with other companies. This reduced the total number of companies to 99; of these, 66 are operating their own roads; the railways of 17 were operated by other companies under lease or contract; 14 have organized and are constructing their railways, and 2 have organized, but have not commenced the construction of their lines.

The total miles of main track operated is 2,215,459, an increase of 242,905 over the previous year. It is also to be noted that the use of horses as motive power has entirely ceased in Massachusetts, the last two roads which had used them have substituted electricity. All of the track owned is surface railway, with the exception of 6.644 miles of elevated railway line and 6.468 miles of elevated second track. All the elevated track is confined to Boston.

The Massachusetts companies now own 1,004,744 miles of street railway lines, 272,233 miles of second main track and 132,090 miles of side track, making the total length of track 2,309,066 miles. The difference between the miles operated and those owned by the

companies is due to the leasing of certain track outside of the state from companies that do not report to the Massachusetts board. The mileage given as owned by the companies is exclusive of the track in the subway. The new construction during the last year added 242,703 miles of street railway lines to the Massachusetts roads and 20,823 miles of second main track, making 263,526 miles of additional main track. There have also been added 7,797 miles of side track, making a total addition of 271,323 miles of single track.

The total capital stock and net debt of the street railway companies of the state advanced during the year from \$84,715,097 to \$99,611,185. The average cost of the railways per mile of main track was \$23,953 for construction, \$8,677 for equipment and \$11,666 for lands, buildings, power plants and permanent properties, making a total average cost of \$44,297 per mile of main track.

The gross assets of the companies were \$107,250,655, and the increase, compared with the previous year, amounted to \$8,550,581.

The gross liabilities, including capital stock, were \$103,508,024, which shows a gain over the figures for 1900 of \$8,535,096.

The total income of the companies from all sources was \$23,179,304, and the total expenditure\* including dividends, were \$23,-

108,237, leaving a net balance of \$18,933 to be deducted from the surplus of previous years.

The total amount of dividends declared last year was \$3,417,117, an increase of \$1,007,243 over the preceding year. Forty-three out of 110 companies paid dividends ranging from 2 to 10 per cent, and 76 companies paid no dividends.

The total number of passengers carried during the last year by all the companies was 433,526,936, an increase of 38,499,737 passengers over the previous year, and the total number of miles run by street cars was 93,005,225, an increase of 11,254,457 miles over the previous year.

The number of persons injured in connection with street railway operation for the fiscal year was 2,533, of whom 76 received fatal injuries. The number of passengers injured was 1,620, of whom 20 were injured fatally. The injuries to employes were 77, in all of which 17 were fatal. The number of injuries to travelers on the streets was 836, of which 39 were fatal. This shows two more passengers, 14 more employes and 9 less travelers on the streets fatally injured than in 1900.

The report of the commission points out that the conditions and restrictions under which street railway locations have been granted show a range of grant from that in the nature of a gift to that upon conditions calling for extraordinary expenditure by the company. Grants to the same railways are often radically different in the various town through which they pass. In one case, the local board relying upon the advantage to demand future returns in accommodation and low fares, may give the use of the street upon liberal terms; in another, the local board, thinking it best to secure at once full compensation for all that it gives, imposes upon the same company heavy expenditures as a condition of the right to use the streets. As railways have become more interurban in character, the need of greater uniformity in respect to the conditions attached to grants of locations is apparent in order to secure just terms as between the several communities which they serve and the observance of rules of state policy. The effect of the diversity of opinion among local boards reaches beyond matters of purely local interest.

While the street railway service in many instances is very excellent, in others the evils of over-capitalization, of the building of roads with no good reason for their existence, and the practice of paying dividends and the expense of proper maintenance are too apparent, in impaired properties, lack of proper car equipment, insufficient power plants and floor track and road beds. Where these conditions exist, a prompt remedy should be applied through the immediate expenditure of the money necessary to bring the property up to the proper standard. Financial inconvenience or temporary embarrassment to dividend-paying power offers no reasonable excuse for delay. The recent consolidation of companies has brought to more than one weak system the advantages of financial strength and able management, from which may be expected improved equipment and service.

The report states that the number of passengers carried last year upon the entire railway system of Boston shows the readiness of people to make use of every additional opportunity for travel at low cost, and the relatively great increase upon the elevated part of the system proves the popularity of rapid transit. Accommodations are far behind the demand for them, and additional facilities to meet the needs of those without as well as within the city limits, who travel daily from their homes to the business centers of Boston, should be provided as promptly as possible.

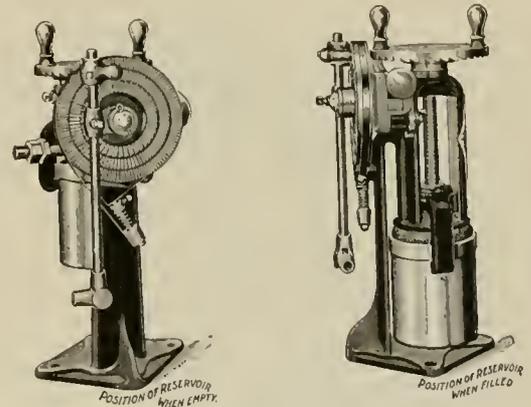

The members of the Board of Railroad Commissioners for the last year were Messrs. James F. Jackson, George W. Bishop and Clinton White.

### THE CHICAGO, ELGIN & AURORA NEAR COMPLETION.

The work of trying and insulating the third rail on the Chicago, Elgin & Aurora road is now being pushed and the completion of the road is looked for within a short time. The large power house near Batavia is being rapidly completed and contains 4 generators driven by engines of 2,000 h. p. capacity. The current from this station will be distributed to five sub-stations along the road which will be located at Aurora, Warrenville, Lombard and Maywood.

### NATIONAL AUTOMATIC CYLINDER LUBRICATOR.

The accompanying illustrations show two views of the National automatic forced feed cylinder lubricator, made by the Stephenson Manufacturing Co., of Albany, N. Y., which is designed to lubricate the cylinders of all kinds of steam engines, pumps, air compressors and similar machines with regularity and without regard to the temperature, consistency of oil or distance from which it is used. This lubricator operates only while the machinery is running and feeds in proportion to the speed of the machine, thereby avoiding any unnecessary oil in the condensed steam. The connecting arm shown in the illustration is attached to some moving part of the engine and the pawl on this arm gradually turns the ratchet wheel at the back of the lubricator. By suitable mechanism the back ratchet wheel moves the top ratchet wheel at the rate of one tooth to each revolution of the back wheel and the oil reservoir is drawn

up against a stationary piston. This motion of the cylinder forces the oil through an outlet to which the parts to be lubricated are piped. A check valve is placed in the outlet to prevent the escape of oil when the removable reservoir is taken out to be refilled. The quantity of oil to be fed is regulated by setting the pawl on the back ratchet to the different rows of teeth and the feed may be increased to any desired extent by setting the ratchet to take two or more teeth in any row. For high speed engines this lubricator is furnished with an attachment which permits reducing the feed as low as may be desired, and at the same time maintaining a regular and positive feed. These lubricators are used by the North River Electric Light & Power Co., New York, the Troy City Railway Co., the United Traction Co., of Albany, the Union Railway Co., of New York City, the Syracuse Traction Co., of Syracuse, N. Y., the Milwaukee Electric Railway & Light Co., and in other prominent plants.

### NEW CARS FOR NORTH JERSEY COMPANY.

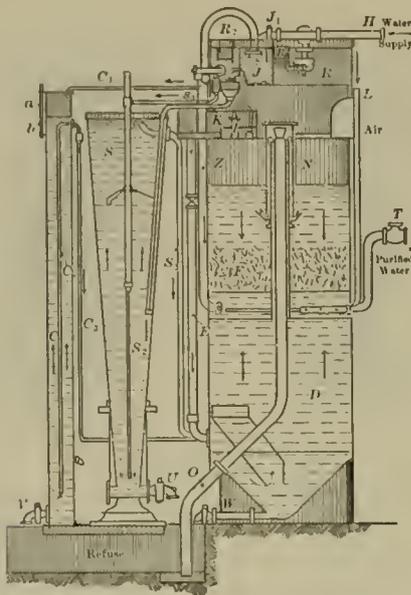

We have just learned some interesting particulars in regard to the 60 cars which the North Jersey Railway Co. has ordered from the John Stephenson Co., of Elizabeth, N. J.

The bodies will have longitudinal seats, and are to be 32 ft. long, with ten windows on a side. The platforms are 4 ft. 6 in. long, making the cars 41 ft. over the dashes. The platforms have open vestibules. In the center of each side between the windows is a panel which affords space for the pipes, etc., of the heater. This is of the hot water type with the store hung beneath the body of the car. The cars are intended for heavy suburban service and are equipped with four large motors.

Two Westinghouse rotary converters of 300-kw. each have recently been purchased by the Manchester (N. H.) Traction, Light & Power Co. They will be located at Hooksett, N. H., and will deliver power for the operation of the Concord and Manchester branch of the Boston & Maine Railroad, this road having entered into a contract for power with the Manchester Traction, Light & Power Co. The machines are to be supplied with three phase alternating current and will deliver direct current at 600 volts.

### AUTOMATIC FEED WATER PURIFIER.

The question of good feed water is always of the greatest importance in a power plant, and our readers will all be interested in the purifying apparatus, a sectional view of which is shown in the accompanying engraving. The operation of this purifier is designed to be entirely automatic and no matter whether the impurities consist of salts in solution or mechanically suspended matter, it is claimed that the water issuing from the apparatus will be in perfect condition for the boilers. The only attention required is the filling of the storage receptacles once each day with the proper proportions of lime and soda ash. The purifier consists substantially of an automatically acting lime saturator, shown at the left as a conical tank, a soda chamber, which is a cylindrical pipe-like receptacle, and an automatic filter in the main part of the apparatus. The lime saturator thoroughly mixes the lime with the incoming water, the water being carried to the base of the cone by an internal pipe and

AUTOMATIC FEED WATER PURIFIER.

rising to the top through the more densely saturated solution at the bottom. By the time it gets to the top, the lime water is perfectly clarified, and leaves the saturator through a pipe which carries it to the bottom of the large cylinder. This portion is known as the reaction chamber, and a concentrated solution from the soda chamber is forced into it through a small pipe. The difference in the methods by which the soda and lime are dissolved is because of the greater solubility of soda, which makes it practicable to dissolve a sufficient quantity for 24 hours at one time in the small soda chamber and send it into the reaction chamber as required. The soda solution is forced out of the soda chamber by allowing water to flow in through a small regulating valve, the difference between the specific gravity of the untreated water and the soda solution being sufficient to prevent the rapid mixing of the two.

Much ingenuity has been shown in the details of the apparatus whereby the correct proportions of the mixture in the reaction chamber are secured. There is a floating valve in a distributing tank at the top, by means of which the level of the water is always kept the same, and the arm is connected to three small valves at an equal height, the first one allowing the inflow of the untreated water, the second for the lime water, and the third for the water which is used to force the soda solution into the reaction chamber. The lime is slaked in a chamber adjoining the distributing tank, and the lime paste resulting is carried to the interior of the conical lime saturator to a point about half way from the top. The untreated water, the lime water and the soda water, remain in the reaction chamber at the lower part of the large cylinder until the chemical reaction of the salts has been completed and the purified water then passes through a filter, to be discharged at the relief valve softened and clarified. The sediment that results from the chemical action in the reaction chamber is precipitated to the bottom of this chamber and can be readily drawn off. An automatic wash-

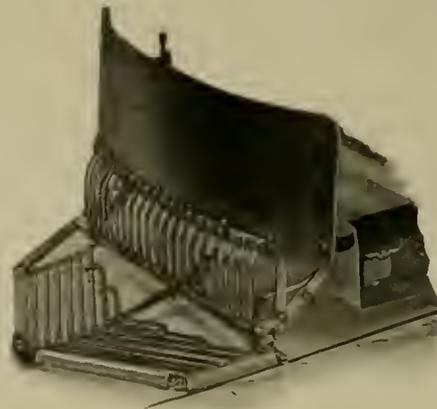

ing arrangement, which is provided for the filter, prevents any clogging up of the apparatus at this point. This is particularly ingenious; a stopping of the filter causes the water to rise until the syphon, N, begins to act, allowing water to escape through pipe O, and drawing air through the pipe, L, which dislodges the sediment; then a definite quantity of washing water is admitted which cleanses the filter bed and carries the sediment out through O.

Two principal advantages are claimed for this apparatus, aside from the fact that it works satisfactorily. One is that it requires absolutely no attention other than the charging once a day with lime and soda, the removing of sediment and the testing of the water to see that no change in its composition has taken place. These operations can be done in a few minutes and the apparatus left to itself for the remainder of the day. The other special advantage is that no chemicals other than ordinary lime and soda are used in the process, and that after the apparatus has been installed in a power house the operating company is at liberty to buy these reagents in the open market. This purifier has been used to a great advantage in a large number of European plants, but its introduction into this country is of recent date.

The rights for the United States are controlled by the Automatic Water Purifying Co., of New York, which will handle all business in this country.

### THE CARR FENDER.

The accompanying illustration shows the street car fender designed by Mr. B. M. Carr, of St. Louis. The fender is made of metal, the front of the deck being rubber-covered, and is detachable from the car. The deck projects about 3 ft in front of the car and normally is carried as low as is possible without striking the pavement. The deck has a jointed tubular frame and spring supporting slats, and is held in the service position by means of coil

springs at either side. On the car is a weight which is connected with the deck and with a spring latch in such manner that by operating a lever the motorman may lift the weight and close the latch adjusting the deck in position.

The point of the fender deck being carried low a body on the track is scooped up and as the additional weight comes upon the deck the latch mentioned is released, permitting the counterweight to drop a short distance, which raises the front part of the deck, and thus prevents the object picked up from rolling off again.

The adjustment of the fender is made when the car is taken out of the barn, and in event of accident the action is automatic.

### THE "PERFECTION" RAIL BOND.

A typographical error on page 244 of our April issue caused us to state the maker of the "Perfection" rail bond as the Protection Rail Bond Co. This should have been the Perfection Rail Bond Co. The general sales agents are F. B. Badt and G. M. Willis, with headquarters at No. 1504 Monadnock Block, Chicago.

The Grand Rapids, Grand Haven & Muskegon Railway Co. inaugurated an interurban express service between Grand Rapids and Muskegon, in April.

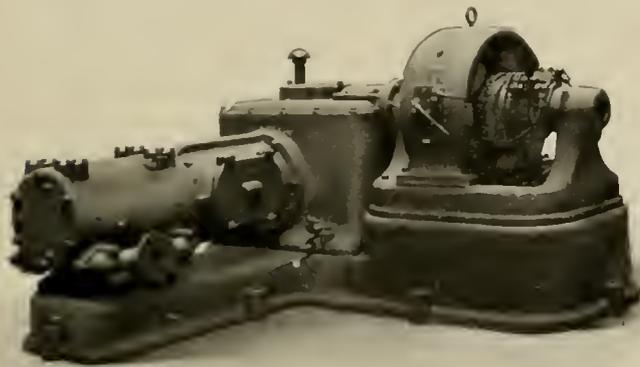

### MOTOR-DRIVEN AIR COMPRESSORS.

The very general adoption of pneumatic tools in shops where electric current is available has resulted in a constantly increasing demand for electrically-driven simple and compact compressing units, to meet which the Christensen Engineering Co., of Milwaukee, Wis., has designed a complete line of motor-driven compressors ranging in capacity from 7½ to 1,000 cu. ft. of free air per minute. Of these the smaller sizes are made for portable as well as stationary use.

The type M compressor, which we illustrate herewith, is built in capacities from 50 to 1,000 cu. ft. of free air per minute.

The motor and the compressor are designed to be compact and self-contained. The air is compressed in the cylinder, shown on the left, by a double acting piston which is operated by means of a connecting rod and steel crank shaft; the latter is mounted in bearings located within the frame of the machine. This shaft carries on the motor end a helical gear which is driven by a pinion on the armature shaft of the motor. The whole machine is mounted on a substantial cast iron base. Both the cylinder and the valve heads are water jacketed throughout and the clearance spaces have been reduced to the lowest practicable limit.

The suction and discharge valves, which are identical and interchangeable, are arranged in cast iron heads bolted directly to the

CHRISTENSEN TYPE M MOTOR DRIVEN AIR COMPRESSOR.

cylinder, and consist of seamless cold drawn steel cups, arranged so that each is removable independent of the other. No springs are used with these valves, they being operated by the compressed air itself and re-seated by gravity. Their peculiar construction renders a small lift possible, and the noise from their operation is reduced to a minimum.

Care has been taken in the design of all the moving parts to render but little adjustment necessary and lubrication easy and effective. The main bearings are made extra long, the crosshead shoes are of large size, the piston rod works in a self-adjusting packing box and the piston rings are of improved form.

The crank shaft is extended at the motor end to carry the gear which is driven by a pinion on the armature shaft of the motor. The gear and the pinion have the helical herring bone type of tooth and are machine cut.

The gear case and the crank chamber are connected and form an enclosure which is partly filled with oil, with which all the working parts are lubricated, including the air cylinder. The latter is connected with the oil chamber so that the proper quantity of oil for lubricating the surface between the cylinder and the piston is automatically supplied and no sight feed lubricator is required. The motion of the crank shaft in the oil causes continuous lubrication of the main bearings, the crank pin bearing of the connecting rod, the cross head guide, the piston rod, the wrist pin in the cross head and the piston. Oil is also supplied automatically to the bearings at the pinion end of the motor. The gear and pinion operate continuously in the oil bath. The machine will remain lubricated as long as the oil is kept up to a level determined by a filling plug on the side of the crank chamber, and one filling inlets for several weeks run.

Either an alternating or a continuous current motor may be used. The illustrations herewith show the continuous current multipolar

type that the Christensen company builds for this service. The lower frame of the motor is of cast iron and the field is composed of low carbon cast steel with detachable steel pole pieces. The motors are series wound and are started and stopped without using resistance.

By unscrewing a few bolts the armature and the field coils of the motor can be removed or exchanged. The gear, pinion, valves or cylinder heads may also be removed without disturbing any other parts. Access to the cross head and wrist pin is obtained by doors on the side of the slide frame. The crank chamber is completely closed, but the upper part may easily be removed to give free access to all the working parts while a smaller hand hole covering is provided for inspection of the interior.

The governor is automatic starting and stopping the motor compressor as the predetermined minimum and maximum air pressures.

### A DISGRACEFUL AFFAIR.

April 24th, Senator H. D. Money, of Mississippi, was ejected from a car in Washington, D. C., for refusing to either pay his fare or produce a transfer. On the senator's refusal to pay his fare the conductor followed the usual rule in such cases by stopping the car and attempting to put off the passenger. Mr. Money resisted so vigorously that a fireman, who was on board the car went to the assistance of the conductor. Just as he was ejected from the car the senator drew a small pen knife with which he stabbed the conductor in the hand. The senator then went before a justice of the peace and swore out warrants for the arrest of the conductor and fireman, but in making his charge against them, the senator admitted that he had insisted on riding without paying his fare, but claimed that the conductor saw him get off another car and therefore knew that he was entitled to a transfer, although he had none to present. The following day Senator Money was placed in custody on information sworn out by O. D. Shaner, the conductor who ejected him from the car. The information charged the senator with assaulting the conductor during the disturbance and the conductor produced witnesses who corroborated his version of the story. The case was settled May 7th out of court, the senator promising not to prosecute either the conductor or the fireman. Both of these men kept their jobs as it was generally considered that the conductor was doing no more than his duty.

### STEAM TURBINES IN LONDON.

A contract for Westinghouse steam turbines for the Metropolitan Railway Co., of London, has just been given to the British Westinghouse Electric & Manufacturing Co., of Manchester, which company is now filling a similar contract for the Metropolitan District Electric Traction Co.

There will be a general similarity in the two stations and it will be easy to arrange for connecting the two and making them interchangeable, as far as the supply of current is concerned, which feature was required by the terms of the franchises of the two roads. The Metropolitan power station will be located at Neasden, in the northwest of London, and will contain three sets of 3,500 kw. capacity each. The Chelsea station of the Metropolitan District Railway will contain four sets of 5,000 kw. each. The electrical machinery for both stations will also be supplied by the Westinghouse company. The current will be three-phase alternating and of 10,000 volts, to be transformed in sub-stations to direct-current for use in the car motors. The aggregate power of the two plants will be 30,500 kw. It is hoped that in a year and a half the equipment will be complete and in working order. Both roads are underground and the change to electric traction will be an important and desirable step in the solution of London's transportation problem.

About 10:30 p. m., on April 26th, a severe gale blew down the two smoke stacks at the power house of the old Heim line in Kansas City, doing about \$1,200 damage, which was covered by cyclone insurance. One stack was 36 in. in diameter and the other 40 in., both being 85 ft. high. The power plant had not been in use for two months so that no delay to traffic resulted. The stacks will be rebuilt and the station used when the season for park travel opens.

**PERSONAL.**

MR. TIREY L. FORD has been appointed general counsel of the United Railroads of San Francisco.

MR. E. S. BREED has assumed the duties of superintendent of the Berkshire Street Railway Co., Pittsfield, Mass.

MR. R. E. DANFORTH, general manager of the Lake Shore Electric Ry., has resigned to become manager at Rochester, N. Y.

M. BIENVENCE, chief engineer of the Paris Metropolitan Underground R. R., is making a tour of American cities to inspect the best approved traction systems.

COL. ALLAN C. BAKEWELL, general manager of the Sprague Electric Co., has recently been elected second vice president of the Pennsylvania Society of New York.

MR. S. P. WOLVERTON, JR., has assumed the management of the Sunbury (Pa.) & Northumberland Electric Railway Co., succeeding Mr. W. L. Keplinger, resigned.

MR. FRED I. GRISWOLD has resigned as superintendent of the Battle Creek lines of the Michigan Traction Co., and will have charge of the Allendale Hotel at Gull Lake, Mich.

MR. THOMAS DOLAN has resigned as a director of the Union Traction Co. of Philadelphia, declining to accept a membership on the board of directors of the new Philadelphia Rapid Transit Co.

MR. DAVID L. BEAULIEU, formerly connected with the Worcester (Mass.) Consolidated Street Railway Co., has been appointed superintendent of the Lansdale & Norristown (Pa.) Street Railway Co.

MR. F. C. RAPP, who for two years has been general foreman of the shops of the Indianapolis Street Railway Co., has resigned that position to become general foreman of the works of the Dorner Truck & Foundry Co., Logansport, Ind.

MR. WILLIAM H. BROWNE, for seven years general manager of the Royal Electric Co., Montreal, Canada, in February last was chosen general manager and treasurer of the Stanley Instrument Co., of Great Barrington, Mass.

MR. OTTO W. UTHOFF, who for the past four years has represented the Columbia Incandescent Lamp Co. in the eastern states, was recently appointed manager of the St. Louis office of the Ohio Brass Co., having charge of the southern and western states.

MR. C. M. MILLS, formerly electrician in the shops of the Metropolitan Street Railway Co., of Kansas City, has been appointed superintendent of the Bozeman Street Railway Co., Bozeman, Mont.

MR. HOWARD R. PORTER, formerly connected with the Cincinnati Traction Co., has been appointed superintendent of the Paducah (Ky.) Railway & Light Co., and will assume the duties of his new position June 1st.

Mr. A. M. MOORE has been appointed master mechanic of the Georgia Railway & Electric Co., of Atlanta, and not chief engineer, as was erroneously announced. Mr. Moore was formerly master mechanic of the Atlanta Rapid Transit Co.

MR. J. A. BENDURE has accepted the general managership of the Lima (O.) Electric Railway & Light Co. and will supervise to a large extent the construction of the company's projected 70-mile interurban which will connect the smaller towns between Lima and Toledo.

MR. WARD S. ARNOLD, who for some years past has been with the General Electric Co., on May 1st became sales engineer of the Chicago office of the Stanley Electric Manufacturing Co. Mr.

Arnold is a brother of Mr. H. J. Arnold and is a well-known factor in the electrical trade of the western territory.

MR. J. I. MANGE has been appointed electrical superintendent of the Oneonta, Cooperstown & Richfield Springs Ry., a 16-mile interurban running out of Oneonta, N. Y. Mr. Mange has been connected with the engineering staff of the Lachine Rapids Hydraulic & Land Co., of Montreal, Que., his present address is at Hartwick, N. Y.

MR. A. L. DRUMM, who has been connected with the Stone & Webster syndicate of Boston, has been appointed assistant general manager of the Union Traction Co., of Indiana. Mr. C. W. McGuire will continue as assistant to the president, and Mr. Charles A. Baldwin will assume the duties of general passenger agent and assistant superintendent.

MR. LOUIS H. MOUNTNEY has been appointed superintendent of the Lewisburg, Milton & Watsonstown Passenger Ry., Milton, Pa., succeeding Mr. W. W. S. Butler, who recently resigned. Mr. Mountney was formerly superintendent for the American Railways Co. at Springfield, Ill., and later was with the Lima (O.) Railway & Light Co.

MR. CHARLES A. SPOFFORD, of New York City, formerly secretary of the Milwaukee Electric Railway & Light Co., has been appointed to assist Mr. Yerkes in the management of the London underground railway system, and will supervise to a large extent the installation of electric traction on the Metropolitan District Ry. Mr. Spofford will arrive in London about June 1st.

MR. GEORGE C. SIKES has resigned as secretary of the Chicago council committee on local transportation, his resignation being effective June 1st. The retirement of Mr. Sikes is to be regretted since he had devoted a great deal of time and study to the traction problem in Chicago, and the tendency of his work was toward a more equitable solution that is popular with the mayor.

MR. W. M. M'FARLAND, acting vice president of the Westinghouse Electric & Manufacturing Co., delivered a lecture on "Electric Power Distribution in Manufacturing" at Cornell University on May 9th. The several different systems of distribution and their relative advantages were discussed and the manner of applying electric motors to machinery illustrated by a large collection of stereopticon views.

MR. WILLIAM G. EVANS, who has been secretary of the Denver (Col.) City Tramway Co. for many years, will succeed Mr. W. N. Byers as vice president, the latter resigning that position to attend to other business interests, but remaining a director of the Denver company. Mr. John A. Beeler, formerly chief engineer, has been made general manager of the system and will superintend the details of the company's new construction.

MR. N. M. GARLAND, formerly representative in the north-eastern states of the Emerson Electric Manufacturing Co. of St. Louis, and who is well and favorably known among the electrical fraternity in that section, on May 1st assumed the management and control of the New York office of the Ohio Brass Co. of Mansfield, O. This appointment has been made owing to the fact that Mr. Alfred B. Edes, formerly manager of this office, has been appointed sales manager of the company, and will hereafter be located at the main office in Mansfield.

MR. JOHN J. STANLEY, vice president and manager of the Utica (N. Y.) & Mohawk Valley Railway Co., will succeed Mr. McCormack as general manager of the Cleveland Electric Railway Co., the appointment being effective May 15th. Mr. Stanley will retain his position as vice-president of the Utica road, but in the capacity of manager will be succeeded by Mr. C. Loomis Allen, formerly superintendent of the Syracuse Rapid Transit Railway Co. Mr. Stanley, in accepting the general managership of the Cleveland line, returns to a position which he held at the time of the Everett-Moore syndicate's securing control of the Cleveland Electric Ry. He was asked to remain when the road came under the control of the Everett-Moore interests, but declined.

MR. C. N. DUFFY, auditor of the Chicago City Ry., left on May 20th to attend a meeting of the committee on standard form of reports for electric railways of the Street Railway Accountants Association at Atlantic City on May 22d. The other members of this committee are Mr. W. F. Ham, of Washington, and Mr. Elmer M. White, of Hartford.

MR. J. W. BUTLER has been appointed manager of the outing department of the Cleveland Electric Railway Co., his duties being to arrange and book parties from societies, conventions, Sunday schools, etc., to the numerous parks and pleasure resorts on the lines of the Cleveland Electric Ry. Mr. Butler has had 20 years' successful experience in handling excursions for railways, and it was he who ran the first railway excursion into the World's Fair at Chicago for a Chicago newspaper. Mr. Butler's headquarters will be at No. 620 Electric Building, Cleveland.

MR. GEORGE F. CHAPMAN has resigned as general superintendent of the North Jersey Street Railway Co. to accept the appointment of general manager of the United Railroads of San Francisco. Mr. Chapman has been connected with the North Jersey Company and its predecessors for the past 12 years. For 8 years he had charge of the lines at Elizabeth, and 4 years ago was made general superintendent of the entire system, comprising lines in Newark, Elizabeth, Jersey City and the Oranges. Mr. Chapman enjoyed a high degree of popularity alike with the officials of the company, the employes and the public.

MR. C. M. SHIPMAN, formerly superintendent of the Essex County division of the North Jersey Street Railway Co., has been appointed general superintendent of that company to fill the vacancy caused by the resignation of Mr. G. F. Chapman. Mr. James Smith, formerly superintendent of the Union County division, has been transferred to the Essex County division; Mr. G. D. Leacock, formerly assistant superintendent of the Roseville division, has been appointed superintendent of the Union County division; Mr. J. A. Campion, formerly assistant superintendent of the South Orange division, has been transferred to the Roseville division; Mr. James McDonough, formerly assistant superintendent of the Springfield Ave. division, has been assigned to the South Orange division, and Mr. W. B. Taylor has been appointed assistant superintendent of the Springfield Ave. division. All the appointments were effective May 10th.

MR. JOHN F. CALDERWOOD, who has been for two years comptroller of the Twin City Rapid Transit Co., of Minneapolis, has resigned to become assistant to President J. L. Greatsinger, of the Brooklyn Rapid Transit Co., and will assume the duties of his new position this month. In his capacity as assistant to Mr. Greatsinger, Mr. Calderwood will be prominently identified with the practical and financial operation of the Brooklyn system, and may also occupy the president's chair in the absence of Mr. Greatsinger. Mr. Calderwood is a well-known member of the Street Railway Accountants' Association of America, and is also a member of the Institute of Secretaries of London.

MR. BERNARD CORRIGAN has been elected president and general manager of the Metropolitan Street Railway Co. of Kansas City, succeeding in the dual capacity Walton H. and Conway F. Holmes, who have been so long and prominently identified with the development of the system. Mr. Corrigan is one of the most generally known men of Kansas City in business and political circles. He is a Canadian who came to Kansas City in 1868 with his two brothers to engage in the building of railways at a time when the transportation facilities of the middle-west metropolis were of the most primitive sort. The Corrigans in 1875 organized a company which purchased all the street railway lines in Kansas City with the exception of the mule line to Westport, which was owned by Nehemiah Holmes. In 1886, the Corrigan Consolidated Street Railway Co., operating the Union Depot Horse Ry., the Kansas City Horse Ry., the Jackson County Horse Ry., and the Corrigan Horse Ry., aggregating 20.7 miles of horse and mule lines, sold its interests to the Metropolitan company which had been chartered in that year and at once undertook the conversion of the horse car lines to the cable system. On retiring from the street railway field Mr. Corrigan engaged in the contracting busi-

ness, and constructed a large part of the Kansas City, Pittsburg & Gulf R. R., and later, an extension of the Choctaw line in the Indian Territory. He is also largely interested in real estate in the Kansas Cities, and is a stockholder and director in the First National Bank. Mr. Corrigan also succeeds Conway F. Holmes as president of the Kansas City Electric Light Co. It is believed that the resignation of Mr. Holmes and the election of Mr. Corrigan as president of the two companies will soon be followed by a consolidation of the street railway and lighting properties under the name of the Metropolitan Traction & Lighting Co.

MR. IRA A. McCORMACK has resigned as general manager of the Cleveland Electric Railway Co. to become assistant general manager of the Harlem division of the New York Central & Hudson River R. R. in which capacity he will have charge of the tunnel and New York City terminals. Mr. McCormack is a native of Pittsburg, and has spent the greater part of his life in connection with the management of steam and electric railways. His first position, after graduating from the schools of Pittsburg, was that of telegraph operator for the Pittsburg & Connellsville Railroad Co., upon the duties of which he engaged in 1872. From 1873 to 1886 he was employed by the Pittsburg, Fort Wayne & Chicago Railroad Co. in the various capacities of brakeman, conductor, freight and ticket agent and general yard master, resigning in the latter year to accept a position as general yard master with the West Shore R. R. He was made trainmaster for the West Shore, and subsequently held a similar position with the Pittsburg & Lake Erie at Pittsburg. Mr. McCormack removed to New York City in 1892 where he was trainmaster for the New York Central for a short time before engaging with the Hall Signal Co. of Chicago in the work of putting up electric signals on the Chicago & Northwestern and the Illinois Central railroads in preparation for the extra traffic of the World's Fair year. When this work was completed he became trainmaster on the Lake Shore & Michigan Southern Ry. between Buffalo and Cleveland. In July, 1895, by the appointment of Mr. Rossiter, president of the Brooklyn Rapid Transit Co., Mr. McCormack was made general superintendent of the Brooklyn system, a position which he held with notable success until October, 1899, when he resigned to become vice president and managing director of the Syracuse (N. Y.) Rapid Transit Railway Co. April 1, 1900, he was appointed general manager of the Cleveland Electric Ry., since which time, through his practical experience and peculiar adaptability for the work, he has been able to effect many improvements for the better in the Cleveland system.

Mr. McCormack was tendered a luncheon, May 4th, at the Enclid Club by Mr. Horace E. Andrews, president of the Cleveland Electric Railway Co. Among the guests were the following prominent steam railroad men: W. C. Brown, third vice president of the New York Central & Hudson River Railroad; Edgar Van Ethen, second vice president of the New York Central, in charge of the Boston & Albany Railroad; C. E. Schaff, general manager of the Big Four Railway; George P. Daniels, general traffic manager of the New York Central; A. J. Smith, general passenger agent of the Lake Shore; P. S. Blodgett, general manager of the Lake Shore; A. H. Smith, general superintendent of the New York Central, and W. H. Marshall, general superintendent of the Lake Shore Railway Company.

#### OBITUARY.

MR. McCLELLAN HERSH, a former general agent of the Union Traction Co. of Philadelphia, and an ex-member of the Pennsylvania Legislature, died in Philadelphia, May 4th. Mr. Hersh was born at New Oxford, Pa., in 1853. In his early business career he was identified with the Collins expedition to construct a railroad in Brazil, but soon returned to Philadelphia where his business interests were varied and extensive.

MR. WELSH H. GOODRICH, secretary of the Omaha Street Railway Co., died May 11th, of pneumonia, after a short illness. Mr. Goodrich had been connected with the Omaha Street Railway Co. since 1887, being one of the large stockholders and an officer of the company. He was a regular attendant at the A. S. R. A. convention and had an extensive acquaintance among the street railway men, all of whom will regret to learn of his death. A wife and three children survive.

### A NEW TYPE OF ST. LOUIS CAR.

The St. Louis Car Co. recently delivered to the Oneonta, Coopers-town & Richfield Springs Railway Co. several interurban cars which differ in many respects from the kind usually seen. It will be noticed from the accompanying illustration that the entrance for passengers is at the center of the car. One end of the car forms the ladies' compartment and the other end is the smoking compartment and the compartment for baggage.

The extreme length of the car is 56 ft. and its greatest width, 9 ft. The ladies' compartment is 20 ft. long and the motorman's cab, which is partitioned off from this, is 3 ft. in length. This compartment contains 12 seats of the St. Louis Car Co.'s, walk-over pattern, covered with plush. It is also provided with a water cooler, toilet room and hot water heater. The smoking compartment is 13 ft. in length and is furnished with 10 walk-over seats. Beyond this is the baggage compartment, which is 10 ft. long and has sliding doors on both sides.

The center platform is 4 ft. wide and has double steps on both sides. The passenger compartments open onto this platform by single sliding doors. The interior of the car is cherry and it has

NEW TYPE OF INTERURBAN CAR—ST. LOUIS CAR CO.

solid bronze trimmings. The sash are in two sections, the upper stationary while the lower drops to the arm rails which are provided with casings to cover the sash pocket when the sash is lowered. The car is mounted on double trucks built by the St. Louis Car Co., of the M. C. B. type. They are equipped with double plate wheels and Christensen air brakes.

### THE LABOR QUESTION IN PROVIDENCE.

In March employes of the street railway properties controlled by the United Traction & Electric Co., of Providence, R. I., presented a form of agreement which they wished the company to accept. In substance this provided:

1. The company to treat with its employes of the Amalgamated Association of Street Railway Employes through the officers of the Association.
2. Differences between the company and the men to be submitted to arbitration.
3. Final answers to questions submitted to either party to be made in 24 hours.
4. All new employes to join the union within 30 days after entering the service of the company.
5. A regular day's work to be 10 hours, performed within 12 consecutive hours, except on Sundays, when it shall be 8 hours.
6. Notice of extra men required to be given in advance if possible.
7. New men to receive 20 cents per hour for first year and 22½ cents per hour thereafter.
8. Assignments of trainmen to be made according to length of service. Extra men reporting to receive 25 cents per hour until excused.
9. The men on any line to be preferred in assigning runs to the men from other lines. Men on cars running less than half a day to be paid 30 cents per hour.
10. The railroad company agrees to meet a committee of the association at some future date to be decided by both parties for the purpose of arranging a different system of conductors turning in

their receipts. And in order to prevent any friction or misunderstanding, and for the smoother working of the service, all time tables that may be changed or instituted (except special time tables, which may be run under 24 hours without submission), shall be submitted to the association and posted in the sub-stations at least 24 hours before going into effect. All time tables must conform strictly to the provisions of this agreement. Should, however, the association be able to show the company where the runs on any time table can be completed in less hours than specified on the company's time table, or short runs consolidated in one run, without changing the service, the company shall adopt the changes suggested by the association.

11. All complaints against any motorman or conductor shall be accompanied by a deposit equal to that man's pay for one day; if the motorman or conductor complained of is found not at fault, he shall receive his day's pay for same. Any member of this association under this agreement laid off for punishment or discharged, and after investigation found not at fault, shall be reinstated in his former position and be paid for the total number of days that he is laid off by the company at the number of hours per day that his run on the time table calls for, and an extra shall be paid an amount

equal to the amount of wages paid to the extra who took his place during the period he was laid off. In case the association suspends a member who is an employe of the company for any violation of their laws or rules, they shall request his suspension in writing, signed by the officers of the association. The officers of the company shall suspend an employe thus requested at once without pay, until such time as the association requests his reinstatement.

12. Agreement to be in force until changed by mutual consent of parties.

13. The business agents of the association to have access to all employes when it does not conflict with the latter's duties.

The reply of the company by its general manager, A. T. Potter, was as follows:

"The demands of the Amalgamated Association of Street Railway Employes in the proposed agreement submitted to the United Traction Co. are certainly far-reaching and comprehensive.

"Not only is it proposed to submit all differences between the company and its employes to arbitration, but, by the terms of the agreement, the operation of the road is practically taken out of the hands of the company and placed in the hands of the association.

"A street railway is operated through two agencies: The time tables which schedule the time and routes of the cars, and the motormen and conductors who run the cars, and the association demands that both these agencies be placed under its supervision and control.

"Under the proposed agreement no changes in the time of running cars which the officers of the company may think advisable in the interests of the public or the company can be made without the approval of the association, and when the association finds that short runs can be consolidated into one run, or that runs on any time table can be completed in less than the schedule time, the company must adopt the changes suggested by the association. In the words of the paper submitted: 'All time tables must conform strictly to the provisions of this agreement.'

"Such is the proposition submitted to the officers of a company charged with a grave responsibility to the public and to the owners of the property. Must the time tables of railway companies in the future be finally made up and revised by associations of this kind,

regardless of the convenience and welfare of the public and the interests of the shareholders?

"But the most important factor in the operation of a street railway are the motormen and conductors who run the cars. Not only does the company rely on these men for the efficiency of the service, but they are the trusted agents of the company, upon whose care and faithful service depends the safety of hundreds of thousands of our people. In the selection, oversight and superintendence of these men, the officers of the company are charged with the highest moral and legal responsibility, but it would be impossible for them to fulfill this obligation if the men are instructed and directed by an outside and irresponsible authority.

"In the proposed agreement the association unhesitatingly demands that it shall manage this part of the company's business, its supervision extending to almost every detail.

"All men now in the service of the company, or who enter the employments of the company, must be members of the association. By this provision the officers of the company are cut off from selecting the best and most careful men for a service which involves danger to life and limb, and the selection is restricted to men who by chance may be members of the association. It is possible that the association may prove as unpopular as some recent unions, in which case the road could not be operated for want of conductors and motormen.

"It is further proposed that the association fix the pay of the employes, and they have prepared and inserted in the contract which they present for signature, a schedule of payments accompanied by such restrictions and conditions that the company is entirely relieved of all responsibility respecting the wages to be paid their employes.

"So likewise in regard to the hours of labor; they determine what shall constitute a day's labor, with special provisions for Sundays, legal holidays and such times as the company is obliged to provide for extra travel, and how and when the men shall be assigned their work.

"Having thus provided the company with time tables, the men who shall be employed, the pay they shall receive, and the hours they shall work, in other words, having got the road into operation, the association then proceeds to regulate the discharge of the men.

"If a complaint is made to the management by any passenger or citizen regarding the misconduct of any motorman or conductor, it must be accompanied by the deposit of a sum equal to the man's pay for one day, which he shall receive if not found in fault.

"Then follows this provision: That the company shall suspend its own employe without pay, and until such time as the association asks for his reinstatement, whenever it shall request his suspension for any violation of the association rules. This proposition is seriously propounded for the favorable action of this company, that it will proceed at once to suspend without pay its most efficient and trustworthy employes, whenever they disregard any rule which the association may choose to make. The carrying into effect of this provision is not only a violation by the company of every principle of right and justice in its dealings with its employes, but it may result at any moment in the suspension of half of the company's men, and the consequent interruption of the running of the road.

"It is further provided that an agent of the association shall have the right to interview all employes at the stations whenever it does not conflict with their duties.

"This agreement to continue in force and remain binding on the respective parties until changed by mutual consent.

"Such is the general purport of the demands submitted by the Amalgamated Association of Street Railway Employes to the United Traction and Electric Company.

"The officers of the company are charged with the responsible duty of the transportation of the public with convenience and safety. In the performance of this important undertaking they are clothed with certain powers, which are essential and necessary. They have no legal or moral right to surrender or delegate these powers; such a course of action would be a wrong committed against the public, whose safety is entrusted to them, and against their own stockholders.

"Corporations have rights and obligations which are just as sacred as individual rights and obligations, and both are equally protected by the same laws.

"The association has the undoubted right to seek the promotion of any lawful purpose through organization, but it has no authority to interfere with the lawful rights of any other person or corporation.

"Inseparable from all rights are corresponding obligations to respect the rights of others, and this applies to corporations as well as to individuals. Among the fundamental rights secured by law to individuals and corporations is the right to make contracts. This right lies at the foundation of all business and trade. The wage worker is free to make any contract for his services with whomsoever he chooses, and a corporation, in the absence of statutory restrictions, is free to contract for the services of whomsoever it chooses.

"It will be the policy of this company in the future, as it has been in the past, to engage the services of the most capable and careful men, regardless of any association. The company has no objection to any of its employes being members of any association, but neither the membership nor non-membership in any association will have the least influence in the selection of its employes. No employe will be discharged because he is a member, or because he is not a member of any association. Our employes may rest assured that their relations to the company and their continuance in its service will depend upon the faithful performance of their duties, and will not be affected by any threat against or demand made upon them by any association.

"The true relation between employer and employe rests upon mutual confidence, which it is a most serious matter to disturb, because it is so difficult to restore this confidence once lost.

"This company trusts that by stating to its employes in a frank and plain way its position, to strengthen that mutual confidence which has always existed.

"The submission to these demands signifies, in substance, that the street railway system now owned and operated by the traction company shall in the future be operated by this association.

"For these reasons the officers of the United Traction Company must decline to take into consideration the proposals contained in the draft of agreement submitted."

"The employes appear to have, on reconsideration, accepted the company's view as the reasonable one, and at this writing the question may be taken as settled.

---

### EXCURSIONS AROUND GRAND RAPIDS.

The Grand Rapids Railway Co. has published a well illustrated pamphlet entitled, "Where and How to Go," which gives directions for visiting numerous points of interest in and about Grand Rapids, Mich., which are reached by the lines of this company. One of the main points of interest is Reed's Lake, where the company has established several pleasure resorts, which are handsomely equipped for summer entertainment. North Park and the Soldiers' Home Park are other points of interest, and the pamphlet contains concise instructions as to the best methods of reaching these and other points of interest and also the time required for the different trips as well as the fare charged. A tour of the city may be taken in these cars, including a trip of 21 miles, which costs but 20 cents.

---

### TROLLEY ROUTE OVER HAMPTON RIVER BRIDGE.

The Exeter (N. H.), Hampton & Amesbury Street Railway Co. has opened a new route connecting the street railway systems in Newburyport, Amesbury, Haverhill, Lawrence and Lowell, in Massachusetts, with the lines centering in Portsmouth, Nashua and Exeter, in New Hampshire, the connecting link of railway crossing a new bridge across the Hampton River, which has been erected at a cost of \$100,000. The road will give communication between a formerly isolated section of the Massachusetts beach and the stretch of beaches and headlands on the New Hampshire coast line well known to pleasure-seekers, and the opening of the Hampton River bridge has an important bearing on the project of a broad ocean boulevard to skirt the New Hampshire seacoast. The structure was erected by the Granite State Land Co. and lacks 200 ft. of being a mile in length. A direct route from Boston to Hampton Beach is afforded.

---

The electric railway between Norristown and Pottstown, Pa., is nearly ready to be opened for general traffic. It is understood that power for the operation of this line will be furnished from the Collegeville plant of the Schuylkill Valley company.

## A TEST OF THE PLANT OF THE UNION TRACTION CO. OF INDIANA.

One of the most elaborate tests of electric railway stations ever undertaken was that which has been conducted by the junior and senior classes of the School of Electrical Engineering of Purdue University, Lafayette, Ind., on the system of the Union Traction Co. of Indiana. The power house and transmission system of this company, which operates 109 miles of interurban and 54 miles of local track, were fully described and illustrated in the "Review" for April, 1901, page 293.

The credit for the admirable arrangements and manner of carrying out this test is due to Prof. W. E. Goldsborough, director of the School of Electrical Engineering at Purdue, Mr. A. S. Richey, electrical engineer of the Union Traction Co., and Mr. Percival Fansler. There were 64 men engaged in the work during the tests proper which covered a period of three days. A great deal of the preliminary work, including the making of schedules and placing of meters, etc., was done by 10 students of the senior class who were preparing theses upon subjects connected with railway topics. The tests began at 4 a. m., Thursday, April 17, and continued until Sunday, April 20th, at 2 a. m., simultaneous readings of the various testing instruments being taken at intervals of 15 minutes. On certain special tests of shorter duration the readings were taken at much shorter intervals.

Some of these duties required especial vigilance. This was notable in the case of watching the ammeter of the booster and battery circuit for twenty-two hours each day and throwing a switch backward and forward as the needle passed zero to the right or the left. To the right of zero the needle showed the current was flowing from the battery out to the line, while to the left of zero the ammeter needle indicated that the battery was being charged. The tests made were very complete and covered every department of the power station, sub-stations and cars. The boilers and steam engines in the generating station were tested, the coal being weighed and the water measured and the temperature taken at stated intervals. Special watchers were also assigned to duty in the generating room and in all sub-stations where readings were taken at stated intervals. Men were also assigned to each car upon which readings were taken every 15 minutes and additional wattmeter readings at the beginning and end of each trip. The time and number of stops were also recorded. Another crew determined the efficiency of the power distributing circuits including high and low tension feeders and track.

During the general tests there was no way to find out the amount of fuel and water consumed by the numerous auxiliary engines. After the test these were coupled to one boiler and the results taken, which were deducted from the general results. The record covers complete runs between the principal stopping points all along the road and gives complete running data for all the cars on all parts of the track. Special prominence was given to determining the acceleration and characteristics of the cars. About 11,000 readings were required for each run and several runs were made with both two and four motor equipment.

## ELECTRIC TRACTION IN GREAT BRITAIN.

(LONDON LETTER.)

The electric traction question in London has this month become involved in further complications by an amalgamation of relatively small competing interests into one large concern with the avowed intention of rivaling and therefore threatening Mr. Yerkes' plans. Almost in the same breath Mr. J. Pierpont Morgan announces his great shipping combine and his schemes for providing London with a complete network of electric traction consisting of 40 miles of new tubes in connection with 90 miles of electric tramways. The latter scheme is the result of the amalgamated interests of the Northeast London Railway, the London United Tramways, the London United Electric Railways & Tramways Co., and the City & Northeastern Suburban Railway. Behind all this is the fact that Mr. Morgan is a large stockholder in American electrical companies, and has, besides, recently acquired the controlling interest in the British Thomson-Houston Co., Ltd., through purchases of stock from the German and French shareholders.

When it is added that Mr. Morgan has secured as allies in his transit schemes, Mr. Arnold Hills (of the Thames Steamboat &

Thames Ironworks fame), Mr. Clinton Dawkins, Messrs. Siemens Bros. and the Hon. Egremont Mills, this forms on the surface quite an imposing announcement, and more especially when considered from the point of view of its possible competition with the Yerkes interests (we say possible, because none of these Morgan schemes are yet fully authorized, with the exception of part of the tramways network of the London United, 16 miles in operation and 42 miles in construction.)

Mr. J. Clifton Robinson, manager and engineer to the London United Tramways, in the interview granted to the representative of the Morning Leader, summed up the Morgan scheme thus: "A scheme which not only meets in the most emphatic way the recommendations of the Joint Committee, but offers the only true solution of the burning question of the hour—the relief of overcrowded London."

If Mr. Robinson be right, then Mr. Yerkes must be wrong. The solution of this knotty problem is at present engaging the attention of Parliament; the following points, however, may be found of interest in connection with the rival schemes. The greatest recommendations in favor of any company making a bid for the control of London's electric transit, or indeed part of it, are a sound financial basis, tried efficiency in business methods, practical experience in dealing with electric traction, ingenuity in adapting new schemes to the existing transit network.

With regard to the first point, it is stated by Mr. Robinson that the Yerkes' millions "simply wouldn't be in it with their funds." This is doubtless true and the sufficient and yet modest capital of the company formed by Mr. Yerkes (by agreement with Messrs. Speyer Bros., Speyer & Co. and Old Colony Trust Co., of Boston) and registered in London as the Underground Electric Railways Company of London, Limited, with a capital of £5,000,000, will probably be quite put in the shade by the capital of the Morgan syndicate.

With respect to the second and third, we have in Mr. Yerkes the successful organizer of electric traction systems of Chicago and other cities, a man with a wide and varied experience, who has devoted the best years of his life to the question at issue, and who has made his plans pay good dividends. A sound practical spirit runs through his gigantic enterprise for London's transit, which although not conceived from motives of philanthropy, shows a wise understanding of the needs of the millions born and unborn. Mr. Yerkes proposes to run his railways to the boundaries of London over ground where business is assured, leaving the speculative development of transit in new regions to others—the County and District Councils with their Tramways, for instance—a sound business policy that recommends itself to shareholders. He secures his position in the heart of London (which he rightly places between Charing Cross and Piccadilly) and utilizing the existing Circle Railway as a starting point, intersects it across busiest London at three points, and radiates from the circle to the confines of Greater London like a spider's web, knowing full well that all subsequent extensions will feed his lines. Further, Mr. Yerkes' scheme renders an invaluable service to the public, not of London alone, but of Great Britain, by interconnecting all the termini of the great trunk railways by means of his electric lines and their elaborate system of passenger interchange stations.

Further, not satisfied with providing this thorough network of trains with frequent stops, Mr. Yerkes has a scheme already sanctioned by Parliament, for giving London a deep level express service, affording facilities for traveling from north to south and east to west with considerable rapidity and at most one or two intermediate stops, which will be varied on alternate journeys. The harmony of this scheme, so carefully and thoroughly thought out and organized by one brain inspires confidence in its operation by and by.

Mr. Morgan cannot claim experience in electric traction, nor has the question absorbed his interest during the best years of his life; his energies have been expended in other fields. The plan which Mr. Robinson indorses as the sole solution of the burning question of the day has many features to recommend it, the most important being its connection with the tramway network of the London United. But here Mr. Yerkes' lines and those already in existence would perform practically the same service with the advantage that most of them, having been already sanctioned by Parliament, they will be put in operation within the shortest possible time. Finally, Mr. Yerkes has made the best use possible of

the existing underground lines as a basis, without unnecessary competition or duplication and the vast area covered by the Metropolitan Railway in connection with the system of the Underground Electric Railway Co., will work in with the imminent electrification of the suburban traffic of the great trunk lines, whose termini are served by Mr. Yerkes' lines.

Just as these notes are being written the announcement is made that the Committee of the House of Lords has found that the preambles of Mr. Yerkes' Charing Cross, Euston & Hampstead Railway and of the Edgware & Hampstead bills (which, by arrangement, is to form an end-on line) have been proved.

D. N. D.

### ABOUT STORAGE BATTERIES.

An interesting pamphlet has recently been published by the Gould Storage Battery Co., of New York, from which we take the following "Facts about the Gould Storage Battery."

The Gould plates are of the Plante type, and are made by "spinning," that is, sheet lead blanks are placed in steel frames which reciprocate between two rapidly revolving shafts on which are mounted alternating steel disks and spacing washers (the gage of the spinning disks determining width of the rib on the finished

plate), and a uniform pressure being maintained by the rolls, the lead is displaced and spun into ribs. The plates are sub-divided into sections varying in number and size with the total dimensions of the plates, the sections being separated by the diamond-shaped bars which are formed at the extremity of the ribs by reason of the disks being round and the lead blanks plane.

The characteristics of the Gould support plate are: Mechanical stability, which results from the unspun cross-bars between sections and the ribbing. Purity, pure lead being used in order to better resist the acid solution, and to reduce secondary actions in the plate. Great density, by reason of the process of manufacture. Integral construction, being of a single piece of lead. Uniformity; large surface presented to active material, from 200 to 400 sq. in. per pound of lead. Uniformity of current distribution, both general and local. Sufficient thickness of the lead base to insure long life; the thickness of the ribs vary from .005 in. to .049 in., depending upon the work expected of the plate. Peroxidation of the entire surface of the plate. Spacing of grooves so as to retain the active material.

For the active material are claimed the following characteristics: It is electrochemically formed. Molecular porosity permitting the peroxide to be surrounded by twice its volume of acid and spongy lead by six times its volume of acid. Uniform distribution of active material, there being no large unused surfaces on the plate. Small volume of material per unit area. Large area of contact with support plate. Large capacity per unit area. Durability. Small excess of active material. Provision for increased renewal. Cohesiveness.

The Gould Storage Battery Co. designs its batteries for stationary work with 250 sq. in. per ampere of discharge. The plates of ordinary size vary from the 4x4 in., with a contact area of 320 sq. in., to the 15 1/2 x 15 1/2 in., with a contact area of 4,800 sq. in. The accompanying illustration shows a pair of 10 1/2 x 10 1/2 in. Gould plates.

The Toledo, Bowling Green & Southern Traction Co. has received nine of its new cars for interurban service and has awarded contracts for its new car house at Findlay. The company is negotiating for an entrance into Toledo over the tracks of the Toledo Traction & Light Co.

### ANOTHER FAKE ACCIDENT WORKER.

One evening about February 1st, a young man was found lying between the tracks on one of the lines of the Metropolitan Street Railway Co., of Kansas City. He was carefully carried to the sidewalk by the train crew, to whom he said his name was William Postum and that he had fallen in getting off of a car and had badly sprained his hip and back. He was taken to a hospital in an ambulance, and after receiving treatment for a week was discharged. The street railway company paid his expenses and gave him a small sum to sign a release.

The injured man carried papers showing that he was a railway postal clerk, running between Kansas City and St. Louis, and was well dressed and of pleasing personal appearance.

About March 1st a newspaper report that one William Postum had fallen from a railroad train at a small town about 40 miles from Kansas City and was being cared for by the company's doctor, caused the claim department of the Metropolitan to write the railroad company. The latter ordered a more careful investigation into the Postum case, but found that in the meantime Postum had left his bed and disappeared.

About the middle of April, Postum was seen in another railroad hospital, where he had been brought apparently suffering from a badly sprained ankle and severe bruises, alleged to have been received in attempting to board a train which started without warning. The hospital authorities were notified but Postum, knowing he had been recognized, succeeded in getting away.

Postum is described as being 5 ft. 10 in. tall, weighing 160 lb., of light complexion, with hair that tends to curl.

### NEW PLANS OF LAKE STREET ELEVATED.

The Lake Street Elevated Railway Co., Chicago, has completed arrangements with the Chicago Edison Co., whereby the latter will furnish a greater part of the power used on the elevated road by a new method which, it is expected, will effect a considerable economy in the operation of the road and improvement in the service. The plan consists in taking the alternating current at a pressure of 9,000 volts, from the Harrison street sub-station of the Edison company, and to transmit it underground on lead-covered cables to a distributing point at Lake and Rockwell Sts., where it will be changed by means of transformers and rotary converters to a direct current of 550 volts for use on the third rail system. The installation will include two rotary converters of 1,000 kw. capacity each and a switchboard provided with oil-break switches operated by small motors, running on low tension currents. The Chicago Edison plant, with the additional apparatus, will furnish power for the operation of the Lake St. road from the river to West 52d St. at all times, and during the middle of the day and night, as far as Harlem Ave. in Oak Park, while the extra power required during the rush hours will be furnished from the Cicero and Proviso stations until the projected new sub-station shall be built to supply the line west of 52d Ave.

### CONSOLIDATION IN INDIANA.

Mr. George F. McCulloch, president and general manager, and others prominently identified with the Union Traction Co. of Indiana, have effected the organization of the Indiana Northern Traction Co., with \$3,500,000 capital stock, to acquire and extend interurban lines and construct new lines forming a consolidated system touching Indianapolis, Anderson, Logansport, Delphi, Kokomo, Lafayette and other important Indiana towns. The seven directors of the new corporation are: Charles A. Baldwin, W. H. Bloss, E. C. Carpenter, Henry Moon, Albert S. Richey, A. W. Brady and Charles Berry, all of whom are connected with the Union Traction Co., and George F. McCulloch will be president of the entire system. The Indiana Northern has completed the acquisition of the Logansport, Rochester & Northern Traction Co.'s property and the Logansport & Kokomo Ry., which gives it control of all the street railway interests at Logansport with the exception of the Logansport Railway Co. and the Wabash River Traction Co. The local lines in Lafayette are next to be acquired, and a line will be built from Lafayette to Logansport by way of Delphi.

### MODERN FENDERS.

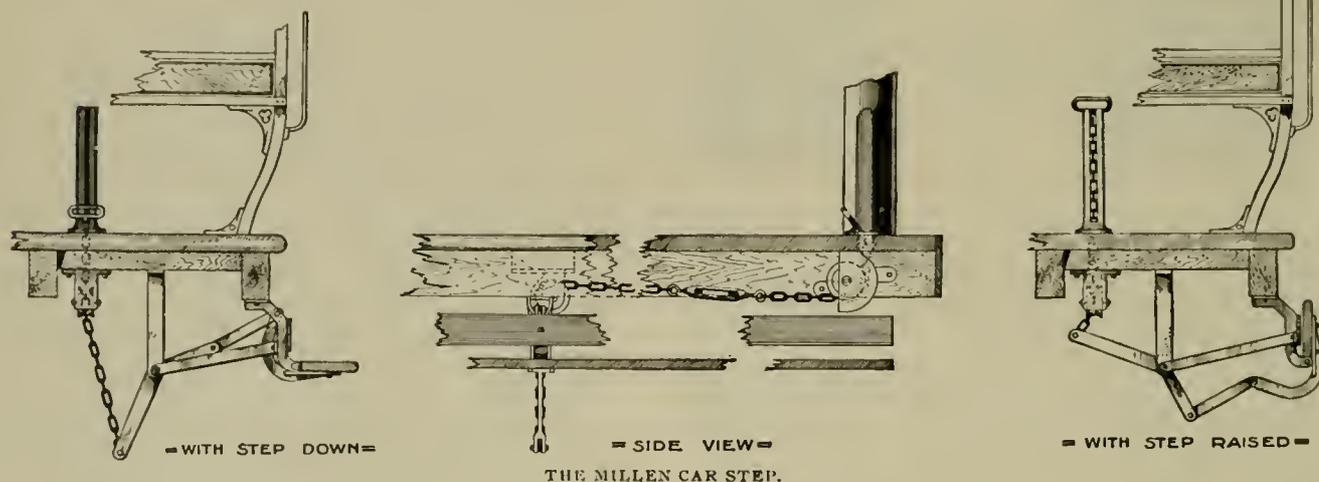

The use of fenders on street railways has become practically universal and in most cities is prescribed by law. Some time ago the prevailing idea of a fender was some kind of a large wooden buffer of the general style of the locomotive pilot which would prove useful in clearing the track of obstructions but was more of a protection to the car than to the person or object struck by it. Of recent years great progress has been made in the design of this class of apparatus and the best fenders of the present day are designed to pick up and carry safely any person or animal struck by the car. It has been stated that during the time when car fenders were the subject of the greatest discussion that the number of applications received at Washington for these safety devices exceeded that of any other single class of patents. During the evolution of the types of fenders now in use it will be noticed that but a comparatively few styles have survived.

Among the most used and effective fenders of the present time are those of the Consolidated Car Fender Co., which are known as "Providence" fenders. These fenders are made in several varieties suitable for all kinds of cars, and we are informed that over 10,000 electric cars are provided with fenders of this type. This company is publishing a catalog describing its various fenders and other apparatus, and a list is given of electric roads using "Providence" fenders exclusively which includes 156 names.

The general appearance of the various types of "Providence"

lifted up and folded against the back dasher in a very compact manner so as not to occupy above 12 in. of space beyond the buffer. The time required for this change is merely a fraction of a minute and need not be considered. It is often necessary, however, to remove the fender entirely from the head end of the car in order to effect a coupling between two cars. When this is necessary this fender can be removed by simply lifting it out of its sockets. When the fender has been removed from the car the intermediate brackets on which it is supported can be shoved under the car entirely out of the way, leaving the end of the car free to push another car in front or to pull a trailer. Another reason for using fenders at both ends of the car is that while it does not require more than a minute to change from one end of the car to the other it requires the services of two men which are not always available.

The model B "Providence" car fender has been designed specially for use on low cars. It was originally intended for use on the closed cars of the Metropolitan Street Railway Co., of New York, and it is equally well adapted to any moderately low car. The steel fingers at the lower part of the fender are not curved as much in this type as in model A, and in adjusting the fenders on the cars the upper wood cross bar can be placed as close as 15 in. to the rail without being struck by the steel fingers when the fender is dropped by the motorman. When not in use on the rear end of the car the model B fender is taken up and fastened to the dash board which lifts it out of the way of the draw bar when carrying a trailer. It also takes up but very little room in the car

fenders is very similar, the difference being chiefly a matter of size to suit cars of different dimensions. The two principal parts of these fenders are a kind of scoop for picking up the person or object struck, and a cushion of springs to prevent injury by the force of the impact. The material is flat spring steel and the scoop part is arranged so that while its front edge normally travels at a few inches above the roadbed, a device is employed whereby the motorman can drop the edge of the fender down to the ground so that the rubber wheels which are carried at the front of the fender rest upon the track. In this position it is impossible for any object struck to be run over. These fenders are made in four styles known as models A, B, C and D.

Model A can be used on any car but is specially adapted to a car of moderate height. The curves in the steel fingers of the lower part of the fender are designed so that when the front end of the fender is dropped by the motorman, the rubber rolls will rest on the track and the curve in the steel fingers will just clear the track. It is of course impracticable to have the rubber rolls on the ground and track all the time so the fender is adjusted to normally clear the roughest part of the roadbed except when brought into use by being dropped by the motorman. Another important feature of this fender is the ease with which it may be folded or taken off from the car when desired. On many roads operating under rapid headway there is scarcely time to change the fenders from one end of the car to the other on reaching the end of the route and for this reason many companies prefer to equip their cars with fenders on both ends. The rear fender in this case may be

barn when folded. Model B is in greater use than any other of the different styles of "Providence" fenders and out of the 10,000 electric cars so equipped probably about one half of them use the model B equipment.

Model C is a new pattern recently brought out by this company which has the advantage of being adjustable so as to ride at any desired distance above the rail, for example, from ½ in. to 18 in. The front of this fender can be dropped to the rail instantly from any position by the motorman, who simply presses a bolt in the platform of the car. The shape of this fender is such that when properly adjusted to the car it will hold a person or child without injury until the car can be stopped. Its holding capacity has been considerably increased by the use of spiral springs which support each side of the fender. Like the other models, model C does not project to exceed 12 in. beyond the buffer of the car in its folded position and it is also easily removable from the car altogether by simply raising it out of the socket.

The model D fender is specially adopted to interurban cars and it is built much larger and stronger than the other models described. It is said to be large and strong enough to pick up a horse and carry it until the car can be stopped, and this is claimed to be the only fender that will pick up and hold the object struck when the car is running at a very high rate of speed. Few persons are struck by interurban cars, but the great danger on these lines is running over animals. The pilot of the form used on steam locomotives will generally remove the animal from the track but if it fails to do so the car will probably be derailed, which en-

dangers the lives of all its passengers. It is claimed with the model B "Providence" fender that an animal will be certainly picked up, and either carried until the car can be stopped or it will be thrown clear of the track.

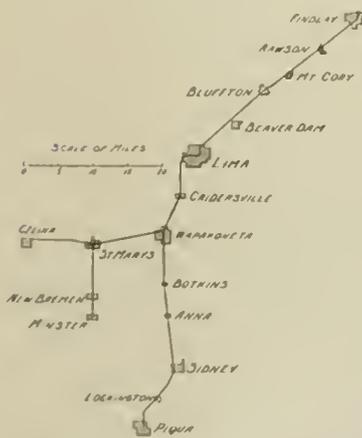

Aside from the protection rendered by these fenders they are designed in a style which does not disfigure the car, but on the contrary adds rather to its general good appearance. As a rule suburban cars run with the same end always in front, so that it is generally only necessary to equip one end of the car with a fender.

In addition to its large manufacture of "Providence" fenders the Consolidated Car Fender Co. also makes the "Millen" car step lifter and Campbell snow brooms. The "Millen" car step lifter, which is illustrated herewith, was invented and perfected by Mr. Thomas Millen, general master mechanic of the Metropolitan Street Railway Co., of New York. This device is a lifting appliance attached to the under side of the car and connected with both the front and rear platforms so that either the motorman or conductor, by lifting up a handle can turn up the running board of an open car and fasten it in its upturned position and also put it down without leaving the platform. It has been the custom generally to fold up the steps of open cars by hand and fasten them with a hook or chain, as it is generally necessary to have the step on the inside of the car folded up and out of the way so as to give more space between two passing cars. By having the inside step folded passengers are also prevented from entering or leaving the car on the wrong side, and it is also frequently necessary in passing wagons in crowded streets to lift up the outside step in order to gain room to pass. With this device either step may be raised or lowered from either end of the car while the car is in motion and without either the motorman or conductor leaving the platform. A large number of cars have been equipped with this device which is reported to be found entirely satisfactory.

The Campbell sand broom is now in extensive use on some of the largest electric roads in this country. The head of this broom is made of malleable iron and is designed to last for many years. The entire expense in maintaining the broom is in refilling the head with rattan and the head is designed so that the filling can be easily accomplished when the old rattan wears out.

**THE WESTERN OHIO RAILWAY CO.**

The accompanying map shows the lines of the Western Ohio Railway Co., part of which were put in operation March 15th. To the system then put in operation about 20 miles were added within a short time. This included a line from St. Mary's to Minster, 10.9 miles in length, and an extension from St. Mary's to Celina, 10.2 miles. It is also expected to have a system connecting Wapakoneta and Piqua in operation by August 1st and the line to Findlay will be completed later in the summer. The road is substantially built with 70-lb. rails ballasted with stone. The cars are large, comfortable and luxuriously furnished, and notwithstanding the fact that the road has been in operation only a few weeks it is now maintaining a faster schedule than the great majority of trolley road. The company reports that business within this short time has been all that could be expected, and that its patrons are much pleased with the service they are receiving. The road is in charge of Mr. E. D. Carpenter, general manager, and Mr. C. N. Wilcox, superintendent.

The Youngtown Sharon Railway & Light Co. has awarded contracts for its proposed new terminal stations at Youngtown, O., and Sharon, Pa., which will cost respectively \$25,000 and \$10,000. The building at Youngtown when completed will contain the company's offices.

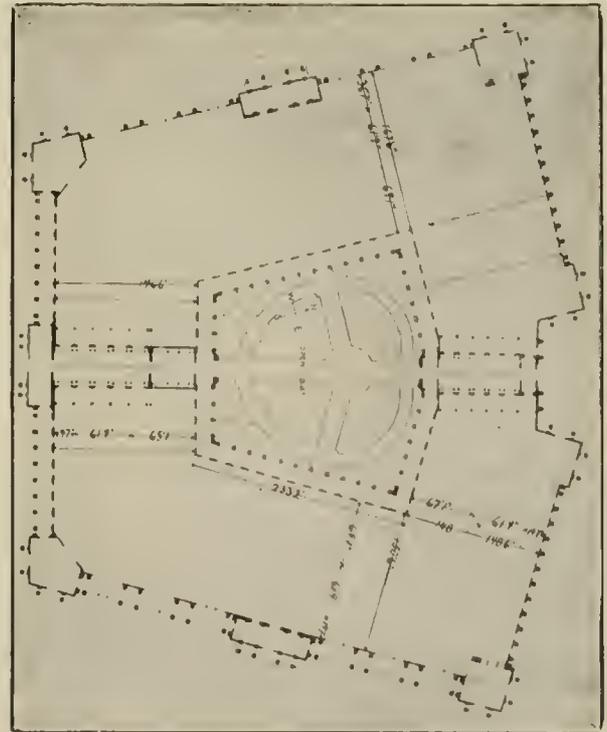

**KANSAS CITY-TOPEKA INTERURBAN.**

The Kansas City, Lawrence & Topeka Railroad Co., of which Willard E. Winner is the principal promoter, has financed its project and begun the construction of the roadbed on the east side of the Kaw River. Contracts have been placed for rails for the entire line from Kansas City to Topeka.

Application has been made for a franchise in Kansas City, Kan., which will give the interurban connections with the Armourdale division of the Metropolitan Street Railway Co., over which cars will be run into the business center of Kansas City, Mo. Through trains to Topeka will run every hour and four express trains will be operated between Kansas City and Topeka and making the distance between the termini in 90 minutes. The plans include the erection of three bridges across the Kaw River.

**WORLD'S FAIR ELECTRICITY BUILDING.**

The provisions that have been made for the exploitation of the electrical industries at the World's Fair, are believed to more than meet the expectations of all interested. The palace of electricity contains over 350,000 sq. ft. of floor space and provides room for an extensive exhibit of the discoveries and inventions in electricity. The accompanying illustration shows a floor plan of this building,

FLOOR PLAN OF ELECTRICITY BUILDING.

and all exhibits of electricity will be installed here excepting such as may be offered for special service of the exposition which will not permit of its being so placed. Steam and gas will be supplied in the building for such direct connected machinery as forms parts of working exhibits. It is the hope of the exposition authorities that working exhibits will be installed as far as possible, as such exhibits are considered vastly more attractive and worth a great deal more to the exhibitor than dead exhibits. The space in the building will be free to exhibitors and they will be granted free power for the operation of working exhibits when it can be shown that they have been developed up to a point of perfection where they are really typical of the processes they represent. The heartiest co-operation will be extended to all exhibitors and it is requested that intending exhibitors will submit as early as possible, an estimate of the space which they will require.

The Birmingham (Ala.) Railway, Light & Power Co. has awarded a contract for 27 new cars to be delivered in the early fall.

FINANCIAL.

PHILADELPHIA CO., PITTSBURG.

The board of directors of the Philadelphia Co. has submitted its report for the fiscal year ending March 31st, showing most gratifying results, since for the purpose of economical operation the several traction and street railway companies have, by operating agreement, been placed under the management of the Southern Traction Co. whose corporate name has been changed to the Pittsburg Railways Co. As has previously been noted the company has acquired, as was authorized by the stockholders Dec. 14, 1902, 232,022 shares of the preferred stock and 246,499 shares of the common stock of the Consolidated Traction Co.; 50,000 shares of the preferred stock and 50,000 shares of the common stock of the Southern Traction Co.; 6,000 shares of the Southern Heat, Light & Power Co. and the shares of several smaller street railway companies. The Monongahela Street Ry. and the Suburban Rapid Transit Street Ry. have been leased to the Consolidated Traction Co.; the Pittsburg & Birmingham Traction Co.'s line to the United Traction Co., and the property of the Monongahela Light & Power Co. and the Southern Heat, Light & Power Co. to the Allegheny County Light Co. The report of the fiscal year is as follows:

	1902.	1901.
Gross earnings from operations.....	\$1,166,227.22	\$1,057,133.27
Operating expenses and taxes.....	630,807.65	464,309.73
Net earnings from operations.....	535,419.57	592,823.54
Other income .....	83,719.38	16,140.26
Total earnings and other income .....	619,138.95	608,963.80
Deductions from income.....	69,996.27	35,497.84
Total income .....	549,142.68	573,465.96
Fixed charges .....	331,281.54	264,339.72
Net income .....	217,384.00	286,497.52

BROOKLYN RAPID TRANSIT.

The financial report of the Brooklyn Rapid Transit system, including all companies, for February and for the eight months ending February 28th, has been submitted as follows:

February.	1902.	1901.
Gross receipts .....	\$861,696.02	\$843,394.25
Expenses, including taxes.....	716,432.03	584,461.49
Net receipts .....	145,263.99	258,932.76
Decrease .....	113,668.77	

For eight months ending Feb. 28.

	1902.	1901.
Gross receipts .....	\$8,395,448.45	\$7,899,100.87
Expenses, including taxes.....	6,016,664.05	5,150,406.38
Net receipts .....	2,378,784.40	2,748,694.49
Decrease .....	369,910.09	

The fact that a large percentage of the earnings from operation has been returned to the property for improvements and extensions explains the decrease in net, while the gain in gross, as reflected in the report, indicates that the business of the system is constantly increasing. Henceforth such betterments will be amply provided for from the proceeds of the recent sale of \$5,000,000 bonds, and with the operating cost charged only with legitimate expenditures, a handsome surplus will undoubtedly be shown for the stock. Two hundred new cars are soon to be put in commission on the Brooklyn Rapid Transit system, a fact which will materially influence the earning capacity of the road.

MANHATTAN RAILWAY CO.

The report of the Manhattan Railway Co. for the quarter ending March 31st shows a gain in the number of passengers carried of 7,588,331, and for the nine months ending with March, a gain of 18,000,000. The gratifying increase in business is principally due to the improved service since electric traction has been installed on the Second and Third Ave. branches, and a commensurate gain may be expected as electricity replaces other motive power on the remainder of the system. The financial report of the Manhattan company is as follows:

	1902.	1901.	Increase.
Gross earnings .....	\$2,878,236	\$2,502,043	\$376,193
Operating expenses and taxes .....	1,400,378	1,348,136	52,242
Net earnings .....	\$1,477,858	\$1,153,907	\$323,951

Other income .....	121,957	200,287	*78,350
Total income .....	\$1,599,795	\$1,354,194	\$245,601
Fixed charges .....	658,330	653,357	4,978
Balance .....	\$941,460	\$700,837	\$240,623
Dividends .....	480,000	480,000	
Surplus .....	461,460	\$220,837	\$240,623
Passengers carried .....	58,037,249	59,448,918	7,588,331
From July 1 to March 31:			
Gross earnings .....	\$7,868,661	\$6,917,680	\$840,981
Operating expenses and taxes.....	4,117,478	8,935,544	191,934
Net earnings .....	\$3,691,183	\$2,992,136	\$699,047
Other income .....	514,511	595,211	*80,710
Total income .....	\$4,205,694	\$3,587,347	\$618,347
Fixed charges .....	2,043,871	2,030,138	13,733
Balance .....	\$2,161,823	\$1,557,209	\$604,614
Dividends .....	1,440,000	1,440,000	
Surplus .....	\$721,823	\$117,209	\$604,614
Passengers carried .....	157,560,097	139,569,670	17,990,227
*Decrease.			

NEW ORLEANS RAILWAYS CO.

The New Orleans Railways Co. has been organized with a capitalization of \$80,000,000 to effect a consolidation of the street railway and electric light companies of New Orleans. The capitalization is divided into \$40,000,000, 4 1/4 per cent sinking fund mortgage bonds, \$10,000,000 4 per cent cumulative preferred stock and \$20,000,000 common stock. Of the bonds \$20,000,000 will be issued to acquire securities of existing companies, \$12,846,000 being reserved to retire existing bonds. Seven million dollars for proposed new construction and improvements.

GENERAL ELECTRIC CO.

The 10th annual report of the General Electric Co. for the year ending January 31, 1902, shows profits (including \$938,584.77 derived from the sale of securities), amounting to \$8,598,241.34, after expenses and the sum of \$1,131,583.98 expended on factory plants and machinery have been deducted. The sales, royalties and sundry profits amounted to \$32,479,428. Dividends amounting to \$1,955,657 were declared and the present surplus and undivided earnings are now \$15,287,141.

The Metropolitan West Side Elevated Ry., Chicago, in April carried an average of 109,246 passengers per day, a gain of 12,228 per day over the corresponding period of last year. The showing was made under normal conditions, and with only five out of seven stations completed on the new extension.

The earnings of the Chicago Union Traction Co. show a gain of \$54,000 for April, \$66,000 for March, and \$62,000 for February.

The Twin City Rapid Transit Co.'s report for March shows net earnings of \$151,423, an increase of \$25,106; and surplus after payment of charges and proportion of preferred stock dividend, \$75,406, an increase of \$20,353.

During the four weeks ending April 26th, the United Traction Co. of Albany gained in receipts \$4,279.56 over the corresponding period last year. Of the amount named, \$3,774.82 was gained on the Albany division and \$504.75 on the Troy lines.

The American Railways Co., of Philadelphia, reports that for the quarter ending March 30th, the gross receipts have shown a uniform increase of about 23 per cent. The company is making extensions of its various systems as warranted by the growth of the cities and increase in traffic.

The St. Louis Transit Co. reports for the month of March, total gross receipts of \$500,117 as against \$461,352 for the same month last year, an increase of \$39,765. From the beginning of the year to April 1st the earnings amounted to \$1,386,251, an increase of \$77,029.

**CHICAGO FRANCHISES.**

May 8th the United States Circuit Court sustained the demurrer of the City of Chicago to the bill in equity filed June 25, 1901, by William L. Elkins, of Philadelphia, praying an injunction restraining interference with rights of the Chicago street railways under the so-called 99-year act passed by the Illinois Legislature in 1865, and a definition of these rights.

Mr. Elkins joined the Chicago street railway companies, in which he is interested, as defendants, so as to give the federal court jurisdiction of the case on the ground of diverse citizenship of the parties, but in its ruling of May 8th the court held that the allegations in the bill were not sufficient to give the court jurisdiction, but leave to file amended bills was granted.

Two amended bills were filed May 12th on behalf of Mr. Elkins, making direct complaint that resolutions passed by the city council have been effective as legislative impairments of the charter rights of the companies, and declaring the action of the council in planning the seizure of the properties of the street railway companies to be a violation of the Federal constitution. It is further alleged that the compulsory issue of transfers is an infringement upon the charter rights of the company. The complainant alleges that all resolutions passed by the city council with reference to franchise forfeiture are based on the idea that the traction property will absolutely revert to the city on July 30, 1903.

**STRIKES OF THE MONTH.**

A general strike on all but three of the lines of the United Railroads of San Francisco was declared at 9 p. m., April 19th, and continued until April 26th, when a compromise was effected. Over 3,000 men were out, their demands being a flat rate of 25 cents per hour, the reinstatement of 28 men who had been discharged, it was alleged, for joining the union, and a complete recognition of the union by the company. Passenger traffic was practically at a standstill, although the mail routes were operated throughout the strike without interruption. No cases of violence were reported. By the terms of settlement the discharged men were reinstated, the wage increase was granted, but the recognition of the union by the company was not conceded.

Motormen and conductors in the employ of the Lima (O.) Electric Railway & Light Co. went out on a strike April 24th, demanding an increase in wages of from 14 to 16 cents an hour in the case of conductors, and from 12 to 16 cents in the case of motormen. Several riots resulted from the company's attempting to run the cars manned with non-union men, and a number of arrests of the strikers were made. The company granted the demand for a wage increase, on April 28th, since which time cars have been running as usual.

The strike of the employees of the Jamestown (N. Y.) Street Railway Co., which began nearly a year ago, has been amicably settled. The details of the settlement have not been given out.

**HOOSAC VALLEY OPENS NEW LINE.**

The Hoosac Valley Street Railway Co., North Adams, Mass., has opened a new interurban to Cheshire, the first car being run over the line on the morning of May 5th, with 46 passengers, including the city officers and prominent townspeople of North Adams and Cheshire, who were the guests of Mr. C. Q. Richmond, president, and Mr. W. T. Nary, superintendent of the Hoosac Valley company. The opening of the road, which is a model one in point of construction and equipment, was conducted under the personal supervision of Mr. Nary and was an occasion for public celebration both cities. Cars are running over the new extension on a half-hour schedule.

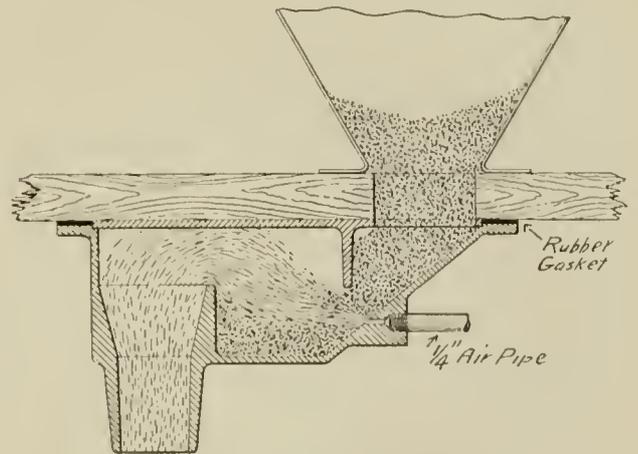

An attractive souvenir pamphlet has been published by the London Street Railway Co., of London, Ont., on Springbank Park, which is reached by the company's lines. The park commissioners are making an unusual effort in the direction of beautifying the summer resort. The walks and drives are being added to and the buildings, among which is a very large pavilion, are kept in perfect order. The railway company is arranging to provide a series of attractive performances and entertainments which will out rival those of any previous season.

**NEW PUBLICATION.**

THE INVESTORS' MANUAL FOR 1902. The Economist Publishing Co., Chicago. The Economist "Investors' Manual" is always of great value to persons interested in the large financial and industrial corporations of Chicago, and particularly to those seeking information concerning the street railways of the city. The issue for 1902 contains complete statements covering all the Chicago street railway properties, and is illustrated by maps of the various systems, which will be found very convenient for reference. The book comprises 100 pages and the index shows over 500 different corporations, including the principal steam railroads of the country.

**PNEUMATIC TRACK SANDER,**

The accompanying diagram represents the new pneumatic track sander manufactured by the Nichols-Lintern Co., of Cleveland, O., and this device is specially recommended for city, suburban and heavy service equipment. The necessity for sanding tracks at certain points is unquestioned and it becomes of importance to have cars equipped with a track sander which will not fail when an

NICHOLS-LINTERN TRACK SANDER.

emergency arises. The makers claim that this device is absolutely air and water tight and that it is instantaneous in operation and constant in action, as well as being economical in the use of sand. There are no levers or valves to get out of order and the device can be placed at any desired point and can be applied to the car without cutting or changing any of the woodwork. The ease with which sand can be applied with this device is one of its chief merits and it is claimed that the actual consumption of air is less on cars equipped with this sander than those without it because less air is used for braking purposes and the air used by the sander is insignificant in amount.

**FAKE ACCIDENT IN PHILADELPHIA.**

Three men are under arrest in Philadelphia, having confessed to a conspiracy to bring fraudulent damage suits for \$10,000 against the Union Traction Co. D. Slutsky, the principal in the affair, entered suit against the company for that amount on November 17, 1900, alleging he had been injured on July 22, 1900, while alighting from the company's car, through the negligence of its servants. The case has since been postponed a number of times pending investigations, with the result that the three conspirators were arrested May 10th. According to the sworn confessions of the trio, the two confederates of Slutsky were to receive \$50 from him for posing as witnesses of his alleged accident and for assisting him to a drug store after he had feigned a fall.

The Scranton (Pa.) Railway Co. has installed a new engine of 1,500 h. p. capacity, which was made by the Alhs Chalmers Co. This addition gives the company sufficient power to put all its cars into commission.

### HALF FARES.

We regret to learn that Mr. Harry Niles, who for several years has been electrical engineer for the street railway at Mexico City, Mex., died on May 10th. Mr. Niles was formerly at Indianapolis and went to Mexico with the late Thomas H. McLean.

The American Railways Co., of Philadelphia, which owns the Chicago & Joliet Electric Ry., contemplates building an electric line from Summit to Lyons in Cook County, Ill., to connect with lines running into Chicago.

The Rochester (N. Y.) & Eastern Rapid Railway Co. will soon begin the construction of its line to Geneva, over a route 41 miles in length, 8 miles shorter than that of the steam lines. The power house will be located at Canandaigua.

The Metropolitan Elevated Railroad, Chicago, carried 109,246 passengers per day, on an average, during April, an increase over the corresponding month last year of 12,228. The Douglas Park extension contributed about 9,000 fares a day.

The Canton-Massillon Electric Railway Co., has increased the wages of conductors and motormen, the new scale being as follows: Seventeen and one-half cents an hour for the first six months of service; 18 cents an hour for the remainder of the first year; 19 cents an hour for the second year, and 20 cents an hour thereafter.

All wooden bridges on the suburban electric railway running out of Bucyrus, O., are being replaced with steel structures. The entire road is being ballasted with crushed stone and new and heavy cars have been ordered. The run between Bucyrus and Mansfield, a distance of 35 miles, will be made in one hour and 20 minutes.

The electric generating station of the Metropolitan Railway, London, will be furnished with Westinghouse steam turbines, a contract for such equipment having been awarded to the British Westinghouse Electric & Manufacturing Co., of Manchester, which is filling a similar contract for the Metropolitan District company.

The Columbus (O.) Railway Co. will install an engine and generator of 1,800 h. p., increasing the capacity of the plant by half. A traveling steel crane will be installed, a new steel roof built over the power house and other improvements made, aggregating a total expenditure of \$100,000. The company has relaid its South High St. line with heavy rails.

The application of the United Traction Co., of Albany, for permission to extend its lines across the grounds at the Watervliet arsenal in constructing its proposed new road in Watervliet has been granted by the War Department with the proviso that the company construct a tunnel under the arsenal grounds. These terms have not yet been accepted.

The Oakland (Cal.) Transit Co. has inaugurated a new wage scale, effective May 1st, increasing the wages of conductors and motormen from 21 cents an hour to 24 cents. The company contemplates a series of summer excursions for the benefit of the men and their families, on which occasions music and other entertainment will be afforded gratuitously.

Two disastrous fires occurred on April 29th, one destroying the carhouse of the Niagara Falls Park & River Railway Co. at Chipewawa, with several freight and passenger cars, and an observation car; the other, at Broad Ripple, Ind., destroyed the carhouse of the Broad Ripple Traction Co., together with two double truck cars and other rolling stock aggregating in value \$20,000.

The New Jersey & Hudson River Railway & Ferry Co., still continues its practice of issuing an attractive artistic calendar each month. That for May, in several colors, being especially appropriate to Decoration Day. On the reverse of the card are printed the common and botanical names of some 25 varieties of wild flowers which grow in profusion along the company's lines through Bergen County.

The York County Traction Co., York, Pa., has nearly completed an extension from New York to Dallastown, Red Lion and Windsorville, and will continue the line to Delta, 35 miles from York. Later, another extension will be built, including Wintertown and Shrewsbury in the southern part of York County. The company owns six acres of fine woodland at Red Lion which will be improved and equipped with park conveniences to serve as a resort for the people of York and nearby towns.

The Tennis Construction Co., of Philadelphia, has purchased the West Chester Street Ry., and will extend the system at once to Downington, Kennett, Coatesville and Parkesburg. The line to

Downington has been partly built, and will be completed by the new owners in a few weeks. Power houses for the proposed interurban lines will be erected at Downington, Coatesville and Kennett Square. The name of the West Chester Street Railway Co. will be changed to the Brandywine Traction Co., under which title the proposed interurban lines will be operated.

The merger of the Hamilton & Lindenwald Electric Transit Co., the Cincinnati & Northwestern R. R., and the Miamisburg & Germantown Traction Co. with the Southern Ohio Traction Co. has been ratified, and the consolidated properties will be operated under the title of the Cincinnati, Dayton & Toledo Traction Co., with a capitalization of \$5,000,000. Under the terms of the merger the Southern Ohio Company will hold \$2,000,000 of the new stock, and in addition, \$1,200,000 in bonds. It is proposed to expend \$2,000,000 for extensions of the system, giving a direct route from Toledo to Cincinnati.

The exhibit submitted by the St. Louis Transit Co. to the State Board of Equalization sets forth the aggregate value of the company's property at \$5,178,006.27, and comprises among other items the following: 146.06 miles of double track in Missouri valued at \$1,251,770, and 58.33 miles of single track valued at \$252,495; rolling stock to the value of \$1,183,167.50, and buildings and miscellaneous property to the value of \$2,490,603.77. The following items are included in the list of rolling stock: 90 passenger cars and 1,120 motor cars, and 42 sweepers and scrapers. The company uses 350.45 miles of trolley wire, valued at \$52,567.50.

Policemen and firemen in Albany will probably lose the privileges they have enjoyed of riding free upon the street cars in that city while engaged in the performance of their duties. The Court of Appeals has rendered a decision to the effect that in this respect firemen and policemen are public officers and debarred from riding free by the constitutional provision which prohibits public officers from using passes. Further, the act of 1895 is declared unconstitutional because in compelling the transportation companies to give policemen free rides it deprives the companies of their property without due process of law and takes private property for public use without compensation.

American methods and British workmen are performing feats in the direction of rapid work, which have hitherto been unknown in England. The record in bricklaying at the British Westinghouse Co.'s works at Manchester was a revelation and this has been followed by some unusually expeditious work in the construction of the stack of the Mersey Railway Co. at Liverpool. This is about 250 ft. in height and work upon it was commenced about Christmas time. It has now been completed for some time and stands as a record-breaker in expeditious building. The work has been carried out by the British Westinghouse Co., which has the contract for converting the Mersey railway tunnel from steam to electric traction. The work has been under the direction of Messrs J. Stewart & Co.

The New York & North Shore Ry., a 7-mile electric line, running between Flushing and Jamaica, L. I., has been sold under foreclosure proceedings instituted by the New York Security & Trust Co., to E. C. Miller of Philadelphia, for \$100,000 over its liabilities. The controlling interest in the North Shore Ry. was owned by the New York & Queens County Railway Co., and it is stated that the plan of reorganization contemplates a consolidation of the North Shore and New York & Queens County properties, and the construction of lines from Flushing to Whitestone, Willet's Point, Bay Side and Manhasset for which franchises have been secured by the North Shore company. Reports are in circulation that the Interborough Rapid Transit Co., which was recently incorporated with \$25,000,000 capital and in which the promoters of the Rapid Transit Subway are interested, has opened negotiations for the acquisition of both the New York & Queens County and the North Shore systems.

### ARNOLD TO ADVISE CHICAGO.

It was announced on May 21st that the committee on local transportation of the Chicago city council had decided to retain Mr. B. J. Arnold to advise the city concerning the engineering problems which have arisen in connection with the street railways. Mr. Arnold, as our readers will remember, is consulting electrical engineer for the New York Central, and for some time has been at work on plans for equipping that company's New York City terminals for electrical operation.

## STREET RAILWAY PATENTS.

This list of patents is furnished by T. Reed Clift, Patent Attorney, Washington, D. C.:

No. 696,408, April 1, John A. Brill, Philadelphia, Pa. Convertible railway car.

No. 696,400. Same.

No. 696,404, April 1, Joseph A. Mead, Cleveland, O. Station indicator.

No. 696,653, April 1, Wm. G. Price, Kingston, N. Y. Brake.

No. 696,752, April 1, John R. Robertson, New York City. Means for automatically controlling motors and brakes.

No. 696,001, April 1, Charles B. Fairchild, New York City. Car brake.

No. 697,070, April 8, Oliver Colborne, Chicago, Ill. Car truck.

No. 697,122, April 1, Thomas E. C. Wilson, Liverpool, Eng. Life guard.

No. 697,208, April 8, Elisha J. Hunt, New York City. Folding step for cars.

No. 697,238, April 8, Troy Cope, New Waterford, O. Switch operating device.

No. 697,283, April 8, Francis F. Shaffer, Cumberland, Md. Car brake.

No. 697,293, April 8, Oscar C. Thomas, Adams, N. Y. Folding car step.

No. 697,308, April 8, John C. Wuerth, St. Louis, Mo. Street indicator for street cars.

No. 697,591, April 15, Amos Youngblood, North Augusta, S. C. Operating railroad switches.

No. 697,674, April 15, Thomas P. Shanahan, Gloversville, N. Y. Automatic trolley catcher.

No. 697,795, April 15, Pembroke A. Brawner, Chattanooga, Tenn. Brake shoe.

No. 698,069, April 22, Lewis O. Sprout, Fostoria, O. Railway torpedo.

No. 698,197, April 22, Thomas E. Stucky and Edward Ware, Indianapolis, Ind. Adjustable trolley supporter.

No. 698,206, April 22, Charles Lilleberg, Chicago, Ill. Railroad crossing.

No. 698,239, April 22, John H. V. Young and Ralph W. Barr, Akron, O. Tramway switch.

No. 698,259, April 22, Henry W. Covert, Waterford, N. Y. Convertible car.

No. 698,395, April 22, John A. Miller, Omaha, Neb. Guiding device for trolleys.

No. 698,421, April 22, Henry Tesseyman, Dayton, O. Brake Shoe mechanism.

No. 698,518, April 29, Frederick Kennington, Leeds, Eng. Adjustable roof or cover for tram cars.

No. 698,754, April 29, Wm. Smith, Bastrop, La. Station indicator.

No. 698,915, April 29, Millard Field, Boston, Mass. Car fender.

No. 698,954, April 29, Clarence P. Hulst, Milwaukee, Wis. Car fender.

No. 698,965, April 29, Wm. Kingsland, London, Eng. Connection of strikers to motor vehicles for mechanically operating switches.

No. 698,986, April 29, Albert J. Michel, Scranton, Pa. Car replacer.

## ALLEGED BRIBERY IN CHICAGO.

Pending the appeal taken from a decision of the Circuit Court regarding the running of transfers between the lines of the Union and the Consolidated companies, the Chicago Union Traction Co. has refused to give transfers. The principal difficulty has been with residents of the suburb of Avon, and some 500 suits against the company are pending. In the first two cases tried the verdict was for the company and the Avon "car baiters," as they are termed, unearthed an alleged scheme of jury bribery which involves a large number of people. The case of the first jury was taken up by the grand jury and indictments found against seven men.

In considering the case of the second jury the grand jury found six more indictments including two against men who had been indicted in the previous case. The third suit which was brought against the company resulted in finding the latter guilty and a maximum penalty of \$2000 was imposed. In the fourth case, tried May 15th, the jury disagreed.

## ADVERTISING LITERATURE.

THE STERION COPPER, BRASS & BRONZE CO., No. 65 and 67 N. Ashland Ave., Chicago, May 1st issued its Bulletin No. 13 describing and illustrating the copper commutator bars made by it.

THE ELECTRIC STORAGE BATTERY CO. has just issued its Bulletin No. 71 containing "The Storage Battery in the Commercial Operation of Electric Automobiles," by W. H. Palmer, Jr. This is a reprint of the article appearing in the Electrical World and Engineer for Apr. 12, 1902.

THE CENTRAL ELECTRIC CO., of Chicago, has published a 1902 edition of its "Fan Motor Catalog," in which is listed a full line of desk, bracket and ceiling fans for all currents and voltages. This catalog also includes power motors, sewing machine motors, battery fans, ventilating fans, etc. Anyone desiring a copy of this catalog can procure it by addressing a request to the Central Electric Co.

THE OHMER CAR REGISTER CO., of Dayton, O., has published a pamphlet giving fac-similes of 10 or more letters from well-known street railway managers affirming their satisfaction in the working of the Ohmer system. The letters state that economy in time is effected by the Ohmer register and that moreover it assures a more accurate accounting of the fares collected than does any of the old fangled methods.

"GRAPHITE," published by the Joseph Dixon Crucible Co., Jersey City, N. J., in the interest of Dixon's graphite productions, contained for May, in addition to the usual quota of technical articles, humorous matter and illustrations, the result of the annual election of the company's officers, as follows: E. F. C. Young, president; John A. Walker, vice president and treasurer, and George E. Long, secretary. The company reports larger sales for 1901 than for any previous year, and larger net earnings.

THE GENERAL ELECTRIC CO., has recently issued the following publications: Bulletin No. 4284 (superseding Bulletin No. 4196), "Prices Paid for Street Arc Lighting in the United States," "The Relation Between Electric Meters and Central Station Revenue," by Caryl D. Haskins, reprinted in pamphlet form; Catalog and Price Lists, Nos. 7553 and 7554 (superseding Nos. 7546 and 7523) on "Parts of Magnetic Blow-out Automatic Circuit Breakers," and "Sockets and Receptacles;" Flyers Nos. 2097 and 2098, "Plain Type Arc Lamps" and "One-Piece Fuseless Rosette;" Price List No. 5098, "Snap and Push Button Switches."

THE H. W. JOHNS-MANVILLE CO., 100 William St., New York, has published a leaflet entitled "Tests," showing the results of recent tests of Keystone hair insulators of this company's manufacture, which have proved to possess exceptional insulating qualities. A table is given condensed from a paper by Mr. John E. Starr, of the Starr Engineering Co., New York, presented at the Convention of American Warehousemen at Buffalo in October, showing the transmission of heat through various insulating structures and commending the qualities for which the Keystone hair insulator is especially remarkable.

THE CROCKER-WHEELER CO., Ampere, N. J., has recently issued the following bulletins: No. 13 (superseding Nos. 6 and 12) "Engine-Type Generators," third supplement to bulletin No. 13, giving partial list of the users of the Crocker-Wheeler engine-type generators. No. 14, (superseding Nos. 4 and 9) "Belt-Type Machines—Large Sizes." No. 16, (superseding Nos. 4 and 11) "Belt-Type Machines—Bipolar Motors." No. 17, (superseding No. 3) "Motor-Dynamos and Dynamotors." No. 18, "Electric Plant of a Graphite Factory," describing the electrical equipment of the Joseph Dixon Crucible Co. No. 20, (superseding Nos. 4, 10, and 15) "Belt-Type Machines—Small Multipolar Sizes."

RUMSEY & CO., Seneca Falls, N. Y. Illustrated catalog and price list of hand and power pumps. The catalogue contains descriptions of hydraulic and pumping machinery made by Rumsey & Co., for all purposes. The book is bound in stiff cloth covers and it forms an excellent book of reference for the subjects which it covers. This company manufactures all styles of pumps from the smallest eastern pump to heavy power pumps, directly operated by steam engines or electric motors. Each of the different styles of pumps is well illustrated and a table accompanies each different type of pump giving the different sizes, capacities, and all the necessary data for the purchaser, including a price list. The book covers 260 pages and includes a telegraphic cipher code and a well arranged alphabetical index.

# Creaghead Flexible Brackets

WRITE FOR CATALOGUE

CINCINNATI, OHIO.

THE SPRAGUE ELECTRIC CO. has issued its Bulletin No. 301 on Landell motors for driving ventilating fans and blowers and its catalog No. 304, entitled, "Landell Fans for 1902."

THE WESTINGHOUSE ELECTRIC & MANUFACTURING CO. has recently issued to the trade an attractive folder on Westinghouse lightning arresters. It contains an excellent description of the new Westinghouse low equivalent arrester, which has been received with general favor.

THE AMERICAN STEEL & WIRE CO. has issued two handsome catalogs of 80 pages each, one devoted to "Crown" and "United States" rail bonds, and the other to springs. Both catalogs are liberally illustrated and contain minute descriptions of the products represented. "Crown" rail bonds were first manufactured in 1897, since which time they have been adopted by 555 electric railways in the United States, and many of the most important street railways in Europe, Asia and South America. It is claimed for "Crown" bonds that they are most easily adjusted, all the work incident to applying the bond being done upon one side of the rail, and the labor and expense of re-laying pavement or concrete on both sides of the rail thereby avoided. The saving thus effected will frequently equal the cost of the bonding. The many shapes in which the "Crown" bond is furnished render it highly practicable for the purpose of double-bonding tracks at each joint, and sketches are given showing how the different shapes may be used. The "United States" rail bond is made with solid terminals and flat strips of copper, and is so designed that it can be used inside the splice-bar of a rail joint when the plate is only one-quarter of an inch from the web of the rail. The company's catalog No. 5 in relation to springs invites the reader's attention to recent innovations in the equipment of the factories at Worcester, Mass., Waukegan, Ill., and San Francisco, Cal. As manufacturer of all grades of steel from the raw material the American Steel & Wire Co. is in a position to meet all requirements and to insure satisfactory results from the use of its comprehensive product.

RIDLON'S REPRESENTATIVE, for May, 1902, has just been issued and contains eight pages of spicy advertising matter interspersed with many witticisms. This issue is a railway edition and is devoted specially to devices and supplies for electric railways.

THE NEW PROCESS RAW HIDE CO., of Syracuse, N. Y., has published a small catalog on its new process noiseless pinions and metal gears. The special field of the new process noiseless pinion is to fill the demand for a noiseless drive that will run silently and still be durable. The raw hide pinions are entirely lacking in any metallic sound and are used extensively on electric railway motors, automobiles, pumps, hoists and other machinery. The catalog contains a brief description of the method of curing the hide and making the pinions, and also contains a complete price list of gears and pinions of all sizes.

THE LORAIN STEEL CO. advises us that on May 27th its New York offices will remove from the present location in the Battery Park building to the nineteenth floor of the Century building, 74 Broadway, New York City.

THE STIRLING CO. of Chicago announces that after May 20th its New York office will be removed from the Havemeyer building to Room 907, Engineering building, 114-118 Liberty St., New York City.

CORRESPONDENCE.

We cordially invite correspondence on all subjects of interest to those engaged in any branch of street railway work, and will gratefully appreciate any marked copies of papers or news items our street railway friends may send us, pertaining either to companies or officers.

DOES THE MANAGER WANT ANYTHING?

If you contemplate the purchase of any supplies or material, we can save you much time and trouble. Drop a line to THE REVIEW, stating what you are in the market for, and you will promptly receive bids and estimates from all the best dealers in that line. We make no charge for publishing such notices in our Bulletin of Advance News, which is sent to all manufacturers.

This paper is a member of the Chicago Trade Press Association.

Entered at the Post Office at Chicago as Second Class Matter.

VOL. XII. JUNE 20, 1902. NO. 6

Five or six years ago the street railway fraternity was much interested in data on the operation of storage battery cars and considerable was published concerning the results at Hanover, Germany. The subject is no longer a live one in this country since the only storage battery line successfully operated here was converted for the overhead trolley about two years ago, and now we learn that the use of storage batteries for street cars has been forbidden in Germany and the companies operating accumulator cars directed to arrange for their supersession within a limited time. Whether the new Edison battery will cause a reversal of this edict remains to be determined.

The attention of intending exhibitors at the St. Louis Fair is directed to the letter, appearing on another page, from a committee of the Chicago Trade Press Association to the director of concessions of the Louisiana Purchase Exposition. At previous expositions of this character facilities for securing photographs of exhibits by the technical and trade journals have been very unsatisfactory, not, it is believed, because there was any intention to inconvenience the press, but because the question had not been placed before the management until it was too late for the latter to act. To those who visit expositions the exhibits speak for themselves, but others, who are perhaps equally, if not more interested, learn of the technical features and details principally through the journal especially devoted to the industries to which the exhibits belong. To an exhibitor who wishes to derive the greatest good from the expense incurred by taking part in expositions it is quite as important that the periodicals covering this field be given proper facilities, as it is to the paper itself.

The present tendency in nearly all business houses where extensive records are necessary is to utilize the card index so far as it is possible to do, and the same thing can be done to advantage in shops as well as in offices and storehouses. In connection with the description of the new repair shops for the street railway system at

Providence, given in the Review for May, 1902, there were shown the forms used for conveniently keeping detailed records of the equipment as well as the price and stock cards.

It is quite impossible to answer the question, Does it pay to do our own work? without complete and accurate shop accounts, and the day has gone by when the management can afford to take things for granted. About seven years ago the writer visited the shops of a steam railroad and noticing a locomotive on which extensive repairs were being made, inquired as to the cost of this work. The reply of the foreman was to the effect that they didn't know, and didn't want to know. This is not the most approved modern view as to the desirability of keeping shop costs, and doubtless has far fewer advocates today than at that time.

The failure to properly keep costs in the shop results in loss to the company in two ways, by permitting inefficiency and waste to continue unchecked and by misleading the management as to the economy of conducting a manufacturing business.

At some of the conventions of the American Street Railway Association objection has been made that too much time was given to excursions and other entertainments, at the expense of the business meetings of the Association, but now the tendency seems to be toward cutting out too much of the entertainment part of the program which was always such an attractive feature of street railway conventions; at the 1901 convention, the annual banquet was practically the only Association entertainment. In the past the Association has not always done full justice to the papers presented at its conventions, for the reason that the subjects treated were not such as could be discussed without previous preparation; now, however, that the papers are printed and published to the membership in advance of the meeting there is ample opportunity for those particularly interested to prepare for discussion, and at the last convention it was evident that this opportunity was greatly appreciated.

Besides thus increasing the opportunity of the Association for working, the number of days for meetings has been reduced from four to two. At Boston, in 1898, meetings of the associations were held on four days; at Chicago and at Kansas City there were but three days for meetings, the fourth day being set apart for the inspection of exhibits; at New York, last year, the time was cut still another day, one day for the exhibits and but two for association meetings. No one regrets the time specially given the exhibits; the only regret is that "supplymen's day" was not instituted several years earlier, for the exhibits are one of the convention's greatest attractions, but it seems to us that by limiting the Association meetings to two days only which necessitates two sessions per day there is danger of crowding out the social features which are really almost as important as the business part of the program.

Street railway men are hard workers and for many of them the convention is the only opportunity for a vacation; such it will no longer be if the Association continues to shorten the time for its meetings and still increase the output.

At the present time the indications are more favorable than ever before for a speedy settlement of the street railway question in Chicago. The appointment of a competent engineer to advise the city was a step in the right direction and had it been taken two years earlier the interests of all would have been better served, save perhaps those who hoped to make political capital out of the situation. Up to now there has been no one representing the city who knew what was reasonable to ask of the railway companies, and the latter were very wise in declining to enter into a controversy with irresponsible parties. The companies have, however, been anxious to arrange with the city for extensions of their franchises, in order that they might be free to make improvements in their systems, involving great expenditures such as could not be made as long as the franchise term was undetermined. Almost immediately after the announcement that Mr. B. J. Arnold had been retained to advise the city the street railway companies signified to the council their willingness to consult with the city's representatives and furnish all information within their power.

The street railways have no doubt as to the validity of the 99-year act, under which their trunk lines could be operated until 1958, but they could not be expected to make any extensive improvements so long as the city disputed the force of this law. It now appears probable that a decision on the 99-year act cannot be had very long

before the time when the city claims the franchises expire; the federal circuit court has refused to take jurisdiction of the suit brought by non-resident stockholders of the Chicago Union Traction Co., and as the question of the jurisdiction of the federal courts cannot be passed on by the United States Supreme Court for several months, and the case may eventually have to be tried in the state courts, the wisdom of not waiting for the adjudication of the question is apparent.

What is a satisfactory method of protecting grade crossings will doubtless be a live question so long as such crossings exist. The most common practice at the crossings of street railways with steam lines is to send the conductor of the street car onto the railroad to see that the way is clear before permitting the car to cross, but this is recognized to be merely a precaution and not an absolute preventive. An accident in Chicago on June 14th, when a train of two street cars became stalled on a railroad crossing by reason of the trolley jumping the wire, and was demolished by a steam train, serves to remind us of an ever-present danger. In the instance mentioned the watchman heard the steam train approaching and the crew and passengers of the street cars made their escape in time.

Absolute security against crossing accidents can be had only by separating the grades of the two roads, and this is usually only practicable in cities by elevating the steam railroad tracks and much has already been done in this line; though the necessary investment is large it is believed that the roads which have elevated their tracks find that the money saved in accident claims and watchmen's wages is sufficient to pay interest on the cost, to say nothing of the time saved. Next to abolishing the crossing a block signal is best, and where by reason of the great number of trains such a place seems impracticable, a suitable inverted trough made of metal arranged over the crossing so as to catch the trolley when it leaves the wire is an additional precaution. Some months ago we illustrated a device of this kind which had been prescribed by the New York State Railroad Commission.

The conditions with which transportation companies in large cities have to contend are perhaps only fully appreciated by the claim departments of the companies, and the executive officers who have to analyze reports for their stockholders. In nearly every city there is a special name for the lawyers who make a practice of handling discreditable personal injury cases against corporations—but whatever the name by which the "ambulance chaser" is known, his methods are the same and he is no better than the hold-up man who uses more violent means to his end. The methods of the personal injury lawyer are a stench in the nostrils of the public and the tolerance of bar associations towards this class of practitioners has resulted in seriously lowering the legal profession.

A mistaken sentimentality on the part of the jurors gives the poor man a verdict, even where it was beyond cavil his own carelessness that caused the injuries; and if the cause is not sentimentality, as we believe it is in most cases, the jurors give way to blind, unreasoning prejudice. Yet the jury is not wholly to blame. Jurors have no means of becoming acquainted with the facts behind the suit; they are not aware of the visit of an agent of the ghoul-lawyer to the injured person; they do not know that these people watch the columns of the newspapers for accounts of accidents and that the injured are run down as legitimate quarry even to their deathbeds at the hospitals. Jurors do not hear the insidious pleading of the shark-lawyer's agent to be allowed to file suit against the company, nor the instructions to hide the truth in many cases, in order to get a rich haul through the courts.

It makes no difference to the accident lawyer whether the injured person was a trespasser or not at the time he was hurt; it matters not whether he took risks which no sane person should take. "Let's bring the suit anyway," says the lawyer. "It will only cost \$10 to file it. You can't lose anything, and we may get a good settlement from the company without even a trial."

The damage suits that such lawyers refuse to handle are unknown. There is no question of good conscience, no troubling theories as to legal ethics. The proposition is a simple one—how much can we make the company pay to avoid expensive litigation, or the risk of a jury's injustice?

The real cause of the abuse lies in the fact that there is no risk worth mentioning in bringing such suits, and the lawyer agrees to divide the spoil. This fact suggests a simple remedy, make the man

who is the chief cause of the groundless litigation bear the pecuniary burden that is now borne by the company. As it is now the personal injury attorney is repaid by one successful suit for his efforts in a great many. He stands to lose nothing—not even respectability—in case of failure. Today the nature of this traffic is so well known, that even the men engaged in it will not defend it; they deny that their practice lies in this direction, while scouring the city for such cases.

The remedy is a matter of legislation. It pertains to legal practice and it would protect defendants from unconscionable suits, while taking no rights from plaintiffs who sue in good faith. It would be a complete bar to speculative litigation of the hold-up character.

In a word; the attorney's fees and costs of all actions should be made part of the judgment. Where the plaintiff failed in his suit, judgment should be rendered against him for all the expenses, including records, briefs, abstracts, counsel fees, etc., to which the other side has been put, the total of which often reaches a large sum. This is no hardship, because the defendant has been declared innocent of the charges of negligence and the plaintiff was at fault in bringing suit. In case the plaintiff succeeded in getting a verdict, in the same way the defendant should pay his costs in addition. Technically, "costs are awarded to the successful party."

In most states all that a party who successfully resists unjust damage claims may recover at the court costs, which are trifling. The main item, such as heavy attorney's fees, must be borne in order to escape worse penalties. The whole matter could be arranged by amending the practice acts. Such we believe is the law in Ontario. In New York the courts are authorized to punish the plaintiff in flagrant cases by giving judgment for the defendant for a percentage of the damages claimed, but even this can have but little effect in most of the fraudulent suits. Whether "costs shall be awarded to the successful party" in all cases, or only in actions of tort, is a debatable question, but there is no doubt that the effect of such a provision in the jurisdictions where it has been adopted has been to discourage frivolous or fraudulent litigation.

On the proper showing, the defendant should also be entitled to security for costs. In dealing with unscrupulous parties this is essential. Such provisions would be very discouraging to the fake personal injury man, but to none else. With zeal worthy of a better cause he will argue that the poor would be unable to bring suits and prosecute them; the poor, however, are protected by statutes giving them the right to sue as paupers. In legitimate suits, plaintiffs could still count on their friend the "damage shark," but he would carefully avoid "hold-up" litigation, knowing that he might be asked to furnish bond and be in the position of the biter bit.

Neither is the just suitor in danger of being assessed exorbitant costs, for that is attended to by a court official known as the "taxing officer," all items of the bill of costs being checked over by him in presence of counsel, and the judge giving final decision on the disputed points and fixing the total, for which a certificate is granted.

It appears to us that a concerted effort on the part of the corporate representatives and attorneys might be effective in stemming the constantly increasing tide of personal injury litigation and the other suits directed against corporations. Here is the opportunity for a "claim agents' association," and since there is no such organization among street railway men it is suggested that every member of the American Street Railway Association send its claim agent to the Detroit convention.

The London Journal of Gas Lighting is apparently out of its element in discussing electrical questions, although it is one of the leading periodicals in its own special field. In a recent issue it seems to have taken up the subject of electric traction in a manner which is somewhat surprising to the electrical railway man, and argues that "electric power which cannot beat steam on main lines of railways cannot beat horses on town tramways from the point of view of remuneration." This will certainly be news to the street railway man. From the fact that electricity has superseded horses in street car work to such an extent that the horse car is viewed in this country almost as a curiosity, it can easily be deduced that electricity in this service has been found to be more economical and generally satisfactory than horses. As a matter of fact the use of electricity has doubled the traffic and consequently the receipts of street railways, and has further cut down the ratio of operating expenses to gross receipts to a marked extent; therefore, such a statement from a conservative paper is extremely out of place.

## Handling Traffic at the Inter-State and West Indian Exposition, Charleston, S. C., Jan. 1 to May 31, 1902.

The Exposition at Charleston, S. C., which came to a close last month was devised, as its name partly suggests, for the purpose of exploiting the resources, industries and attractions of the states along the Atlantic seaboard south of Mason and Dixon line. The results predicted—and in a large measure secured—by the holding of this fair, were, the opening up of new foreign markets for the south principally in the West Indies, and the advertising and promoting of the silk, tea, cotton, tobacco and mineral resources and industries of the eastern southern states and the Mississippi Valley.

Although the Charleston Exposition was not designed on lines as broad as the Chicago World's Fair, the Omaha Exposition, the Pan-American or other similar enterprises of the past decade, it was thoroughly representative, and has been the means of bringing the attention of the world to the remarkable growth and development

Leading from one side of the Court of Palaces was the Midway with its many booths and buildings given over to amusement and pleasure. Here were the Old Mill, Thompson's scenic railway, stage for fireworks, etc. Opening from the opposite side of the main court was the section given over to art, transportation and machinery, stock and other exhibits and also the various state buildings. A miniature railway built according to the patents and designs of Cagney Brothers, of New York City, ran the length of the grounds and reached all the points of attraction.

Practically all of the exhibits pertaining to machinery and transportation were grouped in Machinery Hall and in the Transportation Building adjoining it. While not extensive, the contents of these buildings were instructive and worthy of careful study. The industrial activity of the South was well set forth by the number

THE CHARLESTON EXPOSITION AT NIGHT.

along industrial and commercial lines that have taken place in the South during recent years.

The site selected for the buildings and industrial palaces covered 200 acres of land on the eastern bank of the Ashley River within the corporate limits of the city of Charleston and about three miles from the business center of that city. The architectural and artistic landscape effects were typically southern in motif. Many of the chief buildings revealed traces of old southern colonial design, and southern palms and southern flora were left scattered through the grounds in the rich profusion of their natural state. Wide gravel and asphalt walks were laid out in all the sections, affording easy approach to buildings and providing attractive vistas, and these shaded walks with the beds of blooming flowers interspersed with groups of palms and live oaks formed an attraction hardly less delightful than the contents of the buildings. Occupying the central position of the site were the sunken or floating gardens where were planted rare tropical foliage, century plants, palmettos and flowers arranged in groups and beds with appropriate railings designed of mermaids, dolphins, sea shells and graceful and artistic statuary and figures. In the center of the gardens was placed an electric fountain, lending the final touch of perfection to the scene.

The illumination of the grounds and buildings was elaborate and artistic and some of the effects secured, especially in the sunken gardens, were entirely unique. The water from several streams winding in and out between the flower beds, finally flowed into a central lake through the pipes of a Maenomes Pan. In the center of the garden was a group representing the "triumph of electricity over water power." These effects were enhanced by many incandescent lights judiciously arranged, while the entire outline of both shores was accentuated by gaily colored lamp globes. Supplementing these main illuminations in the center of the gardens were thousands of incandescent lamps varied here and there with electric arc and acetylene gas lights outlining all the buildings and statuary, and scattered through the foliage, the whole making a scene of brilliancy and weird effects seldom equaled.

The artistic conception of the exposition called for five main sections designated as the Art, Natural, Transportation, Midway and Live Stock. The most important buildings, namely the Cotton, Commerce and Architectural Palaces were grouped about the central Court of Palaces, an open space of over a mile in circumference. Connecting these buildings were colonnades and groups of smaller booths and structures containing the United States Government exhibits, minerals and forestry displays, negro exhibits, etc.

and variety of mechanical implements and machinery displayed by southern firms.

When it was decided to hold the South Carolina Interstate & West Indian Exposition in the city of Charleston, the street railway management controlling all the city and interurban electric lines serving the territory adjacent to the site selected for the exposition, was called upon to solve several perplexing questions. Serving a normal population of 55,000, and carrying an average of 12,000 passengers per day, the Consolidated company was confronted with the problem of so expanding its facilities as to enable it to transport to and

SUNKEN GARDENS.

from the exposition grounds from 75,000 to 100,000 people per day, when necessary. This was the estimated attendance for the special days, but as matter of fact, there was very little upon which to base an estimate of the total attendance or the average daily attendance, and this uncertainty added new complications to the task of preparing street railway accommodations for the influx of visitors.

In arranging for extensions to its tracks, new terminals, increased power capacity and additional rolling stock that were decided to be essential to the safe and economical handling of the exposition crowds, the management of the Charleston Consolidated Railway, Gas & Electric Co., following the example of the street railway companies of Buf

falo in preparing for the Pan-American Exposition, determined to make all the improvements so far as consistent, permanent, instead of merely for the life of the exposition. By thus taking advantage of the opportunity offered, many permanent betterments to track, power house and cars have been made, that will greatly increase the future earning power and valuation of the property, and this has been accomplished without excessive outlay over the expenditure that would have been necessary for merely temporary extensions to plant.

The decisions reached by the Consolidated company in meeting the imposed conditions will be suggestive and valuable to managements everywhere who may be called upon to prepare for sudden and heavy increases in traffic, and with the constantly growing disposition of the American people to arrange expositions, fairs, carnivals, conventions and gatherings of all descriptions, this phase of

MACHINERY BUILDING.

street railroading is coming to be almost a science in itself. (For those seeking information on this subject, reference is especially made to the "Review" for June 15, 1901, page 335, where will be found the only complete published description of the plans adopted by the International Traction Co. of Buffalo, for handling the Pan-American crowds.)

At Charleston the same company that owns the street railway lines also owns the electric lighting and gas properties of the city, and was therefore in a position to undertake the work of lighting the exposition grounds and supplying power to exhibitors. This contract it secured and in re-arranging the power generation and distribution scheme, this load had to be provided for. The company owned two power houses: One small station on Sullivan's Island for furnishing power to what is termed the Sea Shore division, covering Mount Pleasant, Sullivan's Island and the Isle of Palms, and also for supplying electric lights for these islands; the second and main power house of the company is in the northern section of the city, not far from the Exposition site. In this plant are concentrated all the generating apparatus for both lighting and street railway purposes in the city and suburbs. To meet the needs of the Exposition as regards power and light, it was decided to install at this station two new three-phase alternating 60-cycle generating units, having a combined maximum capacity of 1,600 kw. From these machines current was transmitted to the grounds at 2,400 volts initial pressure.

By means of a 500-kw. converter and transformer in Machinery Hall at the Exposition, part of this current was changed to 550-volt direct current for use in motors at the different booths. At times of excessively heavy traffic, current from this converter was used to help out the street railway line running to the Exposition grounds. Ordinarily, however, the regular direct current units at the main power house were found adequate to handle the extra Exposition traffic in addition to the regular travel of the company, and no new direct current apparatus was purchased for the railway load.

The final disposition of the three-phase units has not been fully settled, but it is probable they will be retained at this station and used in the regular commercial and city lighting business. One was leased for the six months of the Exposition with the option of purchasing it at the end of that period. The rotary converter will undoubtedly be transferred to the Island station of the company, and will take current from the three-phase units for the use of the Sea Shore street railway division.

The present equipment of the company's two stations and the method of distributing current are noted elsewhere in this article.

The Exposition grounds covering 250 acres were about three miles from the hotel and business center. To reach the grounds a new double track line had to be built from the center of the city, and for doing this work it was thought best to organize a separate com-

pany known as the Exposition Traction Co. It was at first proposed to charge an additional 5-cent fare on this new line, but as there was some fear expressed that the double fare would injure the prospects of the Exposition, the company elected to accept the loss and abolish the additional fare, giving a straight 5-cent rate from any part of the city to the grounds.

The Exposition line was built with second-hand 60-lb. T-rails, as only a portion of it will be required after the Exposition closes.

The arrangement of the Exposition terminal will be understood by reference to the diagram. The main Exposition line passes the gate of the Midway, and then continues on and makes a loop in front of the main entrance. Passengers are discharged at one side of the loop, and board the cars at the other side. The line and loop are enclosed with the American Steel & Wire Co.'s wire fencing and entrance and exit are through turn-stiles.

Going from the Exposition passengers purchased tickets at booths and dropped them in turn-stile boxes before entering the cars. Going toward the Exposition, fares were collected on the cars by the conductors but an inspector was stationed at Line St., the main transfer point, and where the bulk of the Exposition traffic was obtained, in order to insure that all fares were properly registered before the car left that point.

By the arrangements mentioned, the company was sure that none of the Exposition fares into the city, and none of the fares below Line St. going out, these including all fares from the hotel and depot districts, would be missed by reason of the crowded condition of the cars.

Mr. T. W. Passailaigue, superintendent of the Consolidated company, states that the most annoying feature of handling a temporary increase of traffic of this kind, is that there is a class of men who make a business of following up Expositions, and other events likely to draw many visitors, with the view of securing employment on the street railways. Inasmuch as these men are seeking only temporary employment, they lack steadiness and reliability and by their carelessness cause serious loss to the company. He finally adopted the rule of engaging only experienced motormen and only green conductors, and by adhering to this regulation, he avoided a great deal of trouble. As an extra inducement to good men to apply for position on the cars, the company arranged to guarantee all extra men at least a half-day's pay each day, whether they were

COTTON PALACE AT NIGHT.

assigned to a car or not, provided, of course, they reported at the barn each day. This insured each man at least enough to pay his board and necessary incidentals.

The volume of Exposition traffic was very erratic, dropping, for instance, from 50,000 passengers, carried on President's Day to 12,000 the following day, and the company had to maintain a considerable force of extra men to call on in emergencies. The company feels the amount of money paid to the employes when they were not actually working, was well invested, for it provided a body of trained conductors and motormen, who could always be called to man the cars on short notice.

Another department that was directly affected by the increase in business, due to the Exposition, was the auditor's. In order to properly show on the company's books certain expenses and receipts directly chargeable to the Exposition business, the general accounting scheme had to be made somewhat more comprehensive to take in certain new accounts. Mr. P. J. Balaguer, the company's auditor, was fully equal to the task laid down, and there has been not the slightest hitch or confusion in the auditing and accounting department and the books show the exact results of the Exposition as far as the Consolidated company is concerned.

As previously stated, a separate Exposition Traction Co. was formed to care for the Exposition traffic, but as finally arranged, all receipts for the Exposition period went directly into the Consolidated company's account.

A separate item was opened on the books for car tickets which were sold at booths and collected at the street railway turn-stiles just outside the Exposition grounds. The tickets were numbered consecutively, and were treated much the same as register readings on the cars. Each ticket seller was charged with a certain number of tickets and reported every day the opening and closing numbers of the strip of tickets given him in the morning. Mr. Balaguer devised a blank form that greatly facilitated the work of making these daily ticket reports. The form was printed on a slip 10½x4 in. and had spaces enabling the ticket seller to enter at the end of every

the regular business of the company, the exhibitors being regarded as new customers.

For the six months of the show most of the car routes were changed to meet the temporary conditions, and to permit all lines to connect, either directly or by transfer, with the Exposition grounds. The final adjustment of the routes gave universal satisfaction, and some of the principles followed in planning the arrangement would seem to be applicable to almost any average city under similar conditions.

Briefly described, the routes included an outer and an inner belt line, one direct line from the hotel and depot district to the Exposition grounds, a line serving a portion of the hotel and depot section and transferring to the main Exposition line, and a suburban park line carrying visitors to the cemeteries and parks. In addition there

TRACK LAID IN SAND—SULLIVAN'S ISLAND.

was the Sea Shore line, running on some of the islands in the harbor, and connecting with the city lines by ferries owned by the Consolidated company. The different routes were designated as follows:

The Belt Line making the circuit of the city, taking in some of the better residential streets, a portion of Meeting St. (a leading business street) passing the Post Office and City Hall, and lower part of Broad St. (the money center), East Bay (headquarters of the wholesalers) and the docks and shipping.

The Broad St. Line, making an inner circuit, covering another good residential section, and many important business streets.

The King St. Exposition Line, running on the central street of the business section, covering especially the retail district, and within easy reach of the hotels and depots, and making the most direct route to the Exposition grounds.

The Meeting St. Line, traversing one of the more important business thoroughfares, running parallel to King St., and transferring to the King St. cars by cross lines at two points; this line reached a number of the leading hotels and the Post Office, and the finer residences in the southern portion of the city.

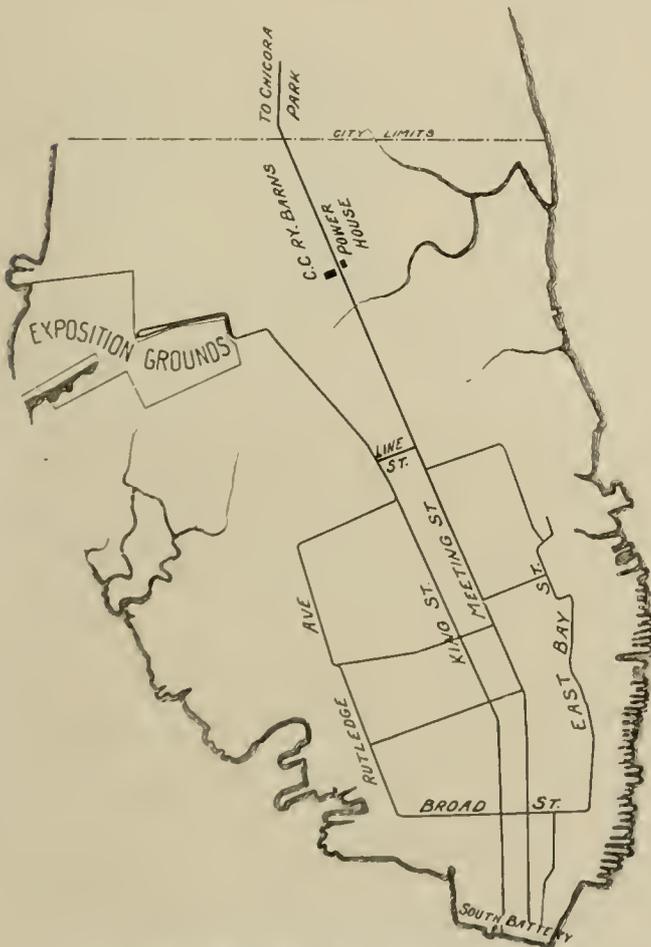

The Suburban and Chicora Park Line, running out Meeting St. and serving the cemeteries and Chicora Park.

The Sea Shore division, affording visitors a fine opportunity to see Charleston from the harbor, Fort Sumter and Moultrie, and the Isle of Palms.

The schedule on these various routes ranged from a minute to an hour, according to the demands of the traffic.

It should be added in this connection that the city of Charleston is laid out similarly to the city of New York. It is on a long, narrow strip of land, running practically north and south between two rivers which come together at the southern point of the city and form a magnificent bay. The southernmost point of the city is called the Battery, which, unlike New York's "Battery," is given over to fine residences and is the aristocratic section of the town.

In the matter of rolling stock, the Consolidated company was exceptionally well prepared for the Exposition demands. It had a number of long closed double truck cars, that had been used on the Sea Shore division as trailers. These were brought to the Charleston side, equipped with two G. E. 57 motors each, and put on the Exposition line. The company owns 26 double truck cars, equipped with two G. E. 57 motors to each car; 16 single truck cars, fitted

CHARLESTON STREET RAILWAY LINES.  
(All city lines are double track.)

two hours of the day, the "number commencing," the "number ending" and the "difference." In this way he was able to account for all tickets in his possession. In another column was entered "Cash from Tickets" and the blank as a whole therefore gave a complete record of the street railway tickets sold and cash received by each seller. The readings from the turn-stiles through which the passengers passed as they deposited their tickets before entering the cars were kept and reported in the same way, and furnished an additional check on the seller's reports.

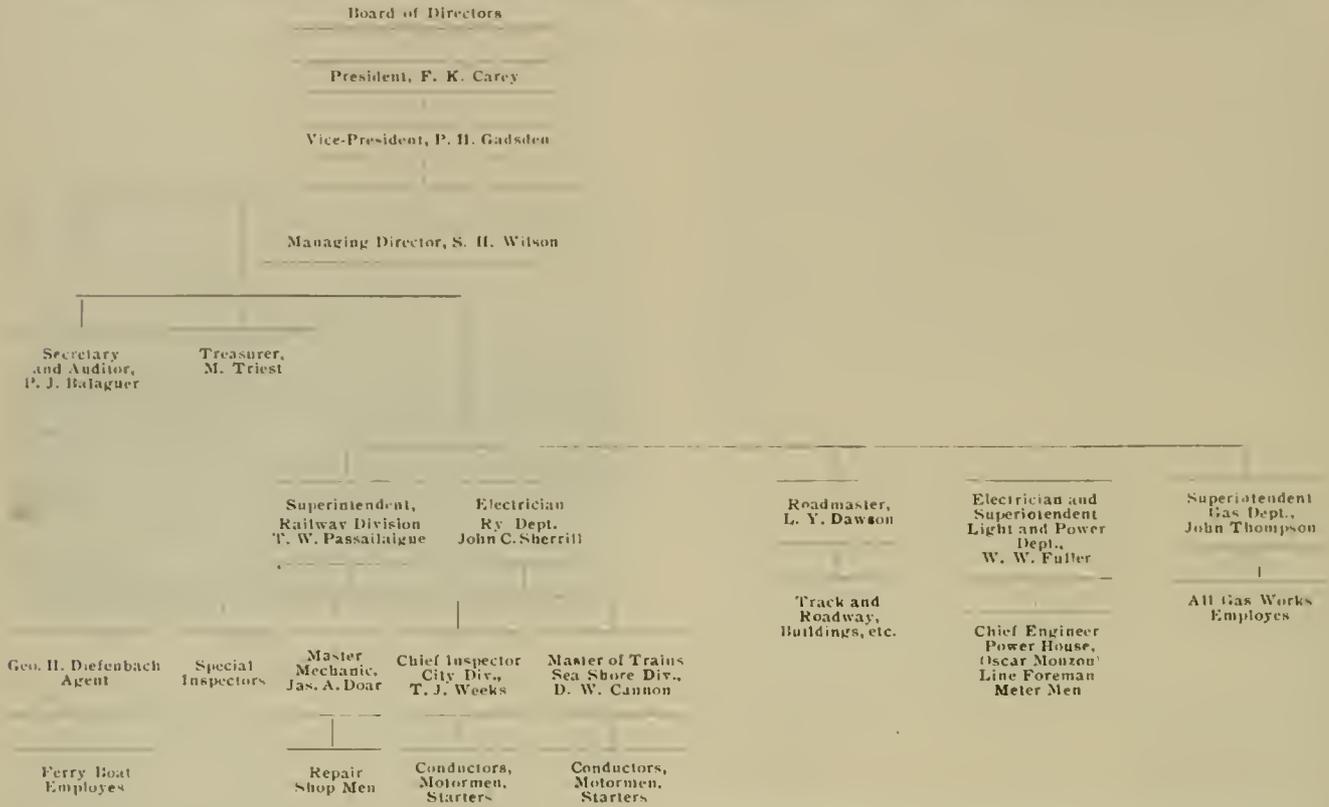

The business of lighting the grounds was handled the same as

with two G. E. 1,000 motors to each car, and 26 single truck cars, fitted with one G. E. 1,000 motor to each car. It might be noticed here that many of the southern roads are still using a single motor to the car, a practice as may be imagined that is not conducive to low cost of maintaining electrical equipment. But these older equipments are still capable of doing good work, and many of the companies do not feel justified in sacrificing them in favor of more

One 250-kw. alternator and one 150-kw. alternator supplying lighting current at 1,150 volts. These are belted to two Harrisburg engines, one rated at 450 h. p. and one at 250 h. p.

One 500-kw. alternator and one 300-kw. alternator supplying current to the Exposition at 2,400 volts, 60-cycles, three phase distribution. These are belted to Harrisburg engines, one rated at 750 h. p. and one at 450 h. p. These three-phase units as previously

DIAGRAM OF ORGANIZATION OF THE CHARLESTON CONSOLIDATED RAILWAY, GAS & ELECTRIC CO.

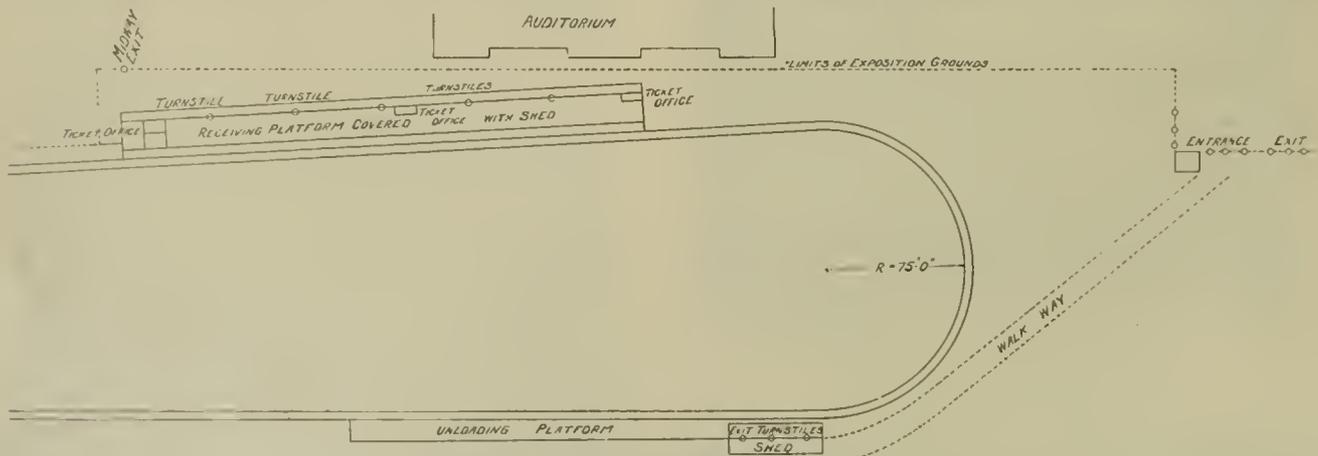

modern apparatus. On level roads, as at Charleston, the single motor under an 18-ft. body serves every purpose, although armatures, bearings and other parts are naturally subjected to greater wear and tear. The cars at Charleston are of various makes. The single trucks are Peckham No. 7; the double trucks du Pont.

mentioned will probably be retained for the regular lighting service and also for furnishing light and street railway power on the islands in the harbor.

At the city station there is also a 300-kw. motor driven booster, 550 to 750 volts, that is used to help out the Island station. When necessary this booster feeds the distant end of the Sea Shore division, a transmission distance of 17 miles.

The main or city power house contains the following apparatus:  
Two 200-kw. General Electric railway generators direct connected

TERMINAL LOOP, CHARLESTON EXPOSITION.

to a 350-h. p. Ball & Wood tandem compound engine, 16 and 27x16 in.

One 525-kw. railway generator, direct connected to a 750-h. p. Ball & Wood compound marine type engine, 22 and 48 1/2 x 24 in.

One 225 kw. railway generator, belted to a 350-h. p. Harrisburg standard engine, 16 and 30x16 in.

One 325-kw. railway generator, belted to a 550-h. p. Harrisburg standard engine, 17 and 35x18 in.

The Island station, which serves the Sea Shore division of the street railway system and also furnishes lighting current, contains one 225 kw. railway generator belted to a Harrisburg engine; and also the necessary lighting apparatus for lighting the islands, particularly the Isle of Palms, where a hotel, pavilion and pleasure resort has been established.

The following statistical statements are furnished us through the courtesy of Mr. Balaguer:

EVERETT-MOORE SYNDICATE.

On June 4th it was announced that, up to that date, 26,000 shares of the Everett-Moore holdings in the Detroit United Ry. had been sold by the syndicate at prices ranging from 71 to 80%. The stock has been absorbed piecemeal by New York, Cleveland and Detroit capitalists, the parties to whom an option on the Everett-Moore holdings in the Detroit property was originally offered at 70 having failed to take advantage of the offer. Members of the banker's committee in charge of the syndicate's affairs are quoted as stating that Messrs. Everett and Moore retain from 12,000 to 15,000 shares in the Detroit United Ry., and will continue to manage the property.

The syndicate has also disposed of 40,000 shares in the Toledo Railways & Light Co. to Kean, Van Courtland & Co., of New York, at \$22 per share; this leaves 40,000 shares still in the hands of Messrs. Everett and Moore, but there is a probability that the control of the business will be in the hands of the purchasers. The stock was purchased at \$14 per share, so there has been a profit of \$8 per share on the stock since it went into the hands of the syndicate. The only change that will be made is to increase the board of directors by two in order to give the purchasers a representation in the company.

SALE AT PROVIDENCE, R. I.

On May 27th the terms under which the United Improvement Co., of Philadelphia, would acquire the United Traction & Electric Co., of Providence, were announced. There has been organized a Rhode Island corporation known as the Rhode Island Co. to take over such properties as the United Improvement Co. may buy.

The announcement to the United Traction stockholders is that the Rhode Island Co. will guarantee 5 per cent on the Traction company's stock and in addition will give one share of its own stock for every four shares of Traction stock. The stock at present pays 4 per cent and is quoted at 121.

It is understood that the Philadelphia concern expects to combine in the Rhode Island Co. the Providence Gas Co. and the Narragansett Electric Lighting Co.

The Milwaukee Electric Railway & Light Co. has awarded a contract amounting to \$200,000 for the structural steel to be used in the erection of its new office building and terminal station.

## Oil as Fuel.

### Data from New Orleans, Mobile and Other Cities Regarding the Utility and Efficiency of Beaumont Oil as Fuel in Street Railway Power Stations—Saving Secured—Oil Burning Apparatus.

The discovery of quantities of petroleum in California and the Gulf States, particularly Texas, has brought prominently before steam users the topic of the general utility and economy of oil as fuel. The California product is as yet confined to a comparatively limited territory but the owners of the Texas wells make announcement that they are prepared to furnish fuel oil to any section of the country and in practically unlimited quantities.

Supplementing the discussion before the Southwestern Gas, Electric & Street Railway Association on the utility and advantages of oil as fuel in street railway power houses, we present some statistical data not heretofore published. We have direct reports from New Orleans and Mobile, Ala., where oil is being used regularly for firing boilers in street railway power stations, and from these and the data furnished at the last meeting of the Southwestern Association the following conclusions may be drawn:

Experience has demonstrated that the Beaumont oil is a practical fuel for street railway and lighting plants, its economy in competition with coal depending entirely upon the price of oil and the price of coal at any given locality. As determining the relative steam producing qualities of oil and coal the following is given as a summary of the results obtained in the several power stations reporting: One pound of oil will evaporate from 13 to 16 lb. of water from and at 212 deg. F.; that is, the calorific value of oil is from one-third to one-half greater than that of the ordinary run of mine coal of grades customarily used for power purposes; oil is as safe as coal and causes no greater wear and tear on the boiler parts; in a plant burning oil exclusively there will be no dirt, odor or smoke and no ash or other residue; where oil is used the services of all firemen and coal passers can be dispensed with and but one man is required on the boiler room floor.

Aside from considerations of relative economy there of course arises the important factor of the future supply of oil.

The so-called Beaumont oil fields comprising a section of western Louisiana and Texas within a radius of 100 miles more or less from Beaumont, Tex., are now supplying most of the oil used for fuel in this country. The initial discovery that oil existed in considerable quantities in this region was made Jan. 10, 1901, when the drills at the Lucas well suddenly and without warning penetrated a large reservoir of oil and a stream of oil rising to a height of 160 ft. immediately began to flow, a steam gage attached to the pipe at the well registering a pressure of 104 lb. per sq. in. Other wells were at once opened up and today there are about 200 distinct wells in action. Many of these are what are known as "gushers" and from them the oil rises under natural pressure. From others the oil is lifted by pumps. According to authentic reports the Beaumont fields at the present day have a combined average capacity of 6,000,000 barrels per day, or 2,100,000,000 barrels per year. How long this supply will last is purely a matter of conjecture. The claim is made that many of the wells formerly gushers, now require to be pumped, but the owners of the fields emphatically state that this is no evidence of the failure of the supply. They point out that it was never expected the wells would continue as gushers inasmuch as the pressure must needs be exhausted as soon as a sufficient number of openings tap the subterranean chamber but that the drop in no way forebodes a lack of oil. As evidencing their faith in the future supply it may be said many of the well owners are making long time contracts for furnishing large quantities of fuel petroleum. It is of interest to note that the United States Navy has been granted an appropriation of \$20,000 to be expended in conducting experiments with fuel oil.

From a pamphlet issued by Tate-Jones & Co., of Louisiana, we take the following data concerning Beaumont oil:

Specific gravity	22 deg. Baume.
Weight per gallon	7.66 lb.
Weight per barrel (42 gallons)	322 lb.
Flash point	180 deg. F.
Fire point	200 deg. F.

Theoretical calorific value: 1 lb. of oil will evaporate 15½ lb.

water, or 48½ lb. of oil will equal in calorific value 100 lb. of ordinary Western coal.

From the same pamphlet we quote the following regarding the use of fuel oil:

"The oil used must be of sufficiently high fire test. If this condition is observed it will dispose entirely of the objection on the score of safety frequently urged against this fuel. In fact, oil with a fire test of say 180 deg. or 200 deg. F. is as safe as coal, which has been known to ignite from spontaneous combustion. Oil with a fire test of 250 deg. to 300 deg. F. may be stirred with a red hot poker without being ignited, or a shovelful of hot coals thrown into it will sink and be extinguished.

"The oil must be supplied to the burners under a sufficient pressure; this is best accomplished by means of small pumps and pressure chamber.

"The oil should be pre-heated to facilitate atomization.

"The burner should feed the oil in a finely atomized condition; a properly constructed burner will show no dark stream of oil entering the furnace from its tip; instead the oil will emerge from it in almost imperceptible spray or vapor.

"The atomizing action above mentioned is best made by the use of steam. Compressed air has been used for this duty, but it is not so satisfactory as steam, not only because it is more expensive, but because a portion, if not all the contained water when steam is used, is dissociated in the fire and recombines later this activity as a distributor of the heat and preventing excessively high temperatures at any one point in the furnace. For this reason steam-blast is generally thought to be easier on the boiler plates and to make a 'softer' flame.

"The steam should be superheated before going to the burner.

"Just the right proportion of air should be admitted to the fire box or combustion chamber to completely burn the fuel. In the practicability of admitting just the right amount lies one of the advantages of liquid over solid fuel.

"The combination heater and pressure chamber should be fitted with a proper arrangement of relief valves to permit any excess of oil to return automatically to the storage tank. This storage tank and all pipes, as far as possible, should be underground.

"Fully as important as any of these matters is it that the setting of the boilers be good. The combustion chamber should be tight to obtain the highest possible temperature, so that every particle of the oil be entirely consumed. To get this result, the chamber must be of refractory, non-conducting substance which soon becomes heated to incandescence. Further, the flame from the burners should be directed against a wall or checker-work of fire brick.

"With care taken on this last point, with a proper adjustment of oil, air and steam, and with the ordinary conditions of good boiler practice, the combustion chamber should show a clear, white incandescence with hardly any flame apparent, and there should be no smoke or foul-smelling unburnt gases issuing from the stack. Such stack products show a waste of fuel.

"In burning oil and natural gas, experience has shown that an excess of oxygen varying from 4 to 12 per cent has been found to give best results. In burning oil where the conditions are in general more uniform, the tendency ought to be towards the smaller rather than the larger quantity. We should look, therefore, in good practice, to obtain, say 6 to 7 per cent of free oxygen in the emerging gases."

#### RESULTS AT NEW ORLEANS, LA.

The New Orleans & Carrollton Railroad, Light & Power Co. began using oil as fuel in the spring of the present year and after preliminary tests decided to fit both its railway power houses for oil firing. Oil is now used exclusively as fuel at both stations, although a supply of coal is kept on hand against a possible emergency arising from shortage in the oil supply or damage to the oil firing apparatus.

At the Claiborne power house the largest railway station of the company, the fuel oil is kept in two 14,000-gallon storage tanks

buried in the yard near the plant with their tops about 4 ft. below the surface of the ground.

Oil is fed to these tanks from the main pipe line of the oil company, the oil company having built a 15-mile pipe line along the river front, running the length of the city, with branch lines at frequent intervals to the plants of the individual customers, the petroleum being distributed much the same as gas or water. The oil company receives the petroleum from the Texas fields in tank steamers, from which it is pumped into a 55,000-barrel elevated tank on the dock at New Orleans. The oil is allowed to settle in the tank for a time in order to get rid of the water that is always found in more or less quantity in the oil. After the water is drained out the oil flows from the tank to the main pipe line and into the small storage tanks of the customers.

When oil was first suggested as a possible fuel it was customary to feed it to the boilers by gravity from stand pipes or elevated tanks in or near the boiler room, but this method has been largely abandoned owing to the objection of the fire underwriters to the storing of quantities of oil above the grate level of the burners.

At the Claiborne station the oil is again allowed to settle for two or three days in the buried tanks before it is fed to the boilers, one tank being used while the other is settling. The oil is drawn from these reservoirs by two suction pumps which feed the fuel to the

sudden contraction and expansion inasmuch as there is no necessity for opening the furnace doors to fire after the burners are lighted.

The method of firing at the Napoleon avenue station is very similar to that just described.

The even steam pressure secured with oil firing is made evident from the accompanying card recorded during an average day's run at the Claiborne station, the total current output of this station for the same 24 hours being about 11,500 kw. h.

The actual performance of the oil is given in the following table prepared after a test at the Napoleon avenue power house.

OIL TEST AT NAPOLEON AVE. POWER HOUSE ON BABCOCK & WILCOX BOILER, NEW ORLEANS & CARROLLTON RAILROAD, LIGHT & POWER CO.,  
MARCH 26, 1902.

Readings Are Hourly Averages.

Time, hour ending	11:45 a.m.	12:45 p.m.	1:45 p.m.	2:45 p.m.	3:45 p.m.

Average evaporation per lb. of oil during 5 hour' run, 15.30 lb.

For this and other tests the company reached the decision to adopt oil as fuel.

In April last Mr. H. A. Davis, assistant superintendent of the New Orleans & Carrollton Railroad Light & Power Co., made an extensive report to his company on the saving that was being effected by the use of oil. This report has been placed at our disposal and from it we make the following abstract.

Mr. Davis in the introduction to his statement explains the basis of the report thus:

"In order to determine the approximate saving in burning oil over coal at our two railroad power stations, I have taken the month of February, 1902, to get the average amount of coal consumed per kilowatt hour in both stations as this was the last month we burned coal entirely alone.

"At station No. 1 the average coal consumed per kilowatt-hour was 3.79 lb. and at station No. 2 it was 3.66 lb. This I believe will be a fair average for both stations.

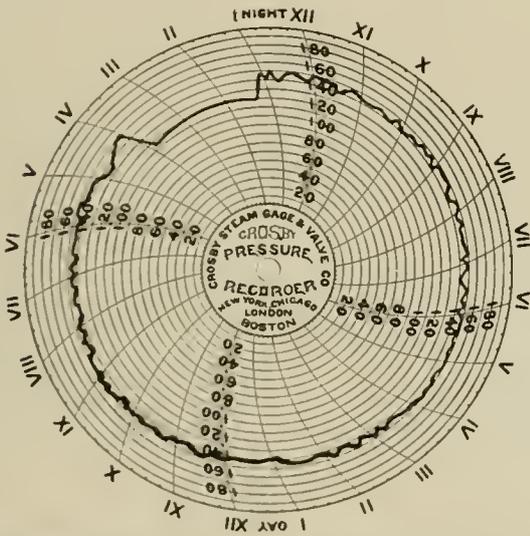

"The consumption of oil in pounds per kilowatt-hour was got from the first 17 days in April, 1902, during which time we burned only oil and no coal. This average for station No. 1 was 2.74 lb. per kw. h. and for station No. 2 2.60 lb. per kw. h.

"It will be evident therefore the difference in efficiency between the two stations in both cases is about 5 per cent.

"I have also taken the output in kilowatt hours during the month of March, 1902, for both stations as a basis for comparing oil and coal, assuming that we had burned oil for the entire month."

The comparative results are as follows:

	Oil.	Coal.
Station No. 1, total output for month of March,	286,760 kw. h.	
Average consumption of fuel per kw. h. ....	2.74 lb.	3.79 lb.
Total fuel consumed .....	2,518 bbl.	543 tons
Total cost of fuel (oil at 45 cents a barrel and coal at \$3.20 per ton) .....	\$1,133.10	\$1,737.60

STEAM PRESSURE DIAGRAM OIL FIRE NEW ORLEANS.

burners at about 45 lb. pressure. A small pipe coil heater taking steam from the pump exhaust is interposed in the pipe between the pump and the boilers serving to raise the temperature of the oil about 15°, or from 76°, the tank temperature, to about 90°, the temperature at which it goes to the burners. The boiler equipment consists of two 350-h. p. and two 450-h. p. Edgemoor water tube boilers and there are eight oil burners under each boiler. The boilers were originally fitted with Hawley down-draft furnaces and these were not removed when the oil apparatus was installed.

The burners are known as the Von Phul pattern which employs live steam as the medium for spraying the oil. The burner is made entirely of brass and comprises a 1/8-in. pipe within a 1/2-in. pipe, the smaller pipe being for oil and the larger one for steam. The tip of the oil pipe enters the tip of the surrounding steam pipe and as the oil flows out in a small stream the steam picks it up and forces it out into the fire chamber in a blast of finely atomized oil, which, when lighted, makes a white flame. This blast does not of course touch the boiler tubes but is directed against fire bricks laid on the grate bars, and piled up at the back of the fire chamber in an open work wall, that is, alternate long and short bricks laid with openings between to allow circulation. In case of failure in the oil supply these bricks can be removed and a coal fire built in less than half an hour.

The flow of oil to the boilers is regulated by hand valves.

The wear and tear upon the boiler structure is found to be less at this plant with oil than when coal was burned. This is partly explained by the fact that the temperature under the boiler remains practically constant and there are no racking stresses produced by

Station No. 2, total output for month of March, 330,420 kw. h.	Oil.	Coal.
Average consumption of fuel per kw. h.	2.60 lb.	3.66 lb.
Total fuel consumed	2,827 bbl.	629 tons
Total cost of fuel (oil at 45 cents a barrel and coal at \$2.55 per ton).	\$1,272.15	\$1,603.95
Saving in cost of oil over coal, Station No. 1.		\$604.50
Saving in cost of oil over coal, Station No. 2.		331.80
Total both stations.		\$936.30
Labor saved by burning oil instead of coal at both stations:		
Four coal passers at \$45 per month.		\$180
Two firemen at \$55 per month.		110
Total.		\$290

At station No. 1 the watch requirements were changed from 8 hours to 12 hours and the salary of the two watchmen was raised from \$55 to \$60 per month; at station No. 2 the salary of the boiler cleaner was increased from \$45 to \$50 per month, making an increase in pay roll of \$15 per month, which deducted from \$290 leaves a saving in cost of labor at both stations of \$275 a month with oil as fuel.

The grand total saving in labor and fuel for the month was therefore \$1,211.30; or, at this rate the saving in oil as fuel over coal at both stations for the year would be \$14,535.60.

RESULTS AT MOBILE, ALA.

The Mobile Light & Railroad Co. has been using oil fuel under a portion of its boiler equipment since last fall with results satisfactory in every way.

The following is data secured from a test at this station:

COMPARATIVE TEST OF COAL AND OIL IN STIRLING BOILER—MOBILE (ALA.) LIGHT & RAILROAD CO., OCTOBER, 1921.

	Alabama Coal.	Beaumont Oil.
Duration of test	24 hours	13 hours 45 min.
Average steam pressure	122 lb.	122 lb.
Average temperature feed water	154.4 deg.	109 deg.
Total water evaporated	168,315 lb.	92,206 lb.
Total fuel fired	15,080 lb.	7,091 lb.
Weight of ash	1,258 lb.	...
Per cent of ash	8.30	...
Weight of combustible	13,822 lb.	...
Heating surface of boiler	3,549 sq. ft.	3,549 sq. ft.
Water evaporated:		
Per lb. of fuel actual conditions	7.18	13.10
Per lb. of combustible actual conditions	7.83 lb.	...
Per lb. of fuel from and at 212°	7.91 lb.	13.84
Per lb. of combustible from and at 212°	8.62 lb.	...

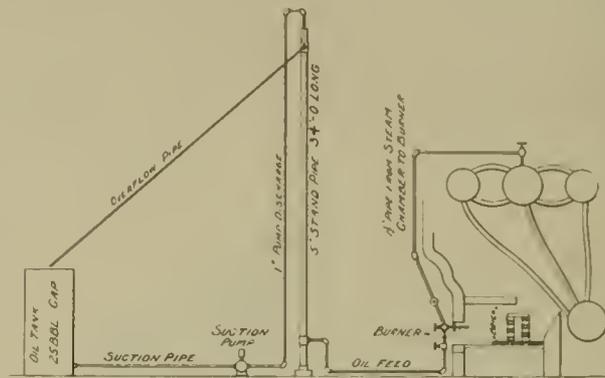

Coal used was "Belle Ellen" Alabama mostly slack run-of-mine.

The following comparative values of Beaumont oil and various grades of southern coal derived from tests at the power house of the Mobile (Ala.) Light & Railroad Co. will be of interest. All coals are run-of-mine.

	Water evaporated per lb. of coal from and at 212	Oil equivalent to ton of coal, gallons.	Oil equivalent to ton of coal, barrels.
Bloekton Underwood	9.67	183.5	4.36
Bessemer Slope No. 1	9.68	172.	4.08

Black Creek	8.76	167.	4.00
Mountain Valley	6.55	125.	2.96
Tide Water	6.73	128.5	3.05
Standard Coal Co.	8.04	152.5	3.62

At the present time Beaumont oil can be purchased at the oil fields for 30 cents a barrel; at New Orleans for 45 cents a barrel; at Charleston, S. C., for 60 cents a barrel, in Illinois for from \$1.00 to \$1.25 a barrel, at Philadelphia for about \$2.00 per barrel.

The method of feeding in this case is set forth in the accompanying sketch. At this plant the stand pipe method of feeding is used. The pipe is 5 in. in diameter and 34 ft. high. Oil is pumped in at the top and flows to the burners by gravity. The burner is of the "Jurnal" pattern which is similar to the design used at New Orleans with the exception that the flow of oil from the burner is controlled automatically. The inner or oil tube is movable within the large steam pipe by means of wheel and screw at the outer end. By adjusting the position of this tube the quantity of oil flowing from the end of the burner is regulated. The steam for the burner is taken through a reducing valve. Under working conditions the inner tube is adjusted so that the oil pressure is just a trifle greater than the pressure of the steam and a fine stream of oil flows. Any variation in the steam pressure on the boilers will be followed by a corresponding change in the quantity of oil flowing. Thus, if the

METHOD OF FEEDING OIL TO BOILERS IN MOBILE.

steam pressure drops, more oil will flow thus increasing the degree of heat and maintaining the proper steam pressure. The burners are hung in the center of the fire doors from eye bolts tapped in over the doors. As in the case previously described the blast from the burner is directed against fire bricks laid on top of the grate bars and built into a wall at the back of the fire chambers the bricks being laid loosely without cement. We are indebted to Mr. J. A. Maloney, chief engineer of power station, Mobile Light & Railroad Co. for the data on oil fuel at this station.

RESULTS AT EL PASO, TEN.

Mr. H. T. Edgar, before the National Electric Light Association in convention at Cincinnati last month gave the following information relative to Texas fuel oil at the electric light station, El Paso, Tex.

The oil is stored in steel tanks buried in the ground, and is drawn from the tanks through a 1½ in. iron pipe, which discharges through a 1 in. pipe into a small chamber about 14 in. in diameter and 2 ft. 6 in. long, placed by the pumps. The oil enters this chamber at one end, passing through a partition of very fine wire gauze, and at the other end comes in contact with a coil heated with the exhaust steam from the pump, thus raising the temperature of the oil to about 145 deg. F. The oil is sprayed from the burners by steam, and in order to insure a steady pressure an auxiliary air chamber is required. It is stated that a very great saving has been made at the El Paso station through the substitution of oil for coal. It is claimed by the advocates of fuel oil that four barrels of 42 gallons are equal to one ton of good bituminous coal. Results of tests made by the waterworks company of El Paso show that the cost of burning fuel oil is but half the cost of burning coal, when the coal costs \$5 per ton and the fuel oil 70 cents per barrel.

Following the reading of the paper on this subject by Mr. W. W. Reed, at the Southwestern Gas, Electric & Street Railway Association, which was abstracted in the "Review" for May 20th, there was considerable discussion which went to show the unusual importance of this subject to companies operating in the vicinity of oil wells.

Mr. Spencer, of Jennings, which is an oil town, was called upon and stated in reply that he was using Beaumont oil and that it put his plant in paying condition very quickly. He formerly used coal costing from \$4.50 to \$4.75 per ton and was now paying from 35

to 40 cents per barrel for oil. One of the points of difficulty which he had experienced was in the selection of the best burner. His company has been testing a large number of burners but he believed that none of them are entirely satisfactory. He attended the convention in the hope of receiving some suggestions from those who had gone into these experiments farther than he had been able to.

Mr. Guthrie, of San Angelo, stated that his company had put in an oil burning plant about nine months ago and found it a great saving, although the oil at that place cost about 60 cents. This company uses the gravity system of feeding and has found it very satisfactory. The speaker stated that he did not see very much difference in the burners or how the system could be more ideal as there was not a sign of smoke or any deposit on the boiler and the company is now saving about \$200 per month out of its former total expense of \$500. He had not been able to notice any deterioration in the plant due to the use of oil. There are some signs of sulphur but as far as the boiler is concerned, it is in a good deal better condition than when coal was used, for the reason that the heat was more regular and there was no inrush of cold air from opening the doors of the fire box. Mr. Guthrie suggested that the various consumers of oil might form a combination and buy a well of their own. He had investigated the matter and found that a good well could be bought at a reasonable price.

Mr. Miller stated in regard to the strength of boiler tubes after oil had been used that boiler inspectors always inspected them when they were cold. It has been suggested that constant burning of sulphur would eventually cause the iron to absorb sulphur and become what is known as hot-short. That it would be tough when it was cold and "short" when it was hot. There was no corrosion or pitting on the outside of the tube and the speaker was surprised to find that the presence of sulphur in the stack did not show any signs of destroying it. He knew from experience that the cheaper grades of coal will destroy a stack.

Mr. Reed stated that the stack was the only place where he had seen the effect of sulphur at all. He had a steel stack and at the joint can be seen where the deposits of sulphur had run down and discolored the stack. Whether it had produced any injurious effects or not he did not know, but thought it had not.

Mr. H. T. Edgar stated in looking the matter up he found that oil had been used as fuel all over the United States and Canada since 1885 and there was considerable data on this subject. Fuel oil was in use under nearly all the boilers at the World's Fair in Chicago and it had been burned in California for some time. One trouble with fuel oil which he mentioned was that if the fires go out and the oil is not shut off immediately it will run out of the burner and get into the fire box, which causes a great deal of trouble. He had seen a case where it had blown the damper out of the chimney. Another feature which appeals especially to the small plants is that the plants are liable to be shut down and the steam to run down, in which case it is impossible to start up with the oil alone for lack of steam to atomize it. In case nothing is done to the boilers except putting a layer of fire brick on the bars it is only a matter of a few minutes to make up a fire in the fire box and get up enough steam to atomize the oil.

Mr. Jennings stated that in his plant he had arranged a small reservoir so that the fire could be started with the gravity feed, and while oil was wasted in this way for perhaps 15 or 20 minutes, at the end of that time enough steam will be raised to start the boilers. This small reservoir contained from 15 to 18 gallons of oil which was delivered through the pumps and in this way the fire was started without injuring the fire boxes.

Mr. Guthrie did not understand why insurance companies have a prejudice against gravity feed as the same pressure is established by the use of pumps and no danger exists if a small tank is used. His company kept a 500-gallon tank above the roof and pumped oil into it every evening.

President McGregor explained that the companies feared the quantity of oil used and the rapid production of gas when a fire occurred. He had had some quarrels with the insurance companies himself on these points but had later had an experience at his plant that satisfied him, as it burned the roof off the power house. The fireman cut off the oil from the tank and there was a pressure in the pump cylinders, so that in disconnecting the burners the oil shot out in range of a torch and the flame went up and destroyed the roof of the house. In two or three minutes it reached the engine room and burned off the roof of the boiler room. There was danger of

the creation of gas from the heat which occurred. A leak or accidental turn of the stop cock in a gravity feed while the boiler was still warm might cause serious results.

Mr. Payne spoke of a burner in which air was used to atomize the oil instead of steam. This burner had not been used at all in Texas although it is in use in Europe and has been experimented with in northern and eastern states of this country. As it is very easy to store air under pressure there would be no trouble in starting up in the morning without any fire. In regard to the damage done by sulphur, Mr. Payne believed that the result of the Houston Electric Light Co. in the use of oil was a very sufficient test because there the conditions of greatest danger were called forth by the boilers being operated up to the limit of their capacity. After working every boiler in this way for several months no trouble had resulted although the surface of the tubes were whitened to some extent either by the sulphur or by the oil flame itself. His boilers had not given any trouble although both the tubes and stack showed signs of the presence of sulphur in white streaks.

Mr. Ludlow was then requested by President McGregor to address the convention in regard to fuel oil. He had noticed in a report of the paper under discussion that the statement was made that the test was hardly fair because the steam used for atomizing the oil was not deducted from the result. The test he was about to refer to was probably correct because the gas for producing the steam used for atomizing was computed in the test both as to the cost of oil and the number of pounds of water evaporated, it having been generated in the boilers under which the test was made. The test referred to was that of the plant of the Dallas Electric Light Co., on a Babcock & Wilcox boiler of 317 h. p. rating. At the time the test was made oil was worth 59 cents per barrel delivered in Dallas and coal was \$3.15 per ton. The evaporation at 212 degrees was 13.77 lb. of water per pound of oil while with coal they had attained an evaporation of 8.87 lb. of water per pound of coal. The tests covered an eight hour run and the actual saving was \$3.62 without including the fireman at \$2 additional. This plant has since adopted the system used during the tests and a saving of approximately \$2,000 per month on its fuel bills and \$26 per day on firemen had resulted. Ever since fuel oil fields were discovered in Beaumont all kinds of arguments have been advanced in regard to the damage done to the boilers, flues, etc., from sulphur. The speaker challenged anyone to substantiate the statement that sulphur had done damage in boilers or flues. Any damage which had been done would be found due to the installation not being properly made. A number of mistakes had been made in installing oil burning plants; for example, one plant had put in a solid brick wall and the flames were shot up against the tubes of the water tube boiler with such intensity that the tubes were damaged and had to be replaced. The construction of another plant was also defective in that the heat was deflected and shot down with such intensity on the foundation that it was melted out and had to be replaced. These instances were cited to show the damage which might result from improper installations. The speaker had installed a number of plants which never gave a particle of trouble until inexperienced experts undertook to improve them. One party for whom he had installed a plant wanted to see what could be done with oil and undertook to carry a load on three boilers for which five were formerly used. The three boilers did the work, but some damage resulted to the boiler brickwork and stack, as they were heated much beyond what was required for the ordinary capacity of the boilers. The speaker stated that Beaumont oil had been fought all the way through. A fight has been waged against it in Texas notwithstanding the people of that state have an opportunity of getting their fuel cheaper than any other place in the country. It is a fact that oil is being used at a cost of from \$1 to \$1.25 per barrel in Illinois and economically at that, yet the people of Texas complain even when they get it at from one-quarter to one third of this price. It is difficult to make public all the points in connection with the saving due to oil because most plants for reasons of their own do not care to give the public the benefit of their experience. Nevertheless, enough information has been given out to warrant the assertion that the saving with oil is from one to two thirds as compared with coal.

The Steubenville (O.) Traction & Light Co. on May 24th formally opened its new interurban between Steubenville and Toronto. The advent of the trolley was celebrated with great enthusiasm by the citizens of Toronto in which the people of the other city shared.

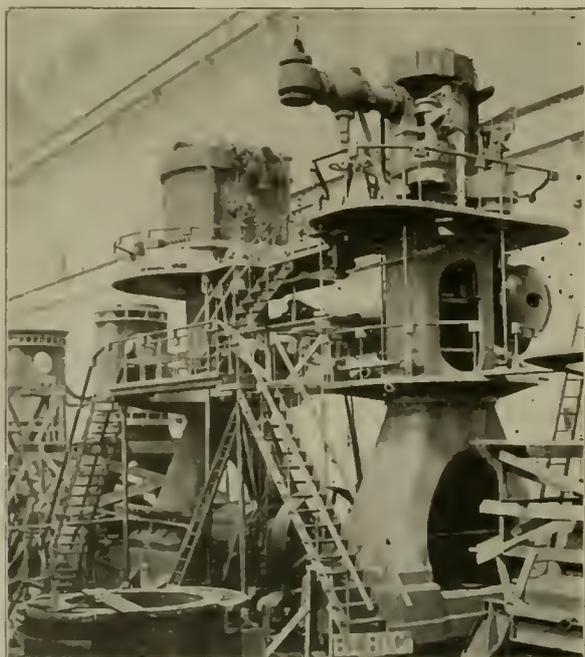

### ADDITION TO THE CHARLESTOWN STATION, BOSTON ELEVATED RY.

In March, April and May, 1900, the "Review" published an extended description of the system of the Boston Elevated Ry., and at that time power was furnished from seven generating stations, the fifth in point of capacity being the Charlestown station located near the Sullivan Sq. terminal of the elevated line. As was noted in the "Review" for May, 1902, page 265, the traffic on the elevated road has been far heavier than was anticipated and the two units provided for at the Charlestown station, one of which will soon be

CHARLESTOWN POWER STATION, BOSTON ELEVATED RY.

operating, will greatly relieve the other stations. The equipment of the old station consisted of three 500-h. p. horizontal water-tube boilers and two horizontal cross-compound Allis engines rated at 1,000 h. p. each. These engines are direct connected to multipolar generators of 800 kw. capacity.

ENGINE ON THE ERECTING FLOOR.

The new unit referred to as being about ready for operation is a Westinghouse vertical cross-compound engine, which was ordered through the Boston office of Westinghouse, Church, Kerr & Co. The cylinders are 44 and 87 in. in diameter with 60-in. stroke, and the engine runs at 75 r. p. m. It is given a nominal rating of 4,500 h. p., using steam at 160 lb. initial pressure with a vacuum of 26 in., and has an ultimate capacity somewhat exceeding 7,000 h. p.

The high-pressure cylinder is fitted with poppet valves for use with superheated steam and the low-pressure cylinder with a corliss valve gear of Westinghouse design. The cast-steel flywheel is 28 ft. in diameter with 26-in. face, and weighs 150,000 lb. The shaft is of hydraulically forged steel, 37 in. in diameter with an 18-in. hole in the center. The total weight of the complete engine is, approximately, 1,125,000 lb.

The armature of a Westinghouse direct-current generator is carried on the main shaft between the high and low pressure cylinders. This is one of the four largest direct-current railway generators in New England. It is a 24-pole machine of 2,700 kw. capacity. The commutator and armature are 12 ft. and 15 ft. in diameter, respectively, and the total weight of the generator is about 338,000 lb.

An interesting feature of the switchboard installation, which was also designed by the Westinghouse company, is to be found in connection with the circuit breakers, which can be thrown out from any portion of the building by means of electric buttons.

The condensing system includes two Allis condensers for the small engines built by the Allis-Chalmers Co. and a Bulkley jet condenser for use with the Westinghouse engine.

The capacity of the boiler room has been increased by adding four 500-h. p. horizontal water-tube boilers. Coal is supplied to the power house direct by rail and loaded from cars into overhead hoppers, although the power house is located so that coal can be brought by either water or rail. The boilers are equipped with Greene economizers arranged in the usual manner with by-pass flues for leading the gases direct to the stack, should occasion require. The method employed for the removal of ashes is of particular interest. The overflow from the condensers and pumps is carried through trenches which pass under the ash pits of the boilers. The ashes can be dumped at will into these trenches and are carried off with the overflow to flats or meadows which are being filled and enclosed.

While the new boilers were primarily installed for the purpose of furnishing steam to the Westinghouse engine, the scheme of piping has been carefully arranged so that the boilers may supply steam to any engine. Cylinder oil for the entire station is forced by city water pressure from a tank located in the basement.

The scheme of electrical distribution and auxiliary equipment has been carefully worked out, the details of this as well as the general installation of the additional power equipment has been under the direct supervision of Mr. C. S. Sergeant, vice-president, and Mr. C. F. Baker, superintendent of motive power and machinery for the Boston Elevated Railway Co.

### PHOTOGRAPHS OF EXPOSITIONS.

Those who contemplate making exhibits at the St. Louis Fair will be interested in the following letter from a committee of the Chicago Trade Press Association to the Director of Concessions of the Louisiana Purchase Exposition:

"The Chicago Trade Press Association has appointed a committee instructed to ascertain from the Exposition officials what courtesies will be extended to representatives of the trade press during the Exposition, and especially what privileges will be accorded them in the securing of photographs for purposes of illustration.

"In the discussion that led to the appointment of the committee it developed that the members of the association felt that at previous expositions they had been unfairly dealt with, especially in having no better facilities for securing photographs than anyone else having to pay high prices, and even then not owning the negatives for which they had paid. Instances were cited in which photographs taken for them by the official photographers under their special supervision and for which they had paid the high prices demanded for special photographs, were in the hands of the public at nominal rates before they could use them in their respective papers.

"It seems to the association that the technical papers are not only entitled to better treatment than this, but that they should have special privileges in this connection.

"The members feel that they should not be compelled to submit to the exactions of a concessionaire or be forced to await his convenience in the taking of photographs. They believe that they should be privileged to take their own photographers, who are often better experienced in this particular line of work, into the Exposition and take what photographs they require for the purpose of illustration."

**ELECTRIC TRACTION IN GREAT BRITAIN.**

From mid-April to the Whitsuntide recess, Parliament displayed extraordinary activity in dealing with electric traction undertakings for London.

The Select Committee of the House of Lords, over which Lord Windsor presides, had under consideration the fourteen leading electric railway schemes, while Lord Ribblesdale's Committee presided over the initial fate of another group of ten underground railway bills of comparatively smaller magnitude and which, moreover, are not competitive.

The struggle for the possession of London's electric network of tube railways has been warmly contested from day to day before the two committees by the rival promoters, who fell into two principal groups known as the Yerkes and Morgan combinations. The Lord's Committees have dealt with the bills under recommendations of the Joint Committee of last year and of special reports furnished by the Board of Trade, and have shown that they are bent on evolving a thoroughly practical and efficient network of electric traction.

The line proposed by the Central London Co. from Shepherd's Bush via Hammersmith, Picadilly and Charing Cross to the city at Liverpool St., completing the circuit of the present "twopenny tube," has been rejected, excepting the extension from the Bank to Liverpool St., mainly owing to the opposition of Mr. Balfour Browne on behalf of the Morgan combination, who objected that the scheme would never be realized and was merely promoted as a block to hinder competition; he quoted from the company's prospectus to the effect that its policy was not one of expansion and reminded the chairman that the company had admitted that the shareholders had not been asked to sanction the acquisition of extra capital for the new line. The Piccadilly and Charing Cross extension of Mr. Yerkes' Brompton and Picadilly scheme (already sanctioned) is rejected, leaving the other sections for further consideration.

The section of the London United Railways (one of the Morgan group) from Addison Road via Shepherd's Bush to Hammersmith is also rejected. The City & North-East Suburban bill, another Morgan scheme, has been withdrawn in consequence of Lord Windsor having refused to sanction the city end of the line, and the portion of the North-East London from Palmer's Green to Southgate is likewise rejected.

Since Whitsuntide Lord Windsor has given a decision concerning the combined scheme presented by the London United Electric Railways (Morgan group) for the Piccadilly & City Railway and the North-East London Railway, which provides for a tube railway from Hammersmith via Kensington, the Strand and to the city and thence on to Tottenham and Palmer's Green, which has been passed; the Marble Arch, Sloane St. and Clapham Junction railway, passed (Morgan scheme), the Yerkes extension section from Piccadilly to Holborn, connecting with the Great Northern and Strand; and the Yerkes deep-level line from Earl's Court to Piccadilly, both passed. The King's Road railway, rejected. The Charing Cross, Hammersmith & District Railway rejected. This concludes the labors of the Lords' Committees.

Of the bills before Lord Ribblesdale's Committee, only two have been rejected, as will be seen from the following statement:

Charing Cross, Euston & Hampstead (Yerkes) with extensions to Golder's Green & Hendon.....	Passed.
Edgware & Hampstead.....	Passed.
Islington, King's Cross & Euston (promoted by City & South London Co.).....	Rejected.
City (Cannon St.) & Crystal Palace.....	Rejected.
North-West London.....	Passed.
Great Northern & City.....	Passed.
Great Northern & Strand (Yerkes).....	Passed.
Baker Street & Waterloo (Yerkes).....	Passed.

The last three bills only sought for extension of time to complete the authorized line.

In the sphere of tramways, the London County Council have so far been successful; it has managed to pass the bill for the line along the Victoria Embankment from Waterloo Bridge (the portion eastward to Blackfriars Bridge being disallowed) to Westminster bridge through the second reading in the House of Commons, but the opposition is sure to be renewed at every subsequent stage; the bill is, therefore, by no means out of peril yet. The Council was likewise fortunate in getting the bill for the construction of a sub-

way tramway from the Embankment to Theobald's Road, under the new Strand to Holborn thoroughfare, through the first committee stage with very little difficulty, but was forced to abandon the large general proposal in the subways bill for powers to construct subway tramways in London wherever it chose. The committee has resolved to report the bill to the House for a third reading, subject to the insertion of certain protective clauses for the benefit of the District Railway Co. The ease with which the bill has slipped through the House of Commons shows that the trend of public opinion is in favor of increased facilities for electric transit. The shallow subway tramways, however, must be regarded as serious rivals to the tube railways.

The bill for the Croydon Tramways is now in committee stage and seems likely to pass, and the proposal to electrify the North Metropolitan lines in Middlesex is meeting with but little opposition. The debate in the House of Commons on the obnoxious Standing Order No. 22 has proved a great disappointment. The amendment proposed by Mr. Chaplin to remove the veto of the local authorities on tramway schemes, and to substitute instead an order to the effect that the committee on the bill should be given proof as to whether the consent of the local authority had been obtained or not, and that if unreasonably withheld a report should be made accordingly, was negatived without division. This right of absolute and unreasonable veto given to local authorities is confined to tramway bills; in the case of lines built under the Light Railways Act, a local inquiry is held by the Light Railways Commissioners and the application for the order may be granted in spite of the opposition of the local authority, if this is proved to be unreasonable. The right of veto gives a small local authority the power to block effectually a large scheme for a line which would benefit several districts. The alteration in the law is as urgently needed as the revision of the law of electric lighting, traction and power distribution, and it is to be regretted that the amendment was not presented officially from the Government instead of being brought forward by a private member without sufficiently preparing the ground beforehand.

A new tube railway, connecting London with the lovely county of Surrey, is being projected under the title of the City & Surrey Electric Railway bill. The scheme proposes to use the City & South London Railway from King William St. to the Borough and to carry the new line thence across Lambeth to the Croydon district, including Caterham, Westerham and Redhill.

Two more schemes are under consideration for the construction of monorails on the Behr system; the first from London to Brighton, to run to a large extent over the lines of the London, Brighton & South Coast Railway. Mr. Behr suggests that a monorail should be laid on an elevated track from Victoria and London Bridge to the outskirts of London in order to obviate all land acquisition troubles, and thence alongside the present track. The trains would travel at a speed of 120 miles an hour, accomplishing the journey in 25 minutes. It is claimed that the scheme would work harmoniously with the London, Brighton & South Coast Railway Co., carrying only first-class passengers; it is expected that, if the negotiations on foot between the company and Mr. Behr's syndicate are successfully arranged, the bill will be presented to Parliament next season. The second scheme is announced from Glasgow, where a start has been made with the survey of a route for a monorail, Behr system, between that city and Edinburgh.

The Board of Trade has sanctioned the plans for the Manchester & Liverpool Express Railway and the company is preparing to proceed immediately (during June, it is hoped) with the construction, when a start will be made simultaneously at Warrington and in the suburbs of Liverpool and Manchester.

D. N. D.

**THE OSAKA COMMERCIAL MUSEUM.**

The rules of the Osaka (Japan) Commercial Museum have been published in book form and the volume contains considerable information of value to merchants in all departments of business. The institution was established for the purpose of stimulating trade and manufactures in Japan by exhibiting the most important domestic and foreign products of manufacture. It collects newspapers, magazines and books that bear upon the above subjects and in this way furnishes information to merchants and manufacturers. It also provides a chemical laboratory for making analytical tests and explains and encourages inquiry into all kinds of industrial problems.

## ANNUAL MEETING OF THE CANADIAN ELECTRICAL ASSOCIATION.

The 12th annual convention of the Canadian Electrical Association was held June 11, 12 and 13, 1902, at Quebec, the headquarters being at the Hotel Frontenac. The convention was welcomed by the mayor of Quebec, Hon. S. N. Parent, after which the president's address was given. This was followed by the reading of the minutes, reports of committees and general business. In the afternoon special cars left the Hotel Frontenac, taking the delegates to the substations of the Quebec-Jacques Cartier Electric Co., which arrived at the car house of the latter company at 3:00 o'clock. Here a paper was presented by Mr. A. B. Lamb, of Toronto, Ont., on the "Electrical Equipment of an Ordinary Street Car." At the evening session, which was held at 8.00 o'clock, a paper on "The Development of Arc Lighting Apparatus from 1870 to 1902, With Special Reference to Modern Arc Light Engineering," was read by Mr. W. D'A. Ryan, Lynn, Mass. On Thursday the morning session was devoted to the reading of two papers, one on "Arc Lighting" by Mr. C. M. Greene, Lynn, Mass., and "Lightning Protection and the Static Interrupter" by Mr. Percy H. Thomas, Pittsburg, Pa.

During the afternoon visits were made to the Shrine of St. Anne De Beampre, Montmorency Falls and Kent House. The power house of the Quebec Railway & Power Co. at Montmorency was also visited. In the evening the delegates were entertained at a concert given by the Royal Canadian Artillery Band, and at 9:00 o'clock the annual banquet was held.

Friday morning two papers were read, the first being "The Use of Storage Batteries in Electric Distributing Stations" by Mr. A. A. Dion, of Ottawa, Ont., and the second "Electric Suburban Railways" by Mr. Ed. A. Evans, of Quebec, Que. In the evening by the invitation of Mr. Frederick Nichols, vice-president and general manager of the Canadian General Electric Co., Ltd., the members of the association enjoyed a trip by steamer around the island of Orleans, including a visit to the dock, harbor and site of the new Quebec bridge.

## INDIANAPOLIS-CINCINNATI ROUTE TO BE OPENED.

The Indianapolis, Shelbyville & Southeastern Traction Co., which projects the establishment within two years of a direct electric railway route from Indianapolis to Cincinnati, has completed track-laying for its interurban between Indianapolis and Shelbyville, and, if a crossing of the Big Four at Fairland can be effected, this portion of the system will be in full operation between July 15th and August 1st. An extension to Greensburg and Batesville will be completed by December of this year, and it is expected that cars will be running to Cincinnati not later than January 1, 1904. Townsend, Reed & Co., to whom the contract for the construction of the line was given, have located the central power house at Shelbyville, with a view to operating the extension to Greensburg and Batesville from this point. The three-phase, high-tension system has been installed, and the plant will have an initial capacity of 800 h. p., which, however, will be more than doubled by the addition of more generators. Seven 50-ft. motor cars have been received and more will be put in commission when the proposed extension shall be opened. The cars are geared for a speed of 50 miles an hour, the motor equipment consisting of four 50-h. p. motors. They are equipped with air brakes and will be heated by the hot water system.

The new interurban runs through a thickly populated rural district, and the terminals, Shelbyville and Indianapolis, are cities of 8,000 and 100,000 inhabitants, respectively. When the through service between Indianapolis and Cincinnati (110 miles) is opened, a limited service and schedule will be inaugurated, and cars will be run at the rate of 70 miles an hour. A freight and parcel express service will be inaugurated with the opening of the line between Indianapolis and Shelbyville.

The officers of the Indianapolis, Shelbyville & Southeastern Traction Co. are: E. K. Adams, president; Albert de Prez, vice-president; T. E. Goodrich, secretary, and John R. Messick, treasurer. The board of directors includes, in addition to the foregoing, W. N. Harding and Charles M. Cooper, of Indianapolis, and Sherman P. Minear, of Greensburg.

## AUGUSTA BENEFIT ASSOCIATION.

The Augusta Railway Athletic and Benefit Association, formed of the employes of the Augusta (Ga.) Railway & Electric Co., is in a flourishing condition. Practically all the employes of the company are now members of the association, and the men take an energetic interest in the welfare of the society, that promises well for its future.

At the last public reception given by the association to its members and friends several hundred people gathered in the association's hall and enjoyed the musical and literary program provided, the features of the evening being whistling solos and choruses by the Baptist Whistling Choir, and music by the mandolin club. Col. D. B. Dyer, president of the railway company, made a happy speech that was much appreciated by the boys and their friends.

In opening the meeting the president of the association explained that the object of the public receptions was to bring the people of Augusta and the street railway, gas and electric light employes into a close and cordial relation, to the end that the service to the public might be constantly improved, and that the public might feel that the company and its servants were always desirous of receiving and acting upon suggestions from its patrons.

After the meeting and reception light refreshments were served. Mr. George Conklin, claim agent for the company, is treasurer of the benefit association. I. H. Woodward, one of the older employes, is president.

## NEW RESORT AT OLCOTT BEACH IS A SUCCESS.

The International Traction Co., of Buffalo and vicinity, has established a summer resort at Olcott Beach which thus early in the season is attracting a large proportion of the traffic over the company's lines and promises to become the most popular pleasure ground between New York and Chicago. Olcott Beach has been very appropriately termed the Manhattan Beach of Buffalo.

Until the International company acquired possession of the Lockport & Olcott Ry., Olcott Beach was practically inaccessible from Buffalo, and the natural beauties of its environs were known only to sportsmen and occasional tourists. This season has witnessed a change, and the company's cars now carry many thousands of people daily to the beach. Among the principal improvements is a modern hotel with accommodations in its dining-room for 1,500 persons, and 100 sleeping rooms. A pavilion, amphitheater and concert hall have been erected, and there are numerous smaller attractions including carousals, etc. The bathing and boating facilities are unexcelled, and from the bluffs a view of the Canadian hills 50 miles distant can be obtained.

The Pittsburg Orchestra, under the direction of Victor Herbert, was one of the attractions at Olcott Beach early in the summer, from which it may be judged that all the amusement features offered by the management will be of the best quality. Mr. W. Caryl Ely, president of the Lockport & Olcott Ry., has been active in promoting the establishment of the resort and it is apparent from the extent to which the beach is being patronized that he has met with a high order of success.

## ELECTRIC RAILWAYS IN MALAGA.

Consul Ridgely writes from Malaga that the municipal council of that place has authorized the operation of the street railway system by electricity. The mileage of this system at present in operation is comparatively insignificant, being only about 8 miles, but concessions have been granted for various extensions and the system is sure to extend considerably in the near future. The company owning the system is a joint stock company with headquarters in Brussels, Belgium. The corporate name of the company is Tramways of Malaga, and all of the officers reside in Brussels. It is said to be the intention of the company to go to Germany for its entire electrical equipment but it is thought that American agents might overcome this plan if the plant is considered to be of sufficient importance.

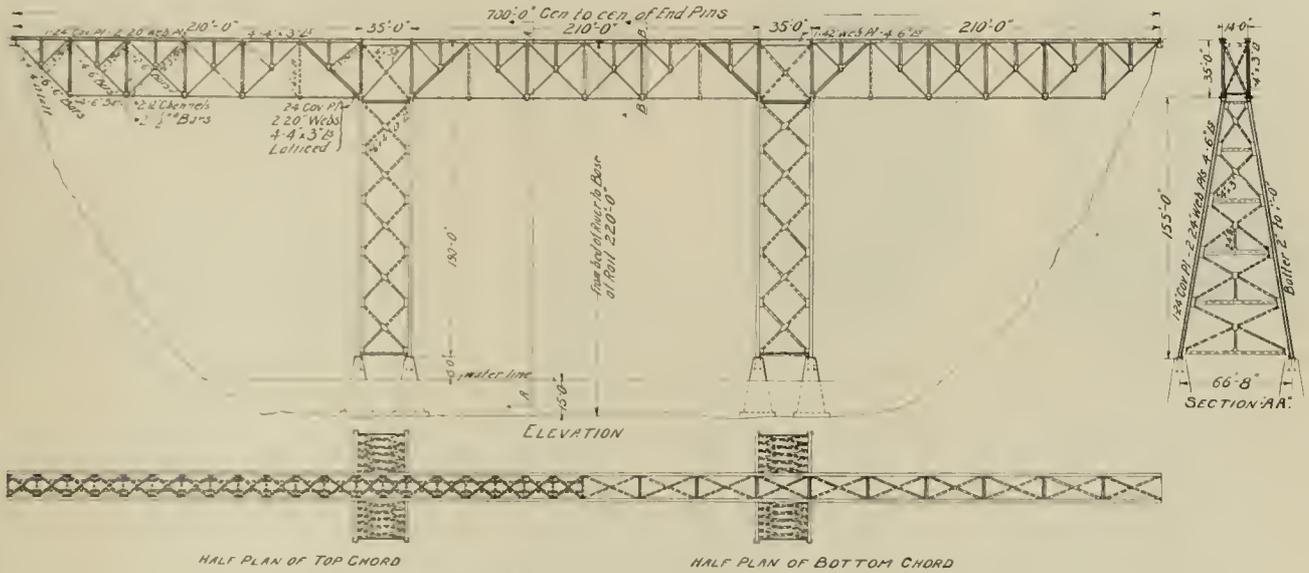

The Binghamton Railway Co. has begun the erection of a new sub-station at Endicott which is to be completed and in operation by July 1st.

**NEW BRIDGE FOR THE BUFFALO, SPRINGVILLE & CATTARAUGUS RY.**

A route has recently been surveyed for the Buffalo, Springville & Cattaraugus Ry., which passes through a very irregular section of country so diversified with hills and valleys as to make it an extremely difficult matter to locate a line free from impossible grades. The same section of country has been surveyed by several interests with the idea of building both steam and street railways, but here-

building from Buffalo to Syracuse. Since then Mr. Upson has been identified with the organization and building of several lines and for some time has been the general manager of the Buffalo, Hamburg & Aurora Ry., which is now to be extended 38 miles to Cattaraugus. In the prosecution of this work he has overcome obstacles which appeared insurmountable to everyone except himself.

Mr. Locke was born in Cattaraugus County, New York, was reared on a farm and secured his education by attending night school during the winter; he then took a position as teacher in a country

HIGH BRIDGE FOR THE BUFFALO, SPRINGVILLE & CATTARAUGUS RY.

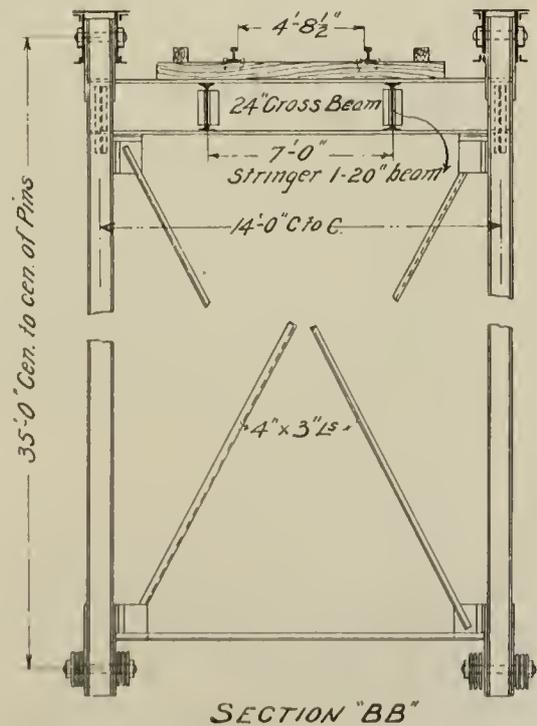

before the difficulties encountered have led to the abandonment of four or five projected lines. The success of the present attempt is due to the perseverance of Mr. U. L. Upson, vice-president and general manager of the Buffalo, Springville & Cattaraugus Railway Co., and to Mr. Charles G. Locke, civil engineer.

The new route involves the building of a bridge which will be the longest and highest trolley bridge in this country, if not in the world. Cattaraugus, as well as several other towns to be connected to Buffalo by this line, have heretofore been almost isolated as far as railway facilities are concerned. The section of the country through which this road will travel is considered to be one of the most fertile regions in the state, and its connection with the markets at Buffalo will stimulate its development to a great extent. The accompanying illustration shows a plan, elevation and section of the new bridge, the total length of which is 700 ft. from center to center of end pins and its height above the water level is 200 ft. The bridge is built of three spans of 210 ft. each, resting upon two towers which are supported on concrete foundations extending to bed rock 15 ft. below the water level. The approach to the bridge on the north side is 400 ft. long and that on the other side 500 ft. long. The construction is of the lattice type with pin connections.

As will be seen from section B B the bridge is designed for a single track road on which 70 lb. rails will be spiked to ordinary cross ties. A wooden guard is used on the outside of each rail. The bridge is designed to carry a dead load of 2,000 lb. per lineal ft. and a live load of 4,400 lb. per lineal ft. The material is to be medium steel.

Mr. Upson is a railway man of many years of practical experience, having worked his way up from water boy on a construction train to organizer and manager of the railroad. He began his business career in 1869 on a construction train working between Hamlet and Southampton as water boy and was advanced successively to the position of time keeper, brakeman and conductor. He was made a conductor before he attained his twentieth birthday. While serving as brakeman he studied telegraphy and in 1873 accepted a position as night operator at Dalton, on the Buffalo division of the Erie road. In 1874 he was transferred to Main St., Buffalo, as freight agent, filling that position until 1882, when he resigned. He then reentered the train service as a construction train conductor on the West Shore Railroad, which was then

school, and in this way earned sufficient money to carry him through the higher schools and enable him to take up the study of civil engineering. For the past 20 years he has been connected with the

SECTION "BB"

railway work in the state of Pennsylvania, where the hills, gulches and ravines make it very difficult to establish a line of survey. In several instances he has, after much difficulty, found a practicable route where others had entirely failed. Mr. Locke has also had

much experience in the oil fields and just preceding his connection with the Buffalo, Springville & Cattaraugus Railway Co. he was engaged for several years in topographical work under the state engineer of New York, and was in charge of some of the most difficult work in the Adirondaek wilderness. In connection with Mr. Upson he established a practicable line for the Buffalo, Springville & Cattaraugus Ry. after spending many weeks of hard work,

U. L. UPSON.

CHAS. G. LOCKE.

but with the determination to secure a line where several others had failed. The route of the new line covers the ground surveyed by several steam railways from 30 to 35 years ago and abandoned because of the heavy grades, sharp curves and other difficulties which seemed to be insurmountable.

WAGES INCREASED AT MILWAUKEE.

June 1, 1900, the Milwaukee Electric Railway & Light Co. voluntarily increased its scale of wages, which was established at 15 cents per hour for the first year and increased at the rate of one cent an hour for each year up to the fifth year, after which 20 cents per hour was the maximum rate. At that time the rate was increased to 17 cents per hour for the first year up to 20 cents per hour for the fifth and succeeding years. On May 29th of this year notice of a further general advance was posted, to take effect June 1st as follows: 18 cents per hour for the first year, 19 cents per hour for the second year, 20 cents per hour for the third year and 21 cents per hour for the fourth year and thereafter. The notice added that the advance was voluntarily made and was in pursuance of the company's policy to do the very best possible for all of its employes. It is also an evidence of the company's appreciation of the honest and loyal service, and it is hoped will prove an incentive for even more careful and enthusiastic service in the future. The notice issued by Mr. John I. Beggs, president and general manager, concludes as follows:

"It may not be amiss to state at this time that our new general office building, central car house and terminal station (the construction of which has just been commenced) will contain the most ample and comprehensive provision for the comfort, instruction and entertainment of our men ever undertaken by any street railway company. When this building is completed I hope to be able to present for the consideration of our employes a plan for the organization of a beneficial society, and likewise a plan for pensioning those who grow old in our service.

"Assuring you of my earnest solicitude for your advancement and welfare and suggesting that you can best serve the company by at all times giving courteous, careful and considerate attention to the safe and comfortable handling of our patrons, and bearing in mind that every act of discourtesy or inattention on the part of a motor-man or conductor is construed by the public as a fault of the management, I beg to remain, etc."

An ordinance was passed in San Francisco, May 19th, providing that the hours during which street railway companies in that city shall receive half fare tickets from pupils going to and returning from school shall be extended to be from 7:30 to 10 a. m.; from 12 m. to 1:30 p. m.; from 2:30 to 4:30 p. m., and from 6:30 to 9:30 p. m. on days during which schools are in session.

IMPROVEMENTS AT LOGANSPORT.

The Logansport local division of the Wabash-Logansport Traction Co., which is under the management of Mr. C. E. Folsom, has been greatly improved during the last three years and is now in fine physical condition. Mr. Folsom who is a thorough electrical engineer and a railroad man of wide experience has put in a new trolley wire on the whole line, thoroughly repaired the tracks, added new cars, motors, trucks, etc. and has also thoroughly overhauled the old equipment. The road is now giving a much better and faster service than formerly and the rates have increased about 25 per cent. This line will soon be connected with an interurban system running to Peru and Wabash. This connection with the extension to the city lines will greatly increase the traveling facilities of the Logansport people and that the changes are greatly appreciated is shown in the very largely increased receipts.

METHOD OF DEPOSITING BILLS IN BANK.

A suggestion is given in the proceedings of the Western Gas Association which might prove of value to street railway companies which are operating electric light and power circuits in connection with the street railway business. Mr. W. A. Bixby, of Decatur, Ill., gives the following method of collecting the bills through the bank. When any consumer complains of its being inconvenient to come to the office to settle his bills or gives any excuse for not paying before the 10th the company asks him to sign a slip as follows:

..... Bank.  
Please accept my gas and electric bills from the Decatur Gas & Electric Co. until notified to discontinue same.  
..... Consumer.

This slip is deposited with the customer's next bills and all later bills are deposited until the consumer gives the company notice to discontinue. The blank space at the top of the slip is filled in

The Decatur Gas & Electric Co.

.....190.....  
.....Bills listed at  
.....Bank.

Table with multiple columns and rows, likely a ledger or record book for bill collection.

with the name of the bank with which the customer deals. The accompanying blank is used by each of the banks and a list of the bills which are deposited is made out on this blank. Only the amount is noted, care being taken to place the bills in the same order as the amounts set down.

The Decatur company collects by this method about \$2,000 per month from about 500 bills and it is constantly adding to the number.

The city council of Kenosha, Wis., on June 2d, by unanimous vote granted the Kenosha Electric Railway Co. a franchise to lay its tracks through the city, thereby removing the last barrier to a direct electric railway route between Chicago and Milwaukee. It is expected to have cars running through from Milwaukee to the southern limits of Kenosha by July 1st, and the work of building the road from Kenosha to Waukegan, which will complete the Chicago-Milwaukee route, will be finished by September 1st.

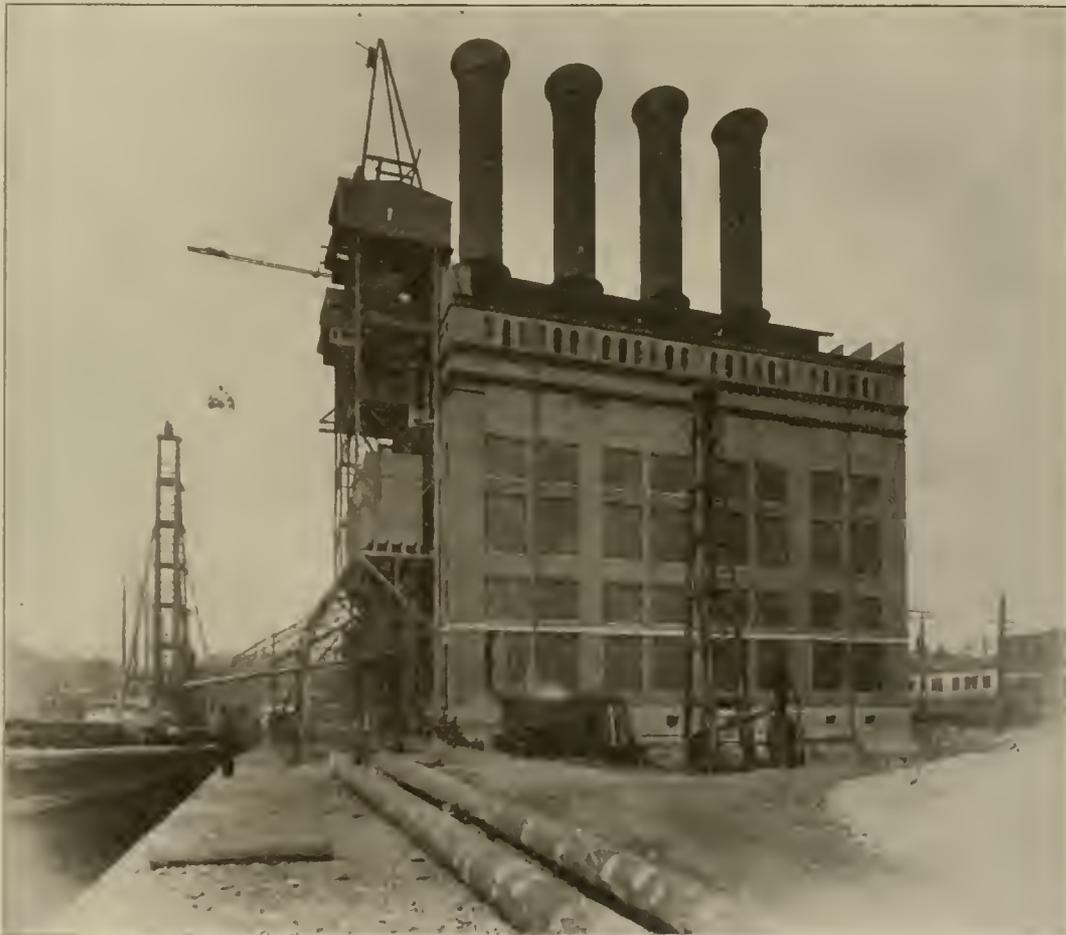

## Increased Power Facilities for the United Railways & Electric Co., of Baltimore, Md.

When the United Railways & Electric Co., of Baltimore, came into existence, by the consolidation of several street railway companies, operating in the city of Baltimore and the outlying districts in all directions, it took over with these properties nine different power houses, most of which had been built to fill the needs of the companies when they were in independent operation, and part of them were, therefore, situated at points which make economical distribution somewhat difficult.

The United system, comprising 360 miles of track, has outgrown the capacity of these old stations and about a year ago the company's engineers were called upon to face the problem of rearranging and enlarging the old stations or practically redesigning the entire power system. A factor in the problem was a recent ordi-

stalled in the old power house, and in addition a new boiler house and generating station are being erected adjoining the site of the old power house. In the new station will be installed alternating current apparatus for supplying by high tension distribution the outlying districts. The suburban lines in the northwest and western sections of the city will be furnished with power from this alternating station through two sub-stations.

In enlarging this station, plans have been made for practically one large building. The former building comprising the northerly wing of the completed plant will contain direct current apparatus. Adjoining this on the west is the old boiler house. The southerly wing, which is to contain alternating current machinery, is now being erected, and a new boiler house, which will supply steam

EXTERIOR OF NEW BOILER HOUSE.

nance of the city requiring that all electric wires and cables be put underground in certain portions of the city. The city has constructed a system of municipal subway and conduits in which the wires and feeder cables of the street railway company are to be housed within certain districts.

The Pratt Street station, which is the largest power house owned by the United company, is well located near the theoretical load center of the system and has the further advantage of being situated on tide water from giving an abundance of water for cooling and condensing purposes, without cost, and also permitting the delivery of coal immediately alongside the boiler room. The station is also situated not far from the center of the city where the bulk of the heavy traffic is concentrated.

In consideration of these advantages it was determined to considerably increase the generating capacity at this point, and to do this new direct current machinery in large units has been in-

stalled in the new addition, has been erected between the site of the new annex and the old power house.

In addition to the Pratt Street power house, the Light Street power house, in which are installed four 500-kw. direct current generators, will be operated, and the Falls Road power house, containing five 300 kw. generators, will also be kept in service, it not being deemed advisable to disturb the overhead feeder systems of these stations, there being no municipal regulation requiring the wires to be underground. The Owings Mills power house, which is about 12 miles from the center of the city, will also be maintained. The Owings Mills and Falls Road stations are run condensing, the Light Street station being run non condensing. The old stations nearer the center of the city will be abandoned.

The plan for the alternating generating and distributing scheme call for 2,000-kw. units at the new addition to the Pratt Street station, generating alternating current at 13,000 volts with a fre-

quency of 25 cycles per second. This current will be transmitted at the initial pressure to the two sub stations where it will be changed by the usual converting and transforming apparatus to 345 volts alternating current, and then transformed to 575 volts direct current for transmission to the line circuit.

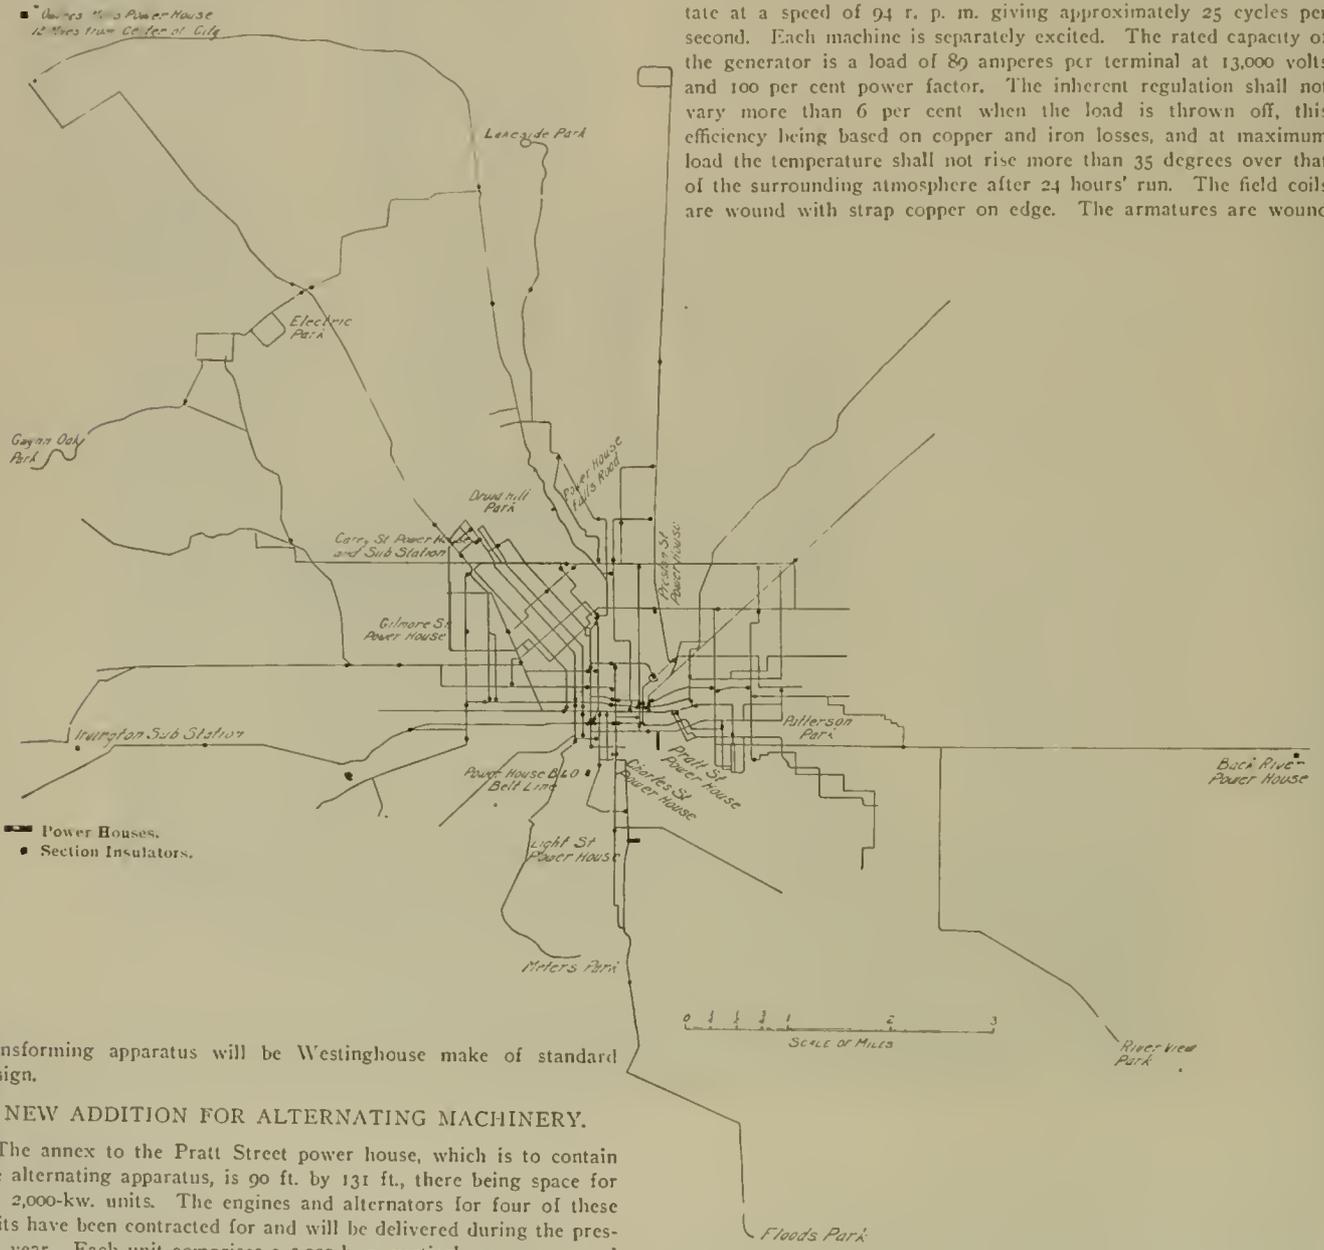

The Irvington sub-station will contain three 500-kw. rotary converters. The Carey Street sub-station will contain four 1,000- and one 500-kw. rotary converters. The transformers for the Irvington plant will consist of three 175-kw. transformers for each rotary. For the larger converters at the Carey Street plant there will be three 350-kw. transformers. All of this converting and

load, (not exceeding rated load) will not exceed 1-72 of the pitch angle between two consecutive poles.

The engines are provided with a speed changing device which is electrically operated, so that the speed of the engines may be raised or lowered four or five revolutions per minute in order to synchronize the generator and also to divide the load between the engines.

The engine bearings have automatic forced lubrication.

The generators are standard Westinghouse construction. The rotating fields are built on a cast iron spider. The exterior frame of the engine is movable in a line parallel to the shaft to allow ready access to the windings. There are 32 poles and the fields rotate at a speed of 94 r. p. m. giving approximately 25 cycles per second. Each machine is separately excited. The rated capacity of the generator is a load of 89 amperes per terminal at 13,000 volts and 100 per cent power factor. The inherent regulation shall not vary more than 6 per cent when the load is thrown off, this efficiency being based on copper and iron losses, and at maximum load the temperature shall not rise more than 35 degrees over that of the surrounding atmosphere after 24 hours' run. The field coils are wound with strap copper on edge. The armatures are wound

transforming apparatus will be Westinghouse make of standard design.

**NEW ADDITION FOR ALTERNATING MACHINERY.**

The annex to the Pratt Street power house, which is to contain the alternating apparatus, is 90 ft. by 131 ft., there being space for six 2,000-kw. units. The engines and alternators for four of these units have been contracted for and will be delivered during the present year. Each unit comprises a 3,000-h. p. vertical cross compound engine, direct connected to a 2,000-kw. Westinghouse alternator of the fly-wheel engine type with rotary fields. The engines will be supplied by the McIntosh & Seymour Co., of New York.

These engines have cylinders 33 x 68 in., with 56-in. stroke, and take steam at a pressure of 165 lb. The i. h. p. is 2,970 at 26-100 cut off, and 4,220 at 1/2 cut off. The shafts are to be fluid compressed hollow forged open hearth steel forgings, as made by the Bethlehem Steel Co. They are to be 28 in. in diameter.

The engine governors are provided with a patented device so as to have no tendency to cause trouble from surging of generators when run in parallel. The weight of the revolving parts is to be so proportioned that the maximum angular variation from the mean angular velocity while the generator is delivering the constant

for 3-phase generation, the phases to be 120 degrees apart and the wave of e. m. f. to be approximately a sine curve.

The high tension feeders to the sub-stations are 3-conductor paper and lead covered cables with 14-32 in. of insulation between the conductors and the lead sheath. The cables will be supplied by the Standard Underground Cable Co., and there will be two cables to each sub-station. These will be laid in the municipal conduits which are Roy multiple duct vitrified clay conduits.

**OLD PRATT STREET STATION.**

The older portion of the Pratt Street station which has been remodeled contains the direct current generating apparatus.

This includes the following: three 2,500-h. p. vertical cross compound engines with cylinders 29 and 60 by 36 in., direct connected to 1,800-kw. General Electric generators of the engine type; two 1,250-h. p. horizontal tandem compound engines with cylinders 24 and 42 by 46 in., direct connected to two 800-kw. General Electric generators; three 800-h. p. tandem compound engines with cylinders 20 and 36 by 36 in., belted to three 500-kw. General Electric generators.

There are also two 800-ampere, 125-volt, steam driven General Electric boosters, and one motor driven booster of 3,000-ampere capacity.

Oil for the engines is forced by compressed air at a pressure of about 70 lb. into manifold tanks, the object of this being merely to avoid the manual labor of carrying oil around the station. From the manifold tanks the oil flows by gravity to the parts on the engine requiring lubrication. The waste oil is caught and is drained back

arrangement has the advantage of greatly simplifying the wiring and connections, and also gives absolute safety, as it is impossible to have a short circuit on the board as the positive and negative leads are over 30 ft. apart. The arrangement is, of course, applicable chiefly to stations of large capacity; it is used in the new stations of the St. Louis Transit Co. The board is in three tiers, mounted on galleries, viz., the generator gallery, the feeder gallery, and the third gallery in the roof where are placed the resistances. The wiring of the board is simple and inexpensive and is made clear in the accompanying diagram. A separate wattmeter is of course provided for each generator, but there is no totalizing wattmeter for the station. It is held that this arrangement permits the wattmeters to work under their best conditions, which is not the case with totalizing wattmeters, especially when running the station at light load in the early hours of the morning. There are two circuit breakers in each generator circuit, one being placed on the

ENGINE AND GENERATOR ROOM, PRESENT PRATT ST. STATION, UNITED RAILWAYS & ELECTRIC CO., BALTIMORE.

to an open tank in which there is a steam coil. There is always considerable water returned with the oil and this water settles to the bottom of the tank leaving the oil at the top. As the steam coils are also located near the top the oil is rapidly heated, thereby reducing its specific gravity and causing all particles of foreign matter to be precipitated to the bottom. The hottest and therefore the cleanest oil is at the top and flows over to another tank from which it is raised by steam pump into the storage tanks.

Air for the oiling system is compressed in a small Westinghouse locomotive compressor which is steam driven. The compressed air is also used for clearing generators and switchboard and for lifting water from an artesian well.

#### SWITCHBOARD.

The switchboard has but one side of the circuit on it. The positive bus bar is mounted on the switchboard and the negative bar is located near the center of the power house in the sub cellar. This

power house floor near each machine and one on the board. By a system of battery circuits and push buttons on the switchboard the attendant is able while standing on the switchboard gallery to throw the breaker located at any machine.

The switchboard has a steel frame and the gallery floors are of circular concrete and expanded metal. The board comprises 15 feeder panels, with two feeders to each panel; 8 generator panels; 2 booster panels and 1 station panel.

Steam for this division of the plant is taken from the old boiler room which contains ten 350 h. p. Campbell & Zell boilers operated at 135 lb. pressure. There are two 11 ft. stacks 165 ft. high.

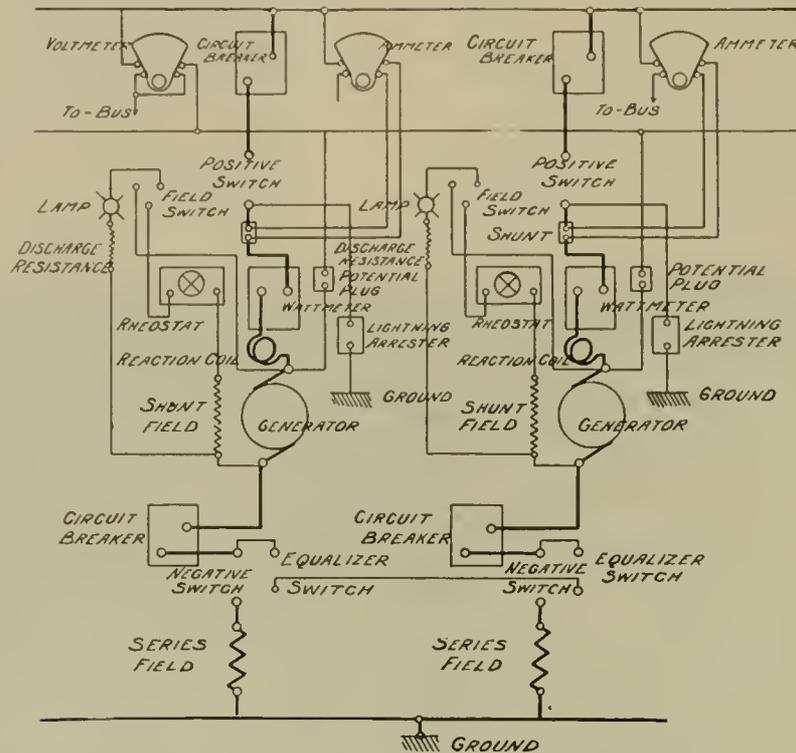

The auxiliary steam apparatus includes Wainwright feed water heaters, Blake vertical air pumps, Blake duplex feed water pumps and Blake jet condensers.

The direct current engine room is provided with a 25 ton crane of 78 ft. span which has two 12 ton hoists.

NEW BOILER HOUSE.

This building, which is of the "steel cage" construction, is 94 by 131½ ft. on the ground line, with brick walls and slate roof. The entire building rests on hard pine piles, spaced 2½ ft. on centers and varying in length from 16 to 20 ft. These are driven to a solid footing of gravel. On top of, and around the piles is laid a founda-

tion bed of concrete which is 7½ ft. thick under the supporting columns and 13½ ft. thick under the four stacks along the center of the building. The boiler room has an ultimate capacity for 16,000 boiler horse power, of which 4,000 h. p. are now in commission and 5,000 h. p. additional are now being installed. The boilers are Babcock & Wilcox make, with wrought steel headers and inside hand hole

tion bed of concrete which is 7½ ft. thick under the supporting columns and 13½ ft. thick under the four stacks along the center of the building.

The boiler room has an ultimate capacity for 16,000 boiler horse power, of which 4,000 h. p. are now in commission and 5,000 h. p. additional are now being installed. The boilers are Babcock & Wilcox make, with wrought steel headers and inside hand hole

200 ft. high and 13½ ft. inside diameter, and are lined throughout with brick to protect the metal.

The piping is extra heavy welded flange pipe with extra heavy fittings. Each of the four main headers are 16 and 20 in. in diameter and all piping is carried overhead on galleries formed of 8-in. I-beams supported from the wall beams and longitudinal trusses, and having open grating floors. The arrangement makes all

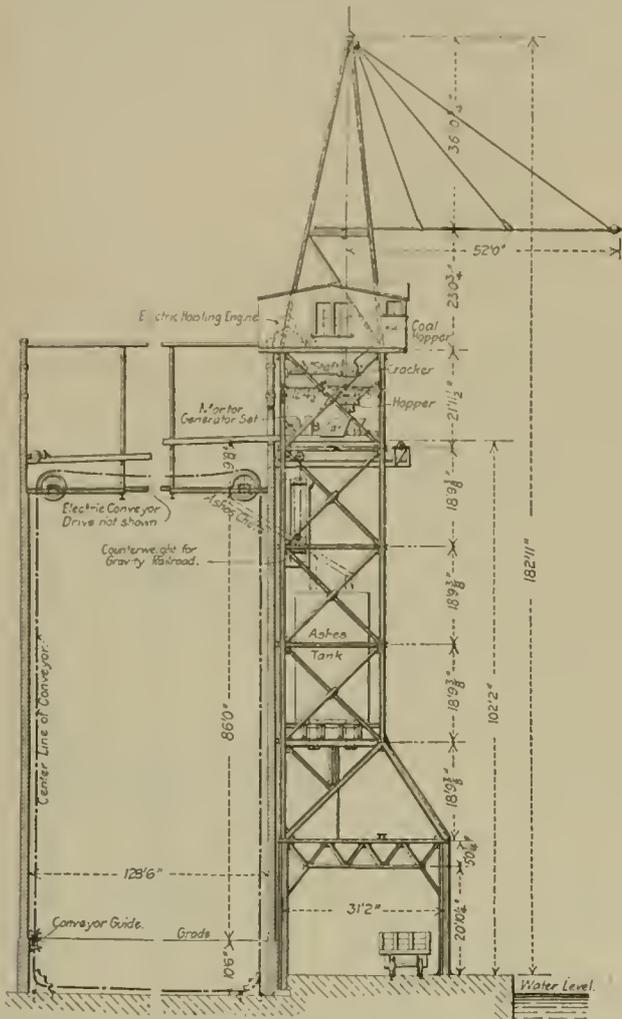

SHOWING ARRANGEMENT OF PIPING AND RONEY MECHANICAL STOKERS.

servng as the lifting rope. The bucket is lowered with the jaws open and deposited on the coal pile. The lifting cable controlling the jaws is then put in motion, causing the jaws to close and the

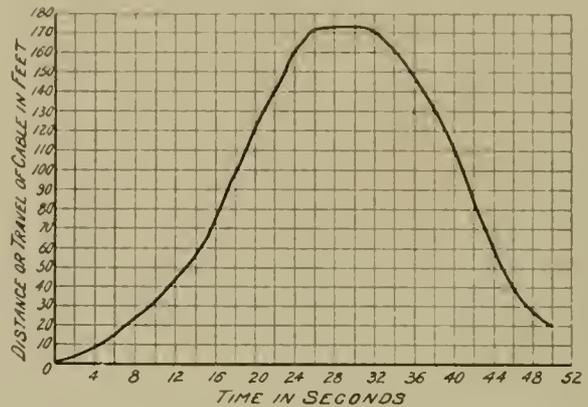

Control of this boom truck and also of the hoisting and lowering apparatus is accomplished entirely by electrical means embodying a number of novel features original with Mr. Keilholtz.

The drums for winding up the ropes attached to the shovel are driven by a plain shunt wound motor which receives power from a generator that is motor-driven. A coil rheostat under the control

Time required to raise filled bucket from ground to top of hoist, unload and return empty bucket to ground.

of the operator's foot is placed in the field circuit of the generator and as the generator speed is constant its e. m. f. is proportional to the strength of its field, and the attendant is therefore enabled to impress upon the hoist motor any desired e. m. f. and so secure a wide range of speed. By fitting the rheostat with numerous steps in the resistance the acceleration may be very rapid and still perfectly smooth and without shock or jar.

The lowering of the bucket is done entirely by gravity and instead of using a band or other form of brake, the shovel is brought to rest by converting the energy developed in its fall into electrical energy working against resistance. This is accomplished by intro-

A PORTION OF THE NEW BOILER HOUSE.

CONNECTIONS BETWEEN HOIST MOTOR AND GENERATOR MOTOR.

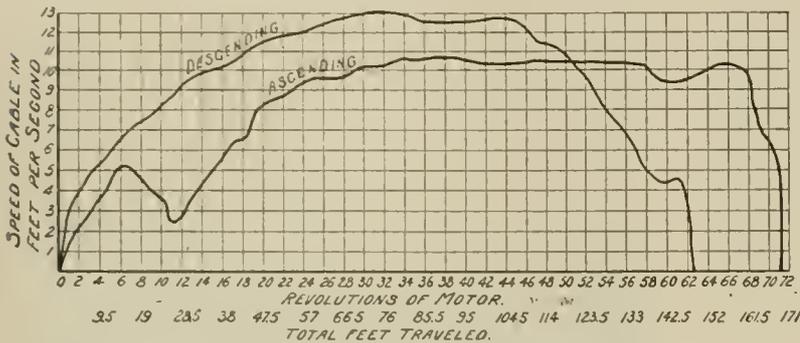

transferred to the other cable. The cables pass over pulleys mounted on a boom truck which runs up and down the boom and may be anchored at any point corresponding to the location from which the hoisting is to be done.

ducing by means of a switch a resistance into the armature circuit of the hoist motor and varying the field strength of the machine by means of the rheostat. It will be understood that as soon as the scoop starts to drop the hoist motor becomes a generator the speed of which is controlled by introducing resistance in its field circuit. This presents a very interesting example of an operation where electrical energy is employed to overcome gravity and gravity is then made to generate electrical energy which is dissipated as heat.

From the curves accompanying this article the rapid acceleration and braking secured will be evident. On this test trip the bucket in descending was allowed to reach a speed of 13 ft. per second, but notwithstanding this the scoop was brought to rest within a fall of less than 30 ft. In one instance the bucket has handled 70 tons of coal per hour, and on a recent test handled for 15 minutes coal

at the rate of 80 tons per hour. In service the current runs from 200 to 500 amperes at from 50 to 270 volts, the current necessary to maintain speed being about 360 amperes at 270 volts.

The coal from the shovel is first weighed and then drops into a crusher from which it passes into a car that runs over an incline railway and automatically distributes the coal to the two 3,000-ton capacity storage bins which are arranged one on either side of the line of stacks. The car holds 4,000 lb. and when filled runs down the incline and strikes a block to which is attached a counter weight. As the loaded car continues on its journey it lifts its weight until a trigger is automatically operated causing the car to dump. When

this is accomplished the weight drops, giving the empty car an impulse that returns it to the loading platform at the head of the incline. The arrangement may be set to dump at any point.

From the storage bunkers the coal passes to the Roney stokers through movable hoppers running on tracks in front of each line of boilers.

Ashes are raised by a traveling bucket conveyor from beneath the boilers to an ash chute at the top of the boiler room. From the chute they pass by gravity to an ash storage tank on the hoisting tower and are dumped into cars or scows for removal.

The apparatus was built and installed after plans prepared by the railway company's engineers.

This entire plant, including both engine rooms, the new boiler house, the coal handling apparatus, and other features, were designed by and erected under the supervision of Mr. P. O. Keilholtz, Associate Member A. I. E. E., and consulting engineer for the United Railways & Electric Co.

PENSION PLAN IN GERMANY.

A pension fund has recently been inaugurated in the Vulcan Ship-building Yards of Stettin, which is described by Consul J. E. Kehl as follows: "All employes of the 'Vulcan' who receive an annual salary of more than \$375 are eligible to membership. Every member pays an initiation fee equal to one month's salary, but not to exceed \$119, after which he pays an annual premium equal to 3 per cent of his yearly salary. This highest basis upon which an initiation fee or premium can be paid is a yearly salary of \$1,428. The Vulcan company pays into the fund an amount equal to the annual premiums collected. Five years' membership, or the paying of back dues so as to make the amount equal to five annual premiums, entitles a member to a pension. The amount paid to an incapacitated or retired member amounts, after five years' service, to 15.60 of his last year's salary and increases 1.60 every subsequent year of actual service until the limit of 45.60 has been reached. The right to a pension is accorded to those permanently disabled through accident or sickness, or who have a forty year membership, or have reached the age of 65. The widow of a member is entitled to one-half of her husband's pension and every child of the deceased (under 18 years) to 1.20 of the pension; but in no case shall the amount paid to widow and children exceed 15.20 of the amount of pension due the deceased husband and father. All officers of the fund, with the exception of the treasurer, furnish their services gratis.

The old horse car line in Fresno, Cal., is being replaced by the Fresno City Electric Ry.

THE FEEDER INSTALLATION OF THE BOSTON ELEVATED.

Supplementary to the extended description of the system of the Boston Elevated Railway Co., which appeared in the "Review" for March, April and May, 1900, the following description of the feeder requirements and installation of the elevated section of this system, by C. H. Hile, superintendent of wires, which was published in the Wisconsin Engineer, will be of interest:

The elevated structure over which the Boston Elevated Railway Co. began operating its elevated car service June 10, 1901, comprises 15.62 miles of track, lying between the Dudley St. Terminal at the southern part of the city, and the Sullivan Sq. Terminal at the north.

The general plan of the route shows a loop in the heart of the city, using the subway for the western leg and comprising 4.44 miles of double track, while north and south from the loop double tracks extend 1.66 miles to Dudley St. Terminal and 1.71 miles to Sullivan Sq. Terminal.

The running distance between the two terminals is 5.015 miles, via the Subway, or 5.567 miles, via the Atlantic Ave. leg of the loop.

The running time between the two terminals via the subway is 22 minutes, the trains making nine stops.

The Subway is used by the elevated trains for a distance of 2.32 miles, and in thus using the Subway as a part of the "L" route, trains must pass from the level of the elevated structure, at an average of 16 ft. above the street to the Subway level of about 19 ft. below the street surface.

Within the 2.56 miles of the so-called Subway section of the elevated system, trains take grades varying from 3 to 8 per cent for 29 per cent of the total distance run, and pass around curves varying in length of radius from 1,600 ft. to 90 ft. for 54.6 per cent of the distance run.

The maximum train service for the present, and immediate future, is intended to furnish four car trains on two or three minutes headway on the main line, and three car trains on seven minutes headway on the loop, thus giving about 24 trains on the line at one time.

Each car is 46 ft. 10 1/2 in. over all, weighs when fully equipped 29.5 tons. The cars are equipped with two 150-h. p. motors.

The trains are operated on the Sprague multiple-unit system. The average power consumed by each four-car train is 219 kw. at the switchboard, or a current consumption of 368 amperes. The maximum power consumption for one four-car train accelerating on one of the 5 per cent grades is 924 kw. or a current consumption of 1,700 amperes.

With the trains operated under the foregoing conditions the power required to operate the entire elevated system is, on an average, 4,718 kw., or requiring an average current consumption of 7,929 amperes. This includes power for light and heat in the cars.

The power for the system is furnished from three of the company's power stations, all in the vicinity of the structure, one feeding in on the southern section at a point about 1.2 miles from the Dudley St. Terminal, another feeding in on the Atlantic Ave. leg of the loop, and the third feeding in at the northern end of the system or at the Sullivan Sq. Terminal.

The feeder system may be divided under the following heads: Feeder mains, third rail, feeder connections, return system.

FEEDER MAINS.

In calculating the copper required for transmitting the power to the motors, a 2,000,000-c. m. wire was determined upon as a unit in the feeder system.

At the switch board each feeder panel carries one carbon break circuit breaker, having a capacity for carrying 3,000 amperes continuously without overheating, one ammeter measuring up to 6,000 amperes, and one quick break switch having a capacity of 3,000 amperes continuously without overheating.

The power is carried from the station to the elevated structure using 2,000,000-c. m. lead covered rubber insulated cables, which are drawn in conduits built of vitrified clay pipe.

The conductor in each cable is insulated with 5-32 in. of rubber

compound, covered with a tape and protected with a lead covering  $\frac{1}{8}$  in. in thickness.

At each end of the cables, where they are carried through the vault of the station to the switchboard and up the posts of the elevated structure to the bare feeders, it was deemed desirable to discontinue the lead covering and splice on from 40 to 60 ft. of rubber insulated triple braided wire. At the structure end the cables are carried from the man holes, which are built about the bottom of the elevated supporting posts, on the inside of the posts, being insulated from the iron by wood supports. The cables terminate in switch boxes placed on the structure, where they terminate on switches, which makes it possible to cut out a cable from the feeding system at any time, for making tests or repairs.

The feeder mains on the structure leading out from the switch boxes are 2,000,000-c. m. bare copper wire, concentric laid and made up of 61 tinned copper strands.

These are carried along the structure in enclosed feeder boxes built between the tracks and having a capacity for six feeders. The feeder boxes run parallel with the tracks throughout and are closed at the sides and top. The top covering is built in sections of planking laid crosswise and tightly fastened together. Each section is about 5 ft. in length and can be easily and quickly removed when it is necessary to get to the feeders. The feeder boxes with their top covering affords a safe and convenient walk along the tracks.

The supports holding the box are placed about every 6 to 8 ft. and inside the box are used to hold the wood pins which carry the insulators, which, in turn, support and protect the feeders.

The wood support on which the boxes are built, the locust pins, and the glass insulating supports, constitute the means by which the bare wires are insulated from the structure.

### THIRD RAIL.

The so-called third rail system is used in transmitting the power from the feeder system to the cars. Each car carries four contact shoes, carried outside the forward and rear trucks and hanging at such a distance as to come in contact with the third rail, which is so placed outside the running rails that its contact surface is  $19\frac{1}{8}$  in. from the gage of the running rail and, approximately, 6.2 in. above.

An ordinary T-rail 85 lb. to the yard, is used for the third rail. It is supported on specially designed insulators built up of malleable castings with "Aetna" insulation between the upper and lower parts. These chair insulators are placed on the end of every third tie, which is about fifteen inches longer than the regular ties, and are held in place by lag screws.

At each joint the third rail is bonded with the short "Protected" type of rail bond, enough bonds being used to bring the joints up to the same carrying capacity as the rail.

At all special work and cross-overs, where the third rail must be broken, cast iron run-offs are fastened to each end, and the continuity of the rail as a feeder is maintained by running a 1,000,000-c. m. rubber or weatherproof insulated wire underneath the structure and connecting with the ends of the rail by means of terminal or feeder tap bonds.

### FEEDER CONNECTIONS.

The feeder taps or connections through which the power is transmitted from the feeder mains to the third rail, are placed throughout the system at such points as the conditions require, and convenient for access; 1,000,000-c. m. and 500,000-c. m. rubber insulated triple braided wire has been used for making the connections, and all connections between the third rail and the feeder mains are carried through switch boxes, so as to make it easily possible to cut out from the feeding system, either a section of the third rail or one of the feeders.

### RETURN SYSTEM.

The steel in the elevated structure throughout is used as a part of the return system. In addition to this, one rail in each track constitutes part of the return circuit.

The joints on the rail, which is of the 85-lb. T type, are bonded nearly to the full capacity of the rail itself, and at 500 to 600-ft. intervals, the rail is bonded to the longitudinal girders of the structure.

One rail of each track is used as a part of the signal circuit and is, therefore, not available for the return system.

As the company controls and operates all surface lines paralleling, crossing under and leading into the elevated system it has been found desirable to connect the elevated structure with the surface tracks and return wires at frequent intervals, thus giving a well balanced return system.

The same power stations feed both the elevated and surface lines, but through separate feeder systems.

## RAPID TRANSIT IN YUCATAN.

One of the quaintest and most picturesque little railways imaginable is that of the Xcalak & Aguada Railway Co., which is owned and operated by the government of Yucatan, and used for transporting troops and army supplies from the coast of the Caribbean sea to a fresh water lagoon in the interior, seven miles across the peninsula.

The nearest large port of entry being Belize, in British Honduras, 75 miles down the coast, supplies whose destination is the interior

LIGHTER ON THE YUCATAN COAST.

of Yucatan are sent by steamer to a point on the Caribbean sea some distance out from Xcalak, where they are met by flat baggage boats, or "lighters," manned and rowed by native Yucatanians, and by them lighted ashore. One of the illustrations shows one of these lighters with its crew.

Reaching the coast, the baggage is transferred to the tiny flatcars of the little railway; and by them all supplies, troops and officers are carried through the seven miles of tropical undergrowth lying between the coast and the fresh water lagoon, which runs up into the interior for a distance of a hundred miles. Transports plying to and fro on the fresh water lagoons carry passengers and supplies to their ultimate destination.

The equipment of the Xcalak & Aguada Railway consists of some fifteen or twenty cars, open and closed; the motive power in all

STREET RAILWAY TRAVEL IN YUCATAN.

cases being the native long-eared mule—a plucky, sure-footed little creature, resembling an overgrown donkey or burro, an important feature in the economy of the country. These patient, cheerful animals plod back and forth over their seven-mile track, looking plump and well-fed on a diet of chopped straw, and needing only an occasional whistle of encouragement from their drivers to keep them at a steady, even jog-trot through every yard of the entire distance.

## THE ELECTRIC RAILWAYS IN VALTELLINA.

The two most notable experiments in electric traction in Italy were made by the two largest Italian railroad companies, namely the Mediterranean company and the Adriatic company. Both of these companies built their electric lines in the neighborhood of Milan. The Mediterranean has constructed a road on the third-rail system running from Milan to Gallarate and thence to Arons, Levano and Porto Cerejio; this is operated by continuous current. The Adriatic company built its lines from Lecco to Colico, Sondrio and Chiavenna, a distance of 106 km., which is operated on the three-phase system at a high potential, and the overhead trolley is used. The road belongs to the state but is operated by a department of the Adriatic company which was formed for the special purpose of carrying on this experiment. The capital interested is principally Italian.

Water power is used to operate this road, and it is obtained through difference of level between the Ponte di Desco and the Ponte di Ganda near Morbegno. The head of water between these bridges is ordinarily about 36 m. and the quantity of water in the Adda passing at this place is about 25 cu. m. per second. If we assume, therefore, an available head of 30 m. this volume of water will give 10,000 nominal horse power, and at an efficiency of 75 per cent there will be 7,500 effective horse power. The canal gate is placed at about 250 m. above the Ponte di Desco, and in front of the gate there is a screen for the purpose of diverting sediment or other matter brought there by floods into the right branch of the Adda. This screen also prevents the passage of gravel into the gate. The gate is placed at 1.1 m. below the summit of the dyke, is slightly inclined, and is 3 m. in height. Immediately beyond the screen there are eight gates, each of 3.2 m. in width and 1.1 m. in height. Each of these is divided into two openings of 1.6 m. by means of a central I-beam and two lateral channel bars in which the bulkheads slide; the gates are supported by pillars 1.2 m. wide and 3 m. in height. The channel is 4,800 m. long and runs partly in tunnels and partly in open cuts. There are 15 sections that run in the tunnels, having an aggregate length of 2,900 m., of which 1,650 m. are natural tunnels and the remainder constructed of masonry. The longest gallery is 770 m. in length and commences immediately beyond the canal gate. There are 14 sections of open cuts, with a total length of 1,900 m. The total section of the canal is 10 sq. m. in area and its grade is 1 per cent. At a distance of about 900 meters from the gate there is a settling basin 100 m. long and 100 m. wide. A second settling basin is placed just beyond the gate at the lower extremity of the channel; this is 80 m. in length and is divided into two equal parts, with a gate placed between them. The head reservoir is 25 m. long, 7 m. wide and 5 m. deep. At a little distance from this bay there is a division forming two channels, each 4½ m. in width and 3 m. in depth. These channels lead to two iron pipes 2½ m. in diameter and 68 m. long, which stand at an angle of 45 deg. These pipes are again divided into two, each of which are 1.2 m. in diameter, so that four pipes are led into the generating station. The dynamo room of the generating system contains four turbines, each direct-connected to a dynamo. Three of these turbines have a capacity of 2,000 h. p. and the fourth 3,000 h. p. Only the first three have been installed up to the present time. These were furnished by Messrs. Ganz & Co., of Budapest, and are designed on the Francis reaction system. They operate at a speed of 150 r. p. m. and each turbine is independent. The generator for this station were supplied by Shukert & Co., Nuremberg, and are three phase machines with fixed armatures and revolving field magnets. They have a frequency of 19 periods per second, and an output of 1,050 kw. at a potential of 20,000 volts. The switchboard was constructed by Shukert & Co., and contains the instrument for the four unit and for two feeder circuits. The measuring instruments of the switchboard are all on low tension circuits, each being operated through a transformer in order to avoid danger to the employes of the station. Each feeder is provided with a voltmeter, an ammeter, a rheostat and a single pole switch. Each alternator is provided with an ammeter, two voltmeters, one for the pressure and the other for the phase indicator, and two three pole circuit breakers. There are three fuses for the protection of the alternator in case of short circuit. Each of the feeder lines has three ammeters, one for each conductor, and a wattmeter, a voltmeter and a three-pole switch. The lightning arresters are of the horned type. The high tension lines are run with bare copper con-

ductors, and these as well as the secondary circuits are carried on poles.

Where the road passes through tunnels the high tension wires are carried outside of the tunnels owing to the danger because of their very high voltage. The terminals of the high pressure systems are at Abbadia, 7 km. from Lecco, and at Castione, 5 km. from Chiavenna. These lines measure about 90 km. Two of the wires for the low pressure system have a section of 50 mm. These are suspended above the rails which form the third conductor of the three-phase system and are at a height of about 6 m. from the ground. In the tunnels this distance is reduced to 4.8 m. The pressure of the low tension service lines is 3,000 volts. These wires are supported upon wooden poles with brackets while in some places span construction is used. A special safety device is used to prevent harm to passers-by in case one of these wires should break; by means of this arrangement the wire is grounded before it falls to the earth and thus becomes harmless.

The rails are bonded at each joint by copper bonds made of wire of 6 km. in diameter and the tracks are cross bonded at every 500 meters. The trolley wires are fed at nine points from the transformers of the sub-stations. There are five sub-stations in all and the machinery in all of them is similar, each containing a transformer of 450 kw. capacity. Four of these sub-stations contain only single units while the one at Abbadia contains two units of the size mentioned. The sub-stations are all divided into two rooms, one containing the transformer and lightning arrester and the other the switches for the primary and secondary circuits and a fan for cooling the transformers.

The rolling stock of this line consists of five cars for first class passengers, five composite cars for first and second class passengers and two baggage cars. The passenger cars are all similar except in regard to their outside finish. The trolleys consist of two bronze rollers each 600 mm. long which are supported on rods made of Mannesmann's tubes. At first only two trolleys were used on the cars, one for each direction, but the company is now equipping each car with four trolleys, two of which will be used at once in order to avoid sparking. The trolleys which act together when running in one direction are at a distance of 19 mm. apart. The trolleys are raised and lowered by means of compressed air, and the cables carrying the current are connected at the trolley wheels. These cables are encased in a metallic tube which is kept in good electrical contact with the rails so that in case of any imperfect insulation of the cables no harm can be done to anyone on board the car.

The cars have two speeds, one being with the two car motor armatures in series and the second with the armatures in parallel. The armature shafts are hollow with a diameter of 300 mm. Through this hollow shaft another axle of 110 mm. in diameter passes which serves as a bearing for the hollow shaft. All the high potential circuits on the car have metallic casings which are securely grounded to the rails as a precaution against accident. The cars are each provided with two motormen's cabs, one at each end. These cabs are similarly equipped and contain a hand and a relay switch, a controller, a reverser, a hand brake, a Westinghouse brake, a valve for raising and lowering the trolley by compressed air and an air whistle.

In case the air in the reservoir should be insufficient the trolley could not be operated and to avoid this difficulty a hand pump is carried in the cab. The cab also contains a voltmeter and a manometer for indicating the air pressure in the reservoir. Just outside of the cabs is an air pump which is operated by means of a three-phase motor, which is automatically cut in and out of the circuit, according to the pressure of air in the reservoir. This pressure is normally maintained at 6 atmospheres. Water rheostats are used for starting the motors and are placed on the cars. The amount of liquid employed is regulated by means of air pressure. The liquid is a solution of carbonate of soda.

The maximum velocity of the car is 60 km. and the second speed 30 km. per hour. The operation of starting the cars is easily accomplished. A main circuit breaker is used to break the high potential current coming from the trolley wires to the motors. This acts automatically and opens the circuit when the limit of 90 amperes is reached. The cars are lighted by means of a battery of accumulators and also by three phase lamps of 110 volts which are supplied with current by means of an 8-kw. transformer. This transformer also supplies current for the Westinghouse brake pump

and is placed inside the car. It also supplies current for the electric heaters. The battery is charged at Lecco, Sondrio and Chiavenna.

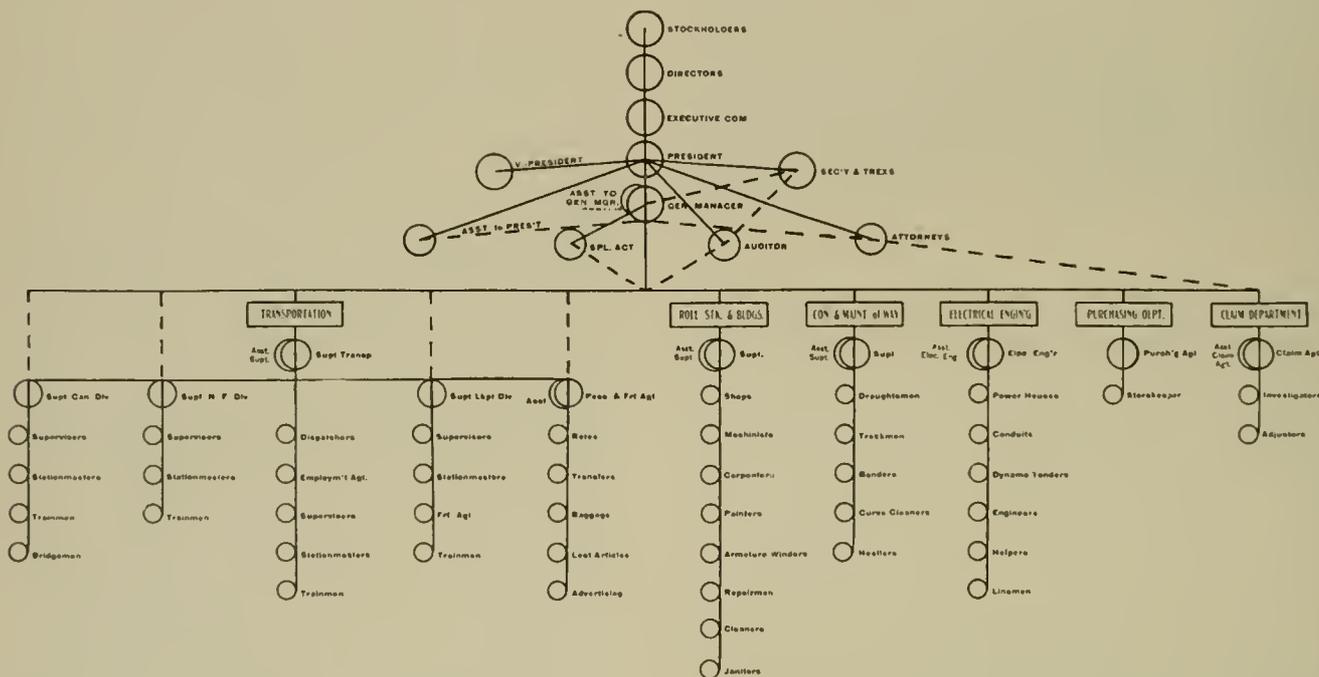

The cars use double trucks, which are placed at a distance of 11½ m. apart. The total length of the car is 19 m. and the height 3.9 m. Each truck has four wheels 1.16 m. in diameter and the axles are 2½ m. between centers. Each truck is equipped with two motors. The first class cars are used only for express trains and the composite cars for the local trains. The first class cars have both smoking and baggage compartments, and ventilation is secured by means of electric fans. The heating is procured by means of electric heaters. They have a seating capacity of 24 passengers, a total capacity of 35 passengers, and they weigh 50 tons each. The composite class cars have a first class compartment at one end and a second class compartment at the other end, with a compartment between them for baggage. They have a capacity for 24 first class passengers and 32 second class, and are heated and lighted in the same way as the first class cars and weigh 53 tons each.

**ORGANIZATION OF THE INTERNATIONAL TRACTION CO.**

The accompanying diagram, for which we are indebted to Mr. T. E. Mitten, general manager of the International Traction Co.,

pushed the controller handle this way and that, while the two passengers rendered their aid and sympathy by giving good advice and jumping up and down on the platform and finally getting off and pushing, but all in vain. Finally Mr. Sprague determined to get out of the curve at any hazard, and with the expectation of wrecking the whole machine he jammed the controller handle on to full speed at once. To the amazement of Messrs. Burt and Greene, the car gave a lurch forward, cleared the curve and sped up the line beyond. With the halt there had collected quite a crowd of spectators, whose numbers had steadily augmented until about 3,000 people surrounded the stalled car. When the fresh start was made some of the derisive ones who had gathered on the track in front of the car were almost bowled over but happily escaped, and the whole procession commenced a mad race after the flying car.

Some distance beyond this there was a steep hill, at the foot of which Mr. Sprague brought the car to a standstill. Mr. Sprague prophesied the car could never mount the hill, but Manager Burt, whose enthusiasm had been fired by the recent burst of speed, declared they could certainly make it and gave the signal to "let her go." This and several other hills were mastered until the car finally reached the steepest grade in the city. Here Mr. Sprague knew too well the end of the ride was reached. Everything underneath the car was in bad shape, and as a last chance he stopped the car in the hopes that the motors might cool down. To his intense relief

of Buffalo, shows the scheme of organization recently put in effect there. The diagram is self-explanatory when it is noted that the solid lines indicates the direct line of report and the dotted lines indirect lines of report which may be necessary when emergencies arise. Where a department head has an assistant the latter office is indicated by a portion of a circle attached to the circle representing the principal officer.

**INCIDENTS AT THE OPENING OF THE FIRST TROLLEY ROAD.**

In a serial article on the captains of industry who attended a dinner given in honor of Prince Henry, the Saturday Evening Post gives an interesting description of Mr. Frank J. Sprague when starting his first trolley road in Richmond, Va. While the story of the Richmond road has been very frequently told, some of the minor incidents of it are not so well known. The first trolley car on this road was run about nine o'clock at night, with Mr. Sprague as the motorman. With him were the late S. Dana Greene and Mr. Burt, manager of the railway company. The car moved out of the shops at a wobbly pace but started off in a satisfactory way until it reached the middle of a sharp curve, where it stuck. The inventor

the crowd overtook the car again and were received with much enthusiasm by Mr. Sprague, as he knew they would want to inspect this new marvel of engineering and this would give the car motors an opportunity to cool off. After waiting as long as possible and welcoming all comers the time came when the start had to be made, and instantly he then found that his worst fears were realized and the armature had burned out. To confess failure here might have imperiled the success of the entire undertaking, so in a loud aside Mr. Sprague told Mr. Greene he had better go back and get the "instruments," as there was probably some slight trouble with the circuit. Then the inventor turned out the lights and stretched himself on the car seats, hoping the crowd would melt away. It was an hour later when Greene returned, bringing the "instruments" with him, the latter being four of the most powerful mules in the city of Richmond. The "instruments" dragged the car back to the shed. It had been demonstrated, however, that a self-propelled car could round the shortest curves and climb the steepest hills, and the completion of the road was only a matter of detail.

It is generally anticipated that the report of the Metropolitan West Side Elevated Railway Co., Chicago, when published, will show an average of about 105,000 passengers carried per day.

### CARRYING EXPRESS AND FREIGHT MATTER BY ELECTRIC CARS AT PROVIDENCE.

About a year ago the several street railway properties controlled by the United Traction & Electric Co. of Providence, R. I., instituted an express and freight carrying service which at first required two special express cars. This business has now grown to an extent where four 41-ft. double truck cars and two single truck cars and one trailer are devoted exclusively to handling packages, merchandise, groceries and other goods presented for transportation.

Perhaps the most interesting feature in connection with the express service as given on these roads is that distributing stations are not maintained and the whole business is carried on from one central station in the city. All records of every kind incident to the details of the business are made and kept at this one depot, making it practically a distributing as well as a receiving station. The company maintains no collection or delivery wagons and all goods for transit on these cars must be delivered at its central

EXPRESS CAR IN PROVIDENCE.

depot. Exception to this rule is made in a few instances where cars pass warehouses, breweries, etc., and any goods these establishments may have are delivered at the car door by their employes. This is permitted only in places where there will be no chance of interfering with the regular passenger cars.

Steam railroad freight methods have been adopted so far as possible. Rates are based on the official classification of the Interstate Commerce Commission with certain minimum charges for small packages and parcels. The employe receiving the goods gives the consignee a receipt similar in form to the receipt used by the steam railroads of New York and other Eastern States. On the back are printed the usual conditions under which the goods are accepted, and the rules defining the liability of the company. The way-bill is also similar to Eastern steam road practice. It is made out in triplicate, one copy remaining in the book for office record, one being sent to the auditor, and the third is taken by a collector who starts out every morning to collect the charges on goods delivered the previous day. Of course if the company had regular distributing agents at outlying points one copy of this way-bill would accompany the goods. But inasmuch as distributing depots are not maintained and it is the desire of the company to give the quickest possible service the way-bill does not accompany the shipment. To serve the same purpose the agent at the central station gives the messenger in charge of each car on every trip a sheet enumerating all the articles on his car. This sheet merely gives the date and designation of each article and the consignee's name and address. It also has a space for the consignee's signature. Deliveries are made in various ways, but shipments are never accepted for delivery away from the line of the road, although goods may be shipped in care of some merchant or store keeper located on the street railway line. In the case of goods or small packages consigned to home addresses along the road the messenger jumps off the car, delivers the package at the house and obtains the consignee's signa-

ture on his shipping sheet as receipt. It is found that this can be done without delaying the regular cars. The messenger on the express car does not very often accept payment for the express charges although he is authorized to do so if the consignee prefers to settle that way. Most of the collections, however, unless charges are prepaid, are made by a special collector who starts out each morning with the way-bills of all goods shipped the previous day. This practice of course introduces greater chances of loss through inability to collect bad accounts inasmuch as the consignee already has the goods, but thus far no serious difficulty from this source has arisen. In fact there have been but one or two instances in the year where there was trouble in collecting the amount.

The system covered comprises about 275 miles of track and all cars make two round trips a day. The same territory is covered to a very large extent by the New York, New Haven & Hartford R. R., but the electric road is in a position to give better service, and in fact can give an express service at freight rates. The advantages are particularly evident on certain classes of goods, such as for instance meat and green goods. The butcher in Providence having a shipment of meat for a suburban town takes it from his ice house early in the morning and delivers it by truck at the central electric express depot. The meat is immediately placed in the electric railway express car, which by the way is very much better ventilated than are the ordinary steam railroad freight cars and the meat is delivered at a point 20 miles away within two hours. If the butcher had relied upon the steam road his meat would have stood in the freight car for a length of time varying from half a day to a day and a half waiting for a full carload to the particular point of distribution. Usually these freight cars stand in the yards where they are exposed to the sun and weather, so that the conditions are all unfavorable to the preservation of perishable goods. The street railway company has a particularly large business in the carrying of vegetables, berries, etc., from the Providence markets to merchants and consumers in the suburbs.

Thus far most of the stuff handled is outgoing freight, very little effort having been made for business coming into Providence. As soon as outlying collecting and distributing stations have been established the volume of incoming freight will undoubtedly increase.

### ELECTRICITY IN CANADA.

The use of electricity in Canada is stated in a recent consular report to be largely on the increase and most of the electrical supplies come from the United States. These supplies are admitted to be of better quality than can be obtained from any other country and they can be ordered and received within a few days. In the annual summary of the use of electricity in Canada compiled by Mr. George Johnson, the Dominion statistician, the number of lighting companies represented has increased from 257 in 1898 to 306 in 1901. The arc lights in use increased from 10,389 to 12,800, and the incandescent lamps from 463,615 to 815,676. The increase in the use of electricity for lighting purposes is 60 per cent.

The legislature has been asked to pass a large number of railway bills this year, and should the charters desired be granted it would add 1,046 miles to the electric railway mileage of the province of Ontario. Twelve companies have made applications for roads extending between Cornwall and Windsor, and the projected lines, if built, will cover this distance with the exception of a short stretch between Glencoe and Tecumseh. Another system is projected which will reach from London to Owen Sound, skirting the shore of Lake Huron. Many of these projected lines tap territory not at present served by railways, and it is stated that American capital is behind the lines projected to radiate from Hamilton to Toronto, Guelph and Waterloo. In the province of Quebec a number of electric railway companies have been chartered by the provincial legislature, and it is expected that 50 miles of electric railroad will be constructed in this province during the coming summer.

The Georgia Railway & Electric Co. has put a new wage scale into effect on the Atlanta lines, considerably increasing the salaries of employes. Motormen and conductors in the company's employ will appear in new uniform on May 18th, and it is stated that a daily inspection of the appearance of the men will be instituted and cleanliness and order insisted upon.

**NEW TRANSFER SYSTEM FOR HAMILTON & LINDENWALD ELECTRIC TRANSIT CO.**

By C. E. WARWICK, DIVISION SUPERINTENDENT

For some time past the Hamilton & Lindenwald Electric Transit Co., of Hamilton, O., has had in use with great success a new transfer system, which has been so very advantageous under the conditions existing on this road that a description of the same may prove of benefit to the managers of other lines similarly situated.

This company has 10 miles of track, with one route running east and west, another north and south, crossing each other at the center of the city, and three short branches all so arranged, with the exception of one or two points, that it is not possible for passengers to belt the lines, making round trip for one fare, or riding continuously as long as they desire for one fare. Instead of having transfers of one color on all lines as was formerly the case, a different and distinct color is used on each line and when a transfer is issued by the conductor, it is good on any route excepting the one from which it was issued, the color alone accurately designating which line issued the transfer, and consequently which lines are

EMERGENCY

No. 271

entitled to receive it. As one color is good on any route except its own, the receiving conductor will readily see when a wrong transfer is offered by certain passengers who make a practice of evading payment of a proper fare by attempting to work an improper transfer on the conductor. At a point where a passenger is apt to make a round trip for one fare the issuing conductor simply punches the direction in which his car is going as the case may be, and the receiving conductor when taking up a transfer of this kind will understand at once where his passenger started from. In case of derailed cars or any other accident, passengers can be transferred from car to car by punching out the word "Emergency," making the ticket good on its own route.

With this transfer ticket the issuing conductor is required to punch out the month, day of month and time of day, making only three punchings for the issuing conductor and three verifications for the receiving conductor, thus reducing the chances for error and collusion between the passenger and conductor to a minimum.

A special feature of this transfer ticket is the time table which explains itself, having half-inch blocks for the hour separated by heavy lines; these blocks are divided into quarter-inch blocks for the minutes, thus requiring but one punch mark for the time of day and allowing an abundance of space for the punch mark, giving the conductor no excuse for punching the wrong time.

Also when hauling large crowds, the conductor can date several transfers in advance and with the punch used can punch the time on from twelve to fifteen tickets at once and transfer a large load of passengers with great alacrity.

Another good feature with the color system is that it eliminates the work of the accounting department in counting and dissecting transfers and checking conductors' reports.

These tickets are put up in pads of 100 each consecutively numbered.

The Elgin, Aurora & Southern Traction Co. has increased the wages of employes on the Elgin division from 16½ cents to 18 cents per hour.

**UNLUCKY THIRTEEN.**

An item in a St. Joseph (Mo.) paper states that the negroes in that place are so superstitious that the street railway company there recently found it necessary to take off car No. 13 from one of its lines. The car with this number was put into service on the route which traverses the most populous negro quarter of the city. Ordinarily the cars in this quarter run heavily loaded, but invariably No. 13 ran through the section with scarcely a passenger. The protests against this car became so general that the company feared to disregard them any longer and car No. 13 was transferred to another part of the town.

**NEW IDEA IN SCHEDULE MAKING FOR SMALL ROADS.**

What is believed to be a novel arrangement of schedules has been put into effect by Mr. F. J. Duffy, assistant superintendent of the Richmond (Va.) Traction Co. The usual practice in assigning runs is to so arrange the trips that each man will work a certain number of hours and then have a certain time of relief in which to eat his meal, after which he returns to work and finishes his day's run. The time for relief necessarily varies with local requirements but most companies now endeavor to give the men 10 hours' work to be performed within 12 consecutive hours. Mr. Duffy pays his men for practically 9½ hours' work a day and this work is all performed within 9½ hours. In other words, the work is continuous and when a man has been on duty 9½ hours he is through for the day. The time for meals is partly gained by quickening the schedule running time for all cars at the meal hours, allowing longer layovers at the terminal for meals. A 5-minute headway is maintained on the main lines all day and to fill the gap between cars resulting from the increased layover time extra cars are put out on the meal trips, so that the schedule is not disarranged.

In this way the men are given varying from 9 to 15 minutes in which to eat the meals that come during their days' work. The early-run men eat breakfast and lunch, and the others eat lunch and supper while on duty, although if a man prefers to eat just before he goes on duty he will have to eat but one meal a day at the layover periods. The meals are not eaten on the cars but a special room is fitted up for this purpose at each terminal where the meal layovers occur.

The scheme seems to work to the satisfaction of all concerned. The men like it because it gives them more time to themselves. For instance, a man who goes on duty at 5:45 in the morning is through with his day's work at about 2:45 in the afternoon. It is of course impossible to arrange the runs to give every man exactly 9½ hours, but that is about the result secured. The assignments are shifted every week so that the men on the early runs one week take the late runs on the alternate weeks and vice versa. The conductors and motormen make arrangements with their families or boarding house keepers to send their meals to the terminal at the proper time or else have the pail or basket at some convenient point on the line where the men can get them on the meal trip.

The extra cars that fill out the meal trip are run by volunteers from the men not on duty, requests and assignments for the meal trips being posted one day in advance.

The proposed electric line between Ephrata, Pa., and Adamstown, for which contracts have been awarded, will afford connections with lines running to Reading and thus give a direct route between Lancaster and Reading.

The new car house of the Hartford (Conn.) Street Railway Co. will be of brick and steel, with a frontage of 245 ft. and a depth of 140 ft. The office section in front will be two stories in height, and the wings on either side will be four stories high. The site of the new building is now occupied by the old barns of the Hartford & Wethersfield Horse Railroad Co., which will be razed to make place for the more spacious and commodious structure.

## RECENT STREET RAILWAY DECISIONS.

EDITED BY J. L. ROSENBERGER, ATTORNEY AT LAW, CHICAGO.

### TURNING BACK OF PEDESTRIAN ATTEMPTING TO CROSS IN FRONT OF CAR NOT TO BE ANTICIPATED — CARE REQUIRED IN CROSSING STREET IN MIDDLE OF BLOCK.

*Lawson v. Metropolitan Street Railway Co. (N. Y. Sup.), 74 N. Y. Supp. 885, Dec., 1901.*

A motorman seeing a woman attempting to cross ahead of him, in the middle of the block, the appellate term of the supreme court of New York holds, was not called upon to anticipate that she would turn around and retrace her steps. Pedestrians attempting to cross a street upon which a line of cars run, especially in the middle of a block, are bound to exercise a reasonable degree of care not to place themselves in a position of danger.

### RIGHT OF PEDESTRIAN TO STAND ON CROSSING WHEN STOPPED BY BLOCKADE OF VEHICLES—FAILURE TO SOUND GONG.

*Hernandez v. Metropolitan Street Railway Co. (N. Y. Sup.), 74 N. Y. Supp. 898, Oct., 1901.*

A pedestrian attempting to cross a street where it would seem there were two different tracks was compelled by a blockade of wagons and carriages to stand between the two tracks, as he testified, over a foot from the inside one, when he was struck by a car, which, but for a curve, he would probably have seen and saved himself from injury by. The appellate term of the supreme court of New York holds that he was not guilty of contributory negligence, as a matter of law, as he had a legal right to go upon the track at the crossing, and stand at the place where he was injured. And failure to sound a gong or to give some notice of the approach of the car, under the circumstances, even though the car was moving at ordinary speed, it holds, would have been negligence, and the question whether notice of the approach of the car was given was properly submitted to the jury.

### RIGHT OF CONDUCTORS TO REGULATE MOVEMENTS OF THEIR CARS—DUTY TO PERSONS ATTEMPTING TO BOARD SLOWLY MOVING CARS.

*Metropolitan Street Railway Co. v. Hudson (U. S. C. C. A.), 113 Fed. Rep. 449, Jan. 14, 1902.*

Unless a car has reached one of its regular stopping places, or its speed has been slowed to permit an intending passenger to board it, or some invitation, express or implied, to board it, has been given by those in charge, the conductor, the United States circuit court of appeals, second circuit, holds, is under no obligation to anticipate that any person will attempt to board; and if, in ignorance of such an attempt, he causes the motorman suddenly to put on speed, he does not violate any duty towards an intending passenger. Conductors of street cars are at liberty to regulate the movement of their cars as they see fit so long as they do not violate their duties to others. If, however, while a car is proceeding slowly, the conductor is made aware that an intending passenger is attempting to board it, although it may not be his duty to stop the car, common prudence certainly forbids that he start it suddenly forward. No man is at liberty to do an act unnecessarily which he knows or ought to know is likely to imperil the person of another.

### STANDING ON PLATFORM OR RIDING ON SIDE STEP OF AN OPEN SUMMER CAR.

*Woodroffe v. Roxborough, Chestnut Hill & Norristown Railway Co. (Pa.), 51 Atl. Rep. 324, Feb. 24, 1902.*

A passenger who stands on the platform of an electric car, when there are vacant seats inside the car, the supreme court of Pennsylvania holds, assumes the ordinary risks of the road, but all the risk incident to that position. The side steps of an open summer car, it likewise says, are not intended for the use of the passenger, except in getting in and out of the car. When a passenger rides on the side steps with the knowledge and consent of the conductor, and from necessity, from the want of room to sit or stand

inside the car, he is entitled to the same degree of diligence as other passengers to protect him from known and avoidable dangers. But a passenger who rides on a side step, when it is reasonably practicable for him to sit or stand inside the car, takes upon himself the risk of his position, from any cause.

In this case, a passenger, while riding on the side steps of an open car, was killed by contact with a pole which supported the electric wire. It was overwhelmingly established by the testimony that his conduct was disorderly and reckless, that he disregarded repeated warnings of his danger, and that when injured he was holding the upright hand rail, with his arms extended, and his body and head thrown back from the car. These facts, the court holds, should have prevented a recovery of damages with the jury. Moreover, every witness for the party suing admitted that there was standing room in the car, and the court holds that this one fact was conclusive against her right to recover, and should have been so declared by the court. There was then, it says, no legal ground for recovery.

### CHANGING SYSTEM OF SANDING TRACKS—CONDUCTOR AND MAN SANDING TRACKS FELLOW SERVANTS.

*Smith v. Philadelphia Traction Co. (Pa.), 51 Atl. Rep. 345, Feb. 24, 1902.*

A conductor standing on the rear platform of his car was injured by the collision therewith of an electric car on an intersecting street of descending grade. The negligence charged to the company was its failure to have on the latter car the proper appliance for sanding the track. It appeared that about two weeks before the accident the system of sand boxes on the cars had been abolished by the company, because the wheels of the cars had been flattened by that method of sanding the tracks, and another was substituted for it. By the substituted system sand was placed on the streets. A man put it on the tracks wherever needed, and one had charge of sanding them where the collision occurred. The supreme court of Pennsylvania holds that the substitution of this new system of sanding the rails was in itself no evidence of negligence by the company. It says that it could be fairly presumed that the traction company, in adopting what it conceived to be a better system of sanding its tracks, relinquished none of the care it was bound to observe in the operation of its lines. It continued to guard against danger resulting from slippery tracks by continuing to sand them, and, without proof that the change in the mode of doing was improper, the jury ought not to have been allowed to guess that it was. The burden was upon the party suing to prove the negligence complained of,—failure to use proper means for sanding the tracks. No proof of such negligence appeared. Other means may have been used that made the slippery tracks safe, but the mere adoption of new ones, in the utter absence of proof, or even an offer to prove, that they were not efficient, or that their use was accompanied with danger, was no evidence of carelessness by the employer towards its employe. It might be that the rails were not properly sanded by the man whose duty it was to sand them, but that would be evidence only of his negligence,—a fellow servant of the injured man,—and not that the system itself was faulty or unsafe.

### NO INTEREST IN SOIL OF HIGHWAY FOR TAXATION AS REAL ESTATE—FRANCHISE TAXABLE.

*Mayor, Etc., of City of Newark v. State Board of Taxation (N. J.), 51 Atl. Rep. 67, Jan. 27, 1902.*

That there is an inherent value in the property of a street railway company over and above the costs of reproducing its rails, stringers, poles, wires, power house, etc., the court of errors and appeals of New Jersey, reversing a decision of the supreme court, says, needs no demonstration. That value, however, springs not out of any ownership by the company of an interest in the soil of the highways over which its road passes, but out of its ownership of the franchise to maintain and operate its road over those highways, and to collect tolls from all persons traveling upon it. This franchise is property, and taxable as such. But under present legislation

the right to tax it has been reserved by the state to itself, through its board of assessors, and not delegated to the several municipalities through which the company's road passes.

#### ASSIGNABILITY OF CONTRACT WITH STREET RAILWAY COMPANY FOR CONSTRUCTION AND OPERATION OF ROAD.

Lakeview Land Co. v. San Antonio Traction Co. (Tex.), 66 S. W. Rep. 706. Feb. 24, 1902.

A contract of a street railway company with a land company by which the former, for a valuable consideration, bound itself to construct and operate a line of street railway out to and through an "addition" owned by the latter, the supreme court of Texas holds, was assignable within the terms of a statute providing that "the obligee or assignee of any written instrument not negotiable by the law merchant may transfer to another by assignment all the interest he may have in the same," there being nothing in this contract to indicate that it was limited to the parties making it either by its terms or by the subject-matter of the contract, the character of the thing to be done, nor any other fact that would go to show that the parties intended it should not be assigned. It sees no reason why the obligations of this contract could not be as well performed to any other owner of the lands referred to as to the original land company. And it is of the opinion that the assignment would be effective under the general rule, independent of the statute. Wherefore the court holds that the purchase of this contract, together with the lands, invested the purchaser with all the rights which the original obligee (land company) would have had under the same circumstances. Nor does it consider that this was rendered otherwise by the fact that the purchase was made by a foreign corporation, before it had procured a permit to do business in Texas.

#### RISK OF JERK ASSUMED BY PASSENGER PREPARING DURING STOPPING OF CAR TO ALIGHT—USE OF APPROVED PATTERN OR STEP.

Phillips v. St. Charles Street Railroad Co. (La.), 31 So. Rep. 135. Dec. 16, 1901. Rehearing denied January 20, 1902.

Where the motoneer of a street car, in answer to a signal, is slowing down his car in order to stop it with the rear platform over the proper crossing, and a passenger has taken his position on the lower step of the platform, preparatory to getting off, the supreme court of Louisiana holds that the fact that the passenger loses his balance, and falls to the ground, it being claimed that such a fall resulted from the sudden jerking of the car and from the passenger catching his shoe in a defective step, will not justify the conclusion that such fall should be attributed to the negligence of the carrier, when it appears that the irregularity of motion complained of was not greater than is usual in the stopping of street cars, and that the step was of an approved pattern, and without discoverable defects. It may be, the court further says, with reference to this case, that the motoneer had slightly miscalculated, and that it became necessary just then to accelerate the motion of the car in order that the rear platform might be exactly over the crossing when the car should stop, and that the passenger resting, possibly, on one foot, was taken by surprise by the forward movement, and lost his balance. But slight irregularities of movement are common incidents in the starting and stopping of street cars, and those who prepare to alight and who do alight whilst the cars are in motion assume the risks resulting from such irregularities.

#### RISK ASSUMED BY PASSENGER IN ATTEMPTING TO BOARD CAR AT TERMINUS BEFORE IT IS READY.

Clark v. Metropolitan Street Railway Co. (N. Y. Sup.), 74 N. Y. Supp. 267. Jan. 17, 1902.

At the end of a line to which a passenger held a transfer ticket he attempted, upon its arrival, to board an open car on the side where the bar had been raised but the step had not been lowered, and was injured by being struck on the knee by the step, as the conductor lowered it. There was nothing to show that the conductor, while attending to his duty in lowering this step and raising the bar on one side of the car, saw that the passenger was in a position in which he could be injured by the lowering of the step.

The evidence was that the whole occurrence—the arrival of the car, the change in the side bars and steps, the rush of the passengers to board the car—all took but a very few moments; and the first appellate division of the supreme court of New York says that this would seem to be a case in which the accident was caused by the act of the passenger in attempting to board the car before it was in such a condition that passengers could safely board it. Continuing, it says that he took the risk of an injury incident to the condition of the car when he attempted to board it. He acted upon the assumption that the step was down without making any investigation as to its actual condition, and without waiting for an investigation from the conductor, with knowledge of the fact that this change in the fixtures of the car was necessary before the car could proceed on its return trip. The fact that other passengers rushed to board the car was not sufficient to justify him in assuming that the car was in a condition that would enable him to board it in safety. And the court does not think that it would be justified in holding the company liable for an injury which resulted from the passenger's attempting to board the car before the necessary changes had been made which he knew had to be made, when an inspection would have disclosed the fact that the car was not ready for passengers to enter from the side from which he attempted to enter it.

#### ADMISSIBILITY IN EVIDENCE OF CONDUCTOR'S TRIP REPORT.

Callihan v. Washington Water Power Co. (Wash.), 67 Pac. Rep. 697. Jan. 4, 1902.

It being in dispute whether a party had been a passenger on a certain car or not, she claiming that she had been and that her fare had been paid with a transfer slip, the conductor was called as a witness and testified, as a matter of independent recollection, that he had eight passengers for the trip all of whom paid cash fares, and that no transfers were taken, excluding by his identification of the passengers the party referred to. He then further testified that at the end of the line he made a written report, showing the number of passengers carried, and the fares paid—whether cash or transfer—and that this report was, in regular course, and as was his custom, turned into the company. This report was then offered in evidence. The instrument purported to show the number of passengers carried by the conductor on his respective trips on the date in question, and the medium in which their fares were paid, and that on the particular trip in question he had eight passengers, all of whom paid cash fares. The introduction of the report was objected to. It was conceded that the conductor in this instance would have had a right to have examined the report for the purpose of refreshing his memory, but it was contended that, having testified independently of the memorandum, the introduction of the memorandum was equivalent to the admission of declarations previously made, which would be self-serving in their nature. But, after an extensive examination of the law involved, the supreme court of Washington holds that no error was committed in admitting the report in evidence. It does not consider that under the circumstances it could be self-serving. Moreover, it says that so pertinent and convincing was this character of testimony in this particular case, that, if it had not been offered, the company might have felt that it was in danger of being subjected to a telling criticism before the jury for omitting to produce for its consideration convincing evidence resting peculiarly within its own knowledge, the omission of which would raise the presumption, or at least a strong suspicion, that such evidence, if adduced, would operate to its prejudice.

#### RIGHT TO USE STREET'S AND TO CROSS STEAM RAILWAY TRACKS—STEAM RAILWAY CANNOT ENJOIN CROSSING OR QUESTION VALIDITY OF ORDINANCE.

Atchison, Topeka & Santa Fe Railway Co. v. General Electric Railway Co. (U. S. C. C. A.), 112 Fed. Rep. 689. Jan. 7, 1902.

The doctrine is firmly established in the state of Illinois, in accordance with the general weight of authority, the United States circuit court of appeals, seventh circuit, says, that by the construction and use of street railway tracks no additional burden is imposed upon the easement, as such use falls within the purposes for which streets are dedicated or acquired; but that the use for steam railway purposes is beyond the general public easement, or right of

use, and imposes an additional servitude. It is equally well settled by the uniform line of decisions in Illinois that the use of a street by a steam railway is legitimate when duly authorized, but that no exclusive use is conferred by the permit, and it can only be enjoyed in common with the use of the street by the public as an ordinary highway, and without materially impairing its usefulness as such.

With the rights of a steam railway in a street crossing thus defined, the court holds that they are in subordination to the use for street purposes, which includes use for a street railway. The right is held in common, is "joint and mutual, not exclusive;" and the primary object of the street is for ordinary passage and travel, of which the public and individuals cannot rightfully be deprived. The proposed use in this case of a street in such a crossing for a street railway, the court goes on to say, was within the public purposes of the street, and imposed only the burden to which the steam railway crossing was subjected by the permit. For such crossing of the steam railway tracks at grade by a street railway damages were not allowable for increased delay or danger in crossing. Furthermore, the court pronounces it plain that a bill could not be maintained on behalf of the steam railway company to enjoin the construction and use to that end. The adjudications in Illinois, it says, are conclusive that the question whether the ordinance was either fraudulently obtained or invalid could not be raised by the steam railway company.

#### SLOWING DOWN SPEED.

Rapid Transit Railway Co. v. Lusk (Tex. Civ. App.), 66 S. W. Rep. 799. Jan. 25, 1902

This was an action for personal injuries received by a passenger who testified that, in attempting to step from a trolley car to the side step, with a view of alighting, he was, by reason of a sudden jerk of the car, thrown therefrom, and he contended that the speed of the car was being slowed down to enable him to alight at the place where he attempted to alight. On the other hand, there was evidence tending to show that by the rules of the company the cars only stopped at the far side of cross streets, and the company contended that the slowing down of the speed of the car was for the purpose of bringing it under control so that it could be stopped at the usual stopping place, the far side of a cross street. There was evidence tending to support each of these contentions, and the court of civil appeals of Texas holds that it was reversible error to assume, in charging the jury, that the object of slowing down the car was to enable the passenger to alight.

If it was the custom and rule of the company, the court holds, to stop its cars only at the far side of the cross streets for the purpose of taking on and letting off passengers, and such custom was generally known and observed by the company's agents and employes in operating the cars, and the purpose of checking the speed of the car was to bring the car under control so that the same could be stopped at the usual stopping place; and if the agents and employes of the company did not know that the passenger was attempting to alight from the car, or ought not to have reasonably anticipated that he or some other passenger might be in the act of getting off the car, and be injured as the result of a sudden movement of the car, then the company was not negligent in so slowing down the speed of the car. If, however, the slowing down the speed of the car was done in response to this passenger's notice that he desired to alight, and to enable him to alight, and in doing so the company did not use the proper care—that is, such care as a prudent and cautious person would have exercised under such circumstances—then it was guilty of negligence; and, if such negligence was the cause of the injury to this passenger, the company would be liable, unless the passenger himself was negligent, and his negligence contributed to the injury. These were questions of fact, which should have been settled by the jury under a proper charge.

#### INJURY OF PEDESTRIAN ON FALLEN FENDER ON REAR OF CAR.

Levison v. Metropolitan Street Railway Co. (N. Y. Sup.), 74 N. Y. Sup. 882. Oct., 1901.

A pedestrian walking east on a cross street at about 7 o'clock in the evening of a February day, when it was quite dark, in under-taking to pass immediately behind a car which had stopped just north of the north crossing stumbled and fell into the fender at-

tached to the rear of the car, which in some way, not explained by the evidence, had fallen down. Instead of extricating himself, he was dragged some distance before the car was again stopped. When the accident happened the conductor was inside the car collecting fares. He consequently did not see the man fall into the fender, and did not know that he had so fallen when he gave the signal to start the car. The cross street was 125th street. The car had started from 106th street, and the fender was then folded up. At 116th street, nine blocks from the scene of the accident, the conductor had noticed that it was still folded up. The car was crowded, and from 116th street to 125th street the conductor was inside the car collecting fares. He therefore did not observe the fender between those streets, and did not know that it had fallen.

Upon these facts, the appellate term of the supreme court of New York holds, the party had no cause of action against the company. He was not a passenger, but a traveler upon the highway, and the company's obligation to him must be measured by that circumstance. The company had a right to stop its car at the crosswalk, and it was not contended that it was so stopped at an improper place. The fender was not inherently a dangerous appliance, but, on the contrary, was a device carried for the protection of travelers. It did not appear that it was improperly constructed, or that its fastenings were, under usual conditions, defective or insufficient. The company was not chargeable with notice that it had fallen down, for no employe had seen it after it had fallen, and the evidence was that only a short time before it had been folded up. The mere fact that it projected behind the vehicle did not necessarily impute negligence to the company, in the absence of actual or constructive notice of it. Upon the party's own evidence judgment was properly rendered in favor of the company.

#### CONTRIBUTORY NEGLIGENCE IN CROSSING ELECTRIC RAILWAYS IN OPEN COUNTRY—ELECTRIC COMPARED WITH STEAM RAILWAYS—MOTORMAN NOT TO EXPECT PERSON TO LEAVE PLACE OF SAFETY.

McNab v. United Railways & Electric Co. of Baltimore City (Md.), 51 Atl. Rep., 421. Mar. 6, 1902.

At a place in the open country where the tracks of a street railway were built like those of a steam railway, a T-rail being spiked to cross-ties and the roadbed ballasted with broken stone, on which cars ran at a speed of from 20 to 25 miles an hour, a woman driving a horse slowed down as she approached the tracks from a cross street, but, seeing no car on the track nearest to her and hearing no gong sounded, drove forward, when, as the horse got in the space between the two tracks, she saw a car approaching at a high rate of speed on the farther track, not more than 40 feet away, and, instead of stopping or turning the head of the horse aside, she gave the horse a stroke with the whip and attempted to cross the track in front of the car, which struck the rear wheels of the carriage. This, the court of appeals of Maryland says, was sheer recklessness. No matter how negligent the company's servants may have been in failing to give signals or warnings of the approach of the car to the crossing, the woman, after she saw the danger of leaving a place of safety and of attempting to cross directly in front of the rapidly moving car, was, when she drove forward, equally guilty of negligence, which immediately contributed to the infliction of the injury which she sustained; and that contributory negligence was a bar to a recovery of damages on her part.

But it was suggested that, however this might be had the collision occurred at the intersection of a steam railroad track and a public highway, it could not be the law of this case, because, the injury was inflicted by an electric railway car. The reply of the court is that it is not because of a difference in motive power employed upon a steam and an electric railway, but because of other circumstances, that acts which would be regarded as acts of contributory negligence in the one instance would not be so treated in the other. It is far more dangerous to attempt to cross in advance of a car moving at a high rate of speed, whether propelled by steam or electricity, than to make a like attempt when the car is moving along the streets of a city at a very moderate rate of speed. The difference in the method of the construction of the tracks in the country from that in the city, the very marked difference in the speed attained in the one locality from that tolerated in the other, the adaptation of city streets to the use of pedestrians and vehicles of all kinds as well as to the cars, are all circumstances, wholly apart from what the

motive power propelling the cars may be, which must be considered in determining whether a given act is or is not an act of contributory negligence. Thus to drive across a street car track at the intersection of two streets in a city, where the rails are flat and offer no resistance, might not be an act of contributory negligence, even though an approaching car going at the rate of six miles an hour, but required to stop or slow up on the near side of the intersected street, were but 40 feet distant; but to make the same attempt in the country, where T-rails themselves interpose obstructions, and where the car is running at the same high rate of speed which cars propelled by steam attain, would be just as clearly an act of contributory negligence as it would be were the car being moved by steam power instead of by electricity. A car making 6 miles an hour can be slowed or stopped much more promptly than when making 25 miles an hour, and this circumstance is of considerable importance in determining whether an attempt to cross in front of it is an act of contributory negligence. It is the relation which the act done bears to the final result in the light of all the attendant circumstances that determines whether the act done is or is not one of negligence or contributory negligence. The conditions as to construction, location and speed and the danger incident to crossing the tracks being precisely the same in this instance as they would have been had the motive power been steam, the legal principles defining contributory negligence could not be different merely because the motive power was electricity.

Furthermore, the court holds that when the motorman saw (and it says that it may be presumed that he did see, because he could have seen) that the woman was in a place of safety, he was under no obligation to assume that she would deliberately leave that place and drive into the jaws of danger.

MAY REFUSE TO ACCEPT DETACHED COUPONS—PAS-  
SENGER GETS NO RIGHTS FROM RINGING UP OF  
UNPAID FARE—OBLIGATION TO PAY FARE—DE-  
MAND OF FARE NECESSARY BEFORE EXPUL-  
SION—SECOND DEMAND OF FARE NOT  
REQUIRED.

United Railways & Electric Co. v. Hardesty (Md.), 51 Atl. Rep., 406. Mar. 6, 1902.

A wife purchased in her own name a 20-trip coupon book, which was issued at a reduced rate, the purchaser agreeing in consideration thereof to comply with the reasonable regulations of the company. The book declared that each undetached coupon would entitle the owner, naming her, a householder, or member of her immediate family, or a servant therein, to ride, between certain points, and in accordance with the conditions of the contract in the back of the book. It was further stipulated on the coupons that they would not be "good unless detached by the conductor." The woman and her husband used this coupon book going one way, after which he tore out coupons for a return trip and handed the book to her, and later, on the same day, but not in company with her, he boarded a car going to his home. He testified that the conductor took one of the detached coupons, rang up the fare, and said that the book would have to be shown, which he was told could not be shown.

It is clear and undisputable, the court of appeals of Maryland thinks, that the husband had no right whatever to ride on the detached coupon. It says that it was not an ordinary railway ticket. Under the specific terms of the contract embodied in the ticket, a detached coupon was wholly void. That was a regulation which the company had the power to make, and one to which the purchaser of the ticket agreed. As a token of the holder's right to ride on the car, the detached coupon was of no more value than a slip of blank paper would have been. The holder of the coupon was bound to know this, and he was equally bound to know that the tender of a detached coupon, even if taken up by the conductor, was no more a payment of the car fare than the tender and acceptance of a counterfeit coin would have been. As the detached coupon was void by the very terms of the contract, it was no ticket; and as the holder had, therefore, presented no ticket at all, he obviously had no right to ride on the car unless he paid his fare. The fact that the conductor had rung up the void coupon, as though it had been a valid coupon, did not make it what it was not, and clearly did not give the passenger a right to be transported, when his right to be carried on the car depended altogether on his complying with the rules by paying his fare, and did not depend on the fact that the conductor had

rung up the fare, as paid, when it had not in reality been paid. He was not, therefore, entitled to be carried as a passenger.

Then, the question was whether, having once demanded the passenger's fare, and having received a worthless ticket instead of the fare, the conductor was legally bound to make a second demand before removing the passenger from the car. The court holds that he was not. It says that it is a matter of common knowledge, of which the court will take judicial notice, and of which the public is bound to take notice, that railroad passenger trains are operated to carry passengers for hire. There were but two ways in which the passenger could pay—either by ticket or in cash. When he tendered the one, and was informed that it was insufficient because detached, he knew just as well as the conductor that his right to remain on the car depended on his doing the only other thing he could do, viz., paying his fare in cash. If he knew this—and he was bound to know it, and therefore must be held to have known it—what possible reason could be assigned for holding, as matter of law, that the company, through its conductor, was legally bound to ask the passenger to do precisely what the latter knew he was obliged to do? And how could the failure of the conductor to ask the passenger to pay a fare, which the passenger was well aware he was required to pay if he wished to remain on the car after he had refused to exhibit the book, relieve the passenger from the obligation to voluntarily pay the fare?

The right of a carrier of persons to collect fares and to receive them, the court continues, does not depend on the fact that the conductor or other servant demands the fare. The right to collect and receive fare arises out of the circumstance that the passenger enters the conveyance for the purpose of being carried therein. By entering the conveyance for that purpose he agrees to pay the fare, and the duty to pay it is thereby imposed. Morally and legally he is as much bound to pay the fare when not demanded as he is when it is demanded of him, because the duty to pay has not its origin in the demand for payment; and a failure to demand it cannot, consequently, be treated as giving him a right to be transported gratuitously. This being so, the primary and continuing obligation is obviously on the passenger to pay the fare. The demand for it by the carrier is made with a twofold view, viz.: First, for the convenience of the passenger, to save him the annoyance of himself seeking the conductor to deliver the ticket or fare to the latter; and, secondly, for the protection of the company against individuals who would not scruple to ride without paying if they could evade making payment. But neither of these considerations can be converted into or treated as a requirement that when a demand has been once made for a fare, and has not been complied with, or, what is the same thing, has been complied with by the delivery of a worthless ticket, which the holder was bound to know was worthless, the conductor must make a new demand before the passenger can be expelled.

While the duty to pay fare does not originate in or rest upon the demand for it, there can be no expulsion of a traveler for not paying until he has refused to pay, and there cannot be a refusal until there has been a demand of some kind. In this case, there was a demand; but there was no second demand, which, as before stated, the court holds was not necessary to be made before the expulsion of the passenger. A railroad company, the court says, may eject from its accommodations all persons who refuse compliance with its reasonable regulations. This has been so often announced by the courts that it may be said to have become axiomatic law. A condition printed on a reduced rate ticket to the effect that a coupon affixed thereto shall be invalid unless detached by the conductor is undoubtedly a reasonable regulation. An attempt to use a previously detached coupon, and a refusal to exhibit the book from which it had been taken, clearly forfeit the right of the holder to proceed farther on the car. If his right to remain on the car is thus forfeited by his own act, it was lawful to eject him, and he could avoid expulsion only by paying or offering to pay his fare. Therefore, if he wished to remain in the car, the duty was on him to tender his fare to the conductor, in the absence of any rule of the company requiring the conductor to demand the fare. Again, the court says that the passenger had ample opportunity to pay the fare, which it was his duty to pay when he declined to show the coupon book. His attempt to ride on a worthless ticket did not impose upon the conductor an obligation to make a second demand for the fare, but did require the holder of the ticket, if he wished to avoid being ejected, to himself make tender of payment. As he was in the wrong throughout, he had no cause of action against the company, and the case should have been withdrawn from the jury.

**CAR DISPATCHING.**

In view of the general interest in the matter of controlling movements of cars on high speed, single track electric roads we have taken occasion during the past few months to secure personal interviews with a number of managers of interurban roads in the hope of collecting information of value on this subject. Practically without exception, those who have had experience along this line, agree that if a mechanical block signal, satisfactory in all respects, could be devised, the ideal arrangement would be to divide the road into absolute or permissive blocks with a telephone instrument at each turnout from which a car crew when off schedule could call the main office for instructions. In the absence of a block signal

orders for each car at every turnout; and the Toledo, Fremont & Norwalk Ry., where the dispatcher gives orders only when cars are off schedule.

As adding to the general fund of information on the subject we give at this time an outline of the methods employed on the Washington, Alexandria & Mt. Vernon Ry. Dispatching on this road is done entirely by telegraph and the rules from which we quote are the same as those adopted by the Pennsylvania R. R., with such modifications in terminology and details as are necessary to meet the needs of an electric railroad.

The Washington, Alexandria & Mt. Vernon Ry., with its branches, is about 26 miles long, most of which is single track with turnouts. It is the practice here to run trains comprising one 40-ft. motor car

FIG. 1 TRAIN ON THE WASHINGTON, ALEXANDRIA & MT. VERNON RY.

satisfactory to all, opinion appears to be divided as regards the relative merits of the telephone and the telegraph for dispatching purposes. Where telephones have been installed it is pointed out that the dispatcher is brought into much closer touch with the train crews; his orders are given verbally directly to the men who are to execute them; questions can be asked and explanations given more readily by telephone than by telegraph; and the telephone system once installed can be maintained at less expense, and it does not require operators at each instrument. In favor of the telegraph it is urged that written records of every message, or order, are more easily secured at at least two points on the line for reference, comparison or checking; the telegraph line and instruments are less susceptible to derangement than the telephone system; and as far as expense is concerned it is pointed out that the telegraph operators may also be employed to good advantage for selling tickets, taking charge of suburban stations, and filling other necessary duties not conflicting with their duties as operators. On the score of accuracy in the transmitting of messages the advocates of both systems claim the advantage. It is argued that there is greater chance for the train crews to misunderstand the orders over the telephone through carelessness, indistinctness in the telephone instrument or other causes, than there is for trained telegraph operators to make errors in the receiving and transcribing of orders. It is also argued that a telephone system installed for street railway service with wires strung on the trolley poles and instruments more or less exposed to the weather is not working under advantageous conditions and line and instruments are apt to get out of order resulting in indistinct messages if not total interruption of service. This is denied by the advocates of the telephone, who claim that the verbal message is always more reliable than the written telegraphic order.

equipped either with two G. E. 1,000 motors or four G. E. 57's, drawing one 38 or 40-ft. trailer. About 40 trains each way are run on ordinary days.

For a part of the distance near the terminal at Pennsylvania Ave. and 13½ St. N. W., Washington, D. C., the company uses the tracks of the Pennsylvania R. R. On this section the electric trains are sandwiched in between regular steam trains and run subject to orders of the Pennsylvania Railroad Co.

The dispatcher for the Washington, Alexandria & Mt. Vernon Ry. is located at the Washington terminal, and telegraph stations

FIG. 2 CAR USED BY PRINCE HENRY.

There are good authorities on both sides of the question. The Union Traction Co., of Anderson, Ind., the Toledo, Fremont & Norwalk Ry., in Ohio, and others use the telephone exclusively.

The Buffalo & Lockport, the Washington, Alexandria & Mt. Vernon Ry., the electric branches of the New York, New Haven & Hartford Ry., and others, employ the telegraph.

We have described in previous issues of the "Review" several schemes of dispatching cars by telephone. Special reference is made to the "Review" for Aug. 15, 1901, page 479, where will be found extended descriptions of the methods in vogue on the Union Traction system of Anderson, where the dispatcher issues special

are located at the principal passing points. The telegraph operators act as ticket agents and perform other duties around their stations and also receive public telegraph messages for transmission. The railway company pays the wages of the operators and the Western Union Telegraph Co. allows a commission on all public messages received for transmission at the railway stations.

As long as trains are on schedule time their movements are regulated absolutely by the time table without orders from the dispatcher. The time table is defined as the "general law governing

the arriving and leaving time of all regular trains at all stations." The time table intended for the information and government of employes is printed on a large sheet 15x41 in. which however can be folded to convenient size for reference. Every employe having anything to do with the movement of trains is required to keep a copy of the table about his person when on duty.

A section of the time table is reproduced with this article. The designation "train" means either a single motor car or a car with trailer.

Trains are operated under train numbers and their class is indicated on the table.

Regular meeting or passing points are indicated by figures in bold-faced type.

Both the arriving and leaving time of a train are in bold-faced

ly giving first his own station number, then the number of the train and the time of leaving, as for example: 11—No. 201—5 55. He must also keep a record of the time at which trains pass his office. This report is sent out on the line without calling and the operators at the station in the rear and also at the one next in advance are required to receive it and record it immediately on daily report blanks provided for the purpose, giving a prompt O. K. and office call. The dispatcher also of course receives the message and enters the information on his dispatching sheet.

At each telegraph station there are signal stands. Red indicates that the block is not clear and means stop. White indicates that the block is clear and is permission to proceed. Green indicates that there are one or more trains on the block and is permission to proceed with this knowledge. The signal always displays red

FIG. 3 SECTION OF TIME TABLE, WASHINGTON, ALEXANDRIA & MT. VERNON RY.

type when both are meeting or passing times or when one or more other trains are to meet or pass it between those times.

The numbers of trains that are to meet or pass are shown in small type adjoining the bold-faced type.

"s" signifies regular stop.

"f" signifies flag station where stops are made on signal only.

It is the duty of the station master to have a train with a competent crew in readiness to leave the terminals for the first runs as called for by the schedule. A few minutes before leaving time these trains are "reported in" to the dispatcher who enters on the dispatcher's sheet (also shown herewith) the number of the train, the car number of the motor car, and the names of the conductor and motorman in charge of the train. The trains leave according to their schedule time without further orders from the dispatcher. It is the duty of each telegraph operator to "report in" each train as it passes his station and the time it leaves. This report is made

except when changed to white or green to permit a train to pass. As soon as the train has passed the signal must be returned to red, and while displaying white or green the signal must be held by the hand and not fastened.

As soon as notice is received that a train is running behind schedule the dispatcher must immediately issue orders to all trains whose passing points will be affected by the delay. He records the incident in the column on his sheet headed "Remarks," giving the designation of the train, the time delayed and the cause, thus, "No. 250 delayed 10 minutes at Four Mile Run by reason of hot bearing."

It then becomes his duty to handle his trains with the view of getting them all back onto schedule at the earliest possible moment consistent with safety.

If the delay is likely to prove serious he orders out another train to take the place of the one that is disabled.

Crews of regular trains of the first class run their trains under the broad assumption that unless they are intercepted by written orders to the contrary they have the right of way and will meet their opposing trains at the scheduled passing points.

All extra trains, including passenger extras and work trains, run only on special written orders, except in the case of trains run

FIG. 4 SECTION OF DISPATCHER'S TRAIN SHEET.

as additional sections of a regularly scheduled train, in which case the regular train and all the additional sections must carry designating flags. Two green flags by day and two green lights by night displayed in the place provided for that purpose on the front of the motor denote that the train is followed by another train, running on the same schedule and entitled to the same time-table rights as the train carrying the signals. Two white flags by day and two

The register of trains is kept by the dispatcher on a blank 32 in. long by 19 in. deep. The upper half of this blank is ruled as shown in Fig. 4, which is a section out of the middle of this portion showing station list headings. Of the lower half a space 6½ in. wide the left end is occupied by a ruling for entering descriptions of trains; the ruling and column heads are indicated in Fig. 5. The rest of the lower half of the register sheet is for remarks. At the top of the sheet are places for entering the date, state of the weather, and the dispatchers' names.

The following are the rules governing the dispatching of trains by telegraph:

MOVEMENT OF TRAINS BY TELEGRAPHIC ORDERS.

Special orders, directing movements varying from, or additional to, the time-table, will be issued by the authority and over the signature of the superintendent. They are not to be used for movements that can be provided for by rule or time-table. They must not contain information or instructions not essentially a part of them.

They must be brief and clear, and the prescribed forms must be used when applicable; and there must be no erasures, alterations, or interlineations.

Each order must be given in the same words to all persons or trains directly affected by it, so that each shall have a duplicate of what is given to the others. Preferably an order should include but one specified movement.

Orders will be numbered consecutively for each day as issued, beginning with No. 1 at midnight.

Orders must be addressed to those who are to execute them, naming the place at which each is to receive his copy. Those for a train must be addressed to the conductor and motorman, and also to a person acting as pilot. A copy for each person addressed must be supplied by the operator.

Each order must be written in full in a book provided for the purpose at the superintendent's office; and with it must be recorded the names of trainmen and others who have signed for the order, the time and signals, showing when and from what offices the order and responses were transmitted, and the train dispatcher's initials. These records must be made at once on the original copy, and not afterward from memory or memoranda.

The terms "superior right" and "inferior right" in the rules, refer to the rights of trains under the time-table and train rules and not to rights under special orders.

When an order is to be transmitted, the signal "31," or the signal "19," meaning "train order," will be given to each office addressed, followed by the word "copy," and a figure indicating the number of copies to be made, if more or less than three—thus, "31 copy 5," or "19 copy 5."

An order, to be sent to two or more offices, must be transmitted simultaneously to as many as practicable. The several addresses must be in the order of superiority of rights of trains, and each office will take only its proper address. When not sent simultaneously to all, the order must be sent first for the train having the superior right of track.

Operators receiving orders must write them out in manifold during transmission, and make the requisite number of copies at one writing, or trace others from one of the copies first made.

When an order has been transmitted, preceded by the signal "31," operators receiving it must, unless otherwise directed, repeat it back at once from the manifold copy, and in the succession in which their several offices have been addressed. Each operator repeating must observe whether the others repeat correctly. After the order has been repeated correctly by the operators required at the time to repeat it, the response "O. K.," authorized by the train dispatcher, will be sent, simultaneously, to as many as practicable, naming each office. Each operator must write this on the order, with the time, and then reply "I O. K.," with his signal.

Those to whom the order is addressed must then sign their names to the copy of the order to be retained by the operator, and he will send their signatures to the superintendent. The response "complete," with the superintendent's initials, will then be given, when authorized by the train dispatcher. Each operator receiving this response will then write on each copy the word "complete," the time, and his last name in full; and will then deliver a copy to each person included in the address, and each must read his copy aloud to the operator.

For an order preceded by the signal "31," "complete" must not be given to the order for delivery to a train of inferior right, until "O

FIG. 5 DESCRIPTION OF TRAINS (FROM TRAIN SHEET.)

white lights by night displayed on the front of the motor denote that the train is an extra.

A train of inferior class, which includes all extra trains, must in all cases keep out of the way of a train of superior class. When running on single track northbound trains have absolute right of track over southbound trains of the same or inferior class. A scheduled train becoming one hour late loses all its rights and can proceed only on special orders.

K" has been given to and acknowledged by the operator who receives the order for the train of superior right. Whenever practicable, the signatures of the conductor, motorman and pilot of the train of superior right must be taken to the order and "complete" given, before the train of inferior right is allowed to act on it.

After "O. K." has been given and acknowledged, and before "complete" has been given, the order must be treated as a holding order for the train addressed, but must not be otherwise acted on until "complete" has been given.

If the telegraph fails before an office has received and acknowledged "O. K." to an order preceded by the signal "31," the order at that office is of no effect, and must be there treated as if it had not been sent.

The specifications for train order form and books for operators for "31" orders are as follows. Form as here shown. Blank space for order 4 in. with no lines. The mode of filling the blanks as indicated by small type. Form 6 1/2 x 9 1/2 in. below perforated line. Book 6 3/4 x 10 1/2 in. 300 leaves. Stitched. Bound at top. Paper cover on face and top. Very stiff back on lower side. Paper opaque, white, sized, and of such thickness as to admit of making seven good copies with No. 1 Faber pencil. To be used with carbon paper, 6 3/4 x 9 in. and a stiff tin, same size, corners rounded.

When an order has been transmitted, preceded by the signal "19," operators receiving it must, unless otherwise directed, repeat it back at once from the manifold copy, and in the succession in which the several offices have been addressed. Each operator repeating must observe whether the others repeat correctly. After the order has been repeated correctly, the response "complete," with the superintendent's initials, will be given, when authorized by the train dispatcher. Each operator receiving this response must write on each copy the word "complete," the time, and his last name in full, and reply "I complete" with his signal, and will personally deliver the order to the persons addressed without taking their signatures.

For an order preceded by the signal "19," "complete" must be given and acknowledged for the train of superior right before it is given for the train of inferior right.

If the telegraph fails before an office has received and acknowledged

when trains are late, they must be delivered in the same way as to conductors of trains.

An order to be delivered to a train at a point not a telegraph station, or while the office is closed must be addressed to "C. and M., No. — (at —) or (between — and —), care of —."

and forwarded and delivered by the conductor or other person in whose care it is addressed. "Complete" will be given upon the signature of the person by whom the order is to be delivered, who must be supplied with copies for the conductor and motorman addressed, and a copy upon which he shall take their signatures. This copy he must deliver to the first operator accessible, who must at once advise the train dispatcher of its having been received, and forward it immediately to the superintendent.

Orders so delivered to a train must be compared, by those receiving them, with the copy held by the person delivering, and acted on as if "complete" had been given in the ordinary way.

Orders must not be sent in the manner herein provided, to trains the rights of which are thereby restricted.

When a train is named in an order, all its sections are included unless particular sections are specified, and each section included must have copies addressed and delivered to it.

Meeting orders must not be sent for delivery to trains at the meeting point, if it can be avoided. When it cannot be avoided, special

TELEGRAPHIC TRAIN ORDER No. 10

Superintendent's Office, Washington, June 1, 1896.

FORM 31 To C. & M. of No. 13. at Alexandria. 31 FORM

Conductor and Motorman must each have a copy of this order.

Time received 2.15 A. M. O. K. given at 2.15 A. M.

Conductor.	Motorman.	Train	Made	At	Received by
Jones.	Brown.	13	Complete.	2.20	Harrison.

FIG. 7 ORDER FORM "31."

the "complete" to an order preceded by the signal "19," the order at that office is of no effect, and must be treated as if it had not been sent.

The order, the "O K" and the "complete" must each, in transmitting, be preceded by "31" or "19" as the case may be, and the number of the order, thus, "31, No. 10," or "19, No. 10." In transmitting the signatures they must be preceded by "31," the number of the order, and the train number, thus, "31, No. 10, Train No. 5." After each transmission and response the sending operator must give his signal.

The specifications for train order form and books for operators for "19" orders are as follows: Form as here shown. Blank space for order 4 in. with no lines. The mode of filling the blanks is indicated by small type. Form 6 1/2 x 6 in. below perforated line. Books 6 3/4 x 7 1/2 in. 300 leaves. Stitched. Bound at top. Paper cover on face and top. Very stiff back on lower side. Paper opaque, green, sized, and of such thickness as to admit of making seven good copies with No. 4 Faber pencil. To be used with carbon paper 6 3/4 x 7 in. and a stiff tin, same size, corners rounded.

The operator who receives and delivers an order must preserve the lowest copy. On this must appear the signatures of those who sign for the order; and on it he must record the time when he receives it, the responses, the time when they are received, his own name, the date, and the train number, in the places provided in the blanks. These copies must be sent to the superintendent.

Orders used by conductors must be sent by them daily to the superintendent.

Motormen will place their orders in the clip before them until executed.

For orders delivered at the superintendent's office the requirement as to record and delivery will be the same as at other points.

When necessary to give orders to persons in charge of work requiring the use of track in yards or at other points, authorizing such use

precautions must be taken by the train dispatchers and operators to insure safety.

There should be, if possible, at least one telegraph office between those at which opposing trains receive meeting orders.

Orders should not be sent an unnecessarily long time before delivery, nor to points unnecessarily distant from where they are to be executed. No orders, except those affecting the train at that point, should be delivered to a freight train at a station where it has much work, until after the work is done.

A train, or any section of a train, must be governed strictly by the terms of orders addressed to it, and must not assume rights not conferred by such orders. In all other respects it must be governed by the train rules and time-table.

Orders once in effect continue so until fulfilled, superseded or annulled. Orders held by, or issued for, a regular train, are to be considered as annulled when the train has lost its rights, and other trains will be governed accordingly.

The Brooklyn Rapid Transit Co. has obtained an order directing that the courts shall decide to whom the company shall pay the \$25,000 reward which was offered in the latter part of 1900 for information leading to the arrest and conviction of persons who had circulated false reports with the intention of depreciating the stock of the corporation. This recent action on the part of the company was rendered necessary by the number of spurious claims made for the reward.

# IN THE POWER HOUSE

This department is devoted to the construction and operation of electric railway power houses. Correspondence from practical men is specially invited. Both the users and makers of power house appliances are expected to give their views and experiences on subjects within the range of the department.

## POWER HOUSE NOTES.

BY ARTHUR B. WEEKS.

There are times when repairs to a generator armature are rendered necessary amid the rattling of machinery and in a constant draught. In such an instance, the use of canvas, as shown in the illustration, will afford temporary protection, retaining commutator heat and preventing the cooling of soldering irons. Where the draught is unusually violent, the work can be wholly enclosed.

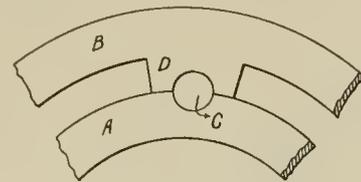

Should it become necessary to remove the collector rings of a rotary converter armature, as herewith illustrated, remove the connections of the rings to the armature conductors. It will be observed that there are twice as many of these connections to the armature as there are pole pieces on the rotary. The rotary converter armature here shown belongs to a 350-kw. Westinghouse machine for street railway service.

After taking off the starting motor armature, insert threaded rods into tapped holes in the collector casting provided for that purpose, and place a heavy strap of iron across the end of the shaft. Tighten up the nuts on the rods which pass through holes in this strap of iron. The collector rings of a General Electric rotary are removed in the same way. It may prove a difficult undertaking, for after years of running, it will have rusted fast; yet after persistent work it can be removed, though one may break several rods and double up the straps of iron, until material is secured which will stand the strain. Collector rings of the raised pattern give far better satisfaction than those whose surface is  $\frac{1}{2}$  to 1 in. below the insulating material separating the rings. Raised rings may be put on in the following manner:

Turn off each ring, and fit over each a ring like that shown in the illustration. The inside ring, A, is a portion of the original ring, and B, a portion of the new one with a lug, D; this allows a ventilating space between the surfaces. The outside ring is fastened with a dowel pin, C, driven into a hole drilled at the intersection of the

bration of floor and machine when the armature is in motion. By all means, let it be corrected as soon as possible. The armatures are, as a rule, bar wound, and connected to copper strips extending up radially from the commutator, in line with the armature coils. An idea prevails that there is something very mysterious about a rotary converter; but one soon becomes familiar with its operation and peculiarities.

Synchronizing, or paralleling rotaries, is an operation which to some men seems very difficult. It may take a great deal of practice, but they will master it in time. The writer recalls an instance where

RAISED COLLECTOR RING.

an engineer found his steam plant replaced by a modern light and power station, equipped with motor generators and rotary converters. It was a question of either learning to run the new apparatus or looking for a new position. He determined to do the former, and surprised himself by the ease with which he grasped the new conditions.

One's record, or ability to properly care for the rotaries, depends largely upon the skill and knowledge of his informant. Incorrect information may cling tenaciously for years, and is a hard thing to overcome. Of course, more things are liable to go wrong with a rotary converter and its alternating current equipment than when a direct current generator of the same capacity is used. If the transformers are oil and water cooled the oil must be maintained at the right height and the water kept in circulation. It is easy to forget to turn on the water again after a shut-down. Should the water occasionally become muddy, it may cut off the circulation to a dangerous degree if not closely watched.

If air blast transformers are used, do not forget to start the motors for the fan. Sometimes such apparatus is placed in subways or poorly lighted places; be the more particular to inspect machinery so located. Take the air supply from outdoors where possible, especially in summer. The writer remembers a transformer room in which there were a number of air blast transformers supplied with air by two fan blowers driven by induction motors, with an air shaft opening on to a side street where a large sand-pile for plasterers was located. To the disgust of everybody the greater portion of the sand disappeared into the transformer room. Burnt out transformers for rotary converters generally cause consternation, but if properly installed, the fuses or circuit breakers, as the case may be, will take care of the machinery.

General Electric rotaries are usually started by a motor generator consisting of an induction motor driving a direct current motor sufficiently large to propel the converter as a shunt motor under no load. At the end of the armature shaft at the direct current end is an electro-magnet connected to a Lincoln oscillator, which periodically produces end thrust of the armature, giving a hard glaze to the commutator, and which also prevents the wearing of grooves in the alternating current rings.

Where there are Westinghouse rotaries in operation also, the General Electric machine is started with current from the direct current bus-bars. There is no difficulty in starting. The Westinghouse converters, as is generally known, may be started either with alternating or direct current.

CANVAS SCREEN FOR REPAIR WORK.

two surfaces. There are three such lugs and dowel pins for each ring. After being replaced on the armature shaft, they should be turned again if they do not run true with the shaft.

The armature may need balancing after fitting these rings. If it has been rewound, this will undoubtedly be necessary. To accomplish it, two nicely planed surfaces are required; portions of an iron girder, each about 3 ft. long, are excellent for the purpose. These should be accurately leveled. Whatever weight is needed to balance the armature is slipped over one or more bolts on the front of the commutator head; replace the nuts and draw up tightly.

Should the armature be out of balance, it is indicated by the vi-

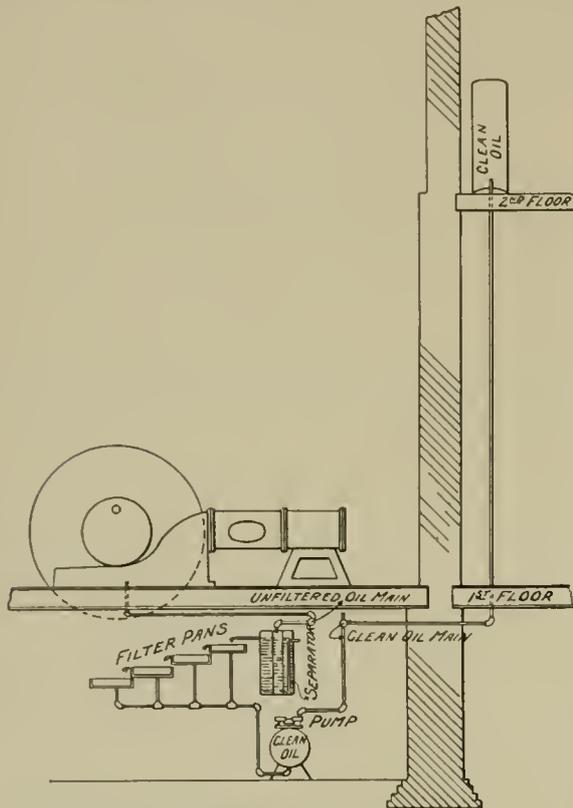

**POWER STATION HELPS.**

BY **FREDERICK L. RAY.**

Power station economies cannot be based on any one part of the station, nor altogether on the larger items of the make-up of a power station. The auxiliaries come in for a large share of the waste or the saving. The method explained and illustrated in this article is in use in one of the railway and lighting stations of the west, where nothing is too good if it will save a dollar.

In the engine room, no oil is handled except through a system of piping; there are no oilers to spill oil on machinery and floor. The engine room force is reduced to the engineers and wipers, and a hot bearing is as unknown as a snow storm in summer. With a stream of clean, filtered oil running to every bearing, the engineer can devote his time to the careful watching of the records.

The engine oiling system as shown in the diagram is a gravity system. The fresh oil from the barrel is dumped into the system, so that oil must go through the separator and filter and then to the

SECTION SHOWING OILING SYSTEM.

pure oil reservoir. This takes out all splinters, etc., that may come from the barrel. All oil used on the engine which is not consumed in lubrication is piped to the separator, where all water, dirt and heavy matter is separated; then it passes to the filter, which consists of a series of pans. These pans are set one above the other, so that if one will not filter all the oil coming over, the next one will, and so on down to the last one. The pans are watched, and if oil begins to travel to the last pan for filtering, then the filtering material, which consists of white waste and outing flannel, is changed. A layer of flannel is put in the pan extending up the sides to the top, with a wire rack in the bottom to keep the cloth off the pan. Afterward the pan is filled with waste. The filtered oil is piped to a pure oil reservoir. From here it is pumped by a small Marsh pump to a second reservoir, which is on the second floor of the boiler room. From this it flows by gravity to the manifold oiler on the engine, and the process of filtering is repeated over and over until all is lost. No loose oil is brought into the engine room, as a pipe extends outside to the oil house, where oil is supplied to the system.

**Cylinder Oil.**

The handling of the cylinder oil is accomplished by a gravity system, aided by compressed air. A system of piping is arranged so

that oil flows to a hand pump and automatic lubricator, so that all the attendants have to do is to open a valve and fill the cups. The oil is raised to the reservoir by compressed air. Another reservoir is placed in the basement of the engine room, into which the oil is piped from the oil house, in the same way as the engine oil. A barrel of oil is let in, the valves are closed, and an air pressure of 50 lb. applied on top of the oil. By this method the oil is forced up to the reservoir on the second floor ready for use. This forcing of oil into the reservoir compresses the air there and gives an air pressure to drive the oil out, which is advantageous, especially in cold weather.

**Condensation.**

The saving of condensation, priming, etc., from all sources is of no little importance. At this plant, the amount saved is about 15 per cent of the total consumption. A system of piping is arranged so that all water from live steam mains, separators, etc., is led to a tank in the basement, and from this tank it is returned to the boiler by a return trap.

The water from the exhaust mains is not so easily handled because of the cylinder oil there is in it. All this water is caught in a tank and then pumped by a small Marsh pump up to the top of the water softening apparatus. It is put through this machine and treated with soda ash; the oil is precipitated and the water comes out as clear as crystal, and we have so much clean, soft water for the boilers.

**Water Softening.**

We have practically soft water for our boilers. This is accomplished by a continuous operating system installed by the Industrial Water Co., of New York City, which treats the water cold with lime and crystal carbonate of soda. The water as it continually passes through the system has added to it certain proportions of lime and soda, by which the scale-forming matter is precipitated to the bottom of the tank, where it is blown off to the sewer. No scale forms in the boilers, and the great trouble we once experienced with tubes bursting is now entirely eliminated.

One of the most expensive auxiliaries about a station is the ordinary boiler feed pump, consuming all the way from 150 lb. to 250 lb. of steam per h. p. hour. This method has been displaced by the more modern idea of a motor-driven pump. This is fitted with a regulating or by-pass valve, and runs constantly; the regulating valve being set at 25 lb. above boiler pressure and the feed valves to the boiler "pinched" down to admit the necessary water to the boiler. In this way the expense is only for the actual cost of generating the current for motor; it would not be fair to charge the motor with the selling price of the current any more than it would be to charge the selling price for current used on the motor-driven exciter.

**Motor-Driven Exciter.**

Instead of the usual method of exciting the field of an alternating current generator by an exciter by a belt from the main machine, it is a great improvement to use a motor-driven direct-connected exciter, independent of all other machines. Of course where you have the motor-driven exciter you should have a duplicate exciter driven by a steam engine, so that if the whole plant is shut down you can get started again. This motor can be a type to use the same voltage as the generator, not needing any transformer interposed.

**Recording Meters and Gages.**

Recording meters and gages are a wonderful stimulus to correct manipulation of the machinery of a power station. A recording meter on the bus bars of a switchboard is a splendid thing, giving the correct voltage for the whole day. It is well also to have several of them on the pressure wires leading out on the main circuits to the center of distribution, with a Stillwell regulator interposed, so that you can take care of the drop in the lines, and in this way give splendid service at farthest point from the station.

One of these instruments on steam mains to give a record of boiler pressure has a great influence toward keeping the fireman up to his duties and turning his attention to the steam gage. How few people know what kind of steam they are using: whether it is wet or dry. If you will put a recording temperature gage on your steam main, you will be able to know just what your steam is, and if you have boilers that give superheated steam, you will be able to tell just how high that superheat is, and if you are trying to get your steam as highly superheated as possible and keep it there, you will

be able to tell at a moment when your boiler is getting foul or the superheat begins to come down and continues to come down on the boiler until it is cleaned. Some water tube boilers easily give 100 deg. F. of superheat, while others give very wet steam.

**Heating System.**

If you have an exhaust steam heating system connected to your engines, put one of these recording gages on that too; then when a customer complains about pressure, just point to your chart, and he will hunt some place else for trouble. Adopt a graduated scale of pressure for the heating system, depending on the temperature of the water, then get a recording thermometer to give you the weather conditions, and you can give perfect service to your heating customers at the least possible back pressure on the engine.

**Air Compressors.**

A motor-driven air compressor is another handy station auxiliary. Air is a splendid thing to clean switchboards, dynamo, etc., to run air drills on boiler work instead of the ratchet drills, for the handling of oil, and many other uses.

**Station Records.**

The more records kept the better. The old commandment of "Know thyself" is equaled by another, "Know what you are doing." How much coal are you burning? What per cent is ash? How much water do you evaporate? What is steam consumption for auxiliaries? What is steam consumption for engines? Where is the rest of the steam going? What is the cylinder oil consumption per engine-hour? How many pounds of water per pound of coal? How many pounds of coal per kw. h. All these questions and many more the wide-awake chief engineer of to-day must be prepared to answer.

**MOVING STAIRWAY FOR CHICAGO ELEVATED**

The Metropolitan West Side Elevated Railway Co., of Chicago, has installed at its new Marshall Boulevard station a moving stairway for taking passengers to the station platform. Moving stairways have been used experimentally by the Manhattan Elevated Ry., of New York, and their successful operation in that city has influenced the Metropolitan Company in deciding to test the device in Chicago with the end in view of ultimately equipping all its prominent stations with some form of lifting stairway or elevator. The apparatus installed in the Marshall Boulevard station is, strictly speaking, not a stairway but an elevated inclined plane having corrugations on its surface to prevent passengers from slipping. The apparatus is made by the Reno Inclined Elevated Railway Co., of New York City, and is very similar to the inclined elevator that has been in use for several months at the Third Ave. and 59th St. station of the Manhattan road in New York.

As installed at the Marshall Boulevard station the elevator is in two sections giving a total lift of about 35 ft., the lower section being 15 ft. in length and the upper section about 20 ft. There is a short landing platform between the two sections.

The moving belt or plane is about 2 ft. wide and moves at a speed a little faster than the average persons would walk upstairs. A hand rail at the side moves in conjunction with the belt and affords passengers a means of steadying themselves during the ascent. The belt is made of a composition metal and travels on small rollers placed at very frequent intervals.

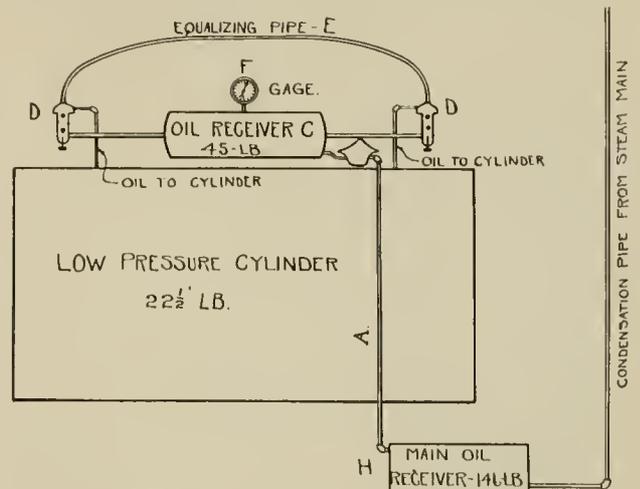

One section of the elevator is driven by a 7-h. p. motor and one by a 5-h. p. motor. Both of these machines take direct current from the line circuit at about 500 volts. They are both controlled by rheostats placed in the ticket booth where they are under the immediate control of the ticket agent. The expense of operation is stated to be merely nominal.

The Marshall Boulevard station is a new depot just established on the new Douglas Park extension of the elevated and will afford an excellent place for testing the elevator, as the station platform is about 40 ft. above the ground, and the station is one that will be used largely by women and children coming from the park. At this point the elevated crosses the C., B. & Q. railroad and the depot is destined to be a very important one.

**CORRESPONDENCE.**

**THE LUBRICATION OF COMPOUND ENGINE CYLINDERS.**

Editor "Review": Having had more or less trouble with the usual "hydrostatic" systems of lubrication for compound cylinders, I venture to send you a sketch of a simple device that I have found will often prevent stoppage of the oil flow. The low pressure cylinder is of course the difficult one to lubricate by the hydrostatic method. In common practice the oiling system is connected to both ends of the cylinder, and sometimes a water column is used in connection with the lubricator. In either case, the steam connections are such as to permit condensation to take place in the sight feed glass, and by making a water column connection to either system, in addition to the steam pressure, the oil is forced through the water in the sight feed glass into the steam chest or cylinder. We all know what frequently occurs with this system in service. The number of drops of oil per minute gradually de-

METHOD OF CYLINDER LUBRICATION.

creases, and if not given attention, the flow of oil will finally stop. Very often this is not due to insufficient pressure, nor is it due to the valves becoming clogged. The stoppage of oil is caused by the low temperature of the steam or by the condensation water in the sight feed glass becoming cool. As a consequence the metal connected with the lubricating system is chilled, causing the oil to thicken and finally stop feeding. By a glance at the accompanying working sketch it can readily be seen how this trouble may be prevented. The oil is under boiler pressure plus the water column in tank II, or about 146 lb. pressure. From this tank or receiver, the oil is delivered through a reducing valve B, to the receiver C, at 45 lb. pressure. It then goes to the sight feed glasses (D), and finally to the steam chest and cylinder. In the ordinary lubricating arrangements the circulation of steam stops at the sight feed glass of the low pressure cylinder and the water or condensation becomes cool. This is remedied by the addition of the steam loop or circulating pipe E. This pipe is connected to the highest point of each sight feed glass, allowing a circulation of steam from one end of the steam cylinder or chest to the other. The steam which condenses at the extreme height of the steam loop will flow to the sight feed glasses, and keep the water hot, causing the oil to remain at the same temperature as the water. While the steam is circulating in pipe E, all connections to the lubricator will remain at a high temperature and keep the oil in the same condition. Yours truly,

Herman Van Ormer,  
Ch. Engr. Hartford (Conn.) Street Railway Co.

The North Texas Traction Co.'s interurban between Dallas and Fort Worth will be put in operation before July 1st. The power house at Handley is completed, and will supply power for the Fort Worth lines as well as for the interurban road.

### WINDING ARMATURES.

Editor "Review": I changed the winding on our Westinghouse No. 3 armatures about 18 months ago and have reduced our armature troubles in this motor about 40 per cent over the old style winding with form wound coils. I have noticed in winding this type of armature with the form wound coils sometimes the insulation would be injured in putting them in place, as it is impossible to put them on without using a hammer, and when the armature was put under heavy load it was liable to ground and burn out. With our new method I have not seen this happen in a single case. I use one sheet of micanite and two sheets of brown paper in lining the slots of the core, making the insulation  $\frac{5}{8}$ -in. longer than the core of the armature. The winding is the same as with the old style coils from slot 1 to 25. When the section is started put the left hand lead in slot 26 until the section is finished in 1 and 25. Then put a piece of lead cover on both leads the length of the core so as to make a good insulation between the sections. This is done so as to bring both leads out on top of the section. On the ends of the armature one thickness of muslin or linen is enough under each section. It takes a little longer to wind an armature in this way but I have found it to be much cheaper in the end. The commutator connections are the same as with the other winding. The ends of the armature are much smaller with this winding.

Foreman Repair Shops,  
Harrisburg (Pa.) Traction Co.

### INDICATING INSTRUMENTS.

Editor "Review:":

In the handling of stations, whether for power and lighting or for street railway work, nothing is so essential as a sufficient number of indicating instruments. While I was with the Detroit Citizens' Street Railway Co. I devised a scheme for indicating to the firemen in the boiler room the amount of the load being carried by the station. A Weston illuminated dial ammeter was placed on the wall in front of the boilers. The shunt circuit was run from the switchboard to the ammeter and the ammeter carefully calibrated to read the total amperes output of the station. The shunt resistance for the ammeter was made by replacing some short copper connecting strips in the main bus bar by iron strips of the same size. This scheme proved very helpful in regulating the steam pressure according to the load, and saved much signalling back and forth from the engine room. I believe this ammeter is still in use there but I have never seen it applied in any other station.

O. A. Honnold,  
Salt Lake City, Utah. Utah Light & Power Co.

### NATIONAL ELECTRIC LIGHT ASSOCIATION AT WORLD'S FAIR.

At the Cincinnati convention of the National Electric Light Association great interest was manifested in the importance of the association meeting in St. Louis in 1904 during the World's Fair. It was unanimously resolved that the association would lend its best efforts to contribute to the achievement of an electrical exhibit such as the exposition management and the industry demands. Prominent members of the association expressed themselves as being highly desirous of showing the industrial application of electricity at the World's Fair, on a very large scale, and their willingness to cooperate in securing this end. It is expected that this exhibit will have the effect of opening up for business a large territory which is now undeveloped electrically.

It is probable that the association will have an exhibit of its own which will demonstrate the method of selling and measuring electrical energy whether for light or power. The action was taken this year to hold the 1904 meeting at St. Louis for the reason that the association believes that much better working exhibits will be forthcoming if the electrical manufacturers understand that the central station men are thoroughly interested in having all electrical apparatus exploited on a large scale.

The Kansas City-Leavenworth Railroad Co. headed the list of donations for the Memorial Day celebration at Leavenworth with a cash subscription for \$50.

### KEEPING GOOD TIME.

A detail of operation that has always been given careful attention by steam railroad managements but is sometimes neglected by street railways is the necessity for making sure that all employes having to do with the movement of cars are provided with reliable watches which should be regulated every morning.

The following precautions in this direction are in force on the Washington, Alexandria & Mt. Vernon Ry. The rules are formulated from those adopted by the Pennsylvania R. R., and are as follows:

Observatory standard time is the only recognized standard, and will be transmitted from the National Observatory to the main office.

The standard time will be signalled to all points on the system from the main office at 12:00 noon, daily.

Certain clocks will be designated on each division as standard clocks.

Where station clocks are provided, those in charge of stations must see that the clocks show correct time, but employes must not take time from such clocks unless they are also designated as standard clocks.

Each conductor and motorman must provide himself with a reliable watch, which must be examined and approved on a prescribed form by a watch inspector appointed by the company, and must file this certificate at the manager's office before he will be allowed to take charge of a car. Watches must be examined and certificates renewed every six months.

Each conductor and motorman must regulate his watch by a designated standard clock before starting on each daily trip or run, and register his name and the time at which he regulates his watch on a form provided for that purpose.

Conductors and motormen whose duties prevent them from having access to a standard clock must compare daily with, and regulate their watches by, those of conductors or motormen who have standard time and have registered their names in accordance with these rules.

The forms referred to are merely standard blanks with space for the foregoing information to insure uniformity in the making of reports.

All the cars of the Washington city systems have a small attachment on the front dash for holding the motorman's watch where it will be in constant view. The motormen are required to become familiar with the time at which they should pass certain prominent points and by having the watch before them at all times they are better able to regulate their speed in order to keep up to the requirements of the schedule.

### POST CHECK CURRENCY.

The "Post Check" currency plan now before Congress contemplates the issue of one, two and five dollar bills which will have the dual properties of money and transferable checks by providing blank lines for assigning such bills to a named payee if desired. An issue of fractional currency of a similar form in denominations of five to fifty cents is also contemplated which would provide for sending small amounts of money by mail. The object of this currency is to provide an entirely safe method of sending money through the mails, as when a bill is endorsed it can only be paid to the payee named upon it upon identification at the post office stated. This makes it as safe for transmission as any bank check.

Post check currency has been widely advocated by leading newspapers and business houses in all parts of the country and it appeals especially to publishers as it provides a ready means for paying subscriptions and avoids the use of postage stamps or silver in sending small amounts by mail. There seems to be no possible objection to this kind of currency while the advantages it offers are many, both to the sender and receiver. It avoids the trouble of going to the post office to procure money orders and it also overcomes the difficulty of handling and disposing of a large number of stamps which can generally only be converted into money at a loss. While publishers are greatly benefited by such a currency, there are a vast number of other interests to which it would appeal with equal force.

The Union Traction Co., of Philadelphia, has inaugurated a through service between Frankford and Willow Grove.

# MECHANICAL DEPARTMENT

## SYSTEM IN REPAIR SHOPS.

BY H. ARNOLD FRENCH, MASTER PAINTER, UNION RAILROAD CO., PROVIDENCE, R. I.

There is but one way to success in any undertaking, and that is to so arrange your task, whatever it might be, so that the end may always be in sight. No engineer would for a minute think of setting his men to work on a job before he made a complete layout of the whole, the end being of as much importance to his as the beginning. The writer has had occasion in a practical way of seeing this fact demonstrated to its full extent.

We will take for instance the regular work of the shops, such as a general renovation of the whole equipment, which should be done over once in twelve months at least. We have seen it done in a great many shops in a sort of haphazard way without any system or method, simply taking the cars in, and when they are done, sending them out, whenever it has pleased the men to accomplish the work. Whether it is done in a week or a month matters not to them so long as they get their pay for it, and we cannot blame them any more than we could a regiment of soldiers after a repulse in a mismanaged charge on the enemy. Such being the case, let us try to reason out a remedy, if possible.

Never losing sight of the end that I first mentioned, let us start in a methodical, business-like way. No manager wants his open cars in the shops in the summer or his closed cars there in the winter. The reason is obvious. Enough equipment has to stand all day in the car houses to do the extra work at night and morning, without having more of it in the shops just for the want of a little energy on the part of the shop management to push it out.

The first of May should see all of the open cars ready for business. The season is liable to open any minute and they will be wanted. Now, the first application of the remedy leads up to the question, How many open cars are there on the list? Say, 200. Figure back from the first of May the number of working days we have to do them in, doing one, two or more a day, as the whole number might require. Then so arrange your work that each man will have a certain amount to do in a day, being particular to be just both to the company and to the men, which, by the way, is a mighty fine line to work by, but which can be accomplished by a little reasonable thought.

Just fancy stepping into your shop in the morning and when the signal to proceed to work is sounded, seeing each man step to his post without a word from the foreman, and begin that same work which is allotted to him every day, with the understanding that he is to finish his particular part at the end of the day. By this method of working each individual man becomes a most proficient workman, and having the end in view, he so regulates his work that at any hour of the day he is never behind. In reality (to use a shop phrase) he keeps tab on himself.

I can hear the practical, unsystematic man, even now as he reads these lines, raise many objections. The condition he has to work under will never allow such a scheme to exist. My answer is this: Just push your handle up one more notch and get away from that "resistance" that is holding you back so much that it certainly amounts to a disease, and you will be surprised to find how easy it is to manage a shop, if you have some system whereby the end is always in view. Now mark the result of systematic work. You see coming from the car houses into the shops every day one, two, or three, or as many cars at your method will accommodate, and a like number going out, all finished and ready to be put into service. Thereby repair work is made as systematic as manufacturing, and it becomes a simple mathematical problem for you to solve when you are asked by the manager the exact time he can have his cars.

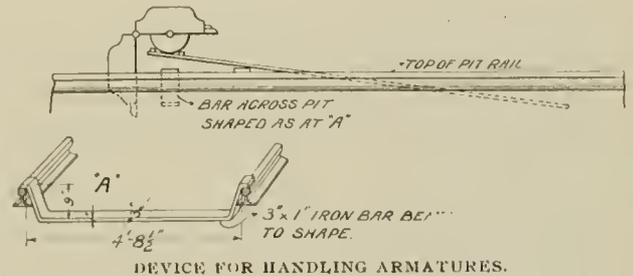

The same methods of doing the open cars can of course be applied to the closed cars, having them all done in the summer months, ready in the fall at any given time.

Now, in conclusion let me impress on the mind of the reader that there is more than one way of working. It is not necessary to work this man's way or that man's way; it may not be practicable that you should; your conditions may not allow it. But you can search out some method whereby without taking observations you can always know what part of your little ocean you are sailing on and can always tell to a day when you are due in port.

## FOR REMOVING OR REPLACING ARMATURES.

A number of schemes for removing and replacing armatures under cars have been described in recent issues of the "Review." Mr. J. C. Sherrill, barn electrician for the Charleston (S. C.) Consolidated Railway Gas & Electric Co., suggests a scheme for accomplishing the same results for roads that do not own a pit jack, or for use at times when the jack is not available.

The essential features of the arrangement are a plank 2x12 in. and 20 ft. long to act as the lever; a smaller piece of board to go across

the top of the pit as the fulcrum; and a 1x3-in. iron bar bent as at A in the sketch and designed to be placed across the pit to support the end of the long plank when the armature has been lowered.

To remove an armature from under a car the lower half of the motor case is swung down. One end of the lever board to which are fastened two cleats to prevent the armature from rolling off is then brought to bear against the lower side of the armature. One man at the other end of the lever supports the weight of the armature while a second man unscrews the bolts that hold the bearings together. The armature is then lowered until the board rests upon the iron strap placed across the pit. The small board which acted as the fulcrum is then moved back along the top of the rails until it supports the power end of the lever. In this way the lever is made to form an incline plane up which the armature may be rolled and so placed on the car barn floor.

Mr. Sherrill states this makeshift fills the requirements as well as an elaborate pit jack would do, though it is not so convenient.

The Interborough Rapid Transit Co., of New York City, which was recently incorporated, has issued stock to the amount of \$25,000,000. The company's system will comprise 7 miles of 4-track and 14 miles of double track and one large power house equipped with eight 7,500 h. p. engines furnished by the Allis-Chalmers Co., and 48 Babcock & Wilcox boilers of 600 h. p. The officers of the Interborough company are: August Belmont, president; E. P. Bryan, vice president and general manager; Frederick Evans, secretary, and J. F. Buck, treasurer. John B. McDonald is the general contractor and George Gibbs, consulting engineer.

**TIME REQUIRED TO REPAIR AND PAINT CARS.**

Through the courtesy of Mr. H. A. Davis, superintendent, and Mr. E. W. Hiller, master mechanic of the New Orleans & Carrollton Railroad, Light & Power Co., we are permitted to publish the following data regarding the time required to repair and paint cars at the shops of this company. The figures are averages secured under working conditions and are valuable as showing what may be expected from average men working in a well regulated shop. They enable the master mechanic to estimate the time necessary to put a given number of cars through the shops with a given force of employes.

These data will be especially valuable to any company having in mind the establishing of a piece work system of paying employes. In this connection reference is made to the "Review" for last April, page 223, where will be found data regarding advantages of the piece system and also the complete schedule of prices paid for piece work at the shops of the North Jersey Street Ry.

In further explanation it may be added that these figures are for work performed on the standard cars of the New Orleans & Carrollton Company. These cars are 20 ft.-body, closed cars, 30 ft. 8 in. over all, having seven cane cross seats on each side of the center aisle. They were built by the American Car Co., of St. Louis.

**WHAT CAUSED THESE FLATTENED FLANGES?**

Mr. S. M. Coffin, master mechanic of the Mobile (Ala.) Light & Railroad Co., has called our attention to a curious wheel trouble which is giving him considerable annoyance. He finds that after the car wheels have made in the neighborhood of 25,000 miles many of them have to be removed owing to the flanges wearing flat on the edges. This wear seems to take place uniformly around the entire circumference and is well illustrated by the sections repro-

VIEW OF FLATTENED FLANGES.

duced on this page which are from actual templets taken from a sample pair of wheels removed for this cause. This particular pair of wheels made 25,000 miles. The standard used on the road is a 400-lb. chilled iron wheel with 2½-in. tread and ¾-in. flange.

The curious part of the matter is that the wheels shown ran entirely on 45-lb. T-rail and were never used on girder or grooved rail and the trouble cannot therefore be due to the wheel running on the flange. It has been suggested that the flattening might be due to too shallow special work, but Mr. Coffin explains that all special work on the road is of the built-up type and is at least 1-in. in depth even in the pieces that have been down some time and are partly worn. It was also suggested that the wear might be caused by improperly adjusted brake-shoes or by the type of shoe used but this can hardly be possible as several different makes of shoes have been tried without relief. It might be added that the brake shoes themselves wear in conformity with the wear of the wheel and section though discarded shoes show the same flattened flanges.

Mr. Coffin is now inclined to believe the trouble is caused by sand drifting in close to the head of the rail, as a large portion of the road is built entirely in sand. He thinks the edge of the flange might be ground flat by constant running in this sand.

We would appreciate receiving suggestions from anyone as to the probable cause of this peculiar trouble and would like to hear especially from companies who may have had similar experiences with flattened flanges.

The Dayton, Covington & Piqua Traction Co., of West Milton, O., expects to open its 34-mile interurban electric line this month. Ten passenger and two freight cars will be operated, and the installation at the power house will comprise two Buckeye engines of 450-h. p. capacity and two 300-kw. generators made by the General Electric Co. The officers of the operating company are: Denis Dwyer, president; W. E. Geer, vice-president; M. J. Randolph, secretary, and Edward C. Spring, general manager and superintendent. R. D. Colburn is chief electrician.

**COMPRESSED AIR CARS IN SEVERE SERVICE.**

Our readers are already familiar with the good record made by the compressed air cars used in the all-night service on the Clark St. line of the Chicago Union Traction Co., and also with the result of the operation of air cars on the Metropolitan Street Ry. of New York. The cars in service in Chicago were illustrated in the "Review" for October, 1900, page 729; some interesting data on the New York installation were given in our issue for October, 1900, page 613, and the latest types of the compressed air storage

FIG. 1 COMPRESSED AIR CAR WITH SNOW PLOW.

tanks and motors were shown in the "Review" for Sept. 15, 1901, page 594.

We reproduce here two engravings which show the results obtained with compressed air street cars under adverse conditions. Fig. 2 is from a photograph taken during the recent flood at Rome, N. Y., and shows the cars running at high speed through a depth of water that would put an underground electric line or a steam locomotive out of business and that would give the ordinary overhead trolley car serious trouble. In Fig. 1 the compressed air car is at work in deep snow.

The advantages offered by an independent motor for car service under exceptional conditions are well known and it is also appreciated that there are various applications for air as an auxiliary in many cases where the overhead trolley is the most economical and desirable for regular service. The mechanism of an air motor being similar to that of the steam engine is quite as reliable and has the same range of speed and power.

The Compressed Air Co., of New York, has extended its field of operations and is preparing to build mining locomotives; its later designs of street car motors have the running parts made heavier than in the earlier types.

**TO EXPEDITE TRAFFIC.**

A communication to the London Daily Mail suggests that foreign street railways have troubles of their own as well as those in many American cities. A coronation visitor staying in London described a trip by the electric street car that runs westward from Hammer-smith. Throughout the trip the car was constantly impeded by farm wagons which were loaded roof high and on which the drivers appeared to be asleep, as it took four or five rings of the alarm bell before they appeared to even notice it. When the drivers thought they would like to let the car pass they turned out of the track at such a small angle that it carried their wagons some 100 yards ahead before the rear wheels were clear of the line. The writer suggested that what it wanted on that line for about a week is an armored train. The cars should be given one alarm bell and if there is no response, then shoot.

**STORAGE BATTERY CARS PROHIBITED IN GERMANY.**

The Zeitschrift für Kleinbahnen for May states that a few months ago the authorities in Berlin and Hagen, Germany, forbade the use of accumulators in street cars. On April 7th the police department of Hanover followed with a decree peremptorily ordering the Hanover Street Railway Co. to remove storage batteries from the street cars of Hanover and Linden within a year from the date of the order. The decree declares accumulators are unsafe and dangerous for this service on account of containing materials which threaten the health and lives of passengers with explosions and conflagration. The alleged dangerous character of the accumulators has not yet led to any serious disasters, but the authorities apparently consider it their duty to forestall any such trouble. The street railway service in Hanover was often unsatisfactory in bad weather and accidents of a minor nature occurred frequently. The Hanover company has been given four weeks to come to an understanding with the municipal authorities about a new way of applying electricity as a motive power for the cars. If it is decided to use an overhead system then the necessary construction work must be completed within a year, and if it is found impossible to reach any agreement with the municipal authorities within four weeks the matter must be at once referred to the courts and the term of one year will date from the time of the court decision. In case any legal action should become necessary against owners of property to which electric wires are to be attached the limit of one year will be extended so as to make up for the time required for such action. Press reports state that there is little prospect for an amicable agreement with the municipal authorities and it is predicted that the courts will be called upon to settle the matter. The decree practically ends the use of storage batteries in Germany. In Prus-

FIG. 2 COMPRESSED CAR IN FLOODED STREET.

sia there is but one company that is still permitted to retain them and in this case their use is partially restricted.

**OUTINGS IN CLEVELAND.**

The outing department of the Cleveland Electric Railway, which is operated under the management of Mr. J. W. Butler, has issued an artistic pamphlet descriptive of the many beautiful neighborhoods which are passed on the various routes of this company. The work is copiously illustrated with views in the principal business and residence districts as well as rustic scenes in the parks and suburbs which are reached by these lines and the several suburban roads with which they connect. The company has 131 miles of track, which reaches all points of interest in Cleveland, and the transfer system is very liberal, permitting passengers to reach almost any destination in the city for a single fare. The company makes a business of special trolley car service and of booking picnics and societies, etc., for the pleasure resorts and public parks in and about Cleveland.

## THE REQUIREMENTS FOR THE PARALLELING OF ALTERNATORS AS VIEWED BY THE ENGINE BUILDERS.\*

BY HENRY E. LONGWELL.

The parallel operation of alternating current generators direct connected to reciprocating engines, has, during the past five years, been the subject of many learned discourses, by many learned electricians. Awed by the formidable array of mathematics, Greek letters and scientific terms, we engine builders have sat humbly at the feet of the masters hoping vainly that there might be let fall some crumb of knowledge that we could assimilate and thereby progress—be it ever so little—towards a reasonable comprehension of the matter.

What the problem needs for its complete and final solution is the advent of another Admirable Crichton, in whom the highest knowledge of electrical and mechanical science will be combined. Failing this, the solution must be the joint work of two or more individuals, with different training and different ways of thinking, and consequently the problem of paralleling alternators is now, and doubtless will be for years to come, complicated with the additional and perhaps equally difficult problem of paralleling brains.

It is not the intent of this paper to advance any unailing recipe for making alternators run in parallel, but rather to call attention to the fact that there are certain things which the electricians have not told us that would be helpful to us if we knew them, and that some of the things they have told us are wrong, and further, to suggest that there is a broader line of investigation than has been generally followed, which will include the action of the generator on the engine, as well as the action of the engine on the generator.

The electrician starts out with the assertion that no electrical question is involved. The stereotyped formula is that "if the alternators are run at uniform speed, and at the same frequency, the paralleling will take care of itself." This we concede without argument, for the reason that it does not have anything to do with the practical case and consequently it makes no particular difference whether it is true or not.

If the prime mover is to be a reciprocating engine, the speed will not be absolutely uniform. It will vary during a single revolution, owing to the irregularity of the tangential effort on the crank pin, and it will vary from revolution to revolution because automatic governing is only a series of approximations above and below the mean speed. This is the actual condition we have to meet, and it is time wasted to discuss ideal and impossible conditions. Admitting that these irregularities, which must exist to a greater or less degree, create certain electrical disturbances in the generators, it must be conceded that these electrical disturbances are communicated from one generator to another, and that there is a resultant reaction back on the engine. It is not enough for the engine designer to merely consider the action of his engine as an independent unit; it is equally necessary that he should have knowledge of the character of the reaction from the generator.

To put the problem of parallel operation before us in kindergarten form so that it could be readily grasped by the purely mechanical mind, we have been told that the whole thing is analogous to, and quite as simple, as running two or more independent engines connected by gears to a common line shaft. It undoubtedly is—almost.

There are to-day quite a considerable number of installations which by dint of strenuous effort blindly applied, and more or less good luck have been made to operate in parallel quite satisfactorily, but as to the reasons for success or failure, opinions have differed so widely that it may be safely said that there is no theory that is not open to attack from some points or other. Some authorities will tell you that dash pots on the governors did the business. Others that the turning moment of the engines was improved; still others will say that the use of copper pole tips or dampers on the generators is what turns failure into success.

I have in mind a certain large installation in which the early attempts to parallel the alternators were far from successful. Shortly afterward the plant was operating in parallel regularly and satisfactorily. I made special inquiry as to what had been done to bring about the result, and my informant said: "Nothing so far as the

apparatus is concerned; we have just learned how to do it,—that is all."

It is perhaps worth while to consider whether or not the expertness of the operator may be a more potent factor than we have hitherto believed.

In a great many instances the difficulties experienced in paralleling alternators have been more or less completely overcome by tinkering with the governing mechanism on the engine, and consequently it has become fashionable to say that the troubles originate in hunting, oscillating, or otherwise faulty governors. This, however, is an unfair statement. Coincidence and cause are two entirely different things. The interaction between the generators is not necessarily caused by the hunting or oscillating of the governors, even though both phenomena are co-existent, and even though the latter tends to aggravate the former.

A more fair statement of the case is, that the parallel operation of alternators imposes a duty on the governing mechanism of the engine, which is abnormal and which is directly opposed to its natural function.

The natural function of a governor is to regulate the supply of motive fluid in proportion to the load. If we have two engines driving alternators in parallel, and, by reason of small speed variations, which we might as well frankly admit are unavoidable, one generator advances ever so little ahead of the other, it takes more load. To restore equilibrium we ought to be able to reduce the steam supply to the engine that is leading and to increase the supply to the engine that is lagging behind. Now the natural tendency of the governor is just the opposite; i. e., to increase the steam supply to the heavily loaded engine and make it capable of taking more load, and to decrease the steam supply to the underloaded engine and make it less capable of taking its share of load. Furthermore, the nearer perfect the governor is as regards the performance of its natural duty, the more promptly and vigorously it does the right things at the wrong time.

Obviously a governor unless endowed with intelligence, cannot assist parallel operation, and the best we can hope to do is to hobble it in such a way as to make it offer as little opposition as possible. In other words, we must sacrifice as far as is safe, all the qualities that have hitherto been regarded as synonymous with excellence, and make the governor so that it will not act quickly under any circumstances, and will not respond at all to moderate changes in load or speed. Hence, dash pots, friction brakes, etc., not because the governor is faulty, but because we must needs make it so to prevent its resisting the contradictory demands of the electrical part of the plant.

No properly designed governor on an engine in any service other than that of running alternators in parallel requires any of these retarding devices, and their presence ordinarily would be an open confession of faulty design.

As regards the required degree of uniformity of angular speed, a common specification issued by one of the leading manufacturers of electrical machinery reads as follows:

" \* \* \* Variations of the rotating part of the generator through the revolution at any constant load not exceeding 25 per cent overload should not exceed one-sixtieth of the pitch angle between two consecutive poles from the position it would have if the motion were absolutely uniform at the same mean velocity. \* \* \* The maximum allowable variation is the amount the rotating part forges ahead plus the amount which it lags behind, the position of uniform rotation is therefore one-thirtieth of the pitch angle between two poles. Generally this is obtained by the use of a heavy fly-wheel."

Another manufacturer makes these limits one-seventysecond and one-thirtysixth respectively.

This requirement presents no particular difficulty, except in the case of slow-moving engines coupled to generators of high frequency where the fly-wheel weights assume proportions that are fearful to contemplate.

The mathematical processes whereby the requisite fly-wheel weights are determined have been so frequently and so ably set forth by various writers in recent years that it would be superfluous to interpolate them here.

In certain instances we have made the angular variation within the specified limit, and even with the governor made as faulty as is safe, the paralleling has been unsatisfactory. Our electrical associate does not say that perhaps his specification was faulty, but

\*A paper read before the Engine Builders' Association of the United States, at the annual meeting held in Pittsburg, Pa., May 22 and 23, 1902.

insists that the variation is not within the required limits. Then there is a dead lock. We have had nothing to submit but calculations, and the electrical engineer holds that figures do not weigh at all, as against the observed electrical phenomena. We are now, however—thanks to Mr. P. O. Keilholtz, of Baltimore—on a firmer footing. Mr. Keilholtz has perfected a method of actually measuring the angular variation throughout the revolution, which method seems to give satisfactory and conclusive evidence of what actually occurs, and it is gratifying to note that the measured departures agree very closely in time and extent with the calculations.

This matter is set forth in a complete and interesting manner in a paper read by Mr. Keilholtz at the 157th meeting of the American Institute of Electrical Engineers in New York City, October 25th, 1901.

Knowing that the specified departure from uniform rotation does not always insure success, we are led to make inquiries as to just what is the object of this specification and to wonder whether it may not be faulty or incomplete, and whether it may or may not be subject to modification on account of varying electrical characteristics in different generators.

In a paper read before the meeting of the American Institute of Electrical Engineers above referred to it is stated in substance that the object of the specification is to limit the amount of cross current that can flow between the generators. With a displacement of one-seventysecond of the pitch angle between two poles, ahead or behind the position corresponding to uniform mean speed, two generators might be coupled together in parallel at the instant when the relative positions of the cranks of the two engines would be such that one generator would be the maximum distance in advance, and the other generator the maximum distance behind the position corresponding to uniform rotation. In this event, the two generators might have a maximum relative displacement of one-thirtieth of the pitch angle between two consecutive poles. With this displacement it is stated that the cross current will be 10-15 per cent of full load current, provided the electrical characteristics of the alternators are such that the short circuit current is  $2\frac{1}{2}$  times full load current.

Now we find that for various reasons—constructional or otherwise—alternators are actually built giving short circuit currents as low as  $2\frac{1}{2}$  times full load current, while others are known to give as much as six times full load current on short circuit, and all of these are supposed to come within the limits of standard representative practice.

If between the generators giving  $2\frac{1}{2}$  times full load current on short circuit when displaced one-thirtieth of the pitch angle between two poles, the cross current is 11 per cent of the full load current, then the cross current between the generators giving six times full load current on short circuit when the phase displacement is one-thirtieth of the pitch angle between two poles—which displacement is allowable under the more liberal specification—would be a little over 31 per cent of the full load current—a ratio of nearly three to one.

If the amount of cross current allowable is a very important matter, it does not seem reasonable that the manufacturer of alternators should put out an invariable specification to cover the requirements of generators which differ so widely.

If 31 per cent cross current is allowable, why should the engine builder be burdened with the expense of making a fly-wheel to give a displacement which will cause only 11 per cent cross current? If, on the other hand, 11 per cent cross current is near the allowable limit, why should the engine builder be blamed when the generator builder furnishes machines that will give 31 per cent cross current with the specified displacement?

We are next led to inquire what is the effect of the cross current and we learn that it represents "synchronizing force" or the tendency of the generators to pull each other into step if the phases are displaced. We also learn that the force is such a percentage of the full load torque of one machine, as the cross current is of the full load current.

For example, in a generator having a full load capacity of 750 kw. which is approximately 1,000 electrical horse power—running at 100 revolutions per minute, the full load torque, or the resistance offered by the load would be approximately 10,000 lb. applied at a radius of 5 ft. 3 in.

With two such units in parallel, if the phase displacement is such that the cross current is 20 per cent of the full load current of one

machine, then the force tending to pull the machines into synchronism is equivalent to that of a spring tensioned to 2,000 lb., and connecting the two generators at radial points 5 ft. 3 in. from their respective centers.

If the total load of the two generators is 2,000 h. p., we may consider that with this amount of cross current flowing one generator is carrying 1,100 h. p. and the other only 900 h. p.; or that the resistance at 5 ft. 3 in. radius is reduced to 9,000 lb. in one generator and increased to 11,000 lb. in the other.

If the two generators are running in parallel without outside load, then with the same displacement we may consider that there is an actual magnetic attraction between the two machines equal to a force of 2,000 lb. applied at the radius mentioned.

We have been told that this synchronizing force is what makes paralleling possible and that the more we have of it the better; we are told that it checks the displacement of the rotating parts of the engine resulting from the irregular crank pin effort, and that with great synchronizing power in the generators, it requires a decided effort on the part of the engines to prevent the generators running well in parallel.

This looks so plausible that we have for years accepted it against the evidence of our senses, when in fact there is just one small grain of truth in it, i. e., that some synchronizing force is necessary to make paralleling at all possible.

Synchronizing force is not one of the few goods things one cannot get too much of.

Synchronizing force cannot pull two generators into phase and hold them there any more than the force of gravity can pull an ordinary pendulum to the vertical position and hold it there. If we displace an ordinary pendulum to one side of the vertical position and release it, the force of gravity tends to pull it to a vertical position and to resist its going beyond that position, yet were the force ever so many times as great as it really is, it could never bring the pendulum to rest without the intervention of some extraneous force like friction or the resistance of the air.

If we have two masses in space connected by a spring capable of extension and compression, and if we displace these masses with respect to each other so that the spring is under stress, these masses if released would approach and recede from each other forever if subjected to no other forces, the amplitude of the motion depending on the primary displacement, and the period on the relation between the spring force and the masses.

The action of the synchronizing force between the alternators is analogous to the action of gravity on the pendulum, or to the action of the spring connecting two otherwise free masses as in the illustration cited above. The synchronizing force tending to check the relative displacement between the generators exists only after the displacement has occurred; when the generators are in phase the force is nil, and consequently there is nothing to hold them there.

I believe I am saying something new when I make the assertion that in every practical case, the effect of the synchronizing force of the alternators is to increase the irregularity of the angular speed of engine instead of to diminish it.

On first consideration this proposition seems absurd, but nevertheless it is capable of being demonstrated practically as well as mathematically.

The matter first suggested itself to me some two years ago in connection with the paralleling of some alternators in which the synchronizing power was rather large. The synchronizing force in an alternator can be varied by increasing or decreasing the field current, and in consequence, the voltage of the machine, and in these particular machines which were of the two-phase type, the synchronizing force could also be greatly reduced by running the machines with only one phase connected in circuit.

Some difficulty was experienced with the paralleling at the start, and a rather extensive line of experimental work was undertaken in the endeavor to locate the trouble and to overcome it. Having a tank load available, these experiments could be carried out independent of the demands of the regular lighting service, and consequently we were able to observe the action of the machines over any desired range of load and voltage. It was found that when the generators were run in single phase, they would parallel very satisfactorily, but when the second phase was cut in, the cross current would increase and quite serious transfers of energy would take place between the machines. At that time it was authoritatively denied by electrical engineers of high standing that any two-phase

machine would ever parallel more readily on one phase than on both, now, however, I believe the fact is freely admitted.

It was also determined beyond question, that by lowering the voltage to 80 per cent of the normal—or in other words decreasing the synchronizing force 20 per cent, the action of the machines in parallel was not open to criticism, even when running with both phases connected up.

The repetition of these experiments a sufficient number of times to determine that the observed phenomena were not accidents, but were in accordance with some fixed law, made it quite apparent that at least over the range covered by the experiments, the difficulties in paralleling increased with the synchronizing force of the generators.

Irrespective of whether a correction of the trouble could be effected by decreasing the sensitiveness of the governor, or improving the turning moment of the engine, or doing both simultaneously the indisputable fact remains that with the original engine performance a variation of 20 per cent in the synchronizing power made the difference between success and failure in operating the generators in parallel, and this seems to indicate the utter fallacy of specifying the same characteristics in the engine for alternators in which the synchronizing force may differ by two hundred or even three hundred per cent.

The fact that the synchronizing force does, under all ordinary conditions, increase the angular variation in the engine may be shown theoretically in a general way without recourse to any abstruse mathematics.

Fig. 1 represents a typical diagram of crank forces in a single crank double acting engine. A, B, represents the path of the crank pin for one revolution, and the ordinates of the curve represent to some chosen scale the tangential pressure on the crank pin at the corresponding point in the revolution; the area included between the curve and the base line A, B, represents the work per revolution in foot pounds.

A, C=B, D represents the mean resistance of a uniform load reduced to the radius of the crank, and neglecting friction the area of the parallelogram A, C B, D also represents the work per revolution in foot pounds.

The shaded portions of the area included between the lines C D and the curve if above the line C D, represent in length the portion of the revolution in which energy is being stored up in the fly-wheel and in area, the amount of this energy in foot pounds. In like manner the shaded areas below the line C D represent the portion of the revolution in which the stored energy is being given up by the fly-wheel, and the amount of this energy.

While the crank is passing from E to G, the fly wheel is absorbing energy and its velocity is increasing. Consequently at G, after having taken up the last foot pound of available energy, the velocity will have reached a maximum, and will then begin to decrease from G to I while the wheel is giving up energy, becoming a minimum at I; similarly other maximum and minimum points will be found at L and E. By mechanical integration of the curve in Fig. 1 referred to the base line C D we obtain a second curve, Fig. 2. The ordinates of this curve measured from the base line A, B, representing uniform mean velocity indicate the velocity of the crank pin above and below the mean velocity. The scale of these ordinates depends on the mass and radius of the fly wheel.

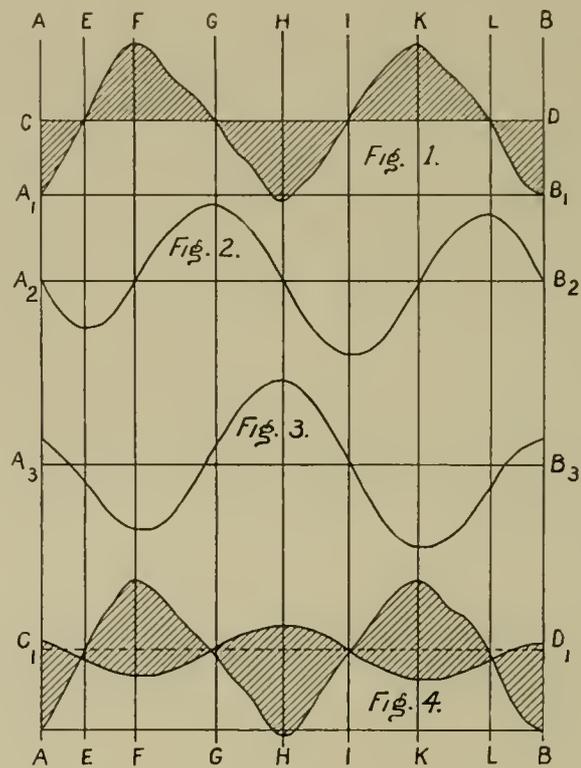

Referring to the velocity curve Fig. 2, it will be noted that the velocity is less than mean from A to F, and consequently at the end of this period, at the point F, the crank pin will be at a maximum distance behind the position corresponding to uniform angular speed. From F to I, the velocity is above the mean, and consequently at the point I the crank pin will be a maximum distance ahead of the position corresponding to uniform angular speed, and so on.

Integrating the velocity curve referred to the base line A, B, we therefore obtain a third curve, Fig. 3, the ordinates of which referred to a base line A, B, drawn midway between the highest and lowest points in the curve, represent the departure at any point in the revolution from the position corresponding to absolutely uniform angular speed.

It will be noted that the displacement curve, Fig. 3, and the curve of crank pin forces, Fig. 1, have a general resemblance in shape, in that each has the same number of nodes; but the nodes of one curve are directly opposite to those of the other. In other words, when the crank pin effort is above the mean and the surplus energy is accelerating the rotating masses, these masses are always behind the position corresponding to uniform angular speed, and when the

crank pin effort is below the mean and the rotating masses are being retarded, these masses are always in advance of the position corresponding to uniform angular speed.

Now let us consider the effect of the synchronizing force of the generators. For simplicity we will assume that the engine driven alternator is coupled in parallel with a number of turbine driven alternators running at absolutely uniform speed, and that the total mass of these alternators is such that the synchronizing force can effect no appreciable change in their velocity. Whenever the steam driven alternator is behind the position corresponding to uniform angular speed, the synchronizing force tends to accelerate the rotating masses, and whenever it is in advance of the position corresponding to uniform angular speed, the synchronizing force tends to retard the rotating masses. The intensity of these accelerating and retarding forces is represented at any point in the revolution by the ordinates of the displacement curve, the scale being proportional to the synchronizing power of the generator. It will therefore be readily seen that the synchronizing force acts in unison with the crank pin force. During the period of the revolution in which we have a

surplus of crank pin effort, this surplus is augmented by the synchronizing force, and during the period in which there is a deficiency of crank effort this deficiency is further augmented by the synchronizing force.

This may be shown graphically in Fig. 4, in which the crank effort curve is reproduced from Fig. 1 and the line of load resistance instead of being represented by a straight line is represented by a curve of the same general form as the displacement curve, indicating the change in load during the revolution, due to the synchronizing force. The shaded areas in this diagram illustrate the unbalanced forces resulting from the combination of the crank pin and synchronizing efforts. It will be noted that the unbalanced forces are very much greater than those due to crank pin effort alone, and as these unbalanced forces are the cause of the departure from the position corresponding to uniform angular speed, it is evident that whatever increases these unbalanced forces, will increase the variation from uniform speed.

The calculation of the exact amount by which the synchronizing force increases the displacement is a tedious and somewhat involved mathematical process. It is necessary to compute the displacement from the force diagram, and after finding the value for the synchronizing force, to construct a new diagram combining the two

forces, and compute the displacement corresponding to the new force diagram. This process must be repeated until no appreciable increase in the displacement curve is found.

As stated previously, the effect of the synchronizing force between the alternators is analogous to that of a spring capable of both extension and compression, and considered apart from all other forces, will produce an oscillation of the rotating masses, the period of which oscillation depends on the intensity of the synchronizing force and the magnitude of the masses.

The period of this oscillation has a very important bearing on the amount the angular displacement is augmented by the synchronizing force. With a period which I believe corresponds with the time of one revolution of the engine, the angular displacement seems to be increased indefinitely. As this natural period of oscillation is increased or decreased from the critical period, the effect of the synchronizing force on the displacement seems to decrease.

Of course if the synchronizing force were infinite, we would have the same effect as if the generators were solidly linked together, and the actual displacement would be the mean of the individual displacements of the several units in parallel, and would be less than that of any unit running independently. There is also perhaps a period of oscillation between the critical period, and an infinitely short period, which would not increase the displacement, and doubtless as the period decreases from the point, the displacement would decrease. I have however at the outset limited the general proposition to practical cases and these are not practical. The rotating masses must of necessity be of such magnitude that it is impracticable to have a synchronizing force sufficiently large to cause oscillations having a period much if any less than the time of one revolution.

I shall feel happy if I have succeeded in indicating a new line of investigation in connection with this troublesome problem, and shall be content to leave the investigation itself to those who are more able to carry it out to a finish.

I shall feel doubly happy if I shall succeed even in the smallest degree in making it plain to the electrical fraternity that the electrical, and the dynamic features in the case are so inter-related that real knowledge can come only when the electrical engineer and the mechanical engineer drop all petty differences and co-operate with each other in the most frank and hearty manner.

As long as one is expected to blindly and unquestioningly follow the dictates of the other, successful paralleling will be by accident rather than design.

The whole matter is one of compromise. Let it be freely admitted that the irregularities in the action of the engine do set up electrical disturbances. The reciprocating engine will always have an irregularity in angular speed and consequently electrical disturbances are inevitable. The engine builder can control the amount of this irregularity to a certain extent, but he is barred by constructional and commercial limits from reaching absolute perfection.

On the other hand, the electrical disturbances react on the engine augmenting the inherent irregularities in the latter, and the intensity of this reaction is within certain limits under the control of the electrical engineer.

It is therefore only when the engine builder and the electrical engineer each recognize the limits beyond which the other cannot go, and each endeavors honestly to make the task of the other as easy as possible, with due regard to the commercial excellence of the direct connected unit as a whole, that we may hope that the parallel operation of direct connected alternators will cease to be a subject for discussion.

### PROJECTED ELECTRIC RAILWAY IN SPAIN.

A report from Consul General Julin G. Lay at Barcelona states that a royal decree of March 7th grants a concession to Don Teodoro de Mas y Nadal to construct an electric railway between the towns of Vich and Amer within the next six years. A memorandum of the project is filed in the Bureau of Foreign Commerce showing in detail the estimated cost of construction, the material required, water power available, and plans and profile of the road. The estimated capital for building this road is given at about \$1,200,000. This has not yet been subscribed but there is little doubt that Senor Mas will be successful in securing foreign capital for putting this road in operation. Contracts for this road will not be considered

until the capital for its construction is subscribed, but Consul Lay advises that manufacturers of electric railway equipment keep in touch with Senor Mas and communicate with him in Spanish at Vich, Spain.

### KANSAS CITY NOTES.

A number of interesting changes have been made in regard to the Metropolitan Street Ry. since May 6th, when the new president, Mr. Bernard Corrigan, took charge of the company. One of these was the abolishing of all passes. Heretofore the company has furnished books of tickets to a large number of people, and while the outstanding books were not called in, all the books on hand were destroyed so that there are none to replace the old ones as they run out. No one is riding free in Kansas City now except employees of the company, policemen, firemen and charity nurses. This action has met with the approval of both the public and the press. Beginning June 5th a universal transfer system was inaugurated by the company. Transfers are given and received at every intersection of the line except where they would enable the passenger to "loop" back to his starting place. The new system adds somewhat to the transfer privileges heretofore enjoyed.

The merit system of discipline was put in effect on the Metropolitan line June 1st and a list of merits and demerits has been posted at each car barn with a notice explaining the operation of the system. So far the merits range from 1 to 50 and the demerits from 1 to 100. When a man is given several merit or demerit marks he received a slip in a sealed envelope telling him the time, place and date the accident occurred and the number of mark received. Another slip is posted at his reporting place giving the same facts but omitting the name of the man. When a man has received 100 more demerit than merit marks he is liable to discharge. This system is considered by both officers and men to be a great improvement over the "lay off" system which has previously been in force.

May 31st the employees of the Metropolitan remembered the former president and the general manager, Messrs. W. H. and C. F. Holmes, in a very pleasing way. During the afternoon of that day as many of the officers and employes as could be spared from their work assembled at the offices of Messrs. Holmes and presented each of them with a large group picture of all the officers and heads of departments of the company handsomely framed. The group contained 34 portraits, in the center of which were those of W. H. and C. F. Holmes, the retiring president and general manager, and around this were grouped all the other officers of the road. Many of the men had worked under the former management for more than 20 years. In addition to the picture they were presented with a valuable watch and fob, the latter being set with a large diamond. The recipients made proper replies to the presentation speeches and at times they displayed much feeling when referring to many pleasant instances of the past. The money for the purchase of the present was subscribed by the employes, and the gift was participated in by every one, from the highest to the most obscure positions.

### WHEELING AS A TRACTION CENTER.

The city of Wheeling, W. Va., is rapidly becoming the center of a network of electric railways which radiate in a number of directions from this center. The lines which are built and building reach a population of over 100,000 people and include the Wheeling Traction Co. extension to Steubenville and a new line to St. Clairsville, the Pan Handle Traction Line now being built to Wellsburg and Lazeurville and the Wheeling and Elm Grove extension to West Alexander, Pa. The places reached by these lines include Wheeling, with a population of 46,000; West Alexander, 800; St. Clairsville, 2,500; Elm Grove, 800; Triadelphia, 500; Bellaire, 11,000; Bridgeport, 8,000; Shadyside, 500; Paltney Bottom, 500; Benwood, 6,000; McMechen, 2,500; Glendale, 300; Moundsville, 5,500; Martin's Ferry, 8,000; Tiltonville, 500; Short Creek, 100; Beech Bottom, 200; Wellsburg, 4,600; Warrenton, 500; Brilliant, 2,000; Mingo Junction, 6,000; Lazeurville, 1,000; Steubenville, 10,000.

Contracts aggregating \$500,000 have been awarded for the equipment required for the proposed street railway system at Dallas, Tex. The St. Louis Car Co. will furnish 20 cars, and the General Electric Co. the generators and electrical apparatus.

## SECOND INTERNATIONAL TRAMWAYS AND LIGHT RAILWAYS EXHIBITION.

The second International Tramways & Light Railways Exhibition will be held at the Royal Architectural Hall, London, July 1st to 12th. The first of these exhibitions which was given under the auspices of the Tramway & Railway World was held in July, 1900. As announced at that time the utility of a well organized exhibition both to the street railway industries and the trade was suggested by the excellent service performed by the exhibition held annually by the American Street Railway Association.

Soon after the close of the first exhibition, which proved a most successful one, it was announced by the promoters that it would not be repeated for three years, but in the autumn of 1900 a new circumstance arose which led to the date of the second exhibition being fixed for July of the present year. An invitation was extended to the Union Internationale Permanente de Tramways by the promoters of the Light Railways Association to hold its twelfth biennial congress in London in 1902. The council of the Union expressed a desire that the tramways exhibition should be repeated at the time of the congress and on the assurance that this would be done if practicable, the invitation was accepted. The promoters of the exhibition found on communicating with a number of prominent manufacturers that the exhibition this year would be generally acceptable and the date was accordingly fixed for the early part of July; the four days' congress will take place on the first four days following the opening of the exhibition.

The success of this exhibition is practically assured, as previous to its public announcement, over 75 manufacturers had secured space for exhibits which included the greater part of the available space in the hall. Since the announcement of the exhibition the list of exhibitors has steadily grown and now comprises over 160 of the leading firms in the street railway industry.

The Permanent International Tramway Union has issued in advance of the meeting a book of 250 pages giving the response made by different member companies to the questions issued as a basis for the reports on current practice.

These questions coming up for discussion at this meeting are:

1. Transfers.
2. Standard and Narrow Gages for Rural Lines.
3. Correct Sizes of Motors and Generators.
4. Brakes.
5. Compensation for Franchises.
6. Obligations as to Paving.
7. Location of Stations.
8. Systems of Traction.
9. Ratio of Car Capacity to Traffic.
10. Central Stations.
11. Best System of Traction for Urban Lines.
12. Heating Systems for Cars.
13. Cost of Power.
14. Carrying Express, Baggage and Freight.
15. Fare Registers.

The first exhibition was recognized to have been the most successful business exhibition ever held in London, and that the second one will be found more successful is predicted from the fact that practically all of the exhibitors of 1900 have expressed their readiness to duplicate their exhibits in 1902, which involves much trouble and an expense by no means inconsiderable on the part of many of them. Both the daily and technical papers have expressed themselves favorably towards the undertaking and there is every reason to anticipate a highly successful affair.

Included among the partial list of exhibitors are the names of a number of American manufacturers, among which may be mentioned the Duff Manufacturing Co., Allegheny, Pa.; the Hale & Kiburn Manufacturing Co., Philadelphia, Pa.; the Ohmer Car Register Co., Dayton, O.; Ohio Brass Co., Mansfield, O.; Roebling's Sons Co., New York; William Wharton, Jr., & Co., Philadelphia, Pa. Mr. F. A. Estep, president of the R. D. Nuttall Co., will also attend the convention.

The official program of the Union Internationale Permanente de Tramways has been published and in addition to the discussion of the subjects mentioned heretofore a number of visits will be made for which invitations have been extended by street railways and other companies in London. The Tramways and Light Railways

Association of London has also tendered the Congress a banquet to be held on the evening of July 4th. The excursions which will be made by the delegates at the convention during the session include visits to the City & South London Ry., the Central London Electric Ry., the Waterloo & Baker Street Electric Ry., the London United Tramways, the London County Council Tramways and the Islington municipal lighting station. At the latter place the mayor and the officers of the corporation have invited the Congress to a breakfast tendered by the municipality.

Besides these excursions, invitations to visit the following places have been received: Messrs. Crompton's electric works, Bank Side electric lighting station, Westminster electric lighting station, Westminster hydraulic power station, Messrs. Siemens' electric works, Doulton's Pottery Works, the Mansion House, House of Parliament, Tower of London, Tower Bridge, etc. Carriage rides from London to Kew and to Richmond, and if time permits, an excursion on the Thames, will be arranged for certain evenings. There will also be arranged for July 5th an excursion to one of the great English industrial centers, probably to Wolverhampton, and the directors of the Dublin tramways have extended an invitation to Congress to visit the tramways and power house of that city.

---

## NEW POWER PLANT FOR CHICAGO.

A plot of land containing over 616,000 sq. ft., situated on the south branch of the Chicago River between Morgan St. and Center Ave. has been purchased by the Commonwealth Electric Co., which proposes to spend from \$750,000 to \$1,000,000 this year and the same amount next year in the construction of the power house. Eventually the company expects to invest in the neighborhood of \$5,000,000 on this tract of land making in this locality one of the greatest electrical plants in the world. When completed it will contain machinery having a capacity of 100,000 h. p., which will be used partly for the Commonwealth Electric Co., and a large portion of it for the Chicago Edison Co., which is not able to keep up with the demand for current even with its present large equipment.

While the area of ground required seems an extraordinarily large one for this purpose, the experience of the Edison company has taught its officers the necessity for providing liberally in advance for future needs.

The machinery for the first 16,000 h. p. to be used in this plant has already been contracted for, and work on the site will be commenced as soon as the details of the business preliminaries are completed.

---

## LOW FARES IN WHEELING, W. VA.

The Wheeling Traction Co. operates a short branch road running from Wheeling to what is known as Wheeling Island. It is a large island in the center of the river and has a population of about 7,000. The total length of this division is about a quarter of a mile. Mr. C. E. Flynn, general manager of the company, states that this road has probably the cheapest fare in the world as people are carried for one cent, or if they buy monthly tickets they secure 100 rides for 50 cents. The cars which operate on this division show a net earning of about \$16 to \$20 per day and after the summer traffic opens this amount will undoubtedly be somewhat higher. This division has only been in operation for about two months and as a result the bridge company which formerly charged 5 cents per round trip to walk over the bridge has been compelled to change its price and is now selling six tickets for 5 cents instead of two for 5 cents as heretofore; but as it is much easier to ride a quarter of a mile for one cent than it is to walk for the same price, it is probable that this reduction in fare will not interfere with the traffic of the cars to any extent. The railway company pays the bridge company about \$16,000 a year for bridge tolls.

The Chillicothe (O.). Mt. Sterling & Columbus Electric Ry. is now under construction, and progress is being made toward its completion. Isaac S. Cook is president of the company.

The United Railways & Electric Co., of Baltimore, is receiving the first consignments of the 110 new summer cars which have been ordered and will be put in commission of the Maryland Ave., Highlandtown and Dundalk lines.

**SEMI-CONVERTIBLE CARS FOR A GREATER NEW YORK SUBURB.**

The accompanying illustration shows one of a lot of cars now being received by the New York & North Shore Railway Co. from the J. G. Brill Co., of Philadelphia. This type of car, known as the Brill patented semi-convertible, has become so widely and favorably known as a suburban and interurban all year round car that it is not surprising to learn that nearly all the box cars in course of construction at the Brill company's shops are of that

BRILL CAR FOR SUBURBAN LINE.

style. It is a type which appeals to the public no less than the operators in that the car is always prepared to meet every change in the weather without going to the barn.

It is puzzling, even to an expert, to understand how large straight-glass windows are contained in the roof when not in use, without changing the appearance, inside or out, from that of a standard type car. Another feature that is hard to understand is the ease with which the windows are operated; their action is partly automatic, but so simple that it is next to impossible to get them out of order.

The length of these cars over the crown-pieces is 34 ft. 9 in.; width over the sills, 7 ft. 8½ in. and 8 ft. at belt. The interiors are finished in natural cherry with birch ceilings. Spring cane reversible-back seats for 36 persons are placed transversely.

Another lot of cars included in this shipment are 14-bench open, 39 ft. 4¾ in. over the crown-pieces, 6 ft. 9¾ in. wide over the sills, and 7 ft. 5 in. at the belt. All the cars include in their equipments the following Brill patented specialties: Angle iron bumpers, Dedenda gongs, radial drawbars and ratchet brake handles, and the open cars have round-corner seat-end panels. The trucks are Brill "Eureka" maximum traction which carry the car bodies as low as four wheeled trucks.

**MOVING PLATFORMS FOR THE BROOKLYN BRIDGE.**

Mr. Julien T. Davies, of the firm of Davies, Stone & Auerbach, attorneys of New York City, has made a proposition to the city of New York on behalf of the Multiple Speed & Traction Co., of Chicago, for the installation of a moving platform on the Brooklyn Bridge and other bridges across the East River. The proposition has been referred to the New York Rapid Transit Commission which now has it under consideration. Arguments in support of the proposition have been made by Mr. George S. Morison, the eminent civil engineer, and Mr. Walter D. Edmonds, a prominent patent lawyer of the city of New York. The chief engineer for the Multiple Speed & Traction Co. is Mr. Max E. Schmidt.

**AMERICAN PRODUCTS FOR EUROPE.**

In the rebuilding of the Royal Warehouses in Antwerp, Belgium, the Belgian Government has awarded to the Kinnear Manufacturing Co., Columbus, O., the contract for 422 "Kinnear" steel rolling doors. As this group of warehouses is considered one of the finest in Europe, the award to an American firm may be considered another instance of the progress of American standards.

**NORWALK HOLLOW TROLLEY WHEEL.**

The accompanying illustration shows the hollow trolley wheel now being placed on the market by the Norwalk Brass Co., of Norwalk, Conn.; special attention is directed to the large oil receptacle provided by making the hub hollow between the bearings. The company is also an extensive manufacturer of solid wheels. It makes a specialty of properly inserted bushings, and standard bearings and an excellent non-friction Babbitt are at all times carried in stock. The Norwalk Brass Co. has a special process for

NORWALK TROLLEY WHEEL.

making brass, aluminum, phosphor, Tobin and manganese bronze, and does a large business in rough and finished castings for marine and stationary engines, launches, automobiles, etc.

**DELANEY CHEMICAL FIRE EXTINGUISHER.**

The Delaney Oil & Lubricant Co., of Milwaukee, Wis., calls attention to the "Delaney" fire extinguisher which has proved to be very effective and is highly recommended by those who have used it. This extinguisher consists of a metal tube 2 in. in diameter and 22 in. long filled with a dry powder. At the upper end is a cover having a ring for hanging the extinguisher at the most convenient point; when needed the tube is pulled away from the cover and is ready for use.

The chemicals with which the tubes are filled, when thrown with force into the fire, produce gases which do not support combustion and the fire is blotted out, so to speak. In case of a chimney fire the powder is thrown on top of the fire in the stove and the gases generated pass up the chimney, extinguishing the fire; in kettle fires the powder is thrown on the surface of the burning fluid, and is particularly successful in this class of fires where the use of water or other fluids would increase the danger by spreading the fire.

The fact that the powder used is neither poisonous, explosive or corrosive is urged as an advantage when this device is compared with extinguishers using liquids.

Mr. J. H. Lancaster, secretary of the Fairmont & Clarksburg (W. Va.) Electric Railroad Co., advises us that the company expects to complete its 28 mile interurban by August 1st. Two power houses will be erected and two 400 kw. Westinghouse generators installed. The Jewett Car Co., Newark, O., will furnish the cars. The Fairmont & Clarksburg company obtained its charter in June, 1900. It has an authorized capital stock of \$1,000,000, of which \$500,000 has been issued. Eight miles of the proposed system are in operation, a part having been opened for traffic in May, 1901, and another in April, 1902.

### REMODELED DIRECT CONNECTED UNITS.

The Chicago City Railway Co. is preparing to change two simple Green-Whelock engines, built originally for cable service, so they can be used for driving two 650-kw. General Electric railway generators. Each of the two engines, which were formerly parts of a twin engine, will be fitted with an 80,000-lb. fly wheel and a 21-in. hammered iron shaft, the generator being mounted directly on this main shaft. The engines have cylinders 32x60 in. and are rated at 1,250 h. p. at 80 r. p. m. taking steam at 125 lb. It will be noticed that the generators are considerably smaller in capacity than the capacity of the engines, but this arrangement was made necessary by the small diameter of the main engine bearings, these being but 17½ in., and it was feared heavier generators would cause trouble in these bearings. The engines were built to run 60 r. p. m. when geared to the cable machinery, but the speed will be increased to 80 r. p. m. for this directly connected electric service. All the parts necessary to effect the change will be supplied by the Filer & Stowell Co., of Milwaukee. The remodeled units will be installed at the 21st and Dearborn St. power house of the Chicago City Ry.

### DOUBLE DECK STEPHENSON CAR.

The double deck closed car illustrated herewith is one of a number recently shipped by the John Stephenson Co. to Cheltenham, Eng., and is a modification of a type which is very popular in that country. It will be noticed that the stairways are reversed and enclosed so that in descending the passenger is entirely protected and cannot be thrown from the car as is possible when the stair faces outwards. The stairway has steel steps and a bronze hand rail and this arrangement is such as to form an efficient brace for the roof. It effectually prevents the longitudinal swaying which is noticeable in cars of this class. The design for the body frame is considerably stronger than that of the regular English type. There are four windows on each side with three large window posts. This strengthens the roof and makes a much stiffer construction than the old style which has only two windows and but one post between the corner posts. The bottom frame is of oak throughout

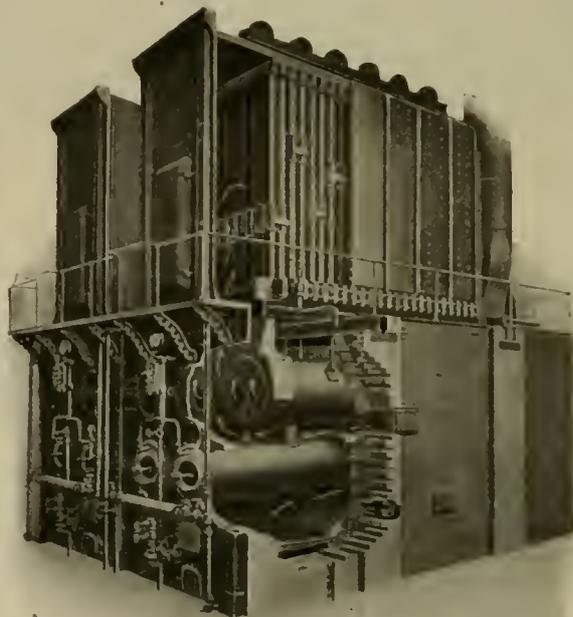

STEPHENSON CAR FOR CHELTENHAM, ENG.

finished with brass tie rods and corner irons. An iron dasher extends around the front of the platform and is connected with the body by a piece of grille work. The roof has a seating capacity for 26 passengers and the lower deck seats 20 passengers. Garden seats are used on the roof. These are made of slats with a single bar back and are of the Kling patent reversible style, arranged so that a dry surface is always available for the passenger. This is of importance in a climate like that of England where rain is frequent and the seats are without protection. The interior seats are longitudinal and are upholstered with springs and hair and covered with crimson plush. The interior finish is hand carved mahogany and the moldings throughout are carefully rounded so as not to collect dust. The trimmings are of bronze and the sash have bronze stiles with mahogany rails. The windows are all of polished plate glass;

the curtains are of the spring roller pattern and on each window post are buttons for signalling the conductor. Alarm gongs and signal bells are placed on each platform and the cars are also provided with sand boxes and electrical head lights. The window panels are decorated with the coat of arms of the city of Cheltenham, while the name of the company fills the lower panels.

### THE AMERICAN WATER TUBE BOILER.

A novel combination of small steel shells with the ordinary fuel economizer is here made to form a water tube boiler occupying comparatively small floor space and possessing many features for which considerable superiority is claimed over other well known types. The illustration shows the arrangement of a double-deck boiler, the two lower and smaller shells without tubes of any kind, the upper one with two tubes located below the water line, and the

TWO 250-H. P. BOILERS IN BATTERY.

whole surmounted by an American fuel economizer through which the gases pass on their way to the chimney. A diaphragm of fire-brick located immediately above the lower shells places the latter in an envelope of the hottest gases directly above the fire and forces the gases to traverse the full length of these shells before passing upward and forward along and around the upper shell. The lower shells are entirely filled with water, the water line, as already noted, being about midway of the upper shell, above the flues. The absence of tubes obviates some of the usual difficulties experienced in tubular boiler maintenance, and the small size of the shells affords greater strength or thinner plates for equal pressures.

The gases of combustion passing to the chimney through the economizer tubes give up much of their heat and reach the uptakes at a very low temperature. The feed water enters at the rear and becomes heated as it flows through the tubes toward the front; thus the gases encounter progressively colder surfaces on their passage through. The greater portion of the total heating surface is in the economizer tubes, and the water reaches the boiler shells at a very high temperature. The economizer tubes are of cast iron, kept clean by the usual automatic scrapers. The scrapings fall into steel pans, which may be flushed out at intervals as required.

The whole boiler is suspended independently of the brickwork on steel beams and columns, suitable castiron fronts are provided, and the usual facilities for access to all parts are given proper attention.

At present the sizes made are of 250 and 300 h. p. The maker is the Bromell, Schmidt & Steacy Co., York, Pa.

**MINIATURE RAILWAYS AT THE CHARLESTON EXPOSITION.**

At the recent Charleston Exposition the lilliputian railways installed by the Miniature Railway Co. undoubtedly comprised one of the most popular attractions and best-paying amusement features on the grounds. The routes touched all points of interest from the Sunken Gardens and the Court of Palaces to the headquarters for hoky-poky, and patrons found these baby trains an indispensable convenience as well as a joyful novelty in the manner of transportation. The outfit consisted of locomotive and tender, with a total length of 9 ft. 6 inches, weighing 1,200 lbs., and cars 6 ft. long and

MINIATURE RAILWAY AT THE CHARLESTON EXPOSITION.

24 in. wide, weighing 125 lbs. each, all as complete in detail and as business-like in aspect as a transcontinental express. The difference, and that's in favor of the Lilliput, is that on this ideal system there are no baggage-men to ladger one, no porters that one must tip, nor any man with a megaphone voice to assail one with magazines and samples of chewing gum. Not since the days of Lohengrin's swan boat and Cinderella's pumpkin coach has a conveyance been invented which, for the fun of the thing, so completely fills the bill.

The Miniature Railway Co., whose address is at 301 Broadway, New York, has issued a catalog giving full descriptions of its various types of diminutive railways and pictures showing them in operation in many of the famous parks throughout the world. The company's exclusive specialty is the manufacture of light steam locomotives of every size and variety of design for any practical gage of track, wide or narrow. The locomotives are well adapted for industrial purposes where ordinary locomotives are unsuitable or too expensive. The logging railroads installed by the Miniature Railway Co. annually haul timber enough to denude 500 square miles, and are generally in use in the southern Atlantic and Gulf states, the northern lake districts and on the Pacific coast.

**WHALOM LAKE AND PARK.**

The Fitchburg & Leominster Street Railway Co. has published a handsomely illustrated pamphlet called the "Whalom Book," which presents typical pictures of Whalom Park, descriptions of which have been published in former issues of the "Review." The scenery in this park is unusually beautiful and the story of the park is well told by the series of illustrations which the book contains. The company takes great pride in the theater which it has operated for several years and the manner in which it is conducted. At present light opera, sung by the Whalom Opera Co., with a change of bill weekly is the attraction offered, and special attention has been paid to novel scenic effects. The popularity of this form of entertainment shows no sign of diminishing and considerable space in this book is devoted to showing the theater and stage settings, which are very elaborate.

The General Assembly of Virginia has passed a bill making it unlawful to expectorate or spit on any part of any street car in that state and providing a penalty of not less than \$1.00 fine nor more than \$10.00 for each offence.

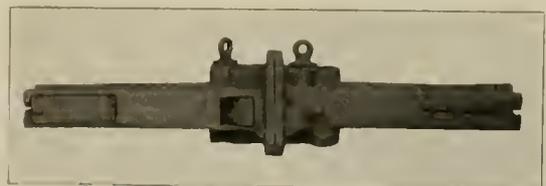

**AMERICAN POWER BRAKES FOR ST. LOUIS.**

After operating its brake for three years on the lines of the Memphis Street Railway Co., and thus demonstrating the good qualities of the device, the American Power Brake Co., of Memphis, Tenn., secured a trial order from the St. Louis Transit Co., equipping six cars. After a thorough test the St. Louis Transit Co. decided to adopt the brake and made a contract for the equipment of the system, and the brake company is now placing the brakes on the cars. The American Power Brake Co. announces its willingness to place brakes on trial, being confident that a service test only is needed to bring out its advantages.

**THE SUCCESS OF VAN DORN COUPLERS.**

The W. T. Van Dorn Co., Monadnock Block, Chicago, is now filling orders for couplings from practically every state in the United States and also from several foreign countries. The Van Dorn coupler has come to be to the street railway what the M. C. B. coupler is to steam railroads, and the company stands prepared to furnish an automatic coupler for any condition or combination of conditions that can possibly arise in electric, cable or elevated railway practice.

Aside from filling contracts for Van Dorn couplers for standard street railway service the company is now working on orders for the Manhattan Elevated Ry., on which road Van Dorn couplers will be used exclusively; the Boston Elevated Railway Co., which called

NO. 5 VAN DORN COUPLER.

for a very special design in order to give perfect flexibility combined with great strength; the Chicago elevated roads and others. Mr. Van Dorn expects to announce shortly several other large orders from new companies for couplings for special service. A noteworthy feature in the making of these automatic couplers is the extreme care used in the finishing, all parts and surfaces being machine finished and fitted.

The accompanying illustration shows the Van Dorn coupling No. 5, which is the one most extensively used on city and interurban roads.

A race between an interurban electric car on the lines of the Union Traction Co. of Indiana and a train on the Big Four "Southwestern Limited" recently, resulted in a decided victory for the former. The race was over a six-mile stretch between Anderson and Indianapolis, and the distance was covered by the electric car in a fraction less than seven minutes.

## PERSONAL.

MR. C. E. FLYNN, general manager of the Wheeling Traction Co., was a recent caller at the new offices of the "Review."

MR. J. M. CROMBLY has been elected secretary and treasurer of the Danbury & Harlem Traction Co., of Danbury, Conn.

MR. HENRY BERND has resigned as president of the Danbury (Conn.) & Harlem Traction Co., and will be succeeded by Thomas F. Barrett.

MR. W. A. SATERLEE, general superintendent of the Metropolitan Street Railway Co., of Kansas City, has been appointed assistant to President Corrigan.

MR. F. A. ESTEP, president and treasurer of the R. D. Nuttall Co., of Pittsburg, will leave for England on June 20th to attend the Framway Convention to be held in London July 1st to 4th.

MR. GEORGE HENRY BOWERS, Secretary of the Peckham Co., New York, was on June 4th married to Miss Eula Constance Godfrey, daughter of Mr. and Mrs. William L. Godfrey, of Brooklyn, N. Y.

MR. SOL JAMES has been promoted from the position of superintendent of the 18th Street Division of the Metropolitan Street Ry. of Kansas City to second assistant general superintendent of the company.

MR. W. E. HAYCOX on June 1st resigned his position as general manager of the Ohio Central Traction Co., of Galion, O., and is spending some weeks at Magnetic Springs, taking a much-needed rest. Mr. Haycox has no intention of retiring from the street railway business, but found that a vacation was imperative.

MR. WILLIAM TYSON GOOCH, formerly of the firm of Harding & Gooch, architects, announces the dissolution of this firm and his association as a partner with the firm of Charles Henry Davis & Partners, to continue the practice of architecture.

MR. C. V. MILLS, formerly of Battle Creek, Mich., has assumed the duties of superintendent of the West Chester (Pa.) Street Railway Co. Mr. Mills has had many years' experience in the street railway field. He will supervise the construction of a number of extensions of the West Chester system.

MR. RODNEY CURTIS has resigned as president of the Denver City Tramway Co. and will spend the summer with his family in Europe. Mr. Curtis continues as a director and large stockholder in the Denver company. He will be succeeded as president by W. E. Evans, secretary of the company.

SENATOR NELSON W. ALDRICH has resigned as president of the United Traction & Electric Co., of Providence, R. I., and will be succeeded by B. A. Jackson, a member of a local banking firm. Senator Aldrich is reported to have accumulated over \$1,000,000 during the past six years through the rise in the value of his holdings of the United Traction & Electric Co.'s stock. This stock had no apparent market value nine years ago, but is now quoted at \$121 per share.

MR. W. R. W. GRIFFIN, who recently resigned as chief engineer and superintendent of motive power of the Lake Shore Electric Railway Co. of Cleveland, has been chosen electrician and superintendent of construction of the Rochester (N. Y.) & Eastern Ry. Mr. Griffin was formerly chief engineer of the Toledo, Fremont & Norwalk Ry. He was presented with a handsome gold watch by his associates on his departure from Cleveland.

MR. E. C. FABER, who recently retired from the general superintendency of the Cleveland Electric Railway Co., was presented on the eve of his leaving Cleveland with a loving cup by the employes of the road, who entertained for him the most cordial admiration and respect. The presentation ceremonies were held in a hall rented for the purpose, and were witnessed not only by all the

employes of the street railway system, but by many of Mr. Faber's friends in the management of the company. Mr. Faber is believed to be the youngest man holding a position of equal importance with any street railway in the country.

MR. EUGENE CHAMBERLIN has resigned as superintendent of equipment of the Brooklyn Heights Railroad Co., a position which he has held for the past three years and in which he has accomplished much toward standardizing the electrical and mechanical equipment of the company's rolling stock. Mr. Chamberlin was formerly in the service of the New York Central & Hudson River R. R. as master car builder of the Western Division for eight years. Since assuming the duties of superintendent of equipment of the Brooklyn Heights Company, he has introduced many innovations in the reorganized 52d St. shops, whose modern methods and improved equipment are largely owing to his effort. A number of his combination cars of a novel type, furnished with individual revolving seats, are now in service on the Brooklyn lines and are giving general satisfaction. In leaving the Brooklyn Heights company Mr. Chamberlin will continue in this business, but his plans have not, however, been definitely announced.

MR. GEORGE B. FRANCIS, who, since January, 1900, has been chief engineer of the street railways at Providence, has resigned this position to engage in the capacity of civil engineer with Westinghouse, Church, Kerr & Co., of New York City. In 1874 Mr. Francis entered the engineering department of the city of Providence, spending eight years in municipal work. He subsequently became connected with the engineering department of the West Shore R. R. and has been identified with the construction work undertaken by the Oregon Railway & Navigation Co.; the Northern Pacific Ry. and the Northern Pacific Terminal Co., of Portland, Ore.; the New Jersey Junction Ry., the South Pennsylvania R. R. and the New York Central & Hudson River R. R. As consulting engineer for the Third Avenue Railroad Co. of New York City, Mr. Francis designed the foundation for the company's Kingsbridge power station, which will be remembered as an engineering problem of considerable difficulty. From 1887 to 1892 he was principal assistant engineer of the New York, Providence & Boston R. R., and later, as engineer of the Terminal Company of Providence, designed and arranged the terminals in that city. Mr. Francis is a director of the Boston Society of Civil Engineers and a member of the American Society of Civil Engineers, and the Institution of Civil Engineers of Great Britain.

Capt. W. H. Lanius was born at Flushing, L. I., Nov. 26, 1843, and is of German extraction on his father's side; his mother's family was French Huguenot stock. His father's ancestors settled in eastern

W. H. LANIUS.

Pennsylvania as far back as 1731. Capt. Lanius removed to York, Pa., at an early age, and grew to his education in the York County maturity in that city. He obtained Academy and other private schools, and after completing his studies, embarked on a business career which has been marked with distinct success. At the age of 17 he enlisted in Company A of the 87th Pennsylvania volunteers and was advanced by successive promotions, receiving his commission as captain June 26, 1864; in October of the same year he was mustered out of service. He participated in many of the battles of the Civil War in all of which he proved himself a brave soldier and gallant officer. After returning from the war he was made a special officer of the United States Treasury Department and in 1865 he resigned this position to engage in the wholesale and retail lumber business, with headquarters at York and Williamsport, Pa. By 1884 he became convinced that the city of York was destined to become a large manufacturing city although at that time it had always been classed as an agricultural district. Capt. Lanius then turned his attention to the development of a number of interests in York and its surroundings. He became the chief promoter of the

West End Improvement Co. of York, an organization which in 1890 became the present York Trust & Real Estate Deposit Co. As the functions of this corporation include the buying and selling of real estate a large tract of land was purchased in the western part of the city and steps taken towards its improvement. In addition to laying out this section into lots and the erection of many handsome suburban residences Captain Lanius decided that it would be necessary to have a street car line to bring this section into closer relation with the central part of the city, so in 1886 he organized what is known as the York Street Railway Co. He was chosen president of the company and he proceeded to develop the system which now traverses all of the principal streets of the city in addition to forming a loop around the outside of the town. A number of other charters have since been granted to this company which is now extending its lines to the various hamlets and villages throughout York county. All of these lines owe their origin to Captain Lanius. He is also president of the Baltimore Harrisburg Railroad Co., a trustee of the old York County Historical Society, the first president of the Board of Trade organized in 1886 and a member of the York Lodge of Free Masons. He is also a prominent member of John Sedgwick Post of the Grand Army of the Republic and was its first commander, and he is a member of the Loyal Legion. In politics Captain Lanius has always been affiliated with the republican party and for a number of years has been recognized as one of the foremost republicans in York county as well as in the state. He was a national delegate to the convention nominating James G. Blaine for the presidency. Captain Lanius leads a very active business life and to him is due the organization of many of the successful business enterprises which have placed York in its present rank as a business center. He is a man of fine social and intellectual qualities and of courteous demeanor and has won many friends not only in York but throughout the state of Pennsylvania. He was married in 1867 to Miss Lucy Smyser, daughter of the late Michael Smyser, of York, and has a son and two daughters.

### OBITUARY.

COL. C. C. HOWELL, general manager of the Knoxville (Tenn.) Traction Co., died Wednesday, May 7th, at Phoenix, Arizona, where

C. C. HOWELL.

he had gone in a vain attempt to stay the progress of a wasting disease of long standing. Mr. Howell was one of the oldest and most prominent street railway men of the South, and was one of the foremost business men of the state of Tennessee. He was essentially a man of action. Born in a small city of New York state in 1848 he started west at an early age and soon laid the foundation for a comfortable fortune, a considerable portion of which he invested in the street railway and electric lighting properties of Knoxville, Tenn. He went to Knoxville in 1895 and before his death he had brought three rival street railway companies and the electric lighting plant under the control of common interests and had given to the city of Knoxville a lighting and transportation system unsurpassed by any other property of equal size in the South. He was an active member of the Knoxville Chamber of Commerce, one of the founders and a vice-president of the city hospital, an ex-member of the state legislature and a director of several private commercial and financial enterprises. He leaves a wife and two daughters.

MR. WALTER V. CROUCH, secretary of the New Orleans & Carrollton Railroad Co., died May 16th last. Mr. Crouch had been identified with the New Orleans property for 27 years.

MR. GASTON MESSEUR, traffic manager of the Grand Rapids (Mich.) Grand Haven & Muskegon Railway Co., died at Grand Rapids June 8th, being stricken with paralysis while at dinner. Mr. Messer had assumed the duties of his new position but ten days pre-

vious to his death. He was 55 years of age, and before coming to Grand Rapids had been for a number of years assistant general passenger agent of the Missouri Pacific Ry.

MR. JAMES F. MANN, who since 1885 has been prominently identified with the development of the electric railway systems in Utica and vicinity, and who was, until a year ago, president and manager of the Utica & Mohawk Railroad Co., died recently at his home in Utica. Mr. Mann was one of the organizers of the Wood & Mann Steam Engine Co.

### STRIKES OF THE MONTH.

At midnight on June 3d the employes of the United Traction & Electric Co., of Providence, R. I., went out on a strike, the immediate cause of which was the determination of the company to secure an adjudication as to the constitutionality of a 10-hour act applying to street railway companies, which was passed by the last Legislature, before complying with its terms. The demands made by the men included a specific observance of the 10-hour law, that all employes now receiving more than \$2.25 a day shall continue to have the same wage for 10 hours' work; that all others be paid 20 cents an hour for 10 consecutive hours the first year, and 22½ cents an hour thereafter; that all employes other than gripmen, motormen and conductors, whether in the car houses, repair shops or power houses shall be employed not exceeding nine hours a day and have the same pay given them, and that all work more than 10 hours shall be at the rate of 25 cents an hour.

The strike tied up practically all the street railways in Rhode Island.

On the night of June 5th there was much disorder and rioting, but on the following day the company was prepared to operate half of its cars.

The refusal of the city authorities to provide adequate police protection for cars resulted in such disturbances that on June 12th state militia were ordered to Pawtucket to restore order.

June 4th the trainmen of the Sheboygan (Wis.) Light, Power & Railway Co. struck for higher wages, and all rolling stock except mail cars were tied up.

At Oil City, Pa., the Citizens' Traction Co. on June 14th withdrew its cars from service and announced that no regular schedules would be followed until the public sentiment in regard to the boycott changed.

At Chicago the Amalgamated Association of Street Railway Employes has organized unions among the men of both the Union Traction Co. and the Chicago City Ry. The companies agreed that so long as no attempt was made to restrict their action in selecting men and dealing with employes, there would be no opposition to the organizations on the part of the company.

### IMPROVEMENTS AT NEW ORLEANS.

The St. Charles Street Railroad Co., of New Orleans, shows the following results for the first five months of 1902: Gross receipts from fares, \$136,843; operating expenses, \$88,411; net earnings from operation, \$48,432; other income, \$1,954; gross income, \$50,386; deductions from income for taxes, interest, etc., \$14,183; net income for five months, \$36,203, which is at the rate of 9 per cent per annum on the present capital of \$553,300.

The company was organized in 1866, and having recently secured an extension of its franchises until 1956, has undertaken improvements that will cost about \$200,000. It now has 18 miles of track and will build 4 miles more, using 90 and 93-lb. rails; 78 cars are now operated.

The officers of the company are: President, Albert G. Phelps, and secretary, Charles J. Macmurdo; the engineers are Coleman & Maloche.

The Boston & Worcester Street Railway Co. expects to complete its line from Boston to Frammingham by September 1st, and to open the route between Boston and Worcester by October or November. The company has a capital stock of \$750,000 and will probably issue \$750,000 of 4½ per cent first mortgage bonds. The road will cost approximately \$1,500,000.

### TRUCKS FOR HIGH SPEED INTERURBAN SERVICE.

One of the most interesting electric railway undertakings in the United States is that of the Aurora, Elgin & Chicago Railway Co., which will probably have the main portion of its line in operation by July 1st. This road belongs to the recently developed class of electric railways which as yet has been given no distinctive name, and has all the distinctive operating features of a steam railroad

The trucks on which the high speed cars will be mounted constitute a very important part of the equipment, and the accompanying illustrations and description will be of general interest. These trucks were built by the Peckham Manufacturing Co., of New York, and are known as the M. C. B. No. 30, and were designed expressly for high speed interurban, elevated or trunk line service.

The side frames combine the equalizing bars used in the Standard Master Car Builders' steam passenger car trucks with that of the diamond frame used in the M. C. B. freight car trucks, the idea of

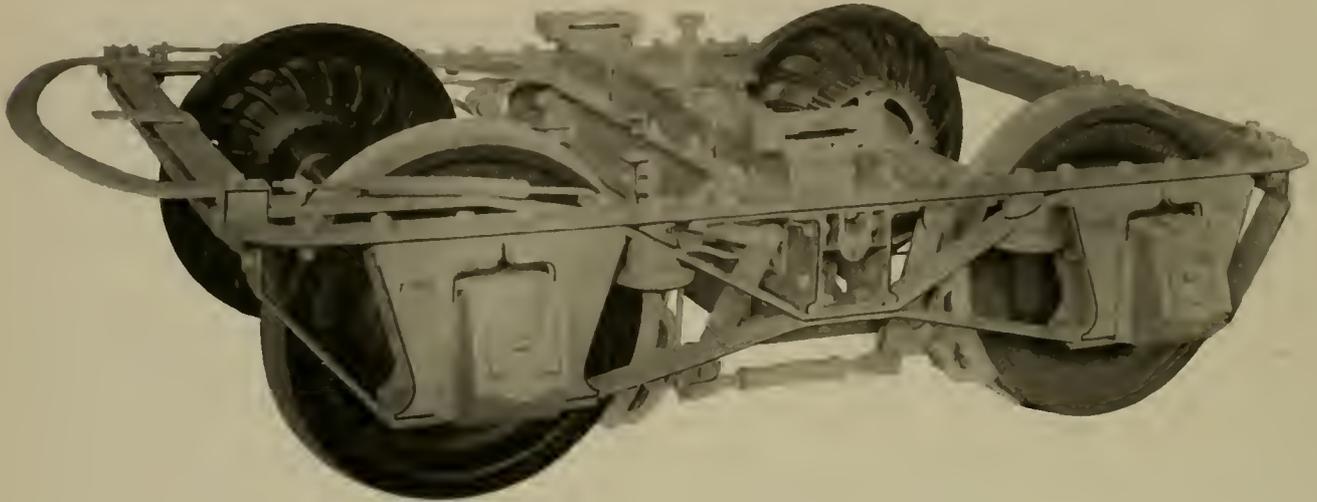

FIG. 1 PECKHAM'S M. C. B. NO. 30 TRUCK WITHOUT EQUALIZERS.

except the motive power. There are double tracks built the entire distance, except in towns, over private rights of way; the track rails weigh 80 lbs. per yard and the third, or conductor, rail, which is used for conveying current to the cars except in Aurora, weigh 100 lbs. per yard.

The line connects with the Metropolitan Elevated, of Chicago, at West 52d St., where there is an incline leading to the elevated structure, and thence west to Wheaton the distance is about 18 miles; at Wheaton the road forks, one branch extending northwesterly to Elgin, a distance of 14 miles, the other running south-

this combination being to give a double factor of safety, as the diamond frame alone is sufficiently strong to carry the weight of the car without the aid of the equalizing bars, which are arranged in pairs, one each side of the pedestals. To prevent the tilting of the top frames, an objectionable feature in the Standard Master Car Builders' steam railway trucks, the spring base of the truck is increased by locating helical springs each side of the journal boxes and supported from them by saddles. These pedestal springs carry a sufficient portion of the load to prevent the tilting of the top frames, the greater part of the load being carried by the equalizing

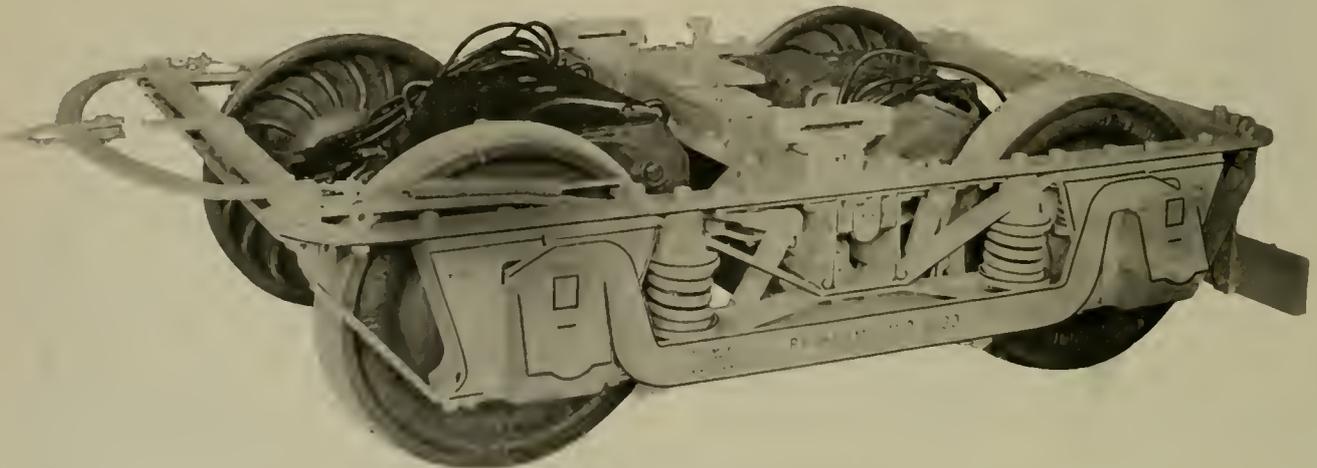

FIG. 2 M. C. B. NO. 30 TRUCK FOR AURORA, ELGIN & CHICAGO.

westerly to Aurora, about 12 miles; there is also a 5 mile branch to Batavia. The right of way is fenced except at highway crossings, and at these points the conductor rail is broken, the sections being connected by underground cables.

It is thus apparent that the physical conditions are such as to permit high speed, and the plans contemplate a schedule of 40 miles per hour, including stops, with a maximum of 65 miles per hour. It is understood that soon after the opening of the line experiments will be made at speeds up to 100 miles per hour.

bar springs. The side and end portions of the top frame are all in one piece, a forging, which insures the trucks always remaining square. The transoms are bulb angles 10 in. deep, which extend full size with the side truss frame to which they are very rigidly secured. Gussets of sheet steel connect the transoms to the side frames hold the frames rigid and square.

Peckham's patent swing bolster is used in this truck. It is constructed of plates in form of a channel 10 in. deep and is carried on four long coil springs and one elliptic spring which support the

bolster from the inside at its top, so as to hold it securely in a vertical position. Straps secured to the transom and extending over the bolsters prevent its being lifted out. The king pin is so secured that the car body cannot be lifted off the truck. The swivel plates are large in diameter, machine fitted, with a boss around the king pin which prevents the escape of the lubricating grease.

The arrangement of bolster springs, i. e., an elliptic in the center and two long helical springs at each end, is designed to give a much easier riding car than the old form of bolster used in steam cars, and it can be more easily regulated so as to prevent rolling motion of cars when running at high speed.

The journal boxes are the M. C. B. standard pattern with standard M. C. B. journals. The axles are 6½ in. in diameter, and the wheels 36 in. in diameter, with 4¼-in. tread and 1-in. flanges. The pedestals are made of cast steel, machine fitted where they come in contact with the journal boxes and top frames; all bolts are

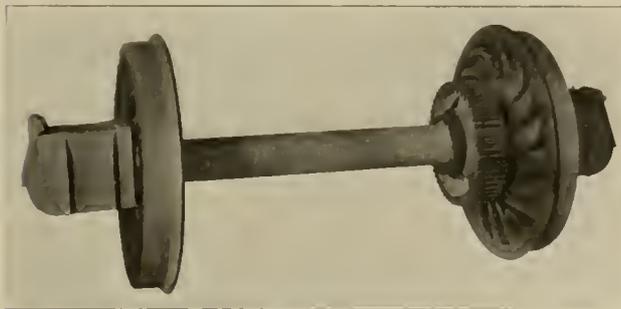

FIG. 3—AXLES AND WHEELS.

machined to size and are driven in reamed holes so as to tie the parts of the truck rigidly together.

The brakes are constructed with shoes on the inside of the wheels and can be easily adjusted to the wheels without placing truck over a pit.

Fig. 1 is an open view of the truck showing the diamond shape side frames and the brake mechanism without the equalizing bars. Fig. 2 is the truck complete with two G. E. 66 motors, 125 h. p. each, mounted; the fittings for the third rail contact are on the side opposite to that shown. Fig. 3 is a view of the wheels and axle used on the Aurora, Elgin & Chicago equipment.

The Peckham company builds the M. C. B. No. 30 truck in three different weights to meet varying conditions of service: Light weight, with 33-in. spoke wheels and 5-in. axles, 7,250 lb. Medium, with 33-in. double plate wheels, 6-in. axles, 8,600 lb. Heavy, with 36-in. double plate wheels and 7-in. axles, 10,350 lb. each.

We have just been advised that the Peckham company has received an order for 64 trucks of this type, with slightly modified bolsters, for one of the London underground roads.

### CHICAGO FRANCHISE SUIT.

As was noted in the "Review" for May, the United States Circuit Court on May 8th sustained the demurrer of the city of Chicago to the bill in equity filed June 25, 1901, by W. L. Elkins of Philadelphia, to test the validity of the so-called 99-year act as affecting the street railway franchises of Chicago. Two amended bills were filed on behalf of Mr. Elkins, May 12th. The court dismissed the amended bills June 4th on the same technical grounds as those given when the original bills were dismissed. A decision which will permit a presentation of arguments on the merits of Mr. Elkins' cases is still hoped for, and the question of jurisdiction will be taken to the United States Supreme Court.

The Chicago & Milwaukee Electric Railway Co., in building a spur from Lake Bluff to Libertyville, offered to pay one farmer who opposed the route \$1,000 for the privilege of crossing his land. The man demanded \$3,000, which was exorbitant, and a condemnation suit was brought with the result that a verdict of \$200 was rendered. The vice-president of the company, however, ordered that the defendant be paid the sum originally offered, \$1,000, and it was gratefully accepted.

### FINANCIAL.

#### PHILADELPHIA CO., PITTSBURG.

The Philadelphia Company and affiliated corporations have issued the following report for the month ending April 30th:

	1902.	1901.
Gross earnings from operations.....	\$1,114,509.57	\$989,512.62
Operating expenses and taxes.....	615,638.68	535,408.78
Net earnings from operations.....	498,870.89	454,103.84
Other income.....	101,433.39	29,820.64
Total earnings and other income.....	600,304.28	483,924.48
Total income.....	518,363.82	442,896.82
Fixed charges.....	324,425.08	264,255.98
Surplus.....	193,938.74	178,641.84
Less proportion of same to credit of owners of capital stock of affiliated corporations other than the Philadelphia Company.....	308.47	5,662.94
Balance representing Philadelphia Company's interest in the total net income.....	193,630.27	172,978.90

#### BROOKLYN RAPID TRANSIT.

The Brooklyn Rapid Transit Co. has issued the following statement for the months of March and April, 1902, as compared with the corresponding period last year:

	March, 1902.	March, 1901.	Increase.
Gross receipts.....	\$1,030,917.42	\$955,503.50	\$75,413.92
Expenses, including taxes....	768,347.86	714,044.35	54,303.51
Net receipts.....	262,569.56	241,459.15	21,110.41
	April, 1902.	April, 1901.	Increase.
Gross receipts.....	\$1,041,706.38	\$989,993.54	\$51,712.84
Expenses, including taxes....	705,010.86	658,282.07	46,728.79
Net receipts.....	336,695.52	331,711.47	4,984.05

#### METROPOLITAN, NEW YORK.

Phenomenal results from operations are shown in the report of the Metropolitan Street Railway Co., of New York City, to the railroad commissioners for the quarter ending March 31st. The operating cost for the quarter was less than half the earnings of the road for the same period, and with taxes on all its property used in operating the system, and on earnings and capital stock, the expenses were but 4½ per cent above half the earnings.

	1902.	1901.
Gross earnings.....	\$3,415,388	\$3,283,208
Operating expenses.....	1,636,805	1,681,403
Other income.....	126,933	203,676
Fixed charges.....	1,171,968	1,128,967
Net income for March quarter.....	733,548	676,513
Net income for three quarters ended March 31.....	2,548,712	2,764,683
Operating cost per cent of earnings.....	47.91	51.21
Operating cost (including all taxes) per cent of earnings.....	54.55	57.27

#### GENERAL ELECTRIC CO.

At a meeting of the directors of the General Electric Co., June 6th, a stock dividend of 66 2-3 per cent to stockholders of record on July 1st was declared. The dividend is payable on July 15th and involves the distribution of about \$17,000,000 to the company's stockholders. Plans are under consideration for an increase of the company's stock to \$45,000,000 and it is understood that dividends at the rate of 8 per cent per annum will be paid on the new capitalization.

#### CHICAGO & MILWAUKEE RY.

The increase in the net earnings of the Chicago & Milwaukee Electric Railway Co. amounts to 85 per cent for the four months ending April 30th. The following report has been filed by the company:

	1901.	1902.
January.....	\$2,592.46	\$5,080.67
February.....	1,147.10	3,875.93
March.....	2,829.34	5,030.35
April.....	4,858.90	7,158.66
	\$11,427.80	\$21,145.61

## UNITED TRACTION CO., PITTSBURG.

The United Traction Co. of Pittsburg, which is controlled by the Philadelphia company, has published the following report for the quarter ending March 31st:

Gross earnings	\$344,000	Inc.	\$28,041
Net earnings	87,135	Dec.	3,431
Total income	89,562	Dec.	2,401
Fixed charges	60,204	Inc.	9,502
Net income	29,358	Dec.	11,093
Net income preceding quarters fiscal year	129,936	Inc.	10,215

## NORTHERN OHIO TRACTION CO.

The Northern Ohio Traction Co. has issued the following report for the month of April, showing a heavy gain over the corresponding period last year:

	1902.	1901.
Gross earnings	\$49,424.83	\$39,618.24
Operating expenses	28,526.06	25,476.51
Net earnings	20,897.87	14,141.73
Fixed charges	12,500.00	10,960.46
Surplus	8,397.87	3,172.27

One year ago the surplus lacked \$994.30 of the amount required to meet the charge of \$4,166.66 as the monthly dividend on preferred stock. This year the surplus meets the dividend charge and leaves a balance of \$4,231.21 to apply on common stock.

## METROPOLITAN ELEVATED, CHICAGO.

The Metropolitan West Side Elevated Railway Co. has averaged an increase of 8,000 passengers per day since the opening of the Douglas Park extension, and the operation of the entire system shows an increase for the month of May of nearly 15 per cent. Following is the company's report for the five months ending May 31st:

	1902.	1901.	Gain.
January	\$ 98,029	\$89,699	\$ 8,330
February	100,466	97,659	2,807
March	105,512	98,339	7,173
April	109,246	97,020	12,226
May	105,799	92,572	13,227

## SOUTH SIDE ELEVATED, CHICAGO.

The South Side Elevated Railroad Co. has issued its report for the five months ending May 31st as follows:

	1902.	1901.	Gain.
January	79,154	71,137	8,017
February	79,386	74,525	4,861
March	80,313	76,266	4,044
April	81,009	77,782	3,227
May	76,063	74,175	1,888

## NORTHWESTERN, CHICAGO.

The Northwestern Elevated Railroad Co., Chicago, has issued the following report of operations for the five months ending May 31st:

	1902.	1901.	Gain.
January	62,010	52,022	9,188
February	64,760	55,256	9,504
March	65,362	57,193	8,169
April	65,430	58,623	6,807
May	63,199	56,099	6,200

## MONTREAL STREET RY.

The report of the Montreal (Que.) Street Railway Co. for the month of April shows a large decrease in the operating expenses and a large increase in net earnings. The report is as follows:

	1902.	1901.
Passenger earnings	\$152,524.57	\$144,131.47
Miscellaneous earnings	1,805.16	662.03
Total earnings	154,389.73	144,793.50
Operating expenses	83,850.03	93,272.10
Net earnings	70,539.70	51,521.40
Fixed charges and interest on loans	15,847.71	9,287.80
Surplus	54,691.99	42,233.60
Expenses per cent. of car earnings	54.07	64.71

The bill for an injunction to restrain the city of Chicago from collecting taxes for 1901 from the Chicago Union Traction Co. and the Chicago Consolidated Traction Co. has been dismissed by the lower court. The money that was deposited by the traction com-

panies with the County Treasurer pending the outcome of the suit has been ordered to be distributed and the city will receive of the amount about \$100,000.

## TOLEDO, BOWLING GREEN &amp; SOUTHERN.

The Toledo, Bowling Green & Southern Traction Co., at a meeting at Cincinnati, June 9th, declared a dividend of one and a half per cent on the capital stock for the first six months of this fiscal year. Gross earnings for May, 1902, were reported at \$20,086.43, as against \$13,731.55 for May, 1901; operating expenses at \$10,672.59, as against \$8,249.43, and net earnings at \$9,458.84, as against \$5,482.12.

## NEW PUBLICATIONS.

"STATIC STRAINS IN HIGH TENSION CIRCUITS AND THE PROTECTION OF APPARATUS," a paper which was recently read by Mr. Percy H. Thomas before the American Society of Electrical Engineers, has been reprinted in full and copies can be obtained from all district officers of the Westinghouse Electric & Manufacturing Co. The subject of this paper is treated in a comprehensive manner and as the work is not mathematical in character it will undoubtedly prove of interest to superintendents and station managers as well as to electrical engineers. The reprint is fully illustrated with views and diagrams.

AMERICAN STREET RAILWAY INVESTMENTS, published by the Street Railway Publishing Co. of New York. Price, \$5.00. The present issue of this well known authority on street railway investments which is generally known as the "red book" is its ninth annual edition. This edition contains reports of 1,281 companies and gives in detail the physical and financial conditions of these properties. The figures include both operating and leased roads as well as data for all new roads. There are 31 folding maps of the most important street railway systems in the United States and a table is included that shows by comparison the gross receipts of all companies earning \$25,000 or more during the past year. Following its usual custom the date of information, as supplied by the street railway companies making the report, is given with the report of each road and this comprises an important feature to any one desiring accurate information.

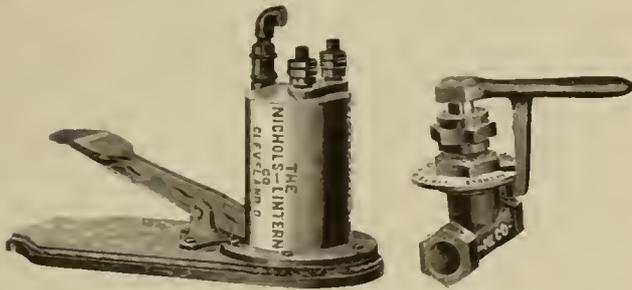

ARMATURE WINDINGS, by E. Arnold, professor at Riga Polytechnic School. Translated from the original German by Francis B. De Gress, M. E., of the Crocker-Wheeler Co. Cloth, 124 pp., price \$2. Published by D. Van Nostrand Co., New York. The difficulty of presenting to students in a simple manner the method of winding armatures for direct current machines so as to enable them to solve any problem in winding led the author to study out a general rule which is applicable equally to closed coil armatures of the ring, drum and disk types. The relation between these different armature windings is brought into prominence and the transition from one winding to another can be accomplished without difficulty by means of this general rule which embraces all known windings and gives a general solution of the winding problem. Many of the designs and connections shown in the work are of historic interest only, but the principle expressed is fundamental and of value to armature designers. The book is copiously illustrated with diagrams of all styles of windings the connections of which are deduced from the general rule established. The book will be found very useful to the student or designer in obtaining a clear understanding of the process of winding armatures.

HAND BOOK FOR STREET RAILWAY ENGINEERS, by H. B. Andrews, C. E., morocco, 202 pp., price \$1.25. Published by John Wiley & Sons, New York. This little work is published in vest-pocket size 3x5 in. and presents in compact form a collection of tables and other information particularly adapted to the use of the street railway engineer. Most of the information has been computed and compiled by the author during his connection with the Boston Elevated Railway Co. for the past eleven years and the entire contents has been selected with a view to its practical value in everyday work. The contents are divided into 13 chapters and covers the subjects of mensuration, curves of various kinds, miscellaneous information in regard to track construction, pavements, rails, etc., strength of materials, data for estimates, electrical information, etc. The character of the information contained makes the work a very handy one for reference purposes.

**NICHOLS-LANTERN PNEUMATIC SANDER.**

The Nichols-Lantern Co., of Cleveland, O., is meeting with excellent success in introducing its pneumatic sander on both electric and steam railways. While sanders are sometimes considered minor accessories in the equipment of a car, the results of an inefficient sanding device or none at all, are sometimes very serious and include waste of power, loss of time, abuse of the equipment and an increase of liability to accident. These sanders are applicable to cars either with or without compressed air.

The company makes a foot compressor, shown in the accompanying illustration, which renders it possible to locate the sander at any

FOOT PUMP.

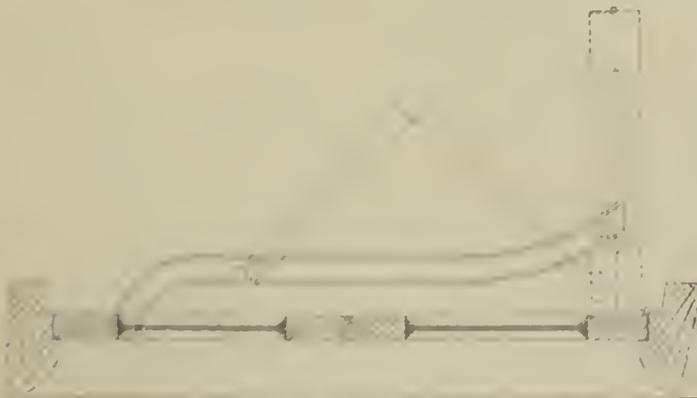

VALVE.

part so that sand can be applied right at the wheels on the driving trucks and prevent the slipping of wheels on starting. The company also uses an improved valve in connection with these equipments which is very durable and uses air with the greatest economy. It is claimed that the air consumption of this sander is so small an item that it can be entirely ignored. Its value in case a quick stop is necessary is very great and the fact that its action is automatic after the valve is open allows the motorman to apply sand while applying the brakes, which prevents skidding of the wheels.

**NEW VESTIBULE FOLDING DOORS.**

Street railway companies using vestibule cars or preparing to place vestibules on their car platforms will be interested in the Duner vestibule folding door which is designed for city, interurban and elevated railroad cars. The patents for these doors are controlled by the Chicago Equipment Co., 41 State St., Chicago, of which Mr. F. K. Howard is manager.

The advantages of vestibules, especially for interurban roads, have come to be generally recognized, but the difficulty of finding a

DOOR IN THREE POSITIONS.

vestibule door has heretofore been one of the objections to their use. The nature of the service makes it difficult to obtain a door that will not rattle, and the small amount of space available on the platform makes imperative a door that will not interfere in any way with the exit or entrance of passengers. The Duner door has been designed to fill the special requirements of street car service. It can be placed and handled as an ordinary swinging door would be used and may be arranged to swing back against the car

body or against the front wall of the vestibule as may be desired. It is, in fact, an ordinary swinging door divided down the center, the two parts being hinged and so arranged that when the door is opened one-half will automatically fold back upon the other half, thus reducing to a minimum the floor space necessary in which to make the swing. This action is accomplished by placing in the roof of the vestibule a curved slot or track in which slides a roller pin attached to one of the halves of the door. This groove slot is indicated by the curved solid lines in the diagram. It will be understood that the hinged half of the door, being free to move, is guided by this slot in the manner indicated by the dotted lines. This illustration shows the door in three positions—i. e., closed, half open and fully open, with the two doors folded back out of the way.

The Chicago Equipment Co. is prepared to furnish this door with or without retaining catches, and with or without operating levers. It has furnished doors for the Northwestern Elevated and also for the Lake Street elevated roads of Chicago, these doors, of course, being operated by levers from the inside of the vestibule. The door is also used by the Calumet Electric Street Railway Co., the South Chicago City Railway Co., the Dayton, Springfield & Urbana Ry., and by other interurban systems.

**A PLEASANT DAY.**

Taking a day for pleasure, he (the Englishman) attends the races, and sees the highest stakes won by an American horse, ridden by an American jockey. Looking over the evening paper, he reads of the placing in American shipyards of orders for American style battle-ships for European as well as Asiatic nations, and learns that the scene of the coronation of the King of England is to be painted by an American artist, and that the forty thousand gold, silver and bronze medals, ordered by the command of the king, to commemorate his coronation, are being made in Massachusetts.—From "America's Invasion of Europe," by George H. Daniels, in Four-Track News for June.

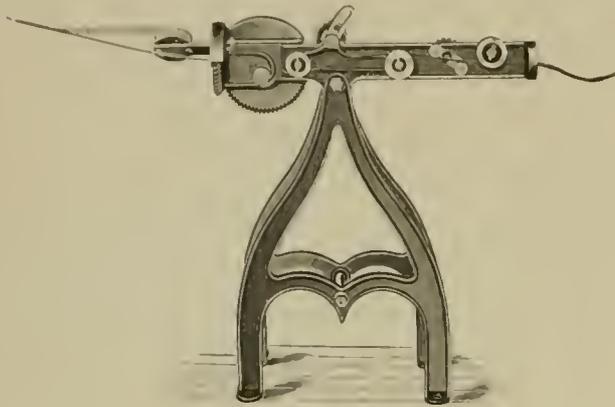

DUNER FOLDING DOOR.

The Gainesville & Dahlonega (Ga.) Electric Railway Co. which obtained a charter for an interurban line between the cities named in the title in May, 1901, expects to open its 34 mile road now under construction early in 1903. The company has an authorized capital stock of \$500,000, of which \$251,000 has been issued. W. W. Murray is president.

### THE "DETROIT" FIELD RE-INSULATING MACHINE.

The Allen & Morrison Brake Shoe & Manufacturing Co., 721 Woman's Temple, Chicago, is now placing on the market the ingenious money and labor saving device illustrated herewith, which has been named the "Detroit" field re-insulating machine. This machine draws the wire from the old field, straightens it, removes the old insulation, re-insulates the wire, and winds it onto the new field coil, all in one operation. The construction is simple and easily understood from the illustration; no extra help is required, and no additional power transmission is necessary to drive the machine. Motion for the tapping device is taken from the wire as it is drawn through the machine, and a strap brake and pulley mounted on the shaft carrying the old field coil to give proper tension in the wire, are all the additional apparatus necessary. In case the

FIELD RE-INSULATING MACHINE.

wire of the old coil is broken in one or more places, it may be spliced in the ordinary way and allowed to continue through the machine.

In our issue of March, 1900, page 175, we published a sketch showing this device before it had been perfected for placing on the market, and at that time it had been used with success in the shops of the Detroit Citizens' Street Railway Co. Since then the Allen & Morrison company, which is the sole agent for the sale of the machines, has placed them in other street railway shops, where they are giving equally satisfactory service.

The company refers to letters received from Mr. T. J. Nichol, vice-president and general manager of the Rochester (N. Y.) Railway Co., and Mr. Willard J. Hield, general manager of the Twin City Rapid Transit Co. The former writes: "The machine has certainly saved us a great many hundreds of dollars in both material and labor. We would not care to get along without it, even if it cost us a good deal more than it did." Mr. Hield says: "The insulating machine which we are now using is in every way satisfactory, and is a money saver."

### OHIO NOTES.

A suit has been brought in the name of the state of Ohio against the Toledo street railway company to compel it to issue universal transfers.

The directors of the Cincinnati, Dayton & Toledo Traction Co., which was organized to take over the Southern Ohio Traction Co., the local lines at Hamilton and some other properties in that section, are as follows: Will Christy, Akron; M. J. Mandelbaum, F. T. Pomeroy, W. H. Lamprecht, H. C. Lang, A. E. Feihl and R. S. Brintnell, of Cleveland; and O. V. Parrish and Peter Schwab, of Hamilton.

It is reported that negotiations have been completed whereby the Cincinnati Traction Co. will in the future operate the Mill Creek Valley and the Hamilton, Glendale & Cincinnati Traction properties under lease. One company is to be formed with a capital stock of \$2,100,000 to own both properties. Of this \$1,100,000 is to be preferred and \$1,000,000 common. The Cincinnati company is to pay 5 per cent on the preferred stock and a graduated rate on the common stock, beginning at one-half of one per cent and increasing

annually until it reaches 4½ per cent. This will give the traction company a line from Fontaine Sq. to the center of Hamilton, although there remains some track to be built at Hamilton. The injunction issued against the road there has been dissolved and work has been resumed on it. The officers of the new company are as follows: President, M. J. Mandelbaum; vice-president, Will Christy; second vice-president, C. V. Parrish, Hamilton; treasurer, F. T. Pomeroy, Cleveland, secretary, H. C. Lang, Cleveland.

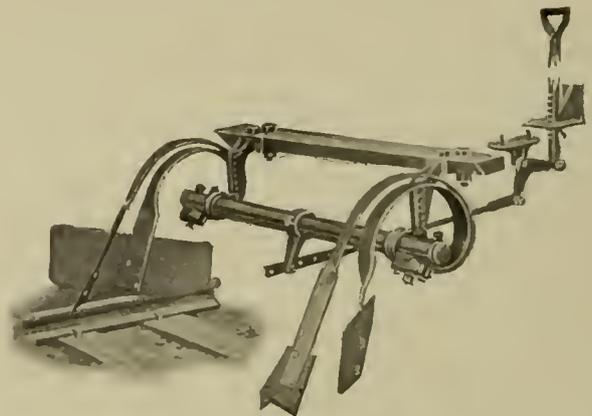

Arthur E. Appleyard, head of the Appleyard syndicate which controls roads between Dayton and Urbana, Springfield and Columbus and Columbus and Newark, has opened an office in Cincinnati for the purpose of handling securities in that market. C. H. MacLille will have charge of the office.

A line is being surveyed from Six-Mile Ferry at Pittsburg to Salem, Ohio. It crosses the Ohio river at Georgetown, a short distance above East Liverpool, and it is the intention to make connections with other lines to reach Canton and some other Ohio towns. It is said that Cleveland, Pittsburg and New York capitalists are behind the plan.

The Canton-Akron Electric Railway Co. has increased its capital stock from \$600,000 to \$1,600,000 in order to be in position to purchase the Canton-Masillon line and also to extend the Navarre line south to Philadelphia.

### ROOT TRACK CLEANER.

A device for cleaning the dirt from tracks and flanges of trolley cars has been put on the market by the Root Track Scraper Co. at Kalamazoo, Mich., and is shown in the accompanying illustration. It is built to stand wear and tear, being made very strong, but is light in weight. Both the scraper and the flanger springs are oil tempered spring steel and any pressure desired can be put upon the track, the pressure being maintained by the lever on the car platform. The flanger works independently of the front scraper as the shoe of the former is only the width of the rail, and it is always on the track, even where the rail is several inches below the pavement. This assures a clean rail at all times, which means good electrical contact for the wheels. The front springs of this device are 3¼ in.

ROOT TRACK SCRAPER.

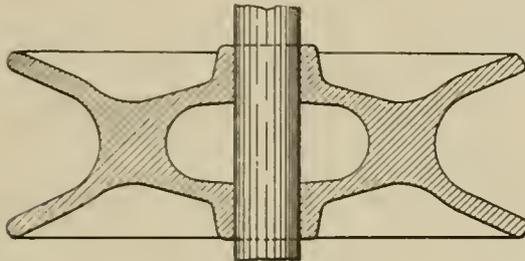

wide of No. 2 gage spring steel, and the rear springs 2 in. wide of No. 8 gage. These springs are fastened to 2-in. wrought iron gas pipe with bolts and jamb nuts. The lever arm in the center is fastened to the pipe so that the lever handle can be placed in any position on the platform as desired. The flanger spring is fastened with a set-screw so as to operate independent of the other spring according to the condition of the track.

The Lewiston (Me.), Brunswick & Bath Street Railway Co. set apart Wednesday, June 11th, as hospital day, donating a large proportion of the proceeds for that day to the Maine General Hospital at Lewiston.

The first through car between Dayton, O., and Newark, over the Columbus, London & Springfield Ry., was run Saturday, June 7th, carrying J. S. Harshman, president, and H. A. Fisher, vice president and general manager, and a number of guests.

**NEW MORRIS TROLLEY WHEELS.**

The accompanying illustration shows a section of one of the special trolley wheels which is being manufactured by the Morris Electric Co., at its factory in East Orange, N. J. It will be seen from this that in the center of the wheel surrounding the shaft a chamber is cored out which is filled with grease by means of which the bearings are kept thoroughly lubricated. In addition to the special

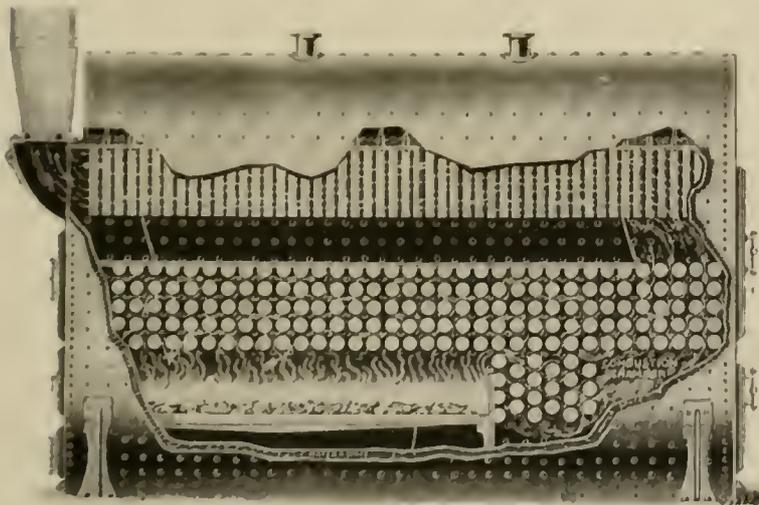

SECTION OF MORRIS TROLLEY WHEEL.

wheel, the company is turning out almost every style of trolley wheel now on the market and its factory contains a large amount of special machinery for this branch of the business. As has been previously stated, the factory is being enlarged to three times its former capacity, which indicates the growth and the present extent of the company's business. Another specialty which will shortly be introduced by this company is a complete line of jackknife switches and panel boards for feeder lines.

The new brass foundry which is being added to this factory will be kept very busy as in addition to the other specialties there will be turned out about 1,000 trolley wheels per day.

**THE KINGSLEY BOILER.**

The illustrations herewith show vertical cross and longitudinal sections of an internally fired, self-contained boiler of the tubulous or tubular pocket type which is constructed of metal throughout and requires no brickwork for either setting or lining. As appears from the line drawing the cross-section is oval in shape with an inner shell, which extends the full length of the boiler and is secured to the outer shell by staybolts, thus providing a water space

THE KINGSLEY BOILER.

around the periphery, the water space is 6 in. at the bottom and 3 in. at the sides, and the distance from the top of the outer shell to the crown sheet is 36 in. at the center. From each side of the inner shell project banks of horizontal tubes screwed into the shell at one end and the other end closed by a blank; these are spaced so as to leave a fire box and ash pit as shown in the half tone engraving. From the crown sheet depend other pocket tubes, staggered as indicated in the line drawing. A bridge wall is placed at the back

end of the grate and a horizontal baffle plate over the horizontal tubes, thus providing for a circulation of the gases that will carry them to all parts of the heating surface. In a boiler rated at 300 h. p. 516 horizontal tubes 3 in. in diameter and 475 vertical tubes 2 in. in diameter are provided.

Access to the interior is had through large cleaving doors at both ends and by hand holes at the bottom, front and back. Water enters at the front of the boiler between the shells at the bottom. It is apparent from the construction that no support or setting other than cast iron legs or saddle blocks, is required.

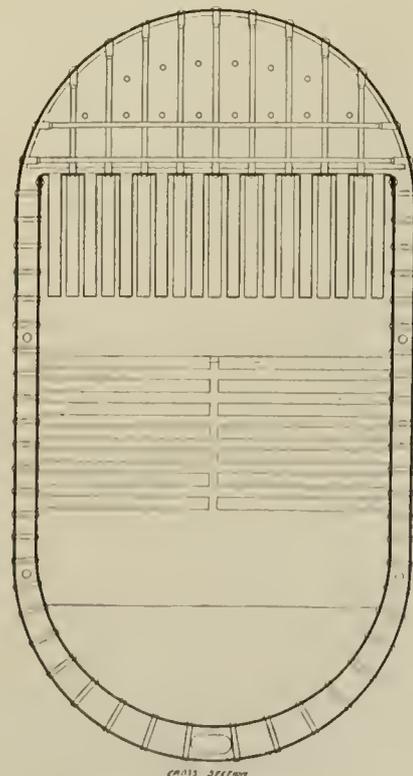

The Kingsley boiler is the invention of Mr. George Kingsley, and is made by the Kingsley Patent Boiler Co., of 30 Broad St., New York. The advantages claimed by the maker include: economy of fuel, economy of space, economy of installation, ability to carry high pressure and make dry steam rapidly, ease of management, safety and durability.

**IMPORTANT CONTRACT FOR STOKERS.**

The Underfeed Stoker Co., with general offices in the Marquette Building, Chicago, last month secured an order from the Milwaukee Electric Railway & Light Co. for 34 Jones underfeed stokers. This apparatus will be placed under the boilers in the main station of the Milwaukee company. The contract is a noteworthy endorsement of the Jones stokers inasmuch as the contract was given after competitive tests lasting four months, in which the Jones apparatus was brought in direct competition with several other makes of stokers.

**EMPLOYEES' BENEFIT AT SYRACUSE.**

The Mutual Benefit Association of the Syracuse Rapid Transit Railway Co.'s employes was given a benefit performance at the Valley theater, Syracuse, on the evening of June 6th, the success of which is another proof of the public approval and widespread popularity which this organization of Mr. Connette's promoting has gained. The performance was of a highly meritorious order and was largely attended.

VERTICAL CROSS SECTION.

The Seattle (Wash.) Electric Co. has applied for a franchise for a new loop system which will afford the cars of the Seattle Tacoma Interurban Railway Co. an entrance into Seattle.

### ADVERTISING LITERATURE.

THE GOULD STORAGE BATTERY CO. has published its bulletin No. 1 on Isolated Plants. The bulletin describes a plant supplied by this company at Biltmore, N. C., for the residence of Mr. George W. Vanderbilt.

THE PROTECTED RAIL BOND CO., of Philadelphia, Pa., has issued an advertising folder under the title of "A Drop in Metal." The folder calls attention to the fact that in this case "protected" means protected from theft as well as corrosion.

THE PETTIBONE BROTHERS MANUFACTURING CO. of Cincinnati, O., has issued a small pamphlet entitled "About Swords and Sword Making in America." The pamphlet described a large number of the characteristic swords used by different nations, which are adapted to be worn with the various styles of uniforms made by this company.

THE ELECTRIC STORAGE BATTERY CO., of Philadelphia, Pa., has published its bulletin No. 72 on the application of storage batteries to isolated plants. The bulletin refers especially to residential lighting and power plants and is illustrated with views of a large number of isolated plants in private residences which have been installed by this company.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING CO., of Pittsburg, Pa., has issued a circular No. 1059 in regard to electrical motor vehicle equipments. This company manufactures motors, controllers, switches and all the necessary electrical apparatus for the complete equipment of storage battery vehicles. The motors are made in a number of different sizes and are of the enclosed pattern.

THE ARNOLD ELECTRIC POWER STATION CO., of Chicago and New York, has published its bulletin No. 6 describing the Grand Rapids, Holland & Lake Michigan Rapid Ry. for which it was the engineer and contractor. The bulletin is a reprint of the paper read before the Chicago Electrical Association by George A. Damon and William D. Ray, an abstract of which was published in the "Review" for March, 1902.

THE OHIO BRASS CO., of Mansfield, O., has published its bulletin No. 9 on "All Wire Rail Bonds." This bond is a "one piece" bond of which the terminals are formed directly from the ends of the cable of which it is composed, so that there are no cast or welded joints in the bond to become loose and interpose additional resistance. These bonds are manufactured in a variety of types and styles all of which are illustrated in the bulletin.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING CO. recently issued an interesting circular describing electric motor vehicle equipments. This company has supplied motors to the electrical vehicle industry for the last five years and is now prepared to furnish a complete line of standard automobile equipments comprising every part of the electrical appliances except the storage battery. These parts are made in sizes adapted to electrical vehicles of any type or capacity. The circular will be mailed upon request.

REYNOLDS-CORLISS ENGINES is the title of a handsomely illustrated catalog published by the Allis-Chalmers Co., of Chicago. The first part of the catalog is devoted to the general views of the company's work at Milwaukee and Buffalo and is followed by a handsome collection of illustrations showing various parts of the shop and office. The catalog gives a brief description of the design, material and economy of the standard engines as well as its pumping engines, hoisting machinery, etc., and concludes with illustrations and descriptions of a large number of plants in which its machinery is installed.

THE CROCKER WHEELER CO., of Ampere, N. J., has issued a small catalog under the title of "Small Power Motors" which contains descriptions and illustrations of various types of small motors made by this company. Small motors may be said to be the specialty of this company as when it started in business in 1888 it confined its attention to building small motors exclusively and although it has since advanced until it now turns out machines up to 1,000 h. p. capacity, the company has built up a reputation for its small motors which has won it a wide reputation. It manufactures these in large quantities, thereby decreasing the cost of production and enabling shipments to be made at a day's notice.

THE CHRISTENSEN ENGINEERING CO., of Milwaukee, Wis., has published a catalog, No. 51, on Motor Driven Air Compressors of both stationary and portable types. These compressors have been designed to form a compact self contained unit with the

electric motor and they can be operated from any railway, power or lighting circuit. They can also be installed at any convenient point for distribution, thereby avoiding expensive piping. The parts of these machines are all made from jigs and templates and are all interchangeable. The working parts operate in an oil bath. Their operation is automatic, the governor being so arranged as to stop the motor as soon as the air pressure reaches a predetermined maximum pressure and to start it when the pressure is reduced to a minimum. The power is therefore used only in proportion to the work being performed.

### STREET RAILWAY PATENTS.

List furnished by T. Reed Clift, Patent Attorney, Washington, D. C., from whom all additional information can be secured.

No. 600,167, May 6, 1902, Joseph P. Hasty, Superior, Neb. Switch actuating mechanism.

No. 600,340, May 6, 1902, Harry M. Loughlin, Stapleton, N. Y. Railway car.

No. 600,573, May 6, 1902, Fred N. Rost, Kalamazoo, Mich. Track scraper adjustment for street railway cars.

No. 600,590, May 6, 1902, Albert A. Stolle, New York. Electric railway.

No. 600,640, May 13, 1902, Gottfred Aye, Kittanning, Pa. Trolley head or wheel.

No. 600,643, May 13, 1902, Robert J. Barney, Westboro, Canada. Controlling attachment for trolley poles.

No. 600,787, May 13, 1902, George L. Campbell, Nyack, N. Y. Electric railway system.

No. 600,895, May 13, 1902, Ludwig Perlhefton, Vienna, Austria. Fare collector.

No. 600,986, May 13, 1902, William Sullivan, St. Louis, Mo. Car fender.

No. 700,084, May 13, 1902, John B. Quinn, Chicago, Ill. Track.

No. 700,126, May 13, 1902, Charles J. Kintner, New York, N. Y. System of electric railways.

No. 700,386, May 20, 1902, James A. Tancock and James C. Coch-rill, London, Canada. Automatic switch.

No. 700,400, May 20, 1902, Frederick Becker, New York, N. Y. Rail brush.

No. 700,461, May 20, 1902, William D. Vabdeear, Grand Rapids, Mich. Electric railroad signal.

No. 700,615, May 20, 1902, Edwin E. Carneal, Washington, D. C. Railway switch.

No. 700,716, May 20, 1902, Alexander Beck, Atlanta, Ga. Fender.

No. 700,719, May 27, 1902, Patrick A. Allen et al., Toledo, O. Water closet receptacles for cars.

No. 700,810, May 27, 1902, Edgar Peckham, New York, N. Y. Car truck.

No. 700,811, May 27, 1902, James S. Perry, Kalamazoo, Mich. Switch and frog.

No. 700,818, May 27, 1902, Charles W. Cowell, Green Island, N. Y. Brake mechanism for cars.

No. 700,836, May 27, 1902, Charles C. Scott, Boston, Mass. Illuminated sign.

In the "Review" for May 20th, our list of patents included No. 608,197, for an adjustable trolley supporter invented by Thomas E. Stucky and Edward Ware. The latter name should have read Edward Hill, and we desire to make this correction as Mr. Hill has experienced some trouble in receiving correspondence under the wrong name.

### PROVIDENCE, R. I. AND RETURN, \$18.90.

On account of the B. Y. P. U. meeting at Providence, the Wabash will sell excursion tickets from Chicago as above July 7, 8 and 9, via Niagara Falls. Return limit, August 15. Write for B. Y. P. U. illustrated folder containing maps and full information. City Ticket Office, 97 Adams St., Chicago.

The serial calendar card mailed by the Bullock Electric Manufacturing Co., Cincinnati, to friends and patrons, for June bears a handsome colored portrait of James Clerk Maxwell on a panel decorated in gold and several colors. The reverse of the card gives a concise and interesting biography of the great physicist.

**THE NEW FARE REGISTER.**

The latest design of fare register made by the Sterling-Meaker Co., has a familiar appearance, being similar to the "Meaker," but we are assured that the mechanism has so many new features that it may almost be considered an entirely novel construction. One idea that has been followed is that of simplicity—to reduce the number of parts, to avoid complexity, to assure direct and positive action, to strengthen the details, to obtain certainty and durability. The size of the machine is about 9 in. square. The company has taken its time in the construction of this machine, has had some of the best register talent engaged on the problem, and the tests have been exhaustive. Patents have been applied for at home and abroad.

**ENLARGEMENT OF THE GOLD CAR HEATING CO.**

Announcement is made that the Gold Car Heating & Lighting Co., which has just been incorporated under the laws of New York with a capital of \$1,000,000 has purchased outright the entire business of the Gold Car Heating Co., of New York, Chicago and London, and also the entire business of the Gold Street Car Heating Co. The new company takes possession on the first of next month of all the property of both of these companies and in addition to nearly one hundred patents formerly owned by these concerns, has acquired a number of new and valuable patents covering electrical heating apparatus.

The business of the Gold companies has increased enormously during the past few years and now extends all over the world wherever railway cars are operated by steam or electricity. The foreign business of the company is larger than ever before, there being at the present time over 2,000 sets of car heating apparatus under construction at the company's shops for shipment abroad within the next three months.

Among the large contracts for electric heaters recently received is one from the Louisville (Ky.) Railway Co. for over 300 sets of electric car heating apparatus. Orders are in hand for about 100 equipments for street railways in New Jersey as well as others for the Boston & Maine R. R., the New York, New Haven & Hartford R. R., the Massachusetts Electric Companies and the South Side Elevated R. R. of Chicago. A contract has recently been closed with the Metropolitan Street Railway Co., of New York City, for electric heating apparatus which will be a departure from anything of this character heretofore undertaken.

The \$1,000,000 in capital stock of the new company has been fully paid in. There are no bonds issued by the new company, and there is no preferred stock. The capital is represented by 10,000 shares of common stock, par value \$100 per share, fully paid and non-assessable, and the statement is made that the company has no other liabilities whatever. The entire property taken over by the new company is valued at \$1,050,000.

Mr. Edward E. Gold of New York City has been elected president of the new company and made chairman of the executive committee. All of the stockholders of the old companies will be numbered among the stockholders of the new company, the plans for the enlargement having received the unanimous approval and consent of every shareholder in all the properties purchased.

The main office of the new company will continue to be at Frankfort & Cliff Sts., New York City, where Gold apparatus has been made for many years.

MR. H. F. SANVILLE, formerly secretary of the Morris Electric Co., of New York, has opened an office for himself in the Girard Building, Philadelphia, Pa., where he will deal in street railway supplies. He will represent among other well known houses Albert & J. M. Anderson, of Boston.

**EXCURSION TO PORTLAND, ME.**

The Wabash road will sell excursion tickets July 5 to 9 inclusive, from Chicago to Portland, Me., at \$21.50 for the round trip via Niagara Falls; \$20.50 via Montreal. Return limit, August 15th. For full information call at or address City Ticket Office, 97 Adams St., Chicago.

**TRADE NOTES.**

DIXON'S SILICA-GRAPHITE PAINT is being used to protect the structural steel work of the Hotel Astor, Long Acre Sq., New York City.

THE DUFF MANUFACTURING CO., of Allegheny, Pa., will make an exhibit at the Tramways and Light Railways Convention in London next month.

THE KENNICOTT WATER SOFTENER CO. of Chicago has established its New England Agency in charge of Mr. J. Edwin McNamee, 10 Sargent St., Boston, Mass.

JOHN A. ROEBLING SONS' CO. was represented at the Charleston Exposition by Cameron & Barkley, agents, of Charleston. Roebling products were well represented, the exhibit including magnet wire, rope, cables, rail bonds, etc.

THE GREEN FUEL ECONOMIZER CO. has received through its Boston office an order from the Massachusetts Electric Companies for its well known fuel saver to be installed in the electric company's new power station at Newport, R. I.

THE GOULD STORAGE BATTERY CO. recently received the contract to furnish a battery of 255 cells with booster and switch-board for the Berlin (Ont.) & Waterloo Street Railway Co. The capacity is 66 kw. with allowance for 50 per cent increase.

THE IRONSIDES CO., Columbus, O., advises us that its latest acquired additional specialty, the "Ironsidess" improved patent Tormay oiler, is being rapidly adopted by the principal plants of the country and that the general demand has taxed the company's facilities.

THE WAGNER-BULLOCK ELECTRIC CO. arranged an interesting display of its apparatus in Machinery Hall at the Charleston Exposition. The exhibit included dynamos and motors and general electrical apparatus, charging sets for automobiles and launches, etc.

THE ELECTRIC INSULATION CO., a New Jersey corporation of which Elijah Woodward is president, on May 29th voted to dissolve. It is reported that L. A. Ziegler, attorney for the company, states that it had bought a secret process which proved to be a "gold brick."

THE STANDARD PAINT CO., of New York City and Chicago, through its Southern agents, the Cameron & Barkley Co., of Charleston, exhibited at the Charleston Exposition, ruberoid roofing, insulating paper, waterproof paper, sheathing paper, and a full line of P. & B. paints and compounds.

THE Q. & C. CO. announces that beginning June 1st it will operate in its own name manufacturing railway specialties, machinery and pneumatic tools. The principal offices will be in the Western Union Bldg., Chicago; New York office, 114-118 Liberty St.; general sales department at the shops, Chicago Heights, Ill.

THE WALWORTH MANUFACTURING CO., of Boston, had at the Charleston show a full line of valve fittings and tools for steam, water and gas plants, including cast and malleable iron pipe fittings, brass and iron valves and cocks, die plates, etc. The exhibit was in charge of Cameron & Barkley Co., agents, of Charleston.

CAMERON & BARKLEY CO., general agents for machinery and supplies, with headquarters at Charleston, S. C., had one of the largest displays in Machinery Hall during the Charleston Exposition. The company showed a diversified stock of specialties for which it is selling agent in the South. Mr. H. R. Thomas was in charge.

THE SPRAGUE ELECTRIC CO., New York City, is supplying large orders for motors to electrotyping and photo-engraving houses where a particular advantage is gained from the use of electrically driven machines. Such an equipment was recently placed in the plant of the United States Playing Card Co. at Cincinnati with highly satisfactory results.

THE PARTRIDGE CARBON WORKS, Sandusky, O., recently had a small fire in the furnace room, of which some greatly exaggerated reports have been published. The fact is that only a small portion of the furnace room was disturbed and this can easily be replaced. The furnaces themselves are fireproof and were not affected in the least.

PAWLING & HARNISCHFEGGER, Milwaukee, Wis., manufacturer of electric traveling cranes and hoists, report among orders recently booked the following: the Falk Co., Milwaukee, one 30 ton with 5 ton auxiliary hoist; the Allis-Chalmers Co., for the West Allis, Wis., plant, two 5-ton wall and one 2½-ton wall hoists; the Milwaukee Electric Railway & Light Co., one 30-ton hoist; the

Pennsylvania R. R., for the Altoona shops, two 12½ ton hoists; the American Foundry & Construction Co., Hazlewood, Pa., two 10-ton hoists, and the Baldwin Locomotive Works, Philadelphia, six 10-ton hoists.

THE PENNSYLVANIA STEEL CO. was represented at the Charleston Exposition by its Southern agents, R. C. Hoffman & Co., of Baltimore, Md. The company exhibited its well known steam railroad and street railway specialties, including grooved and girder rail sections, "New Century" switch stands, switch lamps and parts, and samples of special work.

THE PEERLESS RUBBER MANUFACTURING CO., of 16 Warren St., New York, had a booth at the Charleston show where samples of its various packings, beltings, discs for valves, gaskets, hose, etc., were displayed. This company has won an enviable reputation for superior quality of the various kinds of mechanical rubber goods which it produces.

JENKINS BROS., of New York and Chicago, makers of valves, disks and packing for steam, gas, water or acid pipes, had an interesting display of their goods at the Charleston Exposition. These goods are made from special patterns and embody the latest improvements suggested by years of experience in this line. Mr. J. W. Odiorne had charge of the exhibit.

THE AMERICAN STEEL & WIRE CO. had practically the same display at Charleston as was shown at the Pan-American Exposition. It consisted of a huge pyramid forming a covered booth, in which several hundred different products were displayed for examination. The American Steel & Wire Co. supplied all the steel wire fencing used around the Charleston Exposition grounds and the street railway terminals.

THE PITTSBURG GAGE & SUPPLY CO., of Pittsburg, reports an excellent demand for its "White Star" filters. A recent shipment included four filters for the Varbic mines, Japan. The company has also taken orders for its continuous oiling system using duplex types of the "White Star" filters, to be installed in the plants of the Union Steel Co., Pittsburg, and the Citizens Railway, Light and Power Co., Mansfield, O.

THE UNITED STATES ELECTRIC SIGNAL CO., West Newton, Mass., manufacturer of automatic electric signals for street railways, has issued a mailing card estimating the risk assumed by companies whose lines are not equipped with proper signaling apparatus. The United States company's signals are in successful operation in nine foreign countries, 15 states in the United States and on over 50 of the largest street railway systems in the world.

THE PITTSBURG REDUCTION CO., operating the Hall patents, is stated in the report of the United States Geological Survey to be the sole producer of aluminum in this country. The production of aluminum in the United States during 1900 amounted to 7,150,000 lb., and the price per pound remained practically stationary throughout the year. The total imports of all forms of aluminum in 1901 were valued at \$109,748 as compared with \$50,444 in 1900.

C. J. HARRINGTON, 15 Cortlandt St., New York City, has received a contract for 250,000 ft. of conduit to be shipped to Seattle for Stone & Webster, of Boston, Mass. This is a large contract and there are other large contracts in view. C. J. Harrington has but recently taken up the management of the sales for the Scranton Firebrick & Conduit Co., of Scranton, Pa., and the business done in this line indicates that the firm will be one of the largest dealers in conduit in the country.

THE FALCON ELECTRIC MANUFACTURING CO., No. 432 East 71st St., New York, announces that owing to the large demand for its switches, switchboards, flush receptacles, etc., it has opened an office for the convenience of contractors and the electrical trade at No. 15 Cortlandt St. (Telephone No. 3901 Cortlandt), where it will carry a complete line of the company's standard products. In the future, all communications with the Falcon company should be addressed to No. 15 Cortlandt St.

THE UNDERFEED STOKER CO. of America reports a large number of contracts recently closed for installing Jones underfeed mechanical stokers among which can be mentioned the following: Phoenix Roll Works, Pittsburg; Bureau of Public Lighting, Allegheny, Pa. (second order); Newport Mining Co., Ironwood, Mich. (third order); Michigan Salt Manufacturing Co., Marine City, Mich.; Cornplanter Refining Co., Warren, Pa.; Lehigh Portland Cement Co., Wellston, O. (second order); White Swan Mills, Clinton, Mo.; Bausch & Lomb Optical Co., Rochester, N. Y. (fourth

order); National Biscuit Co., Toledo, O.; Milwaukee Electric Railway & Light Co., Milwaukee, Wis. The company has issued an interesting little pamphlet showing views of a large number of public buildings in various parts of the country which have been equipped with the Jones underfeed stokers.

THE SPRAGUE ELECTRIC CO., New York City, on May 17th gave the employees of the office and sales department in both the New York and Watssing offices a pleasurable outing at New Dorp, Staten Island. The principal feature of the afternoon's entertainment was a ball game in which the chiefs of the departments participated. The outing was voted a great success, and special thanks were tendered Messrs. Bourgeois and Vanderhoof who managed the affair in a highly acceptable manner.

ARTHUR KOPPEL, 66-68 Broad St., New York City, manufacturer of forged steel shoes and dies, railway materials for mines, plantations, industrial works, etc., has issued a booklet concerning the Arthur Koppel shoes and dies which are used for ore stamping mills; single switches, right or left hand, for use in portable track, and turntables made in all styles and sizes. A clever cover-illustration in colors represents the gnomes at work with Koppel dies. The book is especially distinguished by the ingeniousness and merit of the one illustration.

WORK AT THE CAR BUILDING establishment of the John Stephenson Co. has been steadily increasing during the past year, and within the last few months has been so rapid that considerable inconvenience has been experienced from want of power. To remedy this condition, as the works are entirely without line shafting, an electric generating set is necessary. A contract has just been signed for a 300-kw. General Electric generator, and a 450-h.p. tandem compound engine, with cylinders 20 and 34 by 28 in. The installation will be put in operation at the earliest possible date.

CROCKER-WHEELER CO., Ampere, N. J., manufacturer of generators and boosters for electric railways, and electrical engineers, reports a very satisfactory increase in orders received during May over those of the preceding month. Some of the orders booked for May included generators of from 30 to 200 kw. capacity, 50 crane motors with outputs ranging from 1½ to 50 h. p. and a consignment of nine motors. The Crocker-Wheeler Co. has under construction a new building which will increase the floor space by 60,000 sq. ft. and will be occupied by the winding department, the machine shop and a part of the office force.

POWER PLANTS OF THE PACIFIC COAST is the title of a paper recently read before the New York Electrical society by Dr. A. C. Perrine. The paper describes a large number of the long distance transmission plants for which California is famous, and is highly illustrated with half tone views of these plants and their surroundings. The plant of the Standard Electric Co. of California is specially mentioned as being the boldest attempt in the direction of high voltage which has so far been undertaken. This plant operates at 50,000 volts and was designed and supplied by the Stanley Electric Manufacturing Co., of Pittsfield, Mass.

THE HAM SAND BOX CO., of Troy, N. Y., has recently shipped a large order of sand boxes to the Brooklyn Rapid Transit Co., making a total of 2060 Ham sand boxes now in use on this system. Among other large users of Ham sand boxes are the Cleveland City Ry., with 1168 in use, and the Glasgow Corporation Tramways, Glasgow, Scotland, which has 1804 in service. The Electric Tramway & Carriage Works, of Preston, England, has placed in service a total of 5100 Ham sand boxes. Besides these large users, the Ham sand box is to be found on nearly every electric railway in this country, as well as abroad.

THE ELECTRIC STORAGE BATTERY CO., of Philadelphia, has recently closed a contract with the Greenfield & Turner's Falls Street Railway Co. for the installation of a battery of "Chloride" accumulators. This battery consists of 200 cells having a capacity of 200 amperes for one hour with tanks sufficiently large to allow of a 40 per cent increase, and will be placed in the new car houses at Cheapside, a distance of ten miles from the power house. The battery floating on the line is to be used at this point to regulate the drop in voltage due to the heavy grade which occurs near this station at the terminus of the railway company's line.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING CO. has furnished eleven 15-h. p. and three 40-h. p. 500-volt, shunt-wound direct current motors for the smelters and refineries of the Boston & Montana Consolidated Copper & Silver Mining Co., at

Great Falls, Mont. Four years ago the latter company installed a number of Westinghouse 180-volt electrolytic generators, and at the same time put in a number of Westinghouse motors for driving ventilating fans and other machinery about the smelters. Although the smelters are filled with sulphur dust and are extremely dirty the Westinghouse motors have given excellent satisfaction.

J. C. STEWART, the American contractor, whose record brick-laying performance in connection with the erection of the British Westinghouse Electric & Manufacturing Co.'s works at Manchester, England, recently caused so much discussion, has been engaged by the Midland Railway Company to supervise and expedite the work at the large Midland Railway Hotel at Manchester. The contract is in the hands of Messrs. William Brown & Son, of Salford, England, and it is said that they are to receive \$100,000 in bonuses if the work is finished within a year, and \$10,000 a month for each month shorter than that time. The total price is \$5,000,000.

THE GENERAL ELECTRIC CO. had a comprehensive exhibit at the Charleston show, including a complete illuminated model of its several factories and an extensive working exhibit of its electrical machinery and apparatus. This space was the center of the distributing system for furnishing lights and power for all the grounds and buildings. The three-phase transmission lines from the power house of the Charleston Consolidated Railway, Gas & Electric Co. led directly to the General Electric space, and the current was there converted and transformed for the different uses so that the exhibit made an actual demonstration of the work the General Electric Co. is doing in this line.

THE MALTBY LUMBER CO., of Bay City, Mich., recently shipped a special trainload of cedar ties for the street railway of Des Moines, Ia. This is part of an order which the company has been shipping for some time and it took occasion to make quite a display in connection with this trainload. Each car had two large cards 3x4 ft. square on each side bearing an advertising display and by special arrangement with the railways over which the train ran it laid over nights and ran only during daylight hours. The scarcity of cars for western shipment and the scarcity of room in railroad yards have delayed the shipment. If these troubles can be overcome the second shipment of the same kind will be made within two or three weeks. The company is also figuring on a similar display with a telephone pole order to be shipped to points in Arkansas.

THE J. G. BRILL CO., of Philadelphia, had an unusually elaborate exhibit of cars and trucks at the Charleston Exposition. The semi-convertible and convertible cars recently brought out by the Brill company attracted considerable attention, as these types of cars are well adapted to Southern climates. A full line of trucks was exhibited. The Brill solid forged side frame 21 E truck occupied a conspicuous position in the exhibit space. This truck follows standard locomotive practice. The entire yoke, including jaws, spring seats and extension pieces, are forged in one piece. The Eureka maximum traction truck, built for heavy city service, received attention from officials of city roads. A placard on this truck stated that over 4,000 of this type are in use. The "Universal" truck, with equalized center pivotal support, for use under open or closed cars, using single steps, and the "Perfect" truck, No. 27, for fast suburban and interurban service, were also exhibited. The space also

contained stands of photographs of cars and trucks, illustrating the wide range of the company's activities.

THE ALLIS-CHALMERS CO. reports the following among its list of sales of Reynolds-Corliss engines for May, 1902: Wolf River Paper Co., Shawnee, Wis., two "1900" frame engines. Southern Cotton Oil Co., New York City, five girder frame engines. Surry Rubber Co., Baltimore, Md., one "1900" frame engine. S. P. Brown & Co., Albany, Ga., one girder frame engine. Devoc & Reynolds Co., Chicago, Ill., one "1890" frame engine. Carnegie Steel Co., Pittsburg, Pa., five pairs of vertical, cross-compound blowing engines. Jones & Laughlin Co., Ltd., Pittsburg, Pa., one air cylinder. Rapid Transit Subway Construction Co., New York City, two combined vertical and horizontal engines, Union Steel Co., Pittsburg, Pa., three horizontal, cross-compound, direct coupled engines. Willis Coal & Mining Co., Murphreysboro, Ill., one girder frame engine. Gunther Foundry Machine & Supply Co., San Antonio, Tex., one girder frame engine. Buffalo Union Furnace Co., Buffalo, N. Y., one vertical end cross-head blowing engine. Studebaker Brothers Manufacturing Co., South Bend, Ind., one "1890" frame horizontal cross-compound direct coupled engine. Colorado Milling & Elevator Co., Monte Vista Mill, Colo., one girder frame engine. Great Western Gold Co., Cal., one girder frame engine. Park City Sampling Mills, Utah, one "1890" frame engine.

THE DORNER TRUCK & FOUNDRY CO., of Logansport, Ind., reports an extremely satisfactory business in its single and double trucks, and several large orders have been shipped during the current month. Among the roads using Dorner trucks are: Stark Electric Ry., Alliance, O.; Alabama City (Ala.), Gadsden & Attalla Ry.; Ogden (Utah) Rapid Transit Co.; Redlands (Cal.) Street Ry.; Logansport (Ind.) Street Ry.; Kokomo (Ind.) Railway & Light Co.; Union Traction Co. of Indiana; Wabash River Traction Co., Wabash, Ind.; Ft. Wayne (Ind.) Traction Co.; Kanawha Valley Traction Co., Charleston, W. Va.; Toledo (O.) & Western Ry.; People's Gas & Electric Co., Defiance, O.; Springfield (O.) Street Ry.; Dunkirk (N. Y.) & Fredonia R. R.; Evansville (Ind.) Street R. R.; Northern Ohio Traction Co., Akron, O.; Cleveland (O.) City Ry.; Kentucky & Indiana Bridge Co., Louisville, Ky.; Charleston (W. Va.) Traction Co.; Alliance (O.) Street Ry.; Owosso (Mich.) & Corunna Electric Co.; Cleveland Electric Ry.; Oakland Ry., Birmingham, Mich.; Schuylkill Electric Ry., Pottsville, Pa.; Urbana & Champaign (Ill.) Railway, Gas & Electric Co.; Consolidated Light & Railway Co., Huntington, W. Va.; Washington (Ind.) Street Ry.; Cleveland & Eastern Ry.; Cleveland, Berea & Elyria Ry.; Fairmount Construction Co., Philadelphia, Pa.; Bangkok Tramways Co., Bangkok, Siam.

THE BRIDGEPORT BRASS CO., of New York, has issued a new pamphlet published in the usually attractive style for which this company's advertising matter is well known. The pamphlet is entitled "Phono-Electric Telephone and Telegraph Lines" and contains 38 pages of well written text, interspersed with clever pen sketches, all going to demonstrate why "Phono-Electric" wire makes the best working lines for telephony and telegraphy. "Strong" and "tough" are the adjectives that most properly describe the distinctive characteristics of this wire which is now being made by the Bridgeport Brass Co. in enormous quantities for all manner of overhead transmission lines for electric current.

The Bel Air (Md.) & Havre de Grace Railroad & Power Co. expects to begin the construction of its interurban electric line between the cities named in the title this summer. A large power house is to be erected half way between Bel Air and Havre de Grace. John H. Reckord is president of the company.

The Pittsburg, McKeesport & Connellsville Street Railway Co. has placed orders with the Westinghouse Company for additional equipment, which will double the present power house capacity of the interurban system and increase the street railway company's recent expenditures for power facilities to \$1,000,000. The feeder system has been completed by the acquisition of the 12-mile line between Greensburg and Youngwood, and the Connellsville suburban railway, three miles long. Twenty-five palace traction cars, manufactured by the John Stephenson Co., have been delivered and will be put in commission this summer on the Pittsburg, McKeesport & Connellsville company's lines through the coke region.

CORRESPONDENCE.

We cordially invite correspondence on all subjects of interest to those engaged in any branch of street railway work, and will gratefully appreciate any marked copies of papers or news items our street railway friends may send us, pertaining either to companies or officers.

DOES THE MANAGER WANT ANYTHING?

If you contemplate the purchase of any supplies or material, we can save you much time and trouble. Drop a line to THE REVIEW, stating what you are in the market for, and you will promptly receive bids and estimates from all the best dealers in that line. We make no charge for publishing such notices in our Bulletin of Advance News, which is sent to all manufacturers.

This paper is a member of the Chicago Trade Press Association.

Entered at the Post Office at Chicago as Second Class Matter.

VOL. XII.

JULY 20, 1902.

NO. 7

The applications for space from manufacturers who wish to make exhibits at the Detroit convention of the American Street Railway Association are more numerous than ever before. The convenient location of Detroit with respect to those states in which electric railways are already numerous and new enterprises are being rapidly developed, insures a large attendance of street railway men, and all indications point to this being an exceptionally successful meeting.

As at all the A. S. R. A. conventions since 1899, one of the leading features will be the "Daily Street Railway Review," which will be published on October 8th, 9th, 10th and 11th.

An illustration of the difficulty of pleasing all patrons, which is the aim of every street railway manager, a recent meeting of the Chicago Council Sub-Committee to consider the electrical equipment of the North Shore branch of the St. Paul railroad is instructive. Delegation of residents of many of the northern suburbs were present and although the residents of these towns have been clamoring for several years for electric transportation to Chicago over the Evanston branch of the St. Paul, they were so divided on the question of fare that the sub-committee found it impossible to draft an ordinance acceptable to all. While part of the delegation demanded a 5 cent fare into Chicago, as many more advocated a 10-cent fare in order, as they asserted, to maintain property values and exclude fat building which are comparatively unknown in some of these suburbs. As no decision could be reached the meeting was adjourned until the public interested in the matter could decide upon what they wanted.

Since the advent of the trolley the personnel of the uniformed employees of street railways has vastly improved both as to general appearance and character. It is well known to all street railway managers that the improvement in character and appearance of the men on the car, results in an equal improvement in service and for this reason much attention is now being paid to the question of providing desirable and attractive accommodation for the men when off duty. The custom of providing club rooms equipped with baths, lockers, games, and other features of amusement as well as

instruction has become very general, especially upon the larger roads and several of these club houses for street car men have been described and illustrated in the columns of the "Review" from time to time.

Club rooms have been provided in Brooklyn for the use of the employes of the Brooklyn Rapid Transit Co. and President Great-singer recognizing that the men while off duty have nowhere to go for recreation but to saloons, has taken great interest in providing suitable places for the men in order to offset the influence of the saloons. A number of car barns on the company's lines have had rooms fitted up as reading rooms and these have proved so beneficial that the company has decided to advance this plan another step by procuring sites for the erection of a number of club houses. The company is going to establish the new club rooms upon the same system that is followed by the Young Men's Christian Association and similar attractions will be provided in all of them, and every inducement is to be made to get the men to frequent the clubs.

The practicability of operating both steam and electric trains on one track is a subject of wide interest at the present time owing to the desirability as well as the demand for frequent car service on the suburban divisions of many of the large steam roads. The question has been investigated by a number of roads in this country and has also been for some time under consideration by a number of the English roads having terminals in the city of London. While this practice has not been undertaken to any great extent a few cases are now in evidence from which it would appear that no great difficulty exists in operating both classes of service over the same tracks provided that the electric cars are operated under dispatcher's orders and submit to the same rules and codes of signals which govern the steam trains.

One illustration of this practice may be found in the case of the Washington, Alexandria & Mount Vernon Ry. which runs upon the tracks of the Pennsylvania Railroad for a considerable distance. In this case the electric trains have the same status as the steam trains as soon as they enter upon the steam railroad tracks, and are subject to the same regulations as the steam trains. As long as the trains are on scheduled time, their movements are regulated absolutely by the time table without orders from a dispatcher. They are operated under train numbers and their class is indicated on the time table. A full description of the method of operation in this case was published in the "Review" for June, 1902.

Another instance of this practice is found in the case of the Peoria (Ill.) & Pekin Terminal Ry. which combines under one management a steam railroad, an interurban railway and a street railway, all operating upon the same tracks although here the steam locomotive service is used principally for transferring freight and is in a measure subordinate to the electric service. In this case the organization and management of the road are exactly similar to those of steam roads, all trains, whether steam or electric being numbered and operated under the same code of signals. This road, which has now been in operation for several years, has been a decided financial success and no trouble whatever has been reported as due to the mixed character of the service.

Elsewhere in this issue is to be found a paper on "Electric Suburban Railways" by Mr. E. A. Evans, describing the conditions on the Quebec Railway, Light & Power Co's. road, a part of which system was formerly the Quebec, Montmorency & Charlevoix Ry. which is a steam road covering a distance of 30 miles. A service of electric cars upon the same tracks running between the usual steam railway trains was inaugurated and the results have more than justified the innovation and the expenditure incurred. From the figures given in this paper it will be seen that the total number of passengers carried in 1899 on the steam road alone amounted to 253,054, while for 1901 on both the steam and electric cars this figure arose to 571,374. The figures for the year 1900 are omitted as the work of electrically equipping the road was then under way, but during the period from 1899 to 1901 as shown by these figures, the passenger traffic had more than doubled, this result being due almost entirely to the frequent service provided by the electric cars.

Another road using both steam and electric propulsion has been projected to run between Rome and Naples, Italy, and it seems apparent that this mixed service could be generally adopted in the suburban service of steam roads with excellent results.

Probably the most serious difficulty to contend with in the case of such a service is the interference with the electric signals used by many steam roads by the high voltage current of the trolley cars. The practice is to bond a track of the steam road for the return circuit of electric signals and this would be impracticable where the track return was used for electric cars. This difficulty, however, may be considered as merely a matter of detail as other means for operating the return circuits for the signals will undoubtedly be forthcoming when the necessity for them arises.

The meeting of the American Institute of Electrical Engineers which was held at Great Barrington, Mass., last month, was a notable one in regard to the number of papers presented bearing upon electric railways. Among these papers may be mentioned "Comparative Acceleration Tests with Steam Locomotives and Electric Motor Cars" by B. J. Arnold and W. B. Potter; "Method of Ascertaining By Means of a Dynamometer Car the Power Required to Operate the Trains of the New York Central & Hudson River Railroad Between Mott Haven Junction and the Grand Central Station and the Relative Cost of Operation by Steam and Electricity" by B. J. Arnold; "A Study of the Heating of Railway Motors" by A. H. Armstrong, "Railway Speed-Time Curves" by C. O. Mailloux and the announcement of two systems for utilizing electricity for railway propulsion on trunk lines, one by B. J. Arnold, and another by H. Ward Leonard.

The announcement of Mr. Arnold of his electric pneumatic system for long distance railway working was an important feature of the Great Barrington meeting and while it was generally known that Mr. Arnold had developed an alternating system for street railway work the originality of the method he proposes came as a surprise to his hearers. It will be remembered that Mr. Arnold was the pioneer in the use of alternating current with rotary converter sub-stations for interurban work and the announcement of his electric pneumatic system stamps him as a pioneer in the field of electric trunk line railroads.

The principal feature of the new system is the use of a single phase or multiphase motor which is always connected to the line and in which either the rotor or stator or both are always in motion. The rotor is connected directly to an axle and both the rotor and stator are connected to compressed air engines in opposite relation to each other. The air compressed by these motors is stored in tanks and is used to assist in starting the car, helping over grades, for switching purposes and for the operation of the brakes. By means of this arrangement the motor operates continually in synchronism and any excess of power developed, not required by the car, is taken up by the compressed air engines and subsequently utilized anew. When the car is at rest the rotor would therefore be also at rest and the normal speed of the motor would be attained by the stator in compressing air. To start the car, the engine connected to the stator would be throttled and the rotor then begins to revolve and propel the car at a speed equal to the diminution of speed of the stator, as the synchronous relations between the two must be maintained. When the stator is brought to rest the motor has attained normal speed and if a higher speed is desired the stator is revolved in the same direction as the rotor by means of the compressed air in the storage tank. The engine of the rotor can also be put in operation to assist the latter in case a higher than normal torque is required. The use of single-phase current permits this system to conform to the overhead construction of today except that a much higher working voltage can be used and in case this voltage is too high for direct use upon the motor a static transformer can be placed upon each car to reduce the line voltage to the pressure desired for the motors.

Other features of the system involve a multiple-unit and simple system of control and the use of electro-magnetic clutches by means of which either the rotor or stator may be disconnected from the car wheels when it is desired to compress air only. It is also to be noticed that the system of control is entirely mechanical and that there is no manipulation of the electrical circuits; the operations are all effected automatically by a controller lever. The pneumatic auxiliary of this system makes the single phase alternating motor which has been inflexible in regard to speed even more flexible than the present direct current railway motor and the fact that in this system the motors run continually at their normal output and store

energy for use in emergency, which is under ordinary circumstances dissipated as heat, points to a good efficiency for the system. The air storage feature will also be found of great value in a number of circumstances. As pointed out by Mr. Arnold, it will allow the active conductor to be stopped where the private right of way ceases and the car to proceed through the city or town on any tracks, whether electrically equipped or not, until it reaches the point where it can take up the working conductor again. This feature is also valuable in switching work and eliminates the necessity for electrical conductors except on the main line of track.

The other system of electric propulsion for heavy service, announced by Mr. H. Ward Leonard, involves the use of single phase, high voltage transmission, single phase motors upon the cars driving direct current generators which in turn supply the car motors. The Ward Leonard system of control by varying the voltage is used and a system of multiple unit control has also been devised. The system has been taken up by the Oerlikon Works where a 44-ton locomotive is being built for operation upon a 15,000 volt circuit.

\* \* \*

The problem of electrically equipping long distance railways for electric service has been an alluring one to electrical engineers for several years but the limited distance to which direct current distribution is applicable and the unsuitability of alternating current motors for railway work have heretofore proved barriers of such importance that no attempt at converting long steam roads to electricity has been seriously considered. There is no doubt in the minds of most engineers that alternating current, either simple or polyphase at high potentials, is the only practicable method of covering long distances and in all the schemes for long distance work which have recently been brought to public attention the main features have consisted in adopting alternating motors for electric railway work. The systems of Mr. Arnold and Mr. Leonard already mentioned, as well as the Ganz system, which is about to enter the railway field in this country, have all been brought to public attention almost simultaneously so that at present the prospects for the development of electrically operated long distance heavy service roads looks extremely promising. The solution of this question which will undoubtedly be reached in a comparatively short time bids fair to establish a new department of electric railway business of even greater extent than the systems of urban and suburban lines already established.

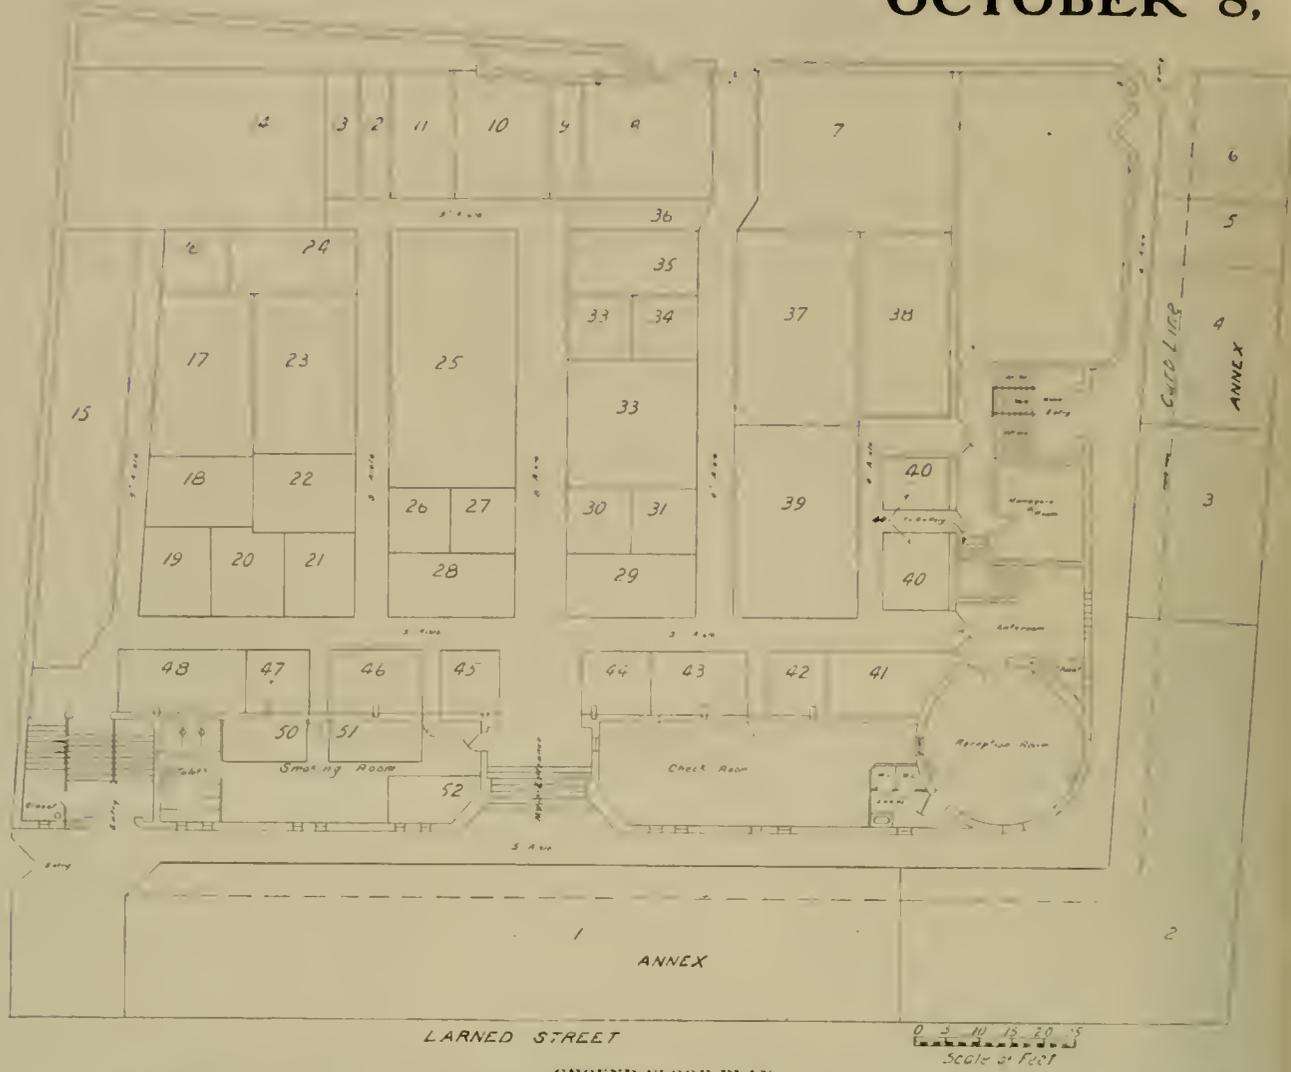

A decision of the New York Court of Appeals which is of much importance to electric railway companies doing a freight and express business is reported on another page of this issue. The litigation arose because the Stillwater & Mechanicsville Street Railway Co., operating an electric trolley line, sought to secure a physical connection of its tracks with those of the Boston & Maine R. R., a steam line, and to interchange freight with the latter. The contention of the Boston & Maine company was that to compel track connection between electric and steam lines would be to impose a burden on the latter not contemplated when the railroad law was enacted, but the Court of Appeals held that travelers and shippers of merchandise and freight are entitled to use all the facilities provided for in the articles of incorporation of transportation companies and the provisions of the railroad law. Further that New York in its legislation has recognized electric railways as an integral part of the transportation system of the state.

The court after referring to the fact that steam railroads have become great arteries over which the greater part of the commerce of the country is carried says: "It has not been considered profitable or practical for steam roads to be constructed to every village, hamlet or productive district in the country. This, however, is rapidly being accomplished by the numerous electric roads that are in process of construction or are contemplated. By their means the farmer, the mill owner and the merchandise vendor in distant places may be able to reach the steam railroads, and through them the great markets of our cities with their merchandise and products, and in this way one road may become the feeder and distributor for the other."

It is apparent from this language that the court does not consider the interest of the two classes of roads to be antagonistic to any serious degree, but regards the electric lines as filling a need which the steam railroads has as yet not been able to supply with advantage to their own stockholders.

## New Orleans & Carrollton Railroad, Light & Power Co.

Topography and Climatic Conditions—Track and Roadbed—Pole and Line Construction—Rolling Stock—  
Special Emergency Wagon—Hose Bridge—Car House, Shops and Shop Practice—Daily  
Report Mileage Blanks—Method of Inspection and Car House  
Repairs—Cost of Power.

As regards its conditions for street railway operation New Orleans—the Carnival City of America—is in many respects a city ideal. Its general topography, especially the absolute freedom from grades, makes possible the most advantageous distribution of lines and feeders. The entire freedom from heavy snow and sleet storms eliminates many of the vexing difficulties that interfere with schedules and time tables in less fortunately situated localities. The water way and steam railroad facilities render available good qualities of coal at reasonable cost, and the nearby fuel oil fields of Texas give promise of making possible still greater economy in the cost of producing power. The cars move, as far as the New Orleans & Carrollton road is concerned, on a grassy strip of ground reserved down the center of the streets, and known as "Neutral Ground." On either side of this are roadways for vehicles, with sidewalks for pedestrians on the outside of the roadways; as

It is often a greater thing to take advantage of opportunities than it is to find them, and in the improving and developing of the New Orleans properties those responsible for the management have not only taken advantage of all opportunities offered, but have created new ones. The companies, and in particular the New Orleans & Carrollton company, have proceeded on the belief that money was well spent when expended in giving the public what it asked in reason, and even in providing conveniences and accommodations unlooked and unasked for. The New Orleans & Carrollton company has worked on that basis from the start, and in demonstrating its faith in the aphorism the very highest engineering and executive skill has been obtained and retained in every department. This is the secret of the company's success.

As outlined in the news columns of the "Review" virtually all the gas, electric lighting and power, and street railway interests of

INTERIOR OF POWER STATION NO. 2, NEW ORLEANS & CARROLLTON RAILROAD, LIGHT & POWER CO.

pedestrians and vehicles are thus diverted from the Neutral Ground the chance of collision and accident is reduced to a marked degree; furthermore, the noise is very much less, the dust even in dry weather is inconsiderable, and the grass and shade trees bordering the track conduce to the comfort of passengers and the attractiveness of the ride. The population of the city is about 300,000, and is made up of a pleasure loving, industrious and prosperous people, that liberally patronizes the street cars both as an aid in executing their business and in seeking their recreation and amusement. Moreover, the city is growing in population, in volume of exports and imports, and in manufactures, at a rate that has already placed it far in the lead of the cities of the South, and will soon bring it to equal standing with the largest cities of the North.

All this, be it understood, is not belittling the difficulties that have beset the originators and builders of the electric railway transportation systems in their work of bringing the properties to their present efficient state. They have had their own serious troubles to meet and they have met and solved the difficulties well.

New Orleans have been merged under one corporate control. It is the purpose of this article, however, to deal only with the property and methods of the New Orleans & Carrollton Railroad, Light & Power Co., which this month passes into the hands of new interests. This property, although of but medium size, deserves to go into record as one of the most interesting, well designed and well managed city street railways in this country.

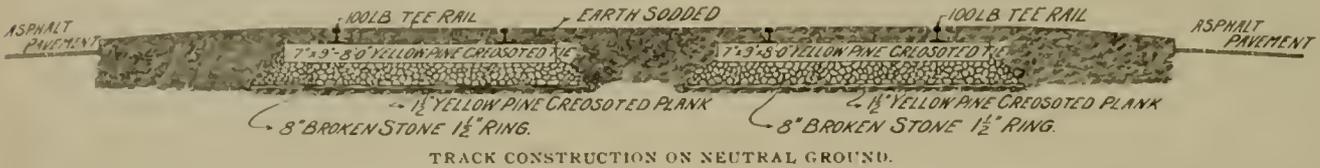

### TRACK AND ROADBED.

The company operates 34 miles of track, comprising for the most part a double track belt line around the heart of the city—and this "circle," or belt, is the distinctive feature of the entire system. The "circle" is about 11½ miles in circumference, cars making the entire circuit in one hour. From the main belt line lead off short spurs to reach the docks and ferries, the railroad depots, certain resident and manufacturing districts, and Canal St., the Broadway of New Orleans. Cars are operated in both directions around the belt and as most of the belt track is heavy T rails laid in Neutral Ground, a

frequent, fast, clean, smooth-riding service is maintained both ways from early morning until late at night, the result being that the cars of the company are comfortably filled at nearly all hours of the days with passengers either on business or pleasure bent.

The converging point for all cars operating in the city of New Orleans is Canal St., and it is good-naturedly admitted that this is the only safeguard the stranger in New Orleans has against getting lost in the labyrinth of crooked streets with unpronounceable names; all routes lead to Canal St. and if the stranger boards a car and remains on it long enough he is sure to arrive at that thoroughfare.

of ballast and ties have been tried in New Orleans, but the best results have been obtained with stone broken to pass a 1½-in. ring, and cypress or yellow pine creosoted ties. The standard design adopted for all new work on Neutral Ground may be described as follows: A trench for each track is excavated to a depth of 2 ft., in the bottom of this is laid a flooring of 1½-in. yellow pine creosoted plank. On this is laid 8 in. of broken stone, on which is placed yellow pine creosoted ties, measuring 7x9 in. x 8 ft., placed 2 ft. c. to c. On the ties are laid 100-lb. A. S. C. E. standard T-rails, or 75 lb. girder rails, as the case may be. The space between the

TRACK CONSTRUCTION ON NEUTRAL GROUND.

It will be information to many that owing to this convergence of routes there are, at certain hours, more cars passing up and down the busiest section of Canal St. than pass up and down Broadway in New York City during the heaviest periods of the day, or converge at the Brooklyn Bridge at the rush hours. This traffic, however, instead of converging on two tracks is distributed over six tracks, all of which are placed in the center of the street on raised Neutral Ground. On Canal St. this reserved space is paved with asphalt, but on virtually all other streets and avenues it is covered with grass without paving.

The present management of the New Orleans & Carrollton company about three and one-half years ago, undertook the task of thoroughly reconstructing the property, and today the track, rolling stock, overhead work and power house equipment may be said to be up to the condition of a newly constructed road.

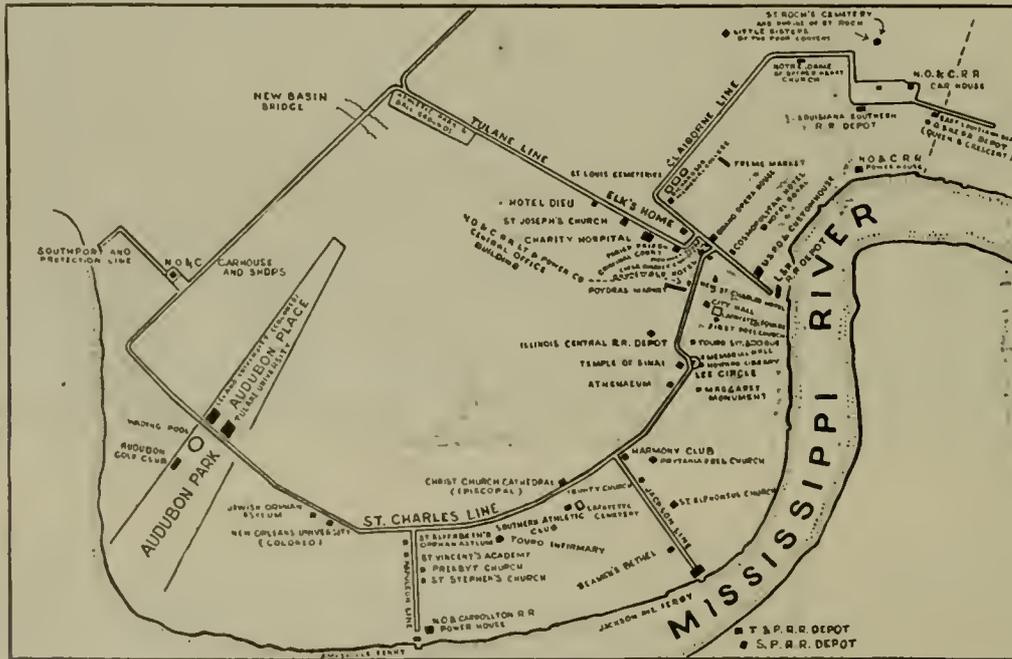

rails and outside the rails is filled in with dirt brought flush with the tops of the rails. In paved streets a 93-lb. girder rail is used. All new special work is supplied by the Lorain Steel Co. The track is bonded with "Crown" bonds under the angle plates.

POLE AND LINE CONSTRUCTION.

The location of the double track in the center of the Neutral Ground gave rise to a special design of center pole double flexible bracket construction for carrying all the overhead work for both tracks as well as railway feeders, and in places electric light wires.

The poles for this purpose are extra heavy iron tubular poles 32-ft. long, made in three sections with shrunk and swedged joints. Two types of poles are used, one 4½ in. in diameter at the top, and one 5½ in. in diameter at the top.

As in the track construction, the saturated condition of the

MAP OF NEW ORLEANS & CARROLLTON STREET RAILWAYS.

Of the total track, 13 miles are laid with 100-lb. T-rail, and 10 miles with 75 lb. girder rail, the rest of the track being of various weights. As before stated the largest portion of the mileage is on Neutral Ground without paving.

As is generally known New Orleans is wholly below mean water level, and the sub-soil in and about the city is so thoroughly unpregnated with water that sub-surface drainage is impossible, and excavations made in the streets almost immediately fill with water. It needs no explanation to realize that these conditions of affairs introduced complications in track building. Various kinds

sub-soil called for special precautions in setting poles. They are usually placed with from 7½ to 8 ft. of the base in the ground and each pole rests on a cypress block. Large broken stone is tamped around the base and the hole is then filled with concrete.

The double flexible brackets were designed by Ford, Bacon & Davis and are made by the Creaghead Engineering Co., of Cincinnati, O. The bracket arm is structural steel tubing 23½ in. outside diameter and .22-in. gage, the bracket supporting rod being of structural steel, 1.90 in. outside diameter and .20-in. gage. All of the dimensions are shown on the drawing. The feeders are carried on glass

company owns no open cars, but operates the standard closed car the year around. It would seem as though an open car would be a necessity in a city as far south as New Orleans. As a matter of fact the type of car adopted, in combination with the fast schedules given over Neutral Ground rendered an open car unnecessary, and in truth, undesirable. The New Orleans weather in summer is apt

colors adopted are olive green and white, and it is interesting to note that the company, in re-painting cars, has discontinued the practice of surfacing the rough stuff. And the foundation work in painting cars is done by "plastering," all rubbing being eliminated. It is found that this reduces the cost of painting a car at least \$10 or \$12, and as a matter of fact the body colors are found to retain their luster and condition better than with the older fashioned "surfacing."

The company owns 120 cars, 70 of which are equipped with two

LADDER WAGON IN USE.

EMERGENCY WAGON LOWERED.

to be unsettled, heavy showers being of frequent occurrence, and chilling winds are often noticeable at the close of a summer day. The closed car, with its large windows and low sash rail, give practically all of the comfort of an open car when the weather is fine, and a great deal more comfort than an open car when the weather is inclement.

The car finally adopted as standard has the following principal dimensions: Length over all, 30 ft. 8 in.; length of body, 20 ft. 8 in.; platform length, 4 ft.; length of step, 3 ft.; width over all, 8 ft. 2 in.; height of body, 9 ft.; height of window sills from floor,

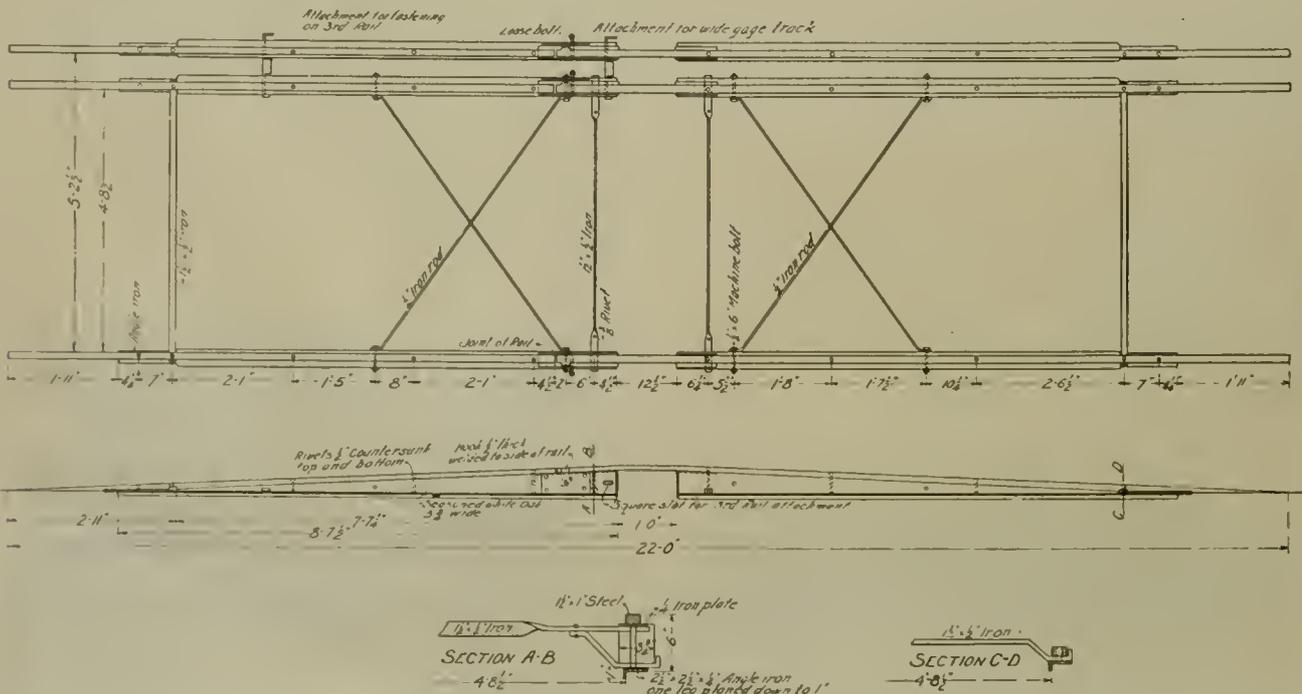

G. E. 1,000 motors each, 15 with one G. E. motor to each cars, and 35 with one G. E. 800 motor to each car.

The cars were built by the American Car Co. and the St. Louis Car Co.

The truck adopted as standard is the "Lord Baltimore" single truck, which is giving entire satisfaction.

SPECIAL HOME-BUILT EMERGENCY WAGON.

The company maintains one hurry-up repair wagon, shown in the half-tone engravings. The tower wagon is not intended for new

HOSE BRIDGE-NEW ORLEANS & CARROLLTON R. R.

28 in.; width of aisle, 20 in.; width of seat, 33 1/2 in. There are seven Hale & Kilburn seats on each side of the aisle. The double sliding doors are of mahogany, the ceilings of maple, and the corner posts and bottom frame of white oak. Exceptionally good light is furnished at night by 15 16-c. p. lamps in the ceiling. The uniform

construction work, but is for repair work only. It can be very easily handled with one horse, which is found to be much more satisfactory than two horses and less expensive to the company.

As will be seen the tower is raised or lowered by a hand windlass, and the tower, when at its full height, permits the men to

work on the overhead line without interfering in any way with the operation of cars.

The working platform is supported at the top of a supporting piece that is practically an extension ladder in two sections. A second supporting piece goes to the edge of the platform, as shown, and serves as an additional brace. The main supporting ladder is hinged to the body of the wagon, and when in the elevated position most of the weight of the platform and linemen is carried on two short uprights as shown, the leverage being such that when the tower is raised to its full height it will safely sustain 400 lb. weight on the elevated platform if the wagon is standing level.

The elevated platform is fitted with a sliding extension foot piece which enables the men to work close to the wire. The platform is mounted on a turn-table, and the men can work either from the sides or ends, as seems most convenient, although the position shown in the engraving is the one most commonly used. The turn table is self-locking at each quarter turn, and is easily handled by one man. The tower can be raised from the collapsed position to full height ready for working by one man in 50 seconds. An automatic safety stop or catch is placed inside of the ladder as an extra protection against the tower falling in case anything about the windlass should suddenly give way.

As the running gear of the wagon is connected very short it can be turned around in very limited quarters, and it also runs much more easily than would a longer geared vehicle. The wagon is home built and is the design of Mr. H. A. Davis, superintendent of the company.

HOSE BRIDGE.

To avoid many of the delays and interruptions to traffic when the fire companies are forced to stretch their hose across the tracks to fight fires occurring along the car routes, especially on the business streets, Mr. H. A. Davis, superintendent of the company, devised the hose bridge or jumper shown in the working drawings reproduced on page 382. The bridge is made in two parts or halves, which bolt together, end to end, by means of loose pins passing through hook attachments. Aside from these two divisions all parts are rigidly joined together and the bridge does not fold up. It is drawn to the scene of the fire on a separate flat car

The two side frames of the bridge are formed of seasoned white oak. Riveted to the under side of each of these side frames is an angle iron strap 2½ in. wide by ¼ in. thick, having its under face planed down to form a perfect contact with the track rail, the angle iron being designed to fit any section of rail, either T, grooved, or girder. To the upper side of the frame is fastened a

INTERIOR OF CAR BARN SHOWING ELEVATED TRACKS.

1½-in. steel bar, upon which the car wheels run when a car is running over the bridge. The loose pins for coupling the two parts together are chained to the side frames and cannot be lost.

As shown in the drawing the bridge is 22 ft. over all and has a total rise at the center of 6 in., the oak timbers of the side frames being tapered toward the ends to give an easy and gradual incline. The opening at the center for the hose is 12 in. As the cars of the Carrollton company run over certain streets that are occupied by a company operating wide gage, the bridge is provided with a third side-frame, designed to be placed on the third or wide-gage rail, so that the cars of both companies can pass over the hose line.

CAR HOUSE, SHOPS AND SHOP PRACTICE.

In laying out the company's present car shed and shops the same attention to details and systematic consideration of the desired

PAINT ROOM.

ARMATURE ROOM.

attached to a motor car, and two men can place it in position in three minutes. Although the device might be handled somewhat more conveniently if it was made to collapse or fold, it is believed its strength would be greatly impaired, it would take longer to lay in place, and its general usefulness would be reduced.

ends in view are noticeable that are in evidence in all other departments of the company. The inter-relation of the various shop departments is recognized, and the various repair rooms, and the work done in each, are arranged to give the best possible results. Cars and car parts passing through the shops go from room to

room with the least possible handling and loss of time, and all converge at one point where the assembling and final inspection is made. Careful records are kept of every detail of the work, largely by the use of the card system, and by advance estimates and reports from foremen of departments, the master mechanic is enabled to arrange the work and his working force to secure the best results. The broad principle on which the work is carried out

system practically eliminates the chance of cars being disabled on the road through "dropped" bearings or burned out armatures.

This "watching" is accomplished in the following way: The mileage for every car is made up each day in the accounting department from the trip sheets, by multiplying the number of trips made by each car on each line by the length of the line. From

EXTERIOR OF CAR SHED AND SHOPS.

WHEEL REMOVING APPARATUS.

is expressed in the maxim "inspection is cheaper than repair." To this end the condition of the cars and every part of all cars is watched, first by a system of car mileage records and then by actual inspection.

When an armature, bearing, wheel or other part is placed on a car a record is made of the part number and the car number.

these figures calculations per car-mile, and per car-hour are made. After the auditor has obtained such data as he desires from the car-mileage sheet the latter goes to the master mechanic for watching the car parts and equipment. Every six months the sheets are returned to the accounting department and bound and filed away as records in the accounting department. The totals for each car

Brought	Fwd.						

(Page 12 inches wide.)

The car mileage made by this car is then watched with special reference to each part, and when the mileage approaches a pre-determined figure the car is called into the barn for the express purpose of examining that part. If the part in question is found to be in condition for still further service it is given a new mileage limit which, in the judgment of the inspector, the part from its condi-

tion, of course, added to the previous record, so that the clerk in the master mechanic's office has on his desk a list of cars with the mileage each has made up to date. This is compared every day with the records showing the date on which each part was put in service, and the prescribed mileage for each individual part. For instance, suppose that a set of bearings were put in car No. 10 on

tion ought to go, and the car is again put in service. When the new mileage limit is approached the car is again called in and the part either removed or given a new lease of life. The parts requiring most attention in this way are, of course, bearings and armatures, although trolley wheels, car wheels, axles, etc., are included in the same systematic "watching." It will be evident that this

July 1st, and their life was estimated at 15,000 miles. When car No. 10 is shown by the sheet on the clerk's desk to have run nearly 15,000 miles from July 1st, the clerk fills out a small notice on the foreman of the repair shops that the bearings in question will need attention on or before a certain date. At the first opportunity the car is called in and the bearings inspected. If in the

opinion of the inspector they will go 5,000 miles additional they remain in the car, a new record is made, and as the new 5,000 mark is approached a new notice is written by the clerk and served on the foreman, who again inspects the bearings at the first opportunity and either replaces them or gives them a new lease of life. All this, it will be understood, is done irrespective of the fact that the bearing are giving no trouble whatever.

The estimated length of life for the parts are determined by previous experiences. In practice, chilled car wheels are estimated to run 50,000 miles, "Kalamazoo" trolley wheels 13,000 miles.

confounded with the storekeeper's card index, which is kept at the general office and is always taken as the official record of stock.

A somewhat unique feature in this plant is that there are no pits whatever in the car barn or shops, due to the fact, as already pointed out, that excavations made anywhere in the soil in or about New Orleans quickly fills with seepage water. The office of pits is therefore taken by elevated tracks. In the main car barn are seven tracks for the storage of extra cars, two of these being on an incline forming elevated tracks at the rear of the barn

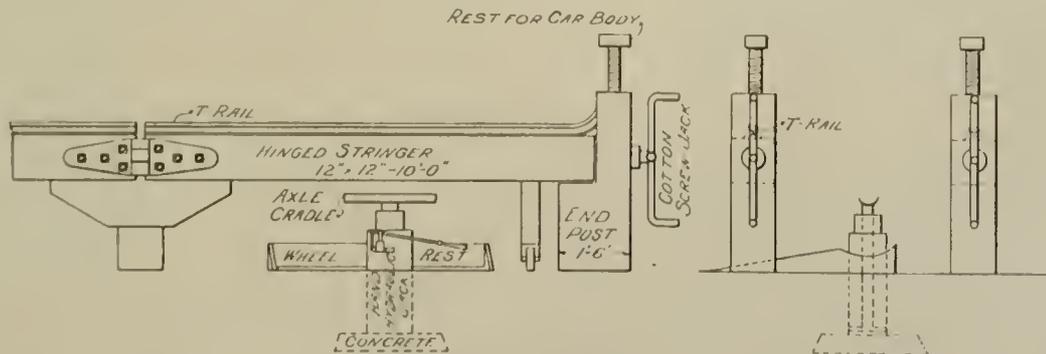

WHEEL CHANGING DEVICE.

steel pinions 150,000 miles, gears 250,000 miles, G. E. 800 bearings 15,000 miles, G. E. 1,000 bearings 20,000 miles. A car after making 45,000 miles is called in to be revarnished, and after 180,000 is repainted. The accounting department reports to the master mechanic the car mileage each day on the blank shown herewith as "A Daily Report of Car Mileage."

A departure from the usual custom is the fact that the general storekeeper has his office in the main downtown offices of the company and seldom actually visits the storeroom, which is at the

main repair shop. He transacts all the details of checking stores in and out through the medium of blanks. The system of storeroom accounting is given elsewhere in this issue under the heading of "Accounting." For his own information and protection, however, the master mechanic keeps a set of "material cards" in his office at the shops, from which he can always inform himself as to the amount of any stock on hand and is therefore in a position to issue requisitions on the purchasing agent for such stock as he will require for the repair and maintenance of cars. Both sides of this card are reproduced herewith, but this material card must not be

main repair shop so that an armature or motor may be dropped from the car onto the table and pushed out into the shop. Permanently embedded in the floor between each of the elevated tracks is a hydraulic lifting jack which is used in the operation of dropping the motor to the small moving table. The table is pushed over the jack head so that the top of the table or platform rests upon the jack head. The top of the table is detachable, and when the jack is raised this top is carried up with the jack cylinder and forms a rest for the motor or armature. When the jack has been raised so as to bring the platform in contact with the motor the bolts are

slackened off and the jack is lowered until the top of the table rests in place on the moving frame. The frame carrying the motor can then be pushed out from over the jack to the overhead cranes and the motor or motor parts can be taken to the various tools in the shop. The moving platform with its detachable top, or table, as it

rest on the end posts, but they are each provided with a leg having at its lower end a small wheel. It will be seen that the operation is to first roll the car up onto these tracks and the weight is then taken off the track rails by means of two cotton screw jacks on the end posts. When the weight of the car is all on the screw jacks

may be called, is illustrated in the working drawings herewith. As may be seen the track has four wheels but only one axle, which permits it to pass over the jack in the manner shown. A small stop is placed on the rail so as to bring the truck in exact position over the jack. The jack is of the Watson-Stillman type with 4 ft. lift and

the hydraulic jack in the center of the track is raised until the axle rests in the axle cradle, on the jack. The two stringers carrying the track rails are then swung outwardly and the jack is lowered, carrying with it the pair of wheels to be removed. The wheels are then turned at right angles to their natural position and rolled

\* Cost of coal per ton at Power House No. 1, \$3.20; at Power House No. 2, \$2.25.

tank 4 ft. in diameter by 24 ft. high, having a capacity of about 360 cu. ft. of air, which is stored under 100-lb. pressure. By the use of suitable nozzles the air is used for cleaning the floor of the shops, for cleaning out cars, cushions, curtains, seats, etc., and for blowing out electrical equipments. There is also in this same shop a portion devoted to blacksmithing work, where are located two soft coal forges with telescoping hoods, one small Bradley coke forge for babbitting bearings and one Bradley coke forge 14 ft. long for long heats.

The paint shop is 36x202 ft. and contains two tracks with a total capacity of 10 cars. The room is lighted from large, high windows, and as the walls are covered with white water paint the light is unusually good, a fact that is reflected in the high grade work turned out by the painters in this shop. Another detail that has given very satisfactory results is the boxing in of the heating pipes. This room is heated by low pressure steam carried in coils of pipes placed around the walls near the floor. By boxing these in and forming something of the nature of a wooden conduit open top and bottom, the air is given a circulation that is found not only to give a more even temperature, but also much drier air. The air enters the bottom of the box and the heated air passes out at the top with a slight impetus which carries it directly upward along the walls from which it gradually turns and curves out into the center of the room some distance above the floor. Before the steam pipes were covered in this way the air was free to dissipate itself directly into the room without any definite circulation. The movement of air, of course, is not enough to cause a draft, but just sufficient to keep the atmosphere changed and in good condition. As will be noticed, the paint room is long and narrow, and it is the practice when painting or varnishing cars to divide the immediate section in which cars are located into practically a room by itself by means of heavy canvas drop curtains, which will be seen in one of the engravings, rolled up near the top of the room. These curtains keep out all drafts, prevent sudden changes of temperature in the room, keep out dust and render the air dry.

DECORATED STACK.

The scaffolding for painting cars is supported by brackets embedded in a line between the tracks. These brackets are made of boiler tube set in concrete, the brackets for carrying the board forming the scaffold projecting out from the pipe stand about 3 ft.

A. H. FORD,  
Lately General Manager New Orleans & Carrollton Company.

8 in. This bracket is free to swing on the stand and can be raised or lowered. It is held in place by pins fitting in holes directly over the stand. The paint room is, of course, supplied with lockers for the use of the men. The varnishing is done in a separate room 30 ft. by 60 ft., where all sash, doors, etc., are taken to be finished. It is the practice here when sash are to be revarnished, not to scrape or sand paper the old varnish off, but use a solvent made by the Eureka Solvent Co., of Chicago. This compound eats the varnish and not the paint, and if any happens to be left on it hardens and gives no trouble.

**POWER GENERATION.**

The New Orleans & Carrollton company owns four power houses, two exclusively for electric lighting service and two exclusively for street railway service. Both of the street railway stations are equipped with comparatively modern direct current railway units of conventional design, and both are showing a remarkable degree of efficiency, the kilowatt hour costing at the bus bar at power station No. 1, 1.13 cents, and at power station No. 2, .90 cents, these figures, however, not including cost of maintaining apparatus and

buildings. The data on cost of power accompanying this article are for the last fiscal year, when coal was burned as fuel at both plants. In the spring of the present year Beaumont oil was substituted for coal at both stations and the cost per kilowatt hour has thereby been materially reduced as compared with the figures given. (For information as to the saving effected see "Oil as Fuel" in the "Review" for May, page 322.)

Railway power station No. 1 is on Napoleon Ave., and located advantageously near the center of heavy load.

It contains the following units: Three 350-h. p. Lane & Rodley tandem compound condensing engines, 16 and 32 in. by 48 in., running 72 r. p. m., each belted to a 200-kw. General Electric railway generator, and connected to independent jet condensers and single acting air pump, 12x14x16 in., made by the Buffalo Steam Pump Co.; one 350 h. p. Rankin & Fritch tandem compound condensing engine, 16 and 32 by 48 in., running 72 r. p. m., belted to a 200-kw. General Electric railway generator, and connected to Worthington

H. A. DAVIS,  
Acting Manager Railroad Department.

independent jet condenser and duplex air pump 7½x10x10¼ in. Condensing water is supplied by one Blake single acting pump, 14x16x24 in., one Blake duplex compound pump, 10x16x10½x18 in., and one Smedley single acting pump 10x12x26 in. There is also one small air pump for cleaning apparatus by compressed air.

Steam is generated in four 150-h. p. Babcock & Wilcox water tube boilers with Hawley down draft furnaces, and two 225-h. p. Babcock & Wilcox boilers with ordinary fire grate furnaces. Feed water is supplied through three Worthington duplex outside packed boiler feed pumps, 7½x4½x10 in., and one Knowles single acting well pump, 10x7x7½ in. There are two Smith & Vale open feed water heaters.

Railway power station No. 2 is located at Elysian Field St. near the river and some little distance east of the belt circle.

It contains the following units: Two 450-h. p. Reynolds-Corliss tandem-compound, condensing engines, 16 and 32 by 42 in., running 100 r. p. m., each direct connected to a 300-kw. General Electric railway generator, with Reynolds independent jet condensers and air pump 8x12x20 in., with Reynolds-Corliss valve gear; one 1,275-h. p. Reynolds-Corliss cross-compound condensing engines, 26 and 50 by 48 in., running 80 r. p. m., direct connected to an 850-kw. General Electric generator, with Reynolds jet condensers and air pump, 12x16x32 in., with Reynolds-Corliss valve gear.

The boiler equipment comprises two 350 h. p. Edgemore water tube boilers with Hawley down draft furnace (52½ sq. ft. grate surface), and two 450-h. p. Edgemore boilers with Hawley furnace (60 sq. ft. lower grate surface). There are two 700-h. p. Webster open feed water heaters.

Formerly the feed water was taken from the 8-in. artesian well, which is 850 feet deep, by ordinary steam lifting pumps, but recently the arrangement has been changed and the feed water is raised from the well by compressed air, which arrangement has proven eminently satisfactory and nearly twice as economical as the steam pump.

The change was made by lowering into the 8-in. pipe to a

depth of 260 ft. Inside of this pipe was placed a 1¼-in. pipe which discharges air under pressure into the 4 in. pipe at a depth of 161 ft. It will be understood this air rising to the surface lifts the water with it. The motor discharges into a 12,000-gallon storage tank supported at an elevation of 25 ft., the water flowing to the feed water heaters by gravity.

The compressed air for this service is furnished either by a Westinghouse large air compressor or a style "B" straight line air compressor with radial air valves. These compressors also furnish air for cleaning purposes in the station, and either one may be connected to the artesian well as desired. The air compressors are driven by steam and their exhaust steam goes to the feed water heaters. It is found it takes about 65-lb. pressure of air to start the water from the well and 45 lb. to maintain the flow.

The power house employes and wages paid per month are as follows:

Power house No. 1: One chief engineer at \$125; one assistant engineer at \$85; three oilers at \$50 each; three firemen at \$55 each; two coal passers at \$45 each; one boiler cleaner at \$45; one helper at \$45.

Power house No. 2: One chief engineer at \$125; one assistant engineer at \$85; one assistant engineer and oiler at \$60; two oilers at \$55 each; two coal passers at \$45 each; two helpers at \$50 each; one boy at \$30.

The foregoing was the scale in force for the period corresponding to that covered by the data given in the table, when coal was burned as fuel. Since oil fuel has been substituted the services of four coal passers and two firemen have been dispensed with.

#### PERSONNEL.

The officers of the New Orleans & Carrollton Railroad, Light & Power Co. are: President, J. K. Newman; vice-president, Joseph H. De Grange; assistant secretary and auditor, W. B. Brockway; general manager, A. H. Ford; superintendent of equipment, H. A. Davis; master mechanic, E. W. Miller. All the recent engineering work has been carried out under the supervision of Ford, Bacon & Davis, of New York and New Orleans. Since the foregoing was written Mr. A. H. Ford has resigned as general manager to enter the office of Isidore Newman & Co., New Orleans, and Mr. H. A. Davis has been appointed acting manager of the railroad department.

#### STREET RAILWAY ACCOUNTANTS' REPORT.

Secretary Brockway, of the Street Railway Accountants' Association of America, has issued under date of July 1, 1902, the official report of the organization meeting of the Association, held in Cleveland, Mar. 23-24, 1897. The publication of this report, which was only recently authorized by the association, will be welcomed by the membership, as it completes the file of the association's proceedings, and the full discussion on the papers presented in March, 1897, is for the first time made available to members. The book comprises 108 pages, and has as a frontispiece a half-tone portrait of the late Morris W. Hall, secretary of the Camden (N. J.) & Suburban Railway Co., who served as chairman at the organization meeting.

Secretary Brockway prefaces the report with the following "explanation:"

"The verbatim report of the meeting at which this Association was organized has never before been published in book form. A synopsis of the proceedings was printed in the April 15th, 1897, issue of the 'Street Railway Review,' which paper was instrumental in the calling of the meeting, formulating the program and making the arrangements necessary for such a gathering.

"There have been many requests for the publication of the complete report in a form to correspond with those issued annually, so that a set of the reports will contain a history of the association, and it is in response to these that the issue is now made.

"The publication is made possible by the courtesy of the 'Street Railway Review,' which furnished the minutes of its stenographer.

"The comparison of the first thoughts and ideals and hopes as recorded in the following pages with what has been accomplished in five years will serve to encourage the association, as well as be interesting history to those members who have, since the organization, added their zeal and strength to the effort toward accomplishing something for the common good."

# Accounting Department of the New Orleans & Carrollton Railroad, Light & Power Co.

Requisitions and Records of Stores—Material Card for General Storekeeper—System of Classification for Securing Accurate Costs on Small Items—Use of Trip Sheets—Forms of Register Report—Combined Pay Roll and Time Sheet—Organization of the Department—Auditor's Monthly Report.

Mr. W. B. Brockway, who is widely known through his prominent identification with the work of the Accountant's Association, holds the office of assistant secretary and auditor of the New Orleans & Carrollton company. Mr. Brockway has courteously placed at our disposal for publication a number of his blanks and

received the purchasing agent checks the bill with the purchasing order, and if the prices and other data agree he sends the duplicate purchasing order with the bill to the general storekeeper in the accounting department. In the meantime the goods have been received and the employe receiving the goods has made out a blank (form 307), this employe having no information whatever as to the quantity ordered or the price to be paid. This blank or receipt goes to the general storekeeper who compares it with the duplicate purchasing order and the bill, already in his possession, and if O. K., all three forms go to the general manager for approval.

If they are approved by the manager the blanks and bill are returned to the general storekeeper, who at the end of each month prepares from them vouchers for material purchased during the month.

The general storekeeper keeps his record of stock on cards here shown as "General Storekeeper's Material Card." There is, of course, a separate card for each item of material. Goods received into stores are entered in the column at the left, and notation of goods delivered out of stores is made in the square spaces at the right. As is apparent there is a square for each day of each month of the year, the only recording necessary being to enter the quantity issued in the proper square. There is also a line in each month's space for striking balances. One side of the card carries the record from January to June, and the reverse from July to December.

Every lot of the same kind of goods received is kept separate and distinct from all other lots, both in the storeroom and in the accounting, and each lot is charged out at the actual price paid for it. This distinction is preserved by giving each lot in addition to its designating number a designating letter. Thus 1/2-in. bolts might be lot No. 120. The first lot of bolts received would be called lot No. 120. If it became necessary to order a new supply of 1/2-in. bolts before the first lot was exhausted the new lot would be designated lot No. 120A, and would be

GENERAL VIEW ACCOUNTING DEPARTMENT.

labor-saving methods, several of which are novel and are original with him.

On this road, contrary to the usual practice, the general storekeeper has his office in the accounting department under the general supervision of the auditor, and does all his stock recording and accounting through a system of well devised blanks.

kept separate and distinct from all other lots, both in the storeroom and in the accounting, and each lot is charged out at the actual price paid for it. This distinction is preserved by giving each lot in addition to its designating number a designating letter. Thus 1/2-in. bolts might be lot No. 120. The first lot of bolts received would be called lot No. 120. If it became necessary to order a new supply of 1/2-in. bolts before the first lot was exhausted the new lot would be designated lot No. 120A, and would be

PACKAGES	COUNTED BY	DELIVERED BY		
	BY			
CASE MARKS	Quantity	ARTICLES	LOT NO.	

GOODS RECEIVED BLANK (ORIGINAL 8 X 7 IN.)

The purchasing agent issues purchasing orders or requisitions in triplicate. The original goes to the merchant or supply house; the triplicate remains in the book as a permanent record; the duplicate is held by the purchasing agent until the bill for the goods arrives. (It is an iron-clad rule that dealer must transmit the bill at the same time the goods are shipped.) When the bill is

kept separate in the bins. Requisitions would be filled from lot No. 120 until the supply was gone, when lot A would be opened and used. This permits of a more careful checking of stock than would be possible if the two lots were mixed and used indiscriminately. In the inventory just taken the material checked practically exact with the cards.

TRIP SHEETS.

This company utilizes to the fullest extent the conductor's trip sheets for collecting and placing on file much valuable information, and, contrary to the usual practice, the data are utilized without transcribing the figures on each individual trip sheet.

The front and reverse sides of a sample trip sheet will be found

**NEW ORLEANS & CARROLLTON RAILROAD,

FRONT OF TRIP SHEET (ORIGINAL 4 1/2 X 11 IN.)

among the engravings accompanying this article. On the front side are columns for recording the register readings and all tickets or fares that are rung on the register. On the reverse side are columns for passes without tickets. At the bottom of the front side are spaces in which the checking clerks record errors in cash, register readings, transfers or tickets. The line designated by the

Conductors will observe the following instructions in making trip sheet:

Be careful to show whether A. M. or P. M. Enter your car number correctly. Do not guess at it.

The half trip provided at top is for the time and register reading at Station A, and the time and register upon arrival at Station D or E. This applies to Napoleon and Jackson lines only. All other lines will show only the time and register when leaving Station A or K, upon the top line of the half trip.

The time, register and station letter, when leaving Station H

Trip No.	Police	Firaman	Sisters Charity	EMPLOYEE'S BADGE

REMARKS

REVERSE OF TRIP SHEET.

will be shown on top line of Trip No. 1, and the same information will be shown on leaving destination on lower line of trip No. 1. This applies to all lines and will be followed throughout the day, except last trip at night, when the arrival and register on arrival at Station A or K will be shown.

Upon completion of the report of the day, the register reading at commencing will be written in space provided in the footing; this subtracted from the last reading, gives the total passengers carried and must agree with the footing of column headed "Total Passengers." The combined footings of columns headed "Transfers," "Tickets" and "Cash Fares" must also agree with the "Total Passengers." The footing of cash fares multiplied by 5 cents must equal the money shown in "Amount" and is the sum of money to be enclosed in bag.

Transfers and tickets enclosed in envelope for the purpose and number of each marked thereon, must agree with the footings of these columns upon the trip sheet.

The transfers, tickets, cash fares, total passengers and amount columns must be ADDED UP to obtain the proper footings. Do not use any total obtained other than by addition.

The conductors deposit their day's receipts with trip sheets for the day in a canvas bag, into which is also placed an envelope containing transfers and passes collected. Notations on the outside of the envelope enumerate the contents.

The small bags are deposited by the conductors in self-closing safes at the car barns. Every morning a messenger opens the safes and after placing the bags in several large sacks delivers them to the accounting department at the general offices. As the bags are taken out of the safe they are counted and the number is again checked when they are delivered to the accounting department. The same messenger also brings to the office a report of

Form 170-12-01.

REGISTER REPORT (ORIGINAL 8 3/4 X 14 IN.)

hand and the words "Conductor Must Not Use These Spaces" is used by the clerks for noting the correct totals whenever a conductor makes a mistake which affects his totals.

To save any of the conductors from making the excuse that he did not understand certain points about his trip sheet the essential features are printed on the reverse side of the sheet, under the head of "Notice":

the final register readings taken in the barn at about 3 o'clock each morning. This comes in on a blank (Form 170) and is made out by the dispatcher, who takes the last register readings only, and the office inserts the previous day's register readings, subtracts, and places the total for the day in the total column on the blank after each car number. The reading of the registers is also verified and report signed by the pit foreman.

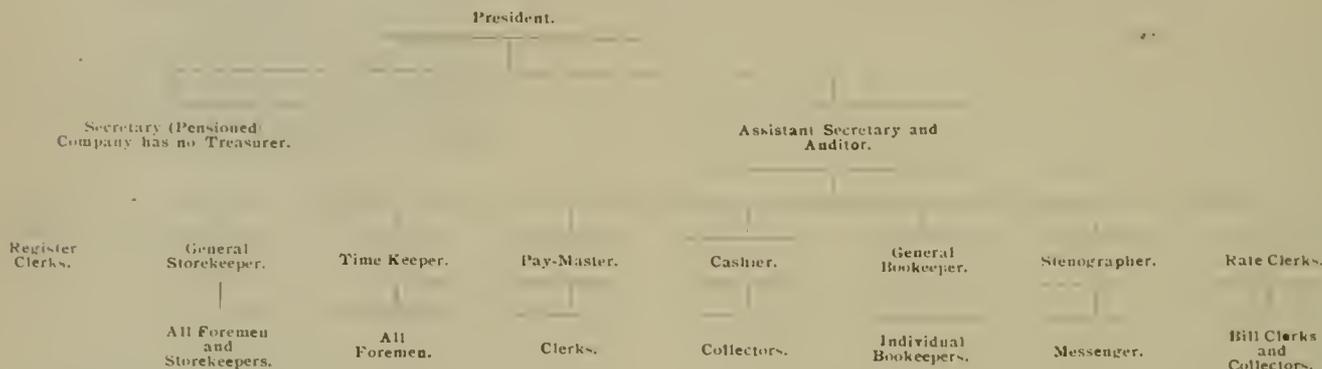

squares shown in the center of the sheet. At the end of each 15-day period the sheet is completed, recapitulated and paid. The paymaster makes one trip over the road and pays off the entire system. He pays with cash and the money is not put up in individual envelopes. The paymaster has one clerk helper, who handles the small receipt blank. The men form in line, receive and sign their receipt blank, and present it to the paymaster at the next window in exchange for their money. At regular periods the pay sheets are permanently bound and filed away.

The statement was made that all materials and supplies are purchased by the purchasing agent. There is one exception to this in that all blanks, forms, and stationery for the entire company are purchased and approved by the auditor, this serving to secure uniformity in size and style.

**ORGANIZING OF ACCOUNTING DEPARTMENT.**

The accompanying diagram shows the organization of the accounting department of the New Orleans & Carrollton company. The entire force employed in this department comprises 18 clerks and one porter, all reporting to the auditor. Both the railway and electric lighting accounting is performed in this same department.

ORGANIZATION OF ACCOUNTING DEPARTMENT, NEW ORLEANS & CARROLLTON RAILROAD, LIGHT & POWER CO.

Mr. Brockway has designed a set of six blanks for showing the comparative statement of income and expenses, general balance sheet, and operation data for the railroad and the light and power departments of the company which will be found very interesting. These blanks constitute the auditor's monthly report.

Each of the six sheets is 16 1/4 x 20 3/4 in. and printed on one side only; they are intended to be folded once making the size 10 3/4 x 16 1/8 in., which is more convenient for handling. Each sheet has on it two rectangles 9 1/2 x 15 1/8 in. ruled in black within which are the tabular rulings, these latter being in red. The six sheets are numbered consecutively 1 to 6.

Sheets Nos. 2, 3, 4 and 5, are reproduced herewith (about one-half the original size) with no alteration except that the tabular rulings are in black instead of red ink. The right hand half of Sheet No. 6 is blank save for the border and this space we have utilized showing the contents of Sheet No. 1. The "Summary" (shown here on the right side of Sheet No. 6) occupies the right side of Sheet No. 1, while the title shown below the "Summary" is on the left hand side of Sheet No. 1 and when the report is folded serves as the title page.

The items and column headings on these various blanks are self explanatory. The columns having blank headings are provided for use in making comparisons or to serve special purposes.

**CLEVELAND THREE-CENT FARE ROADS DEFEATED.**

In the suit to enjoin the promoters of the proposed three-cent fare lines in Cleveland from proceeding under the franchises granted a few months ago to John B. Hoefgen, the Circuit Court rendered a decision, June 21st, overruling the recent decision of Judge Strimple which had dissolved the temporary injunction against the promoters of the three-cent fare roads, and holding the ordinance to construct a railway over three out of the seventeen routes originally advertised for by the city, as illegal. The Court

pointed out that in the original ordinance calling for bids all of the 17 routes were regarded as one road comprising 75 miles, but that in the ordinance as passed only three routes, comprising 13 miles, were considered. This was claimed to be illegal on the grounds that other bidders, who had not cared to compete with Mr. Hoefgen under the provisions of the original ordinance, might have offered to carry passengers for less than Mr. Hoefgen on the 13-mile road subsequently proposed. Such possible bidders had not been given an opportunity to bid on anything but the entire 17 routes comprising 75 miles.

It was also held by the Court that the routes originally advertised for were changed in the ordinance which was passed by the council. The change in one instance was considered unjustifiable as, at the time the routes were advertised for, it was known that it would be almost impossible to secure the necessary consents on the streets covered by this route, a fact which may have prevented possible competitors, who could not have known that the routes would be changed later, from bidding.

The Court also declared against the municipal ownership and labor arbitration clauses in the ordinance as unreasonable provisions. Mayor Johnson, through whose efforts the defeated ordinance had

been passed a few months ago, is quoted as stating that the case will not be appealed to the Supreme Court, but that separate ordinances will be prepared for each of the desired routes and that another and better-advised attempt will be made to secure the low-fare roads.

**BUFFALO, SPRINGVILLE & AURORA.**

The Buffalo, Springville & Aurora Railway Co., mention of which was made in the "Review" for June in connection with our publication of the drawings of the high bridge to be erected by this company, is at work securing the rights of way over private property for a route of 34 miles. The company will have 38 miles of track which will be operated from the central power house and two sub-stations. The rolling stock now contemplated comprises six passenger cars, each seating 48 persons, 10 freight cars and two electric locomotives weighing 40 tons each. The officers of the company are: President, Henry L. Moench, Boston; vice-president, U. L. Upson, 940 Ellicott Square, Buffalo; secretary, Theodore Tindy, Otto; treasurer, W. A. Oakes, Cattaraugus; chief engineer, Charles G. Locke, Randolph, N. Y. The company was chartered Feb. 8, 1902, with an authorized capital of \$1,000,000; at the present time only \$38,000 of this has been issued.

The Rapid Railway Co., of Detroit, contemplates inaugurating a 15-minute schedule on its lines between Detroit and Port Huron to accommodate the steadily increasing traffic. At present cars are run every hour in each direction.

The Montreal (Que.) Street Railway Co. has practically completed several miles of new double track and is extending its system further into the suburbs of the city. In connection with the street railway company's extensions, the city is widening some of the streets through which the lines pass.

**ELECTRIC SUBURBAN RAILWAYS.\***

BY E. A. EVANS, QUEBEC.

A paper was recently read by Mr. C. H. Davis, C. E., before the Canadian Society of Civil Engineers, on the competition of parallel steam and electric lines, in which, among other conclusions, Mr. Davis said: "Steam railroads will, in the near future, handle their suburban and short distance interurban passenger traffic and mail, express, baggage and light local freight carried in these suburban and interurban passenger trams by electric motive power; and this, irrespective of whether operating expenses are affected favorably or unfavorably." In this conclusion the writer firmly agrees, and to show that to carry out this conclusion it is not even necessary to construct a parallel, but on the contrary, steam trains and electric cars can be safely operated upon one and the same track.

The writer (as manager of the Quebec Railway, Light & Power Co., part of which company's system was formerly the Quebec, Montmorency & Charlevoix Railway, a steam road operating between the city of Quebec and Ste. Anne de Beaupre and St. Joachim, a distance of 30 miles), inaugurated a service of electric cars upon the same track and running between the usual steam railway trains. The scheme was generally considered a bold one and one that would not meet with the success anticipated; the results, however, as will presently be shown, have more than justified the innovation and the expenditure incurred.

The Quebec, Montmorency & Charlevoix, as it was formerly called, after leaving Quebec, passes along the flats comprising the North Shore of the River St. Lawrence; for six miles there is a continuous row of farmers' and other dwellings running on both sides of the highway, which, however, is on the top of a cliff running parallel to the railway and at a distance varying from one-half to one mile from the track; at Montmorency the line runs through a small village, the inhabitants of which are mostly operatives in a large cotton factory, and from here the line is through the following parishes: L'Ange Gardien, population about 1,400; Chateau Richer, population about 2,000; Ste. Anne de Beaupre, population about 1,500, and St. Joachim, population about 1,000. Before the operation of the electric system, this population was served in the winter by two daily steam trains leaving Quebec at 8:50 a. m. and 5:15 p. m., and leaving Ste. Anne de Beaupre at 7:15 a. m. and 11:40 a. m.; in the summer by four daily steam trains, leaving Quebec at 7:30 a. m., and 10 a. m., 5 p. m., and 6:15 p. m., and Ste. Anne at 5:45 a. m., 7:23 a. m., 11:50 a. m., and 4:10 p. m. There was also an additional steam train between Quebec and Montmorency, leaving Quebec at 2 p. m. and returning at 3:45 p. m. Special trains, as required, were also put in service to convey the large numbers of pilgrims visiting the shrine of Ste. Anne.

The residents in the thickly inhabited port on top of the cliff, between Quebec and Montmorency, previously mentioned, did not patronize the railway, but traveled by omnibuses, of which there were eight or ten.

In 1889, the year prior to the introduction of the electric cars, the steam trains carried 253,054 passengers, including about 41,500 pilgrims, to Ste. Anne de Beaupre. This did not appear to the writer to be satisfactory, especially during the winter, when residents would take advantage of the good winter roads and drive, rather than have the inconvenience of having to wait and be at a railway station at a certain fixed time to catch a train; as a result it was decided to electrically bond the existing track, put an overhead trolley wire, high enough to allow of brakemen traveling with safety on top of box and freight cars, put in an alternating current—direct current generator at the electric power station at Montmorency and operate electric cars between the steam trains. These cars were each equipped with four 50-h. p. motors and Westinghouse air brakes, operated by an independent motor, and were so geared as to be capable of running at a speed of 45 miles an hour, standard railway car wheels being used.

The cost of this work for the 30 miles of track was as follows:

Electrically bonding existing track.....	\$ 5,022
Overhead trolley, including poles, etc.....	68,804
Six large double truck cars, seating capacity 54, with motors, etc., complete .....	51,606

\* Read before the Canadian Electrical Association, Quebec, June, 1902.

One 600-kw. A. C. D. C. generator and water wheel, and one 200-kw. rotary transformer at St. Anne, including switch boards, etc. .... 43,943

Total ..... \$169,375

Upon the completion of this work, in addition to the regular steam railway service, which was continued as before, cars were sent out between Quebec and Montmorency every hour between 6:30 a. m. and 9:30 p. m., and between Quebec and Ste. Anne de Beaupre about every three hours, and the following comparative statement shows the result of the year's operation in 1901, from which it will be noted that there was an increase of \$29,071.39, with an increased expenditure of only \$5,098.46. From June 30, 1901, to date (June 12, 1902), there has been a further increase of 86,392 passengers over the corresponding period last year.

Comparative statement of tickets sold at different stations.

	1899.		1901.	
	Passengers.	Amount.	Passengers.	Amount.
Quebec .....	108,103	\$20,107.20	259,364	\$33,976.70

Totals .....	253,054	\$44,221.55	571,374	\$73,292.94

The operations for the year 1900 are omitted, as the work of electrifying the road was then only partially completed.

The omnibuses previously referred to have been run out of business, notwithstanding the inconvenience of passengers having to walk up the cliff to get to the public road and their houses, and traffic has now so much increased that it has been found necessary to run cars every half hour between Quebec and Montmorency and about every hour between Quebec and Ste. Anne; and in addition the steam trains are run as formerly. On Sundays and holidays the resources of the company are so fully taxed that it has been found necessary to increase the rolling stock with cars having a seating capacity for 120 passengers, and in addition to the regular cars, to run specials at from ten to fifteen minute intervals. It has also been found absolutely necessary to construct a double track between Quebec and Montmorency.

The writer, as an old steam railway engineer, would like very much to enlarge upon the subject of suburban railways and the desirability of steam railway managers studying and taking up the subject, but sufficient has however been said to show that it is advisable and in the interests of their companies to leave the old groove and not allow other and independent street railways to compete for suburban traffic. It might perhaps be as well to mention that notwithstanding the traffic above mentioned, steam freight and special pilgrimage trains are being constantly handled and that no collision or any other accident has so far occurred.

**DISCUSSION.**

After concluding the reading of the paper, Mr. Evans said: With reference to Montmorency, I think it is important to mention that in 1901 the Kent House and all the property that we saw yesterday was not in existence; that is, the building was there, but it was not open to the public and it had not been thought of as a place of resort for the citizens of Quebec, yet notwithstanding that, you see we carried 64,000 passengers last year and over 17,000 the year previous.

I might add, for the information of the members, there is an absolute necessity of having standard railway car-wheels M. C. B. standard. Of course they are not suitable, and you cannot run them over city tracks, the flange is too deep; but if you want a high-speed suburban service it is absolutely necessary you should have standard wheels, so that there is no danger of their running off the tracks at the different blocks and switches.

The President: You must have found it very much to your advantage to have put in the ballast you have there and the heavy rail?

Mr. Evans: Undoubtedly. That was one of the points I omitted to mention. Before we put in the double track we were operating on the old track, 56-lb. rails, with ordinary old fashioned single fish plates. The traffic increased to such an extent that we had positively to double the track the first six or seven miles, and in doing so we put in 70-lb. rails and a special fish plate, 3 ft. in length with double angle, an angle on both sides; the result of that has been very satisfactory. My electrical engineer has tested the power taken in running the cars on both tracks. On the old track it takes 10 h. p. more to operate our 46,000-lb. car than it does on the new track, showing the advantage of having the heavy rail and good joints, which, in my opinion, is more important than the heavy rail.

Mr. Reynolds: I would like to ask in regard to the distribution of power. Is there a sub-station on the road beyond the power plant, or is that all direct feed, and how many miles?

Mr. Evans: The power is taken from a 600-kw. A. C. D. C. generator at Montmorency, seven miles from Quebec; from there we distribute direct current seven miles to Quebec and seven miles from Montmorency, making seven miles each way. We send alternating current to Ste. Anne de Beaupre, 14 miles away, at 11,000 volts; there it passes through a 200-kw. rotary transformer and feeds back seven miles in this direction, to meet the direct current coming forward from Montmorency.

Mr. Thornton: Without wishing to stop any future discussion on this paper, I would like to move a very hearty vote of thanks to Mr. Evans for his interesting paper. The possibility of investments and profitable returns in suburban railroads and the results obtained with the enterprising management of Mr. Evans is a revelation to most of the members here present. There are many railroad men here and we would like very much to hear their opinions on the subject.

## NEW ELECTRO-PNEUMATIC SYSTEM OF ELECTRIC RAILWAY CONSTRUCTION.\*

BY BION J. ARNOLD.

During the past three years, as many of the members of the Institute know, I have advocated the use of the alternating current motor for certain classes of railway work somewhat earnestly, and have often been asked by my friends why I believed so thoroughly in the alternating current motor, and have been questioned rather closely at times for particulars regarding a certain system which I have been working upon.

I wish to state that long before I had any fixed ideas as to a system of my own, a study of the railway question from an engineering standpoint partially convinced me of the necessity of the ultimate abandonment of the direct current motor for heavy and long distance service, due to the low working voltage that it was necessarily limited to, the resulting heavy investment in transmission lines thereby required, and the many translations between the power station and the car when any great distance was taken into account.

An active connection with the development and construction of electric railways in this country impressed me with the correctness of my preconceived ideas to such an extent that they finally crystallized into a system of electric railway construction upon which I have been working for several years, and to which I have alluded from time to time without giving, to those not interested with me, any definite information regarding it, for reasons well known to those working upon new devices.

I have constructed 20 miles of road for this system, together with the necessary trucks and motor equipments, and as I feel reasonably sure of the interest you will take in this system, I feel warranted in presenting it to the Institute.

As I have previously stated before the Institute, I am particularly anxious that American engineers shall keep abreast with European engineers in the development of the alternating current electric railway, and while some of my brother engineers may not agree as to the practicability of my idea, there are others in the Institute who I think believe as thoroughly in the alternating current motor for railway work as I do, and whether my system proves the correct solution of the question or not, I firmly believe that the alternating current motor will finally prevail for heavy railway work.

\*A paper presented at the 19th Annual Convention of the American Institute of Electrical Engineers, Great Barrington, Mass., June 19th, 1902.

The recent discussions that have been going on between engineers in Europe and the United States of this question have made the subject a live one at present, and this is my reason for presenting a brief description of one embodiment of my system at this meeting.

The principles underlying the system I advocate and which I call an "Electro Pneumatic System," are as follows:

1. A single-phase or multiphase motor, mounted directly upon the car, designed for the average power required by the car, and running continuously at a constant speed and a constant load, and, therefore, at maximum efficiency.

2. Instead of stopping and starting this motor and dissipating the energy through resistances, as is customary with all other systems known to me, I control the speed of the car by retarding or accelerating the parts usually known as the rotor and stator of the motor, by means of compressed air, in such a manner that I save a portion of the energy which is ordinarily dissipated through resistances, and store it to assist in starting the car, helping over grades, for use in switching purposes, and for the operation of the brakes.

3. By this method of control I secure an infinite number of speeds from zero to the maximum speed of the car, which may or may not be at the synchronous speed of the motor, for with the air controlling mechanism working compressing, the speeds below synchronism are maintained, and by reversing the direction of the air through the controller speeds above synchronism may be attained for reasonable distances. This feature gives to the alternating current motor the element absolutely essential for practical railway work, for it permits a car or train to ascend a grade at any speed with the motor working at its maximum efficiency, and imparting its full power to the car. When descending the grade the motor may utilize its full power drawn from the line in compressing air, or it may be used to compress air with the stored energy of the train, thereby acting as a brake.

4. By virtue of the air storage feature, each car becomes an independent unit and capable, in case of loss of current from the line, of running a reasonable distance without contact with the working conductor, and this without the aid of storage batteries. This feature will enable a car to work on a high tension trolley wire or active conductor over private right of way, and allow the active conductor to be stopped where the private right of way ceases, and the car to proceed through a city or town on any tracks whether electrically equipped or not, until it reaches the outskirts of the city or town where it can take up the working conductor again on a private right of way. This feature is also valuable in switching work, for each car being independent it can leave the main line track and operate over switches or sidings without complicating the yards with additional overhead or third rail conductors, thus necessitating through line conductors over main line track or tracks only.

5. Since a single phase motor can be used the motors can be supplied with current from a single overhead wire or third rail, and with a single rail return circuit, thus permitting the overhead construction, or third rail construction, to conform to the standard of to-day, except that a much higher working voltage can be used, provided the insulation is taken care of. Furthermore, in steam railway work this system, by virtue of its single phase feature, will only require the use of one of the track rails for the return circuit, thus leaving the other rail for the use of the signal system, which, up to the present time, does not seem to have been satisfactorily solved without the use of one of the track rails.

6. The current will be taken from the working conductor at any voltage up to the limit of the insulation, and in case this voltage is high (I am building my line for 15,000 volts), a static transformer will be carried upon each car and the pressure reduced from the line voltage to the voltage of the motor, which in the case under construction is designed for 200 volts. Where it is unnecessary to utilize so high a line pressure the motor may be designed for the working voltage, and the current fed directly from the working conductor into the motor, thus eliminating the static transformer. When a high voltage working conductor and static transformer is used, and it is thought advisable to use a working conductor through cities or towns, this working conductor will be supplied with energy through a stationary transformer at each city limit, thus making the working conductor through the cities or towns safe.

7. By virtue of the speed of the motor and its constant load, either when the car is in motion or when it is standing still, and

the motor is compressing air, the variable load now customary in electric railway power plants is eliminated, and the power station works at practically a constant load, thereby eliminating a large part of the investment at present requisite in power station and line construction. Furthermore, by virtue of the air storage feature, each car, in the particular apparatus I have designed, is capable at any time when current is on the working conductor, of delivering to the car wheels a much greater torque in proportion to the capacity of the motor than is possible with any electrical system known to-day.

I believe that by the adoption of this system the following results will be accomplished:

1. The entire elimination of the present standard system of rotary converter substation plant, together with the maintenance thereon, and the cost of the necessary attendants.

2. The absorbing and rendering available for useful work in starting, or otherwise, a large percentage of the energy stored in the moving mass which under the present methods of operation is dissipated at the brake shoes.

3. A large reduction in the first cost of electrically equipping long distance railroads, thereby making it feasible, from an engineering and business standpoint, to equip many roads which cannot now be shown to be advisable, thus opening up the steam railway field to the industry in which we are now engaged.

## STREET RAILWAY INVESTMENTS AND EARNINGS.

ALTON D. ADAMS.

(Copyright, 1902, by Alton D. Adams.)

Great earning capacity and large profits are often associated with electric railways in the popular mind. No doubt the notable expansion of street railway investments and incomes has done much to foster such views on the part of casual observers.

The purpose here is to inquire how far the change of street railways from horse to electric motive power, and their subsequent extensions, have opened a field of extraordinary returns on invested capital. Massachusetts offers an excellent opportunity for investigation along this line, because it stands third among all the states in the extent of street railway development, and because the stocks and bonds of these railways are issued, under the law, only for cash or property actually invested. In 1888, the last year in which the street railways of Massachusetts, except less than a mile of experimental road in Revere, were operated entirely with horses, the total length of their main tracks was 533.59 miles. By 1901 this length was multiplied by four and stood at 2,176.97 miles. Meantime the total investment in the street railways of the state has risen from \$17,237,100 in the earlier to \$99,611,185 in the latter year, having been multiplied by 5.7. This great expansion of investments in street railways was accompanied by the substitution of bonds and other forms of indebtedness for stock. As is well understood, an investment entirely represented by stock is managed by those who contribute the funds, and who may take as profits the entire difference between gross income and operating expenses, but are entitled to nothing more. Investors in bonds or other forms of indebtedness, on the other hand, have no voice in the management of the sums they have contributed, but are in a position to demand a fixed interest return on their money.

Year.	Stocks.	Net debt.	Per cent in stocks.
1888.	\$10,894,850	\$6,342,231	63.2
1889.	12,290,740	7,127,358	63.2
1890.	14,879,130	8,547,973	63.4
1891.	19,553,952	7,943,652	71.1
1892.	23,599,536	11,271,788	67.6
1893.	25,883,575	20,767,103	56.2
1894.	26,971,275	22,223,133	54.9
1895.	27,906,685	25,022,246	52.7
1896.	30,728,818	28,478,245	51.9
1897.	32,670,273	30,442,491	51.7
1898.	38,933,917	29,824,847	56.6
1899.	41,380,143	35,846,071	53.5
1900.	48,971,168	35,743,929	57.8
1901.	54,069,933	45,541,252	54.2

Such investors are naturally content with and are able to command a smaller annual return on their holdings than that necessary to interest capital in stocks which must take all the risks of business with no certain return. A consequence, therefore, of the larger introduction of bonds as a form of investment in street railways is that the public enjoy the use of capital at lower rates than would otherwise be possible. From 1888 to 1901 the stocks of street railways throughout the state rose from \$10,894,850 to \$54,069,933, or almost five times the earlier sum. In these same years the net debts of the railways stood at \$6,342,231 and \$45,541,252 respectively, the latter amount being more than seven times the former. Net debts here include bonds and other forms of obligations such as notes and mortgages not given to secure bonds, less cash and current assets of the companies. In 1901 the gross debt was \$49,528,109, and the cash and current assets \$3,980,857. Throughout the period under consideration bonds of the companies have largely exceeded their unfunded debt, and in 1901 this debt stood at \$15,215,609.

Interest on the unfunded debt is probably paid at a somewhat higher rate than that on the bonds, but at a less rate than would be necessary to induce investments in stocks. In 1888 the stocks of horse railway companies represented 63.2 per cent of the total investment in them, but by 1901 the per cent of these stocks to the sum of stocks and net debt had fallen to 54.2 for the electric roads. So far as stocks have been replaced by debts, electric railways are serving the public at a lower rate of return on the investments than that earned by the horse roads. But net earnings from the operation of electric railways in 1901 amounted to \$7,201,199, or 5.5 times the net sum of \$1,291,520 earned by the operation of horse lines in 1888, and the net earnings per passenger were 1.66 cents in the latter, compared with only 0.96 cent in the earlier year. It may, therefore, appear that stocks are paying larger dividends than formerly, but such is not the case. The fact is that the greater earning capacity and economy of operation of electric over horse railways has only been attained by a more than proportionate increase of investments. Between the net earnings from operations and the stockholder stands the bondholder, with a claim for interest that must be met. While the stocks of electric have gone up to five times the figures for the horse roads, net earnings from operations have increased to five and one-half times the sum for the horse railways in 1888. Meantime, however, bonds and debts have so increased that stocks receive a smaller rate of dividend than that at the beginning of the period. If all expenditures and depreciation charges against street railways, except interest and dividends, are deducted from their gross income of every sort, the remainder represents interest and net income. Of such remainders interest charges are taking an increasing part.

Net incomes and interest:

Year.	Interest and net income.	Interest.	Per cent interest.
1888.	\$1,096,853	\$311,845	28.4
1889.	1,372,690	346,032	25.2
1890.	1,813,043	383,827	21.1
1891.	1,778,820	479,676	26.9
1892.	2,349,775	444,095	18.9
1893.	2,880,270	886,871	30.7
1894.	2,925,228	1,112,560	38.0
1895.	3,425,970	1,168,621	34.1
1896.	3,601,080	1,320,304	36.6
1897.	4,083,138	1,489,991	36.4
1898.	4,102,046	1,568,044	38.2
1899.	4,125,630	1,622,688	39.3
1900.	4,820,299	1,782,797	36.9
1901.	5,291,851	1,893,668	35.7

Between 1888 and 1901 interest plus net incomes increased to almost exactly five times the initial amount, as did also capital stocks, but interest charges meantime grew to more than six times the amount against the horse railways. Before 1893 interest had claimed as little as 18.9 per cent, but not more than 28.4 per cent of net income plus interest in any one year. From 30.7 per cent in 1893, the interest charge has since taken in each year a larger share of the net income plus interest, and reached 39.3 per cent in 1899. These facts make it plain that the possible percentages of dividends on stocks have been reduced.

The actual dividends paid in any year are no certain measure of the real net income on capital stock, because such dividends may

be less or greater in amount than this income. An illustration of this facts exists in the street railways of Massachusetts, which paid as dividends on stock less than the net income above interest charges in each year from 1884 to 1900 inclusive, but in 1901 distributed as dividends slightly more than this net income. When a net income has been earned, but not paid out as dividends, it simply mingles with the assets of the company, and may be drawn out at a future time. Net incomes rather than dividends are thus the true measure of prosperity, and these incomes have declined in relation to capital stocks during the past decade.

Net income and percentages of capital stocks:

Year.	Net income.	Per cent of stocks.
1888.	\$785,008	7.2
1889.	1,025,758	8.3
1890.	1,430,116	9.6
1891.	1,200,153	6.6
1892.	1,005,680	8.0
1893.	1,003,399	7.7
1894.	1,812,668	6.7
1895.	2,257,355	8.0
1896.	2,289,776	7.4
1897.	2,593,147	7.9
1898.	2,534,002	6.5
1899.	2,502,942	6.0
1900.	3,037,502	6.2
1901.	3,398,183	6.2

Between 1888 and 1901 the net income of all street railways of the state has risen from \$785,008 to \$3,398,183, or 4.3 times the amount in the earlier year. Meantime, however, the total of capital stock has increased to five times its sum in 1888. The percentage of net earnings to capital stock, therefore, fell from 7.2 in 1888 to 6.2 in 1901. In intermediate years this percentage has been up to 9.6, the figure for 1890, and down to 6.0, the ratio in 1899. It can hardly be maintained that these rates of income are too high or even fair for stock investments that take the risks of the street railway business. Yet it should be remembered that Massachusetts not only stands third in the Union as to extent of development in street railways, but also that these railways as a group are probably second to none in prosperity. The low percentage of income on the stocks of railways in this state points to entirely unsatisfactory results for some less favored sections. In the notable expansion of street railway through the introduction of electric traction, the general public have been the first and greatest gainers, because of the improved transportation offered. This expansion has only been possible through great extension of investments, and on these investments as a body the average return thus far has been below the normal.

**MAHONING VALLEY RAILROAD EXTENSION.**

A franchise for an extension of the Trumbull division of the Mahoning Valley Ry. from Warren to Leavittsburg was granted some time ago and the extension was completed, with the exception of a railroad crossing, in December, 1901. Considerable difficulty was experienced in making a contract with the Erie Railroad Co., the track of which it was found necessary to cross at grade at a point about half a mile west of the city limits of Warren. The crossing was ordered and delivered on the grounds, but the Erie Railroad delayed its installation. At the next hearing of the case in court the decision was delayed and the crossing was installed by force, but was torn on the same night by employees of the Erie company. The case was again taken into court and a decision in favor of the Mahoning Valley Railway Co. was again rendered in the latter part of July. Owing to the crossing trouble the line, although complete in other details, has not been put in operation, but, according to the latest decision in its favor, the company expects to open the line at an early date.

The reasons for the Union cleared loop in Chicago may be compared with devices which have been aptly termed "fool catcher," consisting of small platforms to be erected at the end of stations slightly above the level of the tracks. They are to prevent persons who persist in trying to board moving trains from being dragged from the superstructure. It has been not infrequently the case,

**BIRMINGHAM (ALA.) NOTES.**

Sunday, June 29th, the first car was put in operation on the Tuxedo, Ensley & Wylam Division of the Birmingham Railway, Light & Power Co's. system. This line has been under process of construction for some length of time and a portion of the route has been used for some time. Wylam is a small inland town composed largely of a colony of Welch people, who had no communication with the outside world save by stage coach. The opening of this new line means a great deal to them and the cars have been very much crowded since the opening by the people, who will ride from one end of the line to the other for the novelty of the thing. The line is a little over two miles long, and only two cars are in service at present, though others will be added as the travel demands.

On July 2d the new Ensley-Bessemer branch road, seven miles in length, was completed. This is a new route to Ensley over a route which hasn't a single railroad crossing. The roadbed has 10 in. of slag ballast, with 6x8-in. sawed ties laid 2 ft. c. to c. The rails are 70-lb. A. S. C. E. standard with Weber joints and the trolley wire is the General Electric Co's. No. 000 grooved with spring frogs at the cross overs, making a practically continuous wire. With no railroad crossing the running time of the present line will be considerably reduced. With the new four motor cars recently put in service the schedule time on this line will be the seven miles in 30 minutes.

On the morning of June 24th the following bulletin appeared on the several bulletin boards at the barns of the company:

"At a meeting of the board of directors of the company held on the 10th inst. the subject of more pay for motormen and conductors was discussed, and authority was given to make the following changes of wages commencing with the second half of the fiscal year, July 1, 1902: First year of continuous service, 15 cents per hour; second year of continuous service, 17½ cents per hour; third year of continuous service, 18 cents per hour; fourth year of continuous service, 19 cents per hour; fifth year of continuous service, 20 cents per hour.

"This increase is made in consideration of the loyal and efficient work of the motormen and conductors who have been in the service of the company for the periods mentioned. The company believes that the value of a man's services is in proportion to his experience and education in the position he holds, and for this reason has made the greatest possible advance that it could afford with the desire of retaining the services of experienced motormen and conductors.

"All motormen and conductors should see the time keeper and see that he has the accurate date of their entering the services of the company recorded.

"Geo. H. Davis,

"General Manager.

J. B. McClary,

Mgr. Ry. Dept."

This came as a very pleasing surprise to the men, because it was purely voluntary on the part of the company and prompted by no suggestion or request from them. Quite a number of the men have been in the service for over five years, and a great many of them called at the office and expressed their thanks. This is the second voluntary raise in wages within the year. Last November a rate of 17½ cents was made for all men who had been in the service over a year and all appeared well pleased with that.

The company, always looking to the welfare of its men, has adopted the plan of supplying its drinking fountains at the different drinking stations on the different routes and at the shops with water from Avondale spring, a cool spring of crystal water which is alleged to be the best water in the district. This was done for the reason that the water supplied by the water company of the city is believed by some to contain impurities, and desiring to promote good health among the men as far as possible the use of this spring water was adopted.

The question of putting a stripe on the sleeve of the men for each year in the service is being discussed, and all the men who have been approached on the subject express themselves as well pleased with the idea. It is believed that should the plan be adopted that it will tend to increase the desire on the part of the men to remain in the service as long as possible.

A street car mail service has been inaugurated on the Rapid Railway Co's. line between Detroit and Port Huron.

**IRWIN FULLERTON.**

Mr. Irwin Fullerton, general auditor of the Detroit United Ry., has been connected with the street railway interests since 1890, when he started as bookkeeper for the Brooklyn & South Side Street Railway Co., of Cleveland, O. He remained with this company until 1893, when the property was consolidated with the East Cleveland Railway Co. and the Broadway & Newburg Street Railway Co., forming what is now the Cleveland Electric Railway Co. Mr. Fullerton was engaged with the new organization as assistant auditor and continued in that capacity until March, 1895, when he was appointed auditor of the Detroit Citizen's Street Railway Co., of Detroit. In December, 1900, the Detroit United

IRWIN FULLERTON.

Railway was organized, taking over all the street railway lines of Detroit, and during the past year this company has purchased eight different suburban street railways having in the aggregate nearly 500 miles and with rates of fare varying from 3½ cents to \$1.00, according to distance. This consolidation afforded Mr. Fullerton a very substantial experience in the merging of street railway properties.

In addition to the problems in accounting resulting from the consolidations mentioned, the work in Mr. Fullerton's department has been further increased during the last year by the inauguration of the extensive freight and express service on the Detroit system which was described in the "Review" for January, 1902.

**CLARKSON MEMORIAL SCHOOL OF TECHNOLOGY.**

The following list of graduating theses has been received through the courtesy of Prof. William S. Aldrich, director of the Clarkson Memorial School of Technology, and will serve to indicate the practical character of the work carried on in this institution:

Development of the Water Power of High Falls on Deer River; A Study of the Possibilities of the Development of Water Power on the Indian River; A Design for a Power Plant on the Indian River; Investigation of the Properties of Liquid Condensers; Influence of Chemical Composition on the Electrical Conductivity of Wrought Iron and Soft Steels; Performance of a Motor Generator Set Compared to a Rotary Converter of the Same Capacity; The Design, Construction and Performance of an Experimental Poly-phase Transmission Line; An Experimental Study of a Single-phase Induction Motor; Installation of, and Experiments on, a 15-h. p. Otto Gas Engine; Experiments on the Flow of Steam Through Rectangular Orifices; Design of a Compound Marine Engine.

The total valuation of franchises in Niagara Falls, N. Y., as determined by the state board of tax commissioners, is \$454,000, which amount is an increase of \$79,700 over last year's valuation. The increase is made principally on the street railway franchises which were assessed last year at a valuation of \$112,000 and are this year valued at \$155,000, an increase of \$43,000.

**ANALYZING CONDUCTORS' REPORTS.**

**An Interesting Method of Computing Percentages and Its Application.**

Editor "Review": For a number of years we have been trying to devise a method of easily computing the percentage that each kind of fare bears to the total for the day. After numerous attempts all of which required too much time we arrived at a plan which is now working admirably, and is in daily use at our office.

The result of our investigation led us to construct a table, bound in book form, with flexible leather back and thumb index, placing 50 numbers on each right hand page. Opposite each number we placed its reciprocal multiplied by 100, using but three decimal places.

50	200	525	190
1	200	6	190
2	199	7	190
3	199	8	189
4	198	9	189
505	198	530	189
6	198	1	188

TABLE 1—PAGE FROM "BOOK OF RECIPROCAL." (Note: The table in the image includes a thumb index on the right side with numbers 5, 50, 8, 50, 7, 50, 8, 50, 9, 50, 10, 50, 11, 50.)

The "5" in the thumb index is large and indicates 500 or from 500 to 549 inclusive. On the next page is only a small "50" indicating that page contains numbers from 550 to 599 inclusive. This table is carried out to 1200 total.

In using this table the clerk has counted all the full fare tickets, children's tickets, coupons, cash fares, and checked up the registers, he proceeds to enter up the earnings for the day in a book ruled as shown in Table 2.

In the first column is entered the number of the car on Run No. 1, in the next the registers as taken "out" and "in" with the subtraction, that being the fares collected on such car. In the third column is entered the run number. In the next column is placed the number of full fare tickets. The next column is left blank. Under the column headed "Children Tickets" is entered the number of children tickets turned in by the conductor on that run, and so on entering the number of coupons and cash fares in their respective columns. The total of all the fares turned in is entered in its column.

This total is not the amount shown by the register, the conductor having been relieved for dinner for which he received a check signed by the relief conductor showing number rung up while the regular was off, which is entered in the column headed "Relief." In the next column is entered the total fares turned by the regular and Relief Conductor, which should agree with the register.

In the column headed "cash" is entered the amount of money turned in by Regular. In the last column is entered the name of the conductor.

Now we will proceed to use the table:

The number of fares turned in by Conductor Rheinart is 742. We now open table by means of the thumb index at page marked with a large "7." On this page is the reciprocal multiplied by 100, to three decimal places of each number from 700 to 749 inclusive; opposite No. 742 we find the decimal fraction .135; this multiplied

Wednesday, June 4, 1902.

			549.17		\$14.05				\$251.35					14 05		
			Number of passengers carried 6855. Earnings \$814.57													

TABLE 2.

by the number of full fare tickets, 113 x .135, gives 15.255 per cent; the number of children's tickets multiplied by the same number, 41 x .135, gives 5.535 per cent; coupons, 8 x .135, gives 1.080 per cent; cash fares, 580 x .135, gives 78.300 per cent. We have by these operations found that Conductor Rheinhart turned in:

Full fares.....	\$5.255 per cent
Children's fares.....	5.535 per cent
Coupons.....	1.080 per cent
Cash fares.....	78.300 per cent

Total ..... 100.170 per cent

But for convenience we enter in the book:

Full fares.....	15 per cent
Children's.....	6 per cent
Coupons.....	1 per cent
Cash fares.....	78 per cent

Total ..... 100 per cent

We enter the per cent in red ink as being more easily seen.

If the table were carried to more decimal places, the per cents as found by multiplying would add up exactly 100. It will be noticed in the table that Nos. 531, 532 and 533 all have the same multiplier, but that it is as near as can be when using but three decimal places. If it is desirable to use four decimal places the multiplier would be for 531, .1883; for 532, .1879; for 533, .1876; but that is a refinement not necessary for the purpose for which we have constructed the table, as the percentage of each class varies slightly each day, and with different runs. Some runs catch many factory people using tickets exclusively, other runs regularly pass depot at train time in that case catching more cash fares, but under like circumstances the runs carry about the same percentage of each class of fare every day.

We will call attention to the report of Conductor on Run No. 7, whose percentages were as follows: Full fares, 18; Children's, 19; Coupons, 1; Cash fares, 62. When we compare this with the other runs, we are lead to believe that substitution was resorted to, that about 9 per cent of the cash fares were taken and the same number of children's tickets substituted instead. We might mention that the name of Mr. \_\_\_\_\_ does not appear on our records after June 4th.

The percentage for any single day should not cast suspicion on a conductor, as he may possibly have a school picnic or a crowd of children on the car for a round trip, but a careful watch kept on the percentages for a week or a month, especially if another conductor is on the same run any day during the time, will be time well spent.

THE PORTSMOUTH STREET RAILROAD & LIGHT CO.,  
S. P. Baird, Genl. Mgr.  
Assoc. Mem. Am. Soc. C. E.  
Portsmouth, O.

NEW PLANT FOR THE HUDSON VALLEY RAILWAY.

The Hudson Valley Railway, an extended description of which was given in the "Review" for April, 1902, is about to make a change in its motive power with a view to ultimately operating the entire system from a central plant of the Hudson River near Waterford. It will be remembered that this company is a consolidation of the Stillwater & Mechanicsville; Greenwich & Schuylerville; Glens Falls, Sandy Hill & Fort Edward, and Warren County railroads and the Saratoga Traction Co. The company now operates over 100 miles of electric road running from Albany and Troy to Saratoga, Lake George and the Adirondacks.

For the operation of the road until the Hudson River power station is completed a somewhat unusual method is to be employed. The company has increased the capacity of the direct current power station at Glens Falls, by the addition of a 250-kw. direct current engine-type generator and has increased the capacity of the Caldwell station with a 270-kw. direct current belted generator. In the power station at Glens Falls there will be installed a 250-kw. rotary converter operating direct current to alternating current with raising transformers. Power will be transmitted by a three-phase 11,000 volt transmission line to Caldwell, where lowering transformers and a second 250-kw. rotary converter operating alternating current to direct current will be installed to supplement the power of the Caldwell direct current generating plant.

In the company's Saratoga station a 400-h. p. engine and a 250-kw., 2,200-volt generator with raising transformers are to be installed and from this station power will be transmitted by a three-phase, 11,000 volt transmission line to a sub-station at Round Lake, where transformers and a 250-kw. rotary converter are to be placed. This sub-station will supply power to the recently completed Saratoga division, which connects the main line at Mechanicsville with the Saratoga-Balston line at Balston Spa. When the alternating current generating plant on the Hudson is completed, which it is expected will be next year, all the generating and sub-station apparatus now installed will be displaced by eight 300 kw. 600-volt direct current rotary converters. All of the electrical apparatus for both the temporary installations and the new plant is of the Westinghouse make.

CHICAGO CITY RAILWAY'S NEW POWER HOUSE.

For about two years it has been understood that the Chicago City Railway Co. would undertake to remodel its power generating and distributing systems as soon as the franchise extension question should be settled. Recently deeds conveying lots 96x124.7 ft. at the northeast corner of Halsted and 39th Sts., 120x123.7 ft. at the north west corner of Emerald Ave. and 39th St., and 37x320 ft. at the southeast corner of Gage St. and 39th Place, were filed for record. About a year ago the Chicago City Ry. purchased other property lying just west of these lots, and, as was announced at the time of the former purchase, the company will erect a large power plant here, distributing alternating current to suitably located substations.

**ADJUSTABLE SEAT FOR MOTORMEN.**

We show herewith the working drawings and some half tone illustrations of a removable and adjustable seat for motormen which was suggested by Mr. T. E. Mitten, general manager of the International Railway Co., of Buffalo, and for which the details were worked out by Mr. Charles A. Coons, superintendent of transportation of this company. The necessity for such a seat was made apparent during the Pan American Exposition, when the

**CONVERSION OF ST. PAUL BRANCH DISCUSSED.**

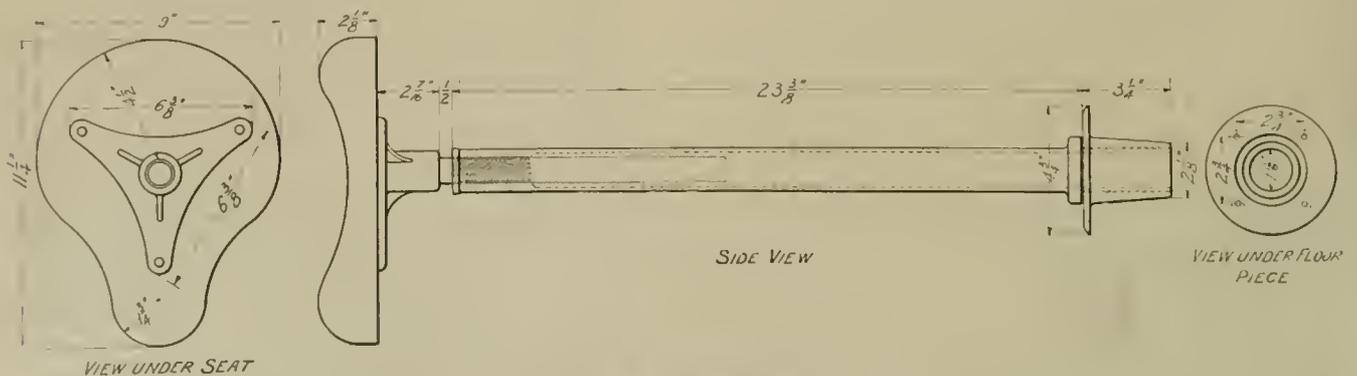

An ordinance providing for the conversion of the Evanston branch of the St. Paul road into an electric line from the northern suburbs of Chicago to the Union loop was discussed at a meeting of the council sub-committee June 25th, and the question of the fare to be charged in the event of a change of motive power created considerable dissension among the different delegations who

ADJUSTABLE SEAT FOR MOTORMEN AS USED BY INTERNATIONAL RAILWAY CO.

company lost a great many good motormen on account of their suffering from varicose veins and swollen limbs and feet because of standing in one position so continuously. The seat is used between cities only and is removed out of the motorman's way while the car is within the city limits. The general arrangement and principal dimensions of this seat are shown in the accompanying drawing. The standard is made of 1 1/4-in. iron pipe 26 in. long, on which a collar is fastened 3 in. from the bottom, and in the top of this standard is a plug having a 1-in. thread. The seat is made of hard wood and is of the same pattern as a bicycle seat. To this is screwed a triangular shaped casting as shown,

were present to represent the towns en route. Residents of Rogers Park and contiguous suburbs asked for a 5-cent fare to the city, while the delegation from Edgewater, which is south of Rogers Park, demanded a 10-cent fare in order that property values might not be jeopardized by the prospective incursion of the flat-hunter. The suburbanites were, however, unanimous in objecting when it was proposed by the representative of the road that a provision for a continuous ride to the Union loop be stricken from the ordinance. The company does not desire to run the tracks of the Northwestern elevated road to convey its passengers downtown, and amendments were asked which should obviate this objection.

SEAT STAND FOR MOTORMAN.

in the center of which is a socket, and to this socket is fastened a piece of 1-in. round iron threaded for 6 in., to fit the thread in the plug at the top of the pipe. By means of this thread the seat can be adjusted to any height desired. There are two iron sockets fastened in the car platform, one of which is used to hold the seat when in use and the other is placed to one side of the platform to hold the seat when not in use within the city limits. The half-tone illustrations show the positions of the seat both in and out of use.

American and Canadian capitalists are promoting an electric railway from Cornwall to Toronto, Ont., which, it is expected, will be one of the finest interurbans in the dominion. The promoters are reported to have capital at command to the amount of \$8,000,000.

The trolley line from York to Red Lion, and thence to Windsorville, has been completed. Capt. W. H. Lanjus and Judge W. F. Bay Stewart have about completed purchasing the right of way from York to York Haven, the seat of the electrical power plant, which is now being installed on the Susquehanna River to operate all of the street railways and trolley lines of York County, Dauphin County and Lancaster County, Pa.

J. J. Henry is promoting an electric railway to connect Baker City, Ore., and Eagle Creek.

## RECENT STREET RAILWAY DECISIONS.

EDITED BY J. L. ROSENBERGER, ATTORNEY AT LAW, CHICAGO.

### RIGHTS OF PASSENGER AT WHOSE REQUEST CAR HAS COMMENCED TO SLOW UP.

*Crow v. Metropolitan Street Railway Co.* (N. Y. Sup.), 75 N. Y. Supp. 377. Mar. 21, 1902.

After the car had commenced to slow down at a passenger's request, she had a right, the first appellate division of the supreme court of New York holds, to prepare to leave the car; and she also had a right to assume that the conditions existing at that time would be continued until the car had been stopped, and she had been afforded an opportunity to get off.

### DUTY OF TRAVELER ON HIGHWAY CONTAINING TRACK AS TO LOOKING FOR CAR—MAY ASSUME MOTORMAN WILL MAKE SOME EFFORT TO PREVENT COLLISION.

*Tunison v. Weadock* (Mich.), 89 N. W. Rep. 703. Mar. 26, 1902.

One traveling on a public highway on which there is a street car track is bound, the supreme court of Michigan holds, to use some caution. If he is turning to drive across the track, he is bound to see whether a car is liable to come in collision with him. He is undoubtedly bound to look ahead for the same purpose. But the court is not prepared to hold that he is, as a matter of law, bound to be constantly looking backward when driving upon or in proximity to the track. He has a right to assume that some effort will be made by the motoneer to prevent a collision; that he is in a position to see in advance, and to note whether a collision is likely if he continues in the course. In this case there was evidence from which it might be found that for a considerable distance, at least, the vehicle in which the party suing was traveling was pursuing a course near the railway track,—so near as to make it reasonably certain that a collision would occur if the car was not brought under control. Under such circumstances it cannot be said, the court declares, that the motoneer had the right to pursue his course, and run this vehicle down.

### INJURY TO CONDUCTOR RIGHTFULLY ON INSIDE RUNNING BOARD WHERE TRACKS ARE TOO CLOSE TOGETHER—NO CONTRIBUTORY NEGLIGENCE OR ASSUMPTION OF RISK.

*True v. Niagara Gorge Railroad Co.* (N. Y. Sup.), 75 N. Y. Supp. 216. Mar. 11, 1902.

Here a conductor who as such had been in the employ of the company for 30 days on a road about 7 miles in length was very seriously injured when at a place where the inside rails of the two tracks were but 3 ft. 10 in. apart, the close proximity of the tracks continuing for about 160 feet. The car was an open one, the seats of which extended entirely across it, and were so close together that it was inconvenient and even impracticable for the conductor to crowd in front of the passengers, between the seats, to collect the fares. The verdict of the jury, the fourth appellate division of the supreme court of New York says, showed that the conductor was riding on the running board of the car in the usual manner, engaged in the performance of his duties in accordance with the instructions given him. He was in the proper place to collect his fares, and was not aware that while he was on the running board he was in danger of being hit by a passing car. The tracks were dangerously close together at this point, not caused by any tapering to unite, for both north and south of the place of the accident the space widened; but the narrow space was probably due to some oversight, for they were removed farther apart after the accident, and apparently to avoid the recurrence of a like catastrophe. It may be added that jutting rocks along where the accident occurred rendered it impossible for him to perform his duties on the running board on the other side.

Under these circumstances the court affirms a judgment in his favor.

It was not important, the court says, whether, when struck by a car on the other track he was standing on the running board, or peering around one of the standard, as long as he was in the line of

his duty, performing it in the ordinary manner, and not cognizant of any danger to be apprehended from the passing car. It was the duty of the company to furnish a reasonably proper place for him to carry on his work. Nor could he be charged with want of care, as matter of law. He was insensible of the danger. It was not observable to him from the car. He had received no warning of it. He was in the discharge of his duties in the ordinary way, and his mind was engrossed in their performance. Again, the court says that this was not a risk which he assumed. It was not an incident to the business; was not manifest, but was due to the oversight of the company, which proper caution would have prevented. The employer must, to a reasonable degree, perform the obligation resting upon him to safeguard the interests of his employes, before the latter can be charged with assuming the risk with reference to the especial thing which should have been remedied. Assumption of risks must rest upon knowledge upon the part of the servant, or the means of acquiring it by the exercise of ordinary diligence.

### ATTEMPTING TO CROSS TRACKS WITH CAR ON FARTHER TRACK CLOSER THAN ONE ON NEARER TRACK.

*O'Callaghan v. Metropolitan Street Railway Co.* (N. Y. Sup.), 75 N. Y. Supp. 171. Mar. 14, 1902.

The party suing was injured on the southerly crossing of Amsterdam Avenue, in Manhattan, at 104th St., being caught between an uptown and a downtown car. It was in the daytime, and she was crossing the avenue from the west. Before attempting to cross she looked up and down the avenue. From the south a car was coming up, and was then a little above 103d St. From the north a car was coming down, and was then at 106th St. When she had crossed to downtown track, the uptown car was so close to her that she could not cross that track with safety, and while she stood between the tracks waiting for that car to pass the downtown car came along quite fast, and without the warning of the gong, and the injury was occasioned. The question of the company's negligence was scarcely raised upon the trial. No witnesses were examined upon the trial, and the second appellate division of the supreme court of New York says that no discussion was necessary to establish the fact that a jury might find negligence from the circumstances presented by the record. Whether the woman was guilty of contributory negligence was a question of fact. She was not bound to assume that it would be dangerous to attempt to cross a street with a car on the nearer track two blocks away, or that that car would come upon her without warning before another car less than half the distance from her would pass upon the farther track; and whether, under such circumstances, she failed in the exercise of ordinary care, was clearly for the jury to determine. A judgment in favor of the party suing affirmed.

### DUTY AS TO SELECTION OF SAFE PLACES FOR PASSENGERS TO ALIGHT.

*Sweet v. Louisville Railway Co.* (Ky.), 67 S. W. Rep. 4. Mar. 12, 1902.

It is stated, and it seems to be true, the court of appeals of Kentucky says, that a different duty attaches to street railway and to steam railway operators in respect to furnishing safe places for discharging their passengers. The latter must furnish such, while the former is under no such obligation, but discharges its passengers at convenient points along the streets it traverses. If the street at the place of discharging the passenger presents a dangerous condition to one alighting there, and such danger is obvious to the passenger, the carrier is not liable to him for injuries received from such defects. But where the danger is known, or is such as must have been known, to the carrier, and is unknown to the passenger,—as where, because of the darkness, he cannot see it,—the carrier is bound to warn the passenger of the danger, or to assist him in safely alighting, or stop the car at a point beyond or short of the dangerous point. Its failure to take one of these precautions renders it liable to the passenger sustaining injury because of such neglect. While the

street railway company is not bound to furnish safe places for depositing its passengers, it is bound to either select them or to warn the passenger of the conditions.

In this case it was dark when a car stopped at or near the usual street crossing, and a passenger severely injured her ankle in attempting to alight. The evidence disclosed that the street in question was a macadam road, which had become so worn at that particular point that a depression was formed two or three feet in length, and six inches deep. It was at the edge of the company's track, and so near it that one stepping from the car would be apt to step into it. It was easily to be seen in the light. Whether it was the cause of the passenger's injury, or was such a defective place for discharging passengers as to render it obviously unsafe, the court holds, were questions of fact that should have been submitted to the jury.

EFFECT ON LIABILITY FOR DEFECT IN PAVEMENT OF  
TRANSFER BY CITY TO PAVING COMPANY OF  
DUTY TO CARE FOR SAME.

*Welch v. Syracuse Rapid Transit Railway Co. (N. Y. Sup.), 75 N. Y. Supp. 173. Mar. 11, 1902.*

A passenger broke her ankle in stepping from the running board of an open car into an unobserved hole or depression in the asphalt pavement at the place the car stopped. This depression was 4 feet 6 inches long; its greatest width, 1 foot 5 inches; and its greatest depth, 3 inches. The edges were beveled and somewhat ragged. The inner edge was 1 foot 5 inches from the outer rail. The jury was instructed, among other things, that by statute (section 98 of the railroad law) the duty was imposed upon the railway company of maintaining the street "two feet in width outside of its tracks" in a reasonably safe condition, and if the place where the passenger stepped in alighting from the car, and which caused her to fall, was within that space and was dangerous, the company was chargeable with negligence for having neglected to repair the defect in the pavement. To meet this proposition, the company offered in evidence a resolution adopted by the common council of the city, and approved by the mayor, which gave a paving company permission to take up certain pavement, which included that which had been at the place of the accident, and at its own expense to lay a new pavement, and to keep the same in repair for five years, to be done in accordance with plans and specifications of the city engineer, and subject to the approval of the commissioner of public works of the city. The fourth appellate division of the supreme court of New York holds that the resolution should have been received in evidence, at least for the purpose of enabling the jury to say whether or not, in view of it and under all the circumstances, the railway company, through its agents, was negligent in not determining that the defect in the street was dangerous, and in not repairing it; and that the exclusion of the resolution was reversible error.

The purpose of the resolution was evidently to enable the new pavement to be tested, to ascertain its durability and wearing qualities; and it is apparent, the court says, that if the railway company or any other corporation could make repairs at will, such test would be useless. By the charter of the city the mayor and common council were given authority to lay out, make, open, regulate, repair, and improve highways and streets; and the council was given authority to order the construction and repair of pavements, and defray the expenses thereof by assessment upon the abutting property owners. Section 98 of the railroad law does not in any manner deprive the city authorities of any of the powers conferred upon them by the charter. The city had the right, acting through its officers or through any other agency, to do with the pavement in question precisely as it saw fit, provided it did not unnecessarily and improperly interfere with the rights of the railway company. It had the right to withdraw from the company the power to in any manner interfere with the pavement upon the street, or to relieve it from the duty imposed by statute, provided other means were adopted which would better or equally well protect the interests and rights of the public. By the action on the part of the city the company was relieved from the obligation during the period of five years of keeping in repair the portion of the street in question. Besides, the resolution was competent upon the question of the company's negligence, even if it was not relieved of its obligation to keep the street in repair by reason of the city's action

in the premises. The company had a right, in determining whether or not the defect was dangerous, to take into consideration the fact that the city authorities had taken control of the street, and to assume that they did not regard it as being in a dangerous condition, because of the fact that they had taken no steps to repair or cause the same to be repaired. The jury had a right to say not only whether the company was negligent in permitting the defect described to exist in the street, as an independent proposition, but also to say whether it was negligent in so doing, in view of the fact that by the resolution which was offered in evidence the city had contracted with the paving company that that company, and not the railway company should keep such street in repair, under the direction and supervision of the municipal officers.

INJURY OF BOY ATTEMPTING TO BOARD CAR AT  
FRONT END WITH VESTIBULE DOOR CLOSED—  
DUTY OF MOTORMAN—RUNNING BACKWARDS  
WITHOUT CHANGING HEADLIGHT OR  
FENDER.

*Barlow v. Jersey City, Hoboken & Paterson Railway Co. (N. J. Sup.), 51 Atl. Rep. 463. Feb. 24, 1902.*

On the return run of a large vestibuled electric car it went for a few blocks reversed from the outward run, and then, by means of a Y in the tracks, was turned around so that the front and rear would be as before. On this short backward run, while the conductor and motorman changed places, and the trolley pole was turned, the fender and headlight, when in use, were not disturbed. At about a quarter before 6 o'clock, one evening in November, just after the car had started on this return run, a boy who would be 12 years old in the following January, and who had been selling newspapers near the terminus, sprang on the step on the right-hand end of what was then temporarily the front platform, with the purpose, as testified, of paying fare as a passenger and riding to his home. He went to the front platform, he said, because it would be eventually the rear platform, and he expected to find it open, as it sometimes was at this terminus. He further testified that he rapped on the door, and that the motorman looked toward him, but did not open the door, or stop the car, or lessen its speed. Shortly afterward, the car collided with a wagon, and he was thrown off by the jar and injured.

Under these circumstances, the supreme court of New Jersey holds that the boy was properly nonsuited in an action brought to recover damages, because the company owed him no duty except to abstain from willful injury. It says that he was in no sense a passenger. He got upon the car at a place where he must have seen, if he had looked, that ingress was barred. That sometimes, in the company's cars, the door at that place was left open, and that passengers were allowed to enter there before the car started, did not excuse him from looking to see if an invitation by an open door was then extended to him to enter there. He knew that the rear platform was the proper place to enter a car, and his excuse that the platform he tried to get upon would eventually be the rear one only emphasized that knowledge. It should be noticed, too, that when the car would be turned, so as to make it the rear platform, the proper place of ingress would have been on the opposite side of the car from that on which the boy attempted to enter it.

If the motorman saw the boy on the step, he owed him no duty but to abstain from willful injury. He was not legally called on to open the door. His attention might be needed in the operation of the controller and brake and in keeping a lookout, especially as he was running without headlight or fender. If it was urged that he was negligent in running his car without those protections, or in not observing that the wagon with which he collided projected over the path of the car, it was sufficient answer to say that only passengers properly in or upon the car or persons lawfully using the highway could have had legal cause to complain of such negligence. The court says that it has never held that to one who jumps on a moving car at a place where he has no right to expect ingress to be afforded, either conductor or motorman owes a duty to stop the car or to lessen its speed, although it has held that where an attempted entrance was at a place where it need not have been looked for, yet, if it was seen, the conductor ought not to have started the car when he saw a passenger getting upon it with

precarious footing. In this case, if the motorman in fact saw the lad, common humanity should have prompted him to do one of these things in order that the danger of the situation might be averted; but legal duty chargeable to the master was a very different matter.

The youth of the boy, the court holds, gave him no extraordinary right of protection. It has, indeed, it says, been held that care may be due to children getting on street cars that is not due to persons sui juris, or under no legal disability. But this boy was of sufficient age and intelligence to be held to the general rules applicable to adults.

**JUMPING FROM CAR UNDER APPARENT NECESSITY  
ONLY—NO DUTY TO FIRST INFORM DRIVER—  
ADMISSIBILITY OF ORDINANCE REQUIRING  
CARS TO STOP AT RAILROAD CROSSINGS.**

*Selma Street & Suburban Railway Co. v. Owen* (Ala.), 31 So. Rep. 598. Dec. 18, 1901. Rehearing denied Jan. 30, 1902.

This was an action brought by the latter-named party to recover damages for personal injuries. It was averred that as a street car upon which she was seated was driven onto a railway track, at a crossing, an engine came running forward on that track at a high and rapid rate of speed, and was about to run into the car; that the driver became terrified, and exclaimed to her: "We are going to be killed. The train is on us," that she thereupon, startled and frightened by hearing the frantic cries of the driver, jumped from her seat, and seeing the engine coming at a high rate of speed, and that it was about to collide with the car, and being thereby still more frightened, she attempted to jump off, and received the injuries of which she complained in jumping off or in being thrown off by a quickened movement of the mule drawing the car, while she was endeavoring to get off. The engine was stopped 20 or 25 feet from the car.

The passenger, the supreme court of Alabama holds, was under no duty, before jumping from a car about to be run over by a locomotive, to inform the driver that she wished to alight. It was immaterial whether the driver, when he caused the mule to quicken its pace, knew that she was about to jump from the moving car. The complaint made no claim on account of the driver having caused the mule to quicken its pace, the averment in that regard being descriptive of the occurrence.

The averments that the engine was coming toward the car at a high rate of speed, and was about to collide with or run into the car, the court says, were to be taken to mean that such collision was imminent; that the engine was near to colliding with the car; that it appeared to be on the point of collision. By such averments, and this construction or interpretation of them, a case was made of apparent necessity for the passenger to jump from the moving car. A reasonably apparent necessity for a passenger to leave a moving car, produced by the negligence of the carrier, stands upon the same footing as a real necessity so produced, and the rights and liabilities of the parties are to be adjudged accordingly. This necessity was a link in the unbroken chain of causation, beginning with the driver's negligence, and culminating in the injury. In legal effect, it was as if the links in the chain were discarded, as if the passenger had remained on the car, and received her hurts from actual collision between the engine and the car. The negligence, in contemplation of law, operated as directly to the infliction of the injury in the case alleged as in the case assumed. In both the injury was the proximate result of the negligence. It was manifestly no defense to such a complaint that the passenger was in no actual peril when she jumped from the car, and was therefore guilty of contributory negligence in leaving the moving car. But the court holds it was reversible error to refuse to give the jury an instruction that, if the passenger, on the occasion complained of, acted in a manner which an ordinarily prudent person would not have acted, and this conduct was the cause of, or contributed materially to, her injury, she could not recover. Of course, her conduct in respect of being prudent or negligent, was to be judged of by reference to all the circumstances surrounding her at the time, and these circumstances the court conceives to be fairly submitted to the jury in this instruction.

A city ordinance requiring all drivers of street cars to bring their cars to a complete stop before going on or driving over any railroad in the city the court holds was properly received in evidence.

**NOTE PAYABLE AFTER COMPLETION OF ROAD—  
REASONABLE TIME FOR COMPLETION—PRERE-  
QUISITE TO RECISSION OF CONTRACT—USE OF  
OTHER TRACKS A SHORT DISTANCE—SINGLE  
TRACK AT CORNER FOR DOUBLE-TRACK ROAD.**

*Los Angeles Traction Co. v. Wilshire* (Cal.), 67 Pac. Rep. 1086. Feb. 28, 1902.

A note dated July 19, 1895, was made payable to the traction company thirty days after the completion of its double track street railway to a certain point. On the faith of this and other similar promises of property owners, the company, in November, 1895, bid and paid the city \$1,505 for a franchise to construct the road. Before April 28, 1896, it commenced work upon said railway, though such work was not performed with the view of prosecuting the construction of the railway continuously and with diligence to completion, and the company did not so commence work upon the railway with said purpose until after July 1, 1897. On that date, the makers of the note mentioned served upon the company a written notice to the effect that they did not recognize any liability, for the reason that the road had not been completed within the time agreed upon. Soon after the service of this notice, the company actively engaged in the construction of the road, and completed it, and commenced operating the same to the point stipulated, before the expiration of the year 1897. Thereafter, and on May 17, 1898, it completed its railway to another point prescribed in the conditions on which the note was placed in escrow. Upon these facts the company obtained judgment on the note, which is affirmed by the supreme court of California.

It was contended that, even without any agreement as to the time for the completion of the road, it should have been completed within a reasonable time. Admitting, for the purpose of the case, that the question of reasonable time was properly before the court, still, the supreme court says, it was a question to be decided on the evidence presented, and the condition of the evidence in that respect was aptly illustrated by a quotation from the opinion of the trial court as follows: "Whether or not this road was completed within a reasonable time must certainly depend upon the character of the enterprise, the obstacles to be overcome, the length of time required by diligent and proper effort to do the work. This would include an inquiry into the topography of the country, the amount and kind of the work necessary to make the improvement. Courts do not take judicial notice, however, of topography or of the physical condition of the streets and the town. There is no testimony which would indicate the length of time reasonably required for this work; hence I am unable to say that the same was not completed within a reasonable time, even though we have this great lapse between the granting of the franchise and the completion of the road."

The contract at the date of its making, the supreme court says, was unilateral, or one-sided, a mere offer that if subsequently accepted and acted upon by the other party to it would ripen into a binding enforceable obligation. When the traction company purchased and paid upwards of \$1,500 for a franchise it had acted upon the contract, and it would be manifestly unjust thereafter to permit the offer that had been made to be withdrawn. The promised consideration had been partly performed, and the contract had taken on a bilateral, or two-sided, character, and if the makers of the note thereafter thought they discovered a ground for rescinding the contract, it was, as it always is, a necessary condition to the rescission that the other party should be made whole as to what he had parted with on the strength of the contract. The notice of withdrawal from the contract was ineffectual, therefore, for several reasons. In the first place, it was based on a wrong theory; the reason given for it was that the road was not constructed within the agreed time, when, as was determined subsequently by the court, there was no time agreed upon. Again, it came too late, after the obligations of the parties had become fixed.

The traction company purchased the right to and used the track of another street railway company, that had been previously built, for a distance of some 1,800 feet, and it was contended that this was not a compliance with the contract to "build the road." But the supreme court thinks that the contract must be held to have been entered into with full knowledge of the law contained in section 490 of the civil code, which provides that two lines of street railway, operated under different managements, may be permitted to use the same street, but not to use the same street or tracks for a distance

of more than five blocks consecutively. The contract, it holds, was complied with when this section was complied with, as to the portion of the line of railway affected by said section. Leaving out of consideration the foregoing statute, the court would say that the contract must receive a reasonable construction, and the company should be held only to a reasonable compliance therewith, and under this rule there was as little force in the contention based on the use of another company's track for a short distance as there was in the contention that the stipulation as to a double-track railway was not complied with for the reason that a single track only was constructed where the railroad turned a corner. The evidence was to the effect that this was the most practical and usual way to build a double-track street railway.

CONTRACT IN ORDINANCE FIXING FARES—EFFECT OF STATUTE GIVING MUNICIPAL AUTHORITIES POWER OF REGULATION—CITY ALONE CANNOT CHANGE FARE—WHAT ACT FOR FORMATION OF COMPANIES MAY COVER EXTENSION OF FRANCHISES BEYOND LIFE OF COMPANY—POWER OF CITY UNDER RESERVED RIGHT TO MAKE RULES AND REGULATIONS.

*City of Detroit v. Detroit Citizens' Street Railway Co.* (U. S. Sup. Mich.), 22 Sup. Ct. Rep. 410. Mar. 3, 1902.

The Supreme Court of the United States says that it may be conceded that clear authority from the legislature is needed to enable a city to make a contract or agreement such as an ordinance providing for the consent of the city to the laying of tracks and the running and operation of a railroad through its streets, and fixing the rates of fare. But there can be no question in this court as to the competency of a state legislature, unless prohibited by constitutional provisions, to authorize a municipal corporation to contract with a street railway company as to the rates of fare, and so to bind during the specified period any future common council from altering or in any way interfering with such contract. The contract once having been made, the power of the city over the subject, so far as altering the rates of fare or other matters properly involved in and being a part of the contract, is suspended for the period of the running of the contract.

Under section 34 of the tram railway act of Michigan, as it was enacted in 1861, a railway corporation organized under the act could not construct a railway through the streets of a city without the consent of the municipal authorities, "and under such regulations and upon such terms and conditions as said authorities may from time to time prescribe." The court, although it does not deem it necessary to conclusively determine the question in this case, thinks that a reasonable construction of the language would seem to be that it did not and was not intended to give the right to the common council to change at its pleasure from time to time those important and fundamental rights affecting the very existence and financial success of the company in the operation of its road, but that by the use of such language there was simply reserved to the city council the right from time to time to add to or alter those general regulations or rules for the proper, safe, and efficient running of the cars, the character of service, the speed and number of cars, and their hours of operation and matters of a like nature.

Section 20 of the street railway act of Michigan of 1867 provided that the rates of toll or fare which any street railway might charge for the transportation of persons or passengers over its road, should be established by agreement between the company and the corporate authorities of the city or village where the road was located, and should not be increased without the consent of such authorities. Section 20 provided that "all companies and corporations heretofore organized in this state for the purpose of building and operating street railways under the statutes then in force shall have the same powers, rights, protection, and privileges, and shall be subject to all the liabilities, as are hereby provided for companies and corporations organized under the provisions of this act." In 1879, while this act was in force, a city ordinance was passed, supplementary to one of 1862, which provided for extensions by the railway company of its tracks through various other streets of the city, and also provided, among other things, for a special tax on the gross receipts of the several lines of railway operated by the company, payable to the city, and to be in lieu of license or other taxes and charges under the existing ordinances, besides which it pro-

vided that the powers and privileges conferred and the obligations imposed on the railway company by the ordinance of 1862 and the amendments thereto should be thereby extended and limited to thirty years from that date. Under these statutory provisions, and by the adoption of this ordinance, the court holds, a binding agreement was made and entered into between the city on the one side and the company on the other relating to rates of fare, and such agreement could not be altered without the consent of both sides.

That is, the rate of fare having been fixed by positive agreement under the expressed legislative authority by the rate of fare provided in the ordinance of 1862 having been made a rate under the ordinance of 1879, the subject was not open to alteration thereafter by the common council alone, under the right to prescribe from time to time the rules and regulations for the running and operation of the road. It may very well be, the court says, that language used by a legislature in merely conferring authority upon a company to fix certain charges for fare might not be regarded as amounting to a contract, when the same language used by parties in fixing rates under a legislative authority and direction to agree upon them would be regarded as forming a contract because the statute provided specially for that mode of determining them.

Nor does the court consider that the language of the ordinance, which provides that the rate of fare for one passenger shall not be more than 5 cents, gives any right to the city to reduce it below the rate of 5 cents established by the company. It says that it is a contract which gives the company the right to charge a rate of fare up to the sum of 5 cents for a single passenger, and leaves no power with the city to reduce it without the consent of the company. The language of section 20 in the street railway act of 1867, which provides that the rate of fare agreed upon shall not be increased without the consent of the city authorities, does not mean that the rate may be reduced without the consent of the railway companies, nor does it show the parties did not suppose there was a contract between them as to rates. That provision does not seem to perform any material function, because without it, the parties having agreed upon the subject of rates, it would follow that the agreement could not be altered by either party without the consent of the other. It may be that it was meant that the company, while unable to increase the rates of fare without the consent of the city authorities, had the right to reduce the rates as it might please it without consulting the city. It was probably inserted from abundant caution, but in no event can it properly or fairly be regarded as an implied permission to the city authorities to reduce the rates of fare as agreed upon without the consent of the railway company.

Narrowly considered, under a constitutional provision that "no law shall embrace more than one subject which shall be expressed in its title," an act to provide for the formation of street railway companies should contain nothing but provisions relating to their formation and organization, but, the court says, it would be absurd to hold that the constitutional provision would prevent the introduction into such an act of various details in regard to the corporations after their formation and in regard to their government, operation, regulation, and other matters which might be fairly considered as germane to the particular object named in the title of the statute. Hence, it thinks that it would be a most narrow construction of the constitutional provision to hold that under such a title it was incompetent for the legislature to provide that the benefits and obligations conferred and provided for in the act should be made applicable to corporations of a like character already organized and in operation. It is germane and appropriate to the subject matter of the act, and to enact under such a title that all companies of the like nature should have the same privileges is fairly within the general object described in the title.

Again, the court sees no reason why the company should not take the extended term, as provided for in the supplemental ordinance of 1879, although the extension was beyond the then limit of its corporate life. It says that the extension formed a good consideration for the agreement on the part of the company to perform the obligations contained in the ordinance. If its life were not extended, the consent being assignable and transferable, particularly by statute, any company itself having corporate existence for that purpose could purchase the outstanding term and operate its road thereunder.

The reservation in an ordinance of the right from time to time to make such further rules, orders, or regulations as to the com-

mon council may seem proper, the court holds, cannot be held to extend to the alteration of a contract as to the rate of fare which shall be charged for the transportation of passengers,—does not include the right on the part of the city at its own pleasure to reduce the rates of fare agreed upon in the ordinance. What such a reservation permits is for the city to make further rules or regulations than those contained in the ordinance, in regard "to all matters incident to the construction and operation of the road, such as the location of the tracks in the streets, the placing of switches and turntables, the repair of the pavement between tracks, the removal or limitation of the number of tracks, in the interest of public travel, the frequency with which cars should be run for the public convenience, the stopping of cars at street crossings, the use of fenders, the rate of speed to be maintained, the sale of tickets, and generally to details of the conduct and operation of the railway, which experience might show to be necessary, in addition to or in amendment of those specified in the consent for the protection of life, the accommodation of the public, and the avoidance of injury to private property. Such regulations are not invasions of the contract rights of the company, and are just and reasonable."

**SLOTTED FIELD MAGNET CONSTRUCTION.**

The method of pole construction shown in the accompanying illustration has been adopted by the Phoenix Electric Manufacturing Co., of Mansfield, O., as a means for obtaining sparkless commutation without excessive weight of material or expenditure of power. The

ture reaction and allows the brushes to remain fixed for all loads. The slots in the pole face also connect the slots in the body of the pole with the armature chamber and supply abundant ventilation to the interior of the field coils whence the heat is usually unable to escape. This construction also permits the pole pieces to be cast in one piece with the frame and the field coils are slipped over the poles without removing pole shoes as is usually necessary.

In machines having solid magnet cores it is necessary to limit the reactive voltage of the armature coil under commutation to about six volts in order to avoid sparking, and many designers limit this reactive voltage to four or five volts. A 150-kw. slotted pole machine having a reactive voltage of 11½ volts is stated to run without showing the least signs of sparking, and this is an important consideration from the maker's standpoint, as it means a much smaller number of armature coils and commutator segments.

The makers of this machine report that after a five-hours run the field coils of a railway generator of this type were 5 deg. cooler on the inner side than on the outer surface, showing the value of this design for ventilating purposes.

**STOP, LOOK AND LISTEN.**

During the Elks' carnival held in Oakland, Cal., the Oakland Transit Co. issued a time card which in addition to giving the schedule of cars added some good advice which if generally heeded would diminish the number of street railway accidents to an insignificant figure. In regard to accidents the card states the following:

"Accidents will happen as long as cars run and people travel, but it can be demonstrated that a seat in a trolley car is the safest place on earth. The number of people injured in proportion to the number who ride is much less than in any other means of transportation, not excepting walking.

"Observance of three simple rules would avoid nine-tenths of the accidents which occur.

"Stop, look and listen before crossing a car track.

"Wait till the car stops before getting on or off.

"Face the front of the car when getting off."

**NEW ORLEANS & SOUTHWESTERN RAILROAD.**

One of the largest electric railway undertakings in the South is the road which is to be built from New Orleans to Montegut, a distance of 90 miles. It is expected by the promoters to have trains running on this road by Feb. 1, 1903, and as soon as this line shall have been equipped the company will at once begin the construction of another line from Thibodaux to Donaldsville, Napoleonville and Lockport, which will bring the total of the company's lines up to 175 miles. Mr. C. P. Young, who is general manager of the new company, states that the construction of the road is no longer in doubt. The first work will be begun during July and it will be pushed as rapidly as possible. The right of way has been secured, plans and specifications have been drawn and contracts for all supplies, machinery and construction let. The power is to be supplied from the power house at Thibodaux, which will be capable of generating 10,800 h. p. The road will be equipped with both passenger and freight cars, which will be drawn by locomotives equipped with four 160 h. p. motors. The locomotives will cost \$170,500 each. The passenger coaches are 50 ft. long and built with all modern appliances and the freight cars will be of from 60,000 to 90,000 lb. capacity. There will be no freight trains run, as these will be more in the nature of express trains, making a speed of from 35 to 40 miles an hour. All the passenger cars will have separate compartments for whites and negroes. The company also proposes to furnish electric power for sugar plantations, as the road will pass through the largest sugar producing section in the state. The officers of the company are C. P. Shever, president; C. P. Young, general manager; H. L. Lancaster, treasurer; Thomas A. Badaux, secretary.

The Elgin (Ill.) Aurora & Southern Traction Co. contemplate the erection of a new cement bridge over the Fox River at St. Charles. The bridge is estimated to cost \$20,000. It will be 60 ft wide with a 40 ft. roadway.

FIELD RING WITH SLOTTED POLES.

method consists of the use of slotted magnet poles, without pole shoes, the commutating tips being formed by hollowing out the core just above the pole face on either side of the magnets. A description of this type of construction was given recently in a paper on "Recent Refinements in Field Magnet Construction" read by Mr. S. L. Hoenesfeldt before the Ohio Society of Mechanical, Electrical and Steam Engineers.

The effect of sparking working in a direct current generator with a given armature winding may be varied considerably by varying the excitation in the air gap. The greater the magnetic density in the air gap and the armature teeth the less the liability to sparking. A higher magnetic density, however, means more power for excitation and greater hysteresis losses in the armature teeth.

Several advantages are claimed for the form of pole herewith illustrated. The hollowing of the magnet reduces the cross section of the magnet where they occur so that at no load the outer ribs are highly magnetized and consequently the magnetization of the pole tips varies very little from no load to full load. This in combination with slot brush gear, the pole face, prevent distortion of the field by arma-

**COMPARATIVE ACCELERATION TESTS WITH STEAM LOCOMOTIVE AND ELECTRIC MOTOR CARS.**

BY B. J. ARNOLD AND W. B. POTTER.

In connection with the preparation of a report on the use of electricity for the propulsion of trains of the New York Central & Hudson River Railroad Co. in the tunnel entrance and terminal in New York City, an invitation was extended by the General Electric Co. to Mr. W. J. Wilgus, chief engineer of the railroad company, to use its experimental track and apparatus at Schenectady, and a series of tests was accordingly carried out under the direction of the authors of this paper. The tests were principally for the purpose of determining the comparison between steam and electric traction on short haul suburban passenger service. Owing to the short curves in the connecting tracks, the General Electric Co's. track could not be used for the steam locomotive tests. The steam tests were, therefore, made on the New York Central main line tracks west of Schenectady.

The steam locomotive used was built from the specifications of Mr. A. M. Waite, superintendent of motive power and rolling stock of the New York Central, by the Schenectady Locomotive Works. It was designed specially for the rapid acceleration work required in suburban service, being provided with large grate area and heating surface and a very large proportion of weight on its driving wheels. The principal dimensions were as follows:

Weight on drivers, 128,000; total weight, 214,000; wheel base driving, 15 ft.; wheel base total, 35 ft. 9 in.; cylinder, diam. x stroke, 20 in. x 24 in.; driving wheels, 63 in.; boiler pressure, 200 lb.; fire box, 93 in. x 98 in.; number of tubes, 365; diameter of tubes, 2 in.; length of tubes, 12 ft.; heating surface of tubes, 2,285 sq. ft.; heating surface of fire box, 180 sq. ft.; grate surface, 63 sq. ft.; tractive power, 25,000; water capacity of tank, 3,500 gals.; tank fuel capacity, 4 tons.

The two electric motor cars were similar in form, 54 ft. over all, each weighing about 35 tons including the electrical equipment, which consisted of four G. E. 55 motors and type M. control. All axles being equipped with motors, the two cars together gave approximately the same weight upon the drivers as the steam locomotive. The acceleration was, therefore, directly comparable for trains of equal net weight and to secure this comparison the same trail cars arranged in the same order were used in both the steam and electric tests.

In the steam runs the draw-bar pull, speed and time were recorded by an Illinois Central dynamometer car, and the same car was used with the electric motor cars to determine the relation between current input and draw-bar pull. The dynamometer car had to be returned before the electric runs were completed, but not before a large number of readings were taken, from which curves were plotted showing the relation between amperes and draw-bar pull with different weights of train behind the motor cars. The draw-bar pull thus determined was plotted on the electric motor car curves, which were taken subsequent to the return of the Illinois Central car.

The order of the tests, both steam and electric, was as follows:

A train of six cars, including five standard passenger coaches loaned by the New York Central, and the dynamometer car, was started and run over a mile of track, acceleration being made as rapidly as possible. These same runs were repeated, dropping off one car at a time, until only the dynamometer car remained. Automatic records were kept of the draw-bar pull, speed, time, distance and the strength and direction of the wind. The condition of rail and temperature were also noted. The same runs were repeated, using the two motor cars in place of the steam locomotive, the dynamometer car being used in some of the runs and a box car loaded to equal weight in subsequent runs. In the electric runs, additional records were kept of voltage, ampere and wattmeter readings. The wattmeter was not carried on the car, but was placed stationary at the point of feeding the third rail, thus avoiding any inaccuracy due to jarring. The voltage leads of the wattmeter were connected to the extreme end of the third rail and track, thus receiving at all times the exact voltage at the train, so that the energy delivered to the motor cars represented the net input and did not include losses in the feeder system.

The cars used in this test and the weights are given below:

New York Central locomotive	No. 4107.	214,000 lb.
General Electric motor car	No. 4	73,000 lb.
General Electric motor car	No. 5	70,000 lb.
Illinois Central dynamometer car	No. 17	45,640 lb.
New York Central coach	No. 1885	48,200 lb.
New York Central coach	No. 545	60,250 lb.
New York Central coach	No. 1700	53,700 lb.
New York Central coach	No. 508	51,450 lb.
New York Central coach	No. 1798	54,600 lb.

During the tests many runs were made, but for the illustration of this paper, representative and average runs only are given.

**ELECTRIC MOTOR CARS NO. 4 AND 5.**

The electric runs were made upon the General Electric experimental track against a head wind of 15 m. p. h. The rail was dry, the temperature 8° C., and the grade practically level. In the middle of the run there was a curve having a minimum radius of 875 ft., equivalent to about 6½° curve, the effect of which may be assumed as approximately equivalent to the 1 per cent up grade of the steam runs.

No. of run	Character of load.	Weight of load, tons	Total weight train, tons	Maximum speed.	Average speed.	Watt hours per ton mile	
						From volt amperes.	From wattmeter.

**NEW YORK CENTRAL STEAM LOCOMOTIVE NO. 1407.**

All steam locomotive runs were made upon the New York Central main line track west of Schenectady against an upgrade of 1 per cent and a head wind of 15 m. p. h. The temperature was 4° C., and the rail wet with a very light falling snow.

No. of run.	Character of load.	Weight of load, tons.	Total weight of train, tons.	Maximum speed, m.p.h.	Average speed, m.p.h.
2	6 Trailers	157.	264.	30.0	28.2

6	4 "	104.	211.	40.9	27.4
8	3 "	77.	184.	45.7	27.3
10	2 "	47.	154.	48.0	30.1
12	1 "	23.	130.	50.9	33.0

Although this locomotive was especially built for suburban or acceleration work, and was provided with a large fire box, giving it facilities for rapid steaming, the pressure dropped from 200 lb. to less than 185 lb., during the first part of acceleration. In starting, the throttle was opened wide and steam used full stroke, the engine being hooked up as acceleration proceeded.

While the electric runs had the advantage of dryer rails than the steam runs, the driving wheels were not slipped in either instance. Although the steam locomotive was able to give a maximum tractive effort at starting equal to that obtained electrically, this high tractive effort was not maintained, but immediately fell off with increased speed, even with the most expert handling.

As the acceleration curves produced by the steam locomotive and electric motor cars have different shapes, and as in the two tests there was about the same weight upon the drivers, it is interesting to note how well this driver weight was utilized. This is shown by the following tables giving the speed reached in ten, twenty and thirty seconds with equal trailing load for both electric and steam trains.

**MILES PER HOUR ATTAINED IN 10 SECONDS.**

An inspection of the tables brings out clearly the fact that the electric motors during acceleration can more effectively utilize the weight upon their drivers than a steam locomotive. As rapid acceleration is especially important when stops are a mile or so apart, the electric motor has an advantage in being able to cover the same distance in the same time with less energy expended and

of passengers carried (each car seating 64 people) and the energy, which for convenience we have given in watt hours, required per passenger for both steam and electric runs.

Number of Cars.	Number of Passengers.	Watt Hours per Passenger.	
		Steam.	Electricity.
6.....	384	43.9	29.7
5.....	320	52.2	32.1

3.....	192	77.4	37.5
2.....	128	103.0	45.2
1.....	64	187.8	45.2

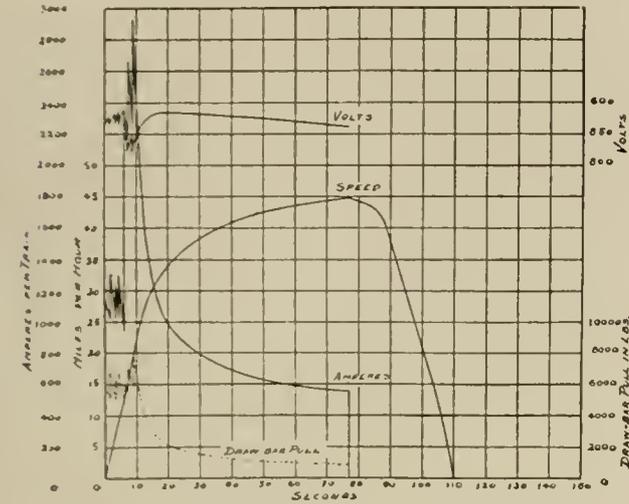

This table is based upon the actual net energy delivered to the wheels of the train and does not include the losses inherent to any system of operation. The results tabulated may, therefore, be considered as fundamental, and typical of the two systems of operation—the steam locomotive and the electric motor car.

The following table gives the efficiencies for the seven electric runs, the efficiency being the ratio between net energy output to the wheels and total volt ampere input:

Trailers.	Average m. p. h.	Watt hours per ton mile. Output.	Watt hours per ton mile. Input.	Per cent Efficiency of run.
0.....	27.2	59.1	79.8	74.0
5.....	28.6	61.0	82.0	74.3
4.....	29.8	63.8	84.9	75.3
3.....	30.6	68.0	90.2	75.3
2.....	32.0	69.6	99.6	69.9
1.....	33.1	75.3	112.8	66.7
0.....	34.6	79.8	130.0	61.5

An accurate comparison of the relative efficiency or coal consumption of steam and electric power for similar service would require an extensive series of tests with indicator and dynamometer on the performance of the steam locomotive.

As a matter of interest we have secured an approximate com-

Electric Run No. 11. 1 Trail Car—Weight 23 tons, including Motor Cars 94.5 tons. Power on 4060 ft. Distance Run 5350 Ft. Watt hours per ton-mile 114.

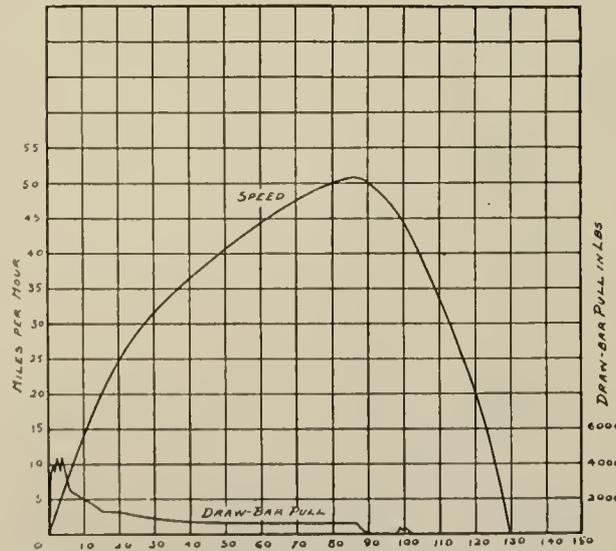

at less maximum speed than with the steam locomotive, owing to its being able to maintain its maximum accelerating rate for a longer period.

The average speed given in both steam and electric tables is the average speed of the train while it is in motion and does not include time of any stop at the end of the run. Starting from rest, the power was kept full on to the three-quarter mile post where the power was shut off and the brakes applied in such a manner as to bring the train to rest as near the mile post as practicable. In the tests the steam train ran from 5 to 15 per cent over a mile before the train was brought to rest and the electric trains from 2 to 4 per cent, but even with the longer distance the average speed of the steam runs only approaches that attained in the electric runs made over a shorter distance. A comparison of the two sets of runs on the basis of average speed is, therefore, not quite fair to the electric motor car, as its average speed would have been considerably higher if the length of the run had been the same as that made with the steam locomotive. An inspection of the tables will show, however, that even with the shorter distance run, the electric motor cars were able to make higher average speeds than the steam locomotive over its longer distance, and these higher average speeds were obtained also with a lesser maximum speed.

The maximum speed of a train making a given run in a given time serves as an indication of its energy consumption. A train, therefore, which is so handled as to make a given run in a given time, with lowest maximum speed, will consume less energy for the run. The electric runs tabulated all show a lower maximum speed and a higher average speed than those runs made with the steam locomotive, and the energy consumption of the electric runs should, therefore, be less for the same service performed than with the steam locomotive.

The motors of an electrically equipped train may be placed upon the trucks of ordinary passenger coaches, each carrying its full complement of passengers, and thus lessen the gross weight by elimination of the locomotive. The true measure of comparison between steam and electrically propelled trains should be the energy per seat mile rather than per ton mile, as the latter value is based upon the total train weight and includes a considerable proportion of dead weight embodied in locomotive and tender. The weight of the electric motors is much less than the weight of a steam locomotive capable of performing the same service, as the latter, in addition to its tender, must be heavy enough upon its drivers to provide a draw-bar pull sufficient to accelerate the train.

As an illustration, the following table has been prepared from these tests showing the number of cars in the train, the number

Steam Run No. 12. 1 Trail Car—Weight 23 tons, including Locomotive 130 tons. Power on 4460 ft. Distance Run—6260 ft.

parison from a single test by weighing the coal and water taken by steam locomotive No. 1407 for a period of 24 hours, covering four trips between North White Plains and Grand Central Station, a distance of 24.75 miles, on the Harlem Division of the New York Central Railroad. The trips occupied about 4 hours, the yard movements about 1 hour, and the locomotive was idle for 19 hours.

The results showed:

Total effective h. p. hours, hauling coaches.....	1861
Coal consumed.....	13,412 lb.
Coal per effective h. p. hour.....	15.6 lb.

The effective h. p. given is the energy required for movement of the cars only, exclusive of the locomotive, and was determined from the draw-bar pull taken by dynamometer car in previous tests over the same route.

The coal consumption covers all coal burned during the period of 24 hours, not only for movement of cars but also movement in the yard and the banking of fires during lay-overs.

The effective h. p. h. to move the cars serves as the basis of comparison with electric service, the coal consumed by the locomotive for whatever purpose being properly chargeable to the net work done by the locomotive during the period.

The efficiency of an electrical system, as an average under variable load, may reasonably be assumed as follows:

	Efficiency, per cent.
Engine .....	90.
Alternator .....	92.
High potential transmission .....	98.
Transformers .....	97.
Converters .....	92.
Third rail .....	95.
Motors, including control .....	75.
Combined efficiency .....	51.3

This percentage of effective horse-power output of motors to i. h. p. of engine will vary somewhat, depending on the load factor. As an even figure we will assume an efficiency of 50 per cent.

Coal consumption per indicated h. p. h. from actual records of electric power stations, is in some cases less than 2 lb., the average being about 2½ lb. At the latter figure, the coal per effective h. p. h. output of electric motors would be 5 lb. Assuming the head end air resistance as 10 per cent and as the electrical equipment would increase the weight of the cars about 20 per cent, the actual comparison of coal consumption would be approximately in the ratio of 6.6 for electric and 15.6 for steam.

Assuming that coal for a power station can be purchased for 80 per cent of the cost per ton of that used in the locomotives and that the cost of coal for electrical power is about one-third of the total cost, including maintenance and interest on investment, it is probable that the actual gross cost of electrical power would closely approximate the coal consumption of a steam locomotive in this class of service, the maintenance of the electrical equipment and attendance required being, however, considerably in favor of the electric power.

We wish to express our thanks to Mr. E. C. Schmidt, Professor of Railway and Mechanical Engineering, University of Illinois, for his able management of the dynamometer car, assisted by Messrs. J. F. Snodgrass and R. W. Lohmann; also to Messrs. A. H. Armstrong and E. F. Gould of the General Electric Co. for their careful supervision and calculations of the electric test.

### ELECTRICAL EXPERIMENTS AND ESTIMATES FOR THE NEW YORK CENTRAL TERMINAL.

A paper on this subject was read by Mr. Bion J. Arnold at the annual meeting of the American Society of Electrical Engineers at Great Barrington, Mass., June 10th, 1902, in which he described the method used for ascertaining the power to operate the trains of the New York Central & Hudson River Railroad between Mott Haven Junction and the Grand Central Station, and the relative cost of operation by steam and electricity. In August, 1901, Mr. Arnold was commissioned by this railroad company to study the conditions governing the operations of its trains upon the division mentioned and to report upon the feasibility of operating them by electricity. This division consists of 5.3 miles of four-track road, forming the main artery over which the trains of the three divisions of the New York Central and the main line of the New York, New Haven & Hartford Railroads enter the city of New York. For 2.58 miles from Mott Haven Junction the tracks are carried on an elevated stone and steel structure, then for 2.04 miles through a tunnel underneath the street, emerging into an open cut .68 of a mile long, and then terminating at the Grand Central Station in an intricate stub-end yard having about eight miles of switching tracks. Over this division are made nearly 600 train movements per day, as almost all trains entering the yard or station must be returned to Mott Haven Junction, owing to the lack of sufficient storage tracks at the Grand Central terminus.

The annoyance of passengers due to the use of steam locomotives

in the tunnel caused the company to examine into the advisability of adopting electricity. All money values relating to the total cost of installation, real estate, etc., and many other elements upon which the final recommendations of the report were based, together with many of the general recommendations and conclusions, were necessarily omitted from the paper, and only sufficient data given to check the technical conclusion arrived at.

Soon after taking up the work it became evident, on account of the number and weights of the trains to be handled and the numerous variable elements entering into the operating system which would not adapt themselves conveniently to formulae, that the most practical and satisfactory way to ascertain the power required to propel the trains was to measure by means of a dynamometer car the draw-bar pull of a sufficient number of trains of various weights to determine the average power required per train, and from this compute the general load diagram. A dynamometer car was accordingly secured and this was coupled between the engine and the train in each case, and operated on trains running over the different divisions of the road so that not less than two runs in each direction were made for each class of train. From the dynamometer records the horse power required at the draw-bar was obtained in the following manner:

The average draw-bar pull of the various trains over the various lines was determined and proper allowance made for increased train weight due to motor equipment and finally a reduction of the draw-bar pull thus obtained to horse power, and eventually to kilowatts. Owing to the fact that the maximum speed on this division seldom exceeds 35 miles per hour and that the trains are never less than three cars in length—often reaching 11 cars in length—no correction was made for head end air resistance. The dynamometer records were made by a pen tracing a line upon the strip of paper passing under it and the average draw-bar pull for any given period was determined by measuring the entire area between the dynamometer pen record and the base line by means of a planimeter and dividing by the length of the base line, the result being the average draw-bar pull.

Passenger records were taken during the dynamometer tests from which the ratio of the weight of the live loads to the light weight of the train was determined. Dividing the average pull in pounds by the total weight of the train the average pound per ton draw-bar pull over the line under consideration was obtained.

The question of grade was eliminated as the average values were obtained from two runs on the same trains, one in each direction. The weight of every train arriving or leaving the Grand Central Station on a given day and its average speed between stops was determined. Knowing therefore, the average draw-bar pull in pounds required to haul the train and the average speed at which this draw-bar pull was exerted, the horse power at the draw-bar becomes:

$$\begin{aligned} \text{H. P.} &= \text{foot pounds per minute} / 33,000 \\ &= \text{draw-bar pull} \times \text{miles per hour} \times 5,280 / 33,000 \times 60 \\ &= \text{draw-bar pull} \times \text{miles per hour} / 375. \end{aligned}$$

The horse power required for each scheduled train over each run was obtained in this manner and from these figures the daily load diagram was made out. The average horse power obtained was converted into kilowatts by means of the following formula:

$$\begin{aligned} \text{kw.} &= \text{h. p.} \times 746 / .70 \times 1,000 \\ \text{where } 1,000 \text{ watts} &= 1 \text{ kw.} \\ 746 \text{ watts} &= 1 \text{ electrical h. p.} \\ \text{and } 70 \text{ per cent} &= \text{efficiency of locomotives,} \end{aligned}$$

which gives the average kilowatt input required at contact shoes of electric locomotives. It was found that the daily average input required would be at the rate of 1,800 kw., and therefore the total annual input required at the contact shoes of locomotives for propulsion alone would be  $1,800 \times 24 \times 365 = 15,768,000$  kw. hours. From the total number of tons hauled yearly over this division, passenger, shop trains and switching service, the ton miles per year were found to be 250,285,710. Hence the electrical energy required to haul a ton one mile over this division under the existing conditions would be  $15,768,000,000 / 250,285,710 = 63$  watt hours per ton mile.

With this figure as a basis, and the load factor as determined from the load diagram, the problem of determining the best method of producing, distributing and applying the power was considered.

CHOICE OF SYSTEMS.

While it is the author's opinion that the alternating current railway motor will yet prove to be the most efficient all things considered, for long distance railway work, it has not yet in his opinion demonstrated its ability to start under load as efficiently or to accelerate a train as rapidly as the direct current motor. The line under immediate consideration was short, the trains numerous and rapid acceleration desirable, all of which are conditions favorable to the direct current motor.

Furthermore, direct current motors with their necessary auxiliaries have become fairly well standardized and it is the only class of electric railway apparatus available from the manufacturers of the United States without involving experimental work and large development expense.

In view of these facts and the probable necessity for rapid construction, the author refrained from advising anything of an experimental nature and, therefore, recommended the direct current system in combination with the third rail for the main line, and overhead construction for the yards, all of which have demonstrated fully their ability to meet the conditions imposed by railway operation so far as motive power is concerned, although there has not yet been an electric installation on any existing terminal that is as complex, or into which anywhere near the number of heavy trains enter as on this section of road.

Had the length of road under consideration been considerably

Column 6, which is Column 4 plus Column 5, represents the total cost per electric locomotive mile.

While the results in Column 6 indicated that Plan No. 1 was the most advisable one to adopt, it was not seriously considered for the reason that it necessitated locating the power station in a part of the city where its erection would probably have been prohibited by the city authorities, but it was here introduced for comparison as indicative of the economy to be gained by placing the power station at the theoretical center of distribution. The same objection applied to Plans 2 and 3.

Plans 4 and 5 bring out quite clearly the difference in the cost of operation between two sub-stations and one, both plans permitting the location of the power station on the river front.

The difference in favor of Plan 5 is entirely due to the saving in labor of one sub-station.

Plans 6, 7 and 8 were studied with the object of ascertaining whether the purchase, instead of the generation, of power would offer a satisfactory solution of the problem.

The purchase of both direct current and alternating current energy was considered on the lowest basis that it was thought possible for any existing company to furnish it, and it was found that the direct current energy, in consequence of the interest, depreciation, maintenance, etc., of the transmission lines, rotary converters and other sub-station apparatus which would have to be furnished by the energy producing company.

TABLE OF ESTIMATES OF PLANS FOR PROPOSED ELECTRICAL EQUIPMENT OF THE N. Y. C. & H. R. R. TERMINAL.

PLAN.	CHARACTER OF STATIONS, ETC.	1	2	3	4	5	6
1.	Direct current power station at center of line and contiguous to tracks. 600 volt working conductor, no batteries	.417c	.60c	1.06c	14.02c	6.58c	20.60c
2.	Same as No. 1, with batteries in power house	.472	.66	1.137	14.65	6.71	21.36
3.	Same as No. 1, with battery substation near Grand Central Station and Mott Haven Junction	.475	.668	1.20	14.7	7.25	21.95
4.	Alternating current power station on river front near center of line, with rotary converter substations near each end of line. 11,000 volt A. C. and 600 volt D. C.	.572	.715	1.287	15.2	7.58	22.78
5.	Combined D. C. and A. C. Power station at Harlem River near one end of line and one rotary converter substation near the other end of line. 11,000 volt A. C., 600 volt D. C., no batteries	.570	.666	1.19	14.7	7.18	21.88
6.	Direct current feeders from Manhattan Railway substation located near center of line. Transmission from substation to working conductor, 600 volts D. C. energy to be purchased.	2.5	2.650	2.748	34.64	2.80	37.53
7.	Rotary converter substation at center of line. A. C. energy to be purchased from Manhattan Substation and transmitted at 11,000 volts. Energy to cost 1 cent less per k. w. hour than D. C. energy delivered.	2.5	2.336	2.508	31.50	4.23	35.73
8.	Two rotary converter substations, one near each end of line. A. C. current to be purchased from Manhattan substation near center of line.	2.1	2.336	2.504	31.50	3.93	35.43
9.	Combined A. C. and D. C. power station near Harlem River at end of line. One substation near other end, and batteries carried on locomotives charged from working conductor	.519	.629	1.122	16.58	7.76	24.31
10.	One rotary converter substation near center of line, A. C. current purchased from Manhattan substation No. 7, batteries on locomotives charged from working conductor	2.12	2.4	2.502	34.40	4.08	38.48
11.	Direct current feeders from Manhattan substation No. 7, near center of line. Batteries on locomotives charged from working conductors.	2.5	2.738	2.742	37.81	2.51	40.32
12.	Combined A. C. and D. C. power station at Harlem River near outer end of line. One substation near other end. Batteries in power station and substation. A. C. transmission 11,000 volts, D. C. conductors 600 volts.	.55	.775	1.335	15.80	7.83	23.63

greater, and had it been thought possible to secure sufficient time to conduct experiments or invite demonstrations by manufacturers of alternating current motor equipments, this class of apparatus would have been more seriously considered.

In the preparation of estimates 12 distinct plans of generation and distribution were considered, and the results tabulated as shown in the accompanying table. All the estimates were computed upon the same basis as far as cost of fuel, labor and losses in transmission were concerned.

In the accompanying table, column 1 represents the operating expense per kilowatt hour at the power house switchboard.

Column 2 represents the operating expenses per kilowatt-hour at contact shoe.

Column 3 represents the total cost per kilowatt-hour delivered to motor terminals exclusive of fixed and operating charges on electric locomotives.

Column 4 represents the operating expenses per electric locomotive mile. The values in this column are directly comparable with values now obtained in the present team locomotive service, except that the operating expense shown by the performance sheets of the motive power department do not include any charges for water. From the best information available, the cost of water on the present service of this division is about 987 cents per locomotive mile (which amount was added to the present cost given on the performance sheets).

Column 5 represents the fixed charges per electric locomotive mile,

The prohibitive annual cost of these purchasing plans is at once observed by reference to Columns 6 and 2, the plans only meriting consideration as representing a temporary arrangement that might be effected in order to allow rapid installation.

Owing to the more or less complex system of overhead or third rail yard construction made necessary by the nature of the case, and the averages to be obtained by their elimination in the substitution of locomotives which could, for switching service, be self contained, though normally supplied with energy from the working conductors, a study was made of electric locomotives carrying batteries.

The results of these studies, made under several different assumptions, are shown under Plans 9, 10 and 11. From Column 6 and 3 it is evident that whatever may be gained by the elimination of the overhead construction is largely offset by the additional cost of operation, although it will be observed that the cost per locomotive mile of Plan 9 compares favorably with the cost of Plan 12.

Plan 12 differed only from Plan 5 in a slight reduction in the capacity of the converting apparatus in the power house and substations and the substitution thereof of two storage batteries (one located in or near the power house and one in the sub-station) each of such capacity that it, together with only a portion of the main station and sub station machinery, would be capable of taking over the entire load of the line for a short period of time in cases of emergency.

The additional first cost and the slight increase in annual expense (as compared with Plan 5) represented by a reserve station capacity

of this nature, was thought to be of secondary importance only, in view of the increased reliability of operation thereby obtained. The increased cost of operation in this plan over that of Plan 5 is due to the fact that the battery maintenance was figured at 10 per cent per annum, which is considerably higher than is ordinarily assumed, and will probably be considered excessive by some.

A battery of this kind would not only serve as a reserve, but would prove of considerable value as a regulator of potential along the line, and in addition it would, notwithstanding its inherent losses, tend to reduce the power house operating costs by taking up the excessive load fluctuations of the system and permitting the load upon the engines to be maintained at or near their most efficient working capacity.

It was considered of the utmost importance in an installation of this magnitude that the number of interruptions of power supply be reduced to a minimum, that no device which could increase the safety and reliability of the plant should be omitted, and that the probability of future extensions of the electrical system should be considered. As best fulfilling the above conditions, therefore, Plan 12 was the one specifically recommended for adoption.

OPERATING EXPENSES.

A careful compilation of all the expenses entering into the operation of the present steam service was made and the following comparative table of relative costs is believed to be correct, assuming that the present locomotives running between Mott Haven Junction and Grand Central Station should be abandoned and the service now performed by them duplicated by electric locomotives operated in accordance with Plan 12. It is assumed that the electric locomotives will be operated by the same class of men as those who now operate the steam locomotives, and that they would receive the same rate of pay that they now receive.

This condition is not favorable to electric traction as it is not ordinarily necessary to have two men to operate an electric motor, but in the writer's judgment, it is not advisable to operate a service of this class under such exacting conditions without two men on each locomotive.

If the motor car system should be adopted, as it probably would be were the electrical equipment extended beyond Mott Haven Junction, or if the forward guard or brakeman were allowed to take the place of the second man while passing through the tunnel and yards, a saving equivalent to his wages could thereby be effected.

With two men of the same skill as at present employed on the locomotives, the figures are as follows:

	Steam.	Elec- tricity.
Operating expenses per locomotive mile exclusive of fixed charges but including water, labor, cost of cleaning and repairing tunnel, and all other expenses of locomotive operation.....	23.05	15.80
Fixed charges per locomotive mile assuming that it now requires 40 locomotives to perform the present service and that 33 electric locomotives could perform the same service.....	1.13	7.83
Total in cents.....	24.18	23.63

From these figures it appears that while there would be a slight annual saving in operating expenses in favor of electricity, it is not sufficient to warrant its adoption on the grounds of economy in operation alone, although its adoption can be justified on other grounds.

These figures could be made more favorable to electricity were an optimistic view of many of its advantages taken, and the probability is that practical operation will show a somewhat greater gain than here indicated, but it has been deemed best by the writer to maintain a conservative view throughout the entire investigation.

It is, however, safe to conclude that the saving in operation expenses of the electric system would be sufficient to offset the increased fixed charges due to the additional investment made necessary by its adoption.

The new Huntington line between Los Angeles, Cal., and Long Beach was opened to general traffic July 4th. The first car was run over the line on the preceding day, carrying officers of the company and their guests.

ELECTRICAL INDUSTRIES OF PITTSBURG.

At a meeting of the American Association for the Advancement of Science recently held in Pittsburg, a paper was read by Mr. G. H. Gibson, on the "Electrical Industries of Pittsburg and their Economic Influence." Mr. Gibson spoke particularly of the extent of the Westinghouse Electric & Manufacturing Co.'s plant which is shortly to be duplicated. He stated that the modern industrial age began with the advent of the steam engine, but in order to utilize its power some means of transmission was necessary, and electricity is especially qualified for power distribution; it has also furnished a most useful means of lighting, and electro-chemistry has opened up a new and rapidly developing branch of the industry. Mr. Gibson spoke of electricity as an important factor in developing cities, building up suburban districts, redistributing populations and affording convenient transportation to farming communities. The use of electricity in modern factories was also considered as well as its applicability to mining. Electro-chemistry has not only made aluminum a rival of copper as an electric conductor, but nearly all the copper in use is now electrically refined. Mr. Gibson stated that the engineering development of a country was a measure of its civilization and pointed out that the United States produces 69 per cent of all the electricity available in the world, 76 per cent of all the portion available for traction, 76½ per cent of all the electric railway mileage and 83½ per cent of all the trolley cars.

LARGER POWER PLANT FOR STEPHENSON CO.

Some months ago we announced that the John Stephenson Co. intended to enlarge its power plant and published some particulars in regard to the company's plans. The first week of July ground was broken at the works in Elizabeth, N. J., for the foundation of the new engine, which will be a horizontal tandem compound with automatic cut-off and will be direct connected to a 400-kw. generator. The top of the copper covered dome of the engine house has been removed and the flat skylight replaced by a large clear story of iron. This is arranged to give light and ventilation on four sides while it excludes direct sunshine.

The company is also putting in an additional 150-h. p. boiler. When this is in place it will bring the boiler capacity up to the requirements of the establishment when the new engine is put in operation. A new 700-h. p. feed water heater of the latest and most approved type is ordered and work has been begun in the piping for its connection.

PENSION SYSTEM IN NEW YORK.

The new system of pensioning superannuated employes which was recently adopted by the Metropolitan Street Railway Co. of New York, became operative on July 1st. Notices were posted in the power houses and barns June 18th directing eligible employes to make application to the proper officer for their pension allowance. The system provides for voluntary and involuntary retirement of all employes of the Metropolitan and constituent companies whose wages have not exceeded \$1,200 per annum, and who have reached a certain age after 25 years or a longer time in the service of the company. The details of the system and the ratio of allowance were given in the Street Railway Review for March, 1902, page 183.

MEDALS FOR AMERICAN STEEL & WIRE CO.

At the South Carolina Inter State and West Indian Exposition, Charleston, S. C., which closed May 31st, the American Steel & Wire Co. was awarded 10 gold, 4 silver and 4 bronze medals and one diploma of merit. The gold medals were for: Merchants Iron and Steel; cold drawn steel shafting. Horse and Mule Shoes. Wire Nails. Rail Bonds. Wire Rope. Machinery and appliances for drawing wire. Springs and Spring Wire. Copper. Iron and Steel. Aluminum Wire. The exhibits awarded silver medals were: Bicycles and Automobile Spokes. Rolled wagon skeins. Underground and Overhead Wires and Cables. Metallurgy of Zinc. Bronze medals were for: Music Wire. Coal and Coke. Bale Ties. Chemicals and Colors. The installation in the Commerce Building was given a diploma of merit.

## Some Street Railway Parks.

Birmingham, Ala.—Pittsburg—Youngstown, O.—Clyffside Park.

As with the transfer system, the practicability of creating travel over street railways by establishing pleasure resorts en route, or at the termini of roads was at first problematical, but they proved so successful that such means of inducing pleasure traffic have been almost unanimously adopted by leading street railway companies. Not only has the park been a money-earning project, but it has, as well, made the relations more intimate between the street railways and the public, and thus in almost every instance furthered the interests of the road. People in general have a friendly feeling for those who furnish them amusement, and the patrons of street railway parks are largely of a class to whom extended summer outings are impossible. To this class the park manager performs what has become an indispensable office. He furnishes cheap and

do so may sit and smoke or partake of refreshments while the performance is going on. On a 3½-ft. elevation above the box floor is another space on which tables are arranged, around which parties may sit and be relieved of the conventional seats in the parquet. All the way around the theater is a promenade 7½ ft. wide. On the end opposite the stage is a high lattice, and in each corner of the front is a refreshment stand in which refreshing drinks are served. The entrance to the theater is over a 25-ft. approach from the bank. A graceful arch surmounts the entrance gates and this is lighted by a string of incandescent lights.

The stage is surmounted by a well proportioned proscenium arch 30 ft. wide at its base, with a radius of 63 ft. The stage itself is 41 ft. long by 21 ft. broad, and is provided with the usual drops

"AQUATIC THEATER" AT EAST LAKE PARK, BIRMINGHAM, ALA.

rapid transportation from the most crowded commercial centers to some modern Eden where the natural beauties of forest and water course are enhanced and improved upon (in the taste of many) by the innovation of merry-go-rounds, dancing pavilions, bowling alleys and out-door theaters. And the public has come to feel at home in such pleasure grounds as the street railways have provided, and in a measure to take a personal pride in them, so that in mentioning his city a man is inclined to boast of its street railway parks much as he boasts of its claims to commercial superiority—such as its exports, its iron works or the beer that made it famous. Every city pretends to peculiar advantages in respect to the location of its parks, which either command a surpassing view from some mountain height or are located on a spot of great historical interest, or have some special attraction not to be found elsewhere. Such good natural rivalry has been a stimulus to the development of park systems with the result that the artificial attractions are more varied and abundant.

### EAST LAKE THEATER, BIRMINGHAM, ALA.

East Lake, the popular pleasure resort controlled by the Birmingham Railway, Light & Power Co., was leased this season with a five-year option to the Webster Amusement Syndicate of Chicago, and everything on the grounds has undergone a thorough overhauling and many new and attractive features have been added. Not least among these is the new "Aquatic Theater," which was built and opened on June 17th.

The theater derives its name from the fact that it is built out into the lake. The building is 138 ft. long by 108 ft. wide and is without cover, as may be seen from the accompanying engraving. It is splendidly equipped and possesses all the conveniences of a modern theater. The parquet has a 6½ per cent slope to the stage and has a seating capacity of 1,400. Arranged on a 3½ ft. elevation above the parquet are four boxes on either side and back of the boxes are arranged tables where those who care to

and wings. There are two large and spacious dressing rooms on each side of the stage, which afford ample space for the making up of a large opera company, if necessary.

The lighting of the theater is by means of five rows of lights strung from the stage to the front of the building and aggregating something over three hundred in number. Besides these are the usual foot lights and other stage lights controlled by switches behind the scenes. The lighting question up to the present season at East Lake has been a rather awkward one, for the reason that the park is seven miles from Birmingham and the lighting heretofore has been by means of current obtained by tapping the trolley wire, and as East Lake is at the extreme end of the line, when many cars were being operated on the line the lights were necessarily dim. This method was, moreover, not desirable on account of the fluctuations in the pressure, so this season a direct line from the alternating current circuit in Birmingham was run to the park, a transformer installed, and now the lighting of the grounds is one of the marked attractions.

Vaudeville has been the offering since the opening night, and judging from the box office receipts has been highly acceptable to patrons. Only the very best people on the vaudeville stage have been engaged and the performance is in every way refined. From four to six "teans" are employed for the bill each week. As an auxiliary to the vaudeville turns a moving picture machine has been obtained for the season and the performance closes with a roll of moving pictures every night. This feature in itself has proven a drawing card, as a great many people take their children out to see this alone. The performance opens at 9:00 and lasts about one and one-half hours. Through trains to the city are in waiting after the performance and those who care to do so may get home promptly, as the run over the new track is now made in twenty minutes. No stops being made except at railroad crossings.

The price of admission to the parquet is 25 cents, to the boxes 50 cents and in the extreme rear of the building are several rows

of benches admission to which is only ten cents, thus providing for all classes. So pleased do the people seem with the show that frequently the late comer is greeted at the box office with the familiar words "Standing room only." It was contemplated to run vaudeville for a while and then secure an opera company, but as vaudeville is producing such satisfaction it will be kept on indefinitely.

At an outlay of something over \$1,000 a "Shoot the Chute" has been erected. It stands 45 ft. high and the slope is 125 ft. long. It has only been provided with two tracks, one for the ascent and one for the descent of boats. It has been found that three boats are all that are necessary to handle the crowds, or rather all that can be conveniently and expeditiously handled. The boats are drawn up by electric power on a steel rail track and the descent is made on a roller track which gives the boats sufficient speed to send them 100 yards or more out in the lake. A steel track, with iron runners on the boats was tried at first, but after a few hours steady running the track would get so hot that the boats would not run. It was then that the roller track was substituted and found to be the proper thing.

The boats used are built with a seating capacity of six and are gondola shaped. Ten cents is charged for a ride on the chute and the capacity is taxed to the utmost quite often, as frequently a party will ride more than once. The top of the chute is gained by several flights of stairs leading up from the old pavilion.

The old theater and dancing hall has been remodeled and converted into a fashionable restaurant with all the appointments of a downtown restaurant. All the delicacies of the season are served at moderate prices, and it has come to be quite the thing for couples and parties to go out early in the evening, take supper, ride the

For those who care to indulge in boat riding are some twenty row boats which may be engaged by the hour, and for those who are more indolent there is the naphtha launch, which takes patrons on a ride around the lake for 5 cents each. Scattered through the grounds are the peanut, popcorn and candy vendors, whose voices may be heard, each crying out the virtues of their wares, each trying to silence the other.

With the beautiful "Aquatic Theater," whose equal is not to be found in the South, the "Chutes" and the numerous other attrac-

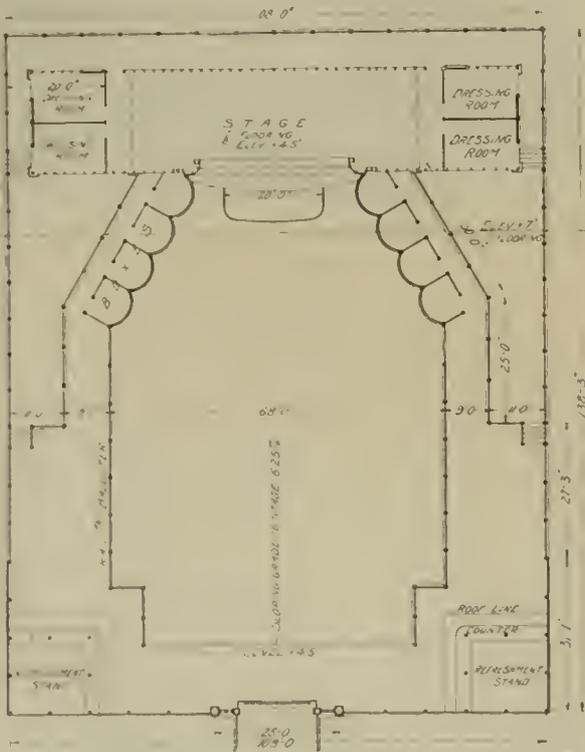

"CHUTE" AT EAST LAKE PARK.

tions, East Lake has grown to be one of the most popular pleasure resorts to be found anywhere. With its many attractions, its never dying breezes, its excellent car service all tend to fill it nightly with gay throngs seeking relief from the hot pavements of the city.

THE PARKS AT PITTSBURG.

By reason of the consolidation of the street railways in Pittsburg and vicinity, the four popular parks of that city, Kennywood, Calhoun, Oakwood and Southern Avenue, are now under one management, and the lines of the Pittsburg Railways Co., extending out of Pittsburg in every direction and touching nearly every suburban town within a radius of 20 miles, afford direct and rapid service to all the parks. Under this arrangement, churches, schools and societies, bound on an outing, can charter special cars to carry any number of persons to any one of the four parks without the inconvenience of transferring, which is a new and important feature of the Pittsburg service. Kennywood, under the management of the Pittsburg Railways Co., has become distinguished. It is served by the McKeesport branch of the company's system, and is situated on the banks of the historic Monongahela River, opposite the thriving city of Braddock. The new street railway line over the steel bridge at Wilkinsburg Junction makes Kennywood easily accessible, eliminates all grade crossings and reduces the distance from Pittsburg, Allegheny, the "East End" and the Wilkinsburg district. Kennywood is kept free to the public on all occasions. The company has expended large sums of money in preserving the natural scenery, in perfecting the sanitary conditions of the park and in installing attractions of the most approved kind. The casino is one of the finest buildings of its class in the country. It is 115x175 ft. in dimensions, two stories high and encircled by a spacious verandah. Here an expert caterer has made his headquarters, and it is one of the boasts of Kennywood that its facilities for feeding the multitude are unexcelled. The auditorium pavilion is also a handsome and modernly equipped structure, and has a dancing floor which is the special delight of devotees of Terpsichore. The theater is carefully planned in regard to acoustics and to the comfort of its patrons, and the highest class musical and vaudeville entertainments are provided. Throughout the park there are pavilions assigned for private picnics, and there are inexhaustible springs and artesian wells. One of the special features on the grounds is a ladies' cottage as secluded and charmingly furnished

THEATER AT EAST LAKE.

boat and go to the theater. The season's business has been better than the most sanguine hoped for.

In one end of this building is a handsome soda fountain where ices and drinks are served and this in itself is proving a drawing card.

Just to the right of the entrance of the park a new double bowling alley has been erected, where the devotees of this sport may try their skill. Along the drive way leading from the entrance are situated several side shows, such as snake dens, human freaks, ball throwing, tin type galleries and others of this ilk.

A large merry-go-round is being put in and from time to time some new side show is added to the already large and noisy lot.

as the famous retreat of Rosamond, and here, with a matron to look after their necessities, the favored sex when fatigued are entertained. We reproduce herewith engravings of the toboggan which is one of the most popular features at the park, and which, moreover, while thrilling enough to gratify the most audacious, is entirely safe. There are band concerts at Kennywood in the afternoons and evenings which draw many thousands of people to the park from Pittsburg and her suburban cities. The music is furnished by the most famous bands and orchestras in the country,

FIGURE 8 TOBOGGAN, KENNYWOOD.

among which may be mentioned the "Royal Italians," Phinney's United States Band, of Chicago, and many other celebrated organizations. The music pavilion is a massive, imposing structure, artistic in appearance and perfect in acoustic properties.

Calhoun Park, situated on the Dravosburg and McKeesport branch of the Pittsburg Rys., eight miles from Pittsburg, is noted for its splendid forest trees and pure spring water. We illustrate a car on the Pittsburg lines at the entrance of Calhoun Park,

sion at the gates of Calhoun Park, can arrange with the management to do so, all privileges being clearly defined in the contract.

Oakwood Park, on the West End lines of the Pittsburg Rys., is a grove of magnificent oaks, situated on a sloping plane which forms one of the shores of a charmingly picturesque lake. The park commands a view of the beautiful scenery of the old Mansfield Valley, and, being located on an eminence, is always swept by a refreshing breeze. Here also are pavilions, merry-go-rounds, shooting galleries, etc. While Oakwood Park is in every sense a popular resort, the management is conducted on lines of uncompromising propriety, and the comfort of those who seek the luxury of quiet and repose in the shade of the oaks is the first consideration. It may be mentioned that the boating facilities of Oakwood are exceptionally good, a large number of boats being at the disposal of those who wish to rent them, and a spacious and handsome boat house affording ample accommodations.

Southern Avenue Park, on the Suburban branch of the company's line, is but 30 minutes' ride from the heart of the city. It comprises all the appointments of Kennywood, Calhoun and Oakwood parks, and, like them, is abundantly supplied with shade and pure water. Concerts are given at Southern Avenue Park on Sunday afternoons and evenings, and other forms of amusement on week days are provided during the park season.

In closing, it may be said of the parks of Pittsburg that the management has spared no pains to provide all modern conveniences and amusement features, and has succeeded in making these resorts particularly attractive by keeping on the grounds a large number of trained employes, whose especial business it is to direct or assist visitors in any possible manner. Patrons are assured courteous treatment at all times and the most careful attention when occasion demands it.

PLEASURE RESORTS NEAR YOUNGSTOWN.

Idora Park and Mill Creek Park are situated at the terminus of the Youngstown Park & Falls Street Ry., four miles (only 15 minutes' ride) from the center of Youngstown, O., at which point

ADVERTISING TRAIN AT THE ENTRANCE OF CALHOUN PARK, PITTSBURG.

decked with flags and electric signs appropriate to some holiday celebration. At this resort the natural features predominate, but there are still a great number of attractions in the dancing and music pavilion, the shooting gallery, baseball field, roller coaster, bowling alley and carnival to afford a variety of entertainment for those who are bent on the more lively forms of amusement. Churches, schools and societies, desiring to sell tickets for admis-

the street railway connects with the Pennsylvania, the Pittsburg & Western, the Erie, the Pittsburg & Lake Erie, and the Lake Shore & Michigan Southern Railroads. Thus it is that both these pleasant resorts are patronized to a great extent by travelers who have a few hours to wait in Youngstown, as well as very generously by residents of that city. The parks contain nearly 450 acres, and the scenery is most picturesque. Mill Creek runs through the

length of Mill Creek Park, and a number of smaller streams empty into the creek within the park boundaries. The remains of an old Indian village border the creek, and near at hand are Lake Cohasset, with its complement of row boats and launches, the old Idora Mill, abandoned and silent in the heart of the woods, bringing to mind the scene of Zola's most spirited romance, and there are the Umbrella Rocks and the Haunted Pool. The company has built a very handsome and comfortable open air theater at Idora Park, and recently an elaborate summer toboggan at a cost of \$15,000. There is an electric merry go round which is always in

A BALLOON ASCENSION AT CLYFFESIDE.

favor with the children, but perhaps none of the attractions excel as a drawing card the deer paddock and the summer quarters of the trained bears, the badgers and the wild cats. Idora Park and Mill Creek Park have the best of sanitary conditions and are liberally equipped with toilet rooms, spring houses, rustic seats, etc. Throughout the season excursionists from Cleveland, Pittsburg, Allegheny, Butler, Canton, Akron, Beaver Falls, New Brighton, Sharon and many other places take advantage of the opportunities offered for an outing at this resort, and the patronage, while steadily increasing, is uniformly of a superior class.

A souvenir booklet illustrating Idora and Mill Creek parks has been issued by the Youngstown Park & Falls Street Railway Co. In addition to many half-tone engravings, showing the popular features and natural attractions here enumerated, the book con-

VIEW IN CLYFFESIDE PARK

tains interesting pictures of the city of Youngstown, and has, apropos of the summer scenes, a good collection of verse from well known authors.

#### CLYFFESIDE PARK, IN KENTUCKY.

Clyffeside Park, midway between Ashland and Catlettsburg, Ky., is directly accessible from these cities and from Ironton, O., seven miles distant, and Huntington, W. Va., 12½ miles distant, by the lines of the Camden Interstate Railway Co. Clyffeside comprises 10 acres of as finely wooded land as can be found in the Blue Grass state, and a lake of 15 acres' area on which a large number of boats are always in use. A commodious boat house and a casino,

the cost of which was \$10,000, have recently been erected, and in addition to these there are dancing pavilions, band stand, restaurant, and a depot where passengers may wait for the interurban cars. The park and its buildings are illuminated by 30 enclosed arc lamps of General Electric manufacture, and by 600 incandescent lamps, the current for which is furnished from the sub-station which has recently been completed to increase the efficiency of the interurban service. Vaudeville attractions are billed at the Casino during the entire season, and an orchestra of nine pieces provides music each afternoon and evening. The grounds are well policed and competent employes are in attendance to assist patrons of the park in any possible way. Through the courtesy of Mr. H. P. Wellman, superintendent of the Camden Interstate Railway Co., we reproduce photographs of Clyffeside Park which illustrate some of its points of interest.

#### CLUB HOUSES FOR BROOKLYN.

President Greatsinger, of the Brooklyn Rapid Transit Co., has secured options on building sites advantageously located in various parts of the borough on which it is proposed to erect club houses for the use of employes, which will be equipped in a manner similar to the branch stations of the Y. M. C. A. The plan of furnishing the men's quarters in the car houses in club-room style has proved so prolific of good results that the development of the system along advanced lines was decided to be highly practicable, and the success of the project of establishing club houses for the exclusive use of the men seems assured. Beside the usual reading rooms, baths and gymnasiums there will be a number of special attractions and every effort will be made to secure the advantages of a fraternal organization.

#### THE SEOUL ELECTRIC CO.

A report was recently published in a Japanese newspaper in regard to the plant of the Seoul Electric Co., extracts from which have been forwarded to the Department of State by Minister Allen, of Seoul. The plant in question is the largest single electric plant in Asia. It was built for a Korean company by an American firm, Collbran & Bostwick, who held the property under mortgage. The company operates an overhead trolley road of about 12 miles and also furnishes power for incandescent and arc lights for the city. The generating machinery is of the Westinghouse type and the boilers Babcock & Wilcox. The generators are direct current alternating current machines producing direct current at 550 volts for the use of the railway and alternating current at 385 volts for the electric lighting. There are over 1,400 incandescent lights supplied in addition to the arc lighting. The consulting engineer for the company is a Japanese graduate of the Massachusetts Institute of Technology.

#### NEW FACTORY FOR THE STANDARD ROLLER BEARING CO.

The Standard Roller Bearing Co., of Philadelphia, Pa., has purchased property in the center of the city on the main line of the Pennsylvania Railroad, where it will build a large factory for the manufacture of its well-known roller bearings. The principal buildings will consist of two factories 200 ft. long and 60 ft. wide, and in addition will be office buildings, etc. The plant will be equipped with every convenience for the rapid and economical handling of the business. Work has already been commenced on these buildings.

The Ball Bearing Co., also of Philadelphia, which recently removed from Boston, will occupy a portion of the new plant. The Standard Roller Bearing Co. has purchased the complete plant and equipment of the Roller Bearing & Equipment Co., of Keene, N. H., and as soon as practicable will remove the machinery and business of this company to the factory now in course of erection. The purchase of this business, together with that of the Grant Roller Bearing Axle & Wheel Co., of Cleveland, O., which was recently noted, will give the Standard Roller Bearing Co. a large proportion of this line of business in the United States. The company's products include ball, roller and all kinds of anti-friction bearings for high-grade machine construction.

## INTERCHANGE OF FREIGHT BETWEEN STEAM AND ELECTRIC ROADS.

### An Important Decision by the New York Court of Appeals—The Right of Electric Railways to Compel Steam Railroads to Make Connections Between Roads and to Interchange Freight.

The decision of the New York Court of Appeals rendered June 27, 1902, is one of the most important to electric interurban railways that has been made in this country and we here publish the text of the opinion which was by Judge Haight.

In the matter of the application of the Stillwater & Mechanicville Street Railway Co. for the appointment of commissioners under Section 12 of the Railroad Law, appellant, v. The Boston & Maine Railroad Co., respondent.

Appeal from an order of the Appellate Division, Third Department, reversing an order confirming the report of commissioners, and an order adjudging that an intersection and connection of the Stillwater & Mechanicville Street Railway Co. be made with the Boston & Maine Railroad.

David B. Hill and Thomas O'Connor for appellant.

Lewis E. Carr and T. F. Hamilton for respondent.

Haight, J.: This proceeding was instituted by the Stillwater & Mechanicville Street Railway Co. to obtain an order permitting it to unite and connect the tracks of its railroad with those of the Boston & Maine Railroad Co. in order to facilitate the free interchanging of cars between the two roads.

The Stillwater & Mechanicville Street Railway Co. was organized under the general railroad law of this state (New York), with the right to transport both passengers and freight, and is operated as an electric railroad by the trolley system.

The Boston & Maine Railroad Co. is a foreign corporation, organized under the laws of Massachusetts, and is operating a steam railroad. It is contended upon its behalf that the statute does not authorize the court to compel a connection of the tracks of the two roads. The question, therefore, raised for our review is, as to the proper construction of the statute.

The Railroad Law of 1890 (Chapter 565, section 12) provides as follows: "Every railroad corporation, whose road is or shall be intersected by any new railroad, shall unite with the corporation owning such new railroad in forming the necessary intersections and connections, and grant the requisite facilities therefor; and if the two corporations cannot agree upon the amount of compensation to be made therefor or upon the line or lines, grade or grades, points or manner of such intersections and connections, the same shall be ascertained and determined by commissioners, one of whom must be a practical civil engineer and surveyor, to be appointed by the court, as is provided in the condemnation law; and such commissioners may determine whether the crossing or crossings of any railroad before constructed shall be beneath, at, or above the existing grade of such railroad, and upon the route designated upon the map of the corporation seeking the crossing or otherwise. All railroad corporations whose roads are or shall hereafter be so crossed, intersected or joined, shall receive from each other and forward to their destination all goods, merchandise and other property intended for points on their respective roads, with the same dispatch as, and at a rate of freight, not exceeding the local tariff rate charged for similar goods, merchandise and other property, received at and forwarded from the same point for individuals and other corporations."

It will be observed that this statute contains two provisions, one for the crossing of the tracks of another railroad at, above or beneath grade; and the other provides for the intersection of the tracks of such railroads, and upon the making of such connections the roads shall receive from each other and forward to their destination all goods, merchandise and other property intended for points on their respective lines.

The court below seems to have been of the opinion that this statute had reference to steam railroads, and did not pertain to roads operated by electricity. In determining this question it became necessary to examine more fully the Railroad Law for the purpose of ascertaining the legislative intent. By referring to section 2 of the act, we find provisions for the incorporation of railroads which is to be accomplished by the execution of a certificate by fifteen or more persons which shall contain the name of the corporation, the number of years it is to continue and the kind of road to be built or operated. The section contains other provisions,

among which is subdivision 11, which provides that "if a street surface railroad, the names and description of the streets, avenues and highways in which the road is to be constructed."

It is thus apparent that the articles of incorporation provided for have reference to all kinds of railroads for public use, including steam railroads, street, surface and electric roads.

Again, passing to section 4, subdivision 5, of the act, we find that every railroad corporation, in addition to the power given by the general stock corporation law, shall have power "to cross, intersect, join or unite its railroad with any other railroad before constructed, at any point on its route and upon the ground of such other railroad corporation, with the necessary turnouts, sidings, switches and other conveniences in furtherance of the objects of its connection."

Section 34. "Every railroad corporation shall start and run its cars for the transportation of passengers and property at regular times, to be fixed by public notice, and shall furnish sufficient accommodations for the transportation of all passengers and property which shall be offered for transportation at the place of starting, within a reasonable time previously thereto, and at the junctions of other railroads, and at the usual stopping places established for receiving and discharging way passengers and freight for that train; and shall take, transport and discharge such passengers and property at, from and to, such places, on due payment of the fare or freight legally authorized therefor."

Section 35. "Every railroad corporation whose road, at or near the same place, connects with or is intersected by two or more railroads competing for its business, shall fairly and impartially afford to each of such connecting or intersecting roads equal terms of accommodation, privileges and facilities in the transportation of cars, passengers, baggage and freight over and upon its roads, and over and upon their roads and equal facilities in the interchange and use of passenger, baggage, freight and other cars required to accommodate the business of each road, and in furnishing passage tickets to passengers who may desire to make a continuous trip over any part of its roads and either of such connecting roads. The board of railroad commissioners may, upon application of the corporation owning or operating either of the connecting or intersecting roads, and upon fourteen days' notice to the corporation owning or operating the other road, prescribe such regulations as will secure, in their judgment, the enjoyment of equal privileges, accommodations and facilities to such connecting or intersecting roads as may be acquired to accommodate the business of each road, and the terms and conditions upon which the same shall be afforded to each road. The decision of the commissioners shall be binding on the parties for two years, and the Supreme Court shall have power to compel the performance thereof by attachment, mandamus, or otherwise."

It will be observed that each of these provisions of the statute, of which reference has been made, expressly refers to every railroad corporation, and thereby includes every railroad incorporated under the provisions of section 2 of the act.

The contention is now made that to compel a track connection with steam railroads by electric, or street surface railroads for the interchanging of traffic, would be a burden and a hardship to steam railroads that was not contemplated when the statute was passed; that to permit connections with steam railroads by the large number of electric railroads which have been, or are being constructed, would result in confusion to the steam railroads and make their operation difficult.

The learned Appellate Division appears to have been impressed with this argument, for it states in its opinion that the proceeding and purpose is new, and obviously opens a field of inquiry of the greatest importance, not alone to railroad corporations, but to the general public, which has an interest in the streets and highways of towns, villages and cities of the state; that if the street surface railways are to be recognized as an integral part of the great system of steam railroads, that the purpose should be made clear by the legislature. We readily concede that the legislative intent should clearly appear, but we are not much impressed with the contention that burden and hardship will result to the steam railroads, or that

confusion will follow in their operation. The provisions of the statute authorizing the courts to compel connections or intersections of tracks between railroads, to our minds was intended to promote the public interests, independent of that of the railroad companies. Travelers and the shippers of merchandise and freight have the right to make use of all the facilities provided for in the articles of incorporation, and the provisions of the statute pertaining thereto, in the conduct of their business. This, we think, is made clear by the provisions of the statute which requires that all railroad corporations whose roads are, or shall be intersected shall receive from each other and forward to their destination all goods, merchandise and other property intended for points on their respective roads, with the same dispatch and at the rate of freight not exceeding the local tariff rate, etc. Bearing this purpose in mind, we pass to a consideration of the meaning of the law. As we have seen, by the statute authorizing the incorporation of railroads, the legislature contemplated making provisions for all kinds of railroads, street surface, as well as steam railroads. By section 4, subdivision 7, all roads organized under the provisions of the act were empowered "to take and convey persons and property on its railroad by the power or force of steam, or animals, or by any mechanical power." It is true that the statute contains numerous provisions which apply alone to steam railroads and other provisions which apply alone to electric or street surface roads; but in most of these provisions there is specific reference to either steam or street surface roads. The great body of the statute was intended to apply to all railroads incorporated under its provisions, especially so far as those provisions were applicable. The revision of the Railroad Law of 1850 is of recent date and after the street surface railroads in our cities and villages had become very numerous. The legislature in undertaking a revision of the railroad laws attempted so far as possible to establish a complete system under which all kinds of railroads could be operated and the public interests subserved. In construing these statutes it does not become us to shut our eyes to the purposes sought to be accomplished, or the discoveries that have been made and the improvements accomplished in the transportations of the country in recent years. The great steam roads have extended across the continent from ocean to ocean, and from the far north down to the tropics. These roads have become great arteries over which is transported the greater part of the commerce of the continent. It has not been considered profitable or practical for steam roads to be constructed to every village, hamlet or productive district in the country. This, however, is rapidly being accomplished by the numerous electric roads that are in process of construction, or are contemplated. By their means the farmer, the mill owner and the merchandise vendor in distant places may be able to reach the steam railroads, and through them the great markets of our cities, with their merchandise and products, and in this way one road may become a feeder and distributor of the other.

If one electric road were seeking a connection with another road operated by the same power, it would hardly be claimed that the provisions of section 12 did not apply. It is practically conceded that electric roads may be united with other roads of the same character and operated by the same power. But the statute has not limited the courts to the requiring of intersections and connections between roads of the same character. Very likely, electric roads tendering cars to steam roads for transportation should only offer those properly equipped with brakes and couplers, so that they may be taken and transported readily and safely. It may be that additional regulations will become necessary in order that equal privileges, accommodations and facilities may be afforded in connecting and intersecting roads, but all this may be controlled by the board of railroad commissioners, which, under the provisions of section 35, to which we have referred, is given full authority in the premises.

It is said that the rights of the public in the streets and highways of our cities, towns and villages should be protected and that cars loaded with merchandise and freight should not be permitted to be run over street surface railroads. It may be that additional regulations should be provided either by statute or by ordinance, limiting the time in which cars of this character should be permitted to run over street surface railroads, especially in cities and large villages; but that the power exists to run such cars is no longer an open question in this court.

This question was elaborately considered in the case of *DeGrauw v. Long Island Electric Railway Company* (43 App. Div. 502),

which case was affirmed in this court on the opinion below (103 N. Y. 597).

Again, bearing in mind the legislative purpose, its intent to our minds appear reasonably clear, in the use made of the provision to cross, intersect, join or unite its railroad with any other railroad. The word "cross" is used in connection with the word "connect" and the Legislature could hardly have intended that one word should mean one kind of a railroad, and the other another kind. One of the most important rights which the Legislature undertook to provide for and to protect was that of the right of one railroad to cross the tracks of another which had previously been constructed. Were it not for this, one road running north and south through the state could absolutely prevent the constructing of another extending east and west. The Legislature was careful to make ample provisions for crossings in the same section in which intersections were provided for, and these provisions with reference to crossings have been held to apply to electric and street surface roads crossing steam roads, or of steam roads crossing electric or street surface roads. (*Buffalo, B. & L. R. R. Co. v. N. Y., L. E. & W. R. R. Co.*, 72 Hun, 583; *Port Richmond & P. P. El. R. R. Co. v. Staten Island R. T. R. R. Co.*, 71 Hun, 179; *aff'd.*, 144 N. Y. 445.)

It appears to us that the Legislature has clearly empowered the court to order connections such as is sought by the petitioner in these proceedings. The order of the Appellate Division should, therefore, be reversed, and that of the Special Term affirmed, with costs.

Parker, C. J., and Gray, O'Brien, Vann Cullen and Werner, JJ., concur.

---

#### NOTES FROM WHEELING, W. VA.

The extension of the Wheeling & Elm Grove Railroad to West Alexander, Pa., will be completed this season. The line has already been extended to Roney's Point at the state line and material is already on the ground for the completion of the road to Alexander. This is generally considered as a start in the project to link all the towns together between Wheeling and Pittsburg. The surveys have already been made for a line to Washington and the remaining link, between Washington and West Alexander, it is believed, will soon be projected.

A consignment of five new cars for the Wheeling Traction Co. has been received. These are 10-bench open cars and they are being equipped with trucks and motors as rapidly as possible. This consignment is the first of an order of 15 cars, all of which are expected to be delivered within a few days. The 42d St. power station of this company has been enlarged by an addition which is practically completed, and part of the new battery of boilers is already on the ground. Excavations have been made for the foundations for a new generating unit which is to be installed.

---

#### ELECTRIC RAILWAY FROM ROME TO NAPLES.

The construction of an electric railway between Rome and Naples which has been under consideration for a long time has been approved by the special commission which was appointed to pass upon the project by the Italian minister of public works. The engineering features of this road have been elaborated by M. Serafius Tarentini.

The two terminal stations have been located in the cities of Rome and Naples and the total length of the line will be 197 km. which will be made by the cars in two hours. The route will touch the cities of Cisterna, Terracina, Formia Mondragone, where the power house will be located, and Quaglinio. The principal substation will be at Fondi. The road will have a double track throughout, and both electricity and steam will be used for motive powers. It will carry passengers, mail matter and certain classes of merchandise only.

---

A new electric line between Augusta, Ga., and Clearwater was opened June 28th, since which time the company has met with a steadily increasing patronage over the extension. The round trip between the cities is made in two hours. The route lies through one of the most picturesque portions of Georgia.

**ST. LOUIS CARS FOR MEXICO.**

An order of 10 cars for the City of Mexico has recently been completed by the St. Louis Car Co. These cars are for use as second class cars, six of them being closed trailers and four having baggage compartments. The length of the car bodies over corner posts is 25 ft. 4 in. and over the platform crown piers 34 ft. 4 in. The doors are of the double automatic pattern and the car has nine windows on each side. The platforms are 12 ft. 6 in. long with entrance step on both sides of the dasher. The platform flooring is made in the most substantial manner. There is a brake shaft on each platform and four folding gates are used, one at each entrance. The draw bars are radial with double acting springs and each car has

in Pittsburg and Allegheny is vested in this department of the Philadelphia Co.

The fuel gas department of the company, over its own lines and those of a number of companies controlled by it, supplies nearly all the fuel gas consumed in Pittsburg and Allegheny and a large number of manufacturing towns lying along the Monongahela and Allegheny Rivers. This territory is well covered by distributing mains and is connected by large mains of ample capacity with the natural gas wells in West Virginia, and elsewhere. The company estimates that it has a supply of gas in sight for the next 25 or 30 years.

For the first five months of 1902 the company reported gross earnings of \$5,773,615; operating expenses and taxes, \$2,807,781; im-

CAR FOR MEXICO, BUILT BY ST. LOUIS CAR CO.

two signal bells. All of the appliances are of the St. Louis Car Co's. pattern. The outside trimmings of the car are of malleable or wrought iron and the inside is finished in ash. The seats are longitudinal and arranged back to back, the backs being made of ash slats. There are four iron rods for window gratings, and wire screen life guards are placed between the trucks. The accompanying illustration shows one of the baggage cars of this order. The baggage compartment is 8 ft. long and is divided by a hard wood partition in which is a sliding door; the door slides on the baggage compartment side of the partition and is protected by slatting. This compartment is provided with hinged seats which fold up against the sides of the car and there is a single sliding door in the end of the compartment leading to the platform besides a 3 ft. 6 in. sliding door on each side of the compartment.

**THE PHILADELPHIA CO.**

In reply to numerous inquiries which have reached the Philadelphia Co., of Pittsburg, from stockholders and others as to the nature of its business and its source of income, the company has issued a circular explaining the diversified character of the interests which it controls. The Philadelphia Co. was organized in 1884 and operates under a special act of the Legislature of Pennsylvania in favor of the Empire Co., its predecessor. Under this act which conveyed many valuable privileges, the company has grown from an organization supplying fuel gas alone, to one which supplies a population in Pittsburg and its vicinity, of about 600,000 people, almost exclusively with fuel gas, illuminating gas and electric light as well as serving this territory with electrical transportation. These properties are subdivided into: (1) street railways, (2) electric lighting and illuminating gas, (3) fuel gas. The street railway property comprises about 404 miles and to conduce to greater convenience and economy of operation the railways are operated under agreement by the Pittsburg Railway Co. whose stock, both common and preferred, is owned by the Philadelphia Co. The gross earnings of the railway department of the company increased from \$5,728,186 in 1899 to \$7,081,472 in 1901, and for the same period the net earnings have increased from \$2,632,184 to \$3,200,178.

The electric lighting and illuminating gas department include the same organization furnishing electric current for heat, light and power in the cities of Pittsburg and Allegheny and the surrounding territory, while the exclusive right to manufacture illuminating gas

improvements, etc., \$163,044; net earnings, \$2,802,780; other income, \$748,357; total net earnings, \$3,551,140. Deducting fixed charges, etc., leaves the net income \$2,015,855.

**SALE OF THE CAMDEN INTERSTATE RY.**

The Camden Interstate Railway Co., of Huntington, W. Va., sold on June 30th all of its electric lines in Huntington, Central City, Ceredo and Kenova, W. Va., Catlettsburg and Ashland, Ky., and Ironton, O., to a syndicate of which John Graham, of Newville, is the head; other prominent members of the syndicate are Edmund McCandish, of Newville; John J. Henry and William North, of Philadelphia. The sale includes the electric light plants and parks in Ironton and Ashland, and the deal is said to have involved about \$2,000,000. It is stated that this syndicate has in view the purchase of several electric railways in other Ohio cities, its ultimate aim being to secure a continuous line between Cincinnati and Pittsburg.

**TROLLEY TRIPS THROUGH NEW ENGLAND.**

White & Warner, publishers, of Hartford, Conn., have recently published a well illustrated booklet describing the numerous trolley trips which it is now possible to make over southern New England, covering the distance between New York and Boston, via Bridgeport, New Haven, Hartford, Springfield, Worcester and other well known New England towns. The book contains 112 pages and is of convenient size for the pocket. It describes all the points of historic interest along the route from New York to Boston, and gives the running time of this trip as 22 hours and 55 minutes. A double page table shows the distances, fare and running time between local points, and also the total distance, fares and running time between New York and Boston. A number of interesting side trips which may be made by the traveler are given in detail and each place of any importance through which the lines pass is the subject of a page or more of description.

At a meeting of the stockholders of the United Railroads of San Francisco June 5th, the plan of the directors to issue bonds to the amount of \$20,000,000 was approved. The proceeds will be used to reimburse Brown Bros., of New York, for their original outlay in purchasing the San Francisco lines.

### NEW CARS FOR THE TOLEDO RAILWAY & LIGHT CO.

The accompanying illustration shows one car of an order just filled by the John Stephenson Co. for the Toledo Railways & Light Co. The order was for 13 bench open cars without seats on platforms. The length over the buffers is practically 43 ft. with platforms 3 ft. 9 in. long. The height from track is 11 ft. 4 in. The posts, letter board and drip rails are of ash, while the plates and rails are of yellow pine, not spled. All the cross and end sills are of white oak, and the seats are of ash slats.

The openings are fitted with spring roller curtains coming all the way to the floor. The interior is neatly finished with the

rights and franchises of any existing street railway companies in Ottawa or adjacent thereto.

During the last session of the Dominion Parliament the following electrical railway bills were adopted: An act respecting the Port Dover, Brantford, Berlin & Goderich Railway Co. and to change its name to "The Grand Valley Railway Co." An act respecting the Niagara, St. Catharines & Toronto Ry. Co. An act respecting the Essex Terminal Ry. Co. An act respecting the Montreal & Southern Counties Ry. Co., and an act to incorporate the North Shore Power and Navigation Co.

The Kingston (Ont.) Street Ry. has purchased the rails, cars and equipment of the Belleville Street Ry., and will have them removed to Kingston and used on that system.

NEW OPEN CARS FOR TOLEDO RAILWAY & LIGHT CO.—JOHN STEPHENSON CO.

usual linings, panels, etc., and the steps are hung on an improved form of bracket. The end of the car is furnished with a vestibule having three drop sash and a steel dasher.

It will be noticed that there are no seats on the platforms and that passengers are excluded from them, so that there is no opportunity to talk with the motorman.

The dasher is fitted with the Wason signal box, which is a very convenient type of illuminated sign. The guard rail is of unusual length, extending as it does from dasher to dasher, closing not only the entrance to the seats but the platform as well. The trim is of bronze with steel arms and hickory handles, and a great deal of consideration has been given to those trifles which go to make up a practical car.

### CANADIAN NOTES.

The Cape Breton Electric Co. has sold the Dominion Coal Co. all the rights and franchises held by it in the County of Cape Breton, Nova Scotia.

The Shawinigan Falls Electric Ry. proposes extending its line through the town of Shawinigan Falls by adding several miles of railway to the present line.

The buildings of the Kingston (Ont.) Street Ry. were recently damaged by fire to the extent of \$10,000.

The Montreal Street Ry. has secured the necessary legislation to permit it to extend the line from the present terminus at Viauville along the river front as far as Longue Pointe, a distance of about five miles. This line will parallel the Montreal Terminal Co's. tracks and is expected to be in operation by the end of July.

The Montreal Terminal Co., which has been fighting for an entrance into the city for the past two years, has finally succeeded in obtaining a ten year franchise. The officers of the Terminal Ry. have signed the ordinance granting the franchise, and work on the new line will be commenced at once and it is the intention to have the new road ready for operation by September 1st.

The Montreal Street Ry. which acquired the lines of the Montreal Park & Island Ry. has practically reconstructed the latter road, and has now on this suburban line a number of new cars which are models of comfort and elegance.

The city council of Ottawa is seriously considering the advisability of making application to the Ontario Legislature at its next session for power to build, equip, maintain and operate a street railway on the streets of that city and for authority to acquire the

The British Columbia Railway Co. intends issuing bonds to the amount of one million dollars. A large portion of this sum will be expended in developing the water power at Coquitlam Lake, and some \$200,000 will be spent for improvements to rolling stock and plant. It is the intention to construct large car shops at New Westminster.

The Toronto Street Railway Co. suffers heavily by a judgment given by the Court of Appeals in the company's appeal against the assessment on its cars. The court holds that the cars are assessable and that the assessment of \$450,000 is reasonable.

A meeting of the shareholders of the Sao Paulo Tramway, Light & Power Co., of Sao Paulo, Brazil, was held at the offices of the Toronto Railway Co. recently, and it was decided to increase the capital stock of the company from six million to seven millions of dollars, the shareholders to be allotted the majority of the new stock at par, and the remainder to be held as treasury stock. A dividend of 5 per cent was declared for the year.

The demand of the employes of the Ottawa Electric Ry. for an increase in wages has been refused by the company on the ground that the receipts will not justify the additional expenditure, and a strike is threatened.

The officials of the Montreal Street Ry. recently decided to grant employes a 10 per cent increase in wages. This was entirely unsolicited, and the men greatly appreciate the action of the company.

### SIMPLEX ELECTRIC HEATING CO.

On July 15th the Simplex Electric Heating Co. took over the electric heating and rheostat business which has been developed by the "Heating Department" of the Simplex Electrical Co. This change separates the electric heating business from the manufacture of insulated wires and cables and is intended to furnish opportunity for carrying out a broader policy in the conduct of the business. Additional factory buildings are now under construction to provide more than three times the present capacity, and this will permit of more prompt service than has been possible in the past.

The management will remain the same as heretofore. The principal office of the company will be at No. 77 Cornhill, Boston, Mass., where all correspondence about money matters should be addressed, but correspondence relating to orders may be sent to 116 Franklin St., Cambridgeport, Mass. The Chicago office will remain in charge of Mr. H. R. Ilixson, 1137 Monadnock Block.

**AUTOMATIC SIGNAL FOR BLOCK SYSTEM AND CAR SPACING DEVICE.**

Believing that the time is approaching when the double track roads operating high speed cars require a block system answering the same purpose as the block system on steam roads, as the cost of one bad rear end collision will equip an entire road with a block system, the American Electric Switch Company, Pittsburgh, Pa., has developed and is placing on the market an automatic signaling device to be used on both single track roads between turnouts and on double track roads. The following description of this system will be of interest to our readers.

There is always a light burning at each turnout, incandescent lamps being used, and the lamps are arranged so that sunlight will not strike them and confuse the motorman. All wiring is done with No. 12 B. & S. gage insulated iron wire or cable as desired. No trolley wire is cut or separate section required, and there is no trigger or any obstruction for the trolley wheel or pole to strike to operate signal, the current being taken directly through trolley wheel, so that signal will operate whether motorman uses power or not. Thus the car crew have nothing to do with setting the signals; the signal is operated by the trolley wheel making contact between the trolley wire and an independent circuit.

For a single track road with turnouts the system is arranged as in Fig. 1. Suppose a car is about to leave a turnout. If a white light signal is set the car proceeds, and when it reaches a certain point the trolley wheel makes contact with an independent circuit operating the signal setting a red light on the next turnout, No. 2, and a green light on the near turnout, No. 1. The motorman seeing this green light knows that the signal is set at danger at turnout No. 2, and any car proceeding in the opposite direction at No. 2 turnout is signalled to stop. When the car reaches turnout No. 2 the trolley wheel again makes contact between the trolley wire and an independent circuit, throws out the red light at turnout No. 2, and the green light at turnout No. 1, lighting white lights at both turnouts. A car may now enter at either end with a clear track.

The system will allow of any number of cars, going in the same direction, to enter a section between turnouts. The first car, seeing a white light, has thrown up a red light at turnout No. 2, and a green light at turnout No. 1. The second car, coming to turnout No. 1, finds a green light, and the motorman knows that there is a car going in the same direction in the section ahead, and therefore he may enter, but must proceed with the car under control. Three, four and five cars or more can run in the section likewise, and the white signal will not be set at turnout No. 2 until the last car has left the single track section. This is done automatically as follows: As number one car passes over the point of trolley wire at turnout No. 1, the trolley wheel makes connection with independent circuit energizing a magnet at turnout No. 2, which operates a drum or disc (made up of separate segments) throwing the drum forward one space so that the brush rests on a red light segment, lighting a red light at turnout No. 2 and a green light at turnout No. 1. Number two car, going in same direction, finding a green light at turnout No. 1, runs ahead and throws the drum one space farther ahead, making the white segment two spaces from the brush. When number one car passes into the second turnout it throws the brush, revolving in the same direction as drum, but operated by a separate magnet, ahead one space, leaving the light still set at danger. And so on until the last car passes into turnout No. 2, when it throws the brush one space ahead onto the white light segment, and safety signals are set at each end.

For a double track road the arrangement is as shown in Fig. 2. As one car on a double track system as per plan No. 2 as one car passes a given point, B, it sets a red light signal at B and a green light signal at the block A behind it. As the car runs off block B onto block C it will extinguish the red light at B and the green light at A, setting a red light at C, a green light at B, and a white light at A. Thus any car following, approaching block A and finding a white light, can proceed at full or schedule speed; on reaching block B, where a green light is set, the car crew know that their leader is one block ahead. At block C, where a red light is set, the car comes to a dead stop or proceeds slowly with car under control, as the management of road desires. Any number of cars can enter a block without disarranging signals.

It is also evident that this system can be used as a car spacer, allowing only one car in a block at the same time.

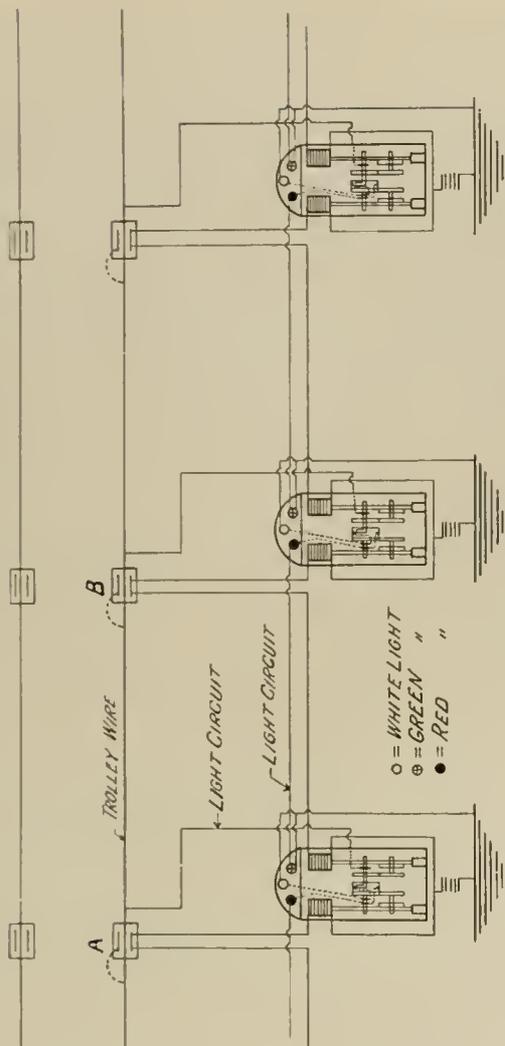

FIG. 2—WIRING FOR DOUBLE TRACK ROAD.

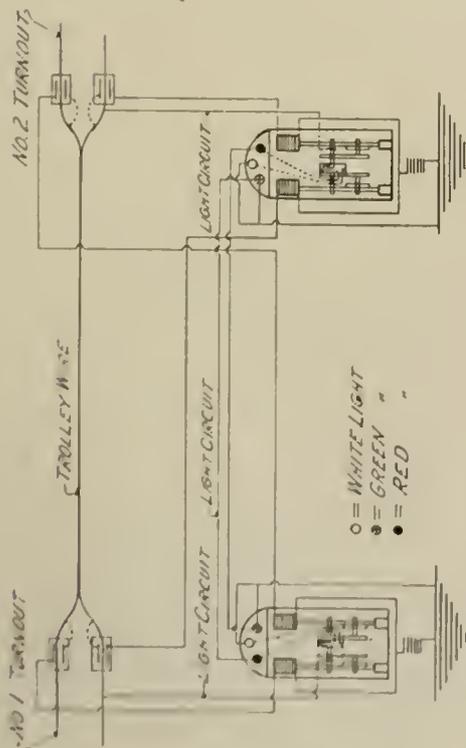

FIG. 1 WIRING FOR SINGLE TRACK ROAD.

**OIL AS FUEL.**

In the article on "Oil as Fuel" on page 322 et seq. of the "Review" for June the price of Texas oil in New Orleans was given as 45 cents per barrel. Mr. H. A. Davis advises us that this was the price obtaining earlier in the year and that at present no contracts are being made in New Orleans at less than 55 cents per barrel.

The following letter from the Mobile (Ala.) Light & Railroad Co. is self explanatory:

Editor "Review" The writer of the article "Oil as Fuel" in your issue of June 20th was misinformed as far as it relates to burning oil at the power house of the Mobile Light & Railroad Co.; instead of burning oil since last fall, we have only tried it one or two days to arrive at a comparative test. The method of feeding oil to the boilers as shown by the cut on page 324 is not allowed by the insurance underwriters, and was used by us only during the short test. We expect to burn oil, and intend to investigate further as to the means of burning.

Yours truly,

J. H. WILSON,  
Pres. and Gen. Mgr.

**ELECTRIC RAIL WELDING.**

The Lorain Steel Co. is now engaged in electrically welding some street railway track at Columbus, O., by its improved process. From a pamphlet recently issued by the company we take the following resume of the work done since 1897:

The first track welded by our present method was a mile of 6-in. rail, at Johnstown, Pa., welded for the Johnstown Passenger Ry., in 1897. This track is in excellent condition today, having been in constant use since welded.

In 1898 about ten miles of track was welded for the Nassau Electric Railway Co., at Brooklyn, N. Y. This was 9-in. rail on Marcy Ave. and on Fifth Ave. Any inquiries respecting this welding should specify these streets, as considerable welding on this road has been done before, and no comparisons should be made with electric welding done prior to the year 1897. During 1899, about 11,500 joints were welded for the Buffalo Railway Co., at Buffalo, N. Y., and 17,500 during 1900. This, with the welding done during 1901, makes a total mileage of electrically-welded track at Buffalo of about 105 miles. A mile of track was also welded in Lockport, N. Y., in 1900. All special work at Buffalo was bonded around by means of 500,000-c. m. cables, electrically welded to the rails.

The breakage on all welding done by the company's improved process and comprising that mentioned is reported at less than 1 per cent.

In addition to controlling the rights to the use of the Thomson electric welding patents, for purposes of rail welding, the company has been granted patents on its improved process. These patents cover the style of bars used and the joint in general. Its process of electrically welding cables to rail is also covered by patents.

**NEW CHASE-SHAWMUT FACTORY.**

Since the recent fire in its factory the Chase-Shawmut Co., of Boston, maker of electrical specialties, has entirely reconstructed its factory on a greatly enlarged scale and it now employs over double the number of men it did when in the old plant. A prominent feature of the new installation is a De Laval steam turbine for the generation of current for both power and light for the factory. This turbine, for which the company is New England agent, has recently received a great deal of attention on the part of those interested in the economic question of power and lighting. These turbines have been in successful operation in Europe, and it is only recently that the De Laval company has entered the field in this country. Its extensive works at Trenton, N. J., are already overtaxed in filling orders. The turbine at the Chase-Shawmut factory is in constant and efficient operation and the company invites its inspection at 390 Atlantic Ave., Boston.

The Rochester (N. Y.) Railway Co. on July 1st assumed control of the Rochester & Sodus Bay Ry.

**EXTENSION OF PITTSFIELD (MASS.) ROAD.**

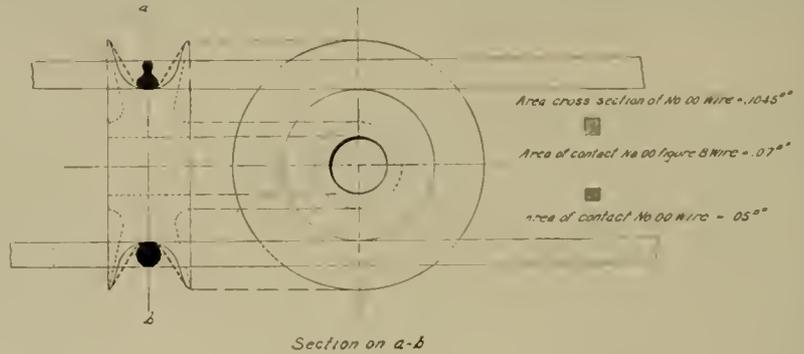

The Pittsfield Electric Street Railroad Co. has completed a one-mile line to Cheshire, where connection is made with the Hoosac Valley Street Ry., thus giving a line to Williamstown through North Adams. Control of the Hoosac Valley company has been purchased by capitalists owning the Pittsfield road and Mr. P. C. Dolan, manager of that company, has assumed the management of the Hoosac Valley. Mr. W. F. Nary of the Hoosac Valley will be superintendent of that division.

It is understood that the Hoosac Valley Ry. will be double tracked between Adams and North Adams, and double truck cars are to be ordered of the Wason company. The Pittsfield power station is to be increased in capacity by a 500-h. p. cross compound engine to be direct connected to a Stanley generator.

**FIGURE 8 VS. ROUND TROLLEY WIRE.**

Although the power equipment of electric cars continues to steadily increase, yet very little attention is given to providing a proportionate increase in the area of contact of the device which is used to collect the current. Large cars frequently require 300 or 400 amperes in starting and on grades, and the area of contact between the trolley wheel and wire is usually too small to properly carry this current.

Recently I made a few measurements to find the relative merits of round and figure 8 wire in connection with the area of surface

exposed to the trolley wheel, and found that the average contact area between the various styles of wheels and the two types of wire was considerably greater for figure 8 wire.

With a 4 1/4-in. wheel having a groove which was comparatively narrow at the bottom, the contact with a No. 00 round trolley wire was .05 sq. in. and with a figure 8 wire .07 sq. in. The cross sectional area of a No. 00 wire is .1045 sq. in.

This shows that the figure 8 wire gives about 40 per cent more area in contact with the wheel than the round wire. In using a wheel with a U-shaped groove results even more favorable to the figure 8 wire are obtained. Of course, there is some contact at the sides of the wire, but only at curves and where the wire is not over the center of the track, and this must not be depended upon.

The reason for this superiority of figure 8 wire over round wire is, as is readily seen, on account of the long radius of the curve which forms the bottom part of the lower lobe, as compared with the radius of a section of round wire.

R. A. Pratt.

**THE CHICAGO TRIBUNE'S CAR**

The Chicago City Railway Co. has put a trolley car in operation on its southside lines especially for the early delivery of the Chicago Tribune, the arrangement being somewhat similar to that which the Tribune effected last year with the Union Traction Co. for the distribution of papers on the north side, and which was described in the "Review" for February, 1901, page 135. The start is made from Clark and Washington Sts. at 3:45 a. m. Papers are delivered at the stock yards and in Englewood, Woodlawn, Hyde Park and South Chicago, the run being made in 40 minutes. The car supplies the Tribune wagons at the stops en route with papers which are distributed by them to carriers, newsboys and news dealers in the vicinity.

**ELECTRIC TRACTION IN GREAT BRITAIN.**

**London Letter.**

Electric traction in Great Britain has just emerged from a period of fervid excitement and has now reached a stage in which progress is no longer by leaps and bounds.

Lord Windsor's Committee concluded its labors on June 5th and all the London electric railway bills promoted this session or standing over from last year have now been disposed of and most of them after the final adjustment of clauses have passed the third reading. The following table will show how matters stand:

Charing Cross, Hammersmith & District Ry.....	Rejected
City & Northeastern Suburban Ry. (Morgan).....	Withdrawn
*†North East London Ry. (Morgan).....	Passed
*†London United Electric Ry.—Hammersmith to Piccadilly (Morgan).....	Passed
*London United Electric Ry.—Marble Arch-Clapham Junction (Morgan).....	Passed
*†Piccadilly City Ry. (Morgan).....	Passed
Kings Road .....	Rejected
Kings Road Putney Extension.....	Rejected
West & South London Junction Ry.....	Withdrawn
†Brompton & Piccadilly Circus Ry.—sanctioned 1897, term extension asked (Yerkes).....	Granted
Brompton & Piccadilly Circus Ry.—Charing Cross extension (Yerkes).....	Rejected
†Brompton & Piccadilly Circus Ry.—Holborn extension (Yerkes).....	Passed
Brompton & Piccadilly Circus Ry.—Parson's Green extension (Yerkes).....	Rejected
Central London (Shepherds Bush-Hammersmith-City)....	Rejected
†Charing Cross, Euston & Hampstead (Bills 1, 2 and 3 Golder's Green extension) (Yerkes).....	Passed
*Edgware & Hampstead Ry.....	Passed
City & South London Ry.—Euston extension.....	Rejected
City & Crystal Palace.....	Rejected
†Great Northern & City Ry.—Lothbury extension.....	Passed
†Northwest London Ry.—Sanctioned 1899—Time extension asked .....	Granted
†Great Northern & Strand—Sanctioned 1899—Time extension asked (Yerkes).....	Granted
†Baker Street & Waterloo—Sanctioned 1893—Time extension asked (Yerkes).....	Granted
District Deep Level—Earls Court to Mansion House—Time extension asked (Yerkes).....	Granted
London, Tillbury & Southend (Power to use electricity)....	Granted

\*New railways authorized this session.

†Bills passed through third reading.

Londoners will in time obtain a magnificent network of electric line, though there are disadvantages resulting from the want of uniformity in the system as a whole. As the joint committee of last year and the Board of Trade both vetoed the intercommunication of tube railways by means of confluent junctions the patchwork nature of part of the network assumes less importance.

In the Yerkes lines the return conductors will be fixed inside the running rails, the positive conductor being the third rail. Mr. Yerkes disagrees from the Board of Trade recommendation to use 13 ft. 6 in. tube; he prefers 11 ft. 6 in. and urges that with his system of conductor passengers can with perfect safety walk along the permanent way in case of a breakdown.

The Morgan system is also worked at a pressure of 500 volts and has a completely insulated return, but in this case the two conductors are placed one above the other on the tube wall, protected by one of the platforms to be constructed on each side of the train for passengers in case of accident. The multiple unit system has been universally adopted and the general practice in all lines will be to generate alternating current at high pressure and to convert it to direct current low pressure before feeding it to the conductors.

Mr. Yerkes has made an agreement with the Hampstead-Edgware line whereby the Charing Cross, Euston & Hampstead Railway Co. shall control the line as far as Edgware with an end on junction at Golder's Green, the six miles between the latter two stations being run in the open

As matters stand at present, the relative positions of the Yerkes and Morgan interests may be thus defined. Mr. Yerkes controls the following lines, which will be supplied with power from the central station at Lots Road, Chelsea: The District Railway, including the Whitechapel & Bow extensions; the Brompton & Piccadilly Railway; the Hampstead, Euston & Charing Cross Railway; and the District Deep Level Line; all intercommunicating by means of exchange stations. Mr. Morgan's combination only controls the Northeast London and Piccadilly-City lines, with a part interest in those of the London United Electric Railway—Hammersmith to Hyde Park Corner. There will be two power stations which will also supply current to the Marble Arch-Clapham Junction Railway.

A special compensation clause has been drawn up for insertion in all Tube Railway bills, providing that all claims shall be made within two years from the opening of the railway by owners, lessees or occupiers. Cases of disputed compensation to be settled by arbitration according to the Act of 1889.

The endeavor of the London County Council to constitute itself sole controlling authority over the tube railways was firmly frustrated by the committee and its application for jurisdiction in the City of London was also refused.

The House of Lords has given the London County Council and its supporters a severe shock and a disagreeable surprise by defeating that part of the council's Subways & Tramways Bill which dealt with the Embankment Tramways.

Lord Newton moved an instruction to the committee to strike out of Clause V. the power to construct any tramway south of the Strand. He mentioned that the Westminster Borough Council and other bodies strongly opposed this particular clause in the bill. The London County Council had itself, moreover, passed a resolution in favor of underground tramways and if it really desired to have a tramway connection between North and South London, it could effect this by constructing a subway under the Thames. The Earl of Morley opposed the instruction in the interests of procedure, declaring that instructions to the Private Bill Committee were excessively inconvenient and almost unknown. The Lord Chancellor powerfully supported Lord Newton's instruction urging that there would be no use in having two Houses of Parliament if they were not to take an independent view of legislative matters. The House divided and the instruction was carried by 77 votes against 32.

The Parliamentary Committee's Report was received at Spring Gardens with dignified indignation by the London County Council, which decided to ask those members who were also members of Parliament to move to disagree with the Lords' instructions.

The deputation to the president of the Board of Trade from the Institution of Electrical Engineers on June 18th was received with courtesy by Mr. Gerald Balfour. Mr. James Swinburne, as leader of the deputation, made out a good case in favor of the urgency for improvement in the electrical legislation of the country. Mr. Balfour frankly admitted the need of a modification in the laws relating to electric lighting and power and stated that the Government had drafted two bills to remedy the situation, but there was little hope of either being proceeded with this year. He could not see his way to recommend the cabinet to appoint a Royal Commission to consider the subject of electrical legislation, but would be glad to receive from the Institution suggestions for modifications and improvements.

D. N. D.

**WORLD'S FAIR TRANSPORTATION DEPARTMENT.**

The transportation exhibits at the Louisiana Purchase Exposition will be contained in one of the largest of the structures devised up to the present time for the Fair. The general plan of this building is rectangular, and its distinguishing feature will be the massing of the three entrances so that they will form an arcade. The building covers an area of 525x1,300 ft., or over 15 acres. It will contain about four miles of standard gage railroad track and in addition to this space, two long bents of the building are left free of rails and afford an exhibiting space of 270,000 sq. ft. All the exhibits in this department will be on the ground floor, and in the main building, and the classification of this department covers all manner of transportation on land and sea and through the air. No charge will be made for exhibit space and applications for exhibits for machinery and mechanical appliances shown in operation must be filed by Oct. 1st, 1903.

**"NARRAGANSETT" TYPE OF CARS FOR COLORADO SPRINGS.**

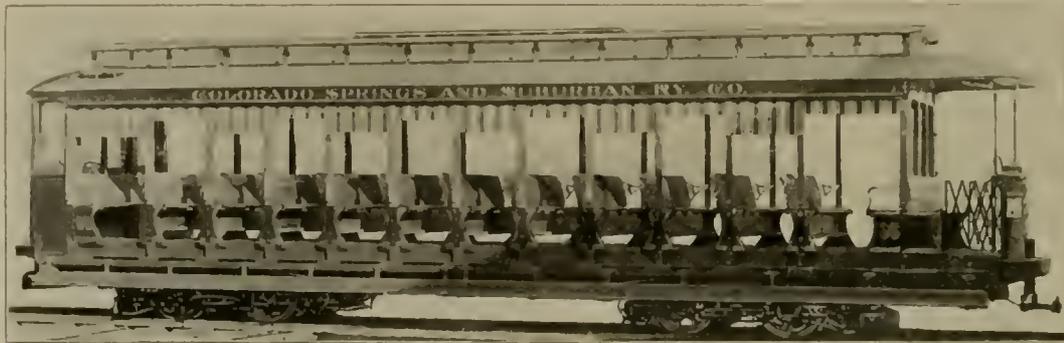

The J. G. Brill Company, of Philadelphia, have recently shipped to the Colorado Springs & Suburban Railway Co. fifteen 14-bench open cars of the Brill patented "Narragansett" type. This type of car is a successful adaptation of the narrow bodied open car to high speed trucks. It is simply a double step car of no greater width over all than the standard single step car and therefore may be used in city streets and will go into barns having limited space between the tracks. The car loads and unloads as rapidly as a single step car because of the greater ease with which it is accomplished. The accompanying illustrations show the simplicity of the arrangement and its neat appearance, and those who are familiar with structural details will be impressed with the great strength added to the framing by the Z iron sill. The brackets on which the seat-end panels rest, form sockets for the posts, which, together with the fact

The cars are fitted with the following Brill patented specialties: folding gates, round-corner seat-end panels, angle-iron bumpers and "Dedenda" gongs. The trucks are Brill 27-F with 33 in. wheels.

**STRIKES OF THE MONTH.**

**TORONTO.**

At a mass meeting of the employees of the Toronto Railway Co., held June 20th, the ultimatum of the company regarding the desired increase in wages was rejected by the men, and a ballot being taken, it was decided by a vote of 918 to 19 to strike. This decision was carried out, and for three days the tie-up was complete. On the first day the company made no attempt to move cars, but on Sunday, June 22d, four cars were started under police protection. These were completely wrecked by a mob of strikers and their sympathizers, and the men roughly handled. Rioting Sunday night as-

BRILL CAR FOR COLORADO SPRINGS & SUBURBAN RY.

that the panels enclose them, gives the posts unusual vertical strength and rigidity.

To obtain a double step within the proscribed limits, the builders have not detracted in any way from the useful features of the standard open car—the seats are just as long, the curtains can be drawn to the floor, and the space occupied by the intermediate step instead of encroaching on the floor area really utilizes space that is more often wasted. Guard rails, sliding behind the grab handles, are generally used in these cars for protection when the speed is high.

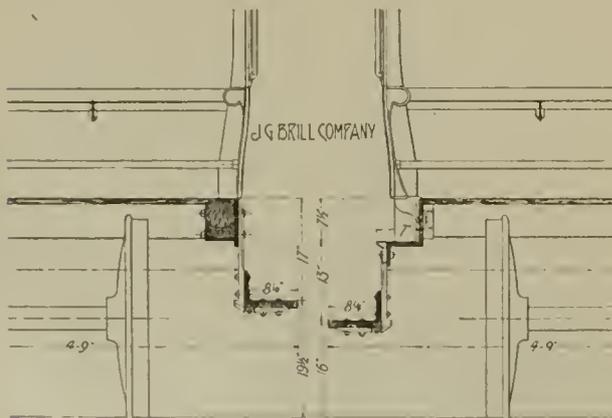

An excellent feature of the Colorado Springs cars is the motor-man's cab, which is a completely enclosed narrow platform at the

sumed such serious proportions as to necessitate the calling out of militia, and some 700 cavalry and 800 infantry were soon disposed at various points of vantage throughout the affected districts, which effectually put a stop to further destruction of property and violence.

After being out three days, the committee appointed by the Board of Trade and the city effected a settlement, and the men returned to work, but trouble is again threatened, the men claiming that the leaders in the strike are being discriminated against, and a renewal of the trouble is possible.

**PROVIDENCE.**

At Providence and Pawtucket, R. I., where a strike was inaugurated June 4th, there was much rioting and disorder, particularly in Pawtucket, as a result of the attitude of the mayor and police. On June 11th Governor Kimball called upon the adjutant-general for militia to enable the company to continue its service, and on the following day six companies of infantry and two of cavalry were assembled in that city. A riot proclamation was issued by the governor demanding that the mobs disperse and residents remain in their homes. These measures were, however, ineffective. Cars were stoned and the men hired for the occasion to operate them were subjected to murderous assault. The car service in Pawtucket, in Central Falls, Albion and Cumberland was temporarily abandoned until the next week, when the military guard was re-enforced and machine guns were so placed that they could sweep the places where the mobs were most likely to congregate. Several of the most important routes were again put in operation, the cars being escorted by a heavy guard, and though hostile demonstrations were of frequent occurrence no organized effort was made by the strikers to stop the cars. The mayor then made an effort to have the troops withdrawn, which was done on June 20th. The company subsequently maintained an irregular service, relying upon the local police for protection. Two accidents were the result of mob violence June 29th. On the Mineral Springs line a large bowlder was placed upon the track, the car was derailed and the crew subjected to a bombardment from the mob, escaping with cuts and bruises. The car, when it was eventually replaced on the track and towed back to the power house, looked as if it had been struck by lightning. On another line the motorman was struck over the heart by

SINGLE AND DOUBLE STEPS COMPARED.

front end affording protection in stormy weather and thereby increasing the efficiency of the operator. The cars can be operated from either end. The length from the rear crown-piece over the front vestibule is 41 ft. 5 3/8 in. The width over the posts is 7 ft. 9 1/2 in.; and over the steps when down 9 ft. 2 in.; and when raised, 8 ft. 3 in. The inside finish is of quartered oak, with ceilings of oak veneer decorated. The sash in the bulkheads and vestibule drop into pockets.

a stone which rendered him helpless. The car, with no one to guide it, continued at furious speed, jumped the track, and was partially wrecked. On July 1st an organized attack was made by the strikers in the streets of Pawtucket and Central Falls, with the result that a number of substitutes on the cars were injured and the service abandoned at 10 p. m. The police had much difficulty in clearing the streets and nearly a dozen arrests were made. By a decision of the District Court July 2d the right of operatives of cars during a strike to protect not only themselves but also passengers and the property of their employers by the use of firearms was recognized. Five motormen and conductors of the Pawtucket line, who had been under arrest on the charge of carrying concealed weapons, were thereupon discharged.

July 6th the strikers voted to withdraw their demands and return to work; the company announced its intention of re-employing only so many of the strikers as it had places for, and on July 7th about 150 men were reinstated, the others, some 200 or 300, being put on the waiting list.

#### RICHMOND, VA.

A general strike of all the street railway employes of Richmond, Va., was declared July 16th. A committee of employes held two conferences that day with President Sitterding, of the Consolidated Passenger Power Co., and at both demanded a nine-hour day and a uniform rate of 20 cents an hour for the men. The men were offered an increase of from 15 and 17 cents an hour to 16 and 18 cents, but the proposition was rejected. The following day the men returned to work, pending arbitration.

#### A NEW INTERURBAN IN TEXAS.

On June 18th the Northern Texas Traction Co. formally opened its new interurban between Fort Worth and Dallas, a technical description of which was published in the Street Railway Review for August, 1901, page 506. A special car left Fort Worth at 5 p. m. on the initial trip, carrying the officers of the company, municipal officers and prominent business men to Handley and Dallas. A barbecue was given at Handley to celebrate the completion of the interurban. A regular schedule between Fort Worth and Dallas could not be permanently established until a week later, owing to the fire on June 16th, which had destroyed the company's transformers at the Handley power house while they were being tested, but the damages were soon repaired and a regular service auspiciously inaugurated.

The cost of construction and equipment of this road approximates \$1,500,000. The company was incorporated in Texas with a capital stock of \$2,000,000, and an authorized bonded indebtedness of \$2,000,000, but only a portion of either has been issued, the surplus remaining for projected improvements and extensions of the system. The rolling stock at present in use comprises eight 45-ft. motor cars with smoking compartments; two motor cars with baggage compartment; one special car and four trailers. The motor cars are equipped with four 60-h. p. motors and air brakes, and have a speed of 50 miles per hour. The company has built at Handley, in addition to its power house, car house and office building, a large artificial lake, and will install park conveniences for the encouragement of traffic from both cities to Handley, which is 10 miles distant from Fort Worth.

The interurban passes through Handley, Arlington, Grand Prairie and Oak Cliff, its total length being 35 miles. The maximum grade of the roadbed is 2 per cent, and the track construction and bridge work are of the heaviest description.

The Northern Texas Traction Co. also operates 22 miles of city lines in Fort Worth. The officers of the company are: George T. Bishop, of Cleveland, O., president; John Sherwin, of Cleveland, first vice president; E. M. Haines, of Fort Worth, second vice president and general manager; George F. McKay, of Cleveland, secretary and treasurer, and C. A. Taylor, of Fort Worth, assistant secretary and treasurer.

The dispatching of cars and intercommunication is by means of a telephone system which was furnished by the Carl Electric Co., of Akron, O. The principal station is in the office of the dispatcher, who is provided with a desk set bridging telephone. A separate line is also run from the dispatcher's office to the power house, car house and superintendent's room, this line having the regular bridging 2,000 ohm wall telephones, and being provided with a

switch for connecting to the main line when desired. An extension bell is provided in the boiler room at the power house, three bridging instruments are connected for use in the offices at Fort Worth, and five telephones are placed at intervals along the line. All the cars have portable car telephones, which are furnished with jointed rods for connecting direct to the line wires.

#### MILWAUKEE COMPANY PROJECTS NEW PLANT.

The Milwaukee Electric Railway & Light Co. recently awarded a contract for a storage battery which will be installed in the company's present power house at a cost of \$250,000 pending the erection of the proposed new building. The storage battery is one of the largest ever installed in a lighting plant in this country and comprises several unique features. The batteries will be of the "Chloride" accumulator type, furnished by the Electric Storage Battery Co., of Philadelphia.

Contracts for the new power house which will be erected in a year or two to replace the present plant will not be awarded until experience shall determine whether it is more practicable to install steam engines or steam turbines. If the steam turbine is to replace the steam engine, a great saving of space in the plant will result. It is the company's intention to begin the building of the projected power house on the river at Biddle St. and to build in a southerly direction, tearing away all the present plant, even removing the recent additions to the power house.

#### WIGAN (ENG.) BOROUGH TRAMWAYS.

The first annual report of the Borough of Wigan Tramways has been issued by the borough engineer, Mr. H. Collins Bishop, for the year ending March 31, 1902. The three sections of tramways now open to traffic include the Martland Mill Bridge section with a length of 2,619 yd. Boar's Head section, 3,080 yd., and Scholes section, 1,713 yd. In addition to the length of track already opened for traffic there are now about 2,800 yd. of track which is practically completed and about to be opened. The total passengers carried for the year numbered 1,997,244; the total revenue from fares was 8,771 pounds, and the total car mileage was 195,970. The average car miles per car were 1,887, and the number of cars in service 18. The passengers carried per car were 105,958, which is equal to carrying the whole population of the borough 31 times over.

#### THE EVERETT-MOORE SYNDICATE.

The affairs of the Everett-Moore syndicate have now been so nearly cleared up that the syndicate is again in position to resume some of the enterprises that were under way when the embarrassment of last January occurred. The syndicate will reorganize and finance the Lake Shore Electric Ry. connecting Cleveland and Toledo, which is now in the hands of A. E. Laug, as receiver. The syndicate will also reorganize the Detroit & Toledo Shore Line Co., which was not completed or financed when the trouble was precipitated last winter. It is said that Cleveland capital will back the syndicate in these matters, which will be carried out as soon as the legal formalities can be complied with. Large blocks of securities belonging to the syndicate are now tied up to secure its floating debts, but all of these will be released when these companies are organized and financed. Enough capital has already been secured to underwrite the securities that both companies will issue.

#### A CHANCE TO SAVE TIME.

Since "time is money," a train that saves time must, of necessity, make money, and the new "Twentieth Century Limited," on the New York Central and Lake Shore railroads, therefore, becomes a great commercial economist. A run from New York to Chicago in twenty hours, a saving of four hours over the fastest time of any competing train, since June 15th, has become an every-day event, and has brought the two great cities two hundred miles nearer together. This is a superbly equipped train, consisting of a combined buffet, smoking, library and baggage car, two sleeping cars, one stateroom and observation car, and one dining car, made up with special reference to meeting the demands of busy men. From Four Track News for July.

## PERSONAL.

MR. FRED H. FITCH, general manager of the Denison & Sherman (Tex.) Ry., recently visited Chicago.

MR. W. P. COOPER, who for nearly nine years has been the Chicago representative of the Consolidated Car Heating Co., is now representing the railway department of Fairbanks, Morse & Co., Chicago.

MR. R. K. HOWARD, superintendent of the Knoxville (Tenn.) Traction Co., resigned July 1st and on July 19th sailed for England, where he will make his home.

HON. CHARLES M. FLOYD has been chosen a director of the Manchester (N. H.) Traction, Light & Power Co., succeeding Hon. Chas. T. Means, deceased.

MR. DAVID YOUNG, JR., has been elected president of the Orange Mountain Traction Co. of Orange, N. J. Mr. Young is the son of the president of the North Jersey Street Railway Co.

MR. WILLIAM G. WOODFOLK has been appointed superintendent of the Knoxville (Tenn.) Traction Co., succeeding Mr. R. K. Howard, resigned. Mr. Woodfolk took charge July 1st.

MR. GEORGE L. EDWARDS has been chosen a director of the St. Louis Transit Co., succeeding W. H. Thompson, resigned.

MR. JOSEPH P. ECCLES, of the firm of Eccles & Smith, of San Francisco, left for Seattle early in July for the purpose of establishing a branch of the railway and electric supply business of the firm in that city.

MR. JAMES ROWLAND BIBBINS has resigned as assistant electrical engineer of the Detroit United Railway Co. to accept a position in the Westinghouse Companies' Publishing Department, Pittsburg and New York.

MR. S. A. FRESHNEY has been appointed superintendent of the Muskegon Traction & Lighting Co., succeeding Mr. F. S. Richmond, who tendered his resignation some time since, to take effect when his successor should be chosen.

MR. J. P. LOVE, who for some years has been claim agent for the Calumet Electric Street Railway Co., Chicago, resigned on June 30th and went to Philadelphia to take charge of the claim department of the Philadelphia Casualty Co.

MR. H. A. DAVIS, superintendent of equipment of the New Orleans & Carrollton Railroad, Light & Power Co., has been appointed acting manager of the railroad department, on the withdrawal of Mr. A. H. Ford as manager.

MR. FRANK J. DUFFY, formerly superintendent of transportation of the Richmond (Va.) Traction Co., has been appointed to a similar position with the Savannah (Ga.) Electric Co., which operates all the street railways at Savannah.

MR. W. R. MASON on July 1st resigned his position with the Sprague Electric Co. and is now western manager for Coe, Smith & Co., selling agents for the Mechanical Boiler Cleaner Co. Mr. Mason's headquarters are at No. 413 Western Union Building.

MR. EDWARD M'DONNELL has been appointed assistant general manager of the International Railway Co., at Buffalo, N. Y. Mr. McDonnell has served for several years as superintendent for the Buffalo & Niagara Falls branch of the International system.

MR. S. L. TONE, formerly assistant to president J. D. Callery of the Pittsburg United Railways Co., has been appointed second vice-president of the company. Mr. Tone was chief engineer of the United and Southern Traction Companies prior to the recent consolidation.

MR. MARSDEN J. PERRY has been chosen president of the Rhode Island Co., which on June 24 assumed control of the Union Railroad, Pawtucket Street Railway and Rhode Island Suburban Railway companies. The new company leases these properties for 999 years.

MR. C. N. DUFFY, who has been auditor of the Chicago City Railway Co. since Sept. 1, 1899, was last month elected secretary of

the company succeeding Mr. Frank R. Greene, resigned. Mr. Duffy assumed the duties of secretary June 20th; he will continue to act as auditor.

MR. THOMAS L. HACKETT has been appointed soliciting freight and passenger agent of the Grand Rapids, Grand Haven & Muskegon Railway Co. The appointment was effective July 1st, and Mr. Hackett has made his headquarters at the company's offices in Grand Rapids, Mich.

MR. F. N. BUSHNELL, chief mechanical engineer of the Union Railroad and the Narragansett Electric Lighting Co. of Providence, R. I., succeeds Mr. George B. Francis as chief engineer of the Union Railroad, the Rhode Island Suburban Ry., the Interstate Consolidated Street Ry. and the Pawtucket Street Ry.

MR. JAMES MACK, of Sharon, Pa., resigned as superintendent of construction of the Youngstown (O.) & Sharon Railway & Light Co., to take effect July 5th. Mr. Mack has had many years' experience in the street railway business, and during his connection with the company has had entire charge of new construction for the street railway and lighting systems at Sharon.

MR. F. J. GREEN, manager of the Dayton, Springfield (O.) & Urbana Electric Ry., has been appointed manager of all the lines now controlled by the Appleyard syndicate, including the Columbus, London & Springfield; Columbus, Grove City & Southwestern; Central Market Street, Columbus; Dayton, Springfield & Urbana, Bellefontaine & Northern, Springfield & Western, and Dayton, Lebanon & Cincinnati.

MR. H. P. QUICK has severed his connection with the Boston Elevated Railway Co. and on July 15th removed to Kansas City where he will represent Ford, Bacon & Davis who are operating the Metropolitan Street Ry. and the Kansas City Electric Light Co. Mr. Quick will be the steam engineer in charge of design and construction of power plants and will have his headquarters at No. 1500 Grand Ave., Kansas City.

COL. ALLAN C. BAKEWELL, second vice-president and general manager of the Sprague Electric Co., was recently elected department commander at the New York State Encampment of the G. A. R., held at Saratoga Springs. There was a strong opposition ticket in the field, but Colonel Bakewell, in recognition of his services in both the state and national work of the organization, was elected by a handsome majority.

MR. M. E. DEMPSEY, secretary of the American Frog & Switch Co., Hamilton, O., called at the "Review" office when in Chicago recently. He reports that his company, which was organized about a year ago, has had a most satisfactory season with prospects for further increased business during the summer and fall. Mr. Dempsey has an extensive acquaintance in the railroad field, having been for 13 years with the Weir Frog Co., of Cincinnati.

MR. B. F. WYLY, JR., of Atlanta, Ga., has been appointed traffic manager of the Lackawanna & Wyoming Valley Rapid Transit Co. and removed from Atlanta to Scranton to assume his new duties June 20th. The Lackawanna Wyoming Valley system is under construction between Scranton, Carbondale, Pittston and Wilkesbarre, Pa., and when completed will include the old Scranton & Northeastern and the Central Valley lines. For the past 14 years Mr. Wyly has been connected with the Atlanta & West Point R. R., for the last five years being general passenger and ticket agent of that road.

MR. A. H. FORD, who has long been connected with the Newman interests at New Orleans, and for the past several years has been general manager of the New Orleans & Carrollton Railroad Co., has resigned this position to enter the office of Isidore Newman & Sons, bankers, of New Orleans. We understand that Mr. Ford will take the place of Mr. J. K. Newman, who will go to New York to manage a branch of the banking house. Mr. J. K. Newman has been president of the New Orleans & Carrollton company since the Newman interests reorganized the system. During the time of Mr. Ford's service with the railway company he has of course been intimately associated with the Messrs. Newman and the fact that they wish him to enter their business is very substantial evidence of the high esteem in which Mr. Ford's character and ability are held.

MR. FRANK R. GREENE, who has for the past 11 years filled the office of secretary of the Chicago City Railway Co. with marked ability and success, has resigned that position to become president and general manager of the Chicago Street Car Advertising Co. Mr. Greene was born at Newport, O., June 8, 1859. He served in the various capacities of bank clerk, bookkeeper and cashier in some of the leading establishments of Marietta, O., Indianapolis, St. Paul and Chicago, until elected secretary of the Chicago City Railway Co. in January, 1891. Mr. Greene is secretary of the Union League Club of Chicago.

MR. CLIFFORD J. ELLIS was on July 1st appointed sales agent for the Pennsylvania Steel Co. and the northwestern office of that company will henceforth be located in the Western Union Bldg., Chicago. Mr. Ellis has heretofore represented the Cambria Steel Co. as sales agent and will now serve both companies in that capacity. Mr. R. E. Belknap, who was formerly at Steelton, Pa., will be assistant sales agent for the Pennsylvania company. The Cambria company announces that there has been no changes in its representation as a result of this consolidation of offices and Mr. Allan F. McIntyre will continue as assistant sales agent for that company.

MR. D. S. SMITH, formerly superintendent of the Twin City Rapid Transit Co., of Minneapolis and St. Paul, has been appointed general superintendent of the Brooklyn Heights Railroad Co. of Brooklyn, N. Y., in which capacity he will have charge of both the elevated and surface lines, having entire control of the Brooklyn system with the exception of the power stations and track work. Mr. Smith who became connected with the Twin City company about eight years ago will be remembered for his excellent work in organizing the operating department of the St. Paul road which system has been brought to its present state of mechanical perfection through his efforts.

MR. W. S. DIMMOCK, general manager of the Richmond (Va.) Passenger & Power Co., resigned that position early in July to become connected with Stone & Webster, of Boston. Mr. Dimmock will have charge of that firm's properties at Tacoma, Wash., which is now his address. Mr. Dimmock has had an extensive experience in electric railway work, having been general manager of the Omaha & Council Bluffs Railway & Bridge Co., before going to Richmond. Before entering the electric railway field he had been engaged in steam railroading. Mr. Dimmock's position at Tacoma is a most desirable one, as the Stone & Webster company is extending the railway lines and greatly improving its properties.

MR. ROBERT I. TODD, second vice-president of the Cincinnati Traction Co., has tendered his resignation to accept a position with the United Gas Improvement Co., in Philadelphia, the work which he will have in charge being in connection with the traction interests of that company. Mr. Todd is a native of New Jersey, having been born near Lakewood, Nov. 29, 1869, and was graduated from Johns Hopkins University in 1893. His first connection with street railway work was as assistant superintendent of the Eckington & Soldiers' Home and Belt Railway companies, Washington, D. C. Later, when these lines and others were merged into the City & Suburban Railway Co., Mr. Todd was made general superintendent and electrical engineer. He resigned in the spring of 1899 to take charge of the experimental work of the Congressed Air Co. in New York City. Mr. Todd left this position in July, 1900, to become mechanical engineer of the Consolidated Traction

Co., of Pittsburg, which position he held until February, 1901, when he became general manager of the Cincinnati Traction Co., after that property was acquired by the Elkins-Widener-Dolan-Morgan syndicate. In January, 1902, he was made second vice-president of that company. Mr. Todd's work has given him experience with all the various methods of street car propulsion, horse, storage battery, air, underground electric, single and double trolley, and his wide experience in the traction field has peculiarly well fitted him for the work which he now assumes.

## OBITUARY.

MR. CHARLES T. CHILD, technical editor of the Electrical Review, of New York, died at Gleasondale, Mass., June 23d, of typhoid fever, after a protracted illness. Mr. Child was a native of Richmond, Va., and was 35 years of age. He assisted Frank J. Sprague in 1887 in building the first successful electric railway in the United States in Richmond. Mr. Child was widely known in this country and in Europe as a writer on scientific subjects, electricity in particular.

PROF. JOHN BUTLER JOHNSON, dean of the college of engineering of the University of Wisconsin, at Madison, Wis., met with a tragic death near Fennville, Mich., June 23d, by falling from a wagon which was conveying his household goods to his summer home at Pier Grove. Professor Johnson fell under the wheels, which passed over his head, completely crushing it. The deceased was a graduate from the University of Michigan of the class of 1878, receiving the degree of civil engineer. After graduating he became United States assistant engineer on the Lake Surveys and the Mississippi River Surveys, and filled this position until 1883 when he accepted the professorship of civil engineering at Washington University, St. Louis, Mo. Professor Johnson had been dean of the college of engineering at Madison since January, 1899, at which time the position was created. He was the author of many well known works on engineering subjects and a frequent contributor to the technical press. He was formerly president of the Engineers' Club, of St. Louis; and at the time of his death was fellow and past vice president of the American Association for the Advancement of Science; and a member of the Society for the Promotion of Engineering Education; the American Society of Civil Engineers and the American Society of Mechanical Engineers.

EDWARD H. JENKINS, president of the Southwestern Gas, Electric and Street Railway Association, and lately president of the San Antonio Traction Co. and the San Antonio Gas & Electric Co., died at San Antonio, June 25, 1902. His demise was caused by blood poisoning following a surgical operation performed about ten days previous. The announcement of his death came as a severe shock to his friends as well as the entire city where he was very widely known and universally beloved.

E. H. JENKINS.

He was born at Indianapolis, Ind., in 1853, and owing to business reverses which befell his father, he was compelled to earn his living when he was but twelve years of age. His first employment was in a stove factory where he remained for four years, and was next employed with the Indianapolis Gas Co. as time-keeper. Here he arose, through intermediate positions in which he learned every detail of the business, to the position of assistant superintendent. In 1897 he was elected superintendent of the Elkhart (Ind.) Gas Co., where he remained for four years; he was then called to Cedar Rapids, Ia., to design a new gas plant, and following this he became superintendent of the Columbus (Ga.) Gas Co., where he remained for 12 years. He was next connected with the Covington (Ky.) Gas Co. where he remained until 1898, when he entered the service of the Emerson-McMillan Co., one of the largest owners of gas companies in the United States. He was made superintendent of the three plants at Buffalo, N. Y., and in 1899 was trans-

ferred to San Antonio to assume charge of both the traction and electric interests which had been purchased by his company. He was given full charge of the reconstruction of this plant and in three years evolved out of almost chaos one of the best street railway systems in the South.

Mr. Jenkins was universally respected and admired in San Antonio and his relations with the working classes were at all times harmonious and sympathetic, while in club circles he was equally popular. He was appointed a member of the Texas World's Fair Commission to the Louisiana Purchase Exposition, was second vice-president of the Texas Associated Commercial Clubs, a director of the International Fair, associated with the Business Men's Club and San Antonio Club; he was a member of the Knights of Pythias and the Masons. In 1875 Mr. Jenkins married Anna E. Burton of Indianapolis, he is survived by his widow, a son and a daughter.

---

### LEGISLATION IN MASSACHUSETTS.

For the past two years there have been attempts in Massachusetts to secure legislation that would make the street railway companies pay a part of the expense of abolishing grade crossings where they have locations involved, but every time it has been put over until the time when a new grade crossing was to be negotiated. The loan bill came up at this session, the money authorized to be borrowed ten years ago having been exhausted.

The old question of bringing in the street railway companies was promptly brought into the discussion, but the trouble was that each party wanted the contribution of the street railways taken from its share. In the old apportionment the steam railroad company paid 65 per cent, the state 25 per cent, and the city or town the remaining 10 per cent. The governor recommended that the street railway's share be taken from the state allowance, and what he said had the most weight, as he had power to veto the bill. An important amendment was made, however.

The process of abolishing a grade crossing is for either the railroad or the city or town authorities to petition the court for the appointment of a special commission to do the work. An amendment was brought in which provided that in cases where abolishments had already been petitioned for, and where the special commission had been appointed, this new apportionment where 15 per cent was put on the street railway company should not apply. The argument in support of this was that the street railway companies in these cases had had no part in the proceedings and no voice in the appointment of the special commissions where in some cases they might have objected to the persons appointed by the court.

This amendment was adopted and the result is that as special commissions have been appointed in Worcester, New Bedford, Haverhill, Attleborough, Canton and several other minor places, the \$5,000,000 loan authorized will all be used up in carrying through these changes alone and there is no chance that the street railway companies will be called upon to pay an assessment for ten years to come.

In financial matters concerning street railway companies the legislature enacted a bill that will allow savings banks to invest in the bonds of street railway companies. The only restriction is that the investment shall be made only in such stocks as have paid dividends of at least 5 per cent for the past five years. By this the legislature has put itself on record as believing that street railway locations are as permanent as those of railroads.

The legislature has also defined for what purposes the railroad commissioners can approve an issue of bonds of street railway companies. There was some contention on this bill, but the railroad commissioners explained that there were grave doubts as to what were considered legitimate expenditures by street railway companies for which bond issues could be authorized. The purposes named in this bill are as follows: For the purpose of building a branch or extension, or of acquiring land for pleasure resorts, or of building power houses or car houses or park buildings, or of acquiring or equipping additional rolling stock, or of changing its motive power, or of abolishing grade crossings, or of paying betterment assessments for widening or otherwise altering streets, or of complying with any requirements lawfully imposed under delegated legislative authority, or of making permanent investments or improvements, or of acquiring any additional real or personal property necessary or

convenient for its corporate objects, or of refunding its funded debt, or for the payment of money borrowed for any of the foregoing purposes, or for other similarly necessary and lawful purposes.

One bill authorized an electric light and power company with a plant just over the line in New Hampshire to furnish electricity to street railway companies near the border but within the state.

The most liberal charter granted this year is the one granted to the New York & Berkshire Company, a prospective line among the steep hills of the western part of the state. No one is very sanguine that the line will ever be built, but it offers a field for investors who are willing to take some chances. The charter allows the hauling of freight cars with physical connections with connecting railroads, and the line is undoubtedly through a very picturesque region, the edges of which, where transportation facilities are ample, have been developed by the summer resort element from New York and other places.

The provisions of the present law regarding the transportation of roadmaking materials by street railway companies have been extended. Up to this time the companies could transport for cities or towns over their own lines, but allowed no transferring over connecting lines. This defect is now remedied.

From now on all locations granted street railway companies by local authorities must be approved by the railroad commissioners before the companies can commence construction. This was recommended by the governor and is brought about by the fight between two companies for locations in his own section of the state. Both companies were opposed by the summer people who look askance at trolley lines. Under the old law if ten real estate owners along a proposed line felt enough aggrieved they could make a formal protest and the same approval as now was necessary. In the governor's section this appeal was made in each case, so it is not clear just what advantage this new law is.

The railroad commissioners were given permission to employ experts to investigate the value of street railway property when the company is asking for the board's approval of the issue of bonds.

The bill authorizing street railway companies to sell electricity for lighting purposes to cities and towns where no lighting company is in operation was passed. It is restricted to lighting and the sale of the current. All the wires, poles, etc., beyond where the physical connection is made with the trolley must be put up and owned by the municipality. At the first of the session there was a dozen petitions from as many different companies asking for authority to do this. These were lines running through the more rural districts and in every case they wanted to sell current for power purposes also.

At the very end of the session a bill was passed requiring street railways to pay a portion of the cost of building or repairing bridges on which they have locations. It was endeavored to secure an amendment limiting the street railway share to 15 per cent, but this was defeated by a narrow margin.

Two accident insurance charters have been granted that are based on petitions of street railway men and are to insure street railway companies against claims for damages for personal injuries. They are patterned after the charter granted in 1895 and now owned by the Massachusetts Electric Companies, and under which those companies are insured.

In the closing days of the session the Boston subway bill was enacted. The House tacked on a labor section to provide for the employing of citizens of the United States only at a rate of \$2.00 or more per day. The Senate struck this out, claiming it would make the work cost \$1,200,000 more. The Boston Elevated road is to have a 25-year lease at a rental of 4½ per cent of the cost estimated at \$4,000,000. There is a referendum clause in the act so that nothing will be done until approved by the voters of Boston next December.

Rob.

---

It was reported on July 11th that all the property of the New York & Queens County Railway Co. of Long Island City, which virtually controls all the electric lines in the borough of Queens on Long Island, had been purchased by Mr. August Belmont, and that the Interurban Street Railway Co., which controls all the trolley lines on Manhattan Island, was associated with Mr. Belmont in the purchase. Among the franchises included in the acquisition is one for a tunnel under the East River, and it is stated that it is now the project to bring the Queens Borough cars into New York through a tunnel from Long Island City to 42d St., Manhattan.

## UNION INTERNATIONALE PERMANENTE DE TRAMWAYS.

The meeting of the Union Internationale Permanente de Tramways which was held in London, England, in conjunction with the International Tramways and Light Railways Exposition, was opened July 1st by an address by the Right Hon. Gerald Balfour. In the afternoon the members of the congress were entertained by a visit to the city, and in the evening they were tendered a reception at the Institution of Mechanical Engineers. On July 2d the business meeting of the union was opened with Sir Charles R. Wilson in the chair. The reports which were prepared by committees of the union were then considered. These reports were based on replies received from members of the Union in answer to series of questions addressed to them, and they therefore summarize the actual experience and conditions obtaining on the numerous tramways and light railway systems of continental Europe.

A report in regard to the carrying of baggage, express and mail matter and the tariffs therefor was read by M. G. Marsal. The question of carrying baggage, express and mail matter on city tramways is by no means developed in the different countries of Europe to the extent it deserves, judging from the responses which were received from the different cities where the tramway companies are members of the Union Internationale. Among the reasons for this are that agencies of the express companies are established in all the cities by the railroad companies and the business is admirably organized, due to the experience of many years. The business forms a monopoly against which the greater part of the city railway companies, even those having long franchises, have never been able to make much progress. The established agencies also have very complete accommodations for serving the public in the way of special vehicles, such as omnibuses, delivery wagons, etc., to serve hotels and to run from house to house, that the tramway companies fear that it would not pay to install equipments of this kind to compete with the established systems. Originally the tramway companies were limited to the carrying of passengers, but in many cities where they connected with railway stations the companies have confined themselves to carrying mail packages when accompanied by the passenger. The exclusive carrying of passengers is an easy and profitable business for tramway companies and was further justified in the case of animal traction where the cars were light and of limited dimensions, but it appears that passenger service only has continued to furnish the business notwithstanding the fact that electric traction makes it possible to establish a special compartment in the cars for carrying baggage and express matter. The carrying of mail matter and postal packages is also capable of great extension, but has not been very largely developed, judging from the reports which were received.

The report then quoted the answers received from several companies, and in conclusion stated that the answers were not sufficient and the examples not sufficiently numerous to permit of reporting in a definite manner on the profits and the benefits which should result from carrying baggage and express matter or even to recommend the organization of a department for the transporting of merchandise. The question depends largely upon local circumstances and the activity of the commercial movement in the cities.

A scheme of uniform accounting for electric railways was reported on by M. Leon Janssen. A uniform method of accounting is essential in the comparison of different roads and no comparison is possible if the accounts are not established on some basis. The scheme proposed in the report is briefly as follows:

The three principal items are the receipts, the expenses and the profits and losses. The expenses are divided under four general heads which are, interest on capital, sinking fund and depreciation, cost of administration, and operating expenses. The last item is subdivided into nine general heads, each of which is again subdivided into several minor items. The nine subdivisions of operating expenses are, management, transportation expenses, power house expense, rolling stock, maintenance of way, electrical conduits, building, general expense and miscellaneous. Under the head of management are included the salary and emoluments of the manager, the salary of the manager's staff; expenses of the manager's staff, cost of furniture; postage, telegrams, telephone, etc.; heating, lighting and cleaning, the repair of furniture; miscellaneous, and other expense. Under the head of salary and emoluments of the manager are given the fixed salary of the manager, the share

of profits of the manager, entertainment, hotel bills, traveling expenses and miscellaneous.

A similar subdivision to that given under the head of management is applicable to all other items into which the operating expenses have been divided, for example, under the head of transportation expenses would be included the salary and emoluments of the superintendent of transportation and his staff, and under the head of central station expenses would come the salary and emoluments of the chief engineer and his staff, the subdivisions being practically the same as given under the heading of management.

The subject of brakes was reported upon by M. Poetz. There were replies from 20 companies to the series of questions sent out in regard to brakes, and owing to the divergent and often conflicting nature of the replies there was some difficulty in drawing any general conclusions. The consensus of opinion, however, was that electric cars should always be equipped with at least two kinds of brakes, and almost invariably the ordinary hand brake forms one of these. The other two brakes mentioned principally are electric brakes and compressed air brakes. The report states that where the electric brakes are employed they should be supplemented by hand brakes, as it is impossible to bring a car absolutely to rest on an incline with the electric brake, and all the axles of the car should be fitted with electric brakes where quick stopping is a condition of safe operation. The electric brake is entirely suitable for use in ordinary service, does not fatigue the motorman like the hand brake, and is exceptionally powerful. Compressed air brakes are regarded as equal to electric brakes and have several advantages on trains of cars. Their cost of installation and maintenance is said to be more than that of electric brakes, and they take up more room under the car.

The second International Tramways & Light Railways exhibition which was held in conjunction with the Union Internationale opened auspiciously on July 30th. It is two years since a similar exhibition was held in London, and the growth of the electric tramway industry is shown from the fact that there are now more than twice as many exhibits as on the previous occasion. Among the prominent exhibitors may be mentioned Messrs. Dick, Kerr & Co., who showed among other things, a very handsome car built for the London County Council. The English Electric Manufacturing Co. and the Electric Railway & Tramway Carriage Works, at Preston, made a joint exhibit with Messrs. Dick, Kerr & Co. The British Westinghouse Electric & Manufacturing Co. made an extensive exhibit which included a completely equipped working trolley line with a car fitted with Newell magnetic brakes. The British Thompson-Houston Co. showed the latest type of apparatus for operating light railways, tube railways and tramways, and the Thompson-Houston master control system was exhibited in operation. Messrs. Askham Bros. & Wilson exhibited a large variety of track material, including rails, joints, crossings, bonds, etc. Messrs. Doulton & Co. showed samples of Doulton multiple conduits and Messrs. Robert W. Blackwell & Co. had a large exhibit in which the Peckham truck was a prominent feature. The General Electric Co. had an interesting exhibit and the Brush Electrical Engineering Co. also made an extensive exhibit of its tramway manufactures.

## ACCIDENTS.

A head end collision between a passenger and a freight car occurred on the Hudson Valley Ry. near Caldwell, N. Y., July 9th, in which 17 persons were injured, one death resulting.

A head-on collision between two loaded cars occurred June 28th on the Hudson Division of the Marlboro (Mass.) Street Ry., about two miles from Marlboro. The cars met on a curve at the foot of a steep grade. The motorman of one car was killed and 35 passengers were more or less injured.

By far the most serious accident of the month occurred the night of July 4th on the Mountain Lake Electric R. R., of Gloversville, N. Y., which is a road of some 4½ miles extending from Gloversville to a pleasure resort on the nearby mountain. There had been a very large crowd on the mountain during the day, and after 9 o'clock in the evening all the cars returning were heavily laden, being dispatched from the resort at intervals of five minutes. At 9:30 an open car left the resort and was followed in a few minutes by a closed car. The motorman of the latter lost control of it, the brake rigging giving way; he then reversed the current, which

threw out the circuit breaker in the power house. The rear car struck the open car ahead of it and the two continued down the grade together and on reaching a curve near the bottom both overturned, crushing a number of passengers, who were thrown out as the cars upset.

Twelve persons were killed, 20 injured so badly that they were taken to hospitals, and 11 others less seriously hurt. On the 6th the motorman of the runaway car died from his injuries, making a total of 13 deaths.

The Mountain Lake Electric Railway Co. began operating its line in August, 1901, and this is the first accident that has occurred.

A rear end collision between two cars on the Toledo, Fostoria & Findlay Electric Ry. occurred at 6 p. m. on July 4th, resulting in serious injuries to two or three passengers. The cars were returning from San Reeves' Park, near Fostoria, and were taking siding to let outgoing cars pass. The first car had stopped on the siding when the second crashed into it, the air brakes having failed to work.

An accident which resulted fatally to one person and in injuries to 20 others, occurred on the Chautauqua line four miles from Boulder, Colo., at 11 p. m. July 4th. The cars, which were heavily loaded, had started down a declivity when the chain brakes used on the trailers became ineffective. The train rushed down hill at a high rate of speed, overturning at a bend in the track, and both motor car and trailers were wrecked. Of the 200 passengers aboard all but 21 escaped uninjured.

Two persons were fatally injured and several others seriously injured in a head-on collision on the Mahoning Valley Ry. near Edenburg, O., at 4:30 p. m., July 4th. The New Castle special leaving Youngstown at 4 o'clock crashed into one of the regular cars going at an equal rate of speed, with the result that both cars were wrecked and 11 out of 200 passengers received injuries, two of them dying after being removed to the hospital.

A storm at Birmingham, Ala., July 4th, damaged the property of the Birmingham Railway, Light & Power Co. to the amount of \$20,000. The principal damage was to the wires and cables, over 40,000 ft. of wire being a complete wreck.

A heavy windstorm which swept Central Indiana June 25th caused the Union Traction Co. of Indiana to suspend operations between Anderson and Indianapolis for several hours. In several places wires and poles were blown down, and trees blown across the track.

Storm and flood at Wheeling, W. Va., July 9th, occasioned much inconvenience to the street railway companies operating in Wheeling and vicinity. A car on the Moundsville line of the Wheeling Traction Co. was struck by lightning and caught fire, but the passengers, though badly frightened, escaped without injury.

A head-on collision between an express and a passenger car on the lines of the Hudson Valley Ry., near Caldwell, N. Y., on the afternoon of July 9th, resulted in injuries to 16 passengers, one of whom died on being removed from the wreck. The cars met between two switches at a point where both were going down grade.

On the morning of July 16th one of the large double truck cars used on the Wentworth Ave. line of the Chicago City Ry. crashed into a smaller 31st St. car at the junction of these two streets. Both the cars were crowded and a number of persons injured, though none fatally. Owing to the recent rain the tracks were slippery and the driver of the Wentworth Ave. car did not see the 31st St. car until he was nearly upon it. The motormen of the cars applied the brakes, but were too late to prevent a collision. The larger car remained on the tracks, while the smaller one was thrown over upon its side on the sidewalk.

The Fond du Lac (Wis.) Street Railway & Light Co. has received a 500-kw. generator which will furnish power for the operation of cars on the Fond du Lac-Oskosh interurban line.

The United Railways & Electric Co., of Baltimore, has completed arrangements to insure the lives of the 3,000 motormen and conductors employed on its lines. The family of a man thus insured will be paid \$1,000 if he be fatally injured while in the service of the company. The insurance is virtually an agreement between employer and employe that in such a case the sum paid shall be accepted as settlement of any claim that might be brought against the company. The United Railways & Electric Co. pays the entire cost of insurance, making no reduction in the wages of the men.

## FINANCIAL.

### PHILADELPHIA CO., PITTSBURG.

The Philadelphia Company and affiliated corporations have issued the following report for the month ending May 31st:

	1902.	1901.
Gross earnings from operations.....	\$1,123,411 60	\$987,984 08
Operating expenses and taxes.....	613,730 99	531,130 72
Net earnings from operations.....	509,680 61	456,853 36
Other income.....	78,025 61	17,460 06
Total earnings and other income.....	588,606 22	474,322 42
Deductions from income.....	70,941 33	34,647 82
Total income.....	511,664 89	439,674 60
Fixed charges.....	323,163 64	264,007 51
Surplus .....	188,501 25	175,667 09
Less proportion of same to credit of owners of capital stock of affiliated corporations other than the Philadelphia Company .....	154 26	56,306 90
Balance representing Philadelphia Company's interest in the total net income...	188,346 99	119,360 19

### BROOKLYN RAPID TRANSIT CO.

The Brooklyn Rapid Transit system, including all companies, has issued the following comparative statement for the month of May, 1902:

	1902.	1901.	Increase.
Gross receipts.....	\$1,156,344 84	\$1,075,576 47	\$80,768 37
Expenses, including taxes...	730,152 44	715,161 32	14,991 12
Net receipts.....	426,192 40	360,415 15	65,777 25

The comparative statement for the 11 months ending May 31st shows:

Gross receipts.....	\$11,624,417 09	\$10,920,174 38	\$704,242 71
Expenses, including taxes...	8,220,062 33	7,237,894 12	982,168 21
Net receipts.....	3,404,354 76	3,682,280 26	*277,925 50

\*Decrease.

### MONTREAL STREET RAILWAY CO.

The Montreal Street Railway Co. has issued the following comparative statement of earnings and expenses for the month of May, 1902:

	1902.	1901.	Increase.
Passenger earnings.....	\$173,901 58	\$160,611 82	\$13,289 76
Miscellaneous earnings.....	4,506 57	671 03	3,834 94
Total earnings.....	178,408 15	161,283 45	17,124 70
Operating expenses.....	86,780 45	90,765 89	*3,985 44
Net earnings.....	91,627 70	70,517 56	21,110 14
Fixed charges.....	18,672 42	11,632 74	7,039 68
Surplus .....	72,955 28	58,884 82	14,070 46
Operating ratio.....	49.90	56.51	

\*Decrease.

### CHARLESTON CONSOLIDATED CO.

The Charleston (S. C.) Consolidated Railway, Gas & Electric Co. has issued a comparative of six months' operations ending May 31st:

	1902.	1901.
Gross receipts.....	\$399,572 38	\$245,745 02
Operating expenses.....	208,324 54	159,422 70
Gross income.....	191,247 84	86,320 32
Fixed charges.....	75,825 61	76,713 82
Net income.....	115,422 23	9,606 50
Deductions sinking fund and new installations .....	5,705 21	4,976 98
Net balances, profit.....	109,717 02	4,629 52
Operating ratio.....	52.1	64.9

For the six months ending May 31st the company carried 4,479,555 passengers as against 2,146,401 for the corresponding period of the preceding year, and made 954,104 car miles as against 665,499 for the six months ending May 31, 1901.

METROPOLITAN STREET RY., NEW YORK.

Kuhn, Loeb & Co., of New York, recently received subscriptions at 97½ for \$11,000,000 of Metropolitan Street Railway Co.'s 4 per cent refunding 100-year gold mortgage bonds, which is a part of the recently authorized issue of \$65,000,000. The balance of \$54,000,000 is reserved to retire outstanding bonds of other issues of the Metropolitan company and on its subsidiary companies. The issue which is limited to \$65,000,000 is secured by a refunding mortgage which is the only obligation of the Metropolitan company covering all its lines and leases and is therefore the only lien embracing the entire system as it is now constituted. The outstanding capital stock of the company is \$52,000,000, and it has paid regular dividends of 7 per cent on its outstanding share capital since January, 1899. The gross earnings of this company show a steady increase during the last four years, and dividends at the same rate have been guaranteed by the Interurban Street Railway Co. to which the Metropolitan system was recently leased.

CHICAGO UNION TRACTION CO.

A synopsis of the report of the Chicago Union Traction Co.'s operations for the fiscal year ending June 30th shows an increase in gross receipts but less satisfactory net results owing to three reasons, i. e., the company has paid out about \$400,000 in taxes this year and met back taxes for the previous year; operating expenses have been increased, and the wage scale has been readjusted in such a manner as to involve an additional annual outlay of about \$125,000. Last year the company's surplus amounted to \$8,575 and one quarterly dividend of \$150,000 was paid on preferred stock. During the current fiscal year no dividends have been paid. The following is a synopsis of the company's report for the fiscal year:

	1902.	1901.
Passengers .....	\$7,801,098	\$7,269,816
Mail, etc.....	16,158	15,101
Miscellaneous .....	4,516	4,222
Total operating income.....	7,821,772	7,289,139
Operation based on an operating ratio of .54 for both years.....	4,223,700	3,942,194
Net .....	\$3,598,072	\$3,346,945
Other income.....	869,671	869,671
Total .....	\$4,467,743	\$4,216,616
*Charges and taxes.....	4,415,080	4,268,040
Balance .....	52,663	158,576
Dividend .....	(114)	150,000
Surplus .....	61,239	8,576

\*Assuming taxes for 1902 at \$750,000 instead of \$320,296, as in 1901.

NORTHWESTERN ELEVATED R. R.

The Northwestern Elevated Railroad Co., Chicago, reports gross passenger receipts for the six months ending June 30th at \$575,414 as against \$503,315 for the corresponding period last year. The total gross receipts are given at \$595,000, and it is shown that the increase of passengers carried for June, 1902, over June, 1901, is 13.4 per cent. Operation for the first six months of the present year are given in the following table:

Gross earnings .....	\$595,000
Operating expenses, including loop rent and taxes.....	320,000
Net earnings, Northwestern proper.....	275,000
Net earnings of loop (six months).....	262,500
Loop expenses.....	132,000
Total income.....	407,500
Northwestern "L" bond interest.....	280,000
Balance for preferred stock, 5.1 per cent.....	127,500

CHICAGO & MILWAUKEE ELECTRIC RY.

A gain of \$9,860, or an increase of 30 per cent, is shown in the report of the Chicago & Milwaukee Electric Railway Co. for the six months ending June 30th, over operations for the corresponding

period last year. The operations for the six months ending June 30, 1902, were as follows:

Month—	Gross.	Op. exp.	Net.
January .....	\$10,953	\$5,873	\$5,080
February .....	9,522	5,046	3,875
March .....	11,215	6,185	5,030
April .....	13,057	5,898	7,158
May .....	16,440	7,352	9,087
June .....	17,750	7,065	10,685
Totals .....	\$78,939	\$38,021	\$40,918

Compared with the previous year the following results are given:

	1902.	1901.	Increase.
Gross earnings.....	\$78,939	\$65,460	\$13,479
Operating expenses.....	38,021	34,402	3,619
Net earnings.....	\$40,918	\$31,058	\$9,860

PENNSYLVANIA TO ENTER NEW YORK CITY.

The franchise which the Rapid Transit Commission decided on June 16th should be granted to the Pennsylvania R. R. for a double track entrance via tunnel into New York City entails an approximate increase in the railroad's annual fixed charges of \$1,961,535. The franchise compensation is estimated in the following table:

To city for tunnel and street rights.....	\$75,535
To city for taxes on real estate (estimated).....	486,000
Total to the city.....	\$561,535
Plus interest on \$40,000,000 investment at 3½ per cent.....	1,400,000
Approximate increase in company's fixed charges.....	\$1,961,535

The annual payments for the franchise are summarized as follows:

	First ten years.	Next fifteen years.
For river rights.....	\$200,000	\$200,000
For tunnel rights in Manhattan borough, being 44,341 feet (partly estimated) of single track.....	22,170	44,341
For tunnel rights in Queens Borough, being 8,100 feet (partly estimated) of single track.....	2,025	4,050
For street rights in Thirty-first and Thirty-third sts., north and south of terminal.....	14,000	28,000
For secondary station at Thirty-third st. and Fourth av.....	1,140	2,280
For parts of Thirty-second st.....	36,000	36,000
Totals each year.....	\$75,535	\$114,871

It is stated that if the route under Thirty-first St. be availed of, these amounts will be increased by \$16,652.50 for the first 10 years, and by \$33,305 for the next 15 years.

The Northern Ohio Traction Co. reports for the month of May receipts, \$60,746; operating expenses, \$33,910; net earnings, \$26,836; surplus, \$10,169. An increase in gross earnings of \$12,242 over the month of May, 1901, is shown.

The sale of the Richmond (Va.) Traction Co., the Virginia Electrical Railway & Development Co. and the West Hampton Railway & Power Co. to the Merchants' Trust Co., a New York syndicate, was consummated at Richmond June 23d. The price realized for these properties, including bonds and obligations assumed by the purchasers, is about \$4,000,000.

The bondholders of the Lake Street Elevated Railroad Co., Chicago, have exchanged more than 25 per cent of outstanding debenture bonds for first mortgage issues at the Northern Trust Co.

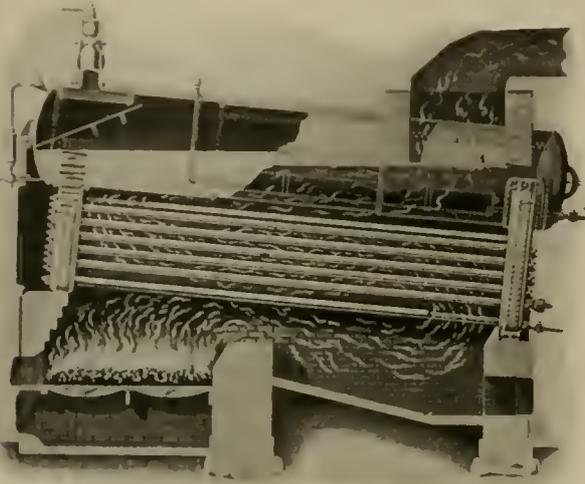

FIRE IN CHICAGO.

Fire destroyed the storage barn of the Chicago Consolidated Traction Co., at Lake St. and Ridgeland Ave., on the evening of July 16th. The loss included 100 box cars, 1 sweeper and 3 snow plows, and the coal handling machinery that was stored in the barn, approximating a total of \$125,000. The cause of the fire is not known. The building, valued at \$25,000, was entirely destroyed.

### FRANKLIN WATER TUBE BOILER.

The accompanying illustration shows in longitudinal section and elevation the water tube boiler built by the Franklin Boiler Works Co., of Troy, N. Y., and known as the "Franklin." The boiler is built entirely of wrought steel and consists of one or more drums, having openings in the bottom near each head at which are connected the water legs, the water-legs being connected with each other by tubes parallel to and under the drums. The water-legs are made of plates, flanged to fit the drums and fastened together by butt strap riveted joints, this construction giving a maximum interior cross section; the water-legs are strengthened by hollow stay bolts.

When set, the boiler is slightly inclined, the water filling the tubes, water-legs and about half the drums. The circulation is from back to front through the tubes, thence up through the front water-leg, through the drum from front to back, and down the back leg. To insure proper direction for the furnace gases, fire brick tiles are placed on the bottom row of tubes, extending from the front of the boiler to within a few feet of the back water-leg, and on the top

FRANKLIN WATER TUBE BOILER.

row of tubes from the back of the boiler to within a few feet of the front leg; this arrangement causes the gases to pass three times under the boiler before reaching the uptake. Rows of tiles rest on the walls of the setting and on bars riveted to the drums, and extend from the front of the boiler to the wall of the up-take chamber.

The outer walls of the water-legs are provided with hand holes directly opposite each tube, for the purpose of cleaning and inspection. No cleaning is done from the sides, so that if desired any number of boilers can be set side by side.

The steam outlet is placed at the front end of the drum where it is farthest from the water, and just below it are placed a separating device consisting of a perforated dry pan and deflection plate. The feed water discharges into a mud drum of thin steel placed below the water line in the drum, this arrangement being designed to collect impurities which are precipitated upon entering the boiler, and also to provide for the heating of the feed water before it has a chance to come in contact with the shell or tubes.

The front end of the boiler is supported on cross beams resting on and bolted to steel columns which extend to the foundation. A lug is riveted to the front head and bears on a roller set in a roller chair placed on the cross beam.

The rear end is supported on the rear foundation wall which is carried up for the purpose. On this wall are set plates and rollers on which rests the back water-leg. This method of supporting the boiler, independent of the setting, provides for any change in the inclination of the boiler and for expansion and contraction.

The upright columns and cross beams form the frame work of the front. Small cross channels are bolted to the upright columns and support the upper half of the front. The lower half consists of wrought steel plate panels to which are bolted the frames for the fire and ash doors.

This method of construction provides for the removal of all or any part of the lower half of the front without disturbing the supports or the upper half, and also provides for the installation of stokers without other change.

The boilers are built in a number of standard sizes, so proportioned that the grate surface, heating surface, steam space, water capacity, circulating openings and draft openings per horse power do not vary more than  $3\frac{1}{2}$  per cent.

### NEW COMPANY BUYS OREGON TROLLEY LINES.

The Oregon Water Power & Railway Co., incorporated last year as the Oregon General Electric Co., and which about a month ago filed amended articles changing its name, has acquired all the rights and holdings of the Portland City & Oregon Co., which has been formally dissolved by action of its board of directors. The same men own the new corporation that owned the old one, however, James H. and Fred S. Morris, the former being president and the latter treasurer and manager of the Morris & Whitehead Banking Association. W. H. Hurlburt is president, J. Frank Watson vice-president, A. B. Croasman treasurer, and W. T. Muir secretary.

The new company is capitalized at \$2,000,000, and its articles of incorporation confer power to issue bonds to the sum of \$3,000,000. All the work started by the Oregon General Electric Co., including the trolley railroad, inures to the new company. Plans for the construction of an electric power station on the Clackamas River and the building of a trolley road to that property, which has formerly been prepared, will now be carried out by the new company, and Mr. F. S. Morris states that the work will be prosecuted vigorously to completion. He says the company contemplates electric developments in the vicinity of Portland that will call for the expenditure of about \$5,000,000.

A number of electric roads will be built to develop this territory and work will at once commence on the extension into Clackamas County. Two ship loads of steel rails are now on the way from Europe. The road to the Upper Clackamas will not have a grade exceeding 1.5 per cent, except in one place, where there will be a short rise of 2 per cent, and the sharpest curve will not exceed 3 deg.

The Seattle Electric Co. will erect a transformer house in Fremont, Wash., at a cost of \$5,000, to supply power to the Green Lake Electric Ry.

Mr. J. T. Vasse, right-of-way purchasing agent for the Central Texas Traction Co., is procuring deeds for a right of way between Waxahachie and Ennis, Tex., for an interurban line.

The survey for an electric railroad running between Oxnard and Hueneme, Cal., has been completed and grade stakes placed. The company promoting this road has consolidated with the Bakersfield road and work has already been commenced.

Mr. H. H. Mellman, chief promoter of an electric railroad from Dayton to Pendleton, Ore., has obtained most of the necessary franchises from the towns and counties along its route. Every effort is being made to secure the remaining franchises, after which the work will be started at once.

### SPECIAL TRAIN FOR THE DETROIT CONVENTION.

For years the Wabash Railroad has made a particular point of running special trains to the convention city on the occasion of the annual meeting of the American Street Railway Association, an attention which has always been greatly appreciated by the street railway men and manufacturers attending these meetings. The special train insures that those coming from considerable distances will have a pleasant trip in congenial company, and in effect extends the convention time for all who are passengers. This year, as heretofore, the Wabash will have "Street Railway Convention Specials" to Detroit.

## NEW PUBLICATIONS.

CASSIER'S MAGAZINE for July is a special mining number of more than three times the usual size and almost constitutes a text-book on mining and metallurgy. It contains 15 principal articles on various mining subjects and nearly 300 illustrations collected from all parts of the world. This number deserves the careful perusal of all interested in mining and metallurgical subjects.

THE GARDNER, (MASS.) WESTMINSTER & FITCHBURG STREET RAILWAY CO. has issued the second edition of a pamphlet and guide directing the readers' attention to the many attractive features of the region traversed by the company's lines. Wachusett Mountain, the lake and park, and the various resorts in the vicinity are shown in abundant half-tone illustrations. Descriptions of the most desirable routes, time tables and miscellaneous information will make this booklet an important acquisition to all who project a summer outing in picturesque New England.

PLATES OF CONSTRUCTION FOR THE DESIGN OF DYNAMOS, (4th edition) edited by Prof. E. Arnold, published by Ferdinand Enke, Stuttgart, Germany, 2 parts. Price of each part, including portfolio, 20 Marks 40 Pfennigs. The first part of this work contains designs for 41 continuous current machines of from  $3\frac{1}{2}$  to 1,000-kw. output. The remaining sheets are devoted to drawings of the important details. The second part contains designs of 29 generators of from 20 to 1,500-kw. output, 9 rotary converters, 13 asynchronous motors and 8 transformers, in addition to 9 sheets of details. The designs of these machines have been selected from a large number which are constructed by the most prominent firms of European manufacturers and the publication, therefore, illustrates the standard forms of European electrical machines of the present day. The drawings are all furnished with the principal dimensions and are to scale while the winding data and other calculations are given in separate tables for easy reference.

THE CINCINNATI, HAMILTON & DAYTON RY. has issued a crisp and clever novelette called "On the Way to Michigan," which will be conceded to be a singularly catchy advertisement. All who see the striking little book gay with pictures in black and red will wish to read it, and will find the story inimitably droll and entertaining. It is all about one white and brindle Cupid, a canine match-maker, and the victims of his hymeneal plots. Cupid careers through the story from Cincinnati to Mackinac and Les Cheneaux with a romantic young bachelor in pursuit. There is a summer girl, of course, at the journey's end, "a regular Diana in a swagger polo cart," and the complications in which Diana and the bachelor become involved through the Machiavelian arts of Cupid afford the fun. Incidentally, the luxury of traveling via the "C., H. & D." is suggested in such a manner that the reader is inclined to board the next train over that pleasant route and seek his summer's recreation among the pines of Michigan. Put-in-Bay, Mt. Clemens, Cheboygan, Alpena and Point Aux Barques are among the desirable resorts accessible by the C., H. & D. lines, and thence, in some cases, via steamer, and a description of such tours forms an appendix to the little book.

## ADVERTISING LITERATURE.

THE WILLARD STORAGE BATTERY CO., of Cleveland, O., has issued its 1902 catalog describing and illustrating its various products in the line of storage batteries. The different types of batteries, showing size, number of plates and capacity, charge and discharge rates, and price are conveniently tabulated, and in addition to this the catalog contains a set of instructions for setting up, putting into operation and maintaining these batteries.

THE ATLAS RAILWAY SUPPLY CO., Chicago, Ill., is distributing a new catalog describing and illustrating its products in the line of rail joints, rolled steel joints, rail braces and rail sections of all descriptions. The materials used in these fittings is a high grade of cast steel and malleable iron, and the castings are warranted as to fit and finish, and are guaranteed against breakage. The catalog also calls attention to the "Atlas" liquid primer and surfacer, which are adapted to application to bare wood without any

previous preparation. Among other claims for these materials it may be mentioned that their use reduces the time required in painting cars from 10 to 15 days over the old methods, and it also lessens the cost of painting the car by \$15 or \$20. Any ordinary old paint can be covered without burning off the old paint.

THE AMERICAN STEEL & WIRE CO. has published a pamphlet under the title of "Electrical Tables" which contains a number of useful tables of dimensions and weights of pure copper wire with comparative sizes of different gages in decimals of an inch, tables of resistances, etc., all of which are very useful for reference purposes. The pamphlet includes a list of products manufactured by this company which are sufficiently numerous to cover 25 pages of type.

"SOFT WATER" is the title of the railroad edition of the new catalog issued by the Kennicott Water Softener Co., of Chicago. The Kennicott process is well adapted to railroad service for the reason that it is automatic and continuous, and the softened water does not have to be repumped at the storage tank. The catalog shows several illustrations of railroad water softening plants which have been installed by this company, and also shows detailed drawings of its apparatus.

INSTALLATIONS OF THE GREGORY ELECTRIC CO. is the title of a large, handsomely printed catalog issued by the Gregory Electric Co., of Chicago. While the catalog contains no descriptive matter there is a very complete story in the large number of installations catalogued, the names of which alone cover 70 pages, and which are distributed throughout almost every part of the United States. Interspersed through this large list of the company's installations are views of its factory, store rooms, repair department, supply department, etc., which describe the extent of the company's works.

THE RAILWAY APPLIANCE CO., of Chicago, dealer in railway specialties, has published a new catalog devoted to the various products handled by the company. These include the Gilman-Brown emergency knuckle, the Jennings car and engine replacer, the auxiliary coupling for use on curves too short for operation of the M. C. B. couplers, "Economic" metallic packing, the Ajax cotton belting diaphragm for vestibule cars and the "R. A." all metal bumping post, besides car movers, special wearing knuckles, etc. These devices are all shown in half tone illustrations, and are very fully described. The company will be pleased to mail its catalog No. 3 upon request.

THE UNITED TELPHERAGE CO., of New York City, has issued its circulars Nos. 22, 23 and 24, describing several kinds of telpher lines which it has installed. One of these methods is expressly adapted to the handling of trunks and baggage at railway stations, and the illustrations show an electrically propelled telpher upon which the baggage can be directly unloaded from the car and by means of which it can be delivered to any desired point without further manual labor. Another form of telpher described is an aerial cross-country line for carrying buckets suitable for handling various materials across country roads, over rivers and other obstructions. Another arrangement is shown for handling stock in paper mills, and the object of these circulars is to show the application of telpherage to various industries.

THE ELECTRIC STORAGE BATTERY CO. has just issued "A Book of Curves Illustrating the Operation of 'Chloride' Accumulators in Railway and Lighting Service," which is of interest to managers and power plant men. There are over 40 plates which graphically illustrate the actual operation of batteries of "Chloride" accumulators in their typical applications to electric railways, central lighting and power stations, isolated lighting plants, etc. The company states that it believes the data will be of assistance in the solution of problems concerning the economical generation and distribution of electric power; the curves shown were selected as being representative examples of the operation of "Chloride" accumulators in railway power stations, rotary sub-stations and line sub-stations, for regulating and peak work; in central lighting stations for peak work, emergency use and supplying the demand during the hours of light load; in isolated lighting and power plants for

assisting the generators at the hours of heavy load, carrying the entire load during the night, regulating the fluctuations of elevator or other motor service, etc.

**PROTECTED RAIL BONDS** is the title of the new catalog just issued by the Protected Railbond Co., for which the Mayer & England Co., Philadelphia, is agent. The book comprises 130 pages, the greater number of which are devoted to illustrating and describing the various types of bonds, their applications, and the tools for putting them in place. Under the heading "A Few Points About Proper Rail Bonding" has been included an interesting treatise on bonds and bond testing, illustrating the present practice in installing and testing. There are given data which will be found useful to street railway managers and engineers, arranged in a convenient form for reference. An interesting feature of the book is a directory of the companies using "Protected" bonds, arranged by states of the United States, and foreign countries. This list includes 42 states and countries. The catalog is copyrighted by A. H. England.

"**SMITH VAILE PUMPING MACHINERY**" is the title of Catalog 42 which is issued by the Stillwell-Bierce & Smith-Vaile Co., of Dayton, O. The catalog contains 136 pages of descriptive matter and illustrations showing the large variety of steam pumps made by this company. No expense has been spared in equipping the hydraulic plants of this company with the most approved machinery, and its products in the line of pumping machinery incorporate every improvement that experience has indicated to be valuable and desirable. Recognizing the demand for economy of steam consumption, the company recommends its compound condensing engines to be operated condensing if possible, as well as its triple expansion engines where sufficiently high initial steam pressure can be had. The company makes a complete line of air compressors, condensing apparatus including jet and surface condensers, vacuum pumps, pumping machinery for municipal water supplies, as well as small boiler feed pumps, etc.

**THE GENERAL ELECTRIC CO.** has recently issued the following advertising literature: Bulletin No. 4285, on Automatic Circuit Breakers, Type M, for 500-volt direct current work. Bulletin No. 4288, Slow and Moderate Speed Belt Driven Generators. Bulletin No. 4289, Adjustable Shunt Field Coil for Thompson Recording Wattmeters. Catalog No. 9103, on Transformers for High Potentials (second edition). Catalog and price list No. 7555, on Parts of Carbon Feed Enclosed Arc Lamps, Form 2, With 220-Volt Direct Current Multiple Circuits. Catalog and price list No. 7556, superseding No. 7516, on Parts of Form 2 Carbon Feed Enclosed Arc Lamps for Alternating Current Multiple Circuits. Catalog and price list No. 7557, on Repair Parts of G. E. 54-A Railway Motor. Catalog and price list No. 7558, on Repair Parts of G. E. 67-A Railroad Motors. Flyer No. 2099, on Blue Printing with Enclosed Arc Lamps. Flyer No. 2101, on Fuse Wire. Flyer No. 2102, on G. E. Porcelain Knobs and Cleats. Flyer No. 2103, Parts for Electric Brakes, and Price List No. 5099, on Fan Motors.

**THE CONSOLIDATED CAR FENDER CO.** is mailing its friends and customers its new No. 5 catalog describing the company's various styles of fenders for wheels, cars, etc. The original Model A car fender of this company was first placed in service on electric cars in 1893, and during the eight years in which the company has been supplying fenders it has kept in constant touch with street railway managers whose experience and suggestions have been adopted from time to time. Different types of fenders, made by this company, are adapted to high and to low cars, to suburban and interurban cars, and others are adjustable to any type of car on the market. The company is also making a wheel guard to be used in connection with the front fenders. The wheel guard is designed on practically the same lines as the fenders, but is reduced in size and is not supplied with a cushion. This is attached to the truck of the car directly in front of the wheels, and it can be dropped at the same time and by the same action on the part of the motorman by which the front fender is dropped. This company also manufactures the Campbell snow broom and the Millen car step lifter. The snow broom is made in half sections of any length and can be applied or removed from the shaft of a car in a few minutes. The Millen car step lifter is attached to the under side

of a car and has connections to both platforms, so that either the motorman or conductor may turn up and fasten the running boards of open cars without leaving the platform. The catalog is fully illustrated and contains a complete price list.

### CHANGES AT PROVIDENCE.

June 24th the Rhode Island Co. assumed control of the United Traction & Electric Co., of Providence, which includes the Union Railroad Co., the Pawtucket Street Railway Co., and the Rhode Island Suburban Railroad Co. The United Traction Co. & Electric Co. owned all the stock of its subsidiary companies, and they have been leased to the Rhode Island Co. for a term of 999 years. There is practically no change in the personnel of the board of directors or the officers, so there will be but little change in the conduct of the system. Mr. Marsden J. Perry, who was vice-president of the United Traction Co., has been elected president of the Rhode Island Co. The other officers are as follows: Vice-presidents, Samuel P. Colt, Providence; Randall Morgan, Philadelphia; Walton Clark, Philadelphia; secretary and treasurer, Lewis Lillie, Philadelphia; assistant treasurer, Cyril A. Babcock, Providence; assistant secretary and comptroller, Walter R. Elliott, Providence; general manager, Albert T. Potter, Providence; superintendent of transportation, Albert E. Potter. Under the terms of the lease the Rhode Island Co. guarantees a 5 per cent dividend from July 1st on the stock of the United Traction & Electric Co.

### SOFT COAL ON MANHATTAN LINES.

Owing to the scarcity of hard coal available for use in its engines, the Manhattan Railway Co., of New York, resorted recently to the use of soft coal, discontinuing temporarily the through trains from 58th St. and 6th Ave. to Rector St. and transferring passengers on this route by shuttle at 50th St. in order to minimize the smoke nuisance resulting from the change of fuel. The change to soft coal, as was inevitable, has called forth a volley of protest from various quarters. With a view to obviating the smoke nuisance in as great a degree as possible the company used its remaining stock of anthracite coal exclusively on the 6th Ave. line from 150th St. to South Ferry, thus relieving the 6th Ave. shopping district of smoke, and every effort has been made to avoid inconvenience to the public.

The Toronto (Ont.) Railway Co. reports traffic returns for Dominion Day for this year at \$8,298.64, which is an increase of \$494 over the returns for Dominion Day a year ago.

franchises for an electric railway system in Havana, Cuba, beginning at a point in that city where the steamers land, passing through the center of Havana, and forming a loop around the principal residence and commercial districts with a line to a resort six miles down the coast. The concessions are estimated to be worth fully \$25,000,000. Work on the line to the resort referred to has been begun, and it is announced that the system will be completed with all possible rapidity. Associated with Messrs. Park and Hamilton in the project are Devitt, Tremble & Co., of Chicago; G. F. Penhale & Co., and H. W. Whipple, of New York; H. W. McDonald & Co., of Chicago, and W. J. Hayes & Sons, of Cleveland.

A strange and very painful accident occurred on the Wheeling-Bellaire line of the Wheeling (W. Va.) Traction Co., July 5th. A conductor, stepping from the running board to the rear platform of his car as it rounded a curve was struck by the shaft of a wagon left standing too near the tracks. The shaft completely pierced his thigh, lifting him from his feet. The horse at this moment started to run away, but was prevented from doing so by the wounded man, who seized the reins, stopped the horse and then pushed himself off the shaft. The conductor, whose name is B. W. Pumphrey, will recover, but the incident is none the less worthy of note for two reasons: first because it is an example of the heroism often shown by men in street railway service, and second because it invites attention to the public disregard of ordinances, which have been passed by most cities, to the effect that horses shall not be left unhitched in streets, particularly where cars are passing.

## ECHOES FROM THE TRADE

THE BOSTON ELEVATED RAILWAY CO. has executed a large contract with the Green Fuel Economizer Co. for installing several economizers at the Central power station.

THE J. G. BRILL CO. is building a new spring shop 200x75 ft. which will be fitted with the most modern machinery and with oil furnaces. The Brill company makes all of its own springs both coil and elliptic.

THE DELANEY OIL & LUBRICANT CO., Milwaukee, reports shipments to Cuba and Porto Rico of Delaney's water purifier, "Dilley's Fat" (a new lubricant), fire extinguishers (chemical powder) and steel cable lubricant.

THE HOLYOKE STREET RAILWAY CO., of Holyoke, Mass., has recently increased its power plant by the addition of a 1000 h. p. engine direct connected to a G. E. 1200-kw. generator and 2700 h. p. Babcock & Wilcox boilers.

THE KENNICOTT WATER SOFTENER CO., 3544 Butler St., Chicago, has one of its water softening machines in operation on the Union Pacific R. R. which removes 335 lb. of lime and magnesia from water every day—over five tons per month.

THE GARL ELECTRIC CO., of Akron, O., has furnished a complete telephone equipment to the Northern Texas Traction Co. The Garl portable telephones with the jointed poles for connecting to the wires are used with cars and stationary telephones are placed at terminals as well as bridge telephones in the offices.

THE AKRON ELECTRICAL MANUFACTURING CO., of Akron, O., is planning to increase its capacity by erecting a new factory in the early fall. This company is steadily increasing its business and has recently opened a Cleveland office, in the Electrical Building, which is in charge of Mr. P. J. Boucher.

CASS HARKINS, of Columbus, O., a well known manufacturers' agent and consulting engineer, who has been in business in Columbus for a number of years, has been appointed sole agent for central Ohio for the We-Fu-Go and Scaife water softening and purifying apparatus manufactured by Wm. B. Scaife & Sons Co., of Pittsburg, Pa.

THE ELECTRIC STORAGE BATTERY CO., of Philadelphia, announces that Mr. G. F. Greenwood, 34 Empedrado St., Havana, Cuba, has been appointed agent for the sale of the "Chloride" accumulator in Cuba. All inquiries and business from this section should be forwarded Mr. Greenwood and will receive from him prompt attention.

THE FOUNTAIN MANUFACTURING CO., maker of electrical outlet, switch and junction boxes, has removed its general offices and sales room from No. 97 Bank St. to No. 15 Cortlandt St., New York, to which all communications should be addressed. A stock room will be maintained at No. 97 Bank St. for the convenience of the local trade.

THE BALL ENGINE CO., of Erie, Pa., is building a large new shop in the western part of the city in which it is planned to have the machinery installed by December next. This company will hereafter devote more attention to the building of large engines and it is this in connection with the increased general demand for its engines that has led to the building of the new plant.

A STEAM RAILWAY 4½ miles long, the Cincinnati, Georgetown & Portsmouth Ry., is shortly to be converted from steam to electric traction. The Tenth Railway Equipment Co., which has the contract, has recently purchased from the Westinghouse Electric & Manufacturing Co. two 600-kw. A. C. generators and a number of 300 kw. rotary converters for supplying current to the line.

THE HEYWOOD BROS. & WAKEFIELD CO., Wakefield, Mass., has recently received orders from the St. Louis Car Co., John Stephenson Co. and Newburyport Car Co., for seats for 72 cars for the Boston & Northern R. R. These seats are the No. 42 with back offset at one end, upholstered in high grade crimson plush, with Wakefield bronze grab handle on the corner of the back.

THE SAN GABRIEL ELECTRIC CO., of Los Angeles, Cal., has recently purchased a 750 kw., two phase, engine type Westing-

house generator which is to be installed in a sub-station of the Pacific Light & Power Co. The latter company has recently acquired the San Gabriel Co. and the new alternator will be used in connection with its general system of lighting and power in Los Angeles and the vicinity.

THE LUMEN BEARING CO., of Buffalo, N. Y., reports that the increased business of the company in the street railway field is such as to require it to enlarge its plant to three times the present capacity. The department now used as a foundry will be changed to the machine shop and a much larger room for the foundry provided. This company makes the well known Lumen bronze bearing and a number of other specialties.

THE UNDERFEED STOKER CO. OF AMERICA has lately closed contracts for Jones underfeed stokers with the following: Worcester Consolidated Street Ry., Worcester, Mass.; Rochester Athenaeum and Mechanics Institutes, Rochester, N. Y.; Municipal Heating Co., Syracuse, N. Y.; Howard Street Pumping Station, Allegheny City, Pa.; Pennsylvania Railroad (tug "America"), New York; Arnold Print Works (Eclipse Mill), North Adams, Mass., third order.

THE MALTBY LUMBER CO., of Bay City, Mich., which recently made a prominent display on a train load of ties shipped to Des Moines, Ia., has made another large shipment of poles to points in Arkansas. The shipment was handled in the same manner as the train load of ties, the whole number of cars being kept together during the run and prominent signs being displayed on both sides of the cars. Through the courtesy of the railroad companies the train made only daylight runs during the entire trip.

PORTER & BERG, of Chicago, report an unusually excellent business for the present season. They make a specialty of handling electric railway supplies exclusively, and carry a very complete line of specialties which they are enabled to offer at very attractive prices. They represent a number of well known eastern makers of electric railway specialties whose goods they carry in Chicago, together with a general line of electric railway supplies, and from this stock they are at all times able to make quick deliveries.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING CO. among recent sales reports the following: Induction motors, reducing transformers, "low equivalent" lightning arresters with choke coils and high tension circuit breakers for the Tom Boy gold mines, of Pandora, Col. Two 500-kw. railway generators for the Steubenville & Wheeling Traction Co. Three 200-kw. engine type generators for the Riter-Conley Manufacturing Co., Pittsburg; these will be direct connected to Westinghouse gas engines, using natural gas.

THE LIBERAL OFFER of Messrs. Adam Cook's Sons of New York to engineers and others to furnish a can of their well known Albany grease, also a grease cup, free of charge, prompts a highly complimentary testimonial from Mr. Roy J. Rivers, superintendent of the Minneapolis Milling Co. He says: "I received a sample can Albany grease and grease cup and have given them a trial and find them very satisfactory. I am using less grease and there is less 'heating' than with any grease I have ever used here. I wish you every success."

THE BUCKEYE ENGINE CO., of Salem, O., has just completed the moving of all its various patterns into the large five-story building recently built. This building was constructed especially for the purpose of storing the patterns. A new building to be used as a pattern shop is now under way and also an office building. The latter is to be of brick and will be a model structure. The business of the Buckeye Engine Co. has been rapidly increasing and the demand for increased capacity has resulted in the continual growth of the plant until it now covers a great deal of ground.

AMONG THE RECENT SALES of the Westinghouse Electric & Manufacturing Co. are ten 75 h. p. induction motors and four 100 h. p. induction motors for the Lackawanna Iron & Steel Co. The small motors will be used for driving the coke oven blowers in the Buffalo plant of the Lackawanna company. The larger

motors are for use in the gas cleaning plant and machine shop. The Lackawanna company has purchased in all, 151 type 6, Westinghouse induction motors ranging from 1 to 100 h. p. in size. Sales have also been made to the Fayette Manufacturing Co. of electrical power transmission apparatus for the company's refractory brick plant at Chester, Pa.

THE RECONSTRUCTED GRANITE CO., of New York, reports having had an unusually prosperous season, the business for the first four months of the present fiscal year being equal to the sales for the whole of the preceding year. It has just completed a large order for over 6,000 surface contact boxes, weighing about 80 lb. each, for the Lorain Steel Co.'s system being installed at Wolverhampton, Eng. It is also filling very large orders for the Yerkes underground system in London, of third rail insulators, as well as other large orders for various portions of the United States. The company is increasing its plant, so as to double its present capacity, and is branching out into several new lines of insulation, including overhead high potential insulators for feed wires.

THE MORSE CHAIN CO. of Trumansburg, N. Y., has issued an interesting catalog entitled "Silent Running High Speed Chains for the Transmission of Power" in which attention is called to the many purposes for which this chain can be used to advantage. Marked advantages are claimed for the Morse chains where room is lacking to get the proper sized pulleys, where short distances between the shafts are necessary or desirable, where the stresses to be transmitted are large, where it is required that the speed ratio be positive or where it is large, where moisture, heat or dust interfere with proper working of belt or where there is grit present which would quickly cut out the joints of ordinary chains. An installation is cited where the Morse chain was used for driving condensing pumps and is subjected to a maximum pull of 10,000 lb. which of course is intermittently applied on the joints. Notwithstanding the severe conditions, this is stated to have run continuously night and day for seven months without noise.

THE LUDLOW SUPPLY CO., which started in the electric railway supply business at 313 Electric Building, Cleveland, O., last October, advises us that owing to its increasing business the company has been forced to move into larger quarters and has leased Rooms 301 and 302 Electric Building, and now occupies three times the space available in the old quarters. This firm now represents the following manufacturers: The Morris Electric Co., New York, on rail bonds and fare registers; the Chi-sholm & Moore Manufacturing Co., Cleveland, on rail joints, braces, chairs, chain hoists and cranes; Frank Ridlon Co., Boston, on "Wilson" trolley catchers; Garton-Daniels Co., Keokuk, Ia., on lighting arresters; Duff Manufacturing Co., Pittsburg, on "Barrett" jacks; H. Gore & Co., Boston, on track drills; Speer Carbon Co., St. Marys, Pa., on carbon brushes; Lumen Bearing Co., Buffalo, on journal bearings and trolley wheels; Kisinger-Ison Co., Cincinnati, on trolley wire splicers; The Nichols-Lintern Co., Cleveland, on track sanders; Crouse-Hinds Electric Co., Syracuse, on headlights; Simplex Electrical Co., Boston, on electric car heaters; R. B. Bliss Manufacturing Co., Pawtucket, R. I., on "Woods" car gates; Garry Iron & Steel Co., Cleveland, on pneumatic compressors and jacks; Automobile & Cycle Parts Co., Cleveland, on "Milwaukee" trolley poles. The territory contiguous to Cleveland is one of the best in the country for electric railways, and the Ludlow Supply Co. is filling a long felt want in that territory.

PAWLING & HARNISCHFEGGER, Milwaukee, Wis., state that the demand for electric cranes and hoists remains highly satisfactory. They advise that present booking of orders is on the average of one crane per day, which fully equals their works' capacity. There is a noticeable broadening of inquiries, particularly from the central and western states, and the prospect for sales in these sections looks very good. The foreign demand is bettering, judging by the inquiries within the last month. Prominent among the recent purchases of cranes and hoists are as follows: Pennsylvania Railroad Co., West Philadelphia, one 6-ton trolley. Grand Crossing Tack Co., Chicago, one 75-ton ladle crane with 25-ton auxiliary trolley. Starley Electric Manufacturing Co., Pittsfield, Mass., for Michigan Lake Superior Power Co., Sault Ste. Marie, Mich., two 15-ton cranes. S. Morgan Smith Co., York, Pa., one 10-ton crane. Pressed Steel Car Co., Allegheny, Pa., one 5-ton special hoist. The Westinghouse Machine Co., East Pittsburg, one 10-ton crane. Pittsburg Plate Glass Co., Ford City, Pa., one 3-ton crane. Bethlehem Steel Co., South Bethlehem, Pa., one 3-ton crane with 10-ton

auxiliary trolley; three 2-ton chain block cranes. The A. & P. Brown Co., Elizabethport, N. J., one 15-ton crane with 3 1/2-ton auxiliary hoist. Jas. B. Clow & Sons, Newcomerstown, O., one 5-ton hoist. American Foundry & Construction Co., Hazlewood, Pa., one 5-ton special hoist. Buffalo Foundry Co., Buffalo, N. Y., two 30-ton cranes with 5-ton auxiliary hoist; four 10-ton cranes. Ball Engine Co., Erie, Pa., one 25-ton crane with 5-ton auxiliary hoist.

THE LUMEN BEARING CO., of Buffalo, N. Y., reports that its business on "Lumen" bronze bearings has increased to such an extent that the company has prepared plans for an addition to its plant which will increase the capacity to three times what it is at present. The company has recently purchased property which will give it a floor space of 18,000 sq. ft. Special attention will be devoted to the street railway trade in journals for trucks and axle bearings for motors, in which specialties the Lumen Bearing Co. has been very successful.

THE ELECTRIC STORAGE BATTERY CO., of Philadelphia, Pa., has published a Bulletin No. 73, on "The Application of Storage Batteries to Lighting and Power Stations." The plant described is situated at Milan, Mich., and the operation of the battery is shown diagrammatically. Since the installation of the battery this plant has been able to do twice the amount of business of which it was previously capable.

THE BAKER ENGINE & MACHINE CO., of No. 112 N. Third St., Philadelphia, is now installing two 600 h. p. compound engines for the Augusta (Ga.) & Aiken Ry., which is building by John Blair MacAfee. The company has also sold two engines of 500 h. p. each to M. P. McGrath, of Easton, Pa., for a plant at West Point, Pa. Two 400-h. p. engines made by the Baker company were put in operation last month at the power house of the Cumberland & Frostburg trolley road, recently completed by the Penn State Construction Co.

THE NEW YORK SWITCH AND CROSSING CO., of Hoboken, N. J., has recently put a new electric derailing switch on the market, which is meeting with very good results. It is simple, consisting of operating and switch boxes, and connections, and so far has stood the test, although perfection is not claimed for it. Six sets have been sold in Long Island; the Standard Electric Co., Danville, Va., has taken four, the Cleveland Construction Co., one, and the Hudson Valley Railroad has ordered one. The switch and crossing company is about four months behind on orders, the chief difficulty being to get good men.

THE NICHOLS-LINTERN CO., of Cleveland, O., has issued an attractive pamphlet describing the track sanders made by it. Each equipment consists of two sanding traps with gaskets and one special operating valve. Special designs are furnished with the outlet at any desired angle and arranged for attaching either rubber hose, wire hose or iron pipe so as to meet all conditions required by steam or electric roads.

THE SLATER ENGINE CO., of Warren, Mass., is now building an 800-h. p. cross-compound engine for the Wabash River Traction Co., Wabash, Ind.

THE OHIO STEAM PUMP CO., of Canton, O., which has heretofore been using a part of the old Whitman & Barnes plant, has just purchased a site and will erect a new factory building which will enable it to handle its increasing business in much better shape.

WESTINGHOUSE, CHURCH, KERR & CO. announce the removal of their Pittsburg office from its former location on the first floor of the Westinghouse Building to more commodious quarters on the eighth floor of the same building. This change is the direct outcome of largely increased business in this district, and is accompanied by the organization of two new departments, those of engineering and of construction, in addition to the original sales department. The object of the management in making the change is to be able to accommodate more thoroughly and promptly the wishes and needs of patrons. They are prepared to give immediate attention to all classes of general engineering and construction work as applied to power and its uses in transportation and industry. They will provide in all cases from their engineering force adequate personal supervision of work in hand, both during construction and subsequent thereto. The office conducts, as formerly, the sales department of the Westinghouse Machine Co., and the increased facilities afforded by their new quarters, in addition to the acquirement of an engineering force, will enable them to fulfill the most extensive contracts.

All correspondence and remittances to Windsor & Kenfield Publishing Co., Chicago, Ill.

**CORRESPONDENCE.**

We cordially invite correspondence on all subjects of interest to those engaged in any branch of street railway work, and will gratefully appreciate any marked copies of papers or news items our street railway friends may send us, pertaining either to companies or officers.

**DOES THE MANAGER WANT ANYTHING?**

If you contemplate the purchase of any supplies or material, we can save you much time and trouble. Drop a line to THE REVIEW, stating what you are in the market for, and you will promptly receive bids and estimates from all the best dealers in that line. We make no charge for publishing such notices in our Bulletin of Advance News, which is sent to all manufacturers.

This paper is a member of the Chicago Trade Press Association.

Entered at the Post Office at Chicago as Second Class Matter.

VOL. XII.

AUGUST 20, 1902.

NO. 8

The regular September number of the "Street Railway Review" will be made the Detroit Convention Souvenir. The convention being from October 8th to 10th, this will enable us to place the special issue in the hands of our readers several days before they leave for Detroit.

The "Daily Street Railway Review," which has been a highly-appreciated feature of the A. S. R. A. conventions since 1899, will this year be published in Detroit on October 8th, 9th, 10th and 11th, the first number appearing early on the morning of the opening day of the convention. As heretofore these four issues will be mailed daily to our subscribers and reach every street railway in the world, giving those unable to attend the conventions their first reports of the association meetings; in Detroit the "Daily" will be distributed at all the hotels as well as at the convention hall.

This will be the fourth year that the "Review" has published its Daily Edition at the Convention, and the growth in the size of these special issues is an index of the increasing importance of the annual meeting of the A. S. R. A. At Chicago, in 1899, there were five numbers of the "Daily Review" aggregating 104 pages of reading matter; at Kansas City the next year there were four numbers with a total of 89 pages of reading matter, a slight average increase; at New York last year the four issues of the "Daily" contained 125 pages of reading matter, or almost the same number as in two of the regular monthly editions of the "Review." Last year we made an innovation in numbering the pages of the "Daily" in sequence with the monthly "Review," so that the last page of the September monthly was 628 and the first of the October monthly was page 723. This plan will be followed with the Detroit "Daily" and therefore to make a complete file for 1902 the four numbers for October 8th, 9th, 10th and 11th should be preserved as well as the October monthly which will be dated the 20th.

On another page will be found the program for the Detroit meeting of the American Street Railway Association and also the

announcements of the chairman of the committee on exhibits concerning the rules governing the exhibition. The program as announced is one of unusual interest and among the papers that are particularly apropos are those on the "Merit System of Discipline," the "Transport of Express and Parcel Delivery," "Steam Turbine Engines," and "Signals for Urban and Interurban Railways," all of which are equally important to interurban and to city companies. The other papers deal with questions that affect rather city railway systems. The subjects of discipline and signals are mentioned elsewhere as being ones to which those who are charged with the operation of high speed lines are giving the most earnest consideration, and there is also a widespread interest in the steam turbine, and its application to railway work.

The Association will this year arrange for the publication of the convention papers well in advance of the meeting and their distribution to the members in ample time to give all those interested an opportunity to collect data and prepare for discussion at the convention. The executive committee has urged that the member companies instruct their delegates to be present at all business meetings of the association, and this suggests to us the idea that possibly the association has gone too far in the direction of cutting down the time allotted to its annual meetings, which is now but two days as compared to four days which was considered short enough a few years ago. The fact should not be overlooked that for many of the delegates the few days spent in attendance on the A. S. R. A. conventions constitutes their nearest approach to a vacation. When the street railway companies acting as hosts offer so much in the way of entertainment and the opportunities for profitable inspection trips over outlying suburban lines are as great as they are, it is not astonishing that the delegates should fail to attend all the association meetings. The setting apart of an entire day for the examination of exhibits has proved to be a most satisfactory arrangement and should by all means be continued, but we believe that hereafter the convention should extend over at least four days.

The applications to the secretary for exhibit space were far in excess of the space at first available, and permission was granted by the city of Detroit to temporarily enclose portions of the streets adjacent to the exhibition hall. In addition to this temporary tracks will also be put down outside the annex. This year those in charge of the exhibit hall have promulgated regulations governing the dimensions and location of signs displayed in connection with the exhibits, which are similar to those adopted at the 1901 convention with such gratifying results in improving the appearance of the hall.

The New York State Street Railway Association is the oldest of the state associations and is but one year junior to the A. S. R. A., the 1902 New York meeting which will be held at Fort William Henry Hotel, Lake George, N. Y., on September 9th and 10th being the twentieth annual convention of the state association. The New York association has devoted a great deal of attention to the consideration of questions which were of peculiar interest to New York roads, and has been a most convenient means of securing cooperation among members when united action was desired in all matters, such as tax and franchise questions, that affect the entire state. While thus by special reports and committee work covering the things within its field as a state, as distinguished from a national association, it has not failed to be of service to the street railways of the entire country; at its annual conventions there have always been technical papers of the highest character, and the discussions of practical subjects have proved of assistance to many an operating man outside of the state. The Association has every reason to be proud of the work it has done, and great credit is due Mr. G. Tracy Rogers, who has been the president for several years, and to the executive committee.

The coming meeting will undoubtedly be well attended as the development of electric railways in New York, particularly interurban lines, has been very rapid during the last two years.

The first decade of the 20th century bids fair to become as distinctly that of the "third rail" road as 1891-1900 was that of the "trolley," and the marked development made in this direction suggests several interesting points in connection with modern interurban railway practice—some in the nature of causes for the changes we see being made, and others that are results of these changes.

The third rail for a current conductor is the result of efforts to get higher speeds on electric railways without danger to the passenger. For safe operation at high speeds, heavy cars and trucks and a well built roadbed are essential, and the trolley wheel, with its small area of contact is entirely inadequate to conduct the larger current demanded because of increase in both car weight and speed. The electrical engineers of the Baltimore & Ohio R. R., in equipping the belt line tunnel for electrical operation, recognized this difficulty, and attempted to overcome it by increasing the number of trolleys on the locomotive, after a few years the overhead trolley system was abandoned and a third rail laid on the surface substituted as the conductor. The successful operation of heavy trams on the Chicago elevated railroads and some of the branch lines of the New York, New Haven & Hartford demonstrated the advantages of the third rail where large currents are to be transmitted to the car, but it was also apparent that an unprotected electrical conductor could not be safely installed in public highways, where most electric railways are located. A private right of way which can be fenced or otherwise protected from the general public is necessary if the electrical conductors are to be placed at the surface of the ground.

The policy of securing for electric lines the fee or a perpetual lease of the land occupied by their tracks was, we believe, first put in practice by the Cleveland capitalists who developed the extensive interurban systems radiating from that city. Their idea was that although the private way might be more expensive at first cost, the elimination of all franchise renewal questions, the opportunity to better protect the company from the results of injuries to trespassers on the tracks and at the same time get a better profile than the highway generally offers, and the possibility of higher speeds with safety, would vastly outweigh the objection of higher first cost. We believe that the failure to adopt this policy has in many cases been due solely to the fact that the laws of many of the states permit electric or "street" railways to depart from the highways only where there is a physical necessity for such a deviation. Where the laws are favorable, there has recently been a marked increase in the extent to which the substitution of a third rail for an overhead wire is considered practicable and desirable. Thus until about a year ago the idea of purchasing a right of way through a town of any considerable size was scarcely thought of, and where this was done it was only as a last resort to prevent a "hold-up" of the new company, the authorities having demanded exorbitant compensations for the franchises granted.

Aside from the two instances mentioned, where steam railroads have put down a third rail for electrical operation, and on the elevated lines, the third rail has been adopted by the Albany & Hudson Railway & Power Co., which put its 36-mile line between Albany and Hudson, N. Y., in operation in 1900, the Grand Rapids, Grand Haven & Muskegon Railway, which began operating over 42 miles of track in western Michigan this summer, and the Aurora, Elgin & Chicago, which it is expected will begin operating during the current month. On both the New York and the Michigan roads it was considered impracticable to use the third rail in cities and villages, but on the Aurora, Elgin & Chicago, which is described at length in this number, the third rail is used everywhere except for a short distance in one of the terminal cities. To do this it was necessary to buy rows of lots or portions of lots, extending through the various towns, and in many cases considerable expense was incurred in removing or tearing down the buildings on the premises bought. We entertain no doubt but that the private right of way will in the near future be considered a necessity for electric interurban roads of any considerable length.

\* \* \*

Along with the question of location which apparently has been solved satisfactorily, come those of signal systems and discipline of trainmen, and these grow in importance as speeds are raised and the volume of traffic increases. The recognized standard for electric railways is now a dispatching system in which, however, the telephone is used rather than the telegraph. Two instances have been cited in recent numbers of the "Review" where steam and electric trams running over the same tracks were successfully handled, the electric cars, which alternated with the steam trains, being given train numbers and subject to the same rules as the latter. Although no special difficulties were experienced in these cases, the idea is gaining ground that to insure the greatest safety of operation on the high speed electric lines a block signal system is desirable, for double as well as for single track lines.

Some complications are introduced by reason of the service rails

being utilized for the return of the electric current, and the signals operated by "track circuits" made and broken by the car wheels and axles are not applicable to electric railways without modification. The manufacturers of signal apparatus, as well as railway managers, are alive to the demand, however, and signal systems carefully designed to meet the conditions are being put in service.

Good discipline is largely a matter of good management, and while there may be at present a scarcity of men who are experienced in the handling of the apparatus on electric cars, and at the same time appreciate the importance of obeying train orders. It will be, we believe, only a short time until the roads needing this class of men will have them.

\* \* \*

Some important developments in regard to the maximum speeds practicable on electric railways may be expected in the near future as it has been announced that the General Electric Co. will conduct special tests over the Aurora, Elgin & Chicago line, probably within the next sixty days. Those in charge of this work are confident that speeds in excess of 100 miles per hour can be attained without difficulty, though no predictions are made. These speed tests will be made under conditions that are in some respects much more favorable than was the case with those made on the Berlin-Zossen experimental line, as the trouble there lay in the track rather than the cars. There have been some attempts made to draw from the Berlin-Zossen experiments the conclusion that an electric car is more severe on the track than is a steam locomotive, but this does not appear to be justified.

The attitude of the daily press toward street railway companies led us, in 1899, to urge the street railways of the large cities to publish weekly or semi-monthly bulletins for themselves and thus be assured of an unbiased medium for presenting their announcements to the public. Since that time several companies have published, during the summer months at least, weekly papers which serve to convey information that patrons of the cars could not readily get in any other way, and at the same time are good advertising mediums when the railway company has a park or pleasure resort on its line. The Detroit United Ry is the latest addition to the number of companies using this method of reaching the public.

The New Jersey & Hudson River Railway & Ferry Co. which operates a suburban road in New Jersey and a ferry across the Hudson River to New York, landing at W. 130th St., has for several years spent considerable sums of money in advertising and with satisfactory results; the idea of the management is to tell people about the attractions of its line and how to reach it. This example could be followed with profit in other cases where suburban or interurban cars do not run into the terminal cities but passengers have to transfer to the city roads; specific instances could be cited of electric lines having city connections where there are no attempts made to notify the public in general how the outlying road can be reached.

In this number we publish the fourth of a series of articles by Mr. W. E. Partridge on special types of cars, which are both interesting and instructive, as showing the development of these peculiar classes of electric railway rolling stock. The first three of the articles by Mr. Partridge were on "California and Combination Cars" and the one now published treats of an allied type, "Convertible Cars," including of course the semi convertible car. A car that can be quickly adapted for either fair or foul weather and is durable, has many advantages which are quite generally appreciated.

The question regarding the advantages and disadvantages of a narrow gage for local suburban railways which was discussed at the International Tramways Congress in London, brings out the fact that it has advocates in Europe, but in this country the companies having narrow gage lines are finding it necessary to lay an additional rail, so that standard gage cars may also be operated. While the first cost is of course favorable to the narrow gage, this construction is hampered by want of space on the trucks and in the cars, and in the case of electric railways the difficulty of adapting the standard sizes of machinery to the trucks. The additional cost of the transshipment of freight and express matter is also an important item in many cases.

## The Aurora, Elgin & Chicago Railway.

The Aurora, Elgin & Chicago Ry., which is now practically completed, constitutes one of the most important suburban electric railway undertakings which has been attempted up to the present time. This road covers one of the most populous suburban districts in the neighborhood of Chicago, and with nearly 100 miles of its own track and physical connections with several other

suburban electric railways the system will serve some twenty cities and towns outside of Chicago having an aggregate population of about 150,000, some data as to the distribution of which will be given in another place.

The construction of this road, including the roadbed, power house, sub-stations, and line work, has been designed in a most careful and substantial manner and no expense has been spared to

principle" that for the security of investors and permanency of the road an electric railway company should own its right of way in fee, or at least have a perpetual easement in the realty occupied by its tracks. With the exception of the city street crossings the company owns the fee of all of the right of way. In the country the strip of land is 100 ft. wide except for a few short stretches, which aggregate perhaps half a mile in length, where the width is 66 ft. In all cities and villages the company bought either the whole or portions of the lots necessary to give it a complete way, in many cases moving or wrecking the improvements on the realty. Being organized under the railroad law the franchise question has no terrors for this company.

The company owes its origin and the successful completion of its plans principally to Mr. L. J. Wolf, of Cleveland, who has been ably assisted by Messrs. Will Christy, of Akron, O., and Charles Jones, of Wheaton, Ill. Mr. Wolf has for years been prominently identified with electric railways, and is at this time president of the

GENERAL VIEW OF ENGINE AND GENERATOR ROOM, POWER STATION, BATAVIA, ILL.

make every detail of the installation as complete and thoroughly up-to-date as possible, and in all of its engineering features this road represents the most modern and approved practice. It is a third-rail system throughout and the curves and grades have been laid out with the idea of operating a high speed schedule.

The road passes through a picturesque section of country which, though served by the suburban lines of several steam railroads, is still greatly in need of more frequent and rapid service. The passenger traffic between all of the suburbs reached by this road and Chicago is capable of vast expansion, but it is at present greatly hampered by the time necessarily lost in making connections between the different steam road branches now operating in this territory, so that at certain times of day a trip which should be made in an hour or less is frequently protracted to two or three hours. By furnishing a frequent and rapid service, as is designed by the Aurora, Elgin & Chicago, the transportation facilities of these suburbs will be greatly improved and a large proportion of the traffic of this territory is certain to be diverted to the new line.

This enterprise has been developed by Cleveland men, and they have acted on what we believe deserves to be called the "Cleveland

Springfield & Xenia Traction Co., which is now building an electric line between Springfield, O., and Xenia; vice-president of the Western Ohio Railway Co., of Cleveland, and president of the Elgin, Aurora & Southern Traction Co. and of the Aurora, Elgin & Chicago. Mr. Christy is one of the pioneers in interurban electric railroading, having been for some years the manager of the Akron, Bedford & Cleveland, which is now part of the Northern Ohio Traction Co.'s system; after leaving this company he, with Mr. M. J. Mandelbaum, of Cleveland, effected the consolidation of the Dayton Traction Co., the Cincinnati & Miami Valley Traction Co., and the Cincinnati, Hamilton & Dayton Electric Railway Co., forming the Southern Ohio Traction Co. Mr. Jones was connected with the construction of the Lorain & Cleveland Ry., which it will be remembered, for some time held the record for high speed on electric lines, and was formerly one of the engineers of the Lorain Steel Co., at Lorain, Ohio. Mr. E. H. Arnold, who has had immediate supervision of the construction on the Aurora, Elgin & Chicago, was assistant chief engineer on the Lorain & Cleveland, and has had an extended experience in electric railway work.

The company is a consolidation of the Aurora, Wheaton &

Chicago Railway Co., the Elgin & Chicago Railway Co. and the Batavia & Eastern Railway Co., and the officers are President, L. J. Wolf, vice-president, M. H. Wilson, secretary, Harry Greenbaum; treasurer, M. J. Mandelbaum. The capital stock is \$3,000,000, one half of which is preferred, and there were authorized \$3,000,000, in 5 per cent gold bonds, to be issued as needed for construction.

The construction force comprised Will Christy, president of the Cleveland Construction Co., who was general manager during construction; W. E. Davis, vice president of the Cleveland Construction Co., consulting electrical engineer; Chas. Jones, chief engineer; E. H. Arnold, construction engineer; Ernest Gozenbach, electrical engineer, W. L. Morris, mechanical engineer.

The operation of the road will be in charge of Mr. Warren Bicknell; the operating staff will include C. E. Flemer, auditor; W. W. Crawford, superintendent of transportation; Ernest Gozenbach, electrical engineer.

The route of the Aurora, Elgin & Chicago Ry. and the steam railroads with which it will be in competition in the territory served are clearly shown on the accompanying map. From the Union Loop, Chicago, to the terminal of the Garfield Park branch of the Metropolitan West Side Elevated Railway at West 52d Ave. is a distance of 6½ miles, the schedule time between these points being 25 minutes. From West 52d Ave., the eastern terminus of the Aurora, Elgin & Chicago, this line is a double track road for 21 miles to the Chicago Golf Club near Wheaton. From Wheaton

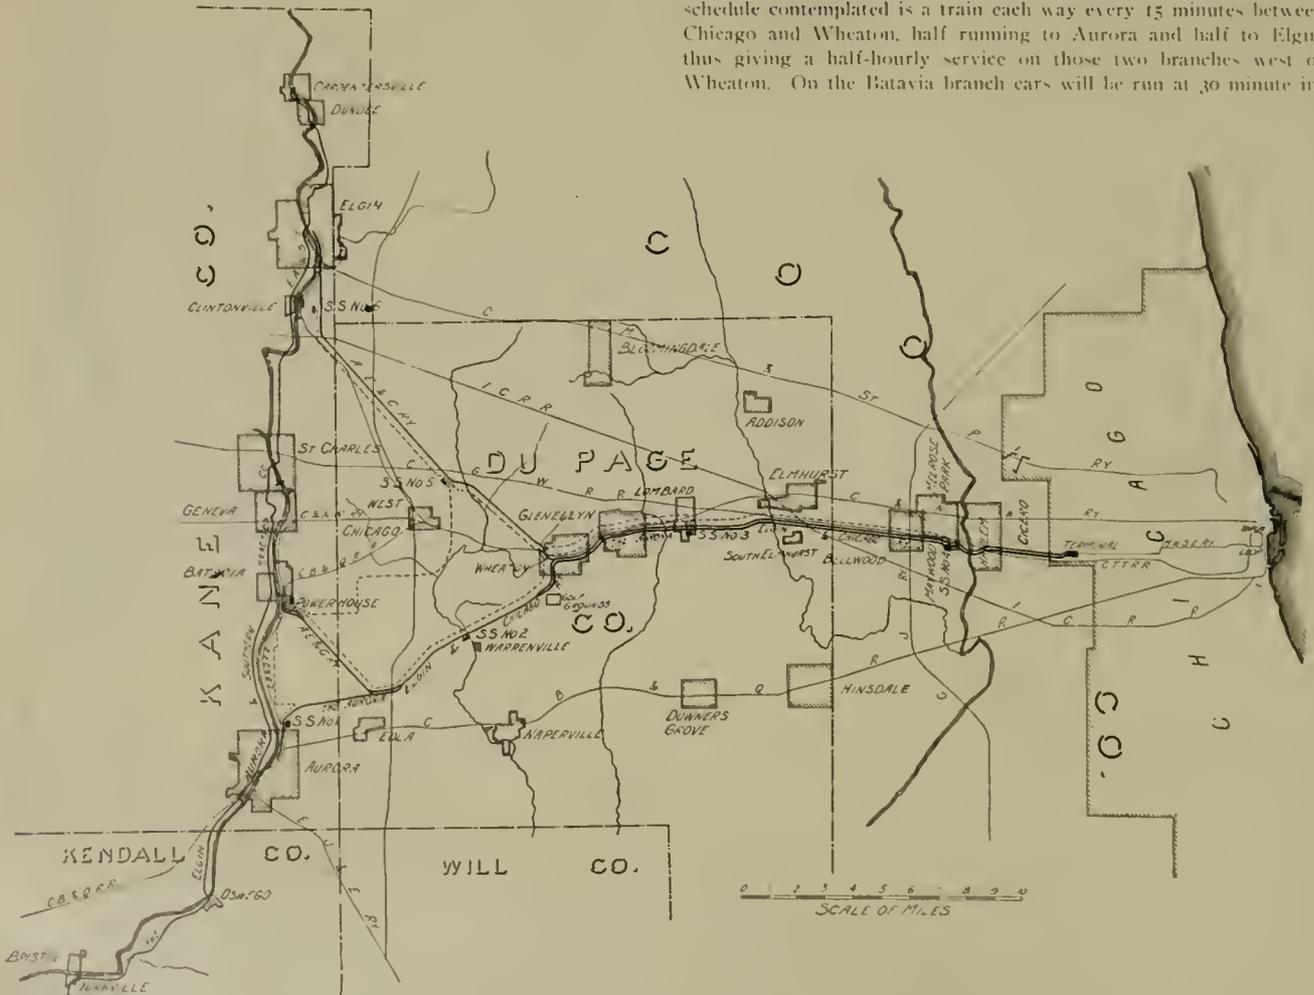

are long sidings, one of 1 mile, one of 1½ miles, two of 1,500 ft. and three of 800 ft., which will bring the total to 82 miles measured as single track.

The running time from Aurora, Elgin or Batavia to Chicago will be 45 minutes for express trains and one hour for local trains. The

VIEW ON COOK COUNTY LINE.

schedule contemplated is a train each way every 15 minutes between Chicago and Wheaton, half running to Aurora and half to Elgin, thus giving a half-hourly service on those two branches west of Wheaton. On the Batavia branch cars will be run at 30 minute in-

MAP OF THE AURORA, ELGIN & CHICAGO RY. AND CONNECTING LINES

there are two branches, one northwest to Elgin, 16½ miles, and one southwest to Aurora, 14½ miles, making the road from the eastern terminus to Aurora 33 miles long. Another branch from the Aurora fork runs to Batavia, 7 miles from the junction. Of the 56 miles of road, 21 miles are double track and in addition there

tervals connecting with Aurora and Chicago trains at Eola Junction. The maximum number of cars per train will probably be four.

The rates of fare have been adjusted so as to be somewhat less than the lowest commutation rates of the competing steam lines. The principal distances and rates of fare, in cents, are as follows:

From W. 52d Ave., Chicago, to

	Distance, Miles.	Single Fare.	Round Trip.
Austin Ave.	1	5	10
Oak Park	2	5	10
Harlem	3	5	10
Maywood	4 <sup>1</sup> / <sub>4</sub>	5	10
Bellwood	4 <sup>3</sup> / <sub>4</sub>	10	20
South Elmhurst	9 <sup>3</sup> / <sub>4</sub>	15	25
Lombard	14	18	30
Glen Ellyn	16 <sup>1</sup> / <sub>2</sub>	20	35
Wheaton	19	25	45
Chicago Golf Grounds	20	30	55
Warrenville	23 <sup>3</sup> / <sub>4</sub>	40	75
Eola Junction	27 <sup>3</sup> / <sub>4</sub>	45	80
Aurora	33	50	90
Batavia	33 <sup>3</sup> / <sub>4</sub>	50	90

Children over six years and under twelve years of age are entitled to half-rate tickets. No fare is charged for children under six years of age when accompanied by an adult. The half-fare rates are about one-half that given in the table.

At Elgin and at Aurora physical connection is made with the tracks of the Elgin, Aurora & Southern Traction Co., which is a consolidation of the companies along the Fox River from Carpentersville to Yorkville, via Dundee, Elgin, Clintonville, St. Charles, Geneva, Batavia, Aurora, and Oswego. The Elgin, Aurora & Southern system includes the Carpentersville, Elgin & Aurora, the Aurora & Geneva, and the Aurora, Yorkville & Morris Railways, and is controlled by the same interests as the Aurora, Elgin & Chicago.

The steam railroads in the territory are the Chicago, Milwaukee & St. Paul to Elgin; the Illinois Central; the Chicago & Northwestern to Wheaton, Geneva and Batavia; the Chicago Great Western to St. Charles; the Chicago, Burlington & Quincy to Batavia and Aurora; the Elgin, Joliet & Eastern to Aurora.

The population of the towns outside of Chicago served by the Aurora, Elgin & Chicago Ry. is as follows:

Austin	15,000
Oak Park	10,000
Harlem	3,500
Maywood	4,500
Melrose Park	2,800
Bellwood	200
Elmhurst	2,000
Lombard	700
Glen Ellyn	900
Wheaton	3,000
Warrenville	500
Eola	200
Aurora	30,000
Batavia	4,500
Elgin	30,000
Total	107,800

To these may properly be added the population along the Elgin, Aurora & Southern as follows:

Carpentersville	1,800
Dundee	2,000
Clintonville	600
St. Charles	3,200
Geneva	3,000
Montgomery	500
Oswego	800
Britton	600
Yorkville	1,200

Total 14,600

In addition to this there is in the territory west of the Fox River and within 40 miles of Aurora, Batavia and Elgin, and tributary to them a population of about 200,000.

Tracks and Bridges.

The route for the Aurora, Elgin & Chicago was chosen only after a most careful survey of the territory as the object was to build a line on which trains could be operated at high speeds. With the exception of the curves near Chicago, which were ren-

dered necessary to avoid crossing streets at angles so acute as to make undesirably long breaks in the third rail, the curves are struck with long radii, and are connected by long tangents. The maximum grade is 1.8 per cent for about 1,000 ft., this being necessary to get down into the Fox River Valley; none of the other grades are above 1 per cent.

The track standards are shown in one of the accompanying engravings. The line is laid throughout with 80-lb. T-rail of the A. S. C. E. standard section, in 60 ft. lengths. The joints are made with 28-in. 4-bolt splice bars; the bolts are 1 in. in diameter by

BRIDGE OVER DES PLAINES RIVER.

4 in. long. Ties are spaced 2,840 to the mile, each fifth tie being of oak 6 x 8 in. x 9 ft., for the support of the third rail insulators. On tangents the other ties are of cedar 6 x 8 in. x 8 ft., and on curves of oak of the same dimensions. The entire line is gravel ballasted except on the sections near the Fox River, where crushed stone is used.

The conductor rail is of T-section, 100 lb. per yard, of a special soft steel, 0.10 per cent carbon; the rail is 5 1/2 in. high, the head being 2 1/2 in. wide and the base 5 1/2 in. It is supported with the inner flange of the head 10 3/8 in. from the gage side of the service rail, and on insulators which bring the top of the rail 11 3-16 in. above

CATTLE PASS AT SOUTH ELMHURST.

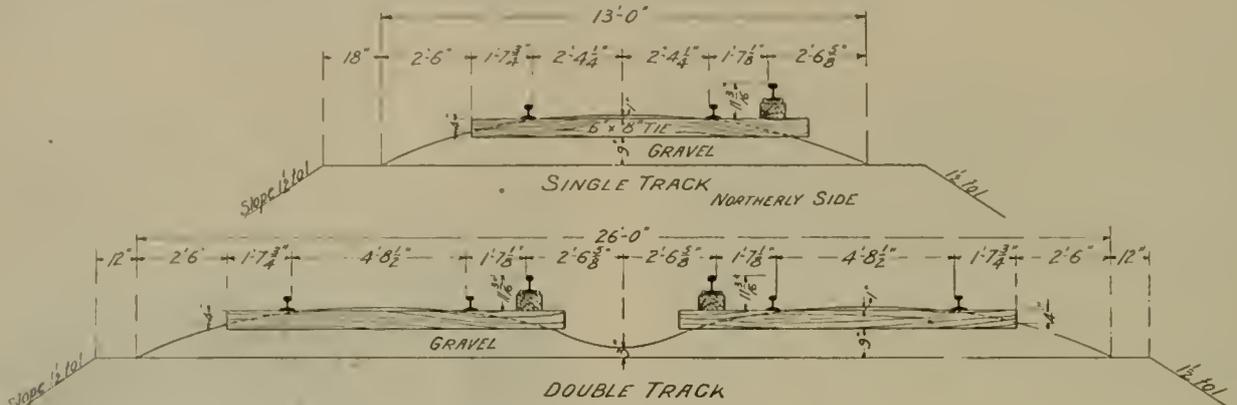

the ties. On that portion of the line first built the third rail insulators are paraffined wooden blocks with foot stands and top plates of malleable iron, but the standard adopted for future work is a malleable iron insulator designed and patented by Mr. Gouzenbach, which is shown here in vertical section. The insulation collar, circular in plan, is made of "Dirigo" and sets on top of the circular malleable iron base; the malleable iron cap fits over this and has two bearing strips for the rail and two vertical lugs to prevent lateral displacements. These insulators were made by the Ohio Brass Co. The weight of the rail is relied upon to hold it in

position and no fastenings are provided; the insulator bases are secured to the ties by two railroad spikes.

At highway and railroad crossings the rail is broken and the car runs the crossing under its momentum. These breaks in the third rail vary from 26 ft. to 100 ft., according to the conditions, there being but two breaks of 100 ft. Wherever there is such a

ground) and the bond terminals are shown in detail in the line drawings. The three bond terminals for connection to the rail are spaced about 2 in. between centers, the holes being drilled in the inner bottom flange, thus making available a large contact area between the bond and rail.

The space between the cable end and the bronze terminal shell is

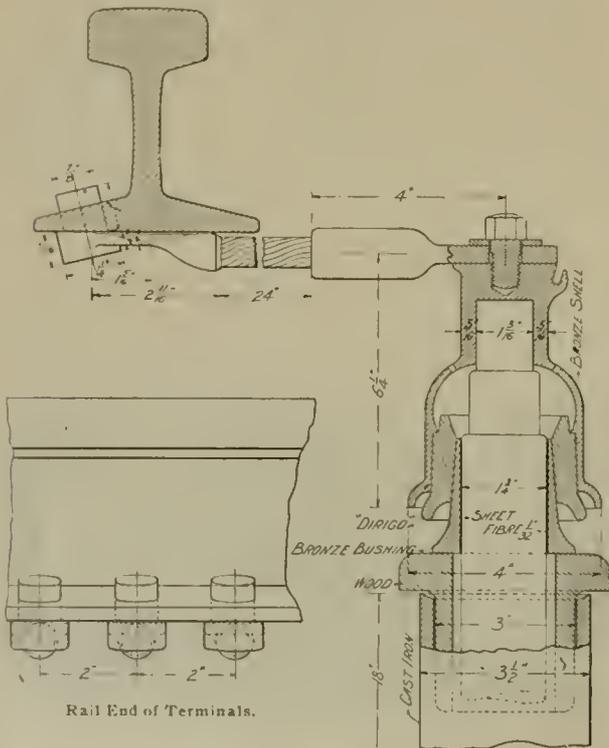

TRACK STANDARDS FOR AURORA, ELGIN & CHICAGO RY.

break, the sections are connected by cables laid 3 ft. underground and covered by planks. These cables are of copper and were furnished by the American Steel & Wire Co.; they are of three sections, 1,500,000, 1,000,000 and 500,000 c. m., the heaviest section being used for a distance of about two miles on either side of the sub-stations, the one million section for succeeding distances which are about six miles, and the lightest cables are used at special work. The

filled with paraffine. The cast pipe which protects the cable end is fastened to a 4-ft. post, the pipe having a band cast on it under which a strap can be conveniently placed.

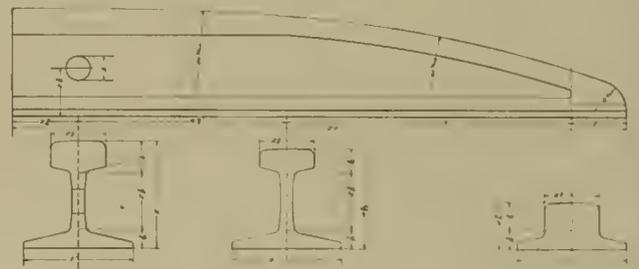

The sections of conductor rails are provided with cast tips 28 in. long which serve to guide the contact shoe into position on the

GONZENBACH CABLE TERMINAL AND "PROTECTED" TERMINAL BOND.

cables first ordered were rubber insulated but later a paper insulation cable was adopted as the standard.

These cables are soldered into terminals, made by the Ohio Brass Co. according to the design of Mr. Gonzenbach. From the cable terminal to the conductor rail connection is by a three-branch stub end bond 24 in. long made by the Protected Rail Bond Co., of Philadelphia. The cable terminal (including the wooden bushing and the cast iron pipe for protecting the cable where it enters the

TIP FOR THIRD RAIL.

100-lb. rail and the adjacent rail, 33 ft. long, is also given an inclination of about 2 in. A drawing of this tip is shown herewith. The splice bars for the conductor rail are similar in design to those used on the Manhattan Ry., New York City, and which were illustrated in the "Review" for December, 1900, page 708. These bars are 83 1/4 in. long, with two bolt holes 1 1/8 x 1 3/8 in. spaced 6 1/4 in. between centers and were made by the Ohio Brass Co. and the Ludlow Supply Co. At each joint of the conductor rail are two 7 in. 500,000-c. m. solid terminal "Protected" rail bonds furnished by the Mayer & Englund Co., of Philadelphia. The track rails are double bonded with 12-in. bonds, 1-in. terminals, the bonds being partly the "Protected" and partly the American Steel & Wire Co's. bonds.

At turnouts and switches it is necessary to depress the conductor rail for a short distance to permit the shoe to change its position

DROP RAIL AT SPECIAL WORK.

without striking the side of the rail. For this purpose sections of the third rail are bent as shown in the line drawing of the "drop rail" and placed with its center 12 in. back of the point of double tread on the service rail switch. In addition the conductor rails for 10 ft. on each side of the 12-ft. drop section are given a slope of 1/2 in. in 10 ft., the ties being dapped where they receive the insulators.

At highway crossings vitrified clay cattle guards, made by the Climax Stock Guard Co., Marquette Bldg., Chicago, are installed.

These guards are made of blocks each 24 in. long by 8½ in. wide, and in section like an inverted W with walls 1¼ in. thick. Forty sections are required for a guard 8 ft. by 8 ft., and these are held in place by strips of wood. The Aurora, Elgin & Chicago ordered over 700 guards, which are used exclusively; the half-tone engraving of the exterior of the sub-station shows one of the "Climax" guards in the foreground.

The road being built with high speed operation in view no expense was spared to make the track the best that it is possible to build. By reason of the exceptionally heavy rainfall this season the settlement of the roadbed has been as great as would ordinarily take place in two or three years, so that when finally surfaced the track will be in perfect condition.

All the steel structures on the road are designed for a live load of two 142-ton Cooper's E-40 locomotives followed by a uniformly distributed load of 4,000 lb. per lineal foot. The steel bridges are of the deck type wherever the conditions permitted, and elsewhere are through girder bridges.

The principal steel bridges are as follows: Des Plaines River, double track through girder, two 100-ft. spans. East branch of Du Page River, double track deck, one 69½-ft. span. West branch of Du Page River, single track through girder, one 89-ft. span, in conjunction with a 22½-ft. deck span. Lombard highway crossing, double track deck, one 36-ft. span. At three other highway overhead crossings are 45-ft. through girder spans. The Elgin branch crosses

Class A.—Portland cement, 1 part; sand, 2 parts; stone, 4 parts. Used for arch sheeting, bridge seats and parapet walls.

Class B.—Portland cement, 1 part; sand, 3 parts; stone, 6 parts. Used for abutments, bench walls for arches, and retaining walls.

CROSSING FOR OVERHEAD ROAD.

Class C.—Portland cement, 1 part; sand, 4 parts; stone, 8 parts. Used for foundations and other work as directed by the engineer in charge.

The foregoing proportions are by volume, one-fourth barrel of

35-FT. ARCHES OF CONCRETE MASONRY.

the Chicago & Northwestern tracks on a 150-ft. through truss bridge. All abutments and piers are of concrete.

In addition to the various steel structures there are concrete arch bridges at various points. Over Salt Creek at South Elmhurst is a concrete bridge with two 35-ft. arches, and at other small streams

cement as packed by the manufacturers being taken as a cubic foot, and the sand and stone measured loosely, the stone to be broken to pass a 1½ in. screen.

The concrete was put down in layers of 4 in. to 5 in. in thickness and thoroughly rammed until water appeared on the surface.

WATERWAY AT BATAVIA

are arches of from 10 to 15 ft. span. Views of several culverts and cattle passes are shown in the half-tone engravings.

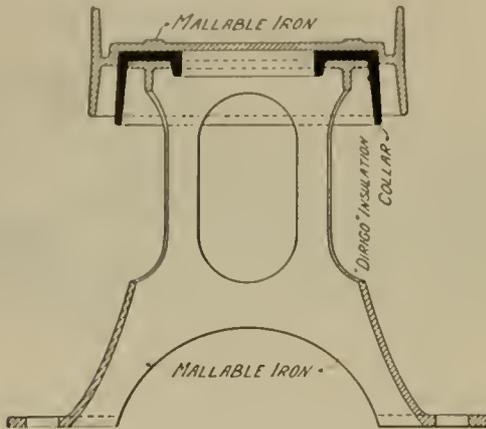

The specifications under which the concrete work was done provide for three grades of concrete, the composition and uses of which were as follows:

DOUBLE-BOX CULVERT AT BELLEWOOD.

In order to get into Chicago with the Aurora, Elgin & Chicago line it was necessary to cross several steam railroads at points where it was impracticable to separate the grades: At Forest Home, three miles west of 52nd St., the Wisconsin Central, Chicago, Great Western and Chicago Terminal Transfer roads are

crossed, about ten miles west of Maywood there is crossing with the Chicago Junction road and at South Elmhurst with the Illinois Central. These three crossings are protected by interlocking signals, with derailing switches in both the steam and electric lines. The derailing switches are of the lifting type which leaves the track rails

GONZENBACH THIRD-RAIL INSULATOR—ONE-THIRD SIZE.

unbroken, this being effected by having the derailing points thrown into a position on top of the service rail; the derailing switches and split switches were made by the Morden Frog & Crossing Works, Chicago.

At intervals of four miles there are cross overs with lights. The turnouts all have spring frogs.

The right of way is all fenced with the American Steel & Wire Co's. woven wire fencing, 55 in. high with 11 wires. The posts are of cedar, 8 ft. long, with 6-in tops, set 3 ft. in the ground; they are spaced 16½ ft. apart.

The eastern terminal of the road where passengers are transferred to the Metropolitan West Side Elevated Railway, of Chicago, is shown in one of the line drawings. The Metropolitan company owns a tract of land at W. 52d Ave. on which it has constructed a

inside the loop gives the means of ingress and egress to passengers without their crossing any of the tracks, these being fenced in. The Metropolitan has built inspection pits and storage tracks as indicated on the plan.

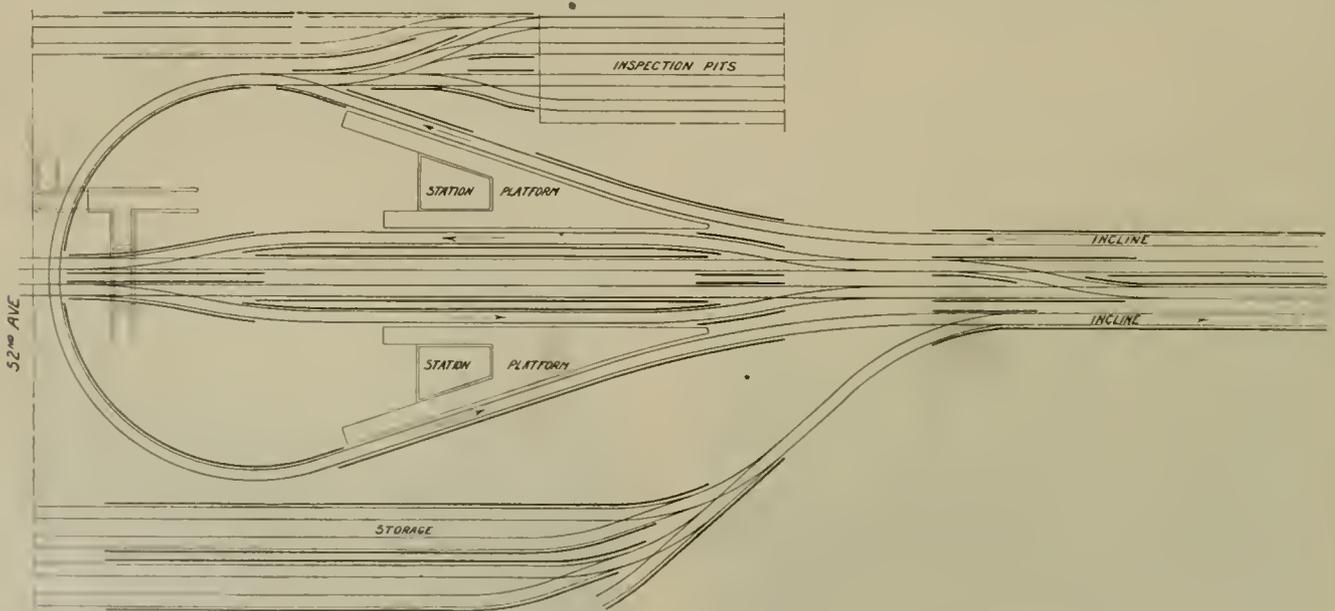

In connection with this terminal, there has recently been completed an interesting piece of engineering work that is quite out of the ordinary. When the Metropolitan incline, which is a double track deck structure with four lines of plate girders, supported on transverse plate girders which rest on two rows of steel columns, was built it was necessary to make a reverse curve at the east end because the necessary rights of way for a straight track could not be secured at that time. The girders carrying the curves, however, were designed for the straight line location to which it was intended

CROSSING AT INDIAN CREEK, NEAR AURORA.

to shift the structure ultimately, and extra plates spliced to the girder ends for temporary use.

Fortunately the Metropolitan company secured the needed rights of way and was enabled to move the incline before it was used for regular traffic. The work of moving was undertaken July 25th and completed Aug. 8th; it was done by contract under the direction of

TERMINAL AT 52D AVE.

Loop and connecting track Metropolitan Road. Central tracks—Aurora, Elgin & Chicago Ry.

terminal loop at grade, the elevated structure being reached by an incline extending between 48th Ave. and 52d Ave. The Aurora, Elgin & Chicago double track line crosses the Metropolitan loop at grade, the platforms for transfer of passengers being located within the loop and between the tracks of the two roads used for the same direction of traffic. A subway with stairs leading to the sidewalk in 52d Ave. and to each side of the Aurora, Elgin & Chicago tracks

Mr. W. S. Menden, chief engineer of the Metropolitan. The three spans of the reverse curves mentioned were cut apart for removing the extra plates referred to and shifted separately. The rest of the incline, comprising 19 full spans, was moved as a whole.

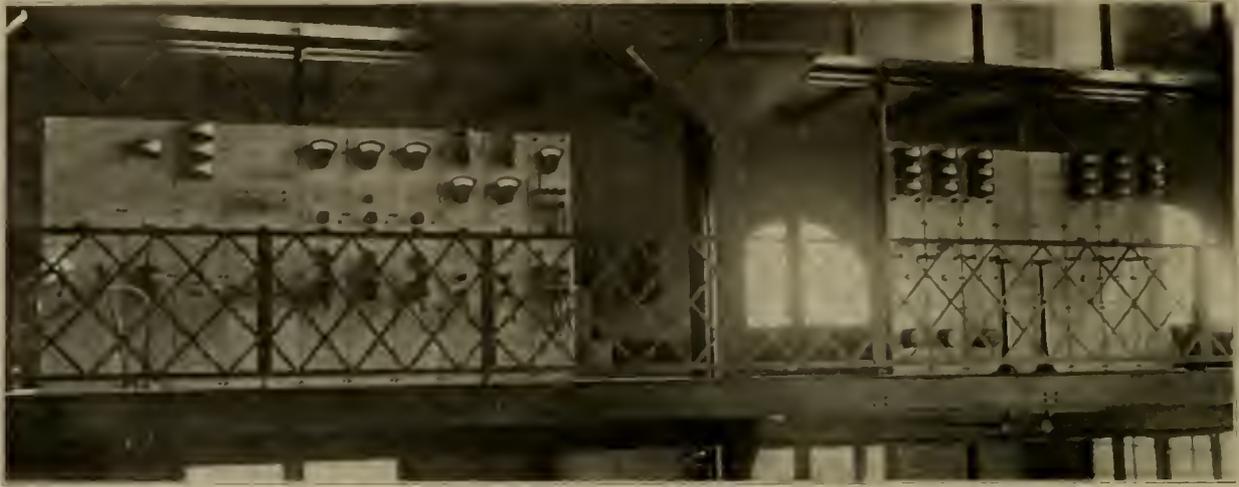

In moving the structure was first jacked up some 18 in. to clear the pedestal anchor bolts and a blocking of 6 and 8 in. timbers was then built between the old and the new pedestals; two lines of 80-lb.

ance, it is constructed of Illinois buff brick with white stone foundations and trimmings, the building, including the coal storage, being 202 ft. 4 in. x 160 ft. 6 in. The engine and generator room measures 109 ft. 6 in. x 83 ft. 5 in. and the boiler room 108 ft. 2 in. x 49 ft. 0 in. The stack is placed at the center of the length of the boiler room with one wall flush with the wall separating the boiler

distribute the power. This plan of arranging the machinery is a most logical one as it permits of additions at either end of the apparatus at present installed without derangement of the general plan that is followed out.

By reference to the half-tone illustrations and the line drawing showing the station in section it will be seen that coal trains may

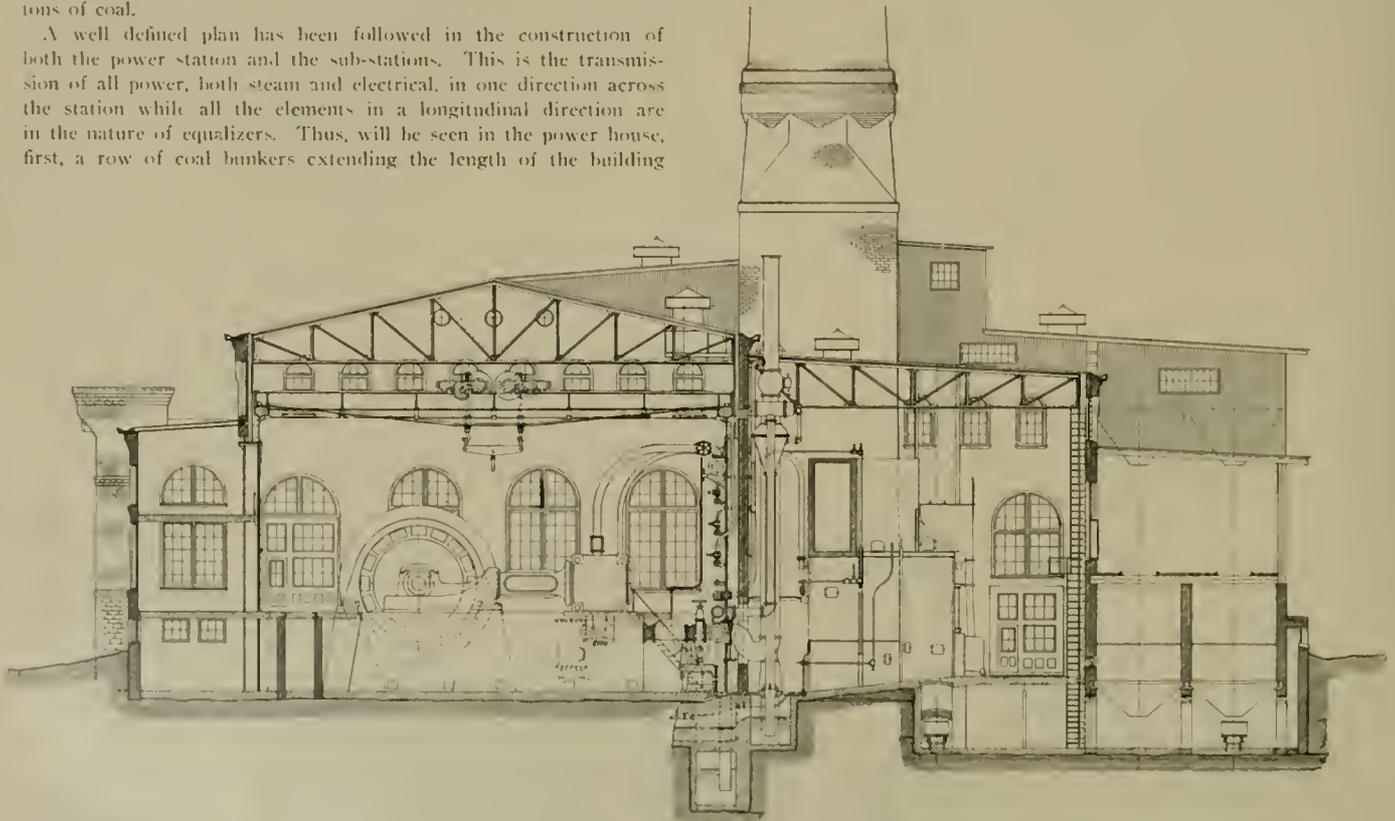

SWITCHBOARD GALLERY IN POWER STATION.

room from the engine and generator room. The coal storage is 25 ft. wide inside the walls and extends the entire length of the building and is divided by brick walls into 18 compartments in the bottom of each of which are two steel hoppers. Each of the 18 bunkers has a capacity of 3,771 cu. ft., and is designed to hold 100 tons of coal.

A well defined plan has been followed in the construction of both the power station and the sub-stations. This is the transmission of all power, both steam and electrical, in one direction across the station while all the elements in a longitudinal direction are in the nature of equalizers. Thus, will be seen in the power house, first, a row of coal bunkers extending the length of the building

be run over the bunkers and the contents dumped. In the basement, under the coal bunkers and boiler room, there are tracks of 20-lb. rails laid to 2 ft. outside gage, over which are run small cars of about 1 ton capacity for transferring coal to the boiler bunkers. The space between these track rails is filled with concrete so that

CROSS SECTION OF POWER HOUSE, BATAVIA.

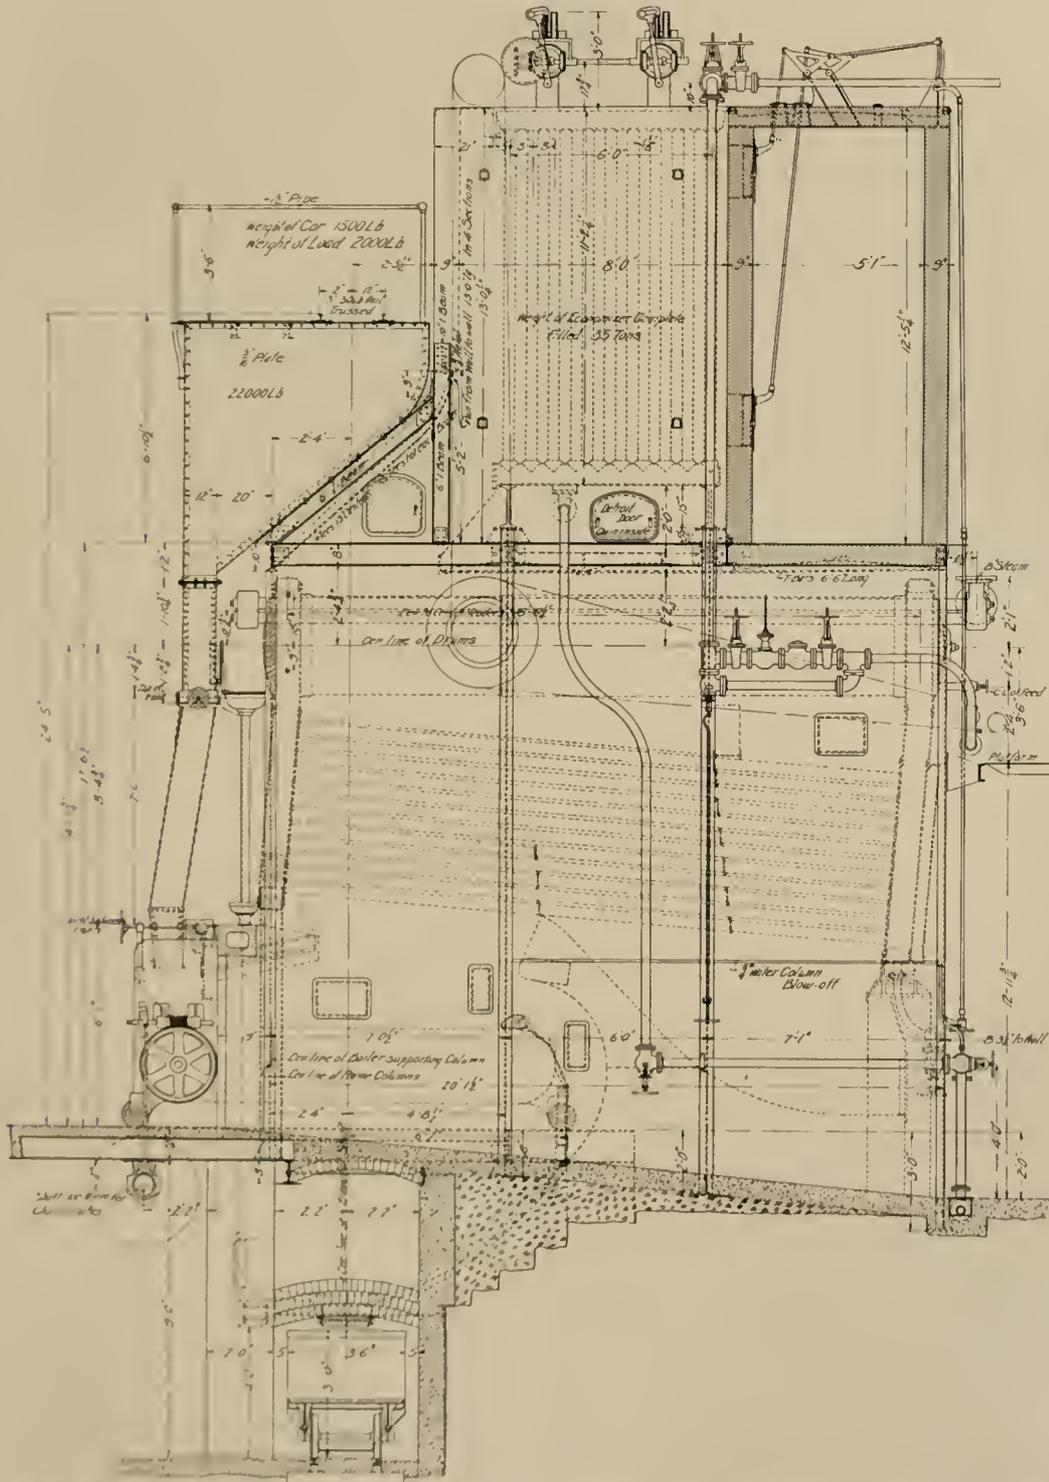

and parallel to these are the boilers. Then comes the steam piping for the entire plant suspended on the partition wall between the boiler and engine rooms. The next row of machinery consists of pumps and auxiliary apparatus followed by the engines, then the dynamos and lastly the transformers, oil switches and cables which

there is no chance for dirt to accumulate and a better footing is afforded for the men handling coal. Two transverse tracks at the center of the building lead to two elevators located in front of the stack on which the loaded cars are lifted to a longitudinal track running above the boilers. In front of and over each boiler is a

steel bunker holding from 5 to 7 hours' supply of coal, the coal being fed down through chutes to the furnaces.

A track in the basement under the boilers permits the small cars to be loaded with ashes, and they are then run to the elevators and lifted to the level of the bottom chords of the roof trusses and run out to ash hoppers, located above the coal tracks. From these

three more are in course of erection. These are all water tube boilers with 4,500 sq. ft. of heating surface and 500 sq. ft. of superheating surface each, and were built by the Edge Moor Iron Co., Edge Moor, Del. A novel feature of these boilers is the front, which on each consists of a single Kinnear rolling steel door; this arrangement of front is particularly desirable in this station where the chutes from the coal bunkers above the boilers would seriously interfere with the opening of doors of the ordinary type.

SECTION SHOWING ARRANGEMENT OF BOILER UNIT—MCKENZIE FURNACE—EDGE MOOR BOILER—GREEN ECONOMIZER.

hoppers ashes may be dumped directly into freight cars and hauled away.

The exterior of the coal storage shelter is of steel, lattice at the top, and sliding doors in the middle.

The boiler room is designed for 10 boilers of 500 horse power, nominal rating, of these five have been placed in operation and

Each boiler has 234 tubes 4 in. by 17 ft. 4 in., the headers being 18 ft. 10 1/4 in. between centers as measured along the center lines of the drums of which there are three, each of 30 in. diameter.

Each boiler has a McKenzie traveling grate with effective area 11 ft. 8 in. long by 11 ft. wide. The arch over the front end of the furnace is of special bricks with longitudinal grooves on the sides which fit to bars of bulb section bolted to a cast iron box girder shown in end view in the line drawing of the boilers.

Each boiler is equipped with a Green fuel economizer, which is located immediately above the center of the boiler. This arrangement, which is different from that in any other installation made by the Green Fuel Economizer Co., makes the economizer practically a part of the boiler, as the gases pass directly into the economizer and on leaving enter the smoke flue. Each economizer is fitted with an automatic scraper which is driven by an electric motor. Each economizer has 2,600 sq. ft. of heating surface, and a water capacity of 20,000 lb.

All the boilers are fitted with Morris patented blow-off valves arranged for use as a combined wash-out and emergency valve. A feature of this valve is the making of the body and cap joints with flanged, tongued, and grooved joints, held together by two swivel eye-bolts made fast to the body of the valve; this arrangement permits the cap and stem to be easily removed when cleaning out the boilers or re-seating the valve.

The entire station has its foundation on rock and for the stack foundation it was only necessary to put in concrete footings extending to a depth below the lowest level of excavating necessary for waterways. This footing is about 15 feet deep.

In section the stack is square up to a few feet above the roof of the station, above which point it is circular. The square portion is of stone and the rest brick. The bottom is 23 1/2 ft. square outside

with walls 36 in. thick, at the top the outer diameter is 13 ft. 2 in. and the internal diameter 11 ft. The inner wall is of brick, 12 ft. internal diameter at the smoke flue entrance and 11 ft. above that point. At the base the inner wall is 17 in. thick and at the top 4 in.; it extends for 150 1/2 ft., and for the first 72 ft. the inner course, 4 in. thick, is of fire brick. The flue openings are oval 5 ft. 6 in. x 12 ft. 6 in. inside. The height of the stack above the grates is 222 ft.

Back of the boilers are two 30-in. Worthington elevated condensers, one in each end of the station. Condensing water flows from the river in concrete lined conduits which extend through the station as shown in the sectional view.

The pumps are placed in a light well extending the entire length of the engine room and are all in full view from the engine room floor. The pumps which will ultimately be installed include the following apparatus, which is arranged symmetrically. Starting at the stack and proceeding in either direction there will be:

One 18 x 18 in. Worthington dry vacuum pump direct driven by a 15-h. p. motor.

One 8 x 10 in. Worthington triplex feed pump driven direct by a 35-h. p. motor.

One 10 x 6 x 10 in. Worthington duplex steam pump.

Two 10 x 15 in. Worthington triplex circulating pumps each direct connected to a 35-h. p. motor.

This arrangement gives one electric driven circulating pump for each of the four large generating units, two electric and two steam driven feed pumps, and two dry vacuum pumps.

All the pump motors are designed for 125-volt current and were made by the Akron Electrical Manufacturing Co., of Akron, O.

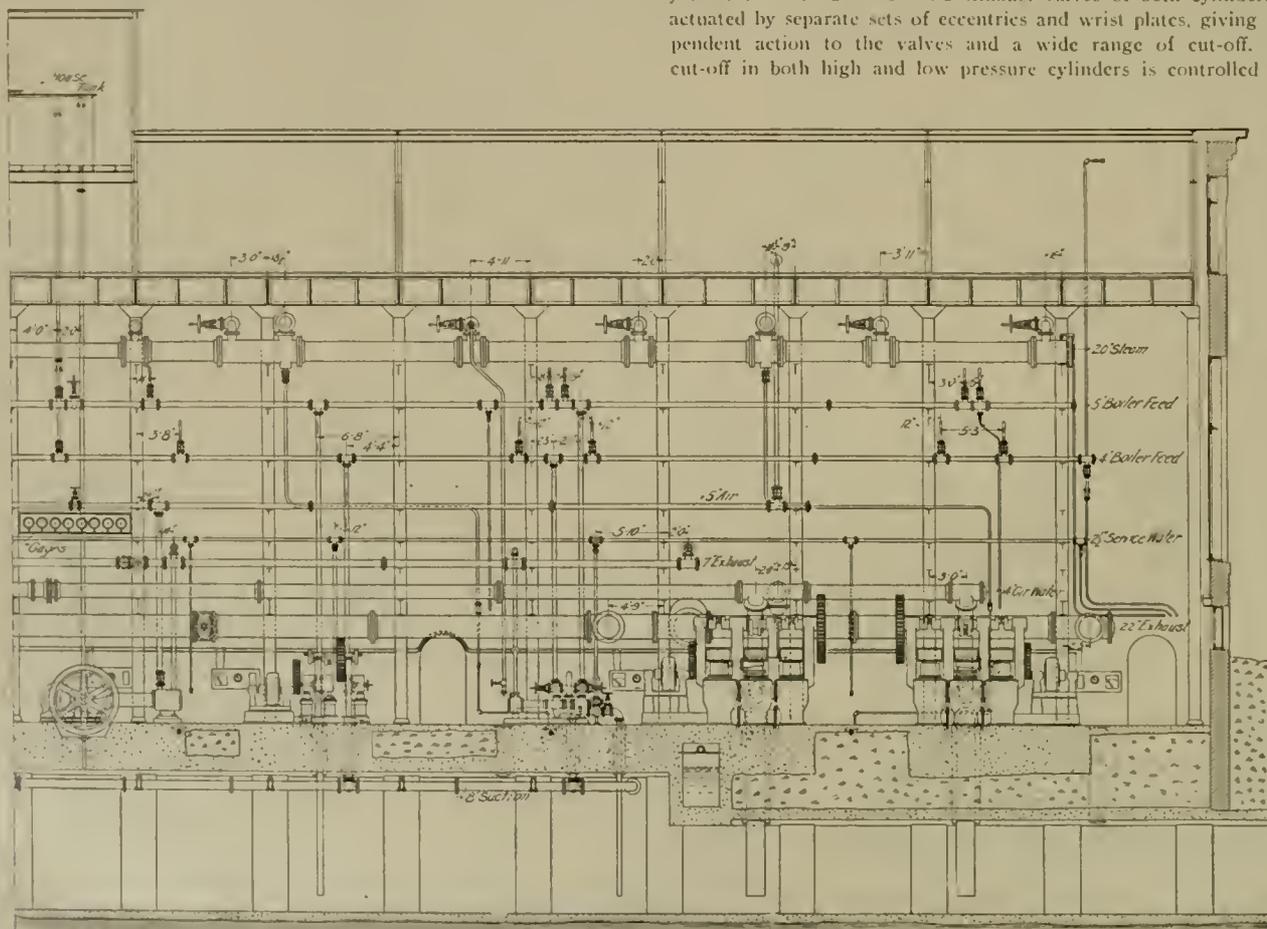

The station was designed for four main generating units, two of which are in operation and the third in process of erection. Each

cylinders are 32 and 64 by 60 in., and the engine has a normal rating of 2,200 h. p. running 75 revolutions per minute under 150 lb. initial steam pressure, with 50 per cent overload capacity. The shaft is of hammered wrought iron and is 27 in. in diameter between the bearings which are 23 in. in diameter by 46 in. long, and water

PUMP WELL.

jacketed. The admission and exhaust valves of both cylinders are actuated by separate sets of eccentrics and wrist plates, giving independent action to the valves and a wide range of cut-off. The cut-off in both high and low pressure cylinders is controlled by a

FRONT ELEVATION OF PIPING ON PARTITION WALL.

of these units comprises a horizontal cross-compound engine of the corliss type direct connected to a 1,500-kw. General Electric generator. The engines which were built by the C. & G. Cooper Co., of Mt. Vernon, O., are necessarily massive in design, but they are at the same time very symmetrical and graceful in outline. The

single governor of the fly-ball type, and close speed regulation and proper operation of the alternators in parallel are guaranteed. A second or supplementary governor is placed on the high pressure side of each engine to operate a quick closing valve in the main steam pipe should the speed for any reason increase 8 or 10 r. p. m.

above normal. A feature which gives a very neat appearance to the engines is the heavy base plate extending over the entire width of the engine foundations under the guide barrels and cylinders, including the dash pots. These plates join with the extended webs at the base of the main bed plates, and are provided with oil channels and heavy beaded edges which unite conveniently with the floor of the engine room. The fly wheels are 22 ft. in diameter, of the segment or built-up type, and weigh 160,000 lb. each.

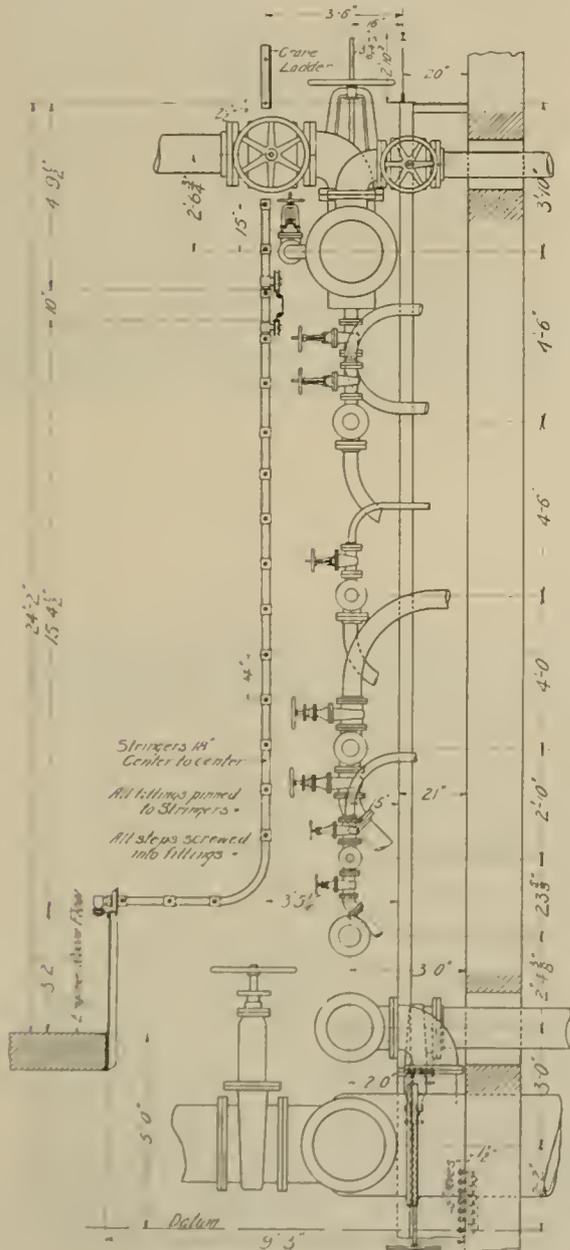

The generators of the main units are General Electric three-phase alternators, type A-T-8 rated at 1,500 kw., the rated output of each phase being 377 amperes at 2,300 volts, when running at 75 r. p. m.

For supplying current to the motors driving the auxiliary apparatus there are two engine driven motor units each consisting of a 14½ x 15 in. simple engine direct connected to an 8-pole 125-volt 160-kw. generator, and a motor-generator set comprising a 300-kw. induction motor and a 125-volt 300-kw. generator. These engines

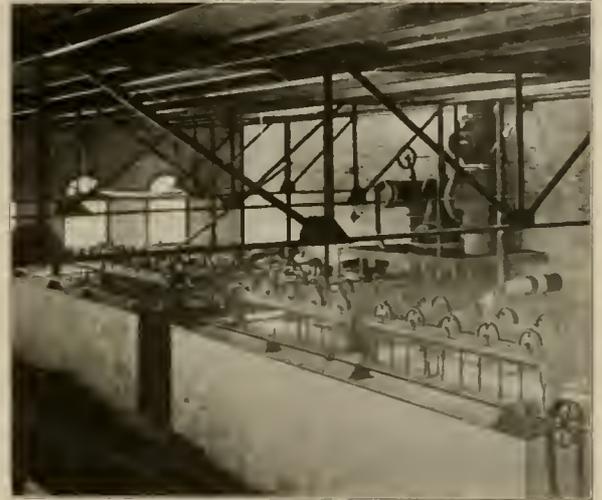

each, which for large weights are hooked to the extremities of a yoke and thus enabled to work together. From the power station plan it will be remarked that a track some 45 ft. long has been laid into the building so that loaded cars may be run in where the crane can be used for handling heavy weights.

The transformers, line switches and blowers are arranged symmetrically along the outside side wall of the generator room, the switchboard being placed in a gallery overhead.

The piping for the plant is, so far as possible, all placed on the engine room side of the wall separating the boiler and engine

SECTION OF PIPING.

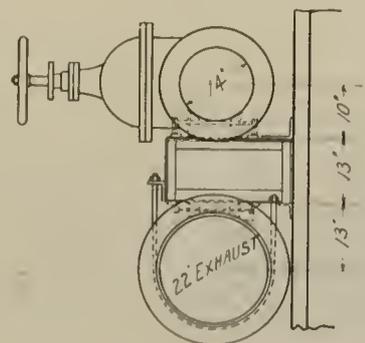

BOILERS FROM ABOVE.

rooms. Supported on suitable brackets which are furnished with rollers capable of adjusting the position of the pipe vertically and laterally, are eight mains arranged in the following order from top to bottom:

- 20-in. steam header, with 14-in. valve.
- 5-in. boiler feed main.
- 4-in. general water main.
- 5-in. dry vacuum main.
- 2½-in. service water main.
- 7-in. exhaust main.
- 14-in. condenser water main.
- 22-in. exhaust vacuum main.

The arrangement and connection of these headers are shown in the front elevation of the piping and by the section, which also shows the pipe leads and traveling ladder by which access to the piping is had. Each main is divided into two sections by a valve placed near the center of its length, and each section of the 16 sections thus formed is piped to a gage on the centrally located board. The front elevation shows eight of these gages, the other

DETAIL OF PIPE BRACKETS.

were built by the Phoenix Iron Work Co., of Meadville, Pa.; the generator are all General Electric.

The station design contemplates three 500-kw. rotary converters, which will make a sub-station equipment in the main plant.

The engine room is served by a 50-ton crane built by Alfred Box & Co., of Philadelphia. The crane has two hoists of 25-ton capacity

eight being on the left of the center line. The piping contract was let to the Crane Co., Chicago.

The station apparatus is supplied with oil by a Siegrist lubricating system, the pumps for which are located on the engine room floor opposite the stack, and the storage tanks in a room in the corner of the basement. In the oil room are two engine oil tanks, 3 ft. in

EXTERIOR OF POWER STATION.

diameter by 8 ft. long, and four cylinder-oil tanks, 2 ft. in diameter by 8 ft. long, two for high pressure and two for low pressure cylinder oil. Over these tanks is a wooden trough wide enough to receive two rows of oil barrels which are rolled into position, tapped and the tanks filled through funnels.

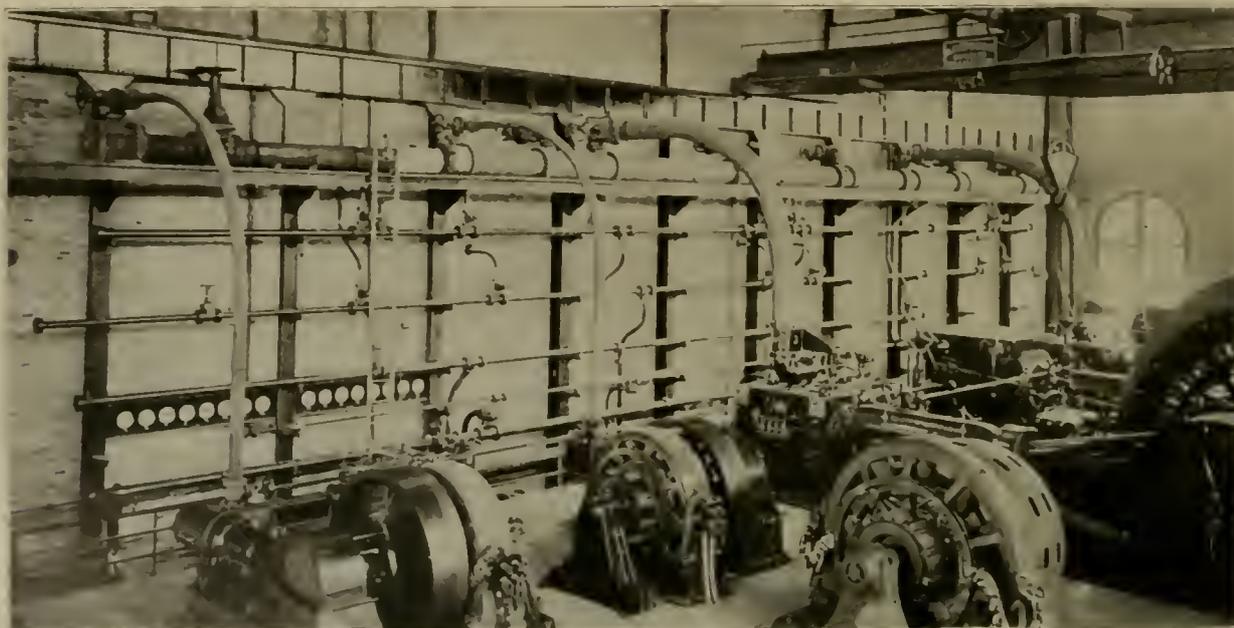

Connections from the house water tank are piped to the bottom of the oil reservoirs and the piping and valves are so that either one of the tanks for each kind of oil can always be in service. To provide against loss of pressure on the oiling system by reason of the temporary demands on the service system an air reservoir is provided in the oil room in which air is compressed to the service

Mr. Morris has arranged an ingenious device for indicating the water level in the tanks without using the gage glasses, which are liable to become broken, with a resulting "muss" in the oil room. Through the blank flange closing the hand hole in the end of the tank is placed a shaft having a suitable handle on the outer end and a section of small pipe on the inner end, placed radially; a hole is bored through this shaft and the outer end closed by a pointed screw which acts as a valve, and when opened established communication between the pipe mentioned and a passage in the lower side of the flanged joint through which oil or water appears,

BOILER ROOM FROM FLOOR.

according to the position of the free end of the radial pipe. A graduated scale indicates the amount of oil in the tank when the pipe has been rotated from a down-hanging position upwards until oil instead of water appears at the opening.

GENERAL VIEW OF PIPING IN MAIN STATION.

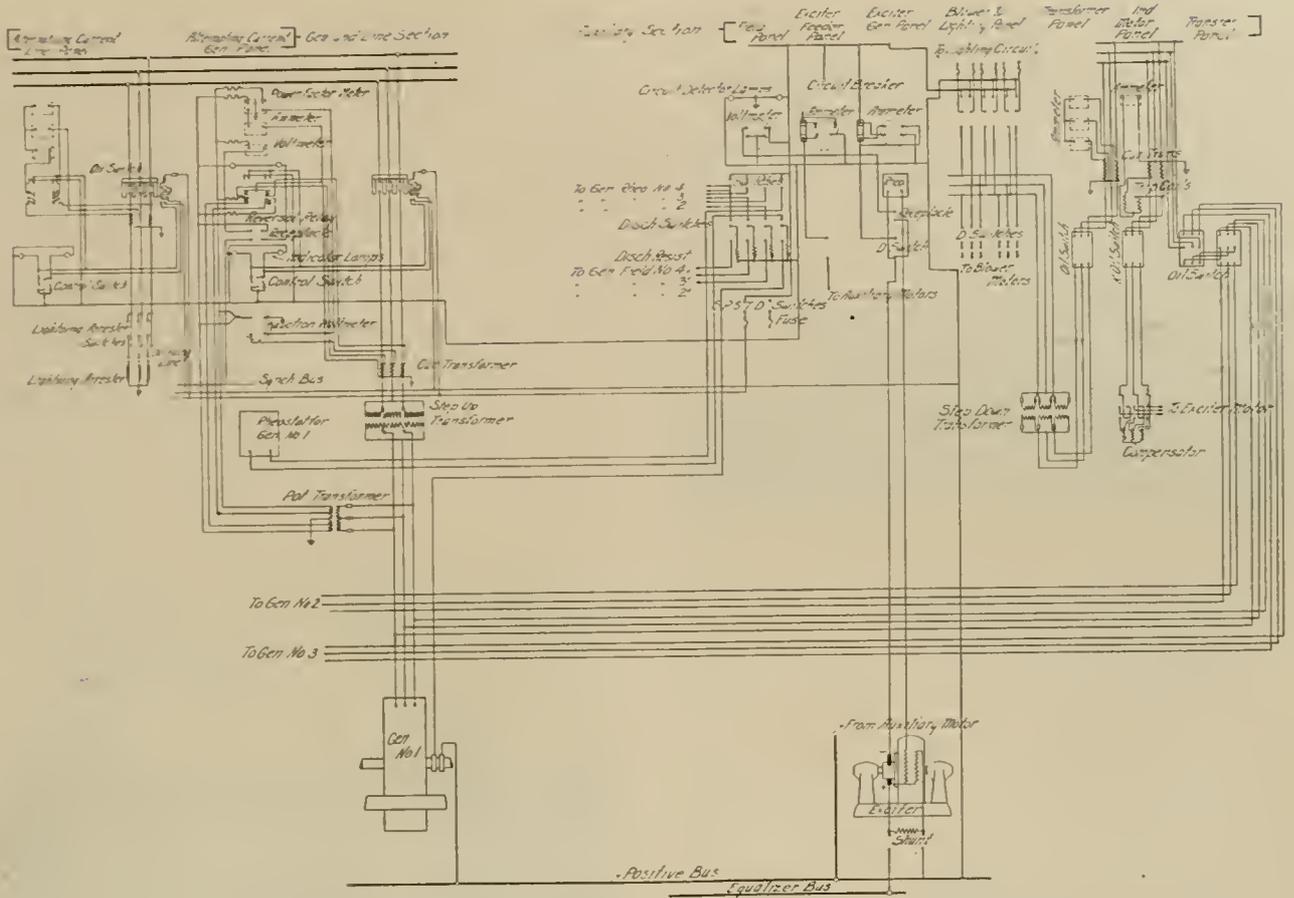

main pressure, and in case the latter is temporarily reduced check valves close and the reservoir comes into action and supplies pressure for distributing the oil.

After use the engine oil is passed through Burt "Cross" oil filters and returned to the tank.

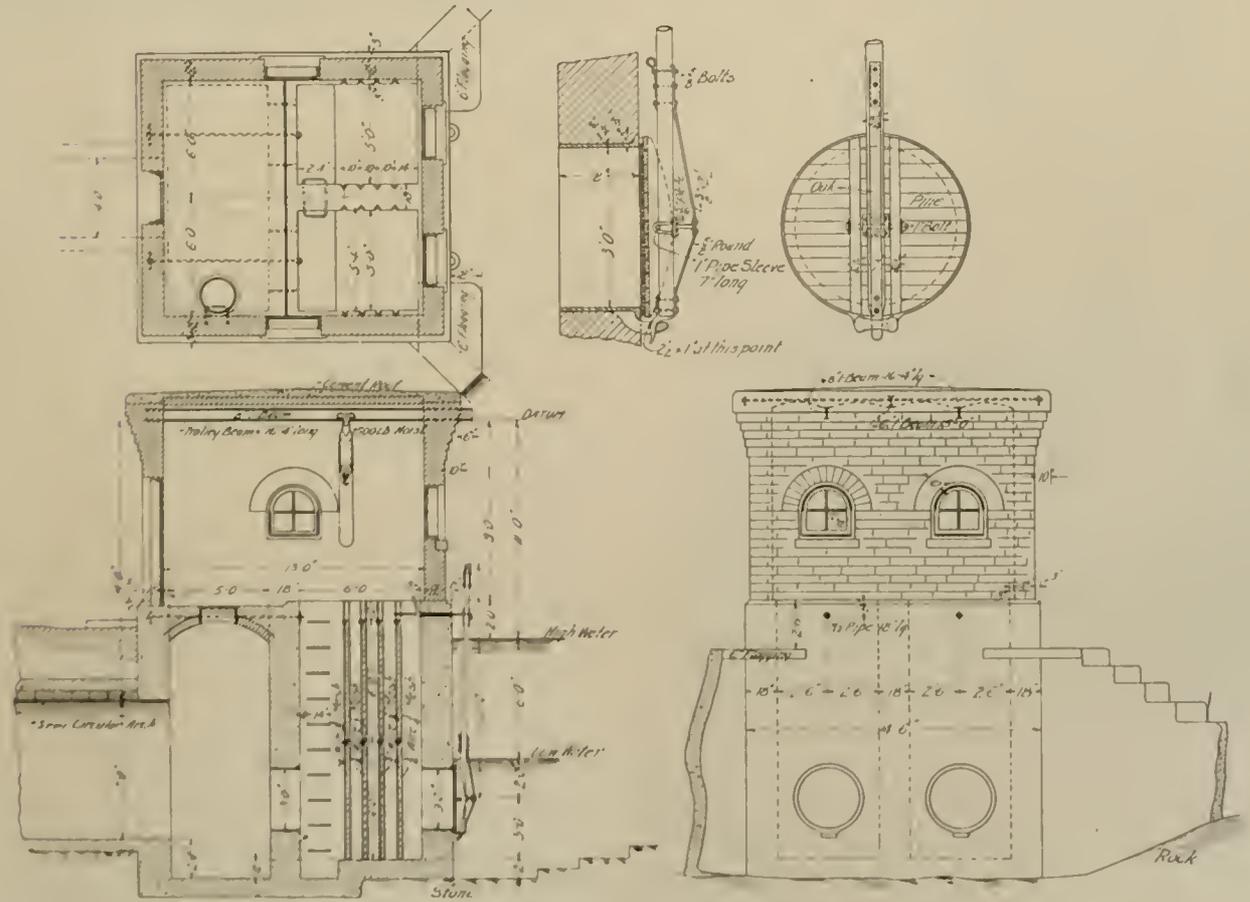

In the centers of the heads of the oil tanks (which are horizontal)

In this station there are an exceptionally large number of ingenious devices and interesting details, a number of which are shown in the accompanying drawings.

The water supply for the station is taken from the Fox River through a small gate house situated on the river bank. An elevation, a plan and section of this house are shown in one of the

WIRING DIAGRAM, MAIN POWER STATION, AURORA, ELGIN & CHICAGO RY.

SCREEN HOUSE AT RIVER END OF CONDENSING WATER TUNNEL.

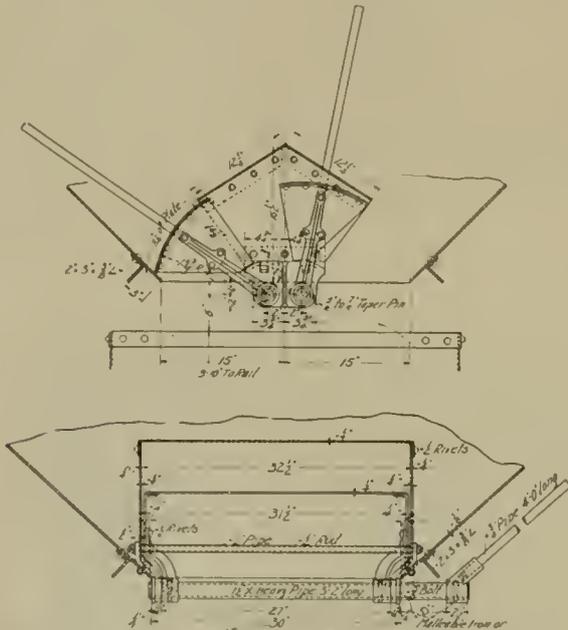

illustrations. The lower part of the house which is built of concrete contains three chambers separated from each other by means of concrete walls. The water enters the two front chambers by means of two circular gates near the lower part consisting of

EXTERIOR VIEW OF POWER HOUSE SHOWING COAL STORAGE.

cast iron pipes with a lug at the bottom for fastening on the cover when it is desired to shut off the water.

On entering these chambers the water passes through four screens with meshes of  $\frac{3}{4}$  in.,  $\frac{5}{8}$  in.,  $\frac{1}{2}$  in. and  $\frac{3}{8}$  in. successively. It then passes through two gates in the partition wall of the same style as

DETAIL OF HOPPER VALVE IN COAL STORAGE BINS.

on the outside wall and which are located in direct line with the former.

From the second chamber water is carried to the water way under the pumps by means of concrete lined semi-circular arches 7 ft. in height. When it is desired to clean out the screen chambers the water may be shut off by means of covers shown in detail in the illustration. These covers are made of pine wood and are circular in shape to fit the gate casting in the concrete walls. Between the casting and the wooden cover is a ring of rubber of 1 sq. in. section which presses against the seat of the casting so as to exclude any water from passing.

Two parallel vertical ribs of oak extend across the cover between which the handle for fastening the cover is hinged at the center of the cover by means of a bolt running through the ribs. On the lower end of this handle is a horn which fits into the lug at the bottom of the gate casting. This handle is long enough to extend above the high water mark of the river and its upper end is fastened by a strap set in the face of the building. By drawing

up this handle to the face of the building by means of the strap the cover is forced tightly against the face of the gate casting, excluding all water.

By covering the outside and inside gate of either screen chamber the latter may be pumped out and the screens cleaned or repaired. In the upper portion of the building two horizontal I-beams are suspended over the center of each screen chamber on which a carriage travels carrying a block and fall. By means of the latter the screens may be removed or replaced in position.

Transmission Lines.

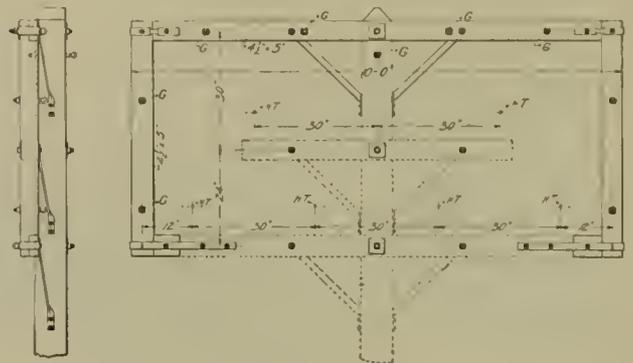

There are six sub-stations located as shown on the map. The high tension feeders are there indicated by broken lines, and it will be noted that there are two lines leaving the main station at Batavia, one following the railway to Sub-station No. 2 at Warrenville and thence to No. 3 at Lombard, and the other running across country to No. 5 and thence to Lombard. These two lines are of aluminum cables of carrying capacity equivalent to No. 00 copper wires. From the main station at Batavia to Sub-station No. 1 at Aurora, from No. 5 to No. 6, and from No. 3 to No. 4, other high

STRAIN TOWER AT SUB-STATION.

tension feeder lines are indicated; these are of aluminum cables, equivalent to No. 2 copper.

The high potential lines are carried on 40 ft. poles with 7 in. tops, which are placed 80 ft. apart. The cross arms are  $4\frac{1}{2} \times 5\frac{1}{2}$  in. in section spaced 24 in. between centers vertically, the upper arm designed to carry two insulators, 60 in. between centers, and the lower arm to carry four insulators, 60 in. between centers, thus providing for duplicating the present feeder system when the demand for it shall arise. The insulators are the Locke No. 117, side and top groove triple petticoat, 7 in. in diameter and  $4\frac{1}{2}$  in.

GUARD FRAME.

high, of glass, made by Fred M. Locke, Victor, N. Y.; these are designed for a working pressure of 30,000 volts. The high tension wires are transposed every mile.

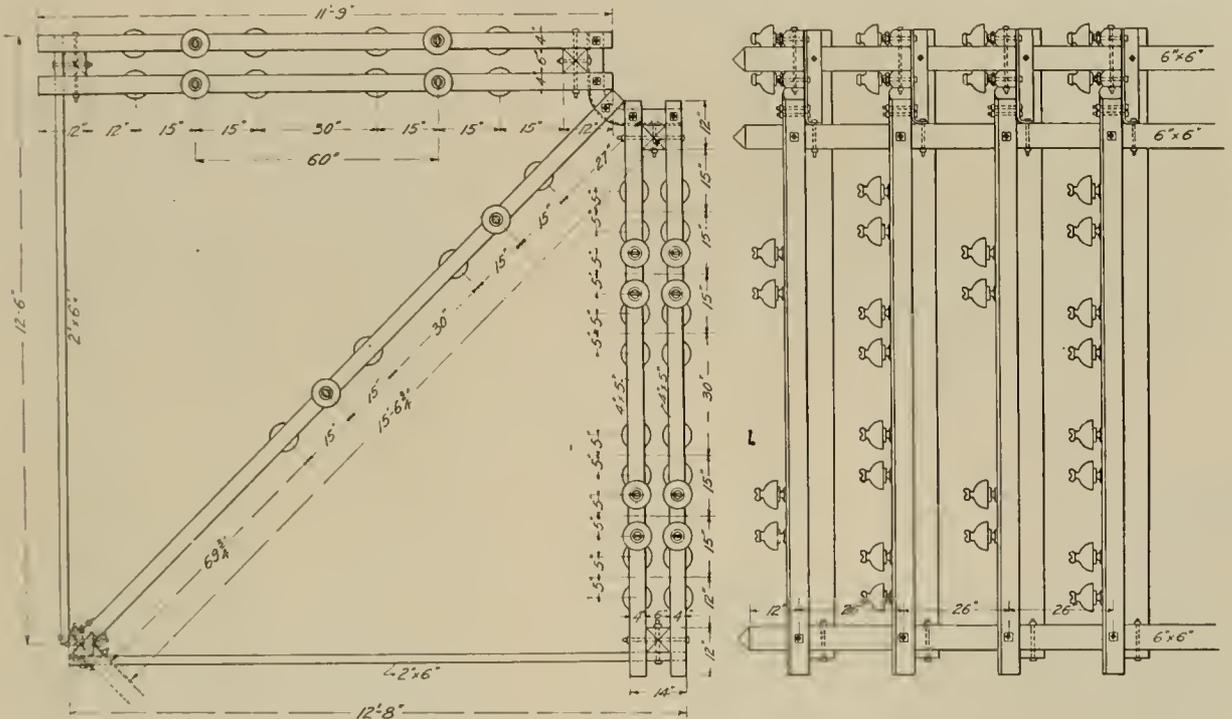

Telephone wires are carried on cross arms about 7 ft. lower on the poles; these wires are transposed at every fourth pole. There

are two complete telephone circuits, one intended for the use of the train dispatcher and one for the general business of the company; but the dispatcher may interchange the systems. Telephone booths are placed at all switches and crossovers and, of course, in the sub-stations. At intervals of about 1,000 ft. wires are brought down the poles for connecting to telephones carried in the cars. A complete bridging telephone system was furnished by the Garl Electric Co., Akron, O.

All the poles are numbered, figures about 2½ in. high being used. Numbers alone are used between Chicago and Wheaton; on the

Sub-Stations.

The six sub-stations are located so that they form convenient centers of distribution. The continuous current produced at the sub-stations is fed directly into the third rails so that all direct current feeders are done away with. Outside of the sub-stations the only cables used are for connecting the ends of the third rail at streets and grade crossings with other railroads. The sub-stations are numbered from one to six and are located as follows: No. 1, at Aurora; No. 2, Warrenville; No. 3, Lombard; No. 4, Maywood; No. 5, Engleton; No. 6, Clintonville.

PLAN AND ELEVATION OF TOP OF STRAIN TOWER.

Wheaton-Aurora branch the letter "A" is used in addition, and similarly "E" on the Elgin branch, "B" on the Batavia branch and "Y" on the cross-country transmission line.

One of the line drawings shows the standard guard frame for high-tension lines, and in the front elevation the cross-arms and braces for the high tension feeders are shown dotted, the centers of the three-phase wires being also indicated by the letters H T. The top of the guard frame is formed by a cross arm 4½ x 5 in. x 10 ft. and bolted and braced to the top of the pole; side pieces of same section are gaged and bolted to the top piece and to 12-in. lengths of the same section at the bottom. These blocks are in line with the lower cross arm to which they are spliced by 1¼ x 1¼-in. iron U straps. Adjacent poles carrying guard frames are connected by eight 7-strand galvanized steel cables which are fastened to eye bolts of ¾-in. round iron located at the points marked G in the drawing, and a ninth which is fastened to an eye-bolt through the pole. The guard wires are 21 in. between centers. The drawing also serves to show the cross-arm braces which it will be noted are twisted near the bottom and fastened to the side of the pole with two lag screws instead of being fixed to the front with but one screw or bolt.

Wherever the Aurora, Elgin & Chicago feeder lines pass under telegraph or telephone wires, guard frames are placed on the poles of the railway line and guard wires stretched. The guard wires are placed sufficiently close together so that it is not expected that a wire falling upon them can reach the high-potential circuits; but all the guard wires are grounded so that in case of such an accident the worst that can happen is the grounding of the railway circuit.

This construction is contrary to the usual practice, but the railway company believes that the use of a strongly built guard and passing underneath other circuits is preferable to introducing a weak place in the line by using taller poles and carrying its wires above the wire lines it has to cross.

The electrical equipment of all the sub-stations is practically identical, but the buildings are constructed according to two different plans, one plan showing a dispatcher's office, waiting room and platform for passengers, while the other is without these rooms, and contains only the rooms necessary for the electrical equipment. The accompanying illustration shows the general ar-

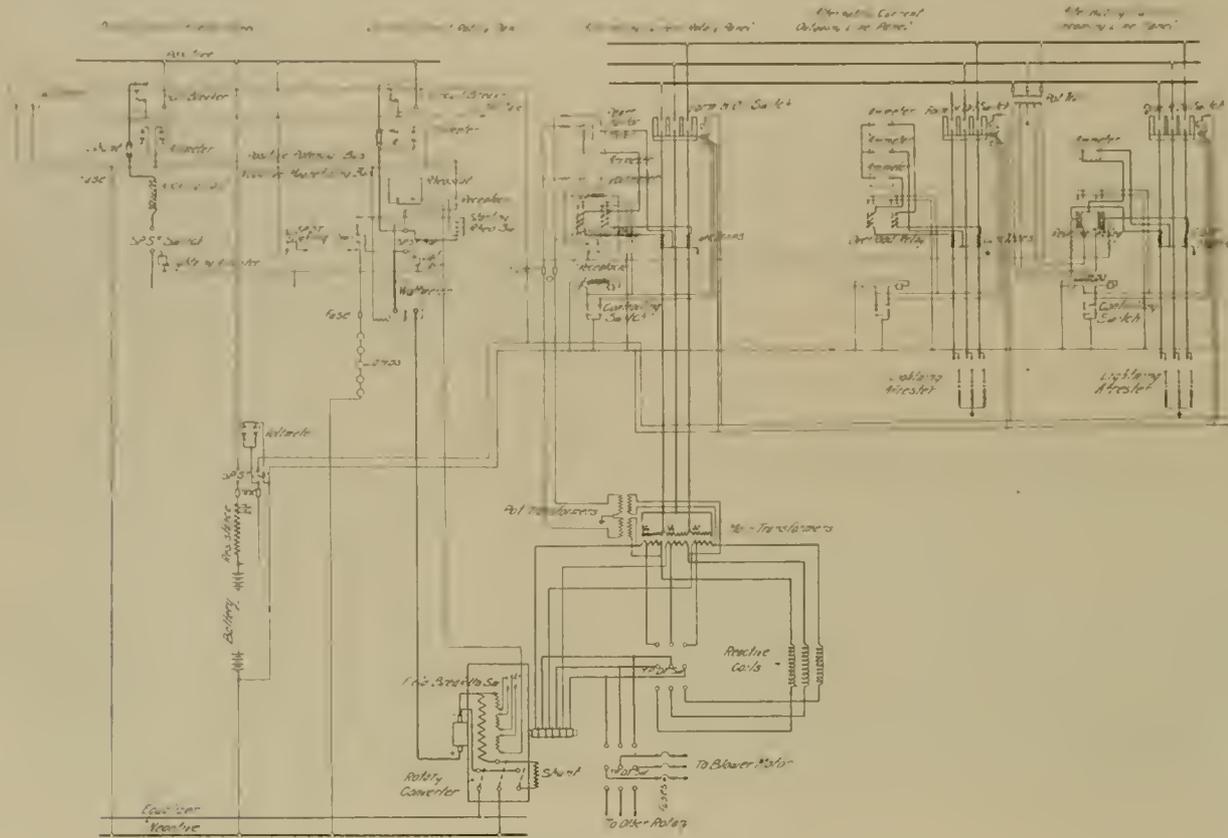

LOMBARD SUB-STATION—"CLIMAX" CATTLE GUARD AND CONDUCTOR RAIL TERMINALS IN FOREGROUND.

angement of the larger sub-stations which are used for passenger stations, and the construction is entirely of brick and stone, making the buildings as absolutely fireproof as is possible. The sub-stations built after this plan are those at Warrenville, Lombard and Maywood; the other three stations are practically the same

with the passenger accommodations omitted. The section in which the machinery is contained is 57 x 30 ft. and consists of a main room, a basement and a loft 12 x 33 ft. into which the high tension overhead lines are brought

In front of each sub-station is a strain structure for taking the

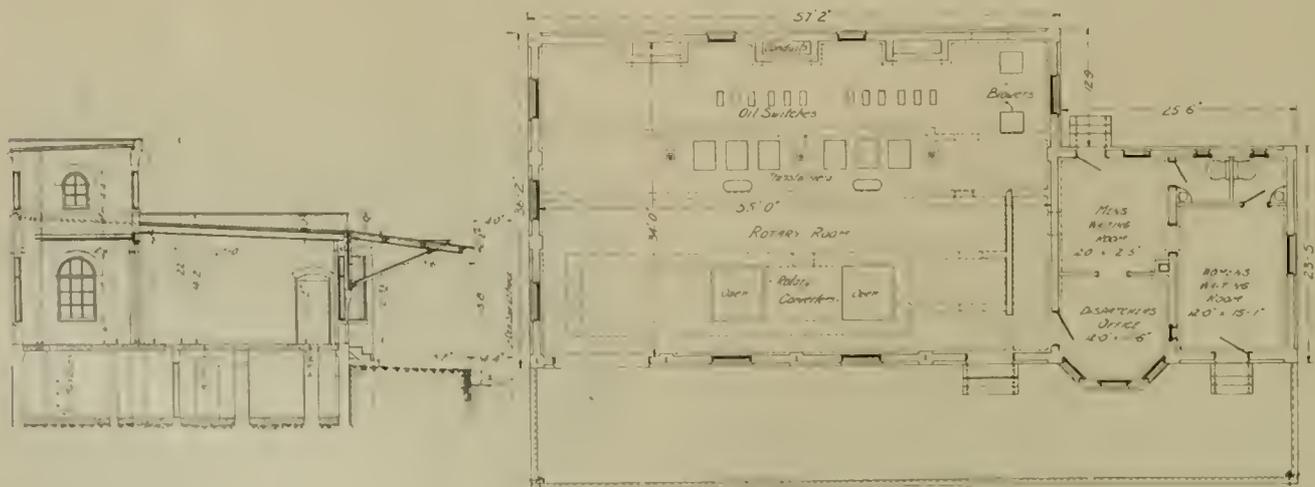

From the strain structure the wires pass into the station loft through special insulating tile and immediately after entering the building are connected to G. E. lightning arresters. The three wires of each circuit after entering the building each connect to large oil switches making two breaks in each circuit, and thence run down to

WIRING DIAGRAM OF SUB-STATION.

strain of the overhead wires before they pass into the sub-station loft. The accompanying illustration shows a working drawing of this structure. Instead of depending upon a single insulator for taking the stress in the direction of the line the insulators are arranged in sets of four. The line cable passes between these and is tied to a yoke made of 8-g-in. iron with the ends slightly bent and

the high tension 'bus bars' in the basement, which are very ingeniously encased in brick conduits which afford almost perfect insulation yet leave all of the wires entirely exposed for inspection. The compartment in the basement which contains these high tension bus bars has iron doors which close hermetically in order to permit a circulation of air under pressure through this chamber.

PLAN AND SECTION OF SUB-STATION WITH WAITING ROOMS.

tied to the insulators. This yoke is secured to the similar yoke on the second pair of insulators by two ties of wire which are twisted until it is apparent that the load is distributed between the two pairs of insulators.

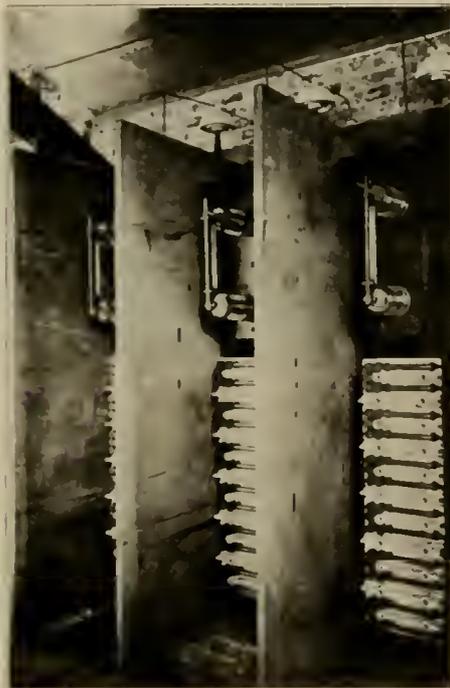

The high tension 'bus bars' consist of No. 2 bare copper wires stretched in a brick and concrete structure erected in the air lock under the transformers, the arrangement being practically the same in the central and the sub-stations. The bus for each branch of the

circuit is located in a tunnel made by placing horizontal partitions of cement concrete between vertical side walls of brick; and the leads to the oil switches and transformers are similarly separated by 4-in. vertical brick walls supported by steel angles at the corners.

It is noticeable that all the sub-station wiring is arranged so that all the wires and cables except those pertaining to the instruments on the switchboard are carried in the basement, and there are no high tension wires or heavy cables to be found in the main room where the machinery is located. This main room contains two General Electric rotary converters type H. C. running at 1,500 r. p. m. These transform alternating current of 25 cycles at 430 volts to constant current at 600 volts. There are six transformers

In the Lombard station from which the illustration is taken are three alternating current line panels for one outgoing and two incoming circuits. These three panels are at the left hand end of the board and the next two panels are used for the alternating current side of the rotary converters.

The diagram of wiring shown herewith will serve to explain the switchboard arrangements of all the sub-stations. The incoming

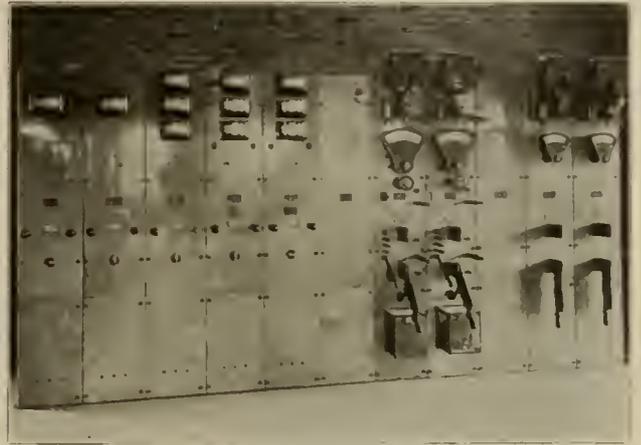

HIGH TENSION LIGHTNING ARRESTERS.

of the A. B. type wound for a primary voltage of 26,400 and a secondary voltage of 430; two reactive coils, type R. C. 48; two Buffalo Forge Co. blowers each driven by a 3 h. p. General Electric induction motor, type I, for furnishing the air for cooling the transformers and the high tension bus compartment in the basement.

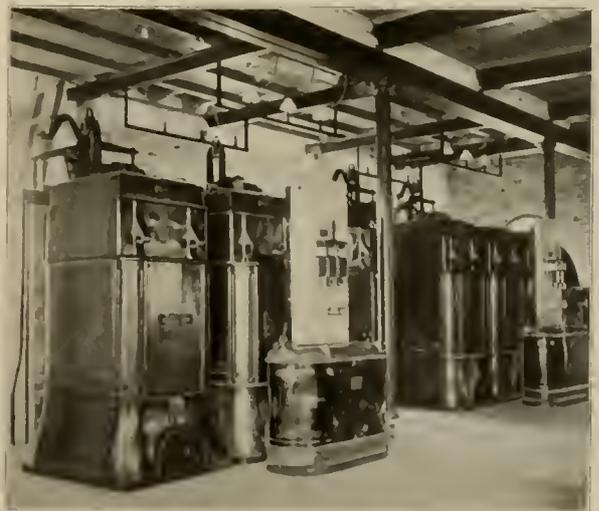

ROTARIES IN SUBSTATION

The accompanying reproduction from photographs of one of the sub-stations shows the relative location of the machinery and the switch board. The latter is arranged in three general divisions which are alternating current high tension line panel, the direct current rotary converter panels and the direct current feeder panels.

SUB-STATION SWITCHBOARD.

line panels each contain one Thompson ammeter, one reversible relay, two signal lamps and a controlling switch for throwing the oil switch which opens and closes the circuit. The oil switch is provided with a motor which operates automatically as soon as the switch has been thrown and which keeps it constantly in readiness

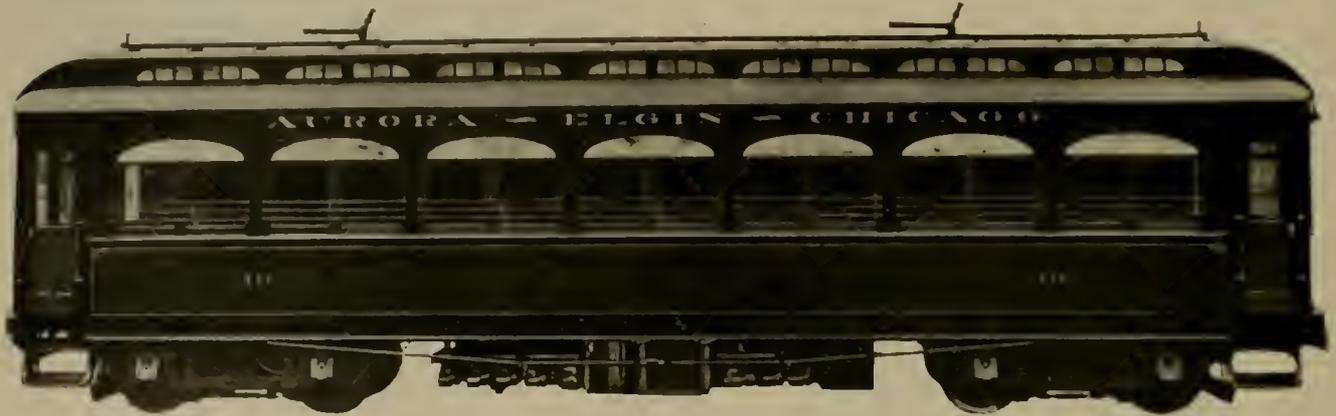

OIL SWITCHES AND TRANSFORMERS.

to be operated by a tripping device which is controlled by a small auxiliary switch at the switchboard. The two lamps above these controlling switches show whether the oil switch is open or closed, one position being indicated by a red lamp and the other by a green lamp. In case the incoming current should tend to reverse the sub-station machinery on account of its higher potential the reversal relay shown in the diagram comes into action. By means of a solenoid it can be adjusted to any required reading. The oil switch is operated if this reading is exceeded, in a similar manner as by the controlling switch. The panel for the outgoing current is similar to the one just described except that it contains an ammeter for each phase of the circuit and in this case a simple overload relay is used in place of the reversal relay on the incoming line. These relays are connected in parallel with the controlling switch and signal lamps, and are operated by means of the solenoid the core of which in rising closes the controlling switch circuit. The panels for the alternating current side of the rotary converter

each contain a power factor meter, an ammeter and a voltmeter, two synchronizing lamps, a plug receptacle for throwing the instruments in circuit, the controlling switch and signal lamps for operating the oil switch. On the back of the panel is an overload relay for operating the oil switch as previously described. The two panels controlling the direct current side of the rotary converter are separated by the width of one panel from the alternating current panels already described. These panels each contain a circuit breaker, an ammeter, a rheostat, a starting switch, lightning arrester and wattmeter. As the relays and controlling switches for operating the oil switches require continuous current a storage

non-telescoping ends. The under framing is entirely of 5-in. and 6-in. steel I beams riveted together with special channels and plates. The lines of the car body are similar in general appearance to what has come to be known as the Pullman style of sleeping car with compound Gothic windows. The Gothic sash is set in art glass, which adds greatly to the general appearance of the car. The interior of the roof presents a rich appearance and is ornamented with stripes and studded with frosted incandescents lamps, each of 16 c. p. set in sockets of oxidized copper. The ventilating sash are elliptical with art glass set in three sections. The ceiling is painted blue and the interior is rubbed down to a dead finish.

STANDARD CAR—NILES CAR & MANUFACTURING CO.

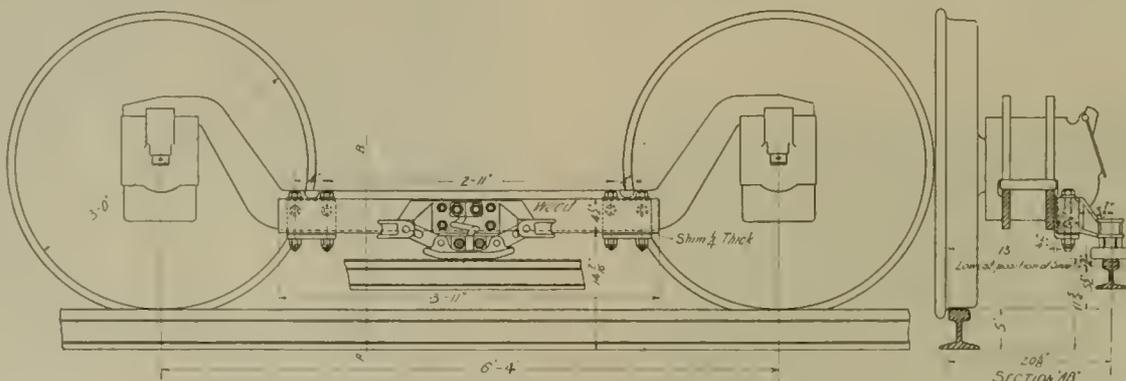

battery is provided for use in starting the plant when the rotaries are not in operation and there is, therefore, no continuous current available. The line current of 600 volts is cut down to a pressure of 125 volts by means of a resistance inserted in series and this pressure of 125 volts is used both to operate the relays and controlling switches and to charge the batteries when required.

The two panels to the extreme right of the board are for the direct current feed to the third rail. These each contain a circuit breaker, ammeter, voltmeter, kicking coil and a lightning arrester. A connection is made in the winding of the transformers so that the rotary converters can be run up to speed as motors with only a portion of the normal pressure. When they reach full speed this intermediate voltage is cut off by means of a double throw switch and the normal pressure is supplied.

the latter being in quarter oak and decorated with marquetry work. The trimmings are of solid bronze.

The seats are of the Hale & Kilburn walk-over pattern made of rattan and furnished with high backs and roll top head rests. Under each seat is supplied a Consolidated car heater. The car is arranged with cross seats and a center aisle, the latter being laid with matting. Each car has a smoking compartment and the trimmings throughout are of polished bronze. On each side are continuous basket racks and the glass is polished plate throughout.

Each car is equipped with four of the Nichols-Lintern Co.'s pneumatic sanders; these enable sand to be as efficiently distributed on curves as on straight track, insuring uniform track conditions when stopping, and preventing slipping of wheels at starting. The other special equipment includes Van Dorn draw bars and couplers,

ARRANGEMENT OF CONTACT SHOE.

Rolling Stock.

The rolling stock of the Aurora, Elgin & Chicago consists at present of 30 cars of the style shown in the accompanying engraving. Twenty of these cars are equipped with motors and the remaining ten are used as trail cars. The car bodies were made by the Niles Car & Manufacturing Co., of Niles, O., and as will be seen from the illustration are very handsome in general appearance. The construction of the framing is novel and was designed for the special purpose of withstanding the exceptionally high speeds to which the cars will be subjected. The length of the bodies over end plates is 47 ft. 3 in. and the extreme width of the cars over the side sills is 8 ft. 6 in. The cars are vestibuled and furnished with

Stanwood double steel steps, foot gongs, push buttons at each window, two trolley poles, rear and front signal lights, rear flags, fire extinguishers and a full line of tools in tool boxes to be used in case of accident. The vestibules have side doors and the step openings are provided with trap doors. The ends of the vestibules are open to allow passage from one car to another when run as a train. These cars are to be put under a speed test by the General Electric Co. and it is the intention to obtain speeds as much in excess of 100 miles an hour as possible.

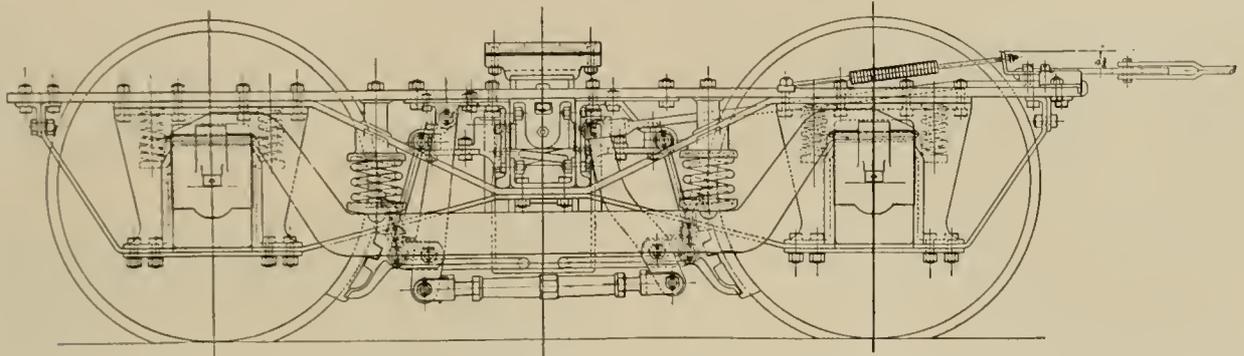

In order to accomplish these tests the cars will be supplied with different types of portable vestibules to overcome the air pressure at high speeds.

The bodies are mounted on Peckham M. C. B. No. 30 trucks with 6½-in. axles and 36-in. M. C. B. standard double plate cast iron wheels. The journals are 5x10 in. A side elevator of the truck and a transverse section through the center of the bolster are shown in the line drawings. These trucks were designed especially for high speed interurban service.

The side frames combine the equalizing bars used in the Master Car Builders' steam passenger car trucks with the diamond frame used in the M. C. B. freight car trucks, the idea of the combination being to give a double factor of safety, as the diamond frame alone is sufficiently strong to carry the weight of the car without the aid of the equalizing bars, which are arranged in pairs, one each side of the pedestals. To prevent the tilting of the top frames the spring

an ordinary Bourdon pressure gage mechanism with a special hand which makes contacts with the conducting stud at the position of minimum pressure and allows current to flow through a magnetic coil which operates a plunger carrying contact pieces for the motor circuit whereby the motor is started up. When the hand strikes the maximum stud the current is reversed and the plunger pulled away so as to break the circuit and stop the motor.

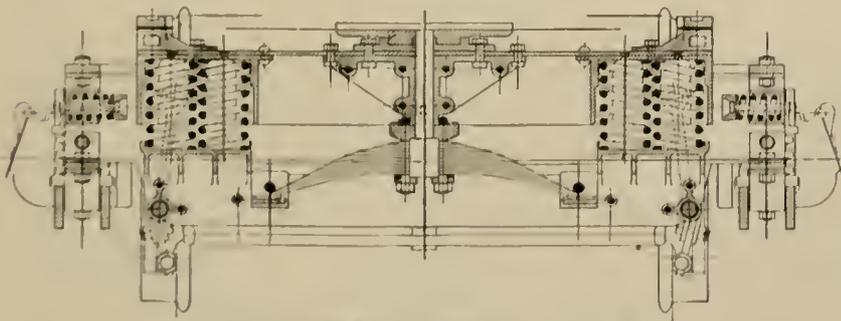

The cars are operated with the General Electric type M control system, which is adapted for running the cars separate or when two or more are coupled together in a train. When the cars are operated in a train the circuit connections are so arranged that the motors on all of the cars may be controlled from either end of any motor car. The type M system consists of two essential parts,

SIDE ELEVATION OF PECKHAM M. C. B. 30 TRUCK.

base of the truck is increased by locating helical springs each side of the journal boxes and supported from them by saddles. These pedestal springs carry a sufficient portion of the load to prevent the tilting of the top frames, the greater part of the load being carried by the equalizing bar springs. The side and end portions of the top frame are all in one piece, a forging. The transoms are bulb angles 10 in. deep, which extend full size with the side truss frame to which they are very rigidly secured. Gussets of sheet steel connect the transoms to the side frames hold the frames rigid and square. The trucks have Peckham's patent swing bolster; this is constructed of plates in form of a channel 10 in. deep and is carried on four long coil springs and one elliptic spring which support the bolster from the inside at its top, so as to hold it securely in a vertical position. Straps secured to the transom and extending over the bolsters prevent its being lifted out.

The arrangement of bolster springs, an elliptic in the center and

TRANSVERSE SECTION THROUGH BOLSTER.

two helical springs at each end, is designed to give an easy riding car and to prevent rolling motion of cars when running at high speed.

Each motor car is equipped with four G. E. 66 motors, 125 h. p. each, making a total of 500 h. p. per car.

These cars are supplied with the Christensen straight air brake equipment with independent motor driven compressors and automatic governor. The compressor and motor are combined in one machine consisting of a series wound motor and a duplex single acting compressor. The motor is mounted directly above the compressor, the motor base forming the top cover for above the compressor, the motor base forming the top cover for the same and this arrangement enables all the working parts to be run on oil. The governor used for this compressor consists of

namely, a series parallel motor controller composed of a number of electrically operated switches called the contactors and a separate electrically operated reversing switch called the reverser, and second, two master controllers, one located at each end of each motor car, which operate the contactors and reversers. A cable running the entire length of the train connects each master controller with the controlling circuits of the several motor cars and these cables are connected from car to car by means of suitable couplers. It is also necessary to continue these cables through any trail cars which may be in the train between the motor cars.

### NORWICH ELECTRIC TRAMWAYS CO.

One of the model electric railway system of England is that of the Norwich Electric Tramways Co., operating 14 miles of railways, of which five miles are double track. Forty double deck closed motor cars, and 10 double deck trail cars, made by the Brush Manufacturing Co., are operated, mounted on single trucks of Peckham manufacture. The motor cars are equipped with Westinghouse 20 h. p. motors. Browett & Lindley 4,300-h. p. tandem horizontal condensing engines are installed in the power house, and the installation also includes four 300-h. p. B. & W. boilers and four 200-kw. Westinghouse generators. The Norwich company was created by acts of Parliament in 1897 and 1898, and has an authorized capital of £264,000, and authorized issue of debenture bonds to the amount of £60,000 all paid. The chairman of the company is Baron Emile De Langer, the managing director, E. A. Hopkins, and the general manager and chief engineer, Allan N. Banister.

The Binghamton (N. Y.) Railroad Co. is now installing a new 500 kw. generator at its main station, and building a new transmission line to the sub station at Casino, Endicott. The company is engaged in double tracking all the Union suburban lines.

The Greenfield (Mass.) & Deerfield Street Railway Co. has about completed its electric line from Greenfield to North Hampton, and expects to put the road in operation over 10 miles of the route in August. The construction of this line was begun last October.

### LONDON'S TRANSIT PROBLEM.

There is no more striking instance than London of the dangers attendant on allowing events to shape their course, when the events are stages in the growth of an important financial, commercial and manufacturing center. The freeborn tourist in a German city is amazed and outraged by the placard "Verboten" which meets him at every turn. But the authorities which are so ready to forbid are at least equally ready with their services, and the cities under their care are spared the problem which vexes Londoners today.

London grew up in the first place without any scheme of street architecture which would have made a rational system of traffic possible, and in the second place without any central authority whose business it might be to provide the city with a system of transit, rational or otherwise. Central London is a comparatively small area, a tangled web of thoroughfares quite devoid of arterial highways for traffic, nevertheless it is the daily goal of an enormous population whose homes stretch for many miles in every direction. There is only one Lombard street and one Bond street, and there are nearly six million souls in Greater London.

If we look at the attempts made to provide for the necessary locomotion of the people from the suburbs to the center and within the central area itself, we find them alike hopelessly inadequate. The omnibus was introduced into London streets by the enterprising Shillibeer in 1820. Horse tramways, equally a private undertaking, made their appearance in 1860. Both are very slow methods of progression. The underground railway was welcomed forty years ago as a final solution of the transit problem. The "Metropolitan" put a girdle round the busiest and most populous part of the town, while the "District" provided for transit from various points on the Inner Circle to the farther suburbs. Within recent years both these lines, but more especially the District, have fallen into much discredit. The circular route is too slow for the twentieth century; the methods of working are out of date, and the accumulations of grime and smoke in the tunnels are becoming intolerable. The opening of the new electric lines sealed the fate of the old steam railways. For thirty years the Metropolitan and the District held good their claim to the title of "The Underground." But in 1890 the City & South London Railway, a deep level tube line, was opened, and a few years later the Waterloo & City Electric Railway provided for the transit from the southwestern terminus to the Mansion House. These lines showed what could be done by electricity, but they did not poach on the preserves of the Metropolitan. The "coup de grace" was given by the Central London which cut right across the most populous part of the area served by the old Underground. The Central London is worked on the most approved modern principles, with a dash and energy more American than British in character. No one with any experience of the comfort and convenience of this line would return to the old method of traveling. The Metropolitan and District companies, with ruin staring them in the face, could only decide to convert their lines to electric traction and adopt the improvements which the Central London had taught the public to regard as indispensable.

The unparalleled success and popularity of the Central London has given an enormous impetus to a number of similar schemes. In suburban traffic the old steam railway, like the old horse-tramway, has fallen out of the race. The electric motor—more especially on the unit system of control—has not only a great superiority in the matter of absolute speed, but has the further advantage that stopping, re-starting and accelerating are comparatively simple and easy matters, and that the whole complex system of shunting is rendered unnecessary. Thus the most effective possible use is made of the material, line and work.

Deep level electric tubes then are the salvation of London, and the only question that need disturb us at present is how to make the best use of our resources, and how to serve the vast area without omission and without overlapping and waste. That, we fear, is not a question of which the best solution is likely to be found with the eight companies whose schemes are now before the House, or with the thirteen new ones of whose undertakings we hear rumors. The problem cries out for some central authority. The Paris Metropolitan affords an interesting example of division of labor between the municipality and private enterprise. The scheme provides for five lines: a circle round Paris, concentric with but inside of the Ceinture, two lines running from east to west, of which one is already in working order, and two lines running from north to south. The circle is not a closed circuit, but consists of two self-contained lines, each worked on the

loop system. Confluent junctions between the different lines, which formed part of the original design, have been discarded owing to their tendency to produce congestion, and have been replaced by a scheme for exchange stations to enable passengers to pass from one line to another. The line between the Porte de Vincennes and the Porte Marlot, which was opened in 1900, corresponds very closely to the Twopeuny Tube, both in its internal arrangements and in the character of the district which it serves. The heavy locomotive is, however, dispensed with and every train consists of one motor and two trailer cars. Each coach is fitted with three brakes, a Westinghouse airbrake, handbrake and an emergency electric brake. All the work below ground is undertaken by the municipality, while the erection of the station buildings and the actual working of the line is in the hands of a private company which takes the whole of the receipts, out of which it pays a royalty to the municipality.

We have looked in vain to our own municipal authorities for a similar interest in our much graver and more complicated transit problem. The London County Council confines its interest to suburban tramways. The new tubes are so many isolated, independent schemes which will stand or fall by their individual merits, and have first of all to face the difficulty of finding the requisite capital. When all is said and done we are only tinkering at the question yet.

D. N. D.

### STEAM AND ELECTRIC PARALLELS IN MASSACHUSETTS.

Several street railways are being built or projected in Massachusetts which will parallel existing steam roads, with the result that the railway fares in these localities are being considerably reduced. It is expected, according to the present progress of the work, that the Boston & Worcester Ry. will operate cars from Framingham to Boston by October 1st, including through cars to Boston, from Marlboro, Hudson and South Framingham. The power house of this road in Framingham is now nearly completed and it is second in size only to that of the Boston Elevated in New England. The stack, which is 185 ft. high, has just been completed. Another interurban line to parallel an existing steam road has been projected to run between Providence and Worcester. It will be as nearly as possible an air line between these cities, which makes its length 40 miles. It will use the tracks of the Union Railway in Providence and those of the Worcester Consolidated Ry. Besides securing an entrance into these cities, the necessary franchises and rights of way in the towns to be traversed have been obtained and the only remaining preliminary work is the securing of charters from the Massachusetts and Rhode Island legislatures.

### THIRD-RAIL SYSTEM IN NEW YORK.

The third-rail electric system is practically completed on the Second and Third Ave. lines of the Manhattan Elevated in New York City, and it is expected that this system will be in operation on all of the lines of the company by the close of the present fiscal year. Through this change of its motive power from steam to electricity the Manhattan expects to make a considerable reduction in its operating expenses and thereby largely increase its earnings available for dividends. For the last fiscal year the operating expenses of the Manhattan were \$3,986,998. At the present time each train of five cars carries an engineer, conductor, fireman and three gatemen. No firemen will be needed on the electric trains, and this alone means a saving of \$330,000 per year. As trains will be one car longer with the electric system, there will be an additional saving in motormen's wages amounting to over \$100,000.

### GRADUALLY GETTING THE NEWS.

The Scientific American of Aug. 9, 1902, quotes Engineering News as authority for the statement that a special trolley car for conveying fire engines is in use at Springfield, Mass. In its issue for June 15, 1897, the "Street Railway Review" illustrated and described the trolley car built for the Springfield fire department by the Wason Manufacturing Co., for the purpose of conveying fire engines. It is gratifying to know that our contemporaries not so intimately concerned with the electric railway field are keeping up to date in regard to the many applications of electricity to transportation.

**THE BOSTON ELEVATED SUED.**

The city of Boston has filed a number of suits against the Boston Elevated Railway Co. for damages to city property by the construction, maintenance and operation of the Boston elevated lines. The city claims that the value of several pieces of real estate has been depreciated, and bases its suits on the loss sustained in the market price of the property should it desire to sell it. In a test case of Edward F. Baker against the Boston Elevated Railway Co., the time for filing briefs has been extended. The fundamental issue involved in this case is whether substantial damages can be recovered for the noise produced by the operation of the road.

**ROOFLESS OPEN CARS.**

The accompanying illustration shows an open car which has recently been put into service on the lines of the Augusta Railway & Electric Co. The car is named "Starlight," and its design is due to Mr. W. E. Moore, superintendent of the company. It at once proved so popular that three or four more of the same kind are being added to the company's rolling stock. The car has no top or sides, and is merely a flat car with seats upon it, and

ROOFLESS CARS IN AUGUSTA.

two high posts are erected on each side at the center of the car to support the trolley pole and a cluster of lights. It is handsomely painted in silver, with gold trimmings, and has proved very popular for pleasure riding on hot evenings and well adapted to the warm climate of southern cities.

The car illustrated is a seven-bench car, equipped with G. E. 800 motors, K. 2 controllers and mounted on a Brill No. 14 truck. It is operated on a regular schedule, but on pleasant evenings only.

**"BY THE WAYSIDE."**

Under this title the Concord, Maynard & Hudson Street Railway Co. has published a very handsomely illustrated booklet describing the route of its road and showing a large number of the historical homes and points of interest, which are passed by the cars of this company. The scenery in this part of New England is unsurpassed, and the ride over the company's line is full of interest. The company has a luxuriously furnished parlor car seating twenty eight persons which can be chartered for special excursions between Concord and any point on its road, or on any of the roads with which it connects.

Purdie University, Lafayette, Ind., has recently received a full sized model of the locomotive "Tornado" which is stated to have been the second locomotive owned by the roads which now constitute the Seaboard Air Line. This locomotive was built in England and was placed in service in March, 1840. The University is indebted to Mr. R. P. C. Sanderson, superintendent of motive power, and J. M. Barr, vice president of the Seaboard Air Line Ry., for this interesting piece of apparatus.

**PLANS FOR LAKE STREET ELEVATED.**

It is stated that a plan to assess the stock of the Lake Street Elevated, Chicago, about \$10 per share is under consideration. While nothing has been definitely decided upon, it is believed that such an assessment would appeal favorably to the stockholders, when the entire plan is fully developed. It is estimated that the assessment would bring in \$1,000,000, to be applied to the floating debt of the company, and that this sum would reduce the latter to such an amount that the company would be enabled to float a 4 per cent bond issue in exchange for the present outstanding 5 per cent bonds. With the outstanding bonds refunded into 4 per cent bonds, and with \$1,000,000 of the floating debt wiped out, the company would be able to earn a good surplus above its fixed charges.

The physical condition and the earning power of the road are being steadily improved, and \$60,000 has recently been spent upon its construction. All the cars of the system have been put through the shops for the first time in several years, and the company has recently added eight new motor cars and twenty new trailers to its rolling stock. The company has decided not to build a power house, and arrangements have been completed with the Chicago Edison Co. whereby this company will furnish current to light, heat and operate the cars this winter. The Edison company will install additional machinery so as to enable it to furnish about 5,000 h. p. to the railway. The Lake Street company has prepared arrangements for operating an express service, but has been prevented by several legal entanglements in the suburbs, and also from the fact that it has been unable to secure the right to connect its lines with the tract of ground purchased for yards.

**ST. LOUIS STREET CAR BILL DEFEATED.**

The endeavors of the mayor and city council and the law department of the city of St. Louis to enact a general law to govern the operation of street cars were defeated August 1st by the legislature. The bill had been very carefully prepared and nearly six months had been spent in revising old ordinances and preparing sections of the bill. It provided running schedules for all the lines, maximum and minimum rates of speed and rigorous regulations for public safety and accommodation. The bill was reported unfavorably by the committee on railroads, and was finally defeated in the House of Delegates by a vote of 16 to 5.

**ELECTRICITY FOR AIRSHIPS.**

The rules and regulations governing the aeronautic competition at the St. Louis Fair have been published, and contain the following paragraph which is of particular interest to electrical inventors:

One prize of \$3,000 for a successful attempt to drive an air-ship motor by energy transmitted through space, either in the form of electric radiation or in some other form of electrical energy, to an actual amount of one-tenth of a horse power at the point of reception and at a distance of at least one thousand feet. The test must be made on the Exposition grounds by experts satisfactory to the jury.

**NEW ROOMS FOR STREET RAILWAY EMPLOYEES.**

August 4th the Rochester railway companies celebrated the opening of the new rooms for the use of the Street Railway Young Men's Christian Association. Among those taking part in the exercises were T. J. Nicholl, vice-president of the Rochester Railway Co.; R. E. Danforth, assistant general manager; George G. Morehouse, secretary; J. E. Dinkey and W. R. Shoop of the Buffalo, Rochester and Pittsburg Railway Co.; John F. Moore, secretary of the international committee of the Y. M. C. A., and others. Refreshments were served both in the afternoon and evening and the day was set apart for the street railway employes and invited guests.

Traffic on the Peoria (Ill.) & Pekin Terminal Ry. was abandoned for several days of the last week of July owing to a flood and wash-out on the line which resulted from the breaking of a dyke along the route. Tracks were submerged in some places for a depth of several feet and obstructed by trees which had been uprooted by the overflow.

### OBLIGATIONS TO CARE FOR STREETS IN MASSACHUSETTS.

The full bench of the Supreme Court of Massachusetts has rendered a decision recently that affirms the claims of the street railway companies that under the law of 1898 they are relieved from taking care of the surface of streets in which their tracks are located. The case came up on the appeal of the cities of Springfield and Worcester where the city officials claimed that this statute of 1898 was unconstitutional because it impaired the obligation of conditions imposed upon the companies to keep the streets in repair. This contention was upon the theory that the conditions constituted a contract; but the court holds that it did not constitute a contract, but that the locations were in the nature of a license or permission. The court also rules that the effect of this legislation of 1898 was to free street railway companies from all obligations thereafter to keep any portion of the surface material of streets, roads and bridges in repair unless the obligation so to do had been imposed in the grant of original location, which the court defines to mean the first location granted to a company in a city or town.

The new law requiring the Massachusetts Railroad Commissioners to approve street railway locations granted by local authorities is making trouble for the board. Several cases have arisen where locations have been granted with conditions as to repairing streets, rates of fare, etc., which the company involved think are too much of a burden, and they, in asking the commissioners to approve them, have asked that they strike out some of these obnoxious conditions. This is a new phase of the matter, and the board is proceeding very slowly and carefully weighing the question whether it shall take the attitude of overriding the local authorities who claim to be better informed of the peculiar circumstances of each case. This was the chief argument made against the measure when it was under consideration by the legislature last winter, and the board would like apparently to avoid giving it a foundation of fact. On the other hand, it is undoubtedly true that the towns are asking more and more for these franchises and a new impetus is given to the movement by the decision above quoted that makes them realize that all they will ever get they must get now.

A loophole has been found in the new grade crossing loan act by which it is expected that new work can be undertaken. The act provides that the railroad commissioners must approve of the finding of the special grade crossing commissioners in each case before the state auditor will approve any expenditure of state money. The railroad commissioners are proceeding on the theory that this money is to be spent in the order in which they approve findings. In this way the small cases where there is less delay are benefitting.

### NEW SPANISH STREET RAILWAY.

A street railway company has been organized, called the *Compania de Tramvays de Gijon*, which will operate a street railway in Gijon, Spain. The company, which received its charter in March, 1889, will build a road 7 km. in length, all of which will be single track. One kilometer will be within the city limits, and there will be 6 km. of single track. Eventually it is proposed to extend the line to a total length of 18 km. The company will operate 15 open and 10 closed horse cars, built by the Brush Electric Company, London, England. The officers of the company are Calisto Alvargonsales, president and general manager, Francisco Cienfuegos, secretary, and Mamerto Morujon, treasurer and superintendent.

### FREE CHILDREN'S ENTERTAINMENT IN AUGUSTA.

Col. D. B. Dyer, president of the Augusta Street Railway Co., invited the children of the city to a free vaudeville entertainment on July 19th at Monte Sano pavillion at the company's amusement resort. The invitation was issued specially to poor children and the inmates of the orphan asylum and other charitable institutions were entertained by the company, which provided free transportation for all of the children. The pleasant ride and outing were enjoyed by several hundred children as much as the vaudeville performance which was arranged to be of special interest to the young folks, and the invitation was responded to by more guests than ever assembled on any one occasion in Savannah before.

### A GRATIFYING ENDORSEMENT.

An accident which occurred June 14th on the Oleott Beach line of the Buffalo Railway Co., of Buffalo, N. Y., has been the subject of an investigation by Mr. C. R. Barnes, the electrical expert of the New York Railroad Commission. The accident was a rear end collision in which a closed car ran into the one ahead of it at 8:30 o'clock in the evening. A large number of witnesses were examined and the company gave Mr. Barnes every opportunity to make a thorough investigation. After detailing the accident from the statements of witnesses and employes Mr. Barnes' report states as follows:

"I find that this accident was caused by the carelessness of Motorman Miller; that the conditions approaching the point of accident are such, and there was sufficient daylight, so that, had he been on the lookout for Car No. 61, which he knew was ahead of him, he could have seen it for about a quarter of a mile, even though there were no lights burning on the car; he could have brought his car to a stop, if running at full speed, in about 500 feet. A test of stopping a car at this point was made under my supervision. \* \* \*

"The fact that there was a man in the front vestibule with him is the only reason which can be assigned for his not bringing his car to a stop before running into car No. 61."

In closing his report Mr. Barnes states: "The method of operation on this line is first class in every respect, the company has a complete time table with full and explicit rules, and cars on this line are operated under the authority of the most complete train-dispatching system in use on any road in this state. Oil tail and signal lights are used on the cars." Mr. Barnes' report places the seal of official approval on the operation of this line, and his investigation has served to show the care which the company exercises for the comfort and security of passengers and the strictness of its rules.

### STORAGE BATTERY IN MILWAUKEE RAILWAY PLANT.

As noted in the "Review" for July, the Milwaukee Electric Railway & Light Co. will install two batteries of "chloride" accumulators. One battery is to be used normally for regulating the fluctuations of the railway load and carrying the evening peak. It is, however, divided into two parts, which may, in case of an emergency, be connected in parallel across the outside wires of the Edison 3-wire system, the units being located in the same power house and discharged in conjunction with the lighting battery.

The other battery is to take care of the lighting peak and it will normally be operated as two independent series of 160 cells each on the Edison 3-wire system. The booster will be used as a shunt machine for charging one battery alone, or both in multiple. In case of an emergency the two batteries may be connected in series and discharged on the railway bus in conjunction with the railway battery. Each battery has a capacity of over 3,000 amperes.

### CHICAGO TRACK REMOVAL.

Under the ordinance providing for the removal of track in the city not in use by the company owning them, the tracks on 40th Ave., between Randolph and Taylor Sts., Chicago, were removed on July 25th. This line is owned by the Harlem and Batavia Railroad Co., and is used by the Suburban Railroad Co., which has operated a single street car with a crew of two men in order to keep its franchise alive. Previous to the removal of these tracks the Suburban company had secured an injunction to restrain the city from tearing them up, but this injunction was vacated by Judge Kohlsaat and the removal of the tracks at once proceeded. The Suburban company, in order to gain the protection of the courts for its tracks, then prayed for the appointment of a receiver, which was granted. Counsel for the company state that the appointment of a receiver will prevent the city from removing any more of the tracks, and it is said that an order may be secured from the Court for the restoration of the tracks already torn out on 40th Ave.

The Erie (Pa.) Rapid Transit Street Railway Co. has inaugurated an express and baggage service, one car at present being devoted to the purpose.

# Convertible Cars.

BY W. E. PARTRIDGE.

Under the title of convertible cars may be included all those forms of railway cars which are intended to combine the leading features of both open and closed cars. The first street cars were partly convertible in having windows that could be opened, while almost every form of open car has been capable of being partly closed. The types have remained quite distinct and most roads have maintained a more or less complete double equipment for the purpose of meeting the public demand for an open car. A few roads have gone so far as to make their closed cars with stationary windows, using them only during that part of the year when absolute protection is necessary. For the remainder of the year the open car pure and simple is made to answer the purpose.

It is recognized that the open car is a necessity, although its use involves several costly items. The number of car bodies must be doubled. The storage space must be large enough to accommodate all the cars. The trucks and electric equipment have to be changed from one set of bodies to another twice a year, or, in the second place, this part of the equipment must be double. In any case, for

there is a heavy cost, interest sometimes balancing the expenditure for labor in changing bodies, etc.

The idea of the convertible car is to build it in such a manner

FIG. 1—EARLY FORM OF CONVERTIBLE CAR.

that a single equipment of rolling stock is all that is required. This reduces the capital locked up in car bodies, does away with the cost

FIG. 2—CONVERTIBLE CAR, ROBERTSON PATTERN.

the sake of the insurance, a set of barn trucks must be provided for the car bodies in storage. Which method is employed depends upon the cost of the changes and the capital available. In either case

of changing from open to closed bodies, reduces the cost of car barns by one-half, and makes corresponding reductions in insurance, interest and various other accounts.

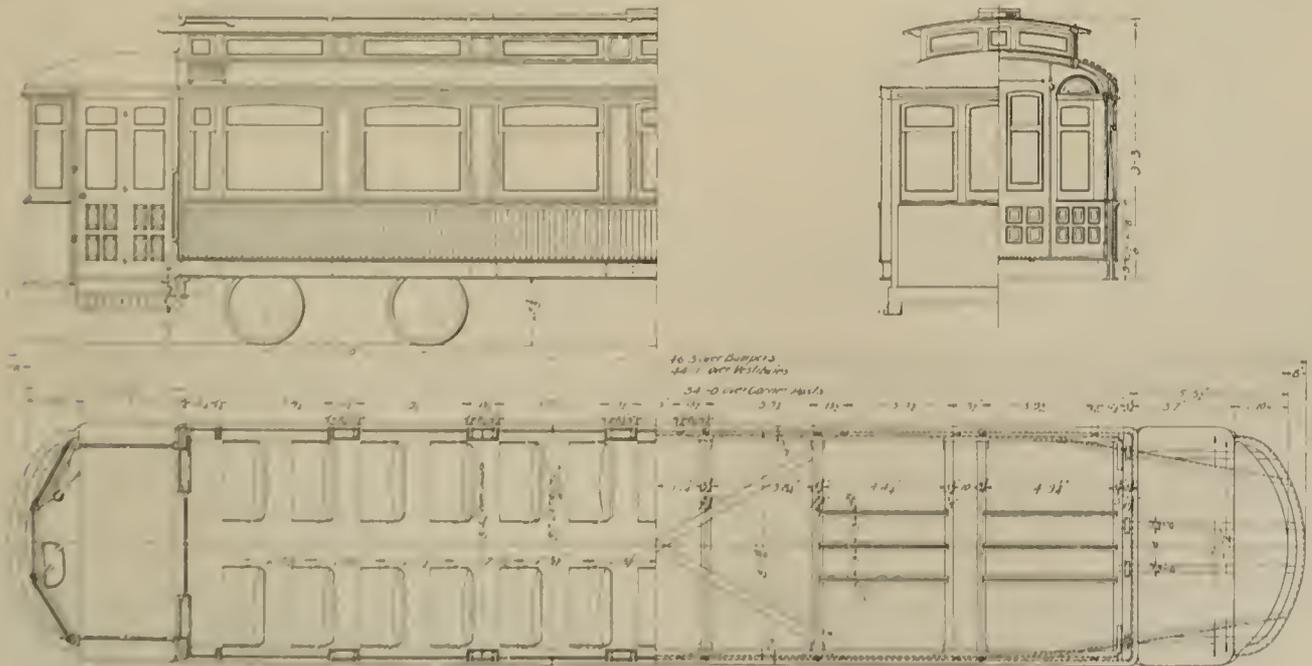

FIG. 3—PLAN, ELEVATION AND SECTION, ROBERTSON CAR.

Since the convertible car in general can be quickly and inexpensively changed from one style to another, it is readily adapted to the season. This is a point of no small importance, and it is pretty thoroughly appreciated by railway men. No further excuse is

Baltimore lines. The essential features are a closed body with a very low stationary side. The seats are transverse, with a center aisle. The windows are large and have below them a panel which is also removable, and when once in place, the windows cannot be

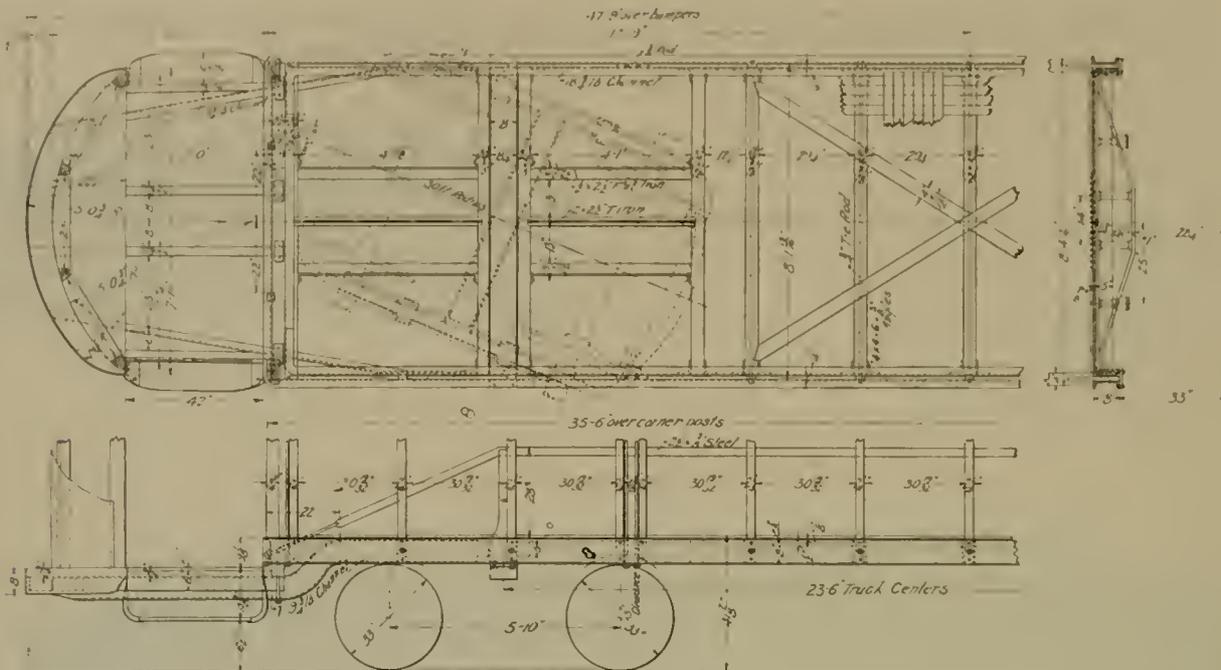

FIG. 4—PLAN AND ELEVATION OF ROBERTSON CAR FRAMING

necessary for presenting some of the leading forms of convertible cars which have been built in this country.

There have been some 60 forms of convertible cars patented in the United States. Not many of these, however, have come into use. The earliest system, perhaps, and one which has been very exten-

opened. The panels bring the solid side of the car about up to the top of the window guard netting. These cars, when windows and panels are both removed, have sides nearly as open as those of the standard open cars, and in some respects they are better liked than an open car. For the passenger they are pleasanter than an open

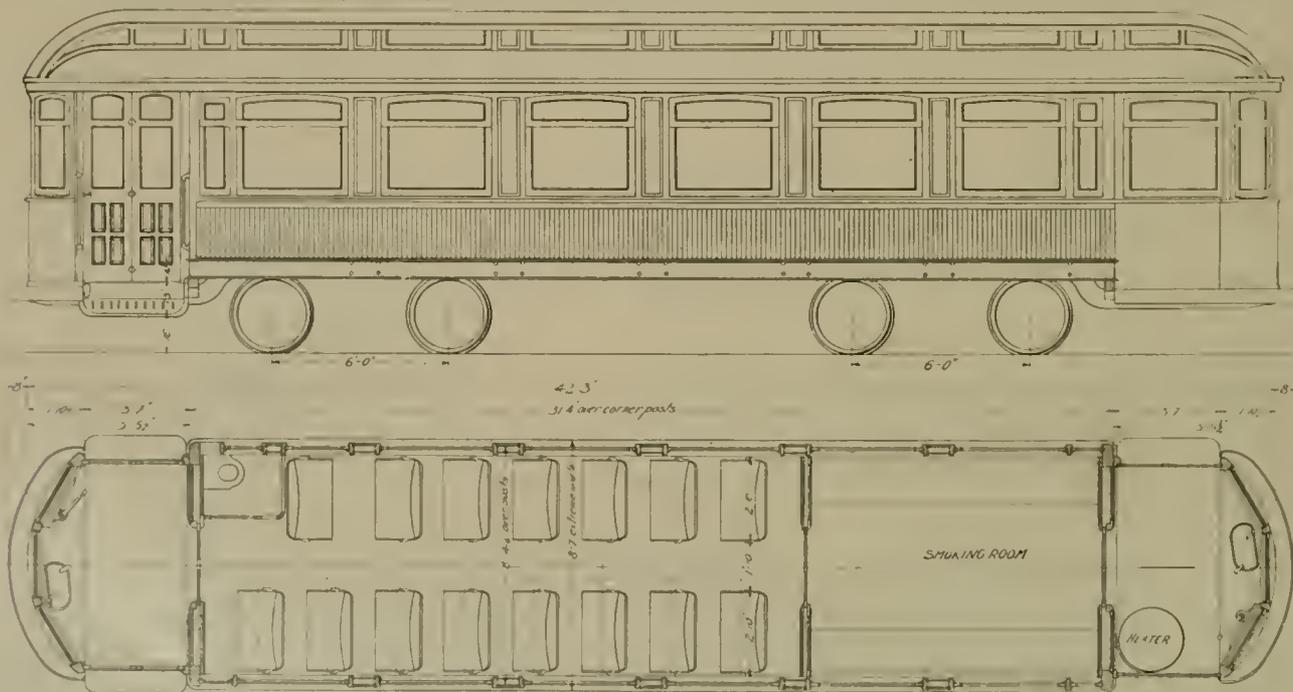

FIG. 5—PLAN AND ELEVATION OF LARGE ROBERTSON CAR.

sively built, is shown in Fig. 1. This form has been popular, and in spite of prejudice has worked its way into service in many parts of the country. Numbers of these cars have been built for the Cincinnati, Newport & Covington road, and also for many of the

car. The seating capacity is somewhat less than that of an open car, and they are not quite as quickly filled or emptied. The form is one which railway men looked at with little favor, but in spite of that it is forcing its way into use as it is liked by the public. Its

really objectionable feature is the cost and time needed for storing the glass and panels, and the large storage room necessary.

The idea of a convertible car has taken strong hold of inventors and several improvements and attempted improvements in design

design. It gave a complete open car with side entrances, and when closed it was a transverse seat car with a central aisle.

The next style of which any considerable number has been built is the Robertson, or Third Avenue car, as it is sometimes called.

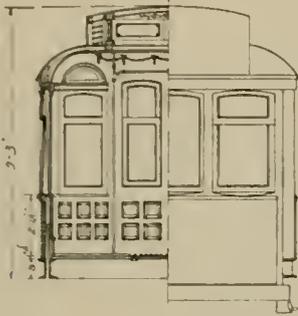

FIG. 5 A—SECTION OF LARGE ROBERTSON CAR.

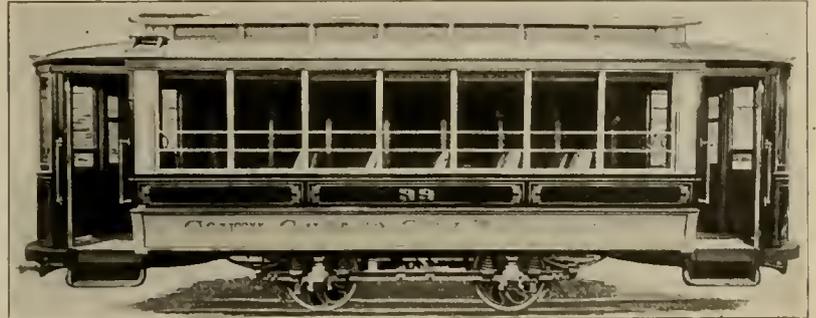

FIG. 6—FOUR-WHEEL CONVERTIBLE CAR OPEN.

have been made and built within half a dozen years. One of these, worth mentioning for novelty, had hinged sides which swung outward and then slid into the body of the car in a horizontal position over the heads of the passengers. The mechanism was intricate and the operation inconvenient.

It was designed by Mr. Robertson, who was at the time superintendent of the Third Avenue Railroad in New York. The cars of this style which we illustrate are from standard designs of the St. Louis Car Co., and are shown in Figs. 2 to 5.

The floor frame of the car is of a novel form. The side sills con-

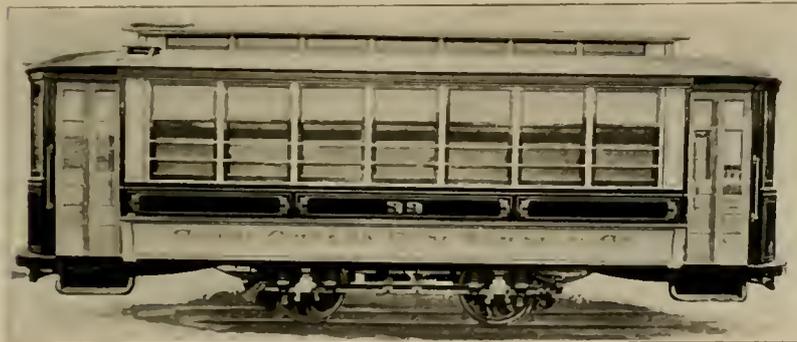

FIG. 7—FOUR-WHEEL CONVERTIBLE CAR CLOSED.

A little later came the duplex car. Glass and panels were arranged to slide in grooves in the posts into the roof. To effect this the body of the car was made circular in section and panels and sash

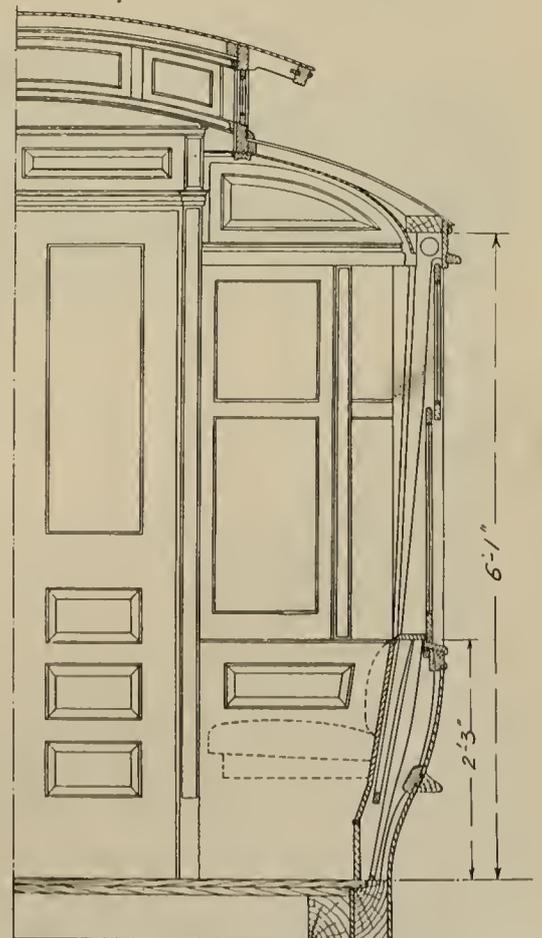

FIG. 8—SECTION OF CARS SHOWN IN FIGS. 5 AND 6.

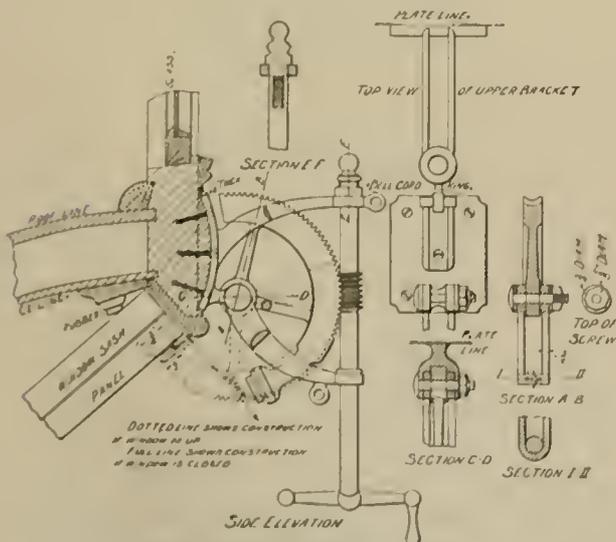

FIG. 10—SASH AND PANEL LOCK.

were segments of circles. The design necessitated the use of bent posts, or ribs. It was also necessary to use bent glass, which was costly. Many inconvenient features seemed inseparable from this

design. They are placed, back to back with a space between them. These are made long enough so that they form the end sills as well, being bent at the end of the car for the purpose, thus forming a continuous sill. These channels are riveted together at the posts, but are separated by a sufficient space to allow the sash to drop into the pocket which is formed between them. The depth of this pocket is a saving of

8 in. in the height of the window rail, or rather it enables the sash to be brought that much lower and at the same time completely houses in the side of the car. The floor plans in Figs. 3 and 4 show the construction. There are no longitudinal intermediate timbers. The cross timbers and tie rods bind the side sills together and with the iron bolsters give ample support for the body. The bolsters are 10 3/8 in. deep in the clear. Truss rods are also introduced into the side of the car as well as below the sill so that the body has ample support.

This form of construction permits the body to come very low, so that with 33 in. wheels, and by dropping the platform 10 in., the step

train on a steam road. The platforms are of rather more than the usual length, measuring almost 5 1/2 feet over the dashers.

A large number of improvements have been made in these cars since the first one was built some years ago. They are now in a practicable shape and are one of the standard styles of the St. Louis Car Co. They can be had of all sizes up to 42 ft. or more over all. They seem to be growing in favor, and a considerable number of roads have adopted them.

About the time when the first of the Robertson cars was built, or a little after, a convertible car was brought out by the J. G. Brill Co. Years ago Mr. John A. Brill invented a car of this kind and some were built. Turning his attention again to the subject, he brought out an improved form which appeared to meet the requirements better than anything which had preceded it. This car was illustrated and described at length in the "Review" for May, 1902.

Mr. Brill also adapted the roof storage system of his convertible car to what is known as the Brill semi-convertible. The car has proved a success and is being used by many large roads throughout the country. Having no wall pockets the seat ends are brought within the posts and thus 6 to 7 1/2 in. are added to the interior of the car. The sides can, of course, be either curved or straight. The windows are raised or lowered by a single operation—the lower section not being hinged to the upper is raised part of the way alone and without pausing automatically engages the upper sash by means

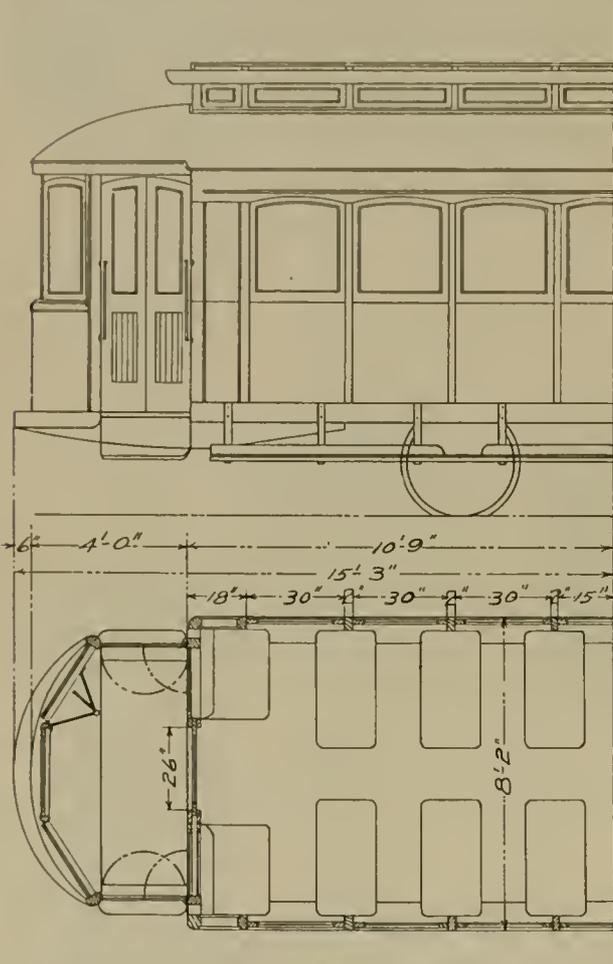

FIG. 9 CONVERTIBLE CAR WITH SIDE ENTRANCES AND CURVED PANELS.

comes within 16 in. of the head of the rail. The method of carrying the platforms is shown in Fig. 4. The side timbers are of iron with a sharp bend under the end sill to obtain the necessary drop.

The diagonal bracing is placed in the center of the floor, as is shown in both Figs. 3 and 4. This form of frame at the height indicated (33 in. 10 under side of sill) permits a truck with 33-in. wheels to radiate clear of everything on a 30-ft. curve, the trucks having 23 ft. 6 in. space between centers.

The body of the car is framed in much the usual way. It is stronger, however, than the usual form of straight side cars, because the sheathing is put on in two thicknesses. The inner layer is horizontal and gaged upon the posts. The outer one is vertical.

The double sills provide, as we have said, a much deeper pocket for the sash than would be possible with solid sills, as will be seen from the end view in Fig. 5A. When the sash are in the pockets a large open window is the result and the car, as far as the passenger is concerned, is practically open. Both the car shown in Fig. 3 and that in Fig. 5 have panels between the windows, a construction that greatly strengthens the body. A novel feature is introduced in the latter car. A heater is placed on the forward platform and a smoking room with longitudinal seats takes up a part of the forward end. In the rear there is a toilet room. This gives all the features of a

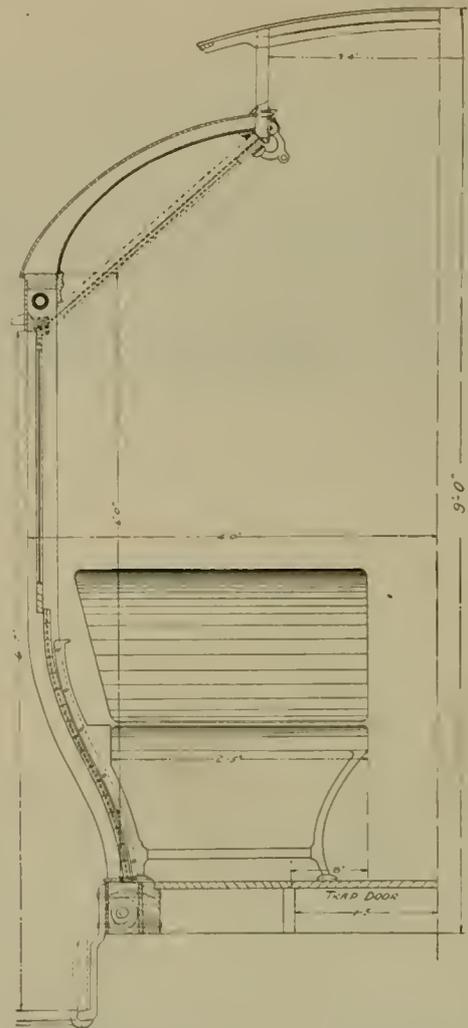

FIG. 11—CROSS SECTION OF CAR WITH SIDE PANELS.

of curves in the sliding grooves. The operation is easily accomplished because of the light weight of the lower sash in starting and the oblique position assumed on entering the roof pocket.

The success of these forms and the great advantages of the convertible type, have led many builders to undertake the design of cars of this kind.

Among other companies which have designed cars of this class is

the Jewett Car Co. It has recently brought out the style shown in Figs. 6 and 7. One of the engravings shows the car open for summer service; in the other it is closed.

FIG. 12—LACONIA CAR CO'S. SEMI-CONVERTIBLE CAR.

The construction in these gives a small curved side. This is a necessity in some situations where streets are narrow. Indeed there are many of our older cities where the straight-sided car is practically out of the question on account of delays arising from teams unloading at the curb. Fig. 8 shows how space is obtained in the wall of the car for such large sash. The division of the sash and the double posts makes a very neat and compact construction. It should be noted that the seats are longitudinal, an unusual feature in the later styles of convertible, but often very desirable.

The same company has another form of construction which is of an entirely different character. It is shown in Fig. 9. Here the glass and panels are raised to the roof and folded out of the way against the lower deck. The glass is hinged for the purpose at the top, as shown in Fig. 11. The mechanism for holding both sash and panels in place is shown in Fig. 10 on a large scale. It consists of a segment of a circle gearing into a worm wheel on a vertical handle. The hand wheel acts with great power and forces the segment firmly against the sash and panels so that falling down or getting loose so as to rattle appears to be out of the question.

From a glance at Fig. 9 it will be seen that this car when open has side entrances and is in every respect like a center aisle open

as completely enclosed platforms. The feature of side entrances is one which is much in demand in places where crowds have to be handled quickly.

Fig. 12 is a convertible car built by the Laconia Car Co. for the Columbus, Grove City & Southwestern Railway Co. This is a large, heavy car, suitable for high speed interurban work. Having straight sides space is found in them for the necessary pockets for the sash. The latter are double. The division comes at such a point that there is ample room for the two parts even with a low window rail.

The car just mentioned and the one shown in Fig. 13 are illustrations of the growing tendency to make interurban riding as pleasant as possible. In the summer season a car as open as possible above the window-rail, and having seats facing forward, gives the greatest satisfaction to patrons. When the Albany & Hudson bought its cars it included among them many of the convertible style shown in Fig. 13. Like that shown in Fig. 12, it closely approaches the steam road type. It is a large double truck car, capable of high speed. While the whole side is practically open so far as the passenger is concerned the side is not weakened by side entrances. It is much safer than any side entrance car. The latter are not safe for interurban service nor for high speeds anywhere.

Lastly, as the most recent of all the convertible cars, comes that of the Stephenson Co. It differs from all of the other designs in stowing the upper part of the sash in the roof and disposing of the

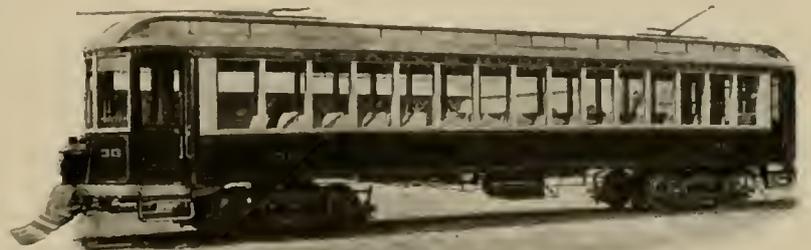

FIG. 13—ALBANY & HUDSON CAR.

lower sash in the side of the car below the window rail. The car is shown in plan and elevation in Fig. 14. In Fig. 15 the arrangement of the roof pocket is shown on a larger scale. The design is by Mr. P. M. Kling, general manager of the Stephenson Co. It is

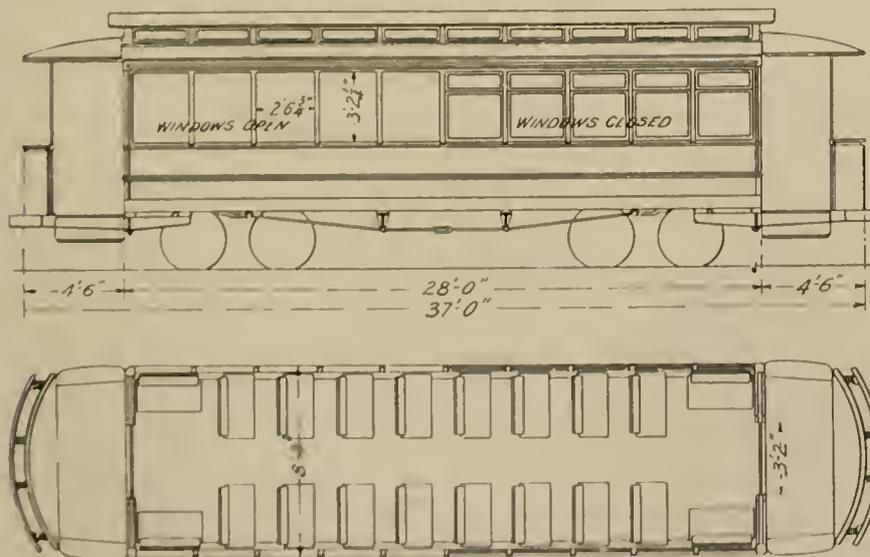

FIG. 14 A NEW FORM OF CONVERTIBLE CAR.

car. When closed it appears to be a standard box car, the only difference being that the posts appear on the outside of the panel. The car is fitted with a continuous top, or running board, as well

applicable to car with either the curved or the straight side, a feature of considerable importance, giving the invention a wider range of use than would otherwise be possible. It can also be

used with longitudinal or transverse seats. The car when closed is precisely like the ordinary box pattern with the one exception that the window rail is low. The form of the roof inside is not altered perceptibly. There is, however, a little more timber in the head of the posts, so that the roof at this point may be considered considerably stronger than in the ordinary construction. By a proper division of the sash the belt rail can be brought down to any

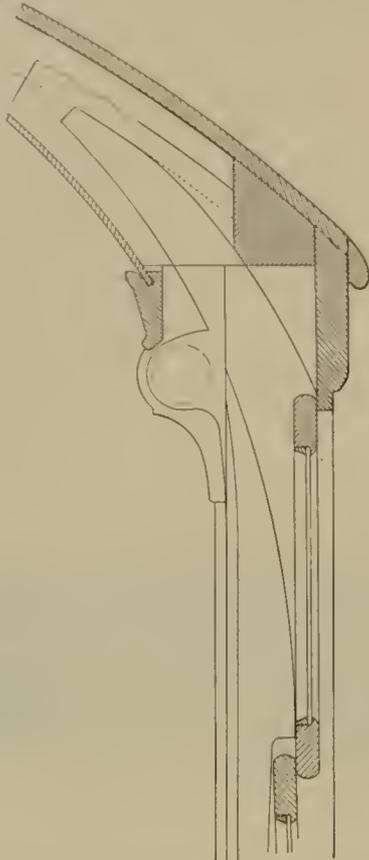

FIG. 15 METHOD OF STOWING SASH IN ROOF POCKET.

desired degree. In the car illustrated it is only 2 ft. 4½ in. above the floor. In these cars the window pockets are at all times closed by covers hinged in place, which form the arm rests. These covers are a small but important accessory. They prevent dirt from getting into the pockets and making the car offensive. This method of construction gives a car which is much stronger than any open car can be, much safer, and it would be difficult to point out any feature which is not as strong and durable as a standard closed car.

## THE MANAGEMENT OF MEN.

BY G. J. A. P.

This is a subject which naturally interests any street railway manager, or, in fact, any person employing help, but my intention is only to refer to employes of street railways. There is no doubt that the merit system is one of the best means of securing good results from employes, but to this should be added a number of other considerations, which are in many cases entirely lost sight of.

A man is a man no matter what his occupation may be, and as such should be so treated. No matter how humble or small his position may be he will resent (if not by word, then in some other manner), any abuse to which he may be subjected.

Under no consideration should a foreman, or superintendent, be permitted to use profane language to an employe, nor should he be permitted to give his orders in a gruff or loud tone of voice, in the presence of the public. If a superintendent has any reason to give an employe any orders or to "call him down" for any cause, it should be done quietly and in such a manner that only the two interested are aware of what is being said. Often a mere look from a superintendent will hurt a car-

man more than all the lecturing he can give him, and the man is apt to remember it just as well.

Suspensions for days or weeks at a time help in some cases, depending upon the nature of the person receiving such punishment. Reduction in rank, however, is to most trainmen the severest punishment they can receive, and has about the best deterrent effect on them.

My experience has been that by winning the friendship and good will of employes more attention to duties and orders will result. A manager or superintendent who has a pleasant word for every one of his men—one who does not get "the swell head" simply because he is in authority—can get more general good results from his employes than can the manager who is too pompous to even notice an employe.

Few men are free from error, and if an employe makes a mistake and does not make an effort to hide it, but is perfectly frank in acknowledging the matter, be lenient with him, and it will result in his being on the lookout to avoid future errors.

A manager should study the disposition of every man he employs, and have all his subordinate bosses or superintendents do likewise. In this manner he will learn the good and bad traits of every man under him.

It does no good, but does considerable harm at times, for a manager to be so self-important that he cannot speak to an employe when he meets him. He can be friendly with all men, yet be positive and determined in his discipline, but under no consideration should he show any partiality.

Once men learn that any one of them can approach the "boss" and obtain a hearing, and that he will deal with all offenders exactly alike, they will feel more secure from the annoyances to which they are only too often unjustly subjected.

One feature which causes men to become dissatisfied with the management of a road is being called to headquarters with loss of time, to answer some trivial complaint which has been made against them. If these complaints were all first traced to their source, a great many would be found to have their origin in some personal feeling, which has no bearing whatever upon the man's acts while on duty, and if properly sifted, even the manager would not ask a man to lose time by reason of such complaints.

Many a complaint has been pigeon holed without a word ever being said to the man complained of, simply because on investigation it was found to be a case of personal animosity, which had no foundation for a complaint.

One rule which companies should strictly enforce is: Do not permit men to enter saloons while on duty, or when in uniform while off duty. A person who becomes intoxicated at any time should not be permitted to hold a position of any kind on the cars. There is nothing which will so demoralize the service of a railway as to allow trainmen to loiter about saloons, no matter at what hour, day or night. Men who spend much time about such places will spend their earnings there, and then grumble because their pay is not greater.

Added to this is the danger of heavy judgments for damages being secured against a company should a motorman (who is known to frequent saloons) have an accident. All that is required for an average jury to render a verdict for full amount is to have counsel show that such motorman was in the habit of frequenting saloons. You may bring in all the testimony you wish to show he was not under the influence of liquor, if it is shown that he is a frequenter of saloons you have a hard case for a defense with an average jury.

Finally, get your men to thoroughly understand that the company's interests are identical with their own, and whatever they do which is of advantage to the company will be recognized and suitably rewarded. If an employe has suggestions to make, have your foremen consider them. It sometimes happens that the men suggest matters pertaining to time schedules, etc., which are not only practical but tend to considerably improve the service and secure business. A trainman who is of an "observing turn of mind" running over the same route day after day, can naturally see where changes might be made for the betterment of the service which ordinarily go unnoticed.

An electric railway will soon be under construction at Ventura, Cal. John Burson and A. L. Russell are the promoters.

**A STUDY OF THE HEATING OF RAILWAY MOTORS.\***

BY A. H. ARMSTRONG.

The electric traction problem presents many new features for investigation which are not met with in steam railroading, and upon which little accurate data has been published. This is especially true of that class of service calling for maximum speeds greater than 35 or 40 m. p. h., where stops are infrequent and cars are run singly or in trains of two cars or more. It is the purpose of this paper to enter into a discussion of some of the variables met with and their influence upon the motive power and station output for the higher as well as lower speed schedules.

The electrical engineer has to take care of two factors with which the steam engineer is unacquainted, keeping the temperature of the motive power within reasonable limits and also the

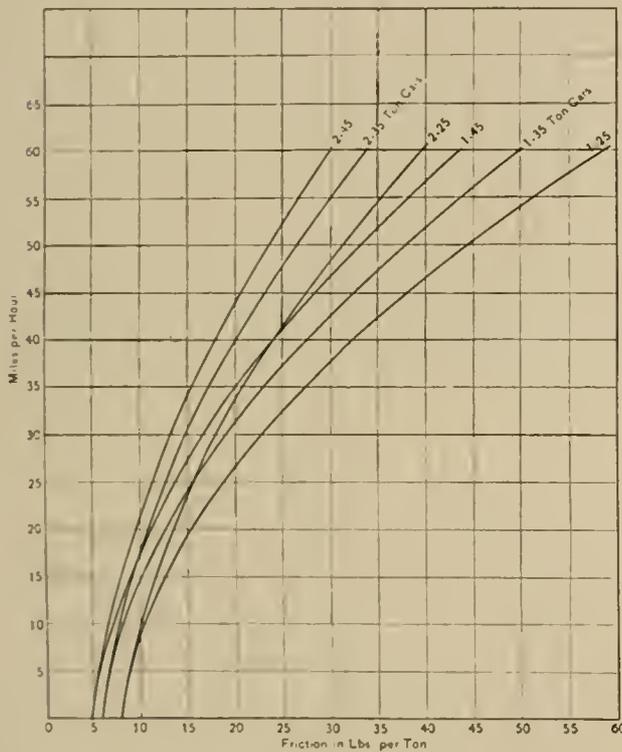

FIG. 1.

operation of single cars at maximum speeds of 60 to 70 m. p. h. That wind friction is a considerable factor with trains operating at high speeds has been abundantly proved by many tests, but these tests are worthless when used to determine the power required to propel a single car at the same high speeds. As the electric motor has invaded the high-speed interurban field and has done so successfully because of the frequency of service furnished with single car tram, it becomes pertinent to inquire into the size of the motive power necessary to prevent overheating and also the amount of power needed with the high speed schedules and frequent stops made.

Regarding the tractive effort required to propel trains of one or two cars at speeds of 60 m. p. h. or more, there is almost a complete lack of experimental data. Formule based upon tests of steam trains made up of a number of heavy coaches cannot be applied with any accuracy to the operation of single car units. A series of tests made by the General Electric Company on the Buffalo and Lockport tracks, with trains of different sizes, provide almost the only data upon which to base such calculations. These tests were carried up to speeds approaching 60 m. p. h. with ordinary steam railway coaches, hauled by a 38-ton electric locomotive. The cars were not vestibuled and the conditions were not, therefore, such as to give results directly applicable to the operation

\*A paper presented at the 19th Annual Convention of the American Institute of Electrical Engineers, June 20th, 1902.

of single suburban cars of the vestibule type. For want of more accurate data, these tests will be used as the basis of the following calculations, and, as the curves deduced are used for comparison only, it makes little difference if the friction values are not absolutely correct. Fig. 1 shows some of these curves as published in an article by Mr. W. J. Davis, Jr.

The tendency of the electric roads has been toward heavier cars, especially on the higher speed lines, where the car weights run from 25 to 45 tons, including equipment and seated passenger load. Suppose we equip cars weighing 25, 35 and 45 tons with the same four-motor equipment, geared for 60 m. p. h. with the 35-ton

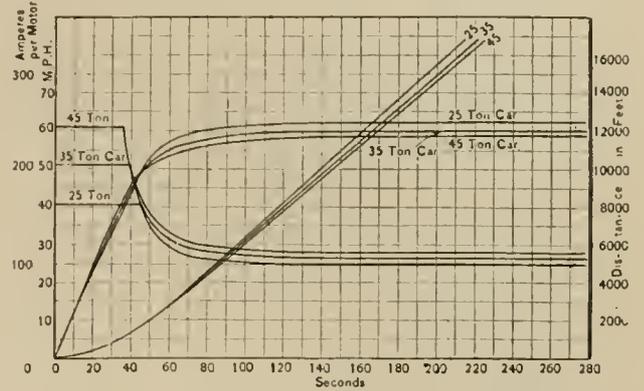

FIG. 2.

car, there would then result speed time-curves as in Fig. 2, the speed curve of the 45-ton car falling below and that of the 25-ton car rising above that of the 35-ton car for the same gear ratio. A tractive effort of 120 lb. per ton gross has been taken with all three equipments, as representing average conditions for this class of work, giving a net acceleration of about 1.06 m. p. h. per second, after deducting friction loss and the power required to accelerate the revolving parts. Any other rate of acceleration could have been taken with little or no effect upon the heating of the motive power or its energy consumption, as will be shown later, the larger part of the energy input being used up in overcoming air resistance at this high speed.

Speed and amperes input are plotted as ordinates with time as abscissa and power may be shut off at any time, the car allowed to coast and brought to rest by brakes, making the enclosed area of

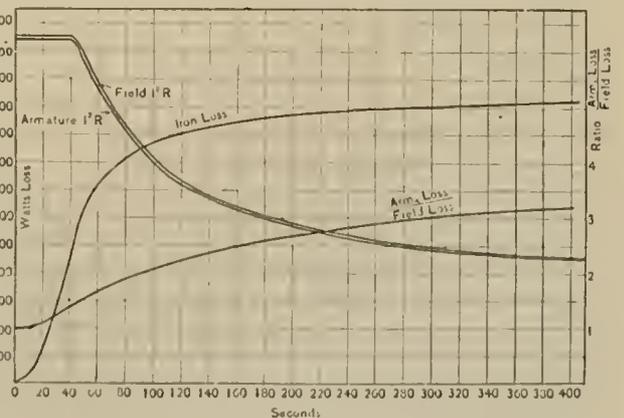

FIG. 3.

the speed time curve proportional to the distance covered, and the area of the ampere time curve equal the ampere hours input. For the sake of simplicity it has been assumed that the friction will be the same at the same speeds during acceleration and coasting; that is, that the energy given up by the rotating parts during coasting will equal the gear and friction loss of the motors running light, an assumption which is approximately correct. The coasting curve will, therefore, follow the shape of the friction curves in Fig. 1, will be curved and show a greater retardation at high than at low speeds.

While power is applied, the motive power has internal losses,

varying not only in intensity but in their distribution. At zero speed, the losses are all in the copper of field and armature, being divided according to their relative resistances, but as the armature speed increases there is an iron loss distributed between the iron of armature and pole face and tips, depending upon the design of the motor. This iron loss starts from zero at standstill and increases to a maximum at the moment of cutting out starting resistances, after which it falls off somewhat, but this again is a matter of motor design. As these various losses are the cause of our motive power heating, it is necessary to trace their influence upon the individual parts of the motor under study.

As the heating of a motor is the result of the average losses

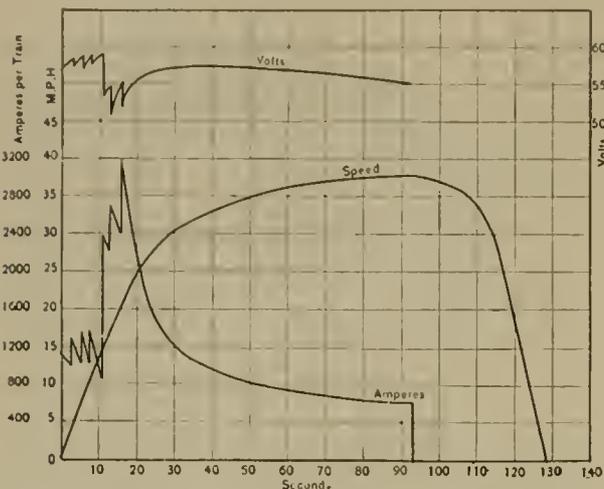

FIG. 4.

within it, the average losses and their distribution up to any moment of shutting off power must be determined. Such losses are shown in Fig. 3 for our 35-ton car equipment, speed and ampere curves of which are shown in Fig. 2. The motor losses for 25 and 45-ton cars have been left off to avoid confusion, but from the shape of the ampere time-curve in Fig. 2, it is evident that the curves will vary greatly from those shown only during the fractional speed or acceleration period, these differences being virtually wiped out with a considerable amount of running upon the motor curve. Thus, while there is a total average copper loss of 5,000 watts during acceleration upon resistance, the copper loss curve becomes flat in about 400 seconds at the value of 1,800 watts in the copper, with the motor constants chosen. As an equipment geared for a maximum speed of 60 m. p. h. would hardly be used for an average run of less than 15,000 feet, requiring power on for fully 160 seconds for its accomplishment, it will be seen that the acceleration losses play a comparatively unimportant part in very high speed work, so far as the motor heating is concerned. That this is not true of low speed work will be discussed later.

The iron loss has been assumed to be dissipated entirely from the armature in arriving at the "ratio of losses" in Fig. 3. This is not strictly true, but the true subdivision of losses, whatever it may be, will be practically the same with the same "ratio of losses," and hence any values of motor heating deduced from curves similar to Fig. 3 must be consistent. For example, if we know the degrees rise per watt loss for field and armature with any given "ratio of losses," the temperature arrived at would be correct, provided the temperature constants were obtained from experimental runs where the motor went through the same cycle as in the run to be determined.

Suppose we take our motor equipment, place it upon a car and run it over a measured length of level track, keeping an accurate record of the current input and voltage per motor at each instant. Then let this sample run be repeated successively for a period of ten hours, or long enough for the motor temperatures to have reached their maximum, and we have the relation between energy lost in the motor and its temperature for a given set of conditions. Vary the length of the test run and repeat the ten-hour test and we have another relation between temperature rise and energy loss for another set of conditions. It is evident that a series of such tests taken on a given type of motor would give material from

which the relation between its internal losses and temperature rise would be known for any set of conditions, and, moreover, these values could be used directly in calculations for any given service as they were obtained under operative conditions, and need no constant applied to make them approximately correct for service conditions.

It may be urged that it is difficult to reproduce with any accuracy the sample run agreed upon, or that it is difficult to follow through and keep an accurate record of just what takes place in the motor during its cycle of operation. If necessary, an automatic device for applying the current could be used, such as a motor to throw on the controller at a pre-determined speed. Sufficiently good results can be obtained, however, by ordinary hand control with a trained operator, while sample runs taken every few minutes by recording instruments, serve as a check and furnish the material upon which to base the motor's performance during the test.

A sample set of curves of such a test is shown in Fig. 4 indicating voltage, amperes and speed upon a time basis, all taken by recording instruments. The voltage indicated is that between third-rail and ground, but the motor voltage during running upon resistance may be taken as proportional to its full internal voltage at the moment of cutting out final starting resistance, without making any appreciable error in arriving at iron loss values. The ampere curves give the means of determining the copper losses by plotting on polar coordinates as in Fig. 5, and determining the area by planimeter, giving directly the square root of mean square value. Both Fig. 4 and Fig. 5 show curves produced by a recording instrument placed directly in the main circuit of the car, thus giving the series parallel effect of the motors so connected. In our motor calculations we are concerned with the amperes per motor which will be independent of the series parallel control. The curves in Fig. 4 and Fig. 5, however, are shown simply to demonstrate the accuracy of the recording instrument, and while Fig. 5 could not be used directly to determine the square root of mean square current per motor, it shows the method used in determining this constant.

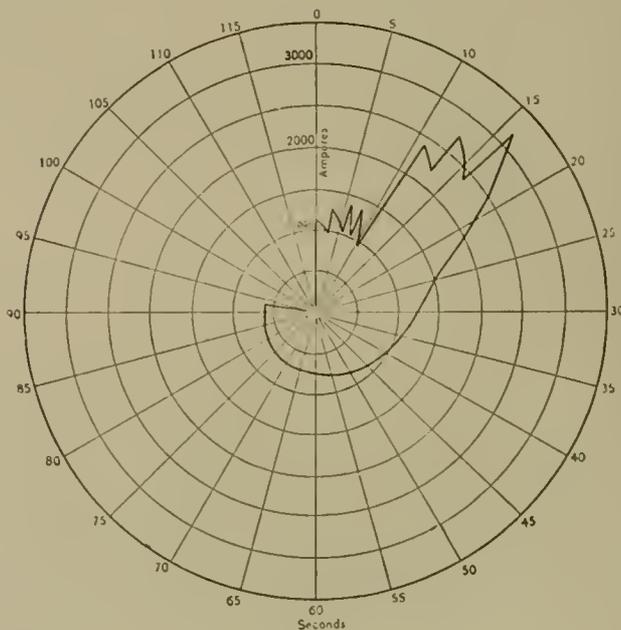

FIG. 5.

It will be seen that by using recording instruments and by taking a sufficiently large number of curves, it is possible to determine very accurately the average losses dissipated as heat by the motor during the test run, and also ascertain the distribution of these losses in the several parts of the motor. The motor ventilation is the same as in a service run; it is operated at varying speeds, remains at rest the required proportion of the total cycle, and in every way the average conditions pertaining to a service run are reproduced in the test run, thus making the data so obtained directly applicable to service problems without the use of any constant.

A curve showing the results of a number of such tests is given in Fig. 6, indicating the degrees rise per watt loss in field copper and

in armature with any relation between total armature and field loss. Here, also, the total iron loss is assumed to be in the armature, and this loss, added to that of the armature copper, gives its total loss, used in determining the "ratio of losses."

Taking up again the study of the motors mounted upon the 25, 35 and 45-ton cars, we are now in a position to apply the motor losses obtained in Fig. 3 with the 35-ton car, and similar curves with the 25 and 45-ton cars. By completing the cycle in Fig. 2 and bringing the car to rest in any given distance, the time

assumed to continue 10 per cent of the duration of the running cycle. Curves of higher temperature cannot be completed without greatly exceeding the commutation limit during acceleration, but would reverse and approach zero the same as those of lower temperature for infrequent stops.

The relation between train weight and temperature rise for a given schedule and frequency of stops is instructive. With one stop per mile and five tons weight per motor, a temperature rise of 54 deg. is noted, while ten tons per motor increases the temperature to 120 deg. rise. That is, the motor temperature increases faster than proportionally to the increase in train weight, due, as we should expect, to copper losses increasing as the square of current; but our friction curves indicate a much larger friction in pounds per ton for the lighter-weight cars, thus bringing the accelerating current required to propel a car at 60 m. p. h. to about that required for cars varying considerably in weight. We would expect, therefore, that for continued runs where the losses due to acceleration are subordinated to the running losses, this increase in

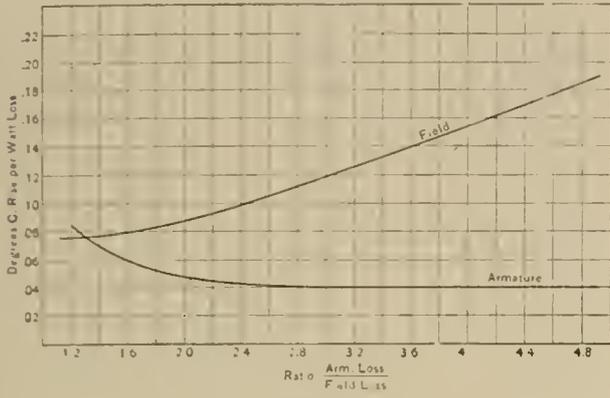

FIG. 6

of shutting off power can be determined, the average losses and their distribution ascertained by curves in Fig. 3, and the temperature rise found out by applying the constants in Fig. 6. That is, for any given schedule, we can determine the temperature rise of field and armature for the three-car train weights and the given gear ratio assumed. By plotting a sufficient number of schedules, a curve similar to Fig. 7 will result, which affords a very interesting study

Such a curve in lieu of a better name might be termed a "service capacity curve" of the General Electric "H" motor. It shows the

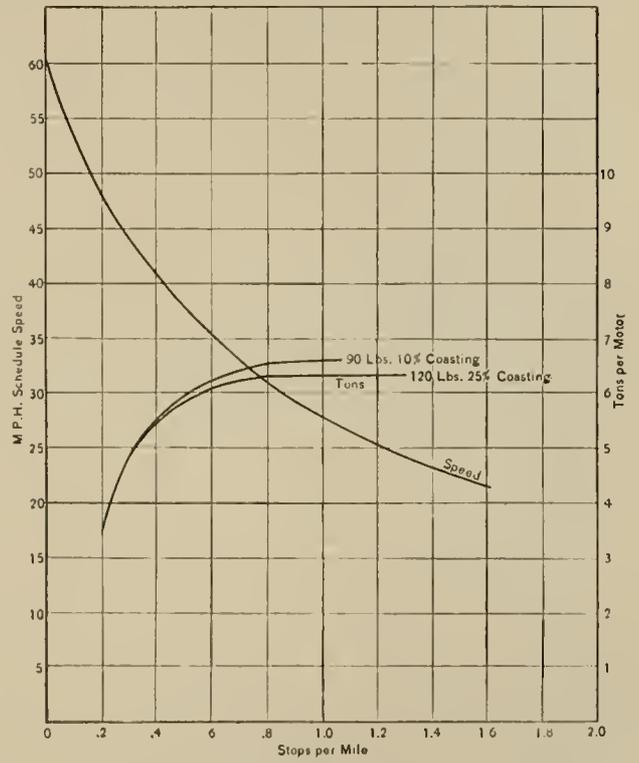

FIG. 8.

temperature with increased car weight would not be so marked. That such is the case is shown by comparing temperatures in the case of train weights of five and ten tons per motor with more infrequent stops, say one stop in four miles, giving temperature rises of 72 deg. and 98 deg. respectively for the same schedule of 48 m. p. h. The curve for 80 deg. rise is very curious, as it indicates a constant weight train with our equipment, regardless of the frequency of stops, while higher temperatures increase and lower temperatures decrease the train weight with the infrequency of stops. The percentage of the time that motors are operating upon starting resistances is indicated by dotted lines.

Curves shown in Fig. 7 are all based upon the same gross tractive effort, giving practically the same rate of acceleration. It is evident that the same schedules could have been made with innumerable other accelerating rates, coasting less with the slower and more with the more rapid rates. In order to make our study of the "H" motor more complete, two sets of curves similar to Fig. 7 were plotted, the first with an accelerating rate of 90 lb. per ton gross and 10 per cent coasting, and the second with 120 lb. per ton and 25 per cent coasting, both making the same schedule with the same frequency of stops. The comparison of these two curves is shown in Fig. 8, plotted for a temperature rise of 60 deg. only in order to avoid confusion. The lower rate and less coasting has some advantage for more frequent stops, but as such an equip-

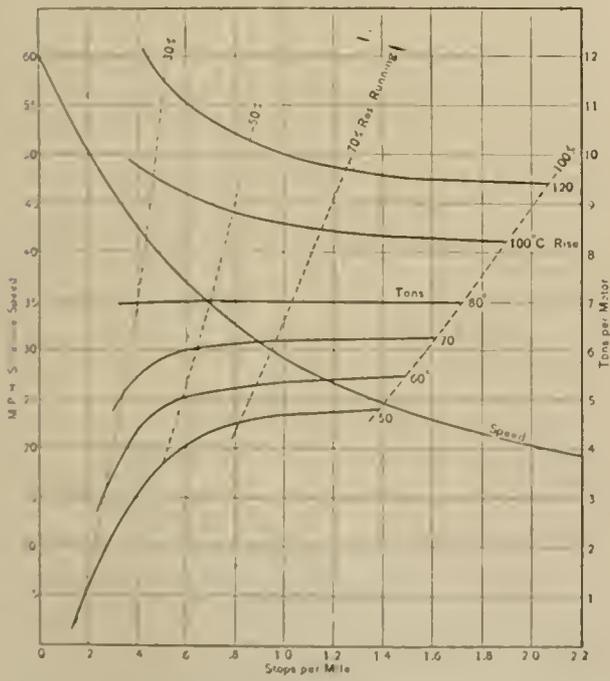

FIG. 7.

temperature rise per motor for any weight of car and the schedule that can be performed with the gear ratio chosen, all plotted in terms of the number of stops per mile. The temperature rise is given as that of the hotter part whichever it may be. The schedule includes top hitting 15 second each. Acceleration is the result of a constant tractive effort of 120 lb. per ton during resistance running, and braking is effected at the rate of 150 lb. per ton. Coasting is

ment would not be used geared for 60 m. p. h. with much less than a two mile run average, it follows that the temperature rise would be virtually the same with either rate of acceleration.

Lower speed equipments, however, present results differing from this, as is shown in Fig. 9, illustrating the 60 deg. rise curve for a maximum speed equipment of 30 m. p. h. Here 160 lb. and 25 per cent coasting contrast very favorably with 120 lb. and 10 per cent coasting. In other words, the motor capacity is greatly increased by raising the accelerating rate while still maintaining the same schedule and frequency of stops. Increasing the accelerating rate does not necessarily mean going beyond the commutating limit of our motors, as a lower speed gearing can increase the rate of acceleration with the same current flowing in the motors as with the slower rate of a higher speed gearing.

A study of the foregoing curves seems to indicate that so far as motor heating is concerned, it is preferable to use the largest gear ratio and highest rate of acceleration possible for the accomplishment of the service contemplated, provided the maximum speeds are low, but that practically any rational rate of acceleration can be used where speeds approach a maximum of 60 m. p. h. As will be shown later, the energy consumption is less for a higher rate of acceleration permitting more coasting, but unfortunately the fluctuations on the distribution system and the load curve on the generating station may both be much poorer if the accelerating rate is carried too high and the number of units in service is small. In the choice of gear ratio for a given service, therefore, not only must account be taken of the question of motor heating with different rates of acceleration, but due heed must be paid to the question of line fluctuations, station load and energy input. It may be possible that what is gained in car energy by a more rapid acceleration, may be lost by the poorer coal economy resulting from a more irregular load curve upon the generating station.

So far we have considered the question of capacity of our "H" motor for one gear ratio only. It is obvious that similar calculations may be made for any other gear ratio corresponding to a different maximum speed on the level, and by combining the results of several sets of such calculations, it is possible to arrive at a capacity of our "H" motor for any schedule, any gear ratio and any

the motor of 60 deg. C. are shown from one stop in two miles to four stops per mile.

A careful study of the curves in Fig. 10 gives very interesting results. For instance, the "H" motor geared for 60 m. p. h. can operate between the limits of one stop in two miles and four stops per mile, making a schedule of from 40 m. p. h. down to 14 m. p. h., with approximately five tons per motor in all cases and the same temperature rise. In other words, an equipment of this character is protected from overheating by properly proportioning

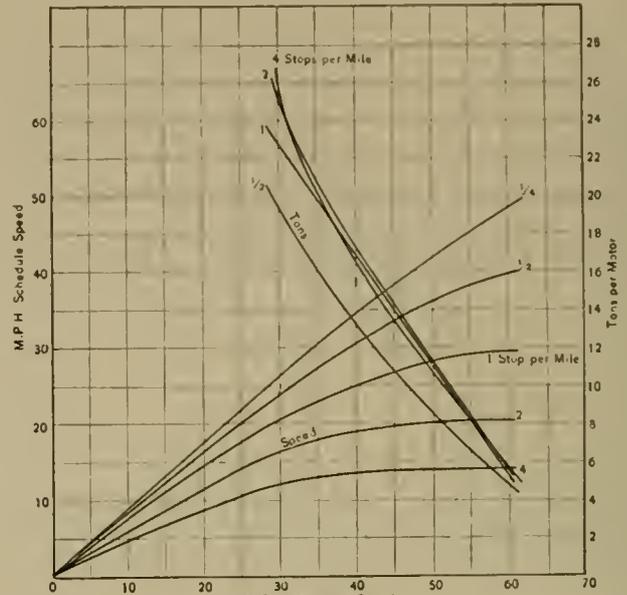

FIG. 10.

its gear ratio to the car weight. The possible schedule speed for a given gear ratio is controlled by the number of stops per mile, but the heating of the equipment, with the proper weight of car, will be the same over a very wide range of schedules and stops. The curves, also, bring out very forcibly the importance of properly gearing an equipment for the work which it has to do. For instance, a gearing giving 60 m. p. h. on a level track can make but 20.5 m. p. h. schedule with two stops per mile with a train weight of 5.6 tons per motor, while the same equipment geared for 47.5 m. p. h. can perform 20 m. p. h. schedule (practically the same), but can do so with a total train weight of 12.8 tons per motor, or more than double the train weight possible for the same temperature rise with the 60 m. p. h. equipment. In other words, the equipment should be geared for the lowest possible maximum speed that will permit the maintenance of the schedule in question, as a gear ratio giving too high a maximum speed for the work to be done not only overheats the motors, but produces needless demands upon the generating and distribution systems.

The curves in Fig. 10 give a fairly complete study of the type "H" motor when applied to the operation of single cars equipped with four motors. All points in the curve except for a maximum speed of 30 m. p. h., are obtained with the operation of single cars, and as our friction curves may be inaccurate, being based upon a single set of tests, or trains of more than one car may be run, it is instructive to reproduce a similar set of curves for two, three, four cars, etc., per train. The motor capacity for a given temperature rise is governed largely by the shape of the friction curve used at high speeds, especially for the longer runs, and in Fig. 11 is shown a comparison between the operation of one and two-car trains making the same schedule, and using the same accelerating tractive effort per ton, braking and stop intervals as in Fig. 10. This set of curves is also plotted for a temperature rise of 60 deg. C., but it is obvious that from the foregoing material we could plot similar curves for any other temperature rise. As the curves showing the relation between tons per motor and maximum speed for a given temperature rise come so close together for the different frequency of stops, this sheet has considered only the relation between tons per motor and maximum speed for one stop per mile. Thus we see that at 60 m. p. h. the type "H" motor

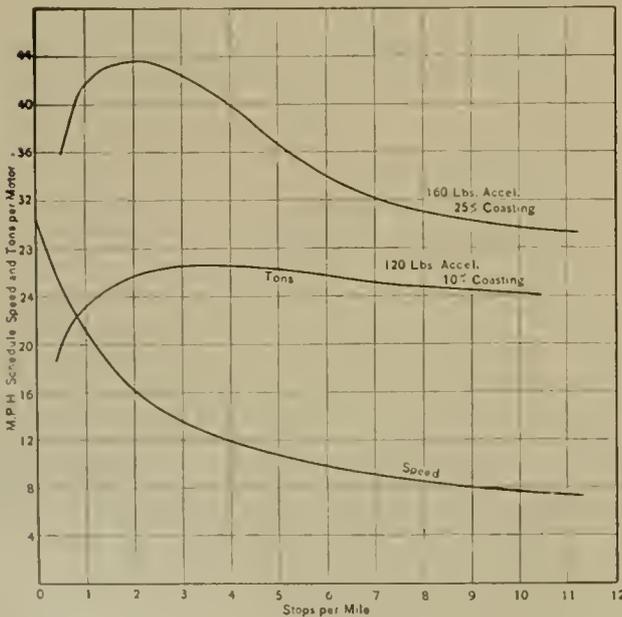

FIG. 9.

frequency of stops. This may be plotted in terms of any temperature rise, and a set of such curves is plotted in Fig. 10 for a temperature rise of 60 deg. This set of curves still retains 120 lb. per ton tractive effort, 15-second stops, 150 lb. braking effort, and is based upon the performance of a single car using a four motor equipment, following the lines of the friction curves given in Fig. 1. The relation between schedule speed and maximum speed on the level is shown with stops varying from one in four per mile, and the tons per motor for a maximum temperature rise in any part of

operating a single car has capacity of but 5.3 tons per motor for 60 deg. rise, while if two cars are coupled together and operated as a single train, the reduction in wind friction per ton of train weight increases the capacity per motor to 7.5 tons for the same 60 deg. temperature rise, an increase of 42 per cent. This opens up a new field of inquiry as to whether it is commercially advisable to run single car units at this high speed when the motive power, and as it will be shown later on, the energy input, are both larger than would result from operating the same seating capacity in trains of two cars or more, with a correspondingly increased time interval between trains. In other words, is the electric traction idea of small units at frequent intervals a proper method of attacking the very high speed electric traction problem, or are we compelled to go back to the steam method of operating heavier trains at more infrequent intervals, in order to prevent a prohibitive investment in motors, and generating and distributing systems, and a ruinous expense for operation? It is true that the electric system, being eminently adapted to subdivision, has created the demand for travel, by means of its frequent service, where none previously existed, but it may be possible that for very high speed work too great a price may be paid for the privilege of operating very frequent small units.

The foregoing discussion has described a method of determining the probable heating of a given motor when operated under any known conditions. The results obtained are so complete and give such a mass of working data directly applicable to service requirements, that the labor of the detailed calculations necessary seems amply justified. Specifications of stationary apparatus are prepared in careful detail and acceptance tests carried out in great exactness, but the tendency to slight the railway motor problem, owing largely to its seeming complexity, is hardly warranted, when it is considered that the capital invested in such apparatus may be double that required for generator power to drive it. Then, too, the generator is carefully housed, provided with an attendant and otherwise taken care of, while the motor is exposed to outside climatic conditions and only gives evidence of being overloaded by burning out. The selection of such apparatus should receive the most careful attention, the proposed service conditions fully worked out and the

servicing commutation at the maximum current for which the motor will probably be called upon in service operation. Some method of rating railway motors which would give an accurate comparison of their service capacity under different conditions, if such a rating is possible, would be of great advantage over the present very general one-hour rating.

The foregoing investigation has pointed out the very variable nature of the work which a railway motor has to do, and the different relations between service performed, distribution of losses and the ultimate heating of the motor. In Fig. 3 the various motor losses are shown for the type "H" motor, taken as an example,

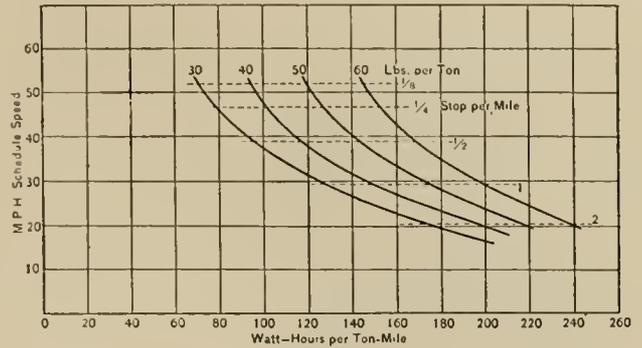

FIG. 12.

but it is evident that different motor loss curves, even for the same service performed, could not be compared directly with any assurance of arriving at their comparative temperature rise. Proceeding further, we come to the values given in Fig. 6, showing the relation between motor losses, their distribution, and the resulting temperature rise per watt loss. Similar curves of different motors could be compared directly and give some means of their relative capacity, but here, also, there is no direct comparison as different motors do not have the same efficiency, and therefore will not give the same loss for the same service performed. In other words, given two motors having the same thermal constants, that is, the same degrees rise per watt loss, the motor having the poorer efficiency will rise to a higher temperature for the same service performed, owing to its greater loss. We cannot, therefore, look to the thermal curves as giving the comparative rating needed.

In Fig. 7 we have a fairly complete history of the type "H" motor operating under a given set of assumptions. These assumptions are those pertaining to service operation, and such a set of curves for another motor calculated for the same conditions would give accurately the comparative size, or in other words, the comparative temperature of the two motors for the same service performed. In Fig. 7, the "service capacity curves" approach much nearer to a basis of comparing different motors, but as a method of rating railway motors it is incomplete. In the first place, we have assumed a given rate of acceleration, while it is obvious that the demands of different classes of service, especially low speed service, will call for different rates of acceleration, and hence a separate sheet would have to be made out for every rate of acceleration. The effect of increasing the rate of acceleration and increasing the time of coasting is shown in Fig. 9, giving such discrepancy between tons per motor for a given temperature as to make sheets similar to Fig. 7 entirely unreliable for comparing different motors, especially when the maximum speeds are low and the acceleration energy is the determining factor in the motor heating.

There is another variable, the rate of braking, which has not been entered into in this discussion, and which also affects the heating of the motor, especially on low speed high acceleration problems. On the higher speed problems, where friction is the ruling factor, it is found that we must also assume a certain friction rate, or in fact a friction curve plotted to a definite formula in order to arrive at consistent results with different motors. Having once determined on this friction curve for a single car, our calculations are immediately disqualified when we couple two of these same cars together and perform the same service, the friction rate at speeds of 50 or 60 m. p. h., falling off considerably as we approach a train composed of several units.

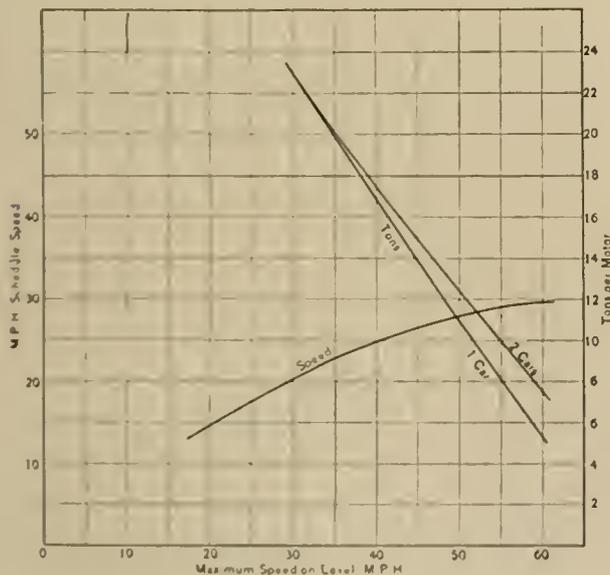

FIG. 11.

proper size of motor and correct gearing chosen to ensure a reasonably small expense for maintenance

The present method of rating railway motors is to determine the current which they will carry at 500 volts on a stand test giving a temperature rise of 75 deg. C. in the hottest part after sixty minutes' run. In other words, the one hour rating of railway motors gives only an indication of the comparative capacity of two motors in actual service, and affords no data to serve as the basis of calculating the service capacity of the motor. It does determine the mechanical qualities of the motor, as the one hour test is generally very severe, and it also affords a means of ob-

In addition to the foregoing variables, we have the element of the energy consumed by the rotating parts during acceleration. This factor is practically negligible at very high speeds, but figures very prominently in acceleration problems with low speeds. In giving the rating of a railway motor, it will be necessary, therefore, to fix definitely upon the weight and center of gyration of car wheels and armatures, and furthermore determine the effect of the motor parts for a given gear ratio.

After all these variables are definitely fixed, we must repeat the same set of conditions for each motor gear ratio, or, as a more general case, for each different maximum speed on level, thus eliminating the question of the total number of teeth in gear

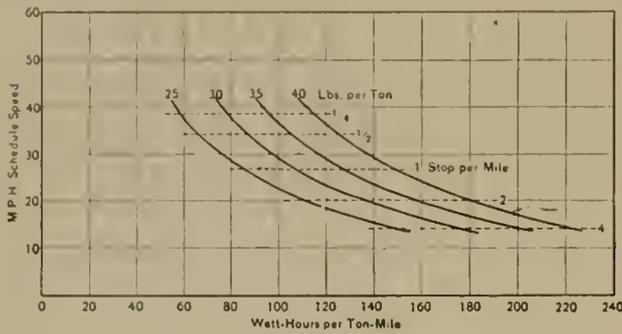

FIG. 13.

and pinion. It is not intended in any way to discourage an effort to rate a railway motor by some method that will give its comparative capacity, but it is well to canvass carefully the large field of variables which must enter into such a rating, and to have clearly in mind the bearing which these different variables have in determining the temperature of the motor. It is evident that by affixing certain values to accelerating rate, train friction, braking effort, energy of rotating parts, etc., it will be possible to prepare a set of curves giving the relations between schedule, frequency of stops and temperature rise for any car weight, which would give accurately the comparative size of a railway motor in relation to any other motor for which curves were similarly plotted. Such work is being done by the General Electric Company on their standard railway motors, and in fact is necessary in order to be able to give the probable performance of a motor under any set of conditions, and follow through the effect of changing the conditions. The method, however, is cumbersome, and has so many factors entering into the case that it probably may never serve as a commercial rating; furthermore, such relation could only be expressed by curves, or a long, tabulated statement, and neither method is short and concise enough for a commercial rating.

As the result of considerable investigation along these lines, the writer has not arrived at any commercial rating of a railway motor which serves its purpose better than the one-hour test now universally used. Admitting that such a test does not give the comparative size of different motors, it does serve the purpose of largely determining its commutating qualities and possesses the advantage of being commercial. Unless a rating can be proposed which will indicate accurately the relative size of motors, the present method of one-hour rating possesses advantages which would hardly warrant its being superseded.

Although insufficient data are at hand from the foregoing calculations to form the basis of a complete treatise on the subject of train energy, sufficient material is provided to furnish some very interesting comparisons. As the basis of calculations, we assume the operation of single car trains composed of 25, 35 and 45-ton cars, geared for a maximum speed of 60 m. p. h. for the 35-ton car. From our friction curves we find that these three cars at 60 m. p. h. require a tractive effort of 59 lb., 50 lb. and 43.5 lb. per ton respectively. The same calculations were carried through for trains composed of two cars or more, the cars being of different weights, so that we are able to plot a set of curves showing the relation between schedule speed and watt hours per ton mile input to the train, virtually ignoring any fixed formula for train friction. Such a set of curves is shown in Fig. 12, being plotted for 30, 40, 50 and 60 lb. per ton friction rate at 60 m. p. h. These curves may be regarded as fairly general in their scope, except that they follow

the general form of the friction curves given in Fig. 1. In other words, we can get from these curves in Fig. 12, the energy consumption for any friction rate at 60 m. p. h., the error introduced by assuming a general shape of curve being very small.

An inspection of Fig. 12 brings out forcibly the fact that the subject of car energy at high speed is most intimately interlinked with the question of train friction. As the schedule speed decreases with the increasing number of stops, or in other words, as the energy of acceleration becomes a more important factor, the per cent difference between the energy values for different train frictions becomes less, as would be expected.

The electric road has almost universally used one car units, and as it has branched out into suburban high speed work, the advantages of more frequent service have made the operators of such roads retain the single car idea. From the curves given in Fig. 12, some figures can be secured of what it costs to operate a single car, and also trains of two or more cars, where the maximum speed is 60 m. p. h., and the stops very infrequent; that is the more advanced type of our private right-of-way suburban road. A single 35-ton car having a friction, say, of 50 lb. per ton at 60 m. p. h., will consume 119 watt hours per ton mile at a schedule of 52 m. p. h. with one stop in eight miles. Let two such cars be coupled together in a train, reducing the friction to 33.5 lb. per ton, and the train will require an input of only 78 watt hours per ton mile, or 65.5 per cent of the energy rate per ton required in single car operation. In other words, single cars on 30-minute headway would require 52.5 per cent more energy for their operation than would two-car trains on one-hour headway. With five-car trains composed of 35-ton cars, the energy is reduced to 56 watt hours per ton mile for the same schedule, or less than half what will be required per ton for the operation of single car trains.

From a purely energy standpoint it would seem that the operation of single-car trains was disadvantageous, but experience has shown that it is not fair to assume that two cars operated every hour will attract the same custom as one car operated every thirty minutes. In other words, the frequency of service creates travel and in many cases warrants the extra expenditure for coal. There is another aspect of the case to be considered and that is that with two-car trains at more infrequent intervals, the load upon the feeding points is more fluctuating, the size of rotary converters must be somewhat increased, and in all probability a larger amount of feeder copper will be required to keep the drop within the same limits. Although a saving may be effected in the coal pile by increasing the train headway and giving the same seating capacity in trains of two or more cars, there is every reason to expect a call for a greater expenditure of money to install the road, and an in-

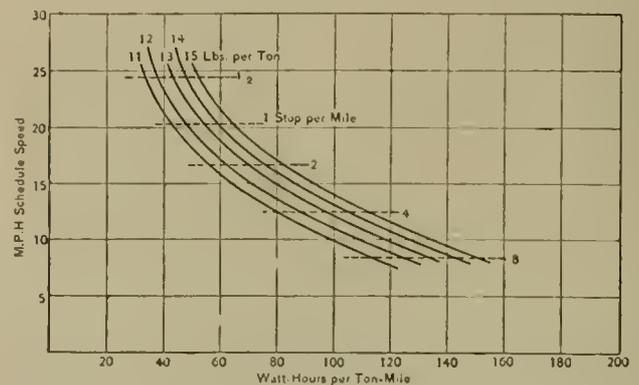

FIG. 14.

crease in interest and maintenance account that may go far toward eating up the saving in the fuel expense.

In Fig. 13 and Fig. 14 are given curves showing the relation between schedule speed and train energy for maximum speeds of 45 and 30 m. p. h., respectively. It will be noticed that, particularly for 30 m. p. h. maximum speed, the train friction becomes a very much smaller factor in determining the energy input, especially as the number of stops per mile increases.

All these three sets of curves are plotted for an accelerating rate, corresponding to 120 lb. per ton, and a braking effort of 150 lb. per ton. The values given will, therefore, be subject to consider-

able variation for different accelerating and braking efforts where the schedule speed is low and stops numerous. The curves are, however, of fairly general use, especially for runs of a mile or more, as the effect of rate of acceleration and braking is not so marked on longer runs.

In Figs. No. 12, 13 and 14 is considered, also, a period of coasting equalling to per cent of the time the train is in motion. While this is a fairly general assumption and will give sufficient margin for a large majority of problems, it will be found in carrying out the subject to a conclusion that the per cent of coasting is a very large factor in determining the train energy input. For instance, a high rate of acceleration with a long period of coasting will demand less energy input to the train than a lower rate and little or no coasting. The reason for this is obviously that the efficiency of acceleration of the two runs may be approximately 70 per cent, while the speed at which brakes are applied is less with a longer coasting period and hence the work demanded by the equipment is less.

In all three of the energy curves given, a variable friction during acceleration and coasting is considered, but straight line braking is assumed. The energy required to accelerate the rotating parts is also considered, so that the curves as given are of fairly general application.

In this paper the writer has attempted to outline a method of determining the probable heating and energy consumption of a given equipment for any class of work, having in mind, also, the possibility of arriving at some short, concise method of rating different railway motors, so that their comparative service capacity might be accurately indicated. As the subject of motor capacity is so dependent upon experimental tests, not only of car friction and braking, but also of heat radiation under working conditions, the conclusions drawn were based so far as possible upon actual experiments made. Were it not for the fact that car friction, or rather, tram friction is such a variable quantity, dependent not only upon the condition of track but upon the speed and composition of the tram, it would be possible to plot a set of curves for a given friction and distance, and apply these curves for similar shaped runs over greater or less distances by taking the coordinates proportional to the square root of the area of the speed-time curves, that is, pro- the wind friction at higher speeds changes the value of friction per portional to the square root of the distances covered. As, however, tion to such an extent, it is only possible to draw up curves for a given set of conditions and generalize, as is done in Figs. 12, 13 and 14 for different friction rates.

While it is thus possible to prepare a set of energy curves which are of fairly general application to all problems, it is only feasible to express the relation between motors of different capacity by a series of curves similar to those described in Figs. 7, 8, 9 and 10. It is entirely possible to approximate the probable heating of motors of different sizes when the resistance, core loss and general construction is known, but such short cut methods are at best only approximations and no true comparison of different motors can be made which will take into account their different losses for the same work performed and their capacity for radiating these losses at different speeds, without considering the subject in detail for each motor alone along the general lines indicated in this paper.

In dealing with the railway motor where the temperatures approximate 60 deg. C. rise in practice, with an air temperature in summer reaching 30 deg. to 35 deg. C., we have not much leeway below a temperature injurious to the insulation, and approximate methods giving rise to errors of 10 deg. or 20 deg. C. in temperature cannot be seriously considered in such important calculations as the determination of railway motor temperature. For this reason the methods outlined, although entailing a large amount of experimental work and subsequent calculation, provide an accurate method of determining the temperature of railway motors operating under any known conditions, and although they fail to provide a method of rating railway motors, it is due to the fact that such a method of rating cannot be expressed by any short term, but necessitates such general curves as are indicated in the paper.

The writer wishes to acknowledge the services of Mr. E. F. Gould in preparing material for this paper, and the kindness of the General Electric Co. in furnishing results of experimental tests which served as a basis of all calculation.

**BAY SHORE TERMINAL CO., NORFOLK, VA.**

This company has just opened a new 12-mile electric railway from the city postoffice of Norfolk to Ocean View, Va. Although the road is built on standard lines now thoroughly familiar in the north, it is interesting as showing the stage of development reached in electric railway construction in the south.

The road at present is mostly single track, but soon will be double-tracked throughout. In the city a 9-in. Pennsylvania Steel Co. 107-lb. girder rail was used with concrete poured between the ties and up to the base of the rail. In the country a 4½-in. 58-lb. T-rail was laid. With the girder rail "Protected" rail bonds are placed under the 8-hole angle plates at each joint.

A large portion of the track work is laid with oyster-shell ballast, a form of ballast extensively used in the South wherever oysters are plentiful. In building it is customary after grading to dig a trench for the roadbed and fill in with oyster shells to a depth of 6, 8 or 10 in., as the condition of the sub-soil may demand. The shells are rolled down hard and the ties placed on top of this bed. Shells are then tamped in between the ties and up to the top of the rail and a steam roller is again used to give a hard, compact surface.

CAR HOUSE AND POWER HOUSE.

At Norfolk the oyster shells cost from 2½ to 3 cents a bushel. Shell ballast is dusty in dry weather, but otherwise makes a very satisfactory roadbed.

On the Bay Shore Terminal road the ties are Georgia pine, sawed for city work and hewn for T-rail work. The company pays 42¾ cents each for its ties either sawed or hewn. Ties are 6x7 in. x 8 ft. spaced 2 ft. c. to c.

On the business streets of Norfolk the paving is granite blocks on concrete. The company pays for paving its tracks and for 2 ft. beyond each outside rail.

There is considerable single track trestle work along the line that is rather interesting. A representative section of this trestling is found not far from the city terminal where the road crosses a small river. The trestle is 600 ft. long. It consists of 40-ft. 12 in. cyprus piles driven three together every 16 ft. On top of each set of three piles is laid a 12x10 in. x 12 ft. cap piece, and on these are the main stringers which are 6x14 in. x 32 ft. long. The ties are bolted to the stringers. This trestling is strong, substantial and inexpensive to build.

As the piles stand in tide water they required some form of protective coating against moisture and also to keep bugs and worms which are very plentiful in this locality from honeycombing the piles. This protection is gained by charring the outside of the piles to a depth of about ½-in. The piles before driving are rolled into an open fire and frequently turned until an even depth of char has been secured all the way around. It is found that worms and insects can make no impression on piles burned in this way and the treatment is believed to be more effective than creosoting.

The trolley wire is No. 00 with Ohio Brass overhead material. The poles are juniper, 30 ft. long, 7-in. at top and 12-in. at butt, placed 6 ft. in the ground with concrete tamping.

The power house is a model station for a small street railway property. The building is of brick, 45 ft. by 93 ft. and is one story high. The boiler room extends across one end of the building and is 30 ft. wide inside. The boiler room floor is at grade, and that of the engine room 7 ft. higher. Concrete footings are provided for the walls and brick and concrete foundations for the engines and generators.

At present the station contains but one 200-kw. unit but an additional 400 kw. unit will be installed at once.

and in case of fire both pumps could be used to pump water to the fire plug connections.

The car house is built of hard pine and cost \$2,700 complete. The main portion is 175 ft. long by 36 ft. wide, making room for three tracks which are entered from one end only. The center track has a pit 80 ft. long near the rear end of the barn. At the rear end, alongside the car house is the shop, 50x15 ft. In a corresponding position at the front end of the car house are a room 20x15 ft. for conductors and motormen and two rooms 15x15 ft. for offices. The

INTERIOR OF POWER HOUSE.

The present unit consists of a 150-h. p. simple Hamilton-Corliss engine, with cylinder 20 in. in diameter and 42-in. stroke, belted to a 200-kw. Westinghouse railway generator. The engine is run non-condensing but will be changed to condensing as soon as the condensing apparatus can be installed.

The new unit will consist of a 600-h. p. Hamilton-Corliss tandem compound engine, with cylinders 18 and 36 in. x 42-in. stroke, direct connected to a 400-kw. railway generator. There is being installed an independent Wheeler surface condenser. Both engines

car house and power station were both designed by Charles P. Breese, consulting engineer, of Norfolk, Va.

The rolling stock consists of three open motor cars, four closed motor cars and three open trailers. The cars are partly Stephenson and partly St. Louis Car Co. make. The motor cars measure 35 ft. over all and the trailers 40 ft. over all. This running of long double truck trailers attached to double truck motor cars is a practice more frequently followed in the South than in the North. It is in vogue on the interurban lines running out of Washington, D. C., at Norfolk, Va., at Charleston and other Southern cities. It seems to be the opinion that the added carrying capacity per train more than overbalances whatever increased liability to accident there may be, incident to running trailers.

The motor cars are equipped with two Westinghouse No. 56 motors to each car and are mounted on McGuire double trucks. Part of the cars are fitted with Christensen air brakes and part with Westinghouse air brakes, both of the motor driven compressor type. When trailers are run it is customary to have a brake cylinder on the trailer which is connected by train pipe with the main air tank on the motor car, and the brakes on both cars are operated in unison from the engineer's valve on the front platform of the motor.

Until the double track is ready cars will be dispatched by telephone.

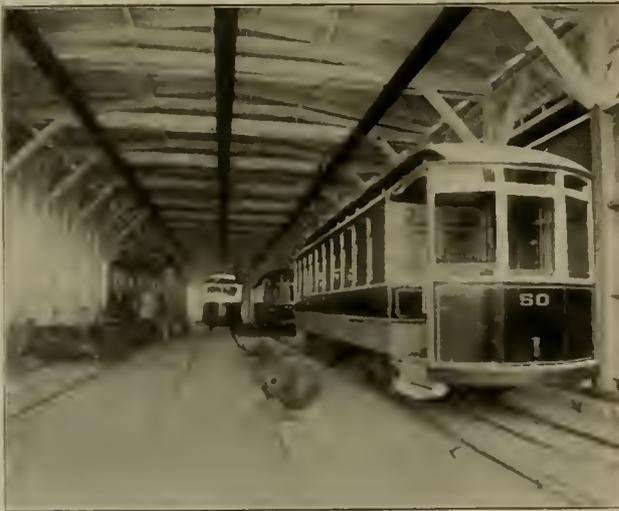

The Bay Shore Terminal Co. was organized in 1900, and has capital stock authorized, \$500,000; issued, \$120,000.

The officers are: President, H. L. Page; vice-president, H. L. Smith; secretary and general manager, J. A. C. Groner; treasurer, A. E. Krise; supervisor, L. C. Johnson; chief engineer, C. P. Breese; electrical engineer, A. L. Crater; auditor, Alex. Hart; attorney, J. E. Cole. The company is building the road under the supervision of its own officers without the aid of contractors. The road when completed will have cost about \$220,000, including cost of franchises.

Mr. L. C. Johnson, supervisor, is in charge of the road department including maintenance and operation. All section foremen, conductors and motormen and laborers report to him. Mr. Johnson is a steam railroad man of wide experience, having been with the Seaboard Air Line for five years, and master builder for the Atlantic & Danville R. R. for 12 years.

Mr. A. L. Carter, electrical engineer, has supervision of car barn property, power house and all electric road work. Foremen in charge of these departments report to him.

The Binghamton (N. Y.) Railway Co. has installed a new 750 h. p. vertical engine and boiler and General Electric generator at its power house, and has put four new cars in commission.

INTERIOR OF CAR HOUSE.

are from the works of the Hooven, Owens, Rentschler Co. of Hamilton, O.

There are two 150-h. p. Stirling boilers run under 150-lb. steam pressure. The boiler capacity will be increased to provide for the new unit. The steam piping is extra heavy with extra heavy fittings. The feed piping is of brass, extra heavy. There is a 70-ft. brick stack, 4 ft. in diameter.

Near the power house is a 70,000-gallon tank elevated to sufficient height to give good pressure in the car barn and power station. The tank is supplied with water from driven wells by a small steam pump. This pump and the feed water pump are so connected that either one can be used for feeding the boilers or for storing the tank

## RECENT STREET RAILWAY DECISIONS.

EDITED BY J. L. ROSENBERGER, ATTORNEY AT LAW, CHICAGO.

### ELECTRIC RAILWAY IN STREET AN ADDED BURDEN.

Peck v. Schenectady Railway Co. (N. Y.), 63 N. E. Rep. 357. Apr. 1, 1902.

The use of a city street for the purposes of a street surface railroad operated by electric power the court of appeals of New York holds, as a settled question in that state, imposes an added burden upon the property rights of the owners of the fee, subject to the public easement for street purposes.

### ONE SEEING A MOTORMAN IS NOT GOING TO RESPECT HIS RIGHTS TO CROSS STREET FIRST MUST NOT TAKE CHANCES.

Schwanewede v. North Hudson County Railway Co. (N. J. Sup.), 51 Atl. Rep. 696. Feb. 28, 1902.

If it appears that the trolley car motorman is not going to respect your rights to cross the street first, you must wait, the supreme court of New Jersey holds, or you are guilty of contributory negligence if hurt. A person cannot take chances, and hold himself free from contributory negligence. There is a difference between an unforeseen peril and being overtaken by one recklessly incurred.

### INJURY OF PASSENGER IN LOOSENING FOOT CAUGHT ON STEP IN ALIGHTING.

Howell v. Union Traction Co. (Pa.), 51 Atl. Rep. 885. Apr. 21, 1902.

The testimony of a passenger that when, in alighting, he had put one foot on the ground the other caught by the heel in the step of the car and he could not get it loose until he made a second effort with such force that it threw him down and he injured his kneecap, the supreme court of Pennsylvania holds, failed to disclose any negligence on the part of the company, and a judgment of nonsuit was properly entered.

### MOTORMAN INJURED BY DEFAULT OF DRIVER OF BEER WAGON ENTITLED TO DAMAGES FROM LATTER'S EMPLOYER.

McCorkle v. Anheuser-Busch Brewing Association (La.), 31 So. Rep. 762. Mar. 17, 1902.

A street car propelled by electricity, and moving at a moderate speed, was run into at a corner by a covered beer wagon, the driver of which, occupying a seat from which his view upon either side was obstructed by the cover of the wagon, drove his mules at a brisk pace along the street which intersected the car tracks, and practically into the car, before looking up or down the track. Upon the facts proven, the supreme court of Louisiana holds, the driver was at fault, and the motorman was entitled to recover from the driver's employer for personal injuries resulting from the collision.

### ADJOURNMENT WITHOUT FORMAL POSTPONEMENT OF ACTION ON FRANCHISE NECESSITATES A NEW NOTICE STOCKHOLDERS ON BOARD GRANTING FRANCHISE.

Hugh v. Smith (N. Y. Sup.), 75 N. Y. Supp. 451. Mar., 1902.

Under a statute requiring the local authorities to give public notice of the time and place when an application for consent to build and operate a street railroad shall first be considered, the supreme court of New York, special term, Fulton county, holds that jurisdiction to act upon the application is lost by an adjournment without date and without postponing the subject for future consideration, and no subsequent action thereon is authorized until notice is again given as in the first instance. Moreover, the court holds that good morals, as well as good law, unite in condemning as illegal any contract made with, or consent given to the applying corporation while any of its stockholders continue a part of the board of trustees of the municipality.

### AUTHORITY REQUIRED TO OCCUPY PUBLIC ROAD IN COUNTRY.

Norfolk Railway & Light Co. v. Consolidated Turnpike Co. (Va.), 40 S. E. Rep. 807. Mar. 13, 1902.

A street railway company cannot lawfully occupy a public road in the country, the supreme court of appeals of Virginia holds, unless it has authority to do so from the legislature, or from the county, where the power to grant such authority has been delegated to the county by the legislature. The authority must be by express enactment, or by implication so clear as to leave no doubt that it was granted. It cannot occupy a public road under a general authority to extend its lines not exceeding 20 miles into the country from the city limits. And this is true whether the proposed service be a commercial street railway or for the purpose alone of transporting passengers.

### DUTY OF DRIVER OF VEHICLE TO LOOK FOR CAR UNTIL TRACK IS REACHED.

Pieper v. Union Traction Co. of Philadelphia (Pa.), 51 Atl. Rep. 739. Mar. 24, 1902.

A driver in a big, high-seated, two-horse wagon, with curtains all down the sides because it was raining, gave one look "out from underneath the cover" of his wagon, for a distance of 50 or 70 feet down the street, to see if a trolley car was coming, when he reached the flag crossing across the street, and seeing no car within the distance named, sat back in his wagon, satisfied that he could cross the track without being struck. The supreme court of Pennsylvania holds that he was properly nonsuited on the ground of contributory negligence. It says that it was his duty, when he was entering the street, to be on the lookout for the approaching car, and, when on the street, to continue to look until the track was reached. A single glance "out from underneath the cover" of his wagon down the street for but 50 or 70 feet was not such a looking as enabled him to see the danger into which he took his wagon an instant later; and this careless looking was in itself negligence. It was a mere heedless glance, and not an adequate performance of the duty required by the situation.

### DUTY OF DRIVER OF VEHICLE APPROACHING TRACKS AS TO LOOKING FOR CARS.

Haas v. Chester Street Railway Co. (Pa.), 51 Atl. Rep. 744. Mar. 24, 1902.

The driver of an open carriage, the supreme court of Pennsylvania here holds, was not required to stop before attempting to cross a street railway track, but it was his duty to look, when in a place where he had a view of the track, in the direction from which a car might be expected to come, and to continue to look as he approached it. Ordinarily on a city street the house line is the proper place from which to look, and looking from a point back to the house line where the view is obstructed does not relieve from the charge of contributory negligence. But if the act of looking, commenced at a point back of the house line, continues when it is reached, and until the driver is so far committed to the act of crossing that it is more dangerous to attempt to stop than to go on, he has done all the law requires in that regard. When a clear view of the track for a safe distance cannot be had, it may be the duty of a driver to stop before crossing the track of a street railway. But this is not a fixed legal duty, as it is in the case of steam railroads; and, unless the necessity for this additional precaution is obvious, the question whether, under the circumstances, it should have been taken, is for the jury. The driver in this case had to look both ways, as a car might come from either direction on the single track. While he was advancing slowly, looking alternately west and east, a car running very rapidly came into view in one direction while his eyes were momentarily turned in the other. Whether, under the circumstances, he exercised due care, was for the jury, and a judgment in his favor is affirmed.

#### LIABILITY FOR INJURIES CAUSED IN CASE OF RUNAWAY BY PROJECTING RAILS.

*Gray v. Washington Water Power Co.* (Wash.), 68 Pac. Rep. 300. Mar. 19, 1902.

A horse driven by a woman became frightened, and ran away. It turned into a street where there were street railway tracks, the rails of which were required by the grant of the use of the street to be kept flush with the surface thereof, but which projected above the surface of the street from one to three inches, and had done so for a considerable time. When the wheels of the buggy struck these rails at an angle, the woman mentioned and another one with her were thrown out, and the former severely injured. A jury returned a verdict in her favor, and the supreme court of Washington holds that it was error to grant a new trial on the ground that the running away of the horse and the loss of control of the horse constituted the proximate cause of the accident and injuries complained of. In other words, it does not think that the court could say, as a matter of law, in this case, where two causes united to produce an injury, which one of the causes was the proximate cause of the injury. The correct rule of law was stated, and the question properly submitted to the jury, the court holds, by an instruction to the effect that before a recovery could be had it must be proved that the company was guilty of negligence in the maintenance of its track at the point of the injury; that the rails were exposed in such condition as to be dangerous to the traveling public, by the ordinary and usual method, in the ordinary and usual way; and that it was necessary for the jury to find that the accident and injury would not have occurred without the existence of the negligent acts complained of.

#### LIABILITY OF CONSOLIDATED FOR DEBTS OF OLD COMPANY—ILLEGALITY OF CONSOLIDATION—NO DEFENSE.

*Shadford v. Detroit, Ypsilanti & Ann Arbor Railway* (Mich.), 80 N. W. Rep. 960. Apr. 8, 1902.

If there is in fact a consolidation between certain street railway companies, the consolidated company, the supreme court of Michigan holds, cannot deny its liabilities, either for contracts or torts, or its liability resulting from such consolidation, upon the plea that its organization is illegal, as, for example, because the street railway act under which it is organized does not authorize a consolidation. The legality of its organization cannot be attacked collaterally in suits by and against it, based upon dealings with it. Its legality can be attacked only in a direct proceeding by the state for that purpose. So long as the state chooses to recognize its validity by keeping silence, it is a corporation de facto, or in fact, though not de jure, or of right, and liable the same as any other corporation in its dealings with others. Nor can the consolidated company say that one of the old companies was insolvent, and that therefore a creditor of such old company was not prejudiced by the consolidation or transfer. By the consolidation the new company is burdened with the debts of the old, and the sole question then is, has the new company sufficient assets to pay its debts which then include those of the old companies? The law will not permit the creditors of two corporations to be deprived of the assets of such corporations in payment of their debts, and turn them over to suits in equity against the stockholders, when the union or consolidation with another company is effected without the passage of a dollar or other valuable consideration passing between the corporations themselves.

#### DUTY OF DRIVER IN COUNTRY TO LOOK FOR CAR UNTIL TRACK IS REACHED.

*Keenan v. Union Traction Co.* (Pa.), 51 Atl. Rep. 742. Mar. 24, 1902.

A driver, in the country, of a one horse, covered delivery wagon stopped at a distance of about 35 feet from the track, climbed out on the swingle-tree far enough to get clear of the curtains, and look down the road, where he had an unobstructed view of 319 feet in the direction from which a car was coming, but seeing no car got back into his wagon and started his horse on a walk. The supreme court of Pennsylvania holds that at the close of his testimony a verdict was properly directed for the company. It says that had he leaned forward beyond the curtains, without getting out on the

swingle tree, and looked, he could have seen the car, and his failure to do so was negligence per se, or in and of itself. He did not continue to look until he reached the track, and yet that was his duty. Continuing, it says that it was urged that the rule that one about to cross a street railway track must continue to look until the track is reached relates only to electric roads in cities, and does not apply to the crossing of such railway tracks in the country, where the views are much more extended, cars pass less frequently, and the obstructions to travel on town streets are not encountered. The answer to this was that care must always be exercised. The degree required may vary, but want of care under the circumstances is always negligence. It is as much one's duty to look out for danger in the country as it is in the town. Trolley cars run into wagons carelessly driven, not only on the streets of a city, but on turnpikes and rural roads as well. The court has never said that the duty of continuing to look until the trolley or street railway is reached is not binding upon those driving teams in the country. The same degree of watchfulness may not be required there as on crowded city streets, but it will never be held that there need be no care at all in the country, as there was not in this case, after the driver climbed back from the swingle-tree into his seat in the closed wagon, where he could not see, and started for the danger which he would have avoided if he had looked.

#### DRIVING ON AND ACROSS TRACKS—ATTEMPTING TO CROSS TRACKS AT NIGHT AFTER SEEING HEADLIGHT.

*Metropolitan Street Railway Co. v. Slayman* (Kan.), 68 Pac. Rep. 628. Apr. 5, 1902.

It requires no citation of authorities, the supreme court of Kansas, division No. 1, says, to prove that persons traveling upon a public street along or across a street railway are not held to the exercise of the same degree of care as when traveling along or upon or across an ordinary railroad. Public streets are intended for public travel, and one who drives a team upon them has the same right to use them as has the street railway company, subject, always, to the duty imposed by necessity upon such driver to turn out for, and not unnecessarily obstruct, the cars, and to use proper care to avoid colliding therewith. For that reason such driver may not undertake to cross the tracks of a street railway company so near a moving car as to impede its passage or incur danger of collision; but even if he does so, in violation of his duty, and those in charge of the car discover his danger, it is incumbent upon them to check its speed, and, if possible, avoid an accident. If to the driver of a vehicle there reasonably appears to be sufficient time for him to cross the track before a moving car will, while running at its ordinary speed, arrive at the place of crossing, and if, in good faith, and in the exercise of due care, he attempts to so cross in front of such car, it cannot be said, as a matter of law, that he is so far negligent in making such attempt as that he cannot recover, should an accident occur because the car was running much faster than usual, and because no effort was made by those in charge of it to prevent disaster. The degree of watchfulness and caution requisite in any case to constitute ordinary care must be commensurate with, and measured by, the danger to be avoided.

Where the driver of a heavy wagon attempts to cross the tracks of a street car company at night, and, before doing so, looks both ways upon the track, and is unable to discover any car approaching, but does see the headlight of one, which he believes to be moving toward him at a distance of three or four hundred yards; and where the evidence justifies the jury in determining that such car was traveling at an unusual, reckless, and dangerous rate of speed, which fact such driver did not and could not know before starting to drive across such track; and when, by reason of such high rate of speed, and the failure of those in charge of the car to make any effort to stop it, such wagon is struck, and the driver is injured,—the question as to whether the latter was so far guilty of contributory negligence as that he may not recover, the court holds, is one of fact, for the jury, under proper instructions of the court. With reference to the statement in this case of the driver that he did not see the car, but saw a light which he took to be the headlight of a car moving towards him, the supreme court says that it thinks, under the circumstances, that the court would have been justified in regarding it as tantamount to an admission that he saw the car. Still it was not error for the court to submit to the jury the ques-

tion as to whether he did in fact see the car, when he, in terms, denied having done so. However, this matter, the supreme court says, was unimportant, for the court plainly told the jury that if the party suing would have avoided the injury which he received, by the exercise of reasonable care and diligence, and he failed to exercise such reasonable care and diligence, and thereby directly contributed to the cause which produced his injury, they should render a verdict for the company. And in other instructions they were advised that, if he failed to exercise ordinary care to avoid a collision, he could not recover in the action.

ALLEGATIONS REQUIRED IN APPEAL FROM REFUSAL TO APPROVE ROUTE—CONTROL OVER HIGHWAYS.

Appeal of Millbridge & Cherryfield Electric Railroad Co. (Me.), 51 Atl. Rep. 818. Jan. 6, 1902.

The supreme judicial court of Maine holds that, in an appeal, based upon the alleged neglect or refusal of municipal officers to approve the proposed route of an electric railroad company, under the provisions of chapter 268, sec. 6, Pub. Laws 1893, as amended by chapter 119, sec. 2, Pub. Laws 1899, relating to the organization of street railroad companies, it is necessary that enough should be alleged to show that the court has jurisdiction, and that the company had the right to apply to the municipal officers for an approval of its route. But it is not necessary to allege all the steps by which the company obtained that right. The statute gives that right to every "corporation organized" thereunder. Under the statute as it existed when the above company was organized, as preliminary to organization, it was necessary that the railroad commissioners should determine that public convenience required the construction of the railroad. But it is unnecessary to allege specifically, in an appeal of the kind stated, that the railroad commissioners had so determined, for it is necessarily implied in the expression "corporation organized," or in any expression meaning substantially the same.

The court holds, too, that chapter 119, section 2, of the Public Laws of 1899, relating to the route and location of street railroads in the ways and streets of a town, to the approval thereof by the municipal officers, and to appeals from their action or refusal to act, is not unconstitutional, as being beyond legislative authority, or as being arbitrary and unjust, or as permitting the property of towns to be taken for street railroad purposes without just compensation. The public has a mere easement in land taken and condemned for a highway or townway. It has the right to use it in certain ways. Within the scope of the easement, the public, which acts through the legislature, may regulate and control, may extend or diminish, the public uses, as it sees fit. The operation of a street railroad is an appropriate public use of a street. While a town is charged with the performance of many duties with respect to roads, and possesses a qualified control over them, it does not own them. When the legislature authorizes a new method of use of the public easement in a way, a town has no such property interest in the way as will entitle it to pecuniary compensation, nor has an injury been done to it of which it can properly complain.

DEFENSE UNDER NEW YORK LAW FOR EXACTION OF EXCESSIVE FARE FROM TRANSFER PASSENGER—REFUSAL TO RECEIVE TRANSFER TICKET FROM PASSENGER NOT NOTICED UNTIL BLOCKS BEYOND TRANSFER POINT—TENDER BACK BY CONDUCTOR OF EXCESSIVE FARE.

Public v. Brooklyn Heights Railroad Co. (N. Y. Sup.), 75 N. Y. Supp. 863. Apr. 18, 1902.

Section 39 of the New York railroad law on "Penalty for Excessive Fare" provides that any railroad corporation which shall ask or receive more than the lawful rate of fare, unless such overcharge was made through inadvertence or mistake, not amounting to gross negligence, shall forfeit fifty dollars, to be recovered with the excess so received by the party paying the same. Section 195, entitled "Contracting Corporations to Carry for One Fare, Penalty," provides for transfer and a forfeiture of \$50 for every refusal to comply with its requirements. The provisions of these sections in respect to excessive fares, the second appellate division of the supreme court of New York holds, are in part *inateria*, or of the same tenor, and must be construed together. They viewed, where the

exaction is in violation of both sections, the defense provided for in section 39 is available, and a railroad corporation, sued as was the company in this case for refusal to honor a transfer and the exaction of an additional fare, can relieve itself from liability for the penalty by showing, as provided for in section 39, that "such overcharge was made through inadvertence or mistake, not amounting to gross negligence."

Under the provisions of section 195 the court thinks it plain that a passenger desiring to make such a continuous trip as that which was contemplated by the party suing could not be deprived of his right to be carried for a single fare by giving him a transfer ticket which should be useless upon the first car which came along after he reached the point at which the transfer was to be made. But the fact that, in this case, the conductor, before the passenger left the car, offered to accept the transfer ticket held by the passenger, and to restore to him the five cents which he had paid, the court holds, warranted and required the inference that the overcharge was mistakenly made, and made under circumstances which did not constitute gross negligence. The omission of the conductor to notice the passenger with the ticket in his hand shortly after he entered the car, it says, might well be regarded as merely an inadvertence, and the conductor's refusal to receive it at first, when the passenger tendered it to him many blocks further on, was a natural mistake, in view of the conductor's supposition that the passenger had then only just boarded the car. If the passenger had accepted the proffered five cents and gone his way, he would have suffered no possible injury; and it would be a very harsh application of the law, and one not justified by the facts, to hold that the statutory penalty was recoverable in such a case.

LIABILITY FOR EJECTION AND SUBSEQUENT ARREST OF HOLDER OF DEFECTIVE JOINT-CONTRACT TRANSFER—RULES WHICH ARE NOT REASONABLE—GOOD FAITH OF CONDUCTOR NO DEFENSE—MEASURE OF DAMAGES.

Jacobs v. Third Avenue Railroad Co. (N. Y. Sup.), 75 N. Y. Supp. 679. Apr. 11, 1902.

The first appellate division of the supreme court of New York reverses in this case the judgment of the appellate term (XI Street Railway Review, 783; IV Street Railway Law, —), which reversed a judgment of the general term of the city court of New York affirming a judgment for the party suing (XI Street Railway Review, 429; IV Street Railway Law, —). The action was brought to recover damages for an alleged assault and false imprisonment, the party suing having been ejected by, and subsequently arrested at the instance of a conductor of the above company sued, who refused to receive a transfer ticket which by mistake had been punched as given at 5:15 p. m., whereas it was then 6:15 p. m., the passenger not understanding the meaning of the numbers and therefore not being aware that the mistake had been made. Between the railroads there existed, it appeared, a traffic agreement, based upon a valid consideration, whereby each railroad company agreed with the other to receive and transport passengers from the cars of the respective companies without further compensation than such as was paid to the company carrying the passenger to the intersection of the two railroads, and that the railroad carrying a passenger who desired a transfer should issue to such passenger a transfer ticket, which should entitle such passenger to carriage from the point of intersection to his destination upon the line of the railroad.

There can be no question, the court holds, but that, under the traffic agreement between these two railroads, each conductor acted as the agent of the respective railroads in issuing transfer tickets for carriage thereon. Each agreed to recognize transfer tickets issued by the other, and such agreement was admitted to be founded upon a valuable consideration. It was therefore clear that the party suing, when he received his ticket entitling him to ride upon the road of the company sued, entered into a contract of carriage with that company, and thereby became entitled to ride thereon to his point of destination. The mistake in punching the ticket was not his mistake. In law, it was the mistake of the company sued, as it was committed by its agent. The party suing could not be charged with contributory negligence in receiving the same, as he was in ignorance concerning whether it was punched right or wrong, and, in the absence of explanation, was unable to discover

that a mistake had been made. Consequently, he was without means of determining it or ability to correct it. Under such circumstances, the company sued was not justified in refusing to honor the ticket. When, therefore, its conductor refused to accept the ticket for transportation of the party suing, ejected him from the car, and caused his arrest and imprisonment, the company was guilty of a wrongful act, and became liable in damages for such injury as he sustained. The refusal to receive the ticket, the ejection from the car, and the arrest and imprisonment were to be treated in law, as they were in fact, as continuous acts, for which the company sued was responsible.

With regard to the contention that the company was justified in making and enforcing reasonable rules and regulations respecting the recognition of transfer tickets, the court holds that there can be no such thing as a reasonable rule and regulation which protects the company against the mistakes of its own agents which result in the invasion of a passenger's rights. And it declares that the good faith of the conductor was of no consequence. It could not authorize or protect against unlawful acts.

Under the circumstances of this case, the court holds, the party suing was only entitled to recover compensatory damages. These embraced loss of time, the amount which he was obliged to pay for passage upon another car, and injury done to his feelings by reason of the indignities under which he wrongfully suffered.

CHALLENGE OF CONSOLIDATION OR LEASE BY STOCKHOLDER—DIRECTORS OF LESSOR COMPANY MADE THOSE OF LESSEE—POWER TO LEASE PROPERTY AND FRANCHISES—WHO TO EXERCISE POWER TO LEASE.

*Dickinson v. Consolidated Traction Co. (U. S. C. C., N. J.), 114 Fed. Rep. 232. Feb. 13, 1902.*

This suit was brought by the executors of an estate owning 100 shares of the capital stock of the above company to have a lease of its property and franchises set aside and its property restored to its stockholders. But consequences that would involve the destruction of the conditions of comfort and convenience to a large community, and the demoralization of settled plans for the administration of large and valuable properties, with possible serious resulting loss to the stockholders of the two companies, the United States circuit court, district of New Jersey, says, ought not to be lightly incurred. That a wrong and injury had been done by the transactions complained of, to the estate of the single decedent stockholder, whose executors were complainants in this case, or to the corporation of which he was a member, should be made clearly manifest before the asked for interference of the court should be granted. However, though it was true that no pecuniary loss or damage had been shown to have resulted to the holders of these 100 shares of stock, by reason of these transactions, the court must nevertheless consider whether a legal or technical wrong had been done them by reason of some contravention of their legal rights as stockholders, or to the corporation itself, by reason of the alleged illegal action or fraudulent mismanagement of its interests, by those who for the time being controlled it. And the court says that, although the stockholder as an individual can never go into a court of equity, and ask for relief against a third person, upon the ground that the corporation has made a bad bargain, whether by the fraudulent or the illegal action of its directorate, yet, if the corporation ought to bring a suit against such third person, and seek, as against him, to take back property, and if the corporation refuses so to do, the minority stockholder may, in equity, be permitted to assert the right which the corporation ought to assert, by alleging that the corporation so refuses to act, after he has made honest and bona fide efforts to induce them to do so, and by making his corporation a party by bringing it in as a defendant, though its real status is that of plaintiff, and seek to obtain for it the relief to which it would have been entitled, had it itself sued.

That the lessee company was controlled by many or most of the same men who, before the lease, controlled the lessor company, the court says, would seem to be to the advantage of the stockholders of that company, and not to their detriment. This state of things as disclosed by the record, was very far from sustaining the allegations of fraud against the individual defendants, directors in the two companies, or any of them, and nothing but the clearest proof of such fraud would justify the interference asked of the court on that ground. The power of the two corporations, the one to be

lessor, and the other the lessee, of the property, rights, franchises and privileges which the lessor company had acquired by the legislative authority that granted it corporate existence, the court says, was not to be implied from any general power connected with the subject of their creation. As the power to negotiate and execute the lease had been challenged, those who would sustain it, must point to some express authority of the legislature of the state by which these corporations were created. But the court considers that there was the requisite authority where both companies were organized under a statute which provided that any company created thereunder might lease the property and franchise of any other corporation owning or operating any street railway, etc., and that "such other corporation and corporations are hereby authorized to make such lease." Every stockholder, in subscribing for his stock, took it subject to the conditions of the act, under the authority of which it was issued, and of the relevant provisions of law existing at the time, and was bound by their several requirements and conditions. The power to lease having been so given, without prescribing any mode in which it was to be exercised, it must be classed with the general powers conferred by a charter, which are to be exercised by the majority of incorporators or stockholders.

DILIGENCE REQUIRED IN EQUIPPING CARS WITH FENDERS WHEN KIND MUST BE APPROVED BY COMMON COUNCIL.

*Platt v. Albany Railway (N. Y.), 62 N. E. Rep. 1071. Feb. 25, 1902.*

October 7, 1895, a city ordinance was passed requiring electric cars to be provided with fenders, but that no fender should be used until approved by the common council. November 25, 1896, the company presented a communication to the common council stating that, after various tests, it had selected a fender manufactured in Rhode Island as the most suitable to prevent accidents, and asking that its use be approved. This communication was referred to the committee on railroads, which made no report upon the subject until May 17, 1897, when it recommended the use of the fender selected by the company. The report was adopted at once, and on the day after its adoption the company ordered the fender, but the first lot was not received until June 16, 1897. In the meantime, on May 29, 1897, a boy was killed; and this action was subsequently brought to recover damages therefor.

Upon request, the trial court instructed the jury that the absence of a fender from the car was not per se or in and of itself negligence. But it refused to charge, as further requested, that the company was not bound to have a fender on the car at the time of the accident. The court of appeals of New York holds that this last was error. It says that the company had a reasonable time, as was properly charged, to obey the command of the local legislature, and it used that time with diligence. It was under no obligation to order fenders in advance of the approval of the common council, for that might have involved useless expense, as there were several kinds in use. All that was required was prompt action as soon as it knew what fender to order, and prompt action was conclusively proved. As the jury had received no instruction whatever upon the subject, the company was entitled to the instruction prayed for. It did not ask to have the question of liability for failing to use fenders wholly withdrawn from the jury, and it was apparently willing that its alleged want of diligence in selecting a fender should be considered by them. Its request simply involved the proposition that it was not bound, as matter of law, to have a fender on its car at the time of the accident; thus impliedly conceding that its diligence or want of diligence in making a selection should be left to the jury, as a question of fact. It was, at the least, entitled to this, and a failure to charge, either literally or in substance, as requested, was reversible error.

Moreover, the trial court not only omitted to comply with the request stated, but went further, and charged that the jury might find whether the company had used reasonable diligence in equipping its cars with fenders after the fender selected had been approved by the common council, although during the short interval that elapsed between the approval and the accident the railroad company had done everything which, so far as appeared, it could have done to procure fenders. This, also, the court of appeals holds reversible error, for it cast a burden upon the company which the law did not require it to bear. The law required reasonable diligence, but the charge, so far as the evidence permitted the court to see it, required an impossibility.

**NEW SHOPS AT LOS ANGELES.**

The Pacific Electric Railway Co., of Los Angeles, Cal., the system of which includes the lines of the Temple Street Cable Railway Co., the Los Angeles & Pasadena Electric Railway Co., the Los Angeles Railway Co., and the Pacific Electric Railway Co., of Arizona, in all some 230 miles of track, has practically completed extensive shops at Los Angeles. Locally, this company is perhaps better known as the Huntington-Hellman syndicate. The officers are: President, H. E. Huntington; vice-president and manager, Epes Randolph; treasurer, J. W. Hellman.

The new shops comprise six buildings—machine and blacksmith shop, store and carpenter shop, pattern and lumber store house, paint shop, repair shop and armature winding department, and oil house. To these will soon be added a brass and iron foundry.

The machine and smith shop is 276x100 ft., and 22 ft. high in the clear; the machine shop occupies 200 ft. of the length of the building. Across the machine room, near one end, are three tracks, each with a third rail for accommodating cars of standard gage as well as of 3-ft. 6-in., which is gage of much of the company's mileage. These tracks have cement lined pits 4 ft. 6 in. deep. The machine shop has a 10-ton traveling crane spanning its 35-ft. central bay and running the entire length of the shop. The shop is supplied with modern machinery for making and repairing cars. The blacksmith

is fitted with storage bins and racks. The carpenter shop has 10 tracks, also for both gages, under three of which cement lined

MACHINE AND CARPENTER SHOP, JUNE 3, 1902.

pits 2 ft. 5 in. deep are provided to facilitate work under the cars. In one end of the carpenter shop the mill machinery is located and

NEW CAR HOUSE UNDER CONSTRUCTION, JUNE 10, 1902.

shop has swinging cranes, and besides the usual forges and fires has a double frame 3,000-lb steam hammer.

The building for the store and carpenter shop is 380x100 ft. and is

is complete for the manufacture or repair of cars. These two buildings stand in a line with one another, and from end to end the distance is 711 ft.

Parallel to this line, and 100 ft. distant therefrom, are the three other principal buildings. First, the paint shop, which is 300 ft. long, 100 ft. wide and 22 ft. high, and contains 20 double gage tracks. Next to this is the car repair shop and winding room building, which is 360 ft. long, 100 ft. wide and 22 ft. high. Eighty feet is partitioned off at one end for the armature winding room, and through this room a track is provided. In the car repair department there are 18 tracks, under all of which are cement lined pits. All the pits are connected with sewers for the disposal of wash water.

Between the two rows of shops there is a transfer table 60 ft. long capable of transporting a load of 160,000 lb., that is, a fully loaded broad gage freight car containing supplies. The travel of the table is 806 ft. This table has only four wheels, traveling on two rails, and is driven by an electric motor with overhead trolley.

The fifth building contains an 80-h. p. boiler for the steam hammers and dry kilns, and also contains on the lower floor the hard wood lumber storage, while on the second floor is the pattern shop. This building is 60 ft. wide, 200 ft. long and two stories high.

The sixth building is the oil house, 34 ft. wide and 40 ft. long, with basement 10 ft. high. The oil is all handled by either gravity or compressed air, as may be most convenient. Oil is used for the

INTERIOR OF PAINT SHOP.

also 22 ft. high in the clear. Of this length 100 ft. is devoted to the store room, through which there is provided a broad and narrow gage track for the receipt or shipment of supplies; this room is

ordinary purposes, and also for fuel under the boiler when the mill refuse is not sufficient, and for all blacksmith shop fires.

The seventh building, soon to be erected, is a brass and iron foundry, 200 ft. long, 100 ft. wide, and 30 ft. high.

The company has also built a car house 263 ft. long and 264 ft. wide, with 20 tracks, each 257 ft. long. This is used for storage and inspection and pits are provided under all tracks.

INTERIOR OF CARPENTER SHOP.

All the buildings are of brick, with trussed roofs, no purlins or jack rafters being used. The roof planks, which are 2x12 tongue and groove Oregon pine, are spiked directly to the trusses. The brick walls extend directly up to this planking, and thence there are no pockets or draft runs for the spread of fire. The inside of all the shops and the car house is coated with white magnite, thereby diffusing the light and also rendering the spread of fire more difficult.

The shops are provided with full fire service of hydrants and hose. No care or expense has been spared to make the buildings complete in every respect and adapted to their purposes.

In the construction of the buildings there were used 3,000,000 ft. of lumber, 3,000,000 bricks, and 8,000 barrels of portland cement.

to the lay of the land, more than 20,000 cu. yd. of earth filling have already been put in place in and around the buildings.

Our correspondent is indebted to Mr. Epes Randolph, vice-president and manager of the company, for the photographs from which the accompanying engravings were reproduced.

### NEW KANSAS CITY FRANCHISE.

The agreement between Kansas City, Mo., and the Metropolitan Street Railway Co., which has been under consideration since June 1st, was signed by the mayor and accepted by the company on July 28th. The agreement consists of 41 sections and in substance is as follows:

In lieu of all state, county, city, school and municipal taxes of every kind and character, the company will pay to the city 8 per cent of its gross receipts.

The company is granted franchises that will enable it to make much desired changes in routes and abandon some steep grades. The new franchises include the following lines: Troost Ave. to 40th St., to be completed by December, 1902; Vine St. to 44th St., to be completed by December, 1903; 15th St. to Crystal Ave., by December, 1904; Prospect Ave. from 15th and Prospect to the east bottom connecting with the East 5th line near Electric Park. Where practicable the grades will be changed so the whole system may be operated electrically. The 8th St. tunnel, built for a cable road and with a grade of over 8 per cent, will be changed so as to make it more practicable for electric cars, and 9th St. incline will be abandoned.

The company will pave between rails and 18 in. outside with the same material as the rest of the street.

The company will give universal transfers.

### OXFORD LAKE PARK.

The Anniston (Ala.) Electric & Gas Co. has recently published a descriptive pamphlet on Oxford Lake Park which is a high-class recreation resort, established by the street railway company in connection with its lines. The company provides swimming resorts,

NEW CARS FOR LOS ANGELES RY.

The shops contain about 10,000 lineal feet of track for the reception of cars under construction or repair, and the car house contains about 5,200 lineal feet of track for the storage and inspection of cars. The first floor area of the shops is over 3 $\frac{3}{4}$  acres, and that of the car house over 1 $\frac{1}{2}$  acres. There are 59 doors 16 ft. high and 12 ft. wide for the admission of cars to the shops. The roof trusses are combination wood and iron. All machinery, except the steam hammers, is driven from electric motors. The first work on the design and construction was done last October. Owing

to tennis courts, ball grounds and other amusement features for its patrons at the park, and it has erected bowling alleys, boat houses, bathing houses, pavilions, etc.

An agricultural fair is usually held each year at the Lake, which provides a large patronage to the park, and recently a new amusement resort has been started in which vaudeville entertainments are given every night during the summer season. The grounds, buildings and all points of interest throughout the park are brilliantly lighted during the summer season with electric lights.

## THE EDUCATION OF THE ELECTRICAL ENGINEER.\*

BY H. W. BUCK.

Electrical engineering is probably the youngest of all the professions, for it has hardly been recognized as a regular profession for more than fifteen years past. As a result, the men who have reached prominence in it today have attained their positions from widely differing courses of preliminary training; many of them are men who started life in other lines of work and afterward turned to electrical pursuits on account of the sudden growth and importance of the business. In consequence of this, all methods of preliminary education are represented and their relative values can be estimated.

The argument runs largely between two classes of men, one represented by the so-called "practical man," and the other by the theoretical electrician; the graduate of the machine shop and the graduate of the university. Both of these types have attained success, but the correct answer to the argument will probably be found in a proper combination of the two types. In the past some of the most successful electrical engineers have belonged distinctly to the class of practical men with little theoretical training, but the conditions have changed. In the early days of the profession there was little theory or pre-determination of results and work was carried on largely by guesswork or by cut and try approximations. At the present time, however, such a state of development has been reached that exactness of result is essential to success and work based upon exact theory becomes imperative.

In a stationary condition of an art a man with practical experience only may become very familiar with all the existing types of apparatus, and, knowing their various applications, may qualify, to an extent, as an engineer. But the extraordinarily rapid growth of the electrical arts places electrical engineering apart from all the other engineering branches, for new discoveries and theories make radical changes from year to year in the construction and operation of electrical machinery. The engineer, whose education is based only upon practical experience, cannot keep up with the progress and change resulting from it, and falls behind, whereas the man, with knowledge of the theory and a mind trained by the theoretical studies and scientific reasoning, easily grasps the theory of the change and readjusts his mind to the new without difficulty or delay. Many instances can be cited of men who have been prominent as electrical engineers who have been dropped out of place in the course of the rapid progress which has been made on account of a lack of theoretical foundation in their knowledge. Those who have retained their positions throughout the growth of the art have done so by persistent study along theoretical lines.

In its present state electrical engineering is the most scientific of all engineering professions. A man must be, to a great extent, a physicist, a chemist and a mathematician, as well as be familiar with machinery and its design, in order to be a worker in the broadest field. Many of the problems connected with other branches of engineering can be solved by common sense and by one's sense of proportion as guided by experience and by the eye. But most of the problems in electricity are invisible, so to speak, and can be understood only through their expression in the form of symbols.

Probably no one will dispute today that the preliminary education of an electrical engineer demands a special training in those theoretical branches—mathematics, physics, chemistry and mechanics—sufficient to train his mind into accurate methods of thought and reasoning and to supply him with the actual technical information which he will need in the practice of his profession. But theory alone is not all. The human mind is such that it works with difficulty in pure theory without a series of mental pictures to fix and coordinate the ideas, and the study of theory is likely to make little lasting impression unless the physical meaning of the theory is brought out by constant association with actual apparatus which demonstrates the application of the physical law.

The best course of training for an electrical engineer would seem to be a broad course of education in general subjects at the preparatory school before entering college, with practical work if possible, along lines of simple mechanics, such as carpentry, in order to

train the mind into a sense of proportion and the relations of parts, which is the basis of all engineering.

Next a college course with general subjects the first year; and afterwards, for the remaining years of the course, those general and theoretical subjects which have a direct bearing upon the practice of the electrical profession, such as mathematics, mechanics, physics, chemistry, theoretical electricity and magnetism and thermodynamics. This should be supplemented by actual daily practical work with machinery operating by the principles covered by the theory studied, and demonstrating all the phenomena incident to the theory.

After graduation an apprentice course should be pursued in some large electrical manufacturing establishment where the commercial relations of the knowledge acquired in college can be clearly set forth. Large machines can be operated which are not available at a college and experience in the installation of large plants can be obtained, and experience gained in the designing departments where all kinds of commercial apparatus are laid out.

After a few years of this training, specialization may begin along the lines selected for the life work, but preferably not before. A man makes a mistake to consider himself a qualified electrical engineer after he has been graduated from college, for he is not one. His mind has been trained into a condition where he can readily absorb the principles of the electrical profession, but that is all, and the subsequent apprentice training is as important as the college course, in order to acquire the broad view-point from which to make the correct start in the direction in which a man is best fitted. It perhaps means a smaller income the year after graduation from college, but it means much more at the end of five years.

But theory and practice are not the only elements necessary for the successful engineer. There are many qualities required in common with other professions; executive ability, business knowledge, presence of mind and ability to handle men, nerve and resourcefulness in handling machinery in times of emergency, are all necessary to the successful engineer. These elements cannot be acquired in the study of theory and practice alone, and many men who have stood high in their college courses have failed afterward in the practice of their profession because of a lack of these qualities.

The study of chemistry becomes more and more important as the profession advances, for the branch of electro-chemistry is rapidly developing and is likely to become one of the largest fields in the application of electrical science.

And almost above all comes a training in the English language. No man who cannot express himself clearly and concisely in writing or in conversation can hope to attain a prominent position in his profession.

The education of an electrical engineer, however, must never be considered as completed. The art advances so rapidly that constant study is necessary, even to keep up with the progress of the times. But an electrical engineer should be willing to do more than this. He should study to keep ahead of progress and do his share toward the instruction of others.

### ST. LOUIS & SUBURBAN REORGANIZED.

The reorganization of the St. Louis & Suburban Electric Railway Co. was effected July 1st at a meeting at which all of the old officers and directors resigned and an entire new board was elected. The reorganization includes in its plans the issue of \$7,500,000 of bonds, which will cover all the indebtedness of the old company and leave a surplus of over a million and a half for improvements and extensions. An important feature of the reorganization is the formation of a voting trust, which is composed of five men from the board of directors. These men control about 20,000 of the total 25,000 shares of stock, and they will have absolute power in voting upon all propositions in regard to the property for three years, both as to financial and physical questions. The board of directors was elected as follows: S. M. Kennard, Julius S. Walsh, Breckenridge Jones, Ben Alheimer, Charles H. Huttig, T. Marquard Forster, Harrison I. Drummond, William F. Noller and Frederick C. Orthwein. Mr. Kennard and Mr. Forster were re-elected as directors, and Mr. Thomas M. Jenkins remains as general manager of the company. Mr. Kennard was elected president, Julius S. Walsh vice president, and Thomas C. Kinder, secretary and treasurer, the latter being re-elected.

\*Paper read at the 19th annual meeting of the American Institute of Electrical Engineers, Great Barrington, Mass., June, 1902.

## COMMUTATOR TURNING ON GENERATORS AND ROTARY CONVERTERS.

BY A. B. WEEKS.

If proper provision has not already been made, when it becomes necessary for the first time to turn a commutator for a rotary converter or large generator, it will be found no simple task to devise and erect a wooden structure which can be depended upon and will not give away when the critical point in the turning is reached. These contingencies should be provided for beforehand. A considerable outlay in expense will be required, but must be made; especially where no machine shop with a lathe large enough to swing the armature is available. Manufacturers can supply the necessary apparatus on order.

If a belt-driven generator and a General Electric Co. lathe be used, place the lathe on the proper side of the commutator, parallel

FIG. 1.

thereto, and as close as is thought advisable. It will be necessary to remove those adjacent brush holders which interfere with the fitting, as well as those which prove an obstruction in turning. Run the tool as far as it will go laterally in both directions, in order to see that it will make a cut the entire length of the commutator, if possible, without resetting. Arrange a brace at the end of the armature shaft to prevent endwise movement; otherwise the tool may gouge into the commutator, and perhaps do material damage.

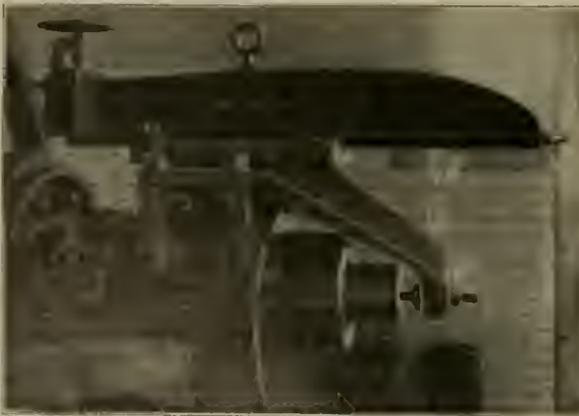

FIG. 2.

With suitable arrangements for a base for this turning device it may be used also for machines having open-work bases. Better still, the device shown in Figs. 1 and 2 is especially well adapted for rotaries. The box cap screws are removed, and special bolts and spacing nuts used. The lower part has an arm extending to

the end of the shaft, and, by means of a center and lock nuts, the end thrust is taken up.

Some means other than the alternating current ordinarily applied at the a. c. end of the rotary, must be provided for driving the rotary converter at slow speed. The machine illustrated is for 500-volt railway use; therefore, the field is to be charged with 500

FIG. 3.

volts, and a 220-volt circuit used for the armature current. But first of all, open all switches, both a. c. and d. c. Remove any brush holders and yokes that may interfere with the lathe. Two lower arms only, positive and negative, will be required. Disconnect the other cables and tape over their copper terminals. Use only two or three of the several brushes in these arms, removing the others. In the series field and armature circuit, have a water

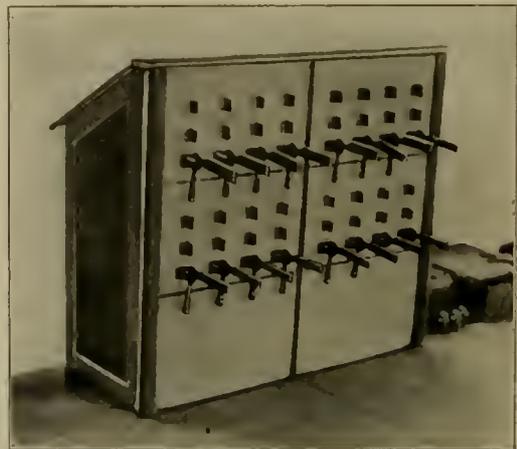

FIG. 4.

rheostat with an ammeter in circuit. It should take from 20 to 30 amperes to drive the armature. In making the shunt connections, if it is not applied by means of the rheostat, perhaps because of connections at the switch board preventing, see that the shunt does not oppose the series coils.

It is better to use only the two lower brush arms, in order that everything may be clear above, to enable one to work freely. There will be a small spark at the brushes, caused by the copper and dust; but this will do no harm. Little current is required to revolve the armature,—between 20 and 30 amperes in the case under discussion, as stated. After turning, sandpaper as usual, to finish smoothly.

The water in the barrel of the water rheostat may become very warm. It is therefore a good plan to keep it in circulation, if there is a drain pipe. First put on the field current; next complete the

armature circuit through the water rheostat, lowering the plates until the proper results are obtained. Set the tool and feed slowly and steadily, removing as soon as the tool drags or forces with difficulty, as it is then dull. There is usually somebody about a plant of this kind who knows how to sharpen a tool in a way to gain the best results. It is not a simple matter to grind one properly for turning copper.

Fig. 3 shows a rotary converter armature which has been re-wound; also a method of putting on the band wires. A rope is passed around the armature several times, and the free end secured to a winch. At the right of the figure is shown a testing transformer mounted on wheels, making it easily portable, and valuable for use in a large station. The engraving shows a familiar scene in the Niagara Falls power plant, the testing transformer being used periodically to test the generators between phases, and from copper to ground, at a pressure of from 3,000 to 6,000 volts, according to the condition of the generator being tested.

When first installed an artificial load was put on each dynamo as needed; a water rheostat of 5,000 h. p. being used for the purpose. Fig. 4 shows the two-phase panels and switches for the rheostat. The coils of wire are located in a rectangular space below the floor outside of the power house, the space being filled with water when needed. By means of the several switches the load can be changed on either phase as may be required, to test the variation in generator speed as well as the governor regulation.

### CONSOLIDATION AT MACON.

The Macon Railway Co. is the name of a new organization which has purchased all the street railway and electric lighting properties in Macon, Ga. Mr. T. A. Carling is president and manager of the new company, J. H. Hertz, secretary and J. T. Nyhan superintendent. The new officers state that \$150,000 is to be expended in developing and improving the properties as fast as the work can be accomplished, and transfers are to be allowed on all intersecting railway lines in the city. The properties merged are the Macon Consolidated Street Railway Co. and the Macon Electric Light & Railway Co. The former company commenced some 14 years ago with a small mule line representing a capital of \$37,000 and has added to its lines and developed its property from time to time until in the present deal it sold for half a million dollars. All of the improvements have been paid for out of the earnings of the company with the exception of about \$75,000. Mr. E. E. Winters, who has been in charge of the property as superintendent, has

served under four different ownerships and has also been vice-president and general manager as well as receiver for a period of 10 months when the reorganization was effected. Mr. Winters has been general superintendent since the reorganization with full charge of the property and the other officers of the company who were in Boston have been in Macon only twice in seven years. Mr. Winters is recognized as one of the pioneers in the development of park theatrical attractions in the South, and organized Crump's Park in connection with the street railway property which has proved

E. E. WINTERS.

a wonderful success. The summer theatre of this park has run for 20 weeks every season for the past seven years and has proved a paying investment.

### NEW ROAD IN INDIAN TERRITORY.

The Choctaw Construction Co. has been organized to build the power house, railway, etc., for the Lehigh Traction Co., Lehigh, I. T., and the Lauffetter-Bendit Mercantile Engineering Co., of St. Louis, has been retained as consulting and contracting engineer on this work. The Lauffetter-Bendit company is proceeding at once to prepare the plan and specification, and will shortly be in the market for about 20 miles of rail, power house equipment, etc.

### A. S. R. A. CONVENTION ANNOUNCEMENTS.

Secretary Penington has made the following announcements concerning the 21st annual convention of the American Street Railway Association to be held in Detroit, October 8th, 9th and 10th, next:

The program includes the following papers and reports:  
 "Registration of Transfers." Brooklyn Heights Railroad Co., by C. D. Meenely, secretary and treasurer.

"Benefit Associations." Metropolitan Street Railway Co., of New York, by Orin W. Root, assistant general manager.

"Discipline of Employes by the Merit System." Metropolitan Street Railway Co., of Kansas City, by W. A. Satterlee, general superintendent.

"Transportation of Light Express and Parcel Delivery." Detroit United Railway, by George W. Parker, general express agent.

"Steam Turbine Engines." E. H. Sniffin, of Westinghouse, Church, Kerr & Co., New York.

"Signals for Urban and Interurban Railways." Old Colony Railway Co., Boston, by C. F. Baneroff, electrical engineer.

"The Adjustment of Damage Claims." Chicago City Railway Co., by M. B. Starring, assistant general counsel.

Report of Committee on Standards. N. H. Hest, president Meriden (Conn.) Electric R. R., chairman; E. G. Connette, vice-president and general manager, Syracuse (N. Y.) Rapid Transit Co.; C. F. Holmes, Kansas City; John I. Beggs, president and general manager Milwaukee Electric Railway & Light Co.; E. A. Newman, general manager, Portland (Me.) Railway Co.; R. T. Laffin, general manager, Worcester (Mass.) Consolidated Street Railway Co.; Will Christy, vice-president Northern Ohio Traction Co., Akron, O.

Report of Committee on Rules for the Government of Employes. J. C. Brackenridge, general manager Brooklyn Heights R. R., chairman; E. C. Foster, general manager Old Colony Street Railway Co., Boston; T. E. Mitten, general manager Buffalo Railway Co.; W. E. Harrington, general manager Camden (N. J.) & Suburban Railway Co.

The annual banquet will be at the Hotel Cadillac, the association headquarters, Friday evening, October 10th.

Thursday, October 9th, has been set apart as "Exhibitor's Day," and no meetings of the association will be held on that day.

All of the exhibit space has been allotted, and in addition to the Exhibit Hall and Annex permission has been received from the city to lay temporary tracks in the streets adjacent to the building. (Plans of the Hall and Annex, showing the assignment of space, were published as a supplement to the "Review" for July 20, 1902.—Ed.)

The executive committee of the A. S. R. A. has passed the following resolution:

"Resolved, That the secretary be directed to request the chief executive officers of the different companies to notify all delegates and heads of departments attending the convention that they are expected to be present at all sessions of the meeting and take part in the discussions."

The citizens of Detroit are doing all within their power to make the social part of the convention pleasant for all.

The steam railroad associations have agreed to sell tickets to Detroit at the rate of one and one-third fares for the round trip to all who get certificates, which must be countersigned by the secretary of the American Street Railway Association.

Mr. John H. Fry, chairman of the exhibit committee, has made the following announcements concerning the rules and regulations governing the exhibition at the convention of the American Street Railway Association to be held in Detroit in October:

1. The exhibition will open Oct. 8, 1902. The building will be open for the reception of exhibits commencing Monday, October 6th. All articles intended for exhibition shall be delivered at the Light Guard Armory by the agent or owner and at his expense; but the local committee has made arrangements with the Riverside Storage & Cartage Co. to haul and deliver all shipments to and from the building, if desired, at low rates. Mark goods to yourselves, care of Riverside Storage & Cartage Co., Detroit, Michigan, send this company bill of lading, or advice of shipment, and prepay charges. Under no circumstances will exhibits be received on which there are charges of any kind.

Ship all goods early to insure delivery in time. All apparatus or material for exhibits should be shipped so as to arrive in Detroit not later than Saturday, October 4th.

2. The building will be well lighted, but any exhibitor so arranging his exhibits as to shut off the light must provide interior lighting at his own expense. Current for special lighting or power will be furnished at the lowest market prices.

3. All electrical construction must be done in strict accordance with the rules of the National Board of Fire Underwriters and Detroit Municipal Departments covering such work, and certificates for same must be secured prior to the opening of the exhibition.

4. The floor of the Exhibition Building is constructed so as to support fairly heavy weights, but in order to insure the safety of apparatus exhibited, and to prevent any damage to the floor, exhibitors should submit to the chairman of exhibits by Sept. 1st a floor plan diagram showing proposed arrangement of their exhibits, and in the case of heavy apparatus, description of the articles to be exhibited with their weights.

5. Height of platform shall not exceed five inches unless by special permission. Decorations, booths or other structures shall be so arranged as not to exclude the light from adjoining exhibits, and in every instance the sides of these decorations, booths or structures facing an adjoining exhibit shall be neatly finished so as not to present a bare or ugly appearance in the adjoining exhibitor's space.

6. It has been considered advisable to adopt rules to govern the size, appearance and location of signs so as to bring the signs into some sort of uniformity and prevent one exhibitor's sign from interfering or shutting out the view of signs in the adjoining exhibits. Signs, banners, etc., containing advertisements thereon will not be allowed except upon space of exhibitors to whom they belong, and no exhibitor will be permitted to display advertising signs or decorations beyond the line of his exhibit. Signs shall not exceed two feet in height. Signs of oil cloth with brown flock ground and gilt letters are recommended.

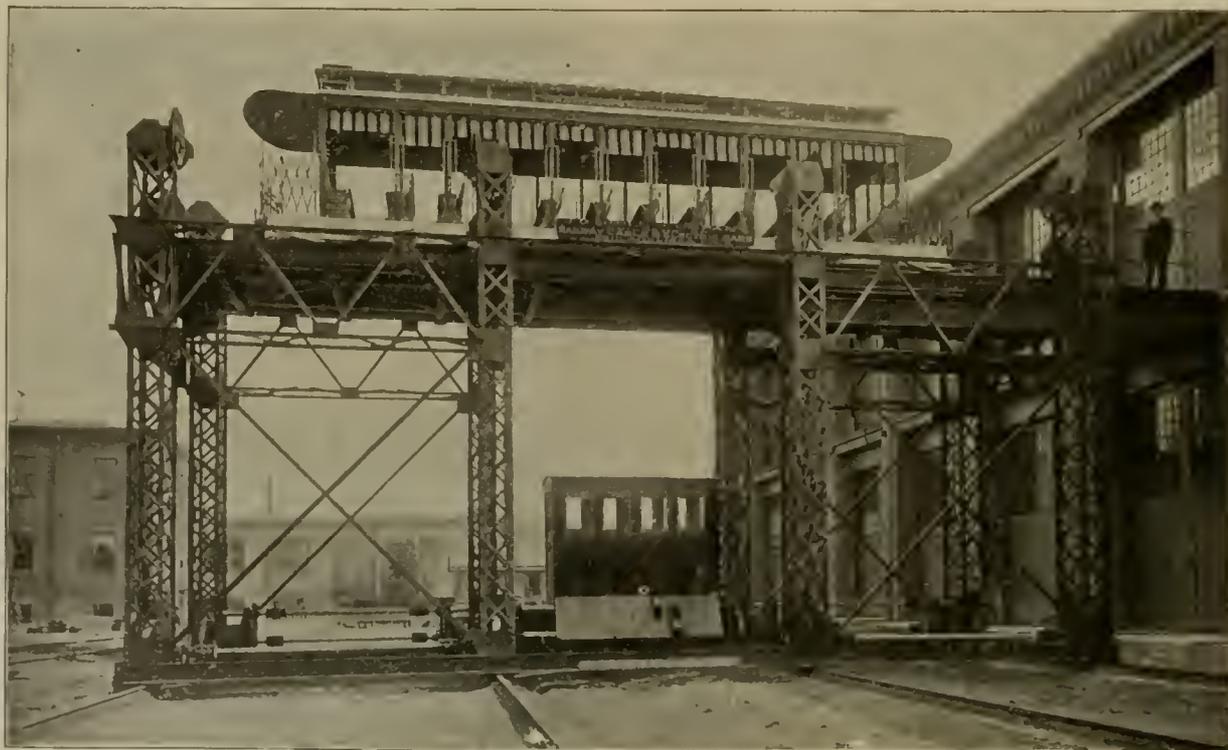

7. No nails, tacks or screws shall be placed or driven into the floor or walls, and all decorating or signs must be put up without

## NOTES FROM ENGINEERING SCHOOLS.

PURDUE UNIVERSITY—Mr. J. R. McColl has been appointed associate professor of thermodynamics and Mr. Fritz B. Ernst instructor in car and locomotive design. Professor McColl is a graduate of the Michigan Agricultural College, class of 1890, and has done work as a graduate student both in that institution and at Cornell University. After serving for a time as an assistant, he was in 1892 placed in charge of the Department of Mechanical Engineering of the University of Tennessee, at Knoxville, and for ten years has devoted himself to its development. The University of Tennessee is a most progressive one, and Professor McColl has done his full share in advancing its growth. Mr. Ernst is a graduate of the Department of Civil Engineering of Purdue University, class of 1900, and since graduating has been a member of the editorial staff of the *Railway Age*, of Chicago, in which position he has had much to do with certain phases of railway design.

## A COMBINED CAR ELEVATOR AND TRANSFER TABLE.

The accompanying illustration shows a novel style of car transfer table which, besides transferring cars from track to track serves also to elevate cars to the tracks upon the second story of the building. This table is in use at the car works of the J. G. Brill Co., of Philadelphia, Pa., and was designed to serve a two story paint shop built to economize the limited ground space available. The device consists of a steel frame mounted on wheels and having a number of steel columns surmounted by rope sheaves. The platform is suspended by wire cables drawn over the top sheaves and down through the lower sheaves to winding drums operated by an electric motor. When the cars are finished they are hauled

COMBINED CAR ELEVATOR AND TRANSFER TABLE.

defacing the building. Exhibitors will be held responsible for any damage to the floor, walls or other parts of the building caused by the act or negligence of the exhibitor or his agents.

The committee reserves to itself the right to cancel applications for space not paid for by Oct. 1, 1902. Payment should be made to Mr. T. C. Penington, treasurer American Street Railway Association, 2020 State St., Chicago, Ill.

from the car shops to the tracks leading to the transfer table and the car is placed upon the latter. The table is then moved along the building to the track on which the car is to be set. If this track is on the first floor the car runs directly upon it from the table in the usual way, but if it is on the second floor the winding drums are used to elevate the platform and car to the upper floor, the lift being 19 ft. 6 in. The table is 50 ft. long over all and has

a platform at the upper level which overhangs 8 ft. It runs on four lines of rails laid on timber stringers. Its hoisting capacity is rated at 30,000 lb., but it has lifted approximately 40,000 lb. under test. The hoisting speed is 15 ft. per minute. The table is also provided with a winding drum for carrying cars on or off when it is either at its upper or lower position. Automatic stops are provided so that the current is cut off from the table when it reaches both its top and bottom position, and the brake is set at the proper point in every case.

The hoisting drum is operated from a motor through a train of spur gearing and a mechanical load brake is provided in this train

END VIEW, COMBINED TRANSFER TABLE AND CAR ELEVATOR.

so that when the load is being lowered this brake is engaged and requires a slight amount of power from the motor to stop its action. This makes it impossible for the load to get beyond the operator's control. A solenoid motor brake is used to stop the momentum of the armature when the current is cut off by the controller of the automatic stop. An auxiliary hand brake is also provided for additional precaution. The power is taken from a trolley wire placed along the front of the building. The table was designed and erected by George P. Nichols & Bro., of Chicago.

#### ANOTHER CONSOLIDATION.

Following the many announcements made during the last three months concerning the consolidation and merger of many of our large manufacturing interests, comes one of peculiar interest to the street railway trade, the merging of the United States Projectile Co. into the F. W. Bliss Co., both of the Borough of Brooklyn, New York.

The United States Projectile Co. manufactures the well-known "Projectile Brand" gears and pinions, and has been compelled the past year to double its capacity in order to care for the constantly increasing demand for these products, and it now has one of the largest and best equipped plants in this country for producing motor gear and pinion. The F. W. Bliss Co. is probably the largest manufacturer in this country, or in the world, of presses, dies and special machinery for metal working. It also manufactures the Whitehead sub-marine torpedo for the United States Government. The plant is one of the largest in the east, and is thoroughly modern in all its appointments.

The controlling interest has always been the same in both companies, and the change will be in the ownership of the stock rather than in the management, which will remain the same as in the past. The United States Projectile Co.'s plant will be known hereafter as the F. W. Bliss Co., Projectile Department. The enlarged

facilities should assure the trade prompt and efficient service with such products as the company manufactures.

#### BABCOCK & WILCOX BOILERS IN MARINE SERVICE.

The following is an extract from the report of the committee appointed by the British Admiralty to investigate questions respecting modern types of boilers for naval service:

"In the course of its investigations the committee has watched the Babcock & Wilcox boilers fitted in the S. S. Martello, of the Wilson Line, employed in the Atlantic trade between Hull, Boston and New York, and copies of the reports of inspections have from time to time been forwarded to their lordships. These inspections have taken place at the end of every round voyage for 14 months, and the committee's opinion is that these boilers have stood the test of usage in the mercantile marine extremely well. The vessel has run about 91,000 miles since the boilers were put in, and has usually been less than a week in port at either end; the only repairs required have been those of the ordinary upkeep of any boiler, such as fire-bars, brickwork, etc., and only six tubes have required renewal. This opinion is strengthened by the inspections of boilers of the same type fitted in the 'Numidian,' the 'Buenos Ayrean,' and the 'Turret Cape.' In the case of the last-named vessel, the boilers have been in use seven years, and cannot have been as well looked after as they would have been in the navy, and their condition when examined recently was satisfactory. The committee has also examined and tested boilers of the same type in H. M. S. 'Sheldrake,' and finds that, although they have been in use for four years, their condition is good and they have given little trouble.

"From the information which has been brought to the notice of the committee, it appears that water tube boilers are being very little used in large ships belonging to the mercantile marine, and that their use in such ships is increasing very slowly. In the British mercantile marine, the only type of water tube boiler installed in ocean going vessels is the Babcock & Wilcox, in some ships of the Wilson and the Petersen-Tat Lines, and in three ships of the Allan Line; in these last, however, only one water tube boiler is fitted in each vessel, to assist the original cylindrical boilers. In the United States mercantile marine, Babcock & Wilcox boilers are used to a small extent, principally in the ships plying on the Great Lakes, and in the American Navy many Babcock & Wilcox boilers are in use."

#### ELECTRIC RAIL WELDING.

We are advised that the improved process of the Lorain Steel Co. for electrically welding rails and bonds has given the very best of satisfaction wherever it has been used. The Lorain Steel Co. now has an equipment at work on the tracks of the Worcester (Mass.) Consolidated Street Ry., and one on the Columbus (O.) Ry., and has completed a contract for welding at Rochester, N. Y. The Worcester Consolidated was so pleased with the results that it has decided to have twice as many miles welded as originally contracted for.

#### AIR BRAKE CONTRACTS.

The use of the Christensen Engineering Co.'s air brake equipments on electric cars is constantly increasing, and during the past few months the company has received a large number of orders, including one for 50 complete equipments for the Government Tramways, Sydney, Australia. Before this order was received the Government Tramways had over 125 Christensen equipments in use. Recently secured contracts in this country include the following equipments: Manchester Street Railway Co., Manchester, N. H., 15; Los Angeles Ry., 70; Twin City Rapid Transit Co., Minneapolis, 50; Middleboro, Wareham & Buzzards Bay Street Ry., 11; Stony Brook Valley Street Ry., Stony Brook, Pa., 18; Greenwich Traction Co., Port Chester, N. Y., 12; Seattle Electric Co., 22; Boston & Northern Street Ry., 30; Middleton & Danvers Street Ry., 16; Old Colony Street Ry., 24; Atlanta Railway & Power Co., 10; Portland (Me.) R. R., 10; Pacific Electric Ry., Los Angeles, Cal., 105; Citizens Traction Co., Oil City, Pa., 14; Los Angeles & Redondo Ry., 10; Worcester Consolidated Street Ry., 82; Los Angeles & Pacific R. R., 28; Cincinnati Traction Co., 20. Many of these roads had other Christensen equipments in operation before placing these orders.

## UNION INTERNATIONALE PERMANENTE DE TRAMWAYS.

In addition to the papers given in abstract in the last issue of the "Review," the International Congress discussed among others the question of transfers. This subject was reported by M. Lavalard, of the General Omnibus Co., Paris. A large number of replies were received from street railway companies in regard to the use of transfers and the question was dealt with at considerable length by the reporter. The conclusions reached were that transfers are to be generally recommended as they usually lead to increase of traffic and of receipts; they are advantageous for the passenger as they permit him to make two trips and to travel on crossing lines for a single fare; where one transfer only is given between two cars it facilitates checking accounts; transfers should not be given out for a line running parallel to the one which has been left by the passenger, and only one transfer should be allowed, as if several changes are permitted it gives rise to frauds; they should only be used at points of junctions or inter-sections. The date and hour should be indicated on the ticket and different colors of paper are always important to indicate the direction of traveling; it is important to limit transfers to the limits of towns, and for suburban lines there should always be an extra fare. Transfers should be suppressed on extra busy days and holidays if possible. In discussing this report it was brought out that in many localities transfers were obligatory by law and it was therefore not a question of whether they should be free, but the main question was how to check the tickets. It was pointed out that the two main abuses to which transfers are liable are first on the part of the public and second on the part of the employe of the company. Passengers frequently obtain transfer tickets and instead of making a through journey they stop off to do shopping or other business, thus abusing the idea of the transfer. The other abuse consists in the exchanging of transfers between employes and defrauding the company of cash fares; a committee was appointed to study this subject of transfers further and to report at the next Congress.

Another question discussed was the basis to be adopted for ascertaining the power of motors and generators, considering the speed, torque, the heating, etc. The replies to this question from various roads suggest that the power of a motor should be as small as possible consistent with obtaining the maximum speed and tractive power without prejudicial heating. The motors should work properly without heating more than 70° C. Some of the roads consider it a mistake to use tramway motors having an excessively high yield as they cost more for repairs, etc., than less efficient ones.

M. Rasch, of the Polytechnic School, Aix-la-Chapelle, contributed an interesting report on this subject which covered the subject very fully and supports the rules and regulations in use by the German Association of Electrical Engineers.

In reply to a request for technical information concerning the maintenance, consumption and output of boilers, steam engines, gas engines, accumulators and other generating machinery, the responses were given in tabular form at great length. M. Thonet, of the General Enterprise Co., of Liege, reported on this question and also in regard to the cost of power in a single paper. His deductions were as follows:

For central stations of large size with machines of over 1,000 h. p. and with fuel at from \$3.00 to \$4.00 per ton, the cost per kilowatt hour will be .8 to 1.2 cents; with stations of medium size with machines of 300 to 600 h. p., with fuel at the same price, the cost will be 1.2 to 1.6 cents; for stations of slight importance with machines of from 100 to 200 h. p., and the same fuel, the cost will be 1.6 to 2.0 cents; for stations with poor gas and with machines from 150 to 200 h. p., and fuel at \$6 to \$8 per ton, the cost will be 1 to 1.4 cents, and with fuel at \$3 to \$4 per ton, the cost will be .8 to 1.2 cents per kw. h.

The method of compensation for franchises was the subject of a report by M. Janssen, of the Brussels Tramways, who in summing up stated that the simplest basis to take for the compensation for franchises is the return of the dividends paid. The stockholders have an interest in seeing everything distributed which is distributable, taking into account the sinking fund and other necessary provisions. The authority granting the franchises will find in this very interest their best guarantee and the owners of the

franchises will not have to submit their books to be audited by the public authorities or have discussion with them. If the arrangement between conceding authorities and companies cannot be made on this basis, which appears the most desirable, an alternative basis was submitted. From the gross receipts there is first withdrawn for the account of the company a sum proportional to the car miles run. This sum is intended to cover the operating expenses. The amount per car-mile should be determined upon between the company and the authority granting the franchise. Of the surplus a certain proportion should be allotted to the authorities, the amount of which must be left to the experience of the company, which before negotiating with the authorities should study the conditions under which other companies are making payments. In Germany the principle of paying for franchises on the basis of profits earned is already established by law. In that country a tax is not imposed for the use of roads unless the railway which uses them realizes a net profit of more than 6 per cent. Mr. R. H. Scotter read a paper upon the same subject in which he recommends that a complete set of laws, rules and regulations of different places should be collected and deposited at the head office of the International Union; that translations of the most useful and the most harmful points and causes should be made available; that an effort should be made to gradually standardize all regulations connected with electric tractions.

The location of car barns in relation to the routes of a tramway system was reported upon by M. Trautweiler, of the Tramways Co., of Strassbourg. Considerable diversity of opinion is found in the answers to this question but the reporter agrees with the advice to establish a small number of large car barns permitting at each one a group of from 100 to 150 cars. A group of 50 cars he considers too small, as a line operating 300 cars would require 6 car barns and this would greatly increase the expense for wages, and would lead to too much splitting up of the service. He admits, however, that the matter must be settled in any case by the local circumstances. As a large number of tramways grow out of the consolidation of old horse car lines the placing of the car barns in such cases necessarily depends on the local circumstances. The question of expense is dealt with at some length, and the reporter concludes that the American experience with very large systems can hardly be applied to European conditions.

The subject of the system of traction, other than the overhead trolley system, was reported on by M. Ziffer, of the Railway Companies of Vienna. Very few replies were received on this subject as most of the companies are using either the overhead trolley or conduit systems. The reporter believes that the conduit system is preferable to surface contact systems which, up to the present time, have not shown sufficient reliability in service. The report was a valuable one, which, however, does not permit of being readily abstracted.

The subject of gage of tracks was reported upon by M. De Burelet, of the National Railroads of Belgium. The question of the relative advantages and drawbacks of narrow gage and standard gage for suburban tracks was responded to by a number of roads, some of which favored the standard gage only, while others believed that a narrow gage is specially advantageous for local railways. The reporter states that the experience of the past 17 years has confirmed the opinion that for local railways in country districts, designed to carry passengers and freight towards the large centers or to the stations of long lines, that a narrow gage presents in most cases advantages which gives it the preference over the standard gage. Its principal advantages are stated to be the economy in the cost of construction and operation and the ease with which topographical difficulties may be overcome. The only inconvenience of a narrow gage is that of transshipment, but this is not really of great importance as experience has proved that it does not constitute an obstacle to the development of traffic. At the same time there may be advantages in the use of a wide gage for the local railway when applied to a line of very short length which connects with a large railway system and is designed especially for heavy freight traffic. The reporter, however, laid stress on the fact that he has not discussed the question of electric tramways but it was a simple question of light railways, and it was not possible to argue from the one to the other.

The subject of heating street cars was reported on by M. Peiser, of the Tramways Co., of Berlin. Comparatively few replies were received in regard to this question and the reporter in summing up

the subject states that serious drawbacks exist in the case of electric heating, owing to the high first costs and the cost of operating, owing to the large consumption of current. The question of the electrical heating of cars is to be brought up at the next general assembly in order to obtain particulars of the results which the different companies may obtain in the meantime. The system is comparatively new in European countries and as yet little comparison between this and other systems could be drawn.

The ratio between the number of passengers carried and the seats available on the cars at different times of the day, and the question of the advantage of employing cars of different size to meet the requirements of the traffic was reported on by M. Neiszen, of the Amsterdam City Tramways. Most of the replies to this question show that the ratio between the number of passengers and available seats is extremely variable and in general it is not considered that reduction in fares would make much difference in it. The reporter in summing up finds that only in very special cases it would be possible to deal advantageously with fluctuations of traffic with cars of different sizes, and with mechanical traction it is greatly preferable to use trailers. It was decided that tramway companies should communicate to Union the measures which they take to deal with rushes of traffic at certain hours of the day, and the results obtained by reducing fares at special times.

### STREET SPRINKLING BY STREET RAILWAY COMPANIES.

The subject of street sprinkling by street railway companies is one which has not been very generally considered up to the present time but which we believe will be found to be of growing importance. There seems to be no question that in many cases street sprinkling would be of great benefit to the railway companies themselves as it would undoubtedly increase pleasure riding on open cars in the summer time to a very considerable extent. One of the principal difficulties in the way of this practice has heretofore been that the railway companies believed that they would be compelled to do the whole sprinkling business gratuitously if they showed any disposition to take up any part of it, but at the present time many of the companies are beginning to look upon street sprinkling as a good investment. There are a number of points of advantage which the street railway may derive from sprinkling; the comfort of passengers is increased by preventing the dust and this makes riding inviting, and incidentally increases the number of pleasure riders; when the surface of the street

paved with brick. This company, however, only sprinkles where the owners of the abutting property pay for the sprinkling which is about one half of the length of the company's tracks. The railway company provides storage room for the sprinkling car, power, trackage, etc., at a cost of 3 cents per car-mile. In Davenport the city has purchased a sprinkling car and does the sprinkling on all of the brick pavements covered by the tracks of the Tri City Railway Co. In this case the cost of sprinkling is assessed with the regular taxes. The city ordinance requires the

BRILL STANDARD SPRINKLING CAR.

street railway company to haul the city sprinkling cars free of charge, to house them and keep them in repair, and this arrangement is considered very satisfactory by the company.

The Studebaker Brothers Manufacturing Co. has built a number of electric sprinkling cars which are in use in different parts of the country. This company's wide sprinkling cars are in use on the Colorado Springs & Suburban Railway Co's. lines and have given satisfaction in service. The difficulties in keeping the streets sprinkled in Colorado Springs are greater than in most cities on account of the universally broad thoroughfares. The warm climate, dry air and wind storms to be found there make sprinkling a necessity the year around and it is necessary to have a machine that will throw a body of water a sufficient distance to spread from curb to curb. The Studebaker car is very much the same in ap-

STUDEBAKER WIDE SPRINKLING CAR.

pearance as an ordinary car, both ends being vestibuled and the motorman operating in the usual position. The car is mounted on a single truck and driven by two 60 h. p. motors of the General Electric make. The load is carried on graduated springs and consists of a steel tank holding 2,600 gals. of water. This is enclosed in a car body so as to leave sufficient room for a person to pass from end to end of the car on either side of the tank. The water is thrown from the sides from two sprinkler heads located near the center of the truck. It is forced from these heads by two individual force pumps operated by a 30-h. p. motor located at the end of the car. The amount of water thrown as well as the width

is thoroughly dampened grit and dirt causing wear of the moving part will not so easily reach the bearings; it has also been noticed that when the rails are thoroughly wet there is an economy in the use of current owing to the better electrical contact between the wheels and the rail. In case of very dirty roads this has been found to produce a marked difference in the cost of operation.

In a number of places the sprinkling is undertaken by private companies who supply their own cars and make arrangements for operating them over the tracks of the street railway companies. In Rock Island and Moline the tracks of the Tri City Railway Co. are sprinkled by an independent company where the streets are

thoroughly dampened grit and dirt causing wear of the moving part will not so easily reach the bearings; it has also been noticed that when the rails are thoroughly wet there is an economy in the use of current owing to the better electrical contact between the wheels and the rail. In case of very dirty roads this has been found to produce a marked difference in the cost of operation.

of the spray is governed by levers on either end of the car. An emergency brake is also used for quick stopping in passing a moving vehicle when running at high speed. The third sprinkling head is located in front of the center of the truck for flushing the tracks. With the car standing still a spray 78 ft. in width from the center of the track can be thrown from one sprinkling head, while with both heads open a width of 120 ft. can be covered. This company also builds gravity sprinkling cars which depend entirely upon the water pressure for the width of spray. These are useful where it is desired to flush the rails and from 12 to 15 ft. on either side of the track. For this service the gravity sprinkler answers the purpose at much less cost than the wide throwing sprinkler.

The J. G. Brill Co. has also supplied a large number of sprinkling cars to the various street railways in this as well as foreign countries. Among the roads which are using sprinklers of this make may be mentioned the Cincinnati Traction Co., the Pittsburg Traction Co., Orange & Passaic Valley Railway Co., the Perth (Australia) Electric Tramways Co., Cape Town (Africa) Tramways Co., Port Elizabeth (Africa) Tramways Co., Cleveland Electric

BRILL SPRINKLING CAR WITH ENCLOSED TANK.

Railway Co., Chester (Pa.) Traction Co., United Railways & Electric Co., Baltimore, New Jersey Street Railway Co., Newark, Camden & Trenton Street Railway Co., Bordentown, N. J., Jersey City, Hoboken & Patterson Ry., Bergen Turnpike Co., United Traction Co., Philadelphia, and many others.

The Brill Co. were pioneers in the building of street railway sprinklers and their products have kept well abreast of improvements in this line. The company builds cars having tank capacities of 1,800, 2,500 and 5,000 gals. The smaller capacity tanks are mounted on four-wheel cars and the latter on double truck cars, being too heavy for operation on four wheels. The valves and fittings of these sprinklers are made of brass or composition in order to overcome any difficulty with corrosion. The running gear of the single truck sprinkler consists of a solid forged frame truck and upon the truck frame are eight helical springs that carry the body of the car. The sprinkling heads used on these cars are novel as they have no holes or perforations which are liable to become clogged, but the head consists of a cone adjusted in the mouth of the discharge pipe which forms a spray nozzle through which water is discharged in a thin film. The stream maintains its unity for a distance of about 18 in. from the nozzle when it breaks up in a series of streams producing regular distribution of water. The opening which is annular and continuous is not liable to be obstructed.

The 2,500-gallon tank carries a sufficient supply of water to sprinkle from 5 to 8 miles of roadbed with one filling. The distance depends upon the amount of water and speed of the car and

the amount of dust in the road. For city use sprinklers are built with enclosed tanks making them appear as much as possible like an ordinary car in order to avoid frightening horses.

This company is now building a new form of sprinkling car, the "Geyser," which is capable of distributing water over the widest as well as the narrowest streets. The water in this car is

TAUNTON SPRINKLING CAR.

distributed from the nozzle by means of compressed air which allows any desired pressure to be maintained with practically no variation whether the tank is full or nearly empty. The apparatus for furnishing compressed air consists of an axle driven compressing pump. The pump is designed to handle a large volume of air at comparatively low pressures. When the car begins to move, the pump furnishes the required air pressure upon the water in the tank and when it has reached the desired amount of pressure further rise is prevented by an automatic valve which allows the air to be blown off. The valve controlling the air pressure can be set to any point from 2 lb. up to 20 lb. With 15 lb. pressure per sq. in. water can be distributed from 30 to 35 ft. outside of the rails with an even distribution over the whole distance. Either or both sides of the street may be sprinkled as desired.

The Taunton Locomotive Manufacturing Co. has built street car sprinklers which are in use on a number of street railways, among which may be mentioned the Quebec Railway, Light & Power Co., the Westfield & Elizabeth Street Railway Co., the Cincinnati, Lawrenceburg & Aurora Street Railway Co., Patterson Railway Co., the New York & Queens County Railroad, Charleston Street Railway Co., Steinway Electric Railway Co., Transit Equipment Co., Bridgeport Traction Co., etc. The Taunton Sprinkler carries its tank pretty high on the car and is equipped with large

MCGUIRE WIDE SPRINKLING CAR.

sprinkling pipes and large valves which tend to reduce the losses by friction and which permit the water to be thrown a long distance. For broad boulevard sprinkling an auxiliary pump and motor is used to throw the water under pressure. These sprinklers are made with steel tanks mounted upon platform cars and are also made covered over so as to present the appearance of an

ordinary car. The sprinkling heads of these cars are situated at the ends near the car platforms. The tanks are made both of steel and cypress and in capacities from 2,500 to 4,000 gallons.

Sprinklers for street railway service have been built by the McGuire Manufacturing Co., of Chicago, up to 5,000 gallons capacity; for capacities of 4,000 gallons and less the tank is usually mounted on a single truck car, but 5,000-gallon sprinklers are mounted on double trucks. Compressed air is used to throw the water to the distances now demanded in street sprinkling. The air reservoir is filled by a compressor driven by an electric motor; and in the pipe connecting the air reservoir with the water tank is a regulating reducing valve by which the working pressure and consequent throw of the sprinkler can be easily adjusted.

The McGuire company has just completed two pneumatic sprinklers for the railways at Durban, Natal, South Africa; these have a capacity of 3,000 gallons and are designed to throw a spray of water for 50 ft. on each side of the track.

**NEW CARS FOR PITTSBURG.**

The accompanying illustration shows the type of open car built by the St. Louis Car Co. for the Pittsburg Railways Co. These are 11-bench cars six of which have just been completed. The total length over the buffers is 24 ft. 3 in. and the width of the body at side posts is 7 ft. 4 in. while the width over all is 7 ft. 10 in. The height from the bottom of the side sills to the top of the roof

OPEN CAR FOR PITTSBURG ST. LOUIS CAR CO.

is 8 ft. 8 in. The cars are finished in ash, are provided with solid bronze trimmings throughout and are fitted with pantasote curtains.

**NORTHWESTERN DONATES PARK TO CHILDREN.**

The Northwestern Elevated Railroad Co., Chicago, through its president, Mr. Clarence Buckingham, has given a space of ground 80 x 300 ft. at Larrabee and Town Sts. to be used as a playground by the children of the congested northside district. The gift of this park has been supplemented by a donation of \$500 which will be invested in swings and other conveniences of a children's playground. The park, which lies partly under the Northwestern elevated structure, will be enclosed in a high fence of ornamented design and it is the intention of the company that it shall be well kept and devoted exclusively to the children's use.

**ACCIDENTS AND BRAKES.**

The Sterling Meaker Co. enters its protest against the action of the daily press in including such sentences as the following in its accounts of street railway accidents: "Effective brakes would prevent such accidents, but very few cars are equipped with powerful brakes or more than one device for checking speed, although they are run up and down hill which would be impracticable for the more solidly built and better controlled rolling stock of team road."

It is considered that this is hardly fair, as not "very few," but

very many cars are equipped with powerful brakes, among which the Sterling safety brake must be reckoned, as thousands of them are in use and have proved their efficiency in years of constant service.

**NEW INTERURBAN OPENED.**

The Rockford, Beloit & Janesville Electric Railway Co. opened its newly completed line between Rockford, Ill., and Beloit, Wis., a distance of 18 miles, August 4th, two cars being put in service and a regular hourly service inaugurated. The company has purchased eight handsome parlor cars, two of which were delivered and put in operation over the line August 11th. So soon as the remainder of the rolling stock is received the line will be opened to Janesville, a total distance of 35 miles, and cars will run every half hour. The line passes through the towns of Rockton and Roscoe, and the trip between the Rockford and Beloit is made in 48 minutes. The road is substantially built and ballasted with gravel. H. H. Clough, of Elyria, O., was interested in this company, and is now its general manager, with headquarters at Beloit.

**THE GAME PRESERVES OF THE NORTHWEST.**

The Northern Pacific Ry's. latest publication is a sportsman's manual of the northwest entitled "Where to Hunt and Fish." The

book contains some 30 admirable half-tone illustrations of game, several of the pictures being reproductions of Thompson-Seton's work. The cougar, mountain goat, elk, moose, grizzly bear and many other native burghers of mountain, plain and forest are represented in the collection, which also comprises a number of charming vignette pictures of mountain scenery and camp life. Of the many appropriate souvenirs issued by the passenger department of this railroad, "Where to Hunt and Fish" is, perhaps, the most noteworthy from an artist's as well as a sportsman's point of view.

The book also contains a collection of reliable data concerning the extent and variety of the game to be found in the region between the Great Lakes and the western coast, and the 45th parallel of latitude and the Canadian boundary, and gives in addition a digest of the game laws in every section and notes concerning hotel accommodations, the employment of guides, etc. In Montana the large game has multiplied and replenished since the Alaskan exodus called the native hunters and trappers to other conquests. Here are found the moose, elk, mountain sheep, deer, bear, cougar, lynx, high-climbing mountain goat and other gentry of the wilderness, while the foothills abound in blue grouse and the streams teem with trout. The adjacent parts of British Columbia afford caribou, while the Big Horn and Bitter Root ranges are pre-eminent for the hunting they furnish. This section comprises without doubt a game preserve unsurpassed by any in the world.

Since the interurban electric lines in Michigan, connecting Grand Rapids and Grand Haven and Grand Rapids and Holland, have been put in operation business in the small villages between the terminal cities is reported to have more than doubled.

**ANNUAL MEETING OF THE CHICAGO UNION TRACTION CO.**

The financial statement for the year ending June 30, 1902, which was submitted at the annual meeting of the Chicago Union Traction Co., held July 23d, shows a deficit of \$247,527.68 for the year. Compared with the statement for the preceding year it is as follows (omitting cents):

	1902.	1901.
Gross earnings from operation.....	\$7,825,120	\$7,289,139
Operating expenses .....	4,570,719	3,942,194
Net earnings from operation.....	\$3,254,400	\$3,346,945
Other income.....	117,350	103,579
Gross income.....	\$3,371,750	\$3,450,524
Fixed charges.....	3,619,278	3,291,949
Deficit.....	\$247,527	*\$158,575
Dividend on preferred stock.....		150,000
Deficit .....	\$247,527	**\$8,575

\*Surplus. \*\*Balance.

Additions to the property during the fiscal year were as follows:

Construction: Track and roadway.....	\$5,915	
Electric line.....	2,474	\$8,389
Real Estate: Buildings.....		\$4,597
Equipment: Power plant equipment.....	\$4,098	
Shop tools and machinery.....	2,077	
New cars.....	65,108	
Electric equipment of cars.....	31,443	
Mail cars.....	294	
Total.....	\$103,021	
Less credit from sale of wagons and coal motor....	2,653	100,368
Other property:		
Furniture for Law Department.....		395
Reconstruction .....		159,987
Total.....		\$273,646

In presenting the report to the stockholders President Roach said:

"The business done by your company during the fiscal year closing June 30, 1902, so far as increased earnings are concerned, was all that your management could reasonably expect under the adverse conditions with which we had to contend. Briefly, however, the financial statement will show that prospective profits have been taxed into a deficit.

"That this is not an overstatement will sufficiently appear by reference to the enormous amounts paid out for taxes during the past year, viz.:

Personal property taxes.....	\$112,492.50
Real estate taxes.....	60,428.61
Capital stock tax.....	311,567.33
Car licenses and amounts paid to city as per requirements of different ordinances.....	64,892.87
Amount paid account taxes reassessed for 1900, as directed by United States Court.....	134,350.03
Total .....	\$683,731.34

\*This is equal to about 8½ per cent of the total gross receipts of the company for the year, and to about 21 per cent of the net receipts for the same period, counting as net receipts the gross receipts less only operating expenses, and not including in operating expenses either interest on bonded indebtedness or rentals paid to underlying companies. We have some reason to hope that for the current year the company may have its property, including capital stock, assessed upon the basis of its earning capacity, the only just method. If this hope shall be realized, the capital stock tax ought to be, and doubtless will be, greatly reduced. The item of \$134,350.03 additional tax for 1900, of course, will not occur this year, and upon the basis of earning capacity the item of \$311,567.33 capital stock tax for 1901, would be reduced by at least \$100,000.00, and should be reduced by \$125,000.00.

"The percentage of operating expenses to increased receipts has been much higher than anticipated, owing to a combination of unavoidable embarrassments. A number of important river bridges over which trunk lines are operated have been entirely out of service, while others have been damaged at frequent intervals, causing temporary shifts of terminals on short notice, much to the inconvenience of the traveling public. This, in the aggregate, amounted to a loss of thousands in receipts, patrons of the road seeking other methods of transportation, sometimes at great inconvenience to themselves, owing to the uncertainties of travel on river-bridge lines. These conditions, however, are temporary. New modern bridges are being erected, river channel obstructions are being removed, and the entire problem of bridge transportation promises shortly to be in a much better condition than ever before, benefiting the public and company jointly.

"Large sums were expended in permanent improvements in right of way, rolling stock and power plants. Several miles of new track have been laid, thousands of rail joints have been cast-welded, and upon streets where city improvements have been made we have resurfaced our tracks, substituting a granite, asphalt or brick pavement in place of cedar block or cobble-stone. The improvements when completed will lessen the cost of operation and improve the service to the public, but at present they eat heavily into the receipts with no immediate financial return. Our rolling-stock has been maintained at a high standard and increased by a large number of new cars. Power houses are now more efficient than heretofore, and contemplated improvements will place the operating department in a position to better care for the traveling public.

"In view of our heavy expenses for improvements, the early settlement of the river-bridge problem and the general prosperity of the community, the management confidently expect (barring unforeseen contingencies) that the ensuing fiscal year will show results more satisfactory to the stockholders of this company."

The treasurer reported that by applying \$74,000 received from the sale of unused real estate reductions amounting to \$3,430 in interest charges had been made and that the income from property leased from the company had been increased by \$5,211, making an annual saving in the fixed charges of \$8,641.

The directors elected were: Jesse Spalding, Walter H. Wilson, James H. Eckels, John V. Clarke, John M. Roach, John Lamson, Henry G. Foreman, Joseph Downey, R. A. C. Smith, H. B. Hollins, W. F. Harray. Four changes were made in the board, William Dickinson, G. K. C. Billings, Charles L. Hutchinson and P. A. B. Widener retiring.

The directors met and elected all of the old officers.

**McGUIRE SNOW PLOWS AND SWEEPERS ABROAD.**

Engineering, of London, thus describes the McGuire exhibit at the International Tramways and Light Railways Exhibition:

Amongst the striking features at the stand of the European McGuire Manufacturing Co., of Elton Fold, Bury, is a snow-sweeper and plough built for the Bolton Corporation, and intended to keep the electric tramway tracks open throughout all the winter snows. The machine is motor driven, picking up its current from the overhead trolley wire. In front it carries a rotary brush, which is driven by a pitch chain from an electro-motor. This chain drive enables the level of the brush to be readily adjusted within a considerable range. The "bristles" of the brush are of rattan canes. This brush is guaranteed to remove snow from the tracks up to 18 in. deep, and it throws it in the way of a movable and adjustable plow plate secured to the side of the car. When not in use this plow plate can be folded up flat against the car, which then occupies no more space than an ordinary tram car. A specimen of the motor trucks supplied by the company for the Great Northern and City Railway rolling stock is also shown. These trucks are largely built of steel castings. They weigh 4 tons each, and a pair will carry safely a load of 80 tons. Mention should also be made of a very compact form of rheostat, in which the resistances are simple rectangular rods of carbon, with terminals fitted at different points along their length. For a 3-h. p. rheostat a single rod about 7-in. long suffices. By making connection to one or other of the several terminals mentioned above, a greater or lesser length of the rod is thrown into circuit and the resistance of the latter correspondingly varied.

### THE LINCOLN POWER STATION OF THE BOSTON ELEVATED.

The Lincoln Station of the Boston Elevated Railway Co. differs in many respects from the various other power plants of the system. It is the most recent addition to Boston's numerous electrical power plants and is located on the lot known for many years as Lincoln Wharf; this is on the water front of the harbor, and in the heart of the old city, near the junction of Commercial St. and Atlantic Ave., where there are excellent facilities for the docking of coal and

LINCOLN STATION, BOSTON ELEVATED.

other supplies. The general appearance of the building is imposing, and the chimney, which is 250 ft. high, is said to be the tallest stack in the city. The building is divided into two longitudinal sections, the boiler room and all apparatus pertaining thereto being in one section and the engines, generators and condensing system in the other. The engine room is served by an electric crane of 40 tons capacity. The walls of this room are faced with white enamel brick, adding much to its general appearance and illumination. The present station contains three units, aggregating about 13,500 h. p. While it is now complete in itself, ample ground area has been provided for the extension of the building and plant on harmonious lines to accommodate four additional units, thus permitting an ultimate equipment of about 30,000 h. p.

The boiler installation consists of eight 468-h. p. and four 490-h. p. Babcock & Wilcox boilers. An equipment of Roney mechanical stokers of the same type as those in the large power houses in New York City has been installed by Westinghouse, Church, Kerr & Co.

Coal will be automatically unloaded from vessels and stored in a large pocket holding 5,000 tons, with a further storage bin of 3,000 tons in the boiler house, or a total storage capacity of 8,000 tons. It is carried to the boilers by a coal and ash conveying system which conducts the coal into overhead conveyors leading to the stokers. The coal may be taken from the pocket to the storage bin in the boiler house, and, in addition, tracks are located on either side so that coal cars can be automatically loaded to carry coal to the various other power stations or to any of the thirty or more car houses situated in different parts of the city. The plant is equipped with Green economizers.

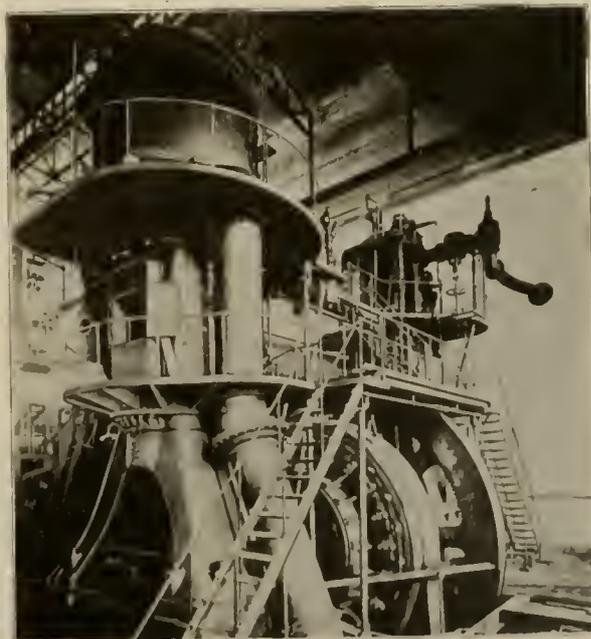

The original engine installation consisted of two vertical cross compound units of 4,500 h. p. each, with the generators and fly wheels carried on the shafts between the high pressure and low pressure cylinders, the generators are direct current machines, rated at 2,700-kw. each. A third unit which has just been completed consists of a vertical cross compound engine of about 4,500 h. p., designed and built by the Westinghouse Machine Co. and installed by Westinghouse, Church, Kerr & Co. It is of the same design as

the one recently furnished for the Charlestown Power Station and is direct connected to a Westinghouse direct-current generator of 2,700-kw. capacity of the same make and similar to one of the two machines mentioned. The engine, however, differs considerably in design and construction from the two engines first installed. The high-pressure cylinder is fitted with poppet valves for use with superheated steam, which is supplied by superheaters built by the Babcock & Wilcox Co.

Steam is conveyed from both sides of the boiler room by 8-in. mains to a 16-in. drum, from which it is conducted by 12-in. risers to receiver separators and thence to the engines. All the live steam drips from the steam drums, separators and reheating receivers are carried back to the boilers by the steam loop and Holly gravity return system.

Ingersoll-Sergeant air compressors, each driven by a 50-h. p. Westinghouse 500-volt motor, supply compressed air for the block signal and switching system, used by this road. Early in the conception of the scheme of running trains at high speed under the rather complex conditions here existing, the engineers of the Boston Elevated Railway Co. realized that a block system was necessary as a safeguard against accident, and the Westinghouse electro-pneumatic interlocking system, made by the Union Switch & Signal Co., of Swissvale, Pa., was chosen.

The elevated road includes some 14 miles of trackage. The switches and signals are controlled from four switch towers and the automatic block signals are located at distances of about 800 ft. apart. Each tower is supplied with indicators showing the approach of trains. The towers at the junctions of the Atlantic circuit and main line control some 1,200 elevated trains daily. The largest tower is located at the Sullivan Sq. terminal, where some 500 elevated trains and 700 surface cars pass in and out daily, involving 6,000 switch and signal movements. A force of only two men on duty is required to operate the switchboard mechanism consisting of 35 pneumatic levers. The terminals are also supplied with lamp indicators showing the relative location of approaching trains. While

2,700 K. W. WESTINGHOUSE UNIT.

the tram movements at Sullivan Sq. are not so complicated as those at the Boston South Terminal Railway Station, the Elevated company has less track room at its disposal and handles a much larger number of trains for a given number of tracks.

The Metropolitan Street Railway Co., of Kansas City, has recently revised its system of discipline, making the demerits awarded less severe on the men. The company has begun work on its new power house, and August 1st commenced changing the Troost Ave. line for electricity.

## PERSONAL.

MR. W. S. HUFF has been appointed general manager of the Richmond Passenger & Power Co., of Richmond, Va.

MR. GEORGE F. McCULLOCH, president of the Union Traction Co., of Indiana, left New York on August 13th for an extended trip in Europe.

HON. W. F. BAY STEWART was born in Chanceford Township, York County, Pa., Feb. 25, 1849, and is of Scotch-Irish extraction, his father being Thomas R. Stewart and his mother a daughter of Judge Thomas Bay, of Cooptown, Md. He attended the district school in his neighborhood until he reached the age of 17, when he learned the trade of blacksmith, at which he worked for a short time. He was compelled, on account of his health, to abandon his trade, and he then attended Pleasant Grove Academy, and later the York County Academy, where he afterwards taught.

He next began the study of law with Col. Levi Maish, then a member of Congress, and was admitted to the bar in 1873. He formed a partnership with John Blackford, then district attorney, who shortly afterwards died, and he next became head of a firm including H. C. Niles and George E. Neff, which soon met with notable success. In 1895 he was elected judge, and has made an enviable reputation as a capable jurist. Judge Stewart has been extremely active in business enterprises aside from his legal work. He became one of the firm of Baugher, Kurtz & Stewart, founders, which is one of the most prosperous in the city of York and employs several

W. F. BAY STEWART.

hundred men. He reorganized and became president of the York Card & Paper Co., established the York Knitting Mill, and organized and built the York Match Factory, all of which proved successful. He organized, built and largely owns the Norway Iron & Steel Co., and was chiefly instrumental in organizing the present York County Traction Co., which is a consolidation of all the street railways in York and York County, and the electric light and steam heating companies. He was the organizer of the Security Title & Trust Co., a banking institution of which he was president until obliged to resign by reason of going on the bench. He also organized and is the vice-president of the Standard Plaster Co., located at Buffalo, New York.

His most recent enterprise is the development of the falls in the Susquehanna River near York Haven, and for this purpose he organized the York Haven Water & Power Co., which will furnish electric current to all the important towns, street railways and electric light companies in the counties of York, Lancaster, Dauphin and Cumberland. Within the near future the lines of the York County Traction Co. will be extended from York to York Haven, and thence to Goldsboro, from York to Wrightsville, a distance of eleven miles, and from York to Hanover, where it is possible a junction will be formed with the McSherrytown Street Ry. This company has already extended its line as far south as Windsorville, a distance of 14 miles, and northwest as far as Dover. The latter line will be extended on through to Dillsburg. The entire system will be operated from the plant of the York Haven Water & Power Co. upon its completion.

MR. C. S. DRUMMOND, manager of the London (Eng.) Transit Co., has been elected president of the Manhattan Transit Co., and left London for New York, August 2d.

MR. H. A. FISHER has resigned as general manager of the Columbus, London & Springfield Railway Co. and the Columbus, Grove City & Southwestern Railway Co., to become general manager of the Columbus, Delaware & Marion Electric Railroad Co., which has a line under construction between the cities named in the title with a branch from Prospect to Richwood.

MR. M. J. LOFTUS has resigned as superintendent of the Newark (O.) & Granville Street Railway Co. to become general manager of the Indianapolis & Martinsville Traction Co.

MR. ALONZO J. WALLER, superintendent of the Michigan Traction Co., of Kalamazoo, recently underwent an operation for appendicitis and was for a time critically ill, but is now rapidly recovering.

MR. B. S. BARNARD has resigned as manager of sales for the American Vitrified Conduit Co. and is now vice-president and secretary of the Standard Vitrified Conduit Co., with general offices at 39 Cortlandt St., New York.

MR. W. A. LARABEE, of Gloucester, Mass., formerly superintendent of the Gloucester, Essex & Beverly Street Ry., has been appointed superintendent of the Gloucester division of the Boston & Northern Street Railway Co.

MR. ANDREW WILKES has been appointed chief engineer of the Rothesay Tramways Co., Rothesay, Isle of Bute, Scotland; Mr. Wilkes was formerly with the Dudley, Stourbridge & District Electric Traction Co., at Staffordshire.

MR. W. PORTER BRAWLEY has been appointed traveling purchasing agent of the Cleveland, Cincinnati, Chicago & St. Louis Railway Co., with headquarters at Chattanooga, Tenn. Mr. Brawley succeeds Mr. W. A. Miller, transferred.

MR. C. W. GEARHART on recently retiring from the superintendency of the bridge division of the Brooklyn Rapid Transit Co., was presented by the men with resolutions of regret, framed in gold. Mr. Gearhart will be succeeded by Mr. E. F. Reeves.

MR. S. P. COWARDIN has been appointed chief engineer of construction in charge of all tracks of the Richmond (Va.) Passenger & Power Co. Mr. George H. Whitfield has been appointed superintendent of the company's shops, in charge of the maintenance of cars.

MR. E. T. SELIG, formerly superintendent of the Fort Scott (Kan.) Electric Railway & Light Co., has been elected secretary and manager of the Mount Vernon (O.) Electric Light & Railway Co., to succeed Mr. C. E. Johnson, who has resigned on account of ill health. Mr. Selig assumed his new duties at Mount Vernon, August 1st.

MR. J. W. PERRY, who was for 14 years with the Philadelphia office of the H. W. Johns Co., and recently the H. W. Johns-Manville Co., has just returned from a two months' trip in Europe. In the future Mr. Perry will be found at 100 William St., New York, as the manager of the railway department of the H. W. Johns-Manville Co.

MR. H. A. NICHOLL, heretofore assistant manager, was on July 28th elected general manager of the Ithaca Street Railway Co., the Brush-Swan Electric Light Co., and the Cayuga Lake Electric Railway Co., of Ithaca, N. Y., succeeding Mr. E. G. Wyckoff, who will hereafter serve as president of these companies, Mr. Wyckoff having formerly acted as general manager also.

MR. W. B. BROCKWAY, auditor of the New Orleans & Carrollton Railroad Co., resigned that position on the occasion of the reorganization of the company and will go to New York with Mr. J. K. Newman, lately president of the New Orleans & Carrollton company, who now represents Isidore Newman & Co. in New York. Mr. Brockway will be railroad accountant in the office of Newman & Co.

MR. WALTON H. HOLMES, formerly president of the Metropolitan Street Railway Co., of Kansas City, who is at present in Europe, has cabled his acceptance of the presidency of a new trust company in course of organization in Kansas City, which, according to reports, it is proposed to style the Monarch Trust Co. The organization committee of the new company includes C. F.

Holmes as chairman, who was formerly general manager of the Metropolitan Street Railway Co.

MR. F. F. BODLER, who was formerly master mechanic of the North Jersey Street Ry., Newark, N. J., has been appointed master mechanic of the United Railroads of San Francisco, and took charge of the rolling stock and shops early in August. Mr. Bodler has devoted a great deal of attention to developing the piece work system for street railway shops and has been very successful in this work. In our issue for April, 1902, page 228, we published a list of Mr. Bodler's piece work prices.

MR. J. P. POTTER, formerly superintendent of the western division of the Oakland (Cal.) Transit Co., has been appointed superintendent of the entire system at Oakland; Mr. A. H. Smith, formerly superintendent of construction, will be assistant superintendent of all the Oakland lines; Mr. E. E. Thornton, formerly inspector of the Alameda division, will be superintendent of the Haywards division, and Mr. C. O. Piper, formerly inspector of the Telegraph Ave. division of the system, will be superintendent of that division.

SENATOR HANNA, president, and G. G. MULHERN, general superintendent of the Cleveland City Railway Co., were both presented with gold headed canes by the employes of the company, August 4th, as an expression of the latter's appreciation of a recent advance in wages, and other benefits. The appearance of Messrs. Hanna and Mulhern in the employes' hall, where the presentation meeting was held, was greeted with resounding cheers and the informal ceremonies which followed were exceptionally demonstrative of good will. Both the recipients of the gifts replied with speeches.

THE NEW ORLEANS RAILWAYS CO. on July 17th assumed charge of the properties of the New Orleans & Carrollton Railroad, Light & Power Co., and announced the following general officers and department heads: President, H. H. Pearson, Jr.; vice-presidents, Charles H. Ledlie and Joseph H. DeGrange; general manager railway department, Capt. John G. Woods; general manager gas department, Bankson Taylor; chief engineer and electrical department, Alexander Black; superintendent power houses, E. B. McKinney; auditor City & Orleans railways, H. A. Ferrandou; master mechanic, E. J. Morris; purchasing agent, John R. McGivney; claim agent, W. H. Renaud.

MR. F. A. BOUTELLE has been appointed superintendent of the Hudson Valley Railway Co., Glens Falls, N. Y., assuming charge of the operating department August 1st. Mr. Boutelle has had extensive experience in connection with the operation of steam railways, having been for 20 years train dispatcher and chief train dispatcher for the Delaware & Hudson Co., at Albany, and for two years train master of the Boston, Hoosac Tunnel & Western R. R. In connection with Mr. Boutelle's assumption of the superintendency of the Hudson Valley Railway Co. the latter will create the office of trainmaster or chief dispatcher and the standard steam railway rules will be adopted without deviation.

**CHICAGO OFFICE FOR MAYER & ENGLUND.**

The Mayer & Englund Co., of Philadelphia, has decided to establish an office in Chicago from which it can more conveniently handle its electric railway supply business in western territory. Mr. J. M. Gallagher, formerly of Boston, will represent the company with headquarters at No. 1101 3 Merchants Loan & Trust Building.

The Union Traction Co. of Indiana proposes to transmit electric current from its power house to a point 60 miles distant at a voltage of 12,000.

The Railways Company General, of Philadelphia, which owns the electric line between Battle Creek and Kalamazoo, Mich., may effect a traffic agreement with the Hawks-Angus syndicate whereby through cars from Detroit will be run to Kalamazoo via the Detroit, Ypsilanti & Ann Arbor Ry. A report has been circulated to the effect that Messrs. Hawks and Angus have opened negotiations to acquire the Battle Creek Kalamazoo line from the Railways Company General.

**OBITUARY.**

MR. LUCIUS CLARK, who was formerly identified with Mr. Yerkes in building elevated and surface railways in Chicago, recently committed suicide at his home in Chicago. Mr. Clark was 46 years old, and a native of Marsailles, Ill. He had within the last few years lost the greater part of a considerable fortune through disastrous mining operations in the west.

MR. JOHN R. LATTIN, superintendent of construction of the Wabash River Traction Co., died in Logansport, Ind., August 7th, of heart failure. Mr. Lattin's home was in Stratford, Conn., and he represented the Blakesley syndicate of New Haven, in the construction of railways in New England and Indiana. The cause of the sudden attack from which he died is believed to have been a message containing bad news which reached him while he was at dinner.

MR. FREDERICK B. ROUNDS, formerly general superintendent of the Metropolitan Street Railway Co., of New York City, died recently at Hoboken from a pistol wound which, there seems reason to believe, was self-inflicted. Mr. Rounds was 38 years old, and his career in the street railway world had been one of unusual promise. His early life was spent at Watertown, N. Y., where he worked as a clerk for a local contractor. Fifteen years ago he removed to New York City to assume charge of the West Side branch of the Railroad Y. M. C. A. in which position he continued until 1890 when ill health caused his resignation. Subsequently he became secretary to the president of the Broadway & Seventh Ave. Railway Co., and, after Mr. Vreeland's accession to the presidency, and the consolidation of the New York roads, kept his position as president's secretary. He was for a time general manager of the Third Avenue R. R. In 1898 Mr. Rounds was appointed general superintendent of all the Metropolitan lines, a position which carried with it much responsibility. Since severing his connection with the Metropolitan in July, 1900, Mr. Rounds had been a salesman for the Sterling-Meaker Co. Mr. Rounds was a man of attractive personality and possessed many friends by whom the circumstances of his untimely death are deeply deplored.

**NEW PUBLICATIONS.**

THE ARMOUR INSTITUTE OF TECHNOLOGY has published its annual year book for the year 1902-1903, which gives a description of the various courses of this institution. The engineering courses are its prominent feature and are very complete. In addition to the theoretical and class-room instruction they include visits of inspection to a number of prominent engineering works in the vicinity of Chicago.

PROCEEDINGS of the Third Annual Convention of The American Railway Engineering and Maintenance-of-Way Association, at Chicago, March 18-20, 1902, has just been published. The volume contains nearly 500 pages of papers, reports and discussions, a number of which were abstracted in the columns of the "Review." Most of the committee reports contain data which are valuable to electric railway as well as steam railroad engineers.

MANUEL DU CHAFFEUR-MECANICIEN et du Propriétaire d'Appareils a Vapeur. By Henri Mathieu, Principal Controller of Mines, Steam Inspector of the Seine, Professor in the Federation generale des Mecaniciens-Chauffeurs-Electriciens, etc. Second edition. Published by Librairie Polytechnique, Charles Beranger, editor, 15 Rue des Saints-Peres, Paris. Octavo, 900 pages, profusely illustrated. Price, \$5.00 (25 francs).

PRODUCTION ET DISTRIBUTION DE L'ENERGIE POUR LA TRACTION ELECTRIQUE. By Henry Martin, Engineer of Arts and Manufactures. Published by Librairie Polytechnique, Charles Beranger, editor, 15 Rue des Saints-Peres, Paris. Octavo, 750 pages, with 870 illustrations in the text. Price, \$5.00 (25 francs).

Those who are familiar with French books on technical subjects cannot fail to have been impressed with the thoroughness with which the authors do their work and the painstaking care to include examples of the most recent designs and most modern practice.

As a consequence of this policy, the English reader can often find collected in the French books data on current practice that in his own language are only to be found after a more or less extended search in the technical periodicals. The two books here mentioned are striking examples of this class of works.

The *Manuel of the Chauffeur Mecanicien* (which we may translate "Fireman and Engineer") is a treatise on boilers and engines, to which are added chapters on the legislation apropos of these subjects, and an appendix in which are collated the laws and decrees relative to steam apparatus which are now in force in France and other European countries. Part I treats of boilers and comprises 540 pages, divided into 35 chapters. The subjects covered are general considerations as to heat, water and fuel, the different types of boilers (including stationary, marine, locomotive and automobile), reheaters, auxiliary apparatus, purifying apparatus, furnaces, chimneys, boiler tests, and a chapter on explosions. Part II comprises 20 chapters on steam engines, including steam turbines. The historical and other introductory chapters are brief, more attention being given to the design and operation of modern engines, and the necessary accessory apparatus.

The work of M. Martin on the "Production and Distribution of Energy for Electric Traction" is a sequel, so to speak, to the two-volume treatise on "Electric Traction" by Andre Blondel and E. Paul-Dubois, which was published in 1898 (Baudry et Cie, the predecessors of Beranger), and which we consider to be the most complete and modern manual on this subject that has yet been issued. M. Martin deals only with the electric railway power station and the transmission system, but covers all forms of electric traction. Part I is on the production of current and includes boilers, steam engines, gas engines, water power plants, direct and alternating current generators, storage batteries, sub-stations and their special apparatus, and costs of operating. Part II covers the design and construction of feeder lines. Part III deals with overhead trolley lines, going into details of line materials and illustrating the different types. Part IV similarly covers the third-rail and sub-surface conduit systems and surface contact systems. Part V is on the return of current to the power house. Part VI is a collection of state and municipal regulations affecting the distribution of electric energy for traction purposes. Naturally, in view of the high development of electric traction in America, there is much space given to American practice, and the work is in every respect up-to-date.

MESSRS. H. ALABASTER, GATEHOUSE & CO., of No. 4 Ludgate Hill, London, have issued their announcement of the 1903 edition of "The Universal Electrical Directory" and request that all companies and firms connected with the electrical industry send the necessary information, name, address and business, at the earliest date possible. All persons and firms are entitled to one entry in the alphabetical section and to one entry in the classified section free. Display announcements and advertising, or additional entries may be arranged for on an advertising basis.

### A NEW PARK AT SPRINGFIELD, O.

The Springfield (O.) Railway Co. has recently acquired Spring Grove Park, a thickly wooded tract on its suburban lines just out of Springfield, and is effecting various improvements which it is expected will make this resort one of the most popular of its size in the country. A handsome and commodious theater has been completed, it being the intention of the company to provide first class theatrical attractions during the summer season. The building is 85x107 ft., with a stage 32x35 ft. The material used throughout is white maple finished in oil. Regular opera chairs are provided, with a total seating capacity of 1,200, and a full quota of stage scenery and properties sufficient for a fairly elaborate production. The theater is lighted by 250 incandescent and four arc lamps, and is carefully designed in regard to acoustics. Other attractions at the park are a bicycle track after a similar plan to that of Madison Square Garden, New York, and a huge and very elaborate merry-go-round, comprising new features, which have recently been erected. A running stream through the grounds and an abundant spring furnish fresh water the year round and supply the means for a number of artificial ponds which will be constructed next season. Rustic seats and promenades have been provided and the park is enclosed by a handsome iron fence.

### TERMINAL COMPANY AT INDIANAPOLIS.

The Indianapolis Traction & Terminal Co. was organized early in August for the purpose of building a system of tracks and passenger and freight terminals or stations to be used by the cars of the following eight interurban companies whose lines are completed or shortly to be completed:

Union Traction Company of Indiana.  
 Indianapolis Northern Traction Co.  
 Indianapolis, Lebanon & Frankfort Railroad Co.  
 Indianapolis & Martinsville Rapid Transit Co.  
 Indianapolis & Plainfield Railroad Co.  
 Indianapolis & Eastern Railway Co.  
 Indianapolis, Greenwood & Franklin Railroad Co.  
 Indianapolis, Shelbyville & Southeastern Traction Co.

The Indianapolis Traction & Terminal Co. is entirely separate and distinct from the Indianapolis Street Railway Co. and its officers are as follows: President, W. Kesley Schoepf, of Cincinnati; first vice-president, Hugh J. McGowan, Indianapolis; second vice-president, James M. Jones, Indianapolis; secretary, John D. Thompson, Indianapolis; treasurer, Clarence Winter, Indianapolis. The company is capitalized at \$500,000.

Each of the interurban companies mentioned has applied for a franchise from the city of Indianapolis, granting permission to use the tracks of the Indianapolis Street Railway Co., and also of the Indianapolis Traction & Terminal Co. in reaching the business heart of the city, and further granting the use of the terminals or stations to be provided by the Traction & Terminal company. Each interurban company has a private agreement with the Indianapolis Street Railway Co. and with the Indianapolis Traction & Terminal Company, relating to the terms on which use of tracks and other property belonging to those companies may be had.

The proposed belt line about the city, if built at all, will be built by the Indianapolis Traction & Terminal Co. The object of the belt line will be partly for the business it will create and partly to afford facilities for trolley parties and long rides to both visitors and residents.

When the Indianapolis Traction & Terminal Co. asked for a franchise to build certain tracks and stations, as already mentioned, the city authorities stated that cross-town lines are needed in the north and south parts of the city and insisted upon these being built as a condition of granting the franchise. The Traction & Terminal company has agreed to build these lines or extensions, and with the permission of the Indianapolis Street Railway Co., to connect them with the existing tracks of the latter company so as to provide street car facilities for portions of the city that are now in a sense without such facilities.

It is quite apparent that the undertaking of the Traction & Terminal company is one of great magnitude. The passenger station to be provided for interurban patrons will alone, it is estimated, cost (building and ground) something over a million of dollars. The new tracks and special work to be put down by the company will require considerably more than another million, and the granting of all the franchises referred to means that within the next five years at least three millions of dollars will be expended in improvements to the street railway system of Indianapolis. When these improvements, or rather additions, have been completed, Indianapolis will have a most complete and comprehensive street railway system, and there will be scarcely a neighborhood in the entire territory covered by the city that will not be readily accessible to street cars.

Other interurban companies than those named are being talked of and will doubtless become realities, but it is believed that all those mentioned will be in operation within the next twelve months. The new ones will have to ask and obtain separate franchises, which will doubtless be of similar tenor to those just requested.

Mr. Konradin Zschokke, an eminent engineer of Aarau, Switzerland, is reported to be the principal promoter of much proposed street railway construction in that country. These roads will be built by the authorities of the townships through which the routes pass, and a committee appointed by such authorities will award contracts for the actual construction of the system and its equipment. Mr. Zschokke will, it is stated, acknowledge all communications addressed to him at Aarau.

**NEW RAILWAY JACK.**

The jack shown in the accompanying illustration is being placed on the market by the Railway & Electric Supply Co., No. 115 Broadway, New York, and is something entirely new in the jack line. The illustration shows a No. 6 jack with an attachment for lifting rails or axles which gives three different heights, and will lift 10 tons 25 inches. It has ball bearings, with double ratchet made of steel and malleable iron, and has both a pawl and a reversible ratchet

**BALL BEARING RAILWAY JACK.**

for adjustment, and a swinging lever instead of a lifting lever as on jacks of the more common designs.

The business of H. W. Shaw & Co., of New York, is now merged into that of the Railway & Electric Supply Co., which has offices at No. 115 Broadway, New York. The new company is a dealer and manufacturer of electric and steam railway material, and will continue all the former business of the Shaw Co., with the exception of the Shaw lightning arresters, which will be manufactured and sold by the Universal Electric Co. at the same address. The railway & Electric Supply Co. will also act as selling agents for the railway department of the Bray Manufacturing Co., manufacturer of ball bearing lifting jacks.

**ACCIDENTS OF THE MONTH.**

A rear-end collision on the Rochester & Irondequoit R. R. occurred at Rifle Range, five miles from Rochester, N. Y., at 10 p. m., July 27th, causing injuries to seven passengers. A party of intoxicated persons had placed obstructions on the track in order to make sure of stopping the car. The motorman of car No. 457 saw the obstructions in time to avoid running into them, and while the crew was engaged in clearing the track a car approaching from the rear crashed into the rear vestibule of No. 457.

Two electric motor trains on the Fifth Ave. elevated line of the Brooklyn Rapid Transit Co. collided at 10 a. m., July 28th, at Concord and Adams Sts. Three coaches were wrecked, the force of the head-on collision driving the car bodies partly off the trucks so that there appeared to be danger of their falling into the street below, but the few injuries to passengers that resulted were not of a serious nature. It is believed that the motorman of one of the trains disregarded the signals in rounding the curve at the point where the accident occurred.

An interurban car on the lines of the Union Traction Company of Indiana leaving Muncie at 1:15 p. m., July 30th, en route for Indianapolis, collided with a rapidly moving freight train at the crossing of the Big Four tracks near Yorktown. A brakeman on the freight train was killed, and the motorman of the electric car severely injured.

An electric car on the Terre Haute, Ind., lines was struck by the Vandalia limited No. 13 on the evening of August 2d, with the result that eight passengers of the former were injured, two of whom, it is stated, cannot recover. It is alleged that the electric car had waited at the crossing of the steam tracks for the limited to

pass, and had been signalled by the gateman in the tower to advance. The rear end of the electric car was struck by the passenger train with force sufficient to turn the car completely around.

A rear-end collision between a regular train and an extra on the third-rail system of the Albany & Hudson Railway & Power Co., occurred at 6 p. m., August 2d, eight miles north of Hudson, N. Y. Two persons were killed and 25 injured. The extra, which was carrying a picnic crowd and was behind schedule time, was going at a high rate of speed, when in rounding a curve the motorman saw the regular just ahead. He applied the brakes, but the extra crashed into the baggage compartment of the regular train.

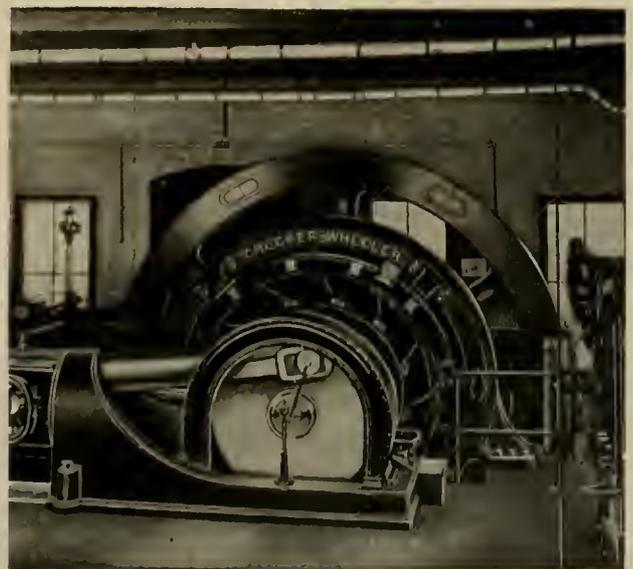

A suburban car on the Elgin, Aurora & Southern Traction Co's. lines leaving Elgin at 4:45 p. m., August 3d, struck an open switch and collided with a string of empty cars on a siding, causing injuries to seven passengers. It is believed the switch had been purposely turned by some unknown person.

Eight persons were injured in a collision between an Indiana Ave. electric car and a Cottage Grove Ave. cable train at the intersection of Indiana Ave. and 22d St., Chicago, on the evening of August 9th. The rear trailer of the cable train was demolished.

**POWER PLANT OF THE NEWTON (MASS.) STREET RY.**

Among the recent installations for railway power service of the Crocker-Wheeler Co. is that of a 400-kw. generator for the Newton Street Railway Co., for operating cars between Newton and Waltham, Mass. The Newton company is affiliated with the Boston Suburban Electric companies, of Newtonville, Mass.

The generator is compound wound, giving 500 volts at no load and 550 volts at full load. The generator field frames are of the usual Crocker-Wheeler internally flanged channel section divided horizontally, and fastened by bolts on the interior of the frame which preserves the neat appearance to the outside. The two halves are held accurately in place by dowel pins let into both sections. The fields have the series coils separated from the shunt by means of wooden spacers, which opening assists in keeping the coils cool. The brush holders are so mounted as to permit of the brushes being adjusted at one time by means of a hand wheel fastened to the frame, and working through a worm connection on the rocker arm. The brushes themselves are of the Crocker-Wheeler parallel movement type. The current from each brush is transmitted by means of

**CROCKER-WHEELER RAILWAY GENERATOR.**

four sets of copper leaves set in such a way that any movement of the brushes is always radical to the commutator. The brush tension is regulated by a spring which plays no part in the carrying of current, and therefore is not submitted to any heat with consequent ruining of temper. The generator is guaranteed to run at continuous full load without any unusual heating in any of its parts, to

operate at all loads between no load and 25 per cent over load without sparking and to withstand overloads of 100 per cent without injury. The engines are of the cross compound corliss condensing type, built by Robert Witherhill Co., of Chester, Pa.

### BELONGINGS LOST IN TRANSIT.

A list of the miscellaneous articles annually lost on street cars by the traveling public might afford a fund of amusement to the humorist and to the philosopher, grounds for speculation as to what per cent of these careless people are women; but the matter of collecting and returning to their owners these vagabond belongings assumes a far more serious aspect to the street railway manager. Through the courtesy of Mr. T. E. Mitten, general manager of the International Railway Co., of Buffalo, we have been furnished with a list of articles found on that company's cars from July 1, 1901, to May 31, 1902, an assortment which would have warranted the owner of the whole in starting a small department store. During the period mentioned, the umbrellas found on the International company's cars numbered 1,622, of which 794 were claimed, 736 returned to the finder and 92 remain to be disposed of; out of 768 "grips" found on the cars, 675 have been claimed, 88 returned to the finder, 2 are accounted for as "perished or destroyed," and 3 as being "on hand." Incredible as it may seem, 1,085 garments are included in the list, of which number 609 have been claimed, 427 returned to the finder, 1 is in the perished or destroyed category, and 43 are on hand. The following table completes the report of the company's lost article department: gloves, 528 found, 130 claimed, 360 returned to finder, 38 on hand; jewelry, 110 articles found, 22 claimed, 84 returned to finder, and 4 on hand; watches, 10 found, 9 claimed, and 1 returned to finder; opera glasses, 4 found, and 4 claimed; purses, 530 found, 253 claimed, 254 returned to finder, and 23 on hand; cameras, 37 found, 34 claimed, 2 returned to finder, and 1 on hand; books, 364 found, 223 claimed, 132 returned to finder and 9 on hand; lunch boxes, 282 found, 91 claimed, 160 returned to finder, 76 perished or destroyed, and 9 on hand; miscellaneous, 2,633 found, 1,190 claimed, 1,222 returned to finder, 98 perished or destroyed, and 123 on hand. Total, 7,968 found (including umbrellas, grips and garments), 4,034 claimed, 3,412 returned to finder, 177 perished or destroyed, and 345 on hand. The purses turned in to the department during the 11 months ending May 31, 1902, contained \$1,334.46, of which amount \$1,153.18 was claimed by owner, \$168.94 returned to finder, and \$12.34 is still on hand. Receipts of owner or finder giving street number are taken and filed in numerical order in such manner that each article found on cars can be traced to final disposition.

### BRILL CAR FOR PUNXSUTAWNEY.

The accompanying illustration shows the type of car adopted by the Punxsutawney (Pa.) Street Passenger Railway Co. It is the

SEMI-CONVERTIBLE CAR FOR PUNXSUTAWNEY.

Brill patented semi convertible car with extra large windows which slide into the roof, leaving the sides practically open for coolness in summer, but always ready to be drawn down in case of bad weather.

The car bodies are 25 ft. 4 in. long, and 34 ft. 9 in. over the vestibules. The width over the sills is 7 ft. 8½ in., and over the posts

at the belt, 8 ft. The inside finish is of natural cherry with ceilings of birch, handsomely decorated. Each car is fitted with specialties of Brill manufacture, angle iron bumpers, radial draw bars, "Ded-end" gongs, steps, brake handles, etc. The trucks are the Brill 27 G pattern.

### AUTOMATIC CAR-TYPE CIRCUIT BREAKER.

The protection of railway motor equipments by the use of a fuse has until recently been the standard practice, but many of the largest street railway companies are now replacing fuse blocks by automatic car circuit breakers, with the idea of securing greater reliability and better protection against injury from carelessness of the

WESTINGHOUSE CAR CIRCUIT BREAKER.

motorman in improperly cutting out resistance. An important feature of the automatic circuit breaker for this use is the convenience in resetting, as the motorman can throw the handle to reset without leaving his position at the controller, and in most cases it is not necessary to stop the car.

The automatic car circuit breaker made by the Westinghouse Electric & Manufacturing Co. is designed to perform the function of the fuse block by opening an overload or short circuit and also replace the platform or canopy switch by providing a hand opening for the circuit. In construction the instrument is made thoroughly fire-proof of the best material and workmanship throughout; and all parts are interchangeable. Its design prevents any arcing at the current-carrying contacts, as the arc is broken on extra contacts especially provided for the purpose, and assisted by a powerful magnetic blow-out which will open the severest short circuit without damage. The breaker is calibrated, and can be set to open at any current within the limit of its range. The automatic opening device insures certainty in opening when the current reaches the predetermined value which feature it is claimed is not found in any latch device, particularly when exposed to such weather conditions as are found in the vestibule of a street car.

The Des Moines (Ia.) City Railway Co. has been granted extended privileges for carrying express and freight in that city. In connection with the prospective state fair at Des Moines the company has made arrangements to haul freight cars from the steam roads over the street railway tracks to the fair grounds, for which purpose an extra large electric engine will be put in use.

The Old Colony Street Railway Co., Brockton, Mass., recently completed its double track system between Neponset and Quincy.

A car house of the New York & Stamford Railway Co., Port Chester, N. Y., was robbed of \$900 by burglars on the morning of July 18th. The burglars were five in number. After binding and blindfolding two men on duty at the barns they blew open the safe with dynamite and secured the receipts of Sunday's operations. The capture of the burglars has not as yet been reported.

**A SUCCESSFUL DEVICE FOR CONTROLLER REGULATION.**

In the earlier days of electric railways the urgent demand for new devices and the desire of manufacturers to get their products on the market as soon as possible, resulted in the street railways doing a great deal of the experimental work at their own expense, but now the general practice has been changed and manufacturers are doing the experimenting, and new apparatus is offered to purchasers only after it has been perfected. Doubtless the majority of our readers will recall that for some time the Garton-Daniels Co., of Keokuk, Ia., has been developing a regulator for attachment to the controllers of electric cars, and they will welcome the announcement of the company that it now offers a perfected device. During the last three years the company has designed several models of the "Automotoneer," which is the invention of Mr. George W. Knox, formerly electrical engineer of the Chicago City Railway Co.; all of these would do the work, but were not all that could be desired from an operating standpoint. The present model, however, has been in use in different parts of the country for the past seven months, and the manufacturer advises us that there is yet to be received the first complaint from the companies using them.

The device consists of the wheel and regulator shown in Fig. 1. The wheel has a zig-zag groove in its periphery, with suitable ratchet teeth for engaging the dog of the regulator, which rides in the grooves. The regulator consists of the dog, or pawl, mounted on a pivoted lever, which is fastened to the back of the controller casting. The outer end of this lever engages a piston working in the cylinder of the dash-pot. This piston has a long bearing surface, and is provided with an adjusting valve to regulate its movement, as well as a release valve to permit easy operation.

When the controller is operated, the wheel, being attached to the

requires the motorman to stop the controller handle on each point for a predetermined time, and this may be adjusted so that the motorman cannot turn on full power in less than five seconds, seven seconds, or ten seconds, as desired. The predetermined time element is considered to be the important feature of the device, as without this a motorman would soon become an adept in manipulating the apparatus, and it would be valueless as a regulator.

Under ordinary conditions it has been found that ten seconds is about the time that should be allowed for the acceleration period to secure best results, and for the purpose of comparison the following table of data for 4-second and 10-second stops is given:

Time, when full power is turned on.....	4 sec.	10 sec.
Time, when full speed is attained.....	9.5 sec.	12 sec.
Distance car travels at time full power is on... ..	13.5 ft.	110 ft.
Distance car travels at time full attained.....	85 ft.	150 ft.

The need of a controller regulator has long been recognized and some years ago, in an article entitled "The Motorman as an Element in Street Railway Economy," read before the Engineers Club of Philadelphia, Mr. Charles Hewitt, electrical engineer of the Union Traction Co., of Philadelphia, gave the results of some tests made on the lines of his company, that show a possible saving of about 45 per cent, and Mr. Hewitt says: "The difference between the men is due almost entirely to the manner in which they handle the controller, and but very little to number of passengers or condition of rails." He also stated that he believed it possible to secure

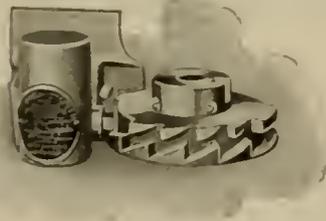

FIG. 1.

FIG. 2.

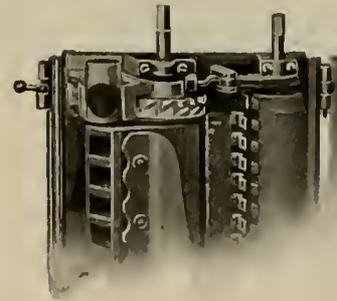

FIG. 3.

left in place of the usual star wheel, rotates, and the inclined surface of the dash raises the pawl and lever, which in turn raises the piston in the dash-pot. The pawl then strikes the ratchet stops, which are far enough back of the vertical portions to allow the pawl to drop when the pressure is relieved upon the controller handle, to the bottom of the groove, so that the upper edge of the pawl clears the bottom of the ratchet stops, when another notch may be taken.

The adjustment of the piston valve determines the speed of the pawl in its downward movement, and regulates the operation of the controller. The piston has no strain on it, simply rising and falling in a vertical bearing.

The pawl is case-hardened and shows practically no wear after continued use. It is held in the groove by a coiled spring; and its back edge is filed so that when the wheel is reversed, in order to throw off the current, the pawl slides back against the tension of the coil spring, thus permitting a ready and sure return of the handle to the "off" position.

Fig. 2 shows a bottom view of the regulator. The thrust against the pawl is taken up by the regulator casting, and does not bind or bring any strain on the dash-pot piston, which rides perfectly free on the outer end of the lever. The dash-pot is to be lubricated with dry powdered graphite only, and each device is sufficiently lubricated when set out for at least one year's service. Oil must never be used in the cylinder.

A casing is provided that covers the regulator parts and prevents the motorman tampering with it, and the device is readily installed by any competent machinist working with complete instructions sent out with each shipment.

The automotoneer is designed to prevent the waste of energy and the damage to equipment incident to "fast feeding," and in action

a saving of about 20 per cent, or, assuming a cost of 1½ cents per kilowatt-hour, a saving of \$185 per car per year, for power alone.

The advantages of proper regulation of the controller are not limited to the saving in cost of power, but the smaller maximum currents are less severe on the equipment, and more cars can be operated with a given station equipment. Another point claimed for the device is that in case of an emergency stop, where the motormen are reversed, it prevents the operator losing his head, and throwing the controller "wide open," which almost invariably opens the circuit breaker, or blows a fuse, thereby cutting off control of the car by means of the current.

Fig. 3 shows a standard G. E. K-10 controller fitted with automotoneer, which is entirely concealed when the controller is closed. The same device may be used on types K-2, K-4, K-5, K-7, K-8, K-9, K-11 and K-12 controllers, and styles applicable to other types are in process of completion.

**DETROIT UNITED RY. WEEKLY.**

The Detroit United Ry. has commenced the publication of a small weekly folder. The paper contains valuable and interesting information pertaining to the operation of the cars, schedules, new routes, etc., and is intended to establish a closer relation between the public and the company. The columns are well written and are enlivened by anecdotes, humorous sketches, notices of the theaters and other current attractions in town. The folder has four pages, each page 4 x 6 in. The Weekly is distributed at the hotels and depots and copies are carried in a small box on all the cars.

### NEW CAR HOUSE FOR CHICAGO CITY RAILWAY CO.

The accompanying illustration shows a front view of the new car house of the Chicago City Railway Co., located at Wentworth Ave. and 77th St., which was described in detail in the "Review" for April, 1902. Each end of the building is enclosed with Kinnear steel rolling doors, those on one end being provided of standard size attached to iron frames and on the other end each opening being enclosed with two doors with a hinged intermediate center post. The latter is so constructed that it can be quickly raised.

NEW CAR HOUSE FOR CHICAGO CITY RAILWAY CO.

leaving the opening entirely clear. Each door is equipped with Kinnear trolley wire connections, which provide an uninterrupted circuit with the door in any position. There are 54 of these doors now in service on the building, and the Chicago City Railway Co. has contracted for 55 similar doors for other buildings now being located at this site.

### THE HARTMAN CIRCUIT BREAKER.

The Hartman automatic oil circuit breaker, shown in the accompanying illustration, is a new device made by F. O. Hartman, Mansfield, O., which has been designed for use in locations where it

HARTMAN CIRCUIT BREAKER.

would be unsafe to use the ordinary air break instrument. It is adapted especially for electric railway use and is claimed to be exceedingly reliable in breaking the circuit where the current exceeds the amount for which the instrument is set. The switch mechanism

operates in oil with which the lower part of the case containing it is filled, and the break in the circuit takes place in this oil, which will prevent a short circuit under the most severe conditions. The operating parts are enclosed in a metal case, which gives them ample protection against the weather and the rough usage to which these instruments are liable. This circuit breaker is arranged so that it cannot be closed as long as an overload or short circuit exists. Each side of the switch operates independently of the other, and both sides must be closed to complete the circuit. If the second switch is closed while a short circuit exists, the first switch will immediately open. This instrument is also designed to

act as an oil break switch as well as a circuit breaker, and where it is used on cars the hood switch may be dispensed with. It may be readily used on old equipments by removing the hood switch and inserting the circuit breaker in its place. It is also designed for use in connection with large motors and is well adapted for damp or other unfavorable locations as the working parts are entirely enclosed.

### NATIONAL BUREAU OF STANDARDS.

A work that is being followed with much interest by all persons connected with engineering and manufacturing is that of the National Bureau of Standards, organized in March, 1901. It has been necessary to greatly increase the scientific and clerical force of the Bureau and to rent additional space for temporary quarters.

Contracts have recently been let for the mechanical laboratory, and those of the physical laboratory, which will be the principal building, are soon to be awarded.

The mechanical laboratory will be 135 ft. long, 50 ft. wide and three stories high, and will contain the power and lighting plant, storage batteries, special alternating current machines for experimental and testing purposes, refrigerating plant, heating and ventilating plant, machine and carpenter shops and laboratories for heavy electrical testing, photometry, gas and water testing. The boiler room will have two 125-h. p. boilers with space to double that capacity. The dynamo and engine room will have two 80-h. p. high-speed engines each direct connected to two 25-kw. direct-current generators, and additional space will be provided for double this equipment and for some special alternators.

For the heating and ventilating system the air will be supplied through ducts by electrically-driven fans, the temperature in each room to be independently controlled by thermostatic dampers and the air to be renewed every 15 minutes. In winter the air to be heated will pass over coils fed with exhaust steam, and in summer it will be cooled by coils through which brine is circulated. The refrigerating plant will cool the air and make ice.

An instrument shop will be equipped with motor-driven lathes,

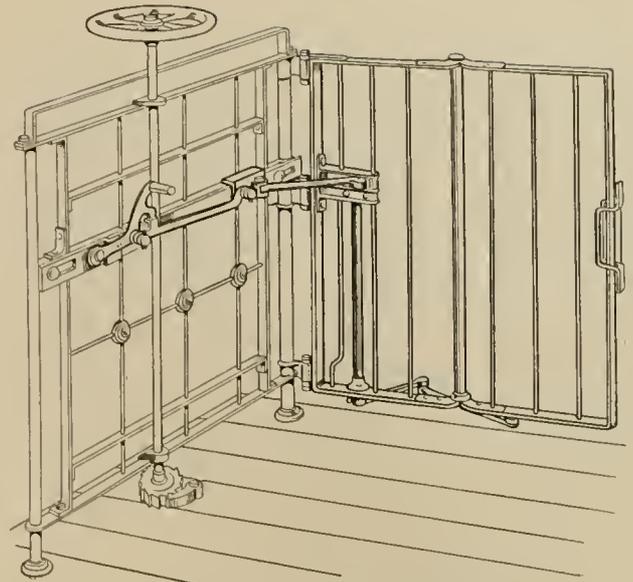

milling machines, shapers, drills, etc. A liquid air plant will also be installed for experimental use.

The main building will be 150 ft. long, 50 ft. wide, four stories high, and will contain 50 rooms. It will be equipped with apparatus for verification work and for special investigations and provided with gas, electric light, compressed air and a number of independent electric circuits. The basement of the main building, which is about level with the ground, will be used entirely for the more precise and accurate work, and there will be four special temperature rooms. The second floor will be used for administrative and clerical work, library and museum; the third floor will contain a well-equipped chemical laboratory, part of which will be a laboratory for photometric research, and this floor will also have a lecture room to seat about 150 people. Both buildings will be of brick with stone trimmings, and the two will cost \$325,000, an additional \$40,000 having been appropriated for equipment, making the total amount available \$365,000.

The site of the Bureau is at Chevy Chase, near Washington.

**FOLDING GATE FOR CARS.**

The illustrations herewith show a new folding gate for steam and electric cars, both elevated and surface, which has been placed on the market by the R. Bliss Manufacturing Co., of Pawtucket, R. I. The gate is designed to be durable, strong and safe, and combines the well-known features of this company's other folding gates, being hinged in the middle and operated by a right-angled rigid lever in connection with lazy tongs and a sleeve and slide, as shown in the illustrations. The gate folding from the center in half its reach will save the room of at least three people on the platform, and where cars are crowded as they must be in large cities, this feature of economy of space is a merit that deserves serious consideration. The new gate is stronger than the ordinary straight gate, being held rigidly in its extreme points and being assisted by a brace obtained from the lazy tongs, as well as from the interlocking hinges in the center post. This reduces to a minimum the danger of passengers being thrown from the car by a sudden lurch or oscillation. The

CLOSED POSITION OF FOLDING GATE.

all conditions. The workmanship and material are the best, while the well-known experience of the R. Bliss company in manufacturing will speak handsomely for the gate in general.

**NEW INTERURBANS IN INDIANA.**

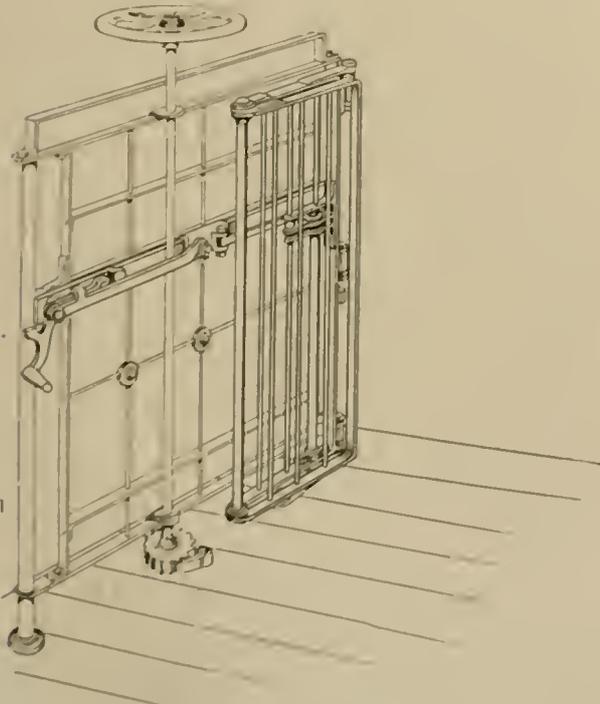

An extensive system is about to be built in Indiana in connection with the Indianapolis and Anderson lines by the same interests controlling the latter systems. The new lines will extend from Indianapolis north to Logansport paralleling the Pittsburg, Lake Erie & Western Ry. and passing through Noblesville, Tipton and Kokomo. At the latter place a branch will be built running to Peru, which will parallel the Lake Erie & Western Ry. Another branch will run between Tipton and Elwood and one between Alexandria and Muncie, both of which will connect with the Union Traction Co. of Indiana system to form a direct route between Tipton and Muncie.

There will be six sub-stations on the new lines located at Ripple, Noblesville, Tipton, Jewell, Logansport and Peru. The current for this system will be supplied from the Anderson power station of the Union Traction Co. and will be transmitted to the sub-stations at a pressure of 30,000 volts. The company will also have a portable sub-station similar to that of the Union Traction Co., which was described in the "Review" for April, 1901, page 212. This is used in cases of emergency or of accident to a regular system, and being mounted upon a car body may be readily moved to any part of the system. The new sub-station car will be provided with an easily removable roof in order that the apparatus in the car may be handled from overhead by a traveling crane.

**CONCORD-MANCHESTER INTERURBAN OPENED.**

The first car over the lines of the Manchester Traction, Light & Power Co. was put into service in the latter part of July between Concord and Manchester. On board the car making the initial trip were several officers of the company and invited guests and the trip to the Boston & Maine railroad bridge near Concord, and return to Manchester, was made everything working successfully. Since this trip cars are operating upon the line under a regular schedule.

A singular accident happened at Troy, N. Y., on the lines of the United Traction Co., August 7th, resulting in the death of two persons. A car left the track in the middle of a switch 200 ft. in length, plunged down an elevation of the roadway and the forward truck jumping the four inch curb of the sidewalk, smashed into a frame house.

OPEN POSITION OF FOLDING GATE.

handle a straight lever hinged at the bottom in connection with the operating sleeve and slide, locks positively in either direction, whether the gate be open or closed, and gives the operator a powerful leverage thus enabling the gate to be operated with ease under

### ADVERTISING LITERATURE.

THE ARNOLD ELECTRIC POWER STATION CO., of Chicago, is mailing to its customers and friends an advertising card calling attention to the central plant it has built for the Chicago & Alton Ry. at Springfield, Ill. The heat, light, power, water and electric light of this plant are all secured from a single source.

THE OSBORN MANUFACTURING CO., of Cleveland, Ohio, has issued its catalog No. 100. The company manufactures brushes, brooms, foundry supplies and hardware specialties adapted to use in the power house, machine shop and factory. The catalog contains 50 pages of illustrated descriptions of all its manufactures, together with price list.

THE PROTECTED RAIL BOND CO., Philadelphia, has issued two handsome colored folders containing illuminated designs and a brief statement of its claims for the Protected rail bond. This bond, being short and made of pure copper, offers slight resistance to the passage of the current, and is therefore highly economical. The Mayer & Englund Co., of Philadelphia, is sales agent for the Protected rail bond.

THE MULTIPLE SPEED & TRACTION CO., of New York, has published in pamphlet form the oral presentation by Mr. Julien T. Davies of the proposition to equip the Brooklyn Bridge with moving sidewalks, and also the arguments by Messrs. George S. Morrison and Walter D. Edmonds on the feasibility of relieving the present conditions.

THE J. G. BRILL CO., under the title of "A Brilliant Idea" has issued a pamphlet describing the illuminated signs which it manufactures. These signs are plainly visible, both by day and by night, and may be made of the turn-over variety with two, three, or four sides containing lettering of patented enamel on transparent celluloid sheets. The sign needs no special lighting arrangement, as it is sufficiently lighted by being placed in front of the transoms or side vents. It is built so as to be practically unbreakable.

THE NEW JERSEY & HUDSON RIVER RAILWAY & FERRY CO. is mailing a handsomely decorated card describing the pleasant trips which may be taken on the company's ferry and electric lines in the vicinity of New York City. The company has recently put in commission the new double-decked propeller "Edgewater" from West 130th St. to Edgewater, N. J. This is one of the nattiest and most commodious ferry boats on the river and is a highly creditable acquisition to the company's line of modern steamers.

THE ELECTRICAL STORAGE BATTERY CO. has issued its bulletin, No. 74, upon "The Application of Storage Batteries to Isolated Plants," which describes the plant of Hastings' Sons Publishing Co., of Lynn, Mass., in which a battery of "Chloride" accumulators has recently been installed. The load on this plant includes elevators, incandescent lights and printing presses and the variation in pressure made it impossible to supply the lights from the same machine that supplied the power, without a storage battery to act as a regulator.

ELECTRICAL AND STEAM MACHINERY is the title of a pamphlet published by Rossiter, McGovern & Co., 141 Broadway, New York. This company now maintains warehouses in New York, Jersey City, Boston, and St. Louis, and carries a large stock of electrical machinery, engines, boilers, railway motors, etc., all of the stock being ready for immediate shipment. All of its machinery is guaranteed to be in first-class condition, and the company also maintains a well appointed repairing department, in which it makes a specialty of electrical repairs.

THE J. G. BRILL CO., of Philadelphia, Pa., is distributing a handsomely illustrated catalog and a folder describing the Brill No. 27 truck, built for both electric railway and steam railroad cars. These trucks are extremely strong and their principal features include three sets of springs working in series and link spring suspended equalizer bars. The side frames are made of solid forgings, lending strength and simplicity to the design. The typo-

graphical appearance of this catalog is fully in keeping with the high standard of this company's advertising literature.

THE JOSEPH DIXON CRUCIBLE CO., of Jersey City, N. J., has published a highly artistic catalog containing descriptions and illustrations of its numerous graphite products. This company is the largest miner and manufacturer of graphite in the world, and is also the oldest in this line of business, having commenced the manufacture of graphite crucibles in 1827. All of this company's graphite is mined or worked by the company itself, and its products are all guaranteed. In addition to this general catalog the company also publishes a number of interesting pamphlets on the special use of graphite.

MOTOR DRIVEN TOOLS is the title of Bulletin No. 24, published by the Crocker-Wheeler Co., of Ampere, N. J. The contents consist largely of engravings of machine tools direct driven by electric motors, in which field this company is the pioneer. The descriptions are generally very brief, as the illustrations suffice to show the method of applying motors to tools of all kinds. The increasing attention which is being given to the driving of mills and shops by electric power makes this bulletin of special interest, and the Crocker-Wheeler Co.'s experience in this line enables it to suggest the equipment which will give the best returns to the purchaser.

ADAM COOK'S SONS, 313 West St., New York City, who are the only makers of "Albany" grease, have issued a booklet which gives considerable information regarding this widely known lubricant in a brief and attractive way. The pamphlet is in two colors, the cover bearing the familiar "Albany" grease trade-mark, reproduced in yellow. The manufacturers state that Albany grease is now used to lubricate everything from an automobile to the U. S. Battleship Oregon and has been adopted by the U. S. Government. Illustrations are presented in colors showing what genuine Albany grease looks like when put in 10-pound pails and purchasers are cautioned to look for the distinctive yellow label. Copies of the booklet will be sent free by Adam Cook's Sons, upon application.

THE GREEN FUEL ECONOMIZER CO., of Matteawan, N. Y., has published a large catalog on the Green improved fuel economizer for steam boilers. This apparatus, which is to be found in a large number of the most prominent steam plants, consists principally of a stack of tubes arranged vertically in the flue leading from the boiler to the chimney. These tubes are designed to utilize the waste heat from the gases passing off from the furnace. The advantages of this economizer are the saving of a large percentage in fuel, heating the feed water economically to a high temperature, a large volume of water always in reserve at the point of evaporation, utilizing the heat in the escaping gases which otherwise goes to waste, prolonging the life of the boiler by preventing expansion and contraction due to cold feed water, and increasing the boiler efficiency. The catalog contains a number of views of these economizers with descriptive matter and results of tests, as well as a large number of testimonials from those who have used the apparatus.

The Exeter (N. H.), Hampton & Amesbury Street Railway Co. is operating a special car equipped with a rotary transformer to supply additional power at any point on the system where such assistance may be necessary. The car might be described as a portable power house, and on days when traffic is unusually heavy it is very serviceable. It is known as the power car and was made at the Laconia shops.

### WABASH A. S. R. A. SPECIAL.

The Wabash Railroad has made a rate of \$0 for the round trip from Chicago to Detroit for the A. S. R. A. convention on the certificate plan. A special train will leave Polk St. Station, Chicago, Tuesday afternoon, October 7, for the accommodation of delegates and in addition to the special there are regular trains leaving Chicago for Detroit at 11 a. m., 3:03 and 11 p. m. The special will leave at an hour to suit the convenience of the Chicago and western delegates and will be personally conducted by Mr. M. C. Keeran, who has had charge of the A. S. R. A. specials for the past five years.

## NEWS OF THE MONTH.

A strike of some 200 employes of the Camden Interstate Railway Co., which lasted for practically two days beginning on the morning of August 3d, caused suspension of traffic on the lines in Ironton and Hanging Rock, O., Guyandotte and Huntington, W. Va., and Ashland, Ky. The cause of the strike was the company's dismissal of a number of employes who had been instrumental in organizing a local union, and its refusal to recognize the union. On Sunday morning, August 3d, the conductors and motormen who had refused to strike were driven from the cars in Ironton by a mob, and on substitutes being obtained, the cars were stoned and the tracks greased. Similar experiences were repeated at Huntington and at Ashland. In the latter city five shots were fired by an unknown person at a car bound for Clyffeside Park, none of them, however, taking effect. A compromise was reached on August 4th, and the men returned to work.

Four hundred employes of the Fair Haven & Westville Railroad Co., of New Haven, Conn., went out on strike at 5 a. m., August 6th, causing a complete tie-up of the 90 miles of railways operated by the company, which lasted until the night of August 9th, with the exception of a very irregular mail car service and a few trips of passenger cars through the down-town district. The cause of the strike was the refusal of the company to recognize the union and its alleged discrimination against union men in the recent discharge of 10 of its employes. The strike was exceptionally free from mob violence, the only disorderly conduct of the strikers reported being their attempt in one instance to pull the conductor of a mail car from the rear platform, an attempt which was promptly checked by the police. The strike, which resulted in considerable financial loss to the merchants of the city, was settled at 6 p. m., August 9th, the company having convinced the leaders that membership in a union had not been and would not be considered a cause of disqualification for service in the company's employ.

The employes of the Yonkers, N. Y., lines of the Union Railway Co., including motormen, conductors, repairers, firemen, engineers and electricians, struck August 9th for the reinstatement of a superintendent whom the company had dismissed, and for an advance in wages, demanding 20 cents per hour for 10 hours' work instead of 18 cents for 11 hours. The first demand, for the reinstatement of the superintendent, has been conceded, but at latest reports the question of wages had not been decided.

The local transportation committee of the Chicago city council returned August 4th from a tour of investigation of street railway systems of eastern cities, and the committee's report, it is inferred, will influence the final action on the proposed subway for Chicago, and the extension of surface lines. The itinerary included New York, Brooklyn and Boston, which cities furnished such a complete exposition of transportation facilities in the opinion of the aldermen that it was considered unnecessary to visit Washington, as had at first been intended. An examination of the New York and Boston subways resulted in a conclusion favorable to subway construction in Chicago, where, the members of the committee affirm, the subway problem is much easier of solution than in New York, since in the former city it would not be necessary to tunnel for miles through the solid rock. The report of the committee will also include such matters as down-town terminals, single car service and grooved rails.

Announcements were recently made that the Metropolitan Elevated, of Chicago, will declare a semi-annual dividend of 1 or 2 per cent. The company paid 3 per cent last year and 3½ per cent the year previous, in both cases the first payment being 2 per cent. There is much discussion of extending the express service on Chicago elevated lines, and as has been announced, the South Side Elevated Railroad Co. contemplates an initial experiment with such a service, but its plans have not yet developed. It is said that the South Side company has under consideration the construction of an extension to the stock yards, which will afford a through route from the stock yards to the lake. The feasibility of a double deck elevated structure has been discussed, the proposition being that the South Side company use the upper track and the Union Stock Yards & Transit Co. the lower tracks.

The Lake Street Elevated R. R. is soon to inaugurate an express service on the West Side, the only stops being at Oakley and 48th Ave. Express trains will run at 10 minute intervals between 6:40 and 8:35 a. m., and 4:36 and 6:20 p. m.

All the interurbans running into Columbus, O., are doing an exceptionally heavy passenger business. The Columbus, Buckeye Lake & Newark Traction Co. expects to inaugurate a street railway mail service, a recommendation having been made to the postal authorities at Washington through the local office to this effect. According to present plans there will be two mails per day for Reynoldsburg, Wagram, Etna and Kirkerville, and one in and out of Hebron. People along the route are generally anxious to see the mail service established.

The Cincinnati & Columbus Electric Railway Co., which is being promoted by Richard Swing, projects a line between the cities named in the title, passing through Norwood, Oakley, Madisonville, Milford, Fayetteville, Hillsboro and Washington, C. H. It is stated that this company is completing arrangements to build without further delay, and that an agreement has been effected whereby its cars will enter the business district of Cincinnati over the tracks of the Cincinnati Traction Co. When this road is completed, two roads from Columbus to Cincinnati will be afforded; one over the route described, the other via the Columbus, London & Springfield Ry., thence through Xenia, Lebanon and Carthage.

The Cincinnati Traction Co. on August 7th gave a free picnic to the inmates of the orphan asylums and children's homes of Cincinnati, entertaining some 1,200 children at the Zoological Gardens. Refreshments and special amusements were provided, and the outing proved a great success.

The Toledo Railway & Light Co. has secured a site of 30 acres in that city on which car shops and storage buildings will be erected, it being projected to rebuild and repair cars at this plant for local and interurban traffic. The Toledo, Bowling Green & Southern Traction Co. is rapidly completing its new power house at Cygnet, and machinery is being installed. A 300-h. p. Corliss engine is included in the installation. Work on the building was delayed to some extent by reason of the difficulty in securing stone suitable for a foundation on which to mount the engine. The Toledo, Fostoria & Findlay Electric Railway Co. has literally struck oil on its right of way. A well on this route, five miles west of Findlay, which had been pumping salt water for six months, began flowing oil on July 25th and since then the product has been 100 barrels of oil per day. The well is owned by a Findlay citizen, who has leased three miles of the company's right of way, and proposes to line it with wells. Apparatus has been installed along the electric line, and there is barely sufficient room for the car to pass without grazing the edge of the derricks.

The Cleveland & Eastern Electric Railroad Co. proposes to straighten its track, eliminating all abrupt curves and reducing the heavy grade, a work which will take a year to complete and which will cost approximately \$100,000. When it is finished the time required to make the round trip over the line will be reduced by half an hour.

The Cleveland City Railway Co. recently submitted its tax returns for 1902, reporting the value of its property at \$900,300. The report includes 28 miles of double track valued at \$16,000 per mile, and 7 miles of single track at \$7,000 per mile. First class cars are returned at \$1,500 each and second class cars at \$700. The Cleveland Electric Railway Co. returned the total value of its property at \$2,603,700. Personal property, including tracks, cars, etc., is valued at \$1,603,900, and real estate, including power houses, machinery, etc., at \$900,800. Superintendent Mulhern of the former company is quoted as stating that the company's valuation of its property this year exceeds that of last year by reason of the number of improvements that have been effected in the system, including the purchase of more than 80 large cars, the erection of additional power houses and the construction of new and heavier track. The majority of the properties included in the return are reported to have been appraised at about 60 per cent of their original value.

The Lake Shore Electric Railway Co., of Cleveland, is rapidly pushing its road to completion. The Sandusky division has been tied up owing to a delay in the construction of a bridge over the Huron River, a fact which will make it impossible to complete this branch until late in the fall, but satisfactory progress has been made on the work to be done on the Detroit & Toledo Shore Line, and it is expected that through trips will soon be made from Toledo to Detroit. As to the remainder of the system, over the greater part of which cars are in operation, the work that remains to be done is chiefly in the nature of rock ballasting until which is completed no considerable speed can be attained. An incident of considerable

interest occurred on the Sandusky division of the Lake Shore Sunday, August 3d. The authorities of Milan, a small village en route, had ordered that no cars from Norwalk should pass through Milan, there having been reported several cases of small pox at Norwalk. The superintendent of the division, according to press reports, attempted to run cars through from Norwalk to Sandusky without stopping at Milan, but the authorities of the latter village, anticipating such an attempt, placed another car on the track, compelling the Norwalk car to stop, and then arrested everybody on board, including the superintendent. The constables of Milan had not, however, entirely the best of it. In thus stopping the electric car the authorities had held up the United States mail and they were threatened with serious trouble on this account until the matter was adjusted.

The Indianapolis & Eastern Traction Co. recently experienced a similar difficulty in running cars, as a result of a quarantine against Knightstown, Ind. Owing to the small-pox cases in that city the company had temporarily suspended operations on the line running from Knightstown to Charlottesville, five miles west, but on August 3d attempted to resume its regular service. The second car through Charlottesville was stopped by a mob, the motorman and conductor were arrested, and the car was side-tracked. Obstructions were placed on the track to prevent other cars passing through the town, and in one instance a wreck was narrowly averted from this cause. Traffic was resumed the following morning, but later the sheriff of the county with a posse of 75 armed deputies was ordered to enforce the quarantine, and cars were not run until it was lifted. For a short time mob violence threatened destruction to the company's property, and as a result a number of arrests were made, when it was found that the mob leaders had purchased a quantity of dynamite and had threatened to blow up a bridge on the company's route.

There are persistent rumors that a consolidation of the Detroit, Ypsilanti, Ann Arbor & Jackson and the Grand Rapids, Grand Haven & Muskegon roads will be carried through, the new company to be capitalized at \$20,000,000 and later acquire other Michigan interurban lines.

August 4th it was announced that Mayor Johnson had won his fight for 3-cent fares in Cleveland, the Circuit Court having dissolved the temporary injunction restraining the city council from granting service franchises. The Supreme Court however granted a stay on the order of the lower court and as we go to press the injunction is still in force.

Considerable meanness has been manifested among the employes of the Chicago streets railways and the radical element among the men has kept the local press well supplied with strike talk. The employes of both the large companies however are under an agreement to arbitrate any differences that may arise between them and the companies, and the situation is not regarded as at all serious.

The Kenosha (Wis.) Electric Railway Co. has again opened negotiations with the Kenosha Gas & Electric Co. to secure power for the operation of the street railway in that city. The work of erecting a bridge on the route through the city has been begun, and it is expected to open the line in October.

The Winnebago Traction Co., Oshkosh, Wis., is building an addition to its power house at a cost of \$30,000.

The bid of the Belmont-McDonald syndicate for the construction of the tunnel extension of the rapid transit system to Brooklyn was unanimously accepted by the rapid transit commissioners, July 24th. The bid was for the completion of the Brooklyn tunnel extension alone at a cost of \$2,000,000. The former bid of the same company to build the Brooklyn extension and the proposed tunnel between Union Square and 42d St. for \$3,100,000 was not accepted for the reason that the Broadway route from 42d St. to Union Square was not included in the specifications. In both bids the additional cost of terminals was estimated at \$1,000,000. The only other bid considered by the board was that of the Brooklyn Rapid Transit Co., which proposed to construct the Brooklyn extension for \$7,000,000 and terminals for \$1,000,000 additional. The Brooklyn Rapid Transit Co. estimated that its bid was \$1,000,000 less than it would actually cost to complete the Brooklyn extension alone, but it also estimated that the loss in the initial cost would soon be more than compensated for by the increased traffic over Brooklyn lines resulting from the tunnel extension. The importance of this prospective increase in traffic was also a basis of calculation of the Belmont-McDonald company in submitting its bid which was estimated to be millions of dollars below cost. The latter claimed that if its bid for

the Brooklyn extension and the 42d St.-Union Square tunnel were accepted, the city would be required to pay only about 25 per cent of the actual cost of the construction work. It should be remembered that the Belmont interests in being already provided with the necessary equipment had an advantage not shared by the Brooklyn Rapid Transit Co. when it submitted its bid of \$7,000,000.

The New York Central & Hudson River R. R. is reported to have authorized the statement that electricity will be substituted for steam on all its lines out of New York if the city will approve the changes it projects at the Grand Central depot in the metropolis. The contract for the erection of power houses will be signed, it is said, so soon as the city shall approve the railroad's terminal plans. The third vice president of the railroad is quoted as stating that two or more power stations with an aggregate capacity of 100,000 h. p. will be built and the third-rail system installed exclusively except in a few of the yards where the overhead trolley system will be used. Even switching in the yards will be done by electric power. At Croton Landing on the main line and White Plains on the Harlem R. R. the change to steam locomotives will be made with a delay not exceeding a minute. The conversion of the system from steam to electric traction within a radius of 30 miles is estimated to cost approximately \$15,000,000 inclusive of the necessary changes in the yards along Park Ave. from 49th to 56th Sts. Above the Harlem River a three-deck passenger station may be erected for the accommodation of suburban traffic.

The points at issue in the franchise of the Pennsylvania R. R. for an entrance into New York may be summarized as the perpetuity of franchises, the ultimate compensation to the city and the right of the city to stipulate the wages to be paid the railroad's employes and the number of hours comprising a working day. The Pennsylvania is said to have assented to a proposition to the effect that the franchise be granted not to the company proper, but to a new corporation working under the jurisdiction of the laws of the state. This provision, in the view of those opposed to the granting of perpetual rights, will give the city the right to acquire the tunnel at any time under condemnation proceedings if due regard is paid to the vested rights of the corporation. It is reported that an agreement was reached whereby the railroad company will be obliged to apply to the president of the borough for street openings, and the latter is quoted as stating that no permit will be granted unless the eight-hours' labor law were made part of it. Various amendments to the proposed franchise have been agreed to, such as the stipulation that the city authorities and the railroad shall adopt a basis of compensation at each period when terms are to be re-adjusted; that the board of health shall have jurisdiction over the tunnel, and that the city shall have the use of the tunnel for police and telegraph wires. The rapid transit commission will pass upon the work of the committees, September 4th.

Press reports state that the Omaha Street Railway Co.'s stock aggregating \$6,000,000 has been sold to a New York syndicate of which J. & W. Seligman & Co. is at the head, the price being 92 on the total capitalization of the company. It is stated that the purchase included the property of the Omaha & Council Bluffs Railway & Bridge Co. Preparations are being made for the construction of extensions of the Omaha lines and various other improvements of the system, aggregating an expenditure of \$1,000,000. New equipment will be purchased and a large and modern power house erected. New machinery has recently been installed in the Council Bluffs power house, which will suffice until plans are completed for furnishing all the lines owned by the company with power from the same plant.

The Seattle-Tacoma Interurban Railway Co. has decided upon a 60 cent fare between Seattle and Tacoma, or \$1.00 for the round trip. Cars will leave either city at intervals of an hour and a half, three of the trains being limited and making but two stops outside the corporate limits of the two terminal cities. The last car will leave Tacoma at 11:30 p. m. and Seattle at midnight. Freight cars will be run only between midnight and 6 a. m. The company has closed a contract with the Snoqualmie Falls Power Co. for furnishing 1,000 h. p. to operate cars between Seattle and Tacoma. The power is to be delivered at Kent, and for this purpose the Snoqualmie Falls company will erect a sub-station at that place.

The Seattle Electric Co. has petitioned for franchises for extensions of its system to suburban districts, contemplating the construction of a number of miles of new lines this year.

The Puget Sound Electric Co. is preparing to install a large

transformer station at Georgetown, Wash., for the new interurban which is under construction between that city and neighboring towns. Power will be transmitted from Seattle.

From present indications portions of the new street railway at Reno, Nev., will be constructed this season. Eventually the road will be extended to the Southern Pacific shops, thence to Wedekind City and back to Reno.

Surveys are being made for the proposed electric line between Ventura and Bakersfield, Cal. The road will be constructed north of the route originally proposed, and it is believed that an extension will be built through the Sunset oil fields.

An electric railway from Torresdale, a suburb of Philadelphia, via Bristol, Pa., to Trenton, N. J., a distance of 22 miles, is projected and when completed will form an important link in the proposed electric railway system between New York and Philadelphia. The promoters have organized as the Philadelphia, Bristol & Trenton Electric Railway Co., and the Union Trust Co., of Baltimore, has closed the underwriting which covers an issue of \$600,000 first mortgage 5 per cent bonds. The money was largely over-subscribed by Philadelphia, Baltimore and New York capitalists. The company has an authorized capital stock of \$1,000,000 and an authorized bond issue to a similar amount.

**NEW CONDUIT COMPANY.**

Mr. Bleecker S. Barnard has been elected vice-president and secretary of the Standard Vitrified Conduit Co., having resigned as sales manager of the American Vitrified Conduit Co., to take the new position. The Standard company, which was recently organized by Mr. Robert W. Lyle, who is its president, will manufacture in vitrified clay every known conduit. It has extensive clay

B. S. BARNARD.

beds and factories at South River, N. J., which will enable it to do business on a very large scale, not only in this country, but abroad as well. It controls several new patented features that are applied to its multiple duct conduit, guaranteeing superior construction. The general offices are at Nos. 39-41 Cortlandt St., New York. Mr. Barnard is one of the most popular men in the trade, as well as one of the best equipped, while in military and social circles he has held a prominent position for years. He has earned his laurels and honestly deserves to be congratulated upon his success.

On August 4th, for the third time within two weeks, the wires of the Mineola, Hempstead & Freeport Traction Co., that cross the tracks of the Long Island R. R. at West Hempstead, L. I., were purposely torn down, it is alleged, by persons in the employ of the Long Island R. R. Shortly before daylight an engine with a gang of laborers aboard reached the crossing, when by means of ropes thrown across the trolley wires from the moving engine, the wires were torn down and left in the roadway. Some of the company's poles were broken off at about three feet above the ground. The traction company, it is stated, will make a determined effort to secure a permanent injunction against the railroad from damaging its property.

**STREET RAILWAY PATENTS.**

This list is furnished by T. Reed Clift, Patent Attorney, Washington, D. C., from whom copies of patents and information thereon can be secured.

- No. 703,536. July 1, 1902. Edwin F. Cannon, Chicago. Street car fender.
- No. 703,561. July 1, 1902. Horace H. Dolly et al, Camden, N. J. Automatic switch.
- No. 703,589. July 1, 1902. Charles J. Johnson et al, St. Louis. Trolley for electric cars.
- No. 703,614. July 1, 1902. Frederick W. Rock, Detroit, Mich. Car brake.
- No. 703,786. July 1, 1902. George W. Hammond, Philadelphia. Apparatus for preventing trolley wheels from leaving the wire.
- No. 703,818. July 1, 1902. Jos. Plattenburg, McKeesport, Pa. Car brake.
- No. 704,092. July 8, 1902. Theo. B. Patch, North Cambridge, Mass. Contact system for electric railways.
- No. 704,093. Same.
- No. 704,141. July 8, 1902. Charles T. Stoelting, St. Louis. Street car fender.
- No. 704,143. July 8, 1902. Max Straus, Denver, Col. Hand strap for street railway cars.
- No. 704,166. July 8, 1902. Casper Zimmerman, Chicago. Street car fender.
- No. 704,228. July 8, 1902. Hubert Witte, St. Louis. Guard gate for railway cars.
- No. 704,432. July 8, 1902. William S. Bradley, Philadelphia, Pa. Guard rail for street cars.
- No. 704,452. July 8, 1902. Charles B. Fairchild, New York, N. Y. Vehicle brake.
- No. 704,461. July 8, 1902. John T. Hodgins, St. Louis. Car fender.
- No. 704,474. July 8, 1902. Enoch C. Deskin, Moberly, Mo. Car heating device.
- No. 704,506. July 15, 1902. Frank O. Brown et al, Dallas, Tex. Car brake.
- No. 704,523. July 15, 1902. Ashford T. Dowden, Prairie City, Kan. Portable chair swing.
- No. 704,695. July 15, 1902. John L. Creveling, New York. Combined electric and gas lighting system.
- No. 704,776. July 15, 1902. Eli A. Booser, Altoona, Pa. Car fender.
- No. 704,870. July 15, 1902. Chas. D. Fox, Appleton, Wis. Car mover.
- No. 705,020. July 22, 1902. Gaston Bellange, Arcachon, France. Safety contact interrupter for electric wires.
- No. 705,028. July 22, 1902. Amel Broheska, Detroit, Mich. Car brake.
- No. 705,075. July 22, 1902. Henry S. Hale, Philadelphia. Car seat.
- No. 705,083. July 22, 1902. F. W. Hild, Schenectady, N. Y. Electric railway.
- No. 705,150. July 22, 1902. Henry J. Schuldt, St. Paul, Minn. Street car fender.
- No. 705,235. July 22, 1902. Wm. H. Harris et al, Eldorado, Col., Street car and railway indicator.
- No. 705,434. July 22, 1902. James M. Osgood, Boston. Passenger car.
- No. 705,466. July 22, 1902. Otto Siplen, Spitzer, Austria. Street car fender.
- No. 705,662. July 29, 1902. Joseph W. Frost, Washington, D. C. Electric signal for railway cars.
- No. 705,668. July 29, 1902. William S. Hadaway, Jr. Electric heater.
- No. 705,705. July 29, 1902. Susie E. Pressler, Toledo, Ohio. Safety attachment for trolley car vestibules.
- No. 705,783. July 29, 1902. Ole Olsen, St. Louis. Street car fender.
- No. 705,798. July 29, 1902. William L. von Hardenberg, Brooklyn, N. Y. Trolley.
- No. 705,814. July 29, 1902. John Bauer, New York, N. Y. Fender.
- 705,825. July 29, 1902. Walter A. E. Davis, Toledo, O. Trolley head and wheel.

No. 705,848. July 29, 1902. Charles J. Kuntner, New York, N. Y. Electric railway.

No. 705,882. July 29, 1902. Thomas W. Sutton, Pittsburg, Pa. Trolley.

No. 705,886. July 29, 1902. John W. Wehmeyer, St. Louis. Car fender.

No. 705,918. July 29, 1902. Charles Giblin, Cleveland, O. Car fender.

### ENGLISH NOTES.

The Corporation of Douglas, Isle of Man, has under consideration whether it will issue fortnightly tickets on the cable trams at reduced rates.

The highways committee of the London County Council has decided to investigate the shallow underground systems of tramways in foreign cities and proposes that the officials who recently visited the United States should go to Paris, Budapest and Munich and report to the council on the matter.

The Stalybridge & Joint Electric Tramway board is going to carry out a tramway scheme costing about \$2,000,000 and has appointed Mr. Schofield, who was connected with the Manchester Tramway Co. as clerk to the board.

The Dewsbury & District Electric Tramway will, it is expected, be completed in from 12 to 18 months. The length of line to be laid is about 15 miles; the contract is in the hands of Dick, Kerr & Co.

A plebiscite is being held in Ayr, Scotland, as to whether the running of Sunday cars should be continued or discontinued; should the latter be the result it will materially affect the earnings of the tramways, as the earnings per car mile on Sunday are nearly twice as much as on week days.

Mr. W. Spaven, traffic manager of the Leeds Corporation Tramways, has been appointed manager of the Portsmouth electric tramways. Forty-four candidates applied for the position. Mr. Spaven, who has risen from the position of a tram conductor under the old company, was appointed traffic manager by the Leeds Corporation in 1899.

The Hastings Town Council has decided against introducing tram ways in the town; but only by the majority of one vote.

The York County Traction Co. has completed the erection of a power station at Red Lion.

A car house of the New York & Stamford Railway Co., Port Chester, N. Y., was robbed of \$900 by burglars on the morning of July 18th. The burglars were five in number. After binding and blindfolding two men on duty at the barns they blew open the safe with dynamite and secured the receipts of Sunday's operations. The capture of the burglars has not as yet been reported.

The Des Moines (Ia.) City Railway Co. has been granted extended privileges for carrying express and freight in that city. In connection with the prospective state fair at Des Moines the company has made arrangements to haul freight cars from the steam roads over the street railway tracks to the fair grounds, for which purpose an extra large electric engine will be put in use.

### TRADE NOTES.

THE ALLIS CHALMERS CO., Chicago, has declared its fifth consecutive quarterly dividend of 13 1/4 per cent, payable August 1st, out of net earnings.

THE SPRINGFIELD (MASS.) STREET RY. has placed a third order for a Green economizer to keep the service of this apparatus co-extensive with the growth of the plant.

THE EDISON ELECTRIC ILLUMINATING CO., Boston, has contracted with the Green Fuel Economizer Co. for an installation of the economizer in its Atlantic Ave. power station.

THE IRONSIDES CO., Columbus, O., reports a substantial increase of business during its late fiscal year recently ended, with encouraging prospects for continued growth in the current year. Its manufactures comprise special lubricants for ropes, gears and machinery, and specially adapted to motor gears of street cars.

THE LUDLOW SUPPLY CO., 301 and 302 Electric Building, Cleveland, advises that it is having a good sale of the Gore track drill, mounted on carriage. In addition to several sold in this country last month, the company received an order for two drills to go to Australia and has recently received inquiries from England and Canada.

IN ORDER TO KEEP before those interested the average physical properties of the solid and hollow steel forgings made by the Bethlehem Steel Co., that company has sent to its friends and customers blotting pads on which are tables showing the tensile strength, elastic limit, elongation and reduction of area of test pieces for the different sizes of the principal grades of steel forgings.

THE SPRAGUE ELECTRIC CO. is meeting with great success in securing important contracts for its motors and generators. Both its Watessing factory and New York conduit factory are rushed to their utmost capacity. In addition to its foreign sales and a large number of orders for small size apparatus, the company reports about forty contracts for large size machines which are for use in almost every variety of business.

THE ALLIS-CHALMERS CO. reports the following among its recent sales of Reynolds corliss engines: Kioto Traction Co., Kioto, Japan, 16 and 32 by 36 in., 1800 frame cross-compound direct connected. Twin City Rapid Transit Co., 46 and 94 by 60 in. vertical cross-compound direct coupled (third order). London United Tramways, London, England, 26 and 54 by 48-in. vertical cross-compound direct connected (second order).

THE H. W. JOHNS-MANVILLE CO., 100 William St., New York, has just issued a new catalog containing 103 pages. It is generously illustrated and is of a very handy size for reference. Complete lines of overhead materials, electric car heaters, "Noark" tuses, "Vulcaheston" and molded mica, manufactured by this company, are thoroughly illustrated and described. The company will be pleased to send one of these catalogs upon request.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING CO. reports the sales of Westinghouse integrating wattmeters for the month of June to have been the largest in the history of the company. Also that the sales of Westinghouse transformers have more than doubled in the past six months, and the transformer building capacity of the Westinghouse company has been largely increased to meet the demand for O. D. and Type "N" transformers.

# TIES FOR SALE

# STREET RAILWAY REVIEW

Vol. XII

SEPTEMBER 20, 1902

No. 9

## The Street Railways of Detroit

A History of Their Development Including a Review of the Agitation for Low Fares and a Table Showing the Relations of the Different Companies Forming the Detroit United Railway.

To one interested in the purely economic questions arising in street railway operation, the history of street railway organization and development in the city of Detroit is of more than passing interest. In no city on the globe have the conditions given rise to so many important discussions, experiments and litigations involving economic theories and questions so vital to the industry at large. Among the topics brought prominently to the front by the situation in Detroit may be mentioned, in passing, the following: An at-

According to good authority Detroit was the fourth city in the United States to have a regularly established street railway line; that is, a line on which cars were drawn at more or less regular intervals over tracks permanently laid in the city streets. The records show that the first horse railway for urban street traffic in America, was laid on Madison Avenue, New York City, in 1852. This was quickly followed by other lines in New York, and by similar railways in other American cities, viz.: in Boston in 1853; in

Majestic Building.

City Hall.

tempt to determine the relations between street transportation companies and the public, as represented in municipal bodies and corporations; rates of fares and tariffs; taxation and percentage payment; franchise values; perpetual and limited term franchises; municipal ownership of public utilities; the fair and just burdens and duties devolving upon private franchise holding corporations, and the extent and scope of powers of municipalities with reference to the granting of franchises for the transportation of passengers through city streets.

Baltimore in 1860; in Detroit in 1862; in Albany in 1863, and in Indianapolis in 1864, after which date the movement became general, and horse railways were established in all the larger cities. Prior to the opening of the first horse-car line in Detroit, in 1862, several unsuccessful attempts had been made to establish lines to various parts of the city, but for one reason or another, none of these lines were financially successful, and all were short-lived. Also, efforts were made with varied success to establish communication by stage lines with the towns and cities around Detroit,

many of these, it is interesting to note, following the routes now traversed by the high speed interurban electric roads radiating from Detroit.

All the street railway companies now included in the Detroit United Railway system were chartered under one or the other of two statutes of Michigan, known respectively as the Tram-Railway Act, passed in 1855, and the Street Railway Act, passed in 1867. The Tram Railway Act provided originally for the construction of "tram railways," but in 1861 was amended to include the building of street railways "in and through the streets of any town or city in the state," and provided that "no such company or corporation shall be authorized to construct a railway under this act through the streets of any town or city without the consent of the municipal authorities of such town or city, and under such regulations and upon such terms and conditions as said authorities may from time to time prescribe." In 1867 this act was further amended by adding an additional proviso, as follows: "Provided further, that after such consent shall have been given and accepted by the company or corporation to which the same is granted, such authorities shall make no regulations or conditions whereby the rights or franchises granted shall be destroyed or unreasonably impaired, or such company or corporation be deprived of the right of constructing, maintaining and operating such railway in the streets in such consent and grant named pursuant to the terms thereof."

The Street Railway Act of 1867 authorized any street railway company organized under the provisions of the act, with the consent of the corporate authorities of any city or village given in and by ordinance, to construct street railways in and upon such streets as the city or village authorities should designate. The road was to be operated under such rules, regulations and conditions, including rates of fare, as the ordinance passed by the authorities should prescribe but it was provided that after the consent and grant had been accepted by the company, the authorities could not revoke such consent or deprive the company of the rights and privileges conferred.

These provisions are quoted here at length inasmuch as they formed the basis for a very important decision by the Supreme Court of the United States, when the city of Detroit in 1899, under its police power attempted by ordinance to reduce the rates of fares on some of the older street railway lines organized under these acts.

By both of these statutes the life of any corporation organized thereunder was limited to a period of 30 years, and the common council of Detroit has followed this wording in granting street railway franchises, all franchises having been limited to 30 years.

The first franchise for a street railway in the city was granted by the common council Nov. 24, 1862, to Eben N. Wilcox, C. S. Bushnell, and others, for a street railway through Jefferson, Michigan, and Woodward avenues, and other streets, which are now the principal down-town streets and avenues. Inasmuch as this was the fundamental franchise upon which (with several amending and supplementing franchises) a large portion of the present Detroit United Railway system was established, it will be apropos to examine its essential features. As originally granted in 1862 this franchise gave to Wilcox and his associates, who were afterwards organized into the Detroit City Railway Co., exclusive and blanket franchises on all the streets named, and the first option to build street railways on all other streets of the city, in consideration of which the grantees were "to keep the surface of the streets, inside the rails and for 2 ft. 4 in. outside thereof in good order and repair, and all snow, ice, and dirt cleared and removed from the same, at the expense of the grantees; provided, however, that upon the paved portions of said streets the materials for repaving shall be supplied at the expense of the city." The rate of fare was "not to exceed 5 cents in any one car or on any one route named in the ordinance, except where cars or carriages shall be chartered for specific purposes; provided cars so chartered shall not be considered regular cars." The only taxation clause in the franchise provided that "the said grantees shall pay to the city of Detroit, annually, \$15.00 for each car excepting only those cars used for cleaning the track." The franchise was granted for a term of 30 years, which would place the expiration date at Nov. 24, 1892.

On Nov. 14, 1879, an ordinance was passed supplementary to the one passed on Nov. 24, 1862, extending the life of the franchises 30 years from 1897 (or until 1909) in consideration of certain

concessions on the part of the company, notably that the company was thereafter to pay the city a tax of 1 per cent on its gross receipts and pave and maintain in all streets occupied by its tracks the space constituting its roadway or track and between the tracks. This special tax and undertaking as to paving was expressly stated by the ordinance to be in lieu of license and other taxes and charges for paving under the previous ordinance. By this same ordinance of 1879 the company was given permission to build extensions in several additional streets not mentioned in the earlier ordinance of 1862.

Under the ordinance of 1862, the original grantees interested several capitalists from Syracuse, N. Y., and in 1863 a single track railway operated by animal power was constructed on Jefferson Ave., extending from the Detroit, Grand Haven & Milwaukee R. R. tracks to the Michigan Central depot, at the foot of Third St. It was about one and one-half miles long, and was used almost exclusively for transferring railroad passengers between the two depots. The volume of travel was far from satisfactory, and the company soon found itself in financial straits. However, new capital was induced to join the enterprise, and additional lines were built on Woodward Ave. for a distance of a mile from the city hall. The operation of the road was turned over to Mr. George Hendrie, who held a contract for the trucking and transfer business between the two depots, and he was therefore chosen as the man who was best fitted to make a success of the new enterprise. Four years of experiment showed that the Detroit City Ry. was not a financial success, unless a larger patronage could be obtained. The city contained about 50,000 people, but the lines did not advantageously connect the residence districts with the business sections, and so were not in position to receive any great amount of passenger traffic. In 1867 the capital stock was again increased, new stockholders were taken into the company, and preparations were made for building new lines that would afford more convenient means of travel between the business and residential sections. Up to 1865 the right of the company to the exclusive use of the streets had not been questioned, but, at about that date, the company having forfeited certain of its franchises, through failure to lay tracks within the specified time, the common council granted franchises on several streets to a new company known as the Fort Street & Elmwood Avenue Ry.

From this time until 1890 there were few developments in the street railway situation worthy of special record. Several additional franchises were granted to Hendrie, to the Detroit City Railway Co., and to other companies which were incorporated at various times. Several of the lines built under these franchises were ultimately absorbed by the Detroit City Railway Co., and the several steps in the history of each one of them may be traced through the accompanying table. It will be seen that during this period the Detroit City company, afterward absorbed by the Detroit Citizens' Street Railway Co., was always the chief factor in the situation.

Sometime after the ordinance of 1879 was passed, a number of differences having arisen between the Detroit City Railway Co., and the city, in respect to the payment of certain taxes on real estate and several suits having been instituted for collecting certain back taxes, claimed to be due to the city, a new ordinance was passed Jan. 4, 1887, over the mayor's veto, providing conditions for adjusting these disputes. The new ordinance provided that for the time from July 1, 1882, to Dec. 31, 1896, the company was to pay an annual tax of 1½ per cent of the gross receipts, and from Jan. 1, 1897, to the end of its franchises (under the ordinance of Nov. 14, 1879) the company was to pay an annual tax of 2 per cent of its gross receipts. In consideration of this increase in the tax on receipts, the city agreed to discharge all claims for back real estate taxes, but the company agreed to pay such taxes on its real estate property as the city should levy on all other city property in the collection of the usual city taxes on lands. It was distinctly specified, however, that this tax on gross receipts and these legitimate taxes on real estate should be the only taxes, license fees and charges of any kind to be levied or assessed by the city against the property, capital stock or franchises of the company during the life of the franchises.

On Jan. 3, 1889, the company asked for franchises on certain important streets heretofore unoccupied by its tracks. These franchises were granted to continue until the expiration of previous franchises, that is until Nov. 14, 1909, but in passing the ordinance

the city council took occasion to impose certain new conditions on the company: i. e., the granting of free transfers at certain points; limiting the speed of cars in the city to 10 miles an hour, and requiring an average speed of at least 6 miles per hour; and the sale of eight tickets for 25 cents, known as workmen's tickets, good on all lines between the hours of 5:30 a. m. and 7:00 a. m., and 5:15 p. m. and 6:15 p. m., said low rate tickets to bear the same transfer and other privileges as the regular 5-cent fare. By an additional ordinance approved Feb. 4, 1893, and amended Feb. 26, 1895, the company was required to place these low rate tickets on sale on its cars as well as at its general offices.

In 1891 the Detroit City Railway Co. sold all its property to the Detroit Citizens' Street Railway Co., and it was in this year that arrangements were made for equipping all the lines of the company for electric traction. True to its promises the new company introduced electricity upon all its trunk lines, and made other costly improvements.

Shortly after the year 1891, the city instituted suit to have the franchises of the Detroit Citizens' Street Railway Co. declared invalid after the year 1892, on the grounds that the common council in passing the ordinance of 1879 extending the franchises of the company for 30 years, had exceeded its legal powers. The first decision in this case was rendered on Jan. 31, 1894, by Judge Taft of the United States Circuit Court, who sustained the claim of the city as to the expiration of the franchise held by the Citizens' company. The case was then appealed by the company to the United States Court of Appeals. The case was argued before this court, and on Oct. 2, 1894, the court reversed Judge Taft's decision, and held that the ordinances of 1879, by which the rights of the street railway company were extended to 1909, was valid, on the grounds that the city could grant privileges in the streets unlimited in duration. The case was reviewed by the Supreme Court of the United States, which fully sustained the decision of the Court of Appeals.

While these cases were still pending, the owners of the property for several reasons decided to withdraw from street railway investments, and accordingly in September, 1894, the property was sold to R. T. Wilson & Co., of Boston and New York, and Mr. Tom L. Johnson became general manager. Three months afterward, in

December, 1894, the famous 3 cent fare franchise was granted to a rival company, and the Detroit street railway war was on.

The history of street railway matters from the year 1860 until 1900 is one long record of agitation, discussion, charges and countercharges, personal and otherwise, and legal controversies involving decisions by the city courts, the circuit and district courts and the supreme court of the United States. The history would also include much of the political history of Detroit and the state of Michigan for that period. It is not necessary to here give a full record of these events. Sufficient it is in this connection to state a few of the main facts as they occurred.

The idea of a 3 cent fare found its chief champion in the person of the Hon. Hazen S. Pingree, who had been elected mayor of Detroit in 1890, and it is undoubtedly true that most of the subsequent agitation on this subject in Detroit was the result of his announced intention to secure cheap fares for the city.

For sometime after Mr. Johnson and his associates had purchased the Detroit Citizens' property, they strenuously opposed any

reduction of fares on the part of the city, and after the common council passed an ordinance reducing the rates of fares on the various street railways, the company took the case to the Circuit Court, and finally into the Supreme Court of the United States. The final decision in this case will be remembered as one of the most important affecting street railways ever rendered. The Supreme Court decided that the franchise granted to the company in 1862, and amended and supplemented in 1897, was in effect a contract between the city and the company, and the city had no power to alter the rates of fare therein stipulated.

As already stated, Mayor Pingree, in 1894, finding he could not secure his cherished 3-cent fare from the Citizens' company, induced outside capitalists to accept new franchises for street railways on most of the streets in Detroit not then occupied by the Citizens' company, these franchises to be granted with the expressed provision that the fare was to be eight tickets for 25 cents, or virtually a 3-cent fare during the day, and six-for-a-quarter tickets during the night.

This 3-cent fare franchise was passed Dec. 4, 1894, and was granted to Henry A. Everett, Greene Pack, Albert Pack, and their associates, who immediately formed themselves into a corporation under the name of The Detroit Railway.

Aside from the low fare, the sensational feature of this franchise was a clause stipulating that the company would not have to pay for nor keep in repair any paving either outside or between its tracks, this expense to be borne entirely by the City of Detroit. It is in this regard that the advocates of 3-cent fares showed considerable inconsistency. They claimed to be saving the people of Detroit several hundred thousand dollars a year in street car fares, without drawing attention to the fact that the taxpayers would be called upon to bear the expense of paving and maintaining the streets in good repair. The new company immediately let contracts for the construction of the road and opened about 40 miles of new lines in the spring of 1895.

The situation therefore shows at this period, the two companies operating very largely on parallel streets, the Detroit Citizens' company, with a straight 5-cent fare, and six tickets for 25 cents, and the Detroit Railway selling eight tickets for 25 cents. The struggle for traffic was very keen, and both companies were brought to the

verge of bankruptcy before the situation was satisfactorily adjusted. The old company had the advantage of location, and the new company had the lower fares.

This condition continued until 1896, when the companies in self-defence arranged a merger of interests, this taking the form of a temporary lease of the Detroit Railway to the Detroit Citizens' Street Railway interests.

In 1899, Mr. Pingree, not satisfied with his achievements, publicly announced that the city ought to purchase all the street railway properties of the city, and operate them as public property. By his efforts, an act was approved March 24, 1899, authorizing the city of Detroit to purchase the street railways and directing the common council to appoint three persons to constitute a board of commissioners known as the Detroit Street Railway Commission, which had power to acquire any street railway property in Detroit. The commission was given full power to operate the properties so acquired, regulate fares, and possessed such other powers as are possessed by boards of directors of corporations.

*H. H. Hutchins*

President Detroit United Ry.

April 24, 1899, a bill for injunction was filed in the Circuit Court for Wayne County to restrain the street railway commission from acquiring the railways for the city, and at the same time quo warranto proceedings were commenced in the Supreme Court of Michigan to test the constitutionality of the act under which, and the council proceedings by which, the commissioners were appointed. The proceedings were ultimately taken into the United States Courts where decision was finally given that the law was unconstitutional, and the Detroit Street Railway Commission had no legal standing.

Before the final decision was rendered, however, the commission had completed negotiations with the street railway companies for the purchase of their properties, and had made its report to the common council. Although the law under which the commission was created was finally declared unconstitutional, the results of the investigation made by the board were exceedingly interesting, and attracted wide attention. In the steps taken by the members of the commission, looking to the acquirement of the street railways of Detroit for the purposes of municipal operation, two elements entered into the question of determining the value of these properties. First, the value of the physical property including real estate, power houses, cars, tracks, equipment, etc., and second, the valuation of the franchise rights and privileges, or in short the earning power of the franchises themselves computed according to the term each had to run. The commission secured the services of

several experts who fixed the aggregate value of the physical property of all the street railways in Detroit, after making allowance for depreciation, at \$7,808,737.42. The railway companies insisted that this amount was too low by a million dollars, but the commission finally decided upon \$8,000,000 as the basis of its report. The commission decided the aggregate value of the franchises owned by the companies to be \$8,478,563.86. The valuation was arrived at by taking the net earnings for the preceding year, namely, \$750,000, deducting 4 per cent annual increase of traffic and earnings during the lives of the franchises, which at that time varied from 11 to 26 years. This franchise value of \$8,478,563.86 added to the value of the physical plant, namely \$8,000,000, gave the total value of the street railway properties and franchises as \$16,478,563.86, this being the price to be paid by the city in acquiring the various properties. After these figures had been submitted, the street railway companies made a counter proposition, fixing their price for all the railway properties and franchises at \$17,500,000, the proposition being that a new security franchise covering all the lines be granted to a new company, which new company would execute bonds secured by mortgage on all the properties of the companies, and the security franchise for \$17,500,000, and then the city would acquire such property subject to the payment of such mortgage indebtedness. At this time the foregoing decision was rendered and negotiations stopped.

On December 31, 1900, the Detroit United Ry. was formed with

#### SYSTEM OF THE DETROIT UNITED RAILWAY.

**Detroit United Railway, organized Dec. 31, 1900, effecting a consolidation by purchase of the several companies named below:**

The following is a complete statement of all the properties it now controls:

I. **DETROIT CITIZENS' STREET RAILWAY CO.**—Organized Aug. 24, 1871. On Dec. 31, 1900, this company sold all its property to the Detroit United Ry., this property comprising all the properties, rights and franchises of the following companies:

1. **DETROIT CITY RAILWAY CO.**—This company was organized in 1863 and received the first street railway franchise granted by the city of Detroit. In 1891 this company sold all its property to the Detroit Citizens' Street Railway Co., this property comprising all the properties, rights and franchises of the following companies:

a. **CONGRESS & BAKER STREET RAILWAY CO.**—This company was organized in 1873 and soon after purchased the property of the Detroit & Grand Trunk Junction Street Railway Co. (franchises to which were granted April 11, 1873, and June 13, 1873). The property of the Congress & Baker Street Railway Co. was transferred to the Detroit City Railway Co. on June 22, 1882.

b. **CASS AVENUE RAILWAY CO.**—This company purchased the property of the Central Market, Cass Avenue & Third Street Railway Co. (franchises to which were granted June 16, 1875). The property of the Cass Avenue Railway Co. was transferred to the Detroit City Railway Co. June 22, 1882.

c. **HAMTRAMCK STREET RAILWAY CO.**—This company was granted franchises dated Aug. 29, 1888, and Aug. 12, 1873. The property was transferred to the Detroit City Railway Co. in 1881.

2. **GRAND RIVER RAILWAY CO.**—This company was organized in 1890 and in December, 1890, purchased the property of the Grand River Street Railway Co. (franchises to which were granted May 1, 1868). The property of the Grand River Railway Co. was transferred to the Detroit Citizens Street Railway Co. Oct. 1, 1891.

II. **DETROIT SUBURBAN RAILWAY CO.**—Organized on Nov. 1, 1892, and effected a consolidation of several street railway companies (named below) operating in the suburbs of Detroit. On Dec. 31, 1900, this company transferred all its property to the Detroit United Ry. This property, in addition to certain franchises granted during 1890, 1891 and 1893 to the company itself, included the properties, rights and franchises of the following companies:

1. **DETROIT ELECTRIC RAILWAY CO.**—This company purchased the property of the Dix Avenue Ry. (franchises to which had been granted April 11, 1886, and May 10, 1886). The property of the Detroit Electric Railway Co. was transferred to the Detroit Suburban Railway Co. Nov. 1, 1892.

2. **HIGHLAND PARK RAILWAY CO.**—This company was organized in 1886 and received various franchises from the city of Detroit and outlying townships during the period from 1886 to 1891. The property of this company was transferred to the Detroit Suburban Railway Co. on Feb. 1, 1893.

3. **JEFFERSON AVENUE RAILWAY CO.**—This company was organized in 1891 and purchased certain franchises granted in 1891 by outlying townships to Hendrie, et al. The property of the company was transferred to the Detroit Suburban Railway Co. in 1892-3.

4. **EAST DETROIT & GROSSE POINT RAILWAY CO.**—This company was organized in 1887 and purchased certain franchises granted in 1887 by outlying townships to Brandon, et al. The property of the company was transferred to the Detroit Suburban Railway Co. in 1892-3.

III. **DETROIT, FORT WAYNE & BELLE ISLE RAILWAY.**—Organized Feb. 28, 1898, Dec. 31, 1900, all the property of this company was transferred to the Detroit United Ry., this property comprising all the properties, rights and franchises of the following company:

1. **FORT WAYNE & BELLE ISLE RAILWAY CO.**—This company was organized May 23, 1892. Early in 1898 the property of this company was transferred to the Detroit, Fort Wayne & Belle Isle Railway Co., this property comprising all the rights, property and franchises of:

a. **FORT WAYNE & ELMWOOD RAILWAY CO.**—This company was chartered originally in 1865 as the Fort Street & Elmwood Avenue Ry., but by special act of Legislature, in 1871, the title was changed to Fort Wayne & Elmwood Railway Co. On July 1, 1892, the property of this company was transferred to the Fort Wayne & Belle Isle Railway Co. This property, in addition to numerous properties, rights and franchises granted to individuals and to the company itself by the city of Detroit and outlying townships at various dates from 1865 to 1891, included certain rights and franchises granted in 1889 to the Detroit, Springwells & Dearborn Railway Co., afterward transferred, on March 23, 1893, to a company known as the Detroit, Rouge River & Dearborn Street Railway Co., by which company they were assigned to the Fort Wayne & Elmwood Railway Co.

IV. **THE DETROIT ELECTRIC RY.**—Organized July 9, 1896, Dec. 31, 1900, all the property of this company was transferred to the Detroit United Ry., this property comprising all the property, rights and franchises of:

1. **THE DETROIT RY.**—This company was organized in November, 1891, to receive certain low-fare franchises granted in 1891 and 1896 by the city of Detroit and outlying townships. On July 11, 1896, all the property rights and franchises of this company were transferred to the Detroit Electric Ry.

V. **DETROIT, PORT HURON & SHORE LINE RAILWAY.**—This company comprises what is known as the Rapid Railway System. The capital stock of this company was purchased in 1902 and is held in trust for the Detroit United Ry. (For history of the Rapid Railway System, see separate diagram.)

VI. **WYANDOTTE & DETROIT RIVER RAILWAY.**—This company was organized about 1898 and transferred all its property to the Detroit United Ry. Feb. 20, 1901.

VII. **DETROIT & NORTHWESTERN RAILWAY.**—This company was organized in 1899, and May 1, 1901, transferred all its property to the Detroit United Ry., this property comprising all the properties, rights and franchises of the following companies:

1. **GRAND RIVER ELECTRIC RAILROAD CO.**  
2. **PONTIAC & SYLVAN LAKE RAILWAY CO.**  
3. **DETROIT & HOWELL PLANK ROAD CO.**

VIII. **DETROIT & PONTIAC RAILWAY CO.**—This company was organized in 1897, and on June 1, 1901, transferred all its property to the Detroit United Ry. The company had previously purchased the property rights and franchises of the

1. **OAKLAND RAILWAY CO.**

IX. **DETROIT & FLINT RAILWAY.**—This company was organized Aug. 9, 1901, and in August, 1901, transferred all its property to the Detroit United Ry. The company had previously purchased the property of:

1. **DETROIT, ROCHESTER, ROMEO & LAKE ORION RAILWAY.**—This company was organized March 22, 1899, as the "Detroit & Lake Orion Ry.," but name was changed shortly after organization. The company owned the property, rights and franchises of the following companies:

a. **DETROIT, LAKE ORION & FLINT RY.**—Organized March 6, 1901.

b. **NORTH DETROIT ELECTRIC RY.**—Organized July 21, 1899.

c. **DETROIT, UTICA & ROMEO RY.**—Organized Aug. 10, 1898.

X. **ROCHESTER LIGHT & POWER CO.**—This company was organized Nov. 13, 1899, and owned the electric lighting franchises and plant in the city of Rochester, Mich. The capital stock was purchased in 1902 and is held in trust for the Detroit United Ry.

XI. **SANWICH, WINDSOR & AMHERSTBURG RAILWAY CO.**—This company was organized in 1873. It is a Canadian corporation and the stock is held in trust for the Detroit United Ry. by purchase in 1901. The company owns the capital stock of:

1. **SOUTH ESSEX ELECTRIC RAILWAY CO.**—This company is a Canadian corporation. It was organized in 1902, and the same year transferred its property rights and franchises to the Sandwich, Windsor & Amherstburg Railway Co.

XII. **CITY RAILWAY CO., OF WINDSOR, ONT.**—This is a Canadian corporation. Its stock is held in trust for the Detroit United Ry. by purchase in 1901.

XIII. **ELECTRIC DEPOT CO.**—This company was organized in 1901 for the purpose of providing terminal facilities for the freight and express business on the interurban lines running out of Detroit. The capital stock is held in trust for the Detroit United Ry.

\*EXPLANATION.—In 1896 the Detroit Citizens' Street Railway Co. took over control and virtually leased the Detroit Suburban Railway Co., the Detroit, Fort Wayne & Belle Isle Railway Co., and the Detroit Electric Ry., but these leases have now been superseded by the transfer of all these properties to the Detroit United Ry.

the Everett-Moore interests in control, and ultimately took over all the street railway properties in Detroit and the suburbs (with the exception of the interurban road to Jackson) as outlined in the accompanying table. On the original low fare lines tickets are still sold at the rate of eight tickets for 25 cents, but on the other lines

	1901.	1900.

Assistant Secretary and Purchasing Agent.

A. E. ROSSO,  
Chief Dispatcher.

a straight 5-cent fare is charged with lower fare tickets at certain hours of the day, as described by Mr. Stanley on another page.

This in brief is the history of the low-fare agitation in Detroit. Reviewing the entire matter, it is difficult to see how anyone has profited by this agitation. Both the city and the companies have been put to great expense in fighting the various suits, and there is considerable useless mileage being operated, as the result of the competing lines built by the Detroit Ry. It is true the public has the advantage of practically a 3-cent fare on about 40 miles of track, but on the other hand the city has to maintain the paving on those lines. As far as can be determined by an outside observer, neither the citizens of Detroit, nor the companies have been benefited by the agitation which would seem to merit the criticism of having been uncalled for and entirely useless.

FINANCIAL.

The following is a summary of the business of the Detroit United Ry. (not including the Rapid Ry.) for the year ending Dec. 31, 1901, as compared with 1900:

	1901.	1900.
Gross earnings .....	\$2,919,171.36	\$2,575,276.54
Operating expenses including taxes.....	1,596,765.60	1,439,057.78
Net earnings from operation.....	1,322,495.76	1,136,418.76
Income from other sources.....	23,066.99	14,558.88
Gross income from all sources.....	\$1,345,472.75	\$1,150,777.64
Deductions:		
Interest on funded debt....	\$975,343.73	\$638,316.91
Dividend March 1st.....	125,000.00	
Dividend June 1st.....	125,000.00	
Dividend September 1st.....	125,000.00	
Dividend December 1st.....	125,000.00	
Surplus income .....	170,129.00	512,460.73

The comparison includes all lines operated for the same period both years.

Passenger Statistics.

Revenue passengers carried in 1901 .....	62,822,749
Transfer passengers .....	17,470,227
Employee passengers .....	826,135
Total passengers .....	81,119,111
Average receipt per passenger.....	.0354
Average receipt per revenue passenger .....	.0457

The following is a summary of the business of the six months ending June 30, 1902, compared with the six months ending June 30, 1901:

OFFICERS.

The corporate officers and directors of the Detroit United Ry. are as follows: Chairman of the board, H. A. Everett; president and general manager, J. C. Hutchins; vice-president, Arthur Pack; treasurer, Geo. H. Russel; secretary, Edwin Henderson; assistant secretary, A. E. Peters; directors, J. C. Hutchins, E. W. Moore, R. B. Van Cortlandt, H. R. Newcomb, Arthur Pack, R. A. Harman, H. A. Everett, J. G. Schmidlapp, Geo. H. Russel.

# Review of the Detroit United Railway System from an Operating Standpoint.

BY A. H. STANLEY, GENERAL SUPERINTENDENT.

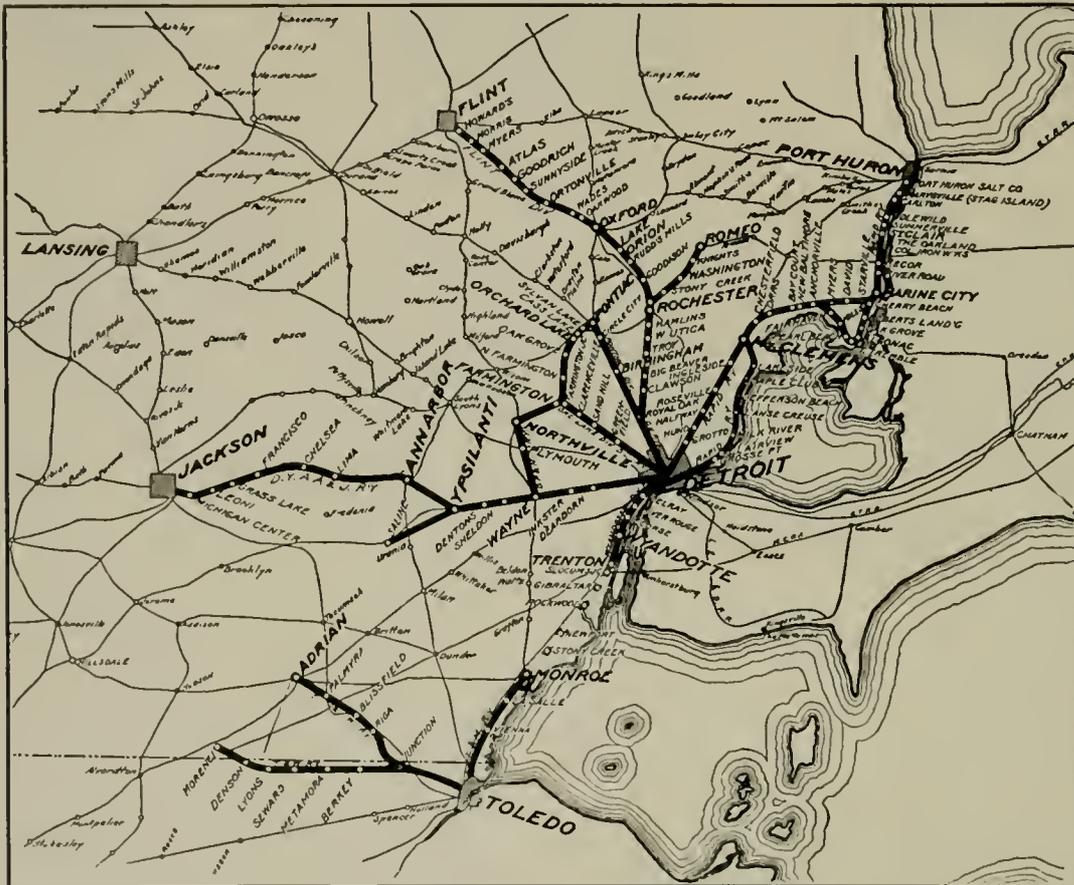

To a street railway man visiting Detroit for the first time, a number of features about the Detroit United Railway System will appear prominently as being distinctly characteristic. A full description of the company's property and methods in all departments will be found in the following pages of this issue. It is the purpose of this article to speak briefly, from purely an operating standpoint of some of these distinguishing characteristics.

In the first place the general lay-out of the lines and particularly the number and length of interurban lines present a situation believed to be unparalleled in the United States. There are seven distinct interurban lines coming into the city, varying in length from

directly to the heart of the business district, where a temporary waiting room is established on lower Woodward Avenue.

The management has made a very close study of the transfer conditions and in many instances has combined short lines in order to do away with transfer points in the center of the city; thus leaving in existence only the short lines necessary to take care of the boat and depot travel.

There are lines operated under a 5-cent fare with eight-for-a-quarter tickets good in the morning between the hours of 5:30 and 7:00, and in the evening between the hours of 5:15 and 6:15, called workingmen's tickets. There are also a certain number of miles

MAP OF INTERURBAN ELECTRIC RAILWAYS ABOUT DETROIT.

All lines controlled by Detroit United Railway except the Detroit, Ypsilanti, Ann Arbor & Jackson; the Detroit, Plymouth & Northern, a short spur connecting Wayne and Northville, and the lines out of Toledo.

20 to 79 miles, and, with one exception, all under the control of the Detroit United Railway. The topography of the city admits of better than the average speed in cities the size of Detroit; the schedule speed for the city lines being 10.67 miles per hour. The closest headway on the heavy lines is 30 seconds at 6 o'clock at night, and on the crosstown and main north and south lines this headway is maintained during the rush hours. To insure this schedule timers are placed at different points in the city and the cars on all lines are timed. Under normal conditions all lines are required to have an average of at least 85 per cent of cars on time. These lists from each line are checked with the schedules on the following day, and their percentage shown and sent to the division superintendent in charge of each line for the purpose of inspection and noting what men were not on time.

All of the cars on the interurban lines enter the city, running

operated with eight-for-a-quarter tickets good from 5:45 a. m. to 8:00 p. m., after which time a six-for-a-quarter ticket or 5-cent fare is collected. Transfers are issued to all lines on payment of a 5-cent fare, but the transfer on eight-for-a-quarter lines is restricted to those particular lines on payment of an eight-for-a-quarter fare. Transfers are not issued from a 5-cent to an eight-for-a-quarter line on payment of a fare with a workingman's ticket (eight-for-a-quarter) but are issued from one 5-cent to another 5-cent line on these tickets during the hours these tickets are good. Owing to our rates of fares being so very much lower at certain hours in the morning and evening, there results an enormous congestion of traffic at that time, as all the factories and institutions employing labor adapt the working hours to suit the time when these tickets are good. As a result this company is required to increase its service mornings and evenings

134 per cent above the average schedule maintained during the day, this service running during the entire time that the workmen's tickets are in effect. On the interurban lines round trip and one-way tickets are on sale. Traffic arrangements are in effect between the steamboat companies and the Detroit United Railway whereby passengers on the interurban lines can buy a ticket from any of the stations to and from Detroit and to almost any point on the lakes; also to any Eastern point on most of the steam railroad lines.

The organization of the Detroit United Railway is shown by one of the accompanying diagrams.

The Detroit United Railway operates 187 miles of city tracks and nearly 300 miles of interurban road. Practically all of the track

to do with the rolling stock while in the car houses other than to see it is kept clean; the motor inspectors are under the motive power department. The standard closed car is 22-ft., single truck; the standard open car is 12-bench, 33 ft. long. Our experience indicates the desirability of having a larger closed car but not a large open car. With too large an open car the people are slower to get on and off and the conductor cannot collect all the fares. We run both city and interurban cars the same end on at all times, all of the cars being equipped with controllers at one end only. We believe this is the most satisfactory way to operate. We have about 1,300 conductors and motormen in service, including the city and interurban lines. The rate of wages paid on all lines except the

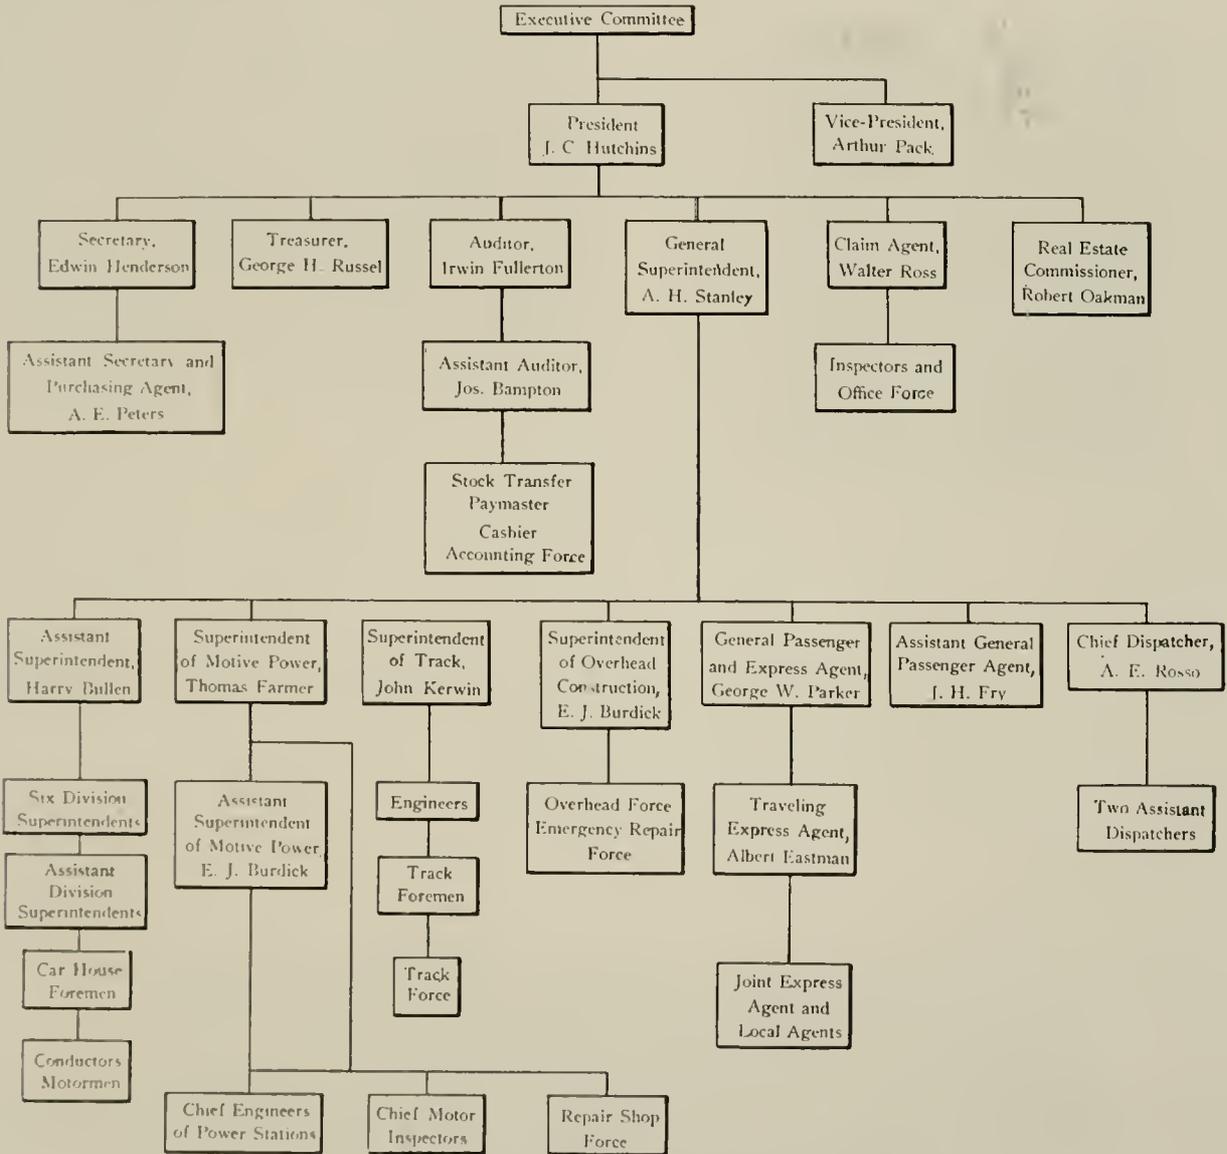

DIAGRAM OF ORGANIZATION OF THE DETROIT UNITED RAILWAY.

construction in the city of Detroit is 9-in. girder groove rail with concrete foundation. Our experience in Detroit has shown that 6 in. of concrete is not a sufficient foundation for heavy rails. We are satisfied with concrete construction, only it should be deeper and heavier. The interurban lines are of 60-lb. T rail construction, located in most cases on the highway; some of it is on private rights of way.

We have seven division superintendents, each one of whom has two or more lines under him, depending on the length of the lines and traffic conditions. Each of these division superintendents has at least one assistant known as an assistant division superintendent, and at each of the car houses, are day and night car house foremen. Neither division superintendents nor their assistants have anything

Rapid Railway System is 23½ cents per hour; on the Rapid it is 22 cents per hour, irrespective of the length of service and the amount of work done. The men work nine hours in twelve with one-half trip lee-way; Sundays eight hours, excepting in the summer months, when they work as the service requires. The conductors and motormen are disciplined under what is known as the Brown system, which was put in effect on Jan. 1, 1902.

There were 81,119,111 passengers carried on the entire system in 1901. To handle this traffic 16,080,041 car-miles were run. The regular schedule provides for 186 city cars and about 36 interurban cars, including the Rapid Railway.

On the 5 cent lines the company is required to maintain the pavement between the rails and it is stipulated that the paving

material shall be the same as the remainder of the street excepting where asphalt pavement is laid, when the company may substitute brick. On the 3 cent lines we are not required to maintain and keep in repair either the pavement or the foundation; nor are we required to lay the original foundation and pavement excepting where a car line is laid on a street already paved, where we are required to do the work. On unpaved streets we simply make the grade, trenching 6 in. beneath the base of the rail, lay rail, lift up track to grade, and the city does the paving and concreting, and is required to keep it in repair afterwards. Should the foundation become disturbed, we merely lift the rail to grade, and the city is required to put the foundation in proper shape. Since all of the

A. H. STANLEY,  
General Superintendent Detroit United Ry.

interurban lines have come under one management, an express and passenger department has been inaugurated. The express department, which was described in the "Review" for January, 1902, is in charge of experienced steam railroad men, and the general policy of steam railroads in reference to express has been put into effect over the entire system. An electric express depot has been erected in Detroit and express service given to all points at least twice daily on all the interurban lines.

Inasmuch as Detroit is so well supplied with pleasure resorts of all kinds the street railway company does not maintain parks or places of amusements of its own, but it is always ready to aid such enterprises and encourage them by giving good service.

A general passenger agent has charge of all advertising, special

applies directly to our patrons, and with which they come in direct contact in their daily life, for example: Information as to the transfer system, instructions as to how to get on and off cars properly, etc.

A somewhat unique service has been arranged by the management of the Detroit United Railway for the special benefit of visitors in Detroit who desire to obtain a comprehensive idea of the city in a short time. This service includes the use of a special parlor car known as the "Yolande," which leaves Cadillac Square near the Soldiers' Monument in the heart of the city every two hours. This special car takes passengers through the principal wholesale and manufacturing districts, as well as the finest residence portions of the city, and affords a magnificent view of Detroit and its surroundings, including the public buildings, the art museum, the churches, educational institutions (public and private), large hospitals, the House of Correction, the County Buildings, the large apartment houses and fine residences which are located in every part of the city; also the famous Water Works Park, Belle Isle Park and the Detroit River. A competent attendant accompanies the car and explains the points of interest along the route.

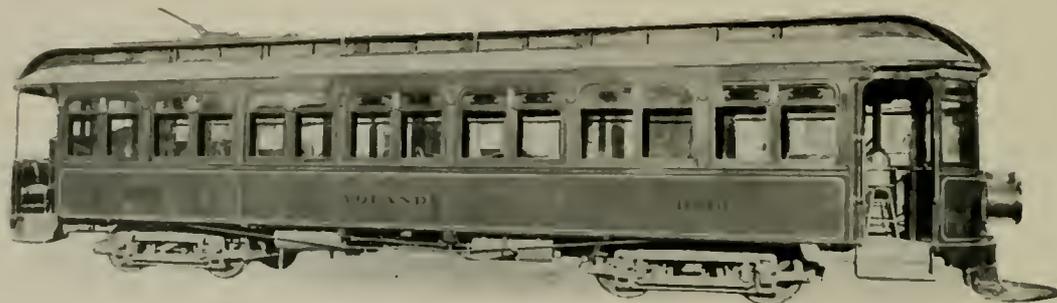

The fare for the round trip is but 25 cents, and the car stops at any street crossing on the route to receive passengers and to deliver them after the trip. This car has been in service for two years and has reached a point where it is almost necessary to put on an additional car to care for the people who are anxious to take this ride.

We have operated for some years a single truck funeral car, but the demands for interment at outlying cemeteries and points on the interurban lines is so great that we have found it necessary to build a double-truck funeral car, which is now in process of construction at our shops. It is similar to an interurban passenger car with a front compartment having doors on each side, which drop down and permit the casket being rolled in from the side. The front end is draped in black and the car is draped in black with silver trimmings; the inside is furnished with dark plush. The car is being constructed in our Jefferson Avenue shop.

We charter special cars on application. The price for the ordinary city cars run as specials is \$3.00 per hour from the time of leaving car house until return thereto. There is a regular schedule of rates in effect for cars running to the different interurban points, based on a service of 10 hours for a round trip. For over 10 hours an additional charge of \$1.00 per hour is made, and a charge of \$5.00 per hour is added in case the suburban power houses are required to keep open over-time to take care of the service.

#### MERIT SYSTEM.

The idea of placing the merit system in effect on the Detroit United Railway originated with our president, Mr. Hutchins. The system, which was described in the "Review" for February, 1902,

SPECIAL CAR YOLANDE DETROIT UNITED RY.

tickets, etc. Folders are issued for distribution giving schedules of all interurban lines in Michigan, Ohio and Indiana, connections with steamboats and steam railways and showing the different points of interest adjacent to Detroit which can be reached by interurban cars. In the city cars, what is known as the Detroit United Weekly is carried in a box placed in the front end of the car. The object of this Weekly is to place before the public in an attractive form the different attractions along our lines and to bring the public into closer touch with the inner workings of the system, particular attention being paid to that part of the railroad system which

is what is known as the Brown system of disciplining conductors and motormen and on Jan. 1, 1902, was put in effect for all the properties of the Detroit United Railway, affecting some 1,200 conductors and motormen; and embracing both the city and interurban lines operating on the regular schedule, 186 city cars and 24 suburban cars; on the maximum schedule 400 city cars and 50 interurban cars.

A circular was issued, addressed to conductors and motormen, on Dec. 23, 1901, notifying them that "commencing Jan. 1, 1902, all punishment of conductors and motormen by suspension from duty

with loss of time would be abandoned, and thereafter punishment for neglect of duty, violation of rules, and bad conduct, would be by reprimand, demerit marks, or dismissal from the service. The circular describes the system as follows:

"On Jan. 1, 1902, every conductor and motorman starts with a clear record, except that when subsequent records show that past offenses are being repeated, the persons concerned will be either

INTERIOR OF "YOLANDE."

dismissed from the service or double the demerit marks entered against them.

"It will be understood that disloyalty, intemperance, insubordination, willful negligence, immorality, making false reports or statements, or concealing facts surrounding matters under investigation, will be considered as cause for discharge.

"A complete record of all conductors and motormen will be kept,

will be deducted from any that may have been previously entered against an employe's record. When 60 marks are entered against the record of any employe, his services will be dispensed with.

"On January 1st of each succeeding year, the name of each conductor or motorman who has gone through the previous year with a perfect record will be posted at each of the car houses.

"In the promotion of employes, their previous record will be fully considered.

"Record Bulletins will be issued at least weekly and posted at all of the car houses on a special bulletin board. These bulletins will be educational, and will give a brief account of each case that has resulted in discipline, giving the number of demerit marks that have been inflicted, but will omit all reference that would identify the person at fault. A copy of the same will be sent to the person at fault.

"Each employe will be afforded an opportunity for appealing against any decision regarding the number of demerit marks imposed, but such appeal must be made to his division superintendent within 10 days of receipt of notice.

"The objects to be obtained under this new system are

"1. To avoid loss of wages by persons employed and consequent suffering to those who are dependent upon their earnings.

"2. To stimulate and encourage all persons engaged in the company's service in the faithful and intelligent performance of their respective duties.

"This system is introduced with the belief that it will be directly beneficial and that it will meet with the approval and cordial co-operation of all concerned."

Our records for the first six months of service under the merit system show as follows:

237 conductors and 341 motormen have perfect records.

89 conductors and 124 motormen have between 10 and 20 merit marks.

33 conductors and 16 motormen have 20 merit marks.

267 conductors and 180 motormen have under 30 demerit marks.

13 conductors and 22 motormen have over 30 demerit marks and under 60 demerit marks.

21 conductors and 16 motormen have been discharged.

The number of merit and demerit marks given has been changed

and all discipline imposed will be shown thereon, and credit given for excellent conduct, deeds of heroism, loyalty, etc., and these records will be given full consideration in connection with the charges entered against any conductor or motorman. This record will be a private one, and no employe will be shown any record therein except his own.

"For every 12 consecutive months of service free from demerit marks, or free from necessity for imposing a reprimand, 10 marks

several times, and is the decision arrived at by all of the division superintendents of the company in executive session. They meet weekly and review all of the cases, which are pending and have a personal hearing with the employes at fault. It has been found necessary to make several changes in the number of marks given for certain offenses, particularly in the matter of missing. The marks now given are the result of some six months' experiment. Today we are satisfied that the marks as given for the different

reward. It greatly encourages men in the performance of their duties to have any deserving acts they perform brought to the attention of the officers of the company, and in that way get a word of praise or encouragement for it. Now we give a man five merit marks for every three consecutive months' of perfect service. Since this system was inaugurated, it has been a very rare occurrence that our lines have been blockaded by broken trolleys. We give merit marks to the conductors and motormen who clean up trolley trouble, and it very rarely happens that cars are delayed longer than

is sent for and directed to one of the car houses with a letter to the division superintendent in charge, instructing him to put him on with a careful conductor or motorman (whichever position he applies for) to instruct him in the respective duties. If a motorman he is kept on practising by days for about two weeks; if a conductor, about seven days; after which he is turned over to a night man and kept on a week or three days longer. If the motorman or conductor in charge reports him competent to take charge of the car alone, the division superintendent rides with the man

WALTER ROSS,  
Claim Agent.

IRWIN FULLERTON,  
Auditor.

JOSEPH BRAMPTON,  
Assistant Auditor.

the time necessary for the crew of the first car to reach the break, to pick up the line with their trolley rope. We have also escaped several very serious wrecks which might have occurred from wash-outs had not the crews been particularly alert because of their wish to obtain merit marks, and having heard of trouble from wash-outs, observed extra caution and discovered the danger in time to stop the car and avoid accident.

This system has received the approval of the great majority of the conductors and motormen, and has aroused among all of them a strong desire to avoid demerit marks and to take advantage of every circumstance to get merit marks; and those who have been given merit marks have been very much encouraged. The intelligent performance of the duties of conductors and motormen has very materially advanced.

EMPLOYMENT OF EMPLOYEES.

Applications for employment with the Detroit United Railway are received every Wednesday and Friday morning at 11 o'clock. The applicant is required to appear in person and make application

and closely watches him in the performance of his duties. If satisfactory to the division superintendent, he is given a letter to the general superintendent. He is given an outfit consisting of cap badge, riding badge, rule book and (if he is a conductor) punch. He is then placed at the bottom of the board as last extra and does not lose his place on that board unless he is discharged from the company's service. He moves up only as those above him are moved. That portion of the merit system bulletin which relates to promotion refers only to promotions to positions in the car house or office, and does not relate to the change in position on the board. After 60 days' trial he is sent to the company's physician for examination as to his eyesight, hearing and physical condition, which he must pass. The examination costs the applicant \$2.00. There probably remain in our service after 60 days about 40 per cent of the total number of men whose applications are accepted. The reason for this 60-day limit is that after that time the man is required to become a member of the union and is amenable to the conditions of an agreement between the company and the union. Previous to that the company can do what it chooses as to accepting

for a blank. If his appearance and recommendations are satisfactory he is given an application blank, and after filling it out, he presents it at the office on the next application day. His application is then received and he is questioned closely on the application, and told if his services are required he will be notified by mail. If his appearance and endorers are satisfactory, the latter are communicated with personally if they live in the city or near-by, and otherwise by mail. If reports are satisfactory and a vacancy occurs, he

the man. It is the policy of the company to promote conductors and motormen to positions in the car houses and as division and assistant division superintendents. The division superintendents do not employ or discharge conductors or motormen. The employment is all done in the regular employment bureau, and in discharging a man, the case comes before the general superintendent. A man has the right to appeal to the president of the company should he question the decision of the superintendent.

# Power Stations of the Detroit United Railway.

BY THOMAS FARMER, SUPERINTENDENT OF MOTIVE POWER.

The power generating plants of the Detroit United Ry. consist of six stations and three storage battery houses, as follows:

Two city power houses, known as "A" and "B," located near the business heart of Detroit. These two stations are operated from one switchboard, located in Station "A."

Four suburban stations, known and located as follows: Station

THOMAS FARMER.

"D," at Farmington Junction, 19 miles from Detroit City Hall; "E," at Birmingham, 18 miles from City Hall; "F," at Pontiac, 26 miles from City Hall, and used only in emergencies; "G," at Rochester, 28 miles from City Hall.

Three storage battery houses, known as stations "C," "H" and "I," respectively.

Atwater St., near the river front. There is no switchboard in "B," the board controlling both "A" and "B" being located in "A."

Station "A" contains an engine room 243 x 65 ft., and boiler room 253 x 58 ft. The equipment is as follows:

Four Reynolds-Corliss compound condensing tandem engines, 28 and 32 by 48 in., direct connected to 1,000-kw. Siemens & Halske direct current outside armature generators.

Twelve Babcock & Wilcox boilers, 250 h. p. each, set in batteries of two. Boilers are fitted with Murphy stokers and Hoppes live steam purifiers.

Thirteen pumps, as follows: Four Worthington duplex jet condensers, 14 x 22 x 15 in.; two Worthington duplex compound, 10 x 16 x 8 1/2 x 10 in., for boiler feed; one Worthington duplex, 10 x 5 x 10 in., for fire protection, washing boilers, etc.; two Worthington duplex 3 x 2 x 3 in., and one Davidson, 3 x 2 1/4 x 4 in., for oil distribution; one Davidson, 6 x 4 x 7 in., for bleeder; one Gordon, 6 x 4 x 6 in., pit pump; one Westinghouse air pump for cleaning generators.

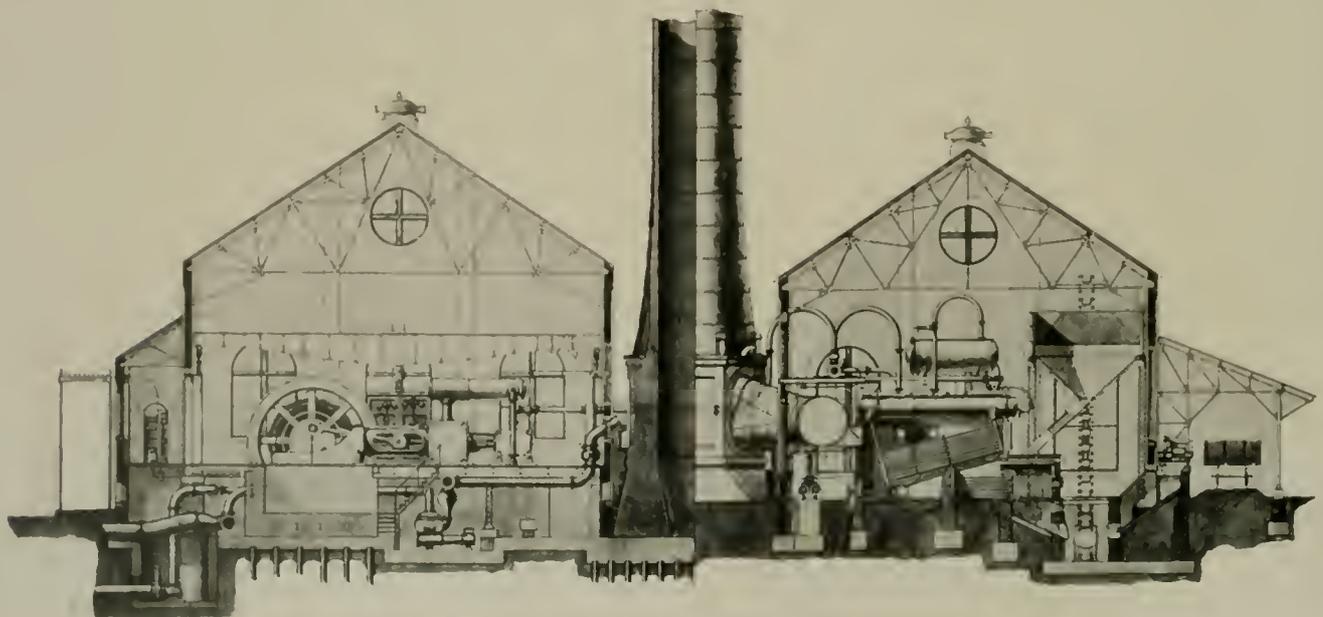

Hunt conveyor for handling coal and ashes, driven by double engines, 4 x 6 in.

The engine room is served by a 25-ton Brown hand crane.

Between the boiler room and engine room is a self-supporting steel stack, 180 ft. high, by 11 ft. 6 in. inside diameter.

The engines are fitted with gravity oiling system, fed from a tank of 200 gallons' capacity. In this connection the oil piping to and from bearings, tanks, filters and cooler is somewhat novel. The pipes are painted different colors, supply being light yellow, return dark yellow, by-pass to sewer, dark red.

As there is quite a multiplicity of pipes and valves in the system, the different colors make their manipulation very simple. For example, should a bearing become hot, so that it is necessary to use water on it, the valve on the return pipe from this bearing, i. e., the dark yellow pipe, would be closed and the valve in the by-pass to the sewer (dark red) would be opened. This would run the oil used on the bearing to waste, but it would save getting the entire system full of water, as all other bearings would remain in normal

CROSS SECTION OF STATION A - DETROIT UNITED RY.

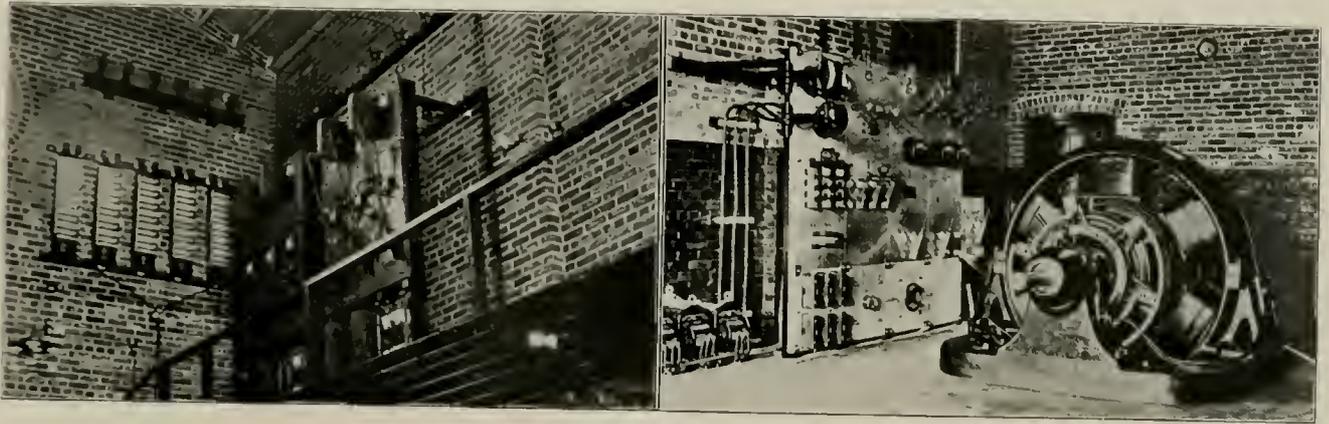

Station "A" is the one built originally for the Detroit Citizens' Street Ry. Station "B" was built by The Detroit Ry., and both properties were afterwards acquired by the Detroit United Ry. These two houses are situated diagonally opposite each other on

condition as regards the return of oil to the filter. As a matter of record, however, water has not been used on a single bearing in over six years. The oil filters are also original and have a capacity of 500 gallons per hour. The method of low pressure cylinder

lubrication is also original. The cylinder is drilled on both sides on its center line right through the walls, and is connected by piping to a special double sight feed lubricator. The piston in passing by the openings acts as a wiper and insures the most perfect lubrication. This has been used for over seven years, and has not only

One booster set, made up of one Westinghouse 525-volt direct current motor, direct connected to two 500-volt T. H. generators of 150 kw. capacity each.

The boilers comprise eight Sterling of 300 h. p. each, and eight Sterling of 250 h. p. each, set in batteries of two, and equipped with

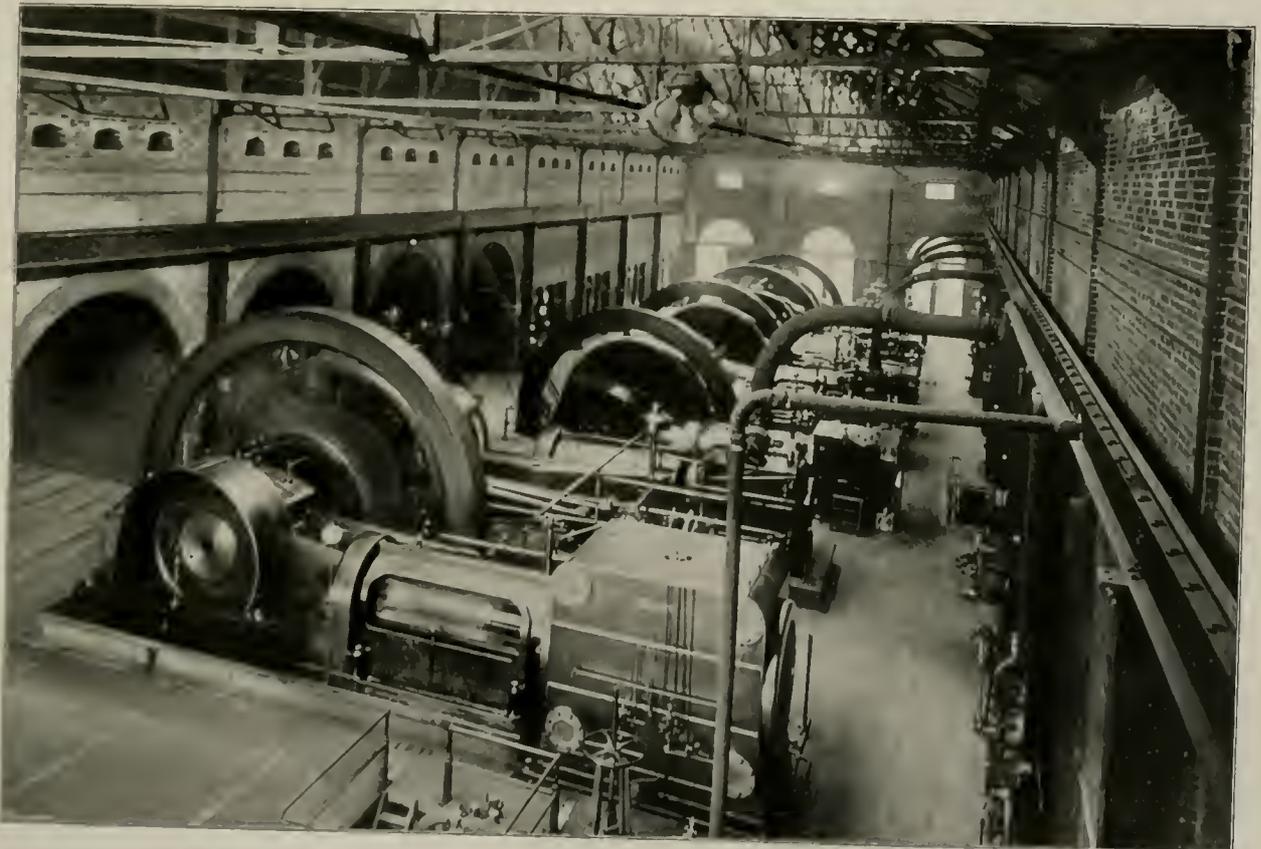

HIGH TENSION SWITCHES AND STANLEY APPARATUS IN OXFORD SUB-STATION.

effected a great saving in oil, but has been so effective that but two cylinders have required reboring, a somewhat unusual result on tandem engines.

The equipment in Station "B" is as follows: Two Reynolds-corriss cross compound condensing engines, 20 and 40 by 48 in., direct connected to 400-kw. direct current 525-volt Walker generators.

Murphy stokers and Green fuel economizers and connected to a brick stack 185 ft. high by 10 ft. flue.

Fourteen pumps, as follows: One Blake vertical duplex jet condenser, 15 and 24 x 38 x 21 in.; two Davidson jet condensers, 12 x 18 x 20 in.; two Davidson jet condensers, 12 x 20 x 24 in.; four Davidson, 12 x 8 x 12 in., boiler feed; two Davidson, 4 x 2 x 4 in.,

INTERIOR OF STATION B DETROIT UNITED RY.—FILER & STOWELL AND ALLIS ENGINES.

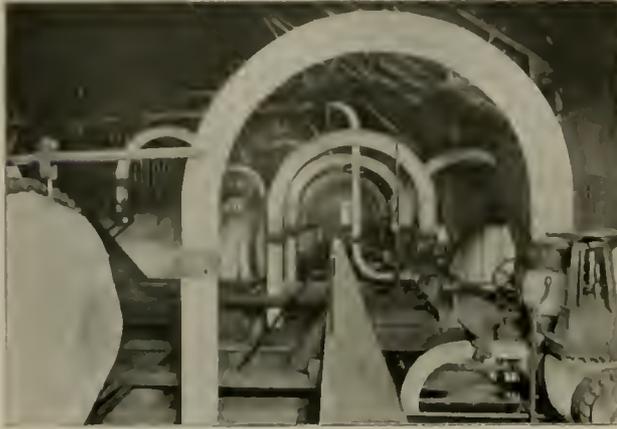

Two Reynolds corriss cross compound condensing engines 24 and 48 by 48 in., direct connected to 800 kw. direct current 525-volt Walker generators.

One Filer & Stowell cross compound condensing engine, 32 and 64 by 60 in., direct connected to a 1,500-kw. direct current 625 volt Westinghouse generator

oil distribution; one Marsh, 4 x 2 x 4 in., bleeder; two Davidson automatic pumps and receiver.

As before noted, the switchboard in Station "A" controls Station "B" as well as "A." It is made up of nine machine panels, 36 feeder panels, two booster panels, two main instrument panels, and four blank machine panels, and is 96 ft. long. The bus bar arrange-

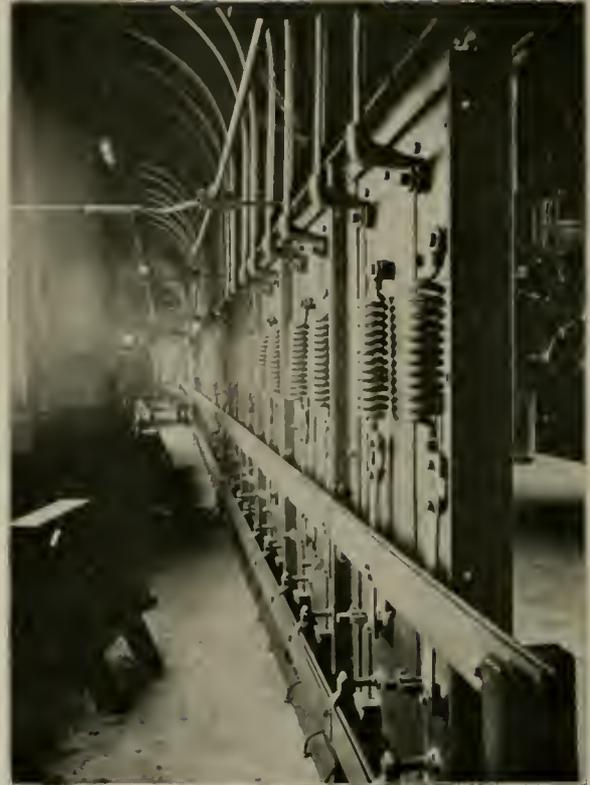

ment is as follows. There are three positive bars on the board, the negative bar being in the cellar below the board. All machines are tied in, and equalized on, the ground side. Of the three positive bars the upper one is Station "A" bar, the lower one is Station "B" bar, and the center bar is also fed from Station "B." The center and lower bars are connected through a switch which can be opened

STEAM PIPING, STATION A.

and each bar operated independently, that is, a voltage of 585 can be maintained on middle bar, using the four 525-volt units at Station "B," and the 625-volt unit cut in on lower bar, thus raising the voltage for outlying lines. The upper and lower bars can be connected so that the night load can be carried by either station; also by means of double throw switches to upper and lower bars load on each house can be equalized.

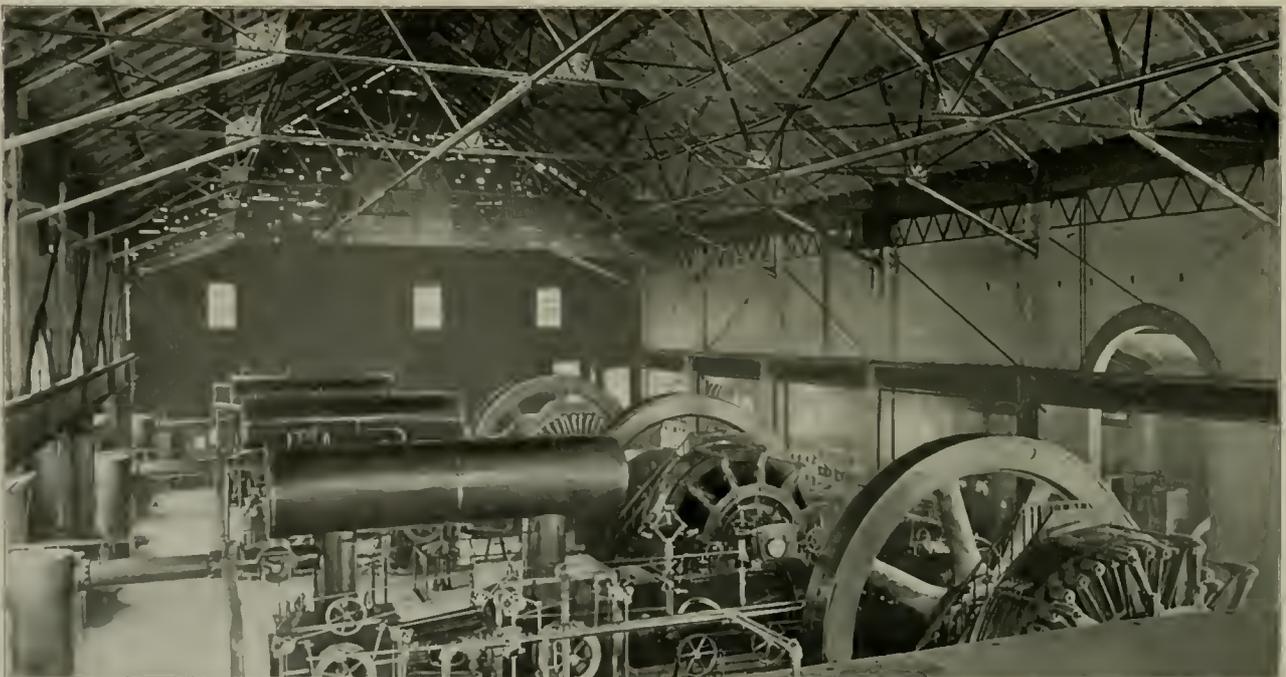

About  $3\frac{1}{2}$  miles from the power house, and running directly across the center of the city, is an equalizing feeder of about 1,300,000 c. m. capacity and about  $1\frac{1}{2}$  miles long. All feeders that radiate from the power house and cross through this district are tied into this equalizer wire through circuit breakers. Tied to the equalizer is also a 2,000-ampere-hour storage battery, which serves to carry the evening and morning peaks. The general feeder distributing scheme, including the use of this equalizing wire, is shown in the accompanying feeder diagram. The load situation on this

REAR OF SWITCHBOARD IN STATION A.

The third positive bus commences at the knife switch at the center of the board. The feeder connections are the curved rods.

wire will be understood from the curves, Fig. 6, which will also explain the advantages of the third bar at the switchboard. Under normal conditions the low voltage machines at the power houses are sufficient to carry the load on the equalizing wire. As the load increases the 625-volt machine is connected in through the medium of the third bus and the available pressure at the center and at the ends of the equalizing wire correspondingly increased. When the heavy peaks begin to come on, the battery located near the center

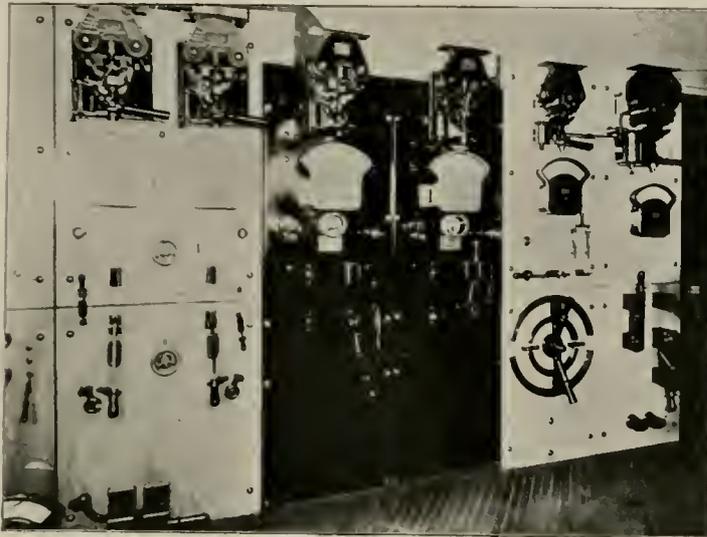

INTERIOR OF STATION A—REYNOLDS-CORLISS ENGINES—SIEMENS & HALSKE GENERATORS.

of the equalizer will take the added load, not only maintaining the voltage, but also protecting the engines against violent fluctuations in load.

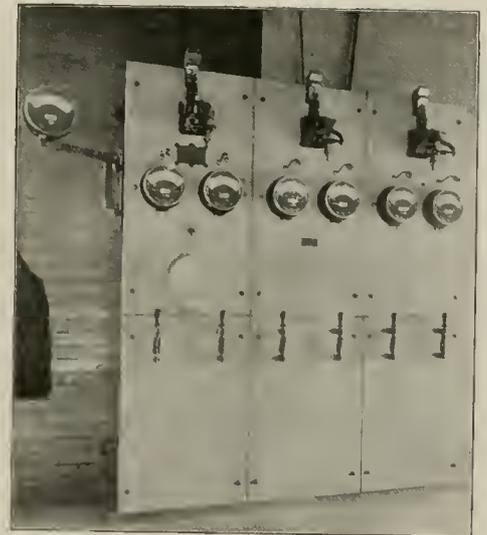

Both stations "A" and "B" were erected in 1895, the only additions since that time being the 1,500-kw. Westinghouse generator and the Filer & Stowell engine. A duplicate of this latter unit is now be-

can be had to piston without removing head. Total weight of engine, 640,000 lb.; speed, 75 r. p. m.

Station "D" is situated at Farmington Junction, on the Orchard Lake Division, 19 miles from the City Hall. The engine room is 120 x 52 ft. and boiler room 120 x 52 ft., built of brick, with brick stack. The equipment is as follows:

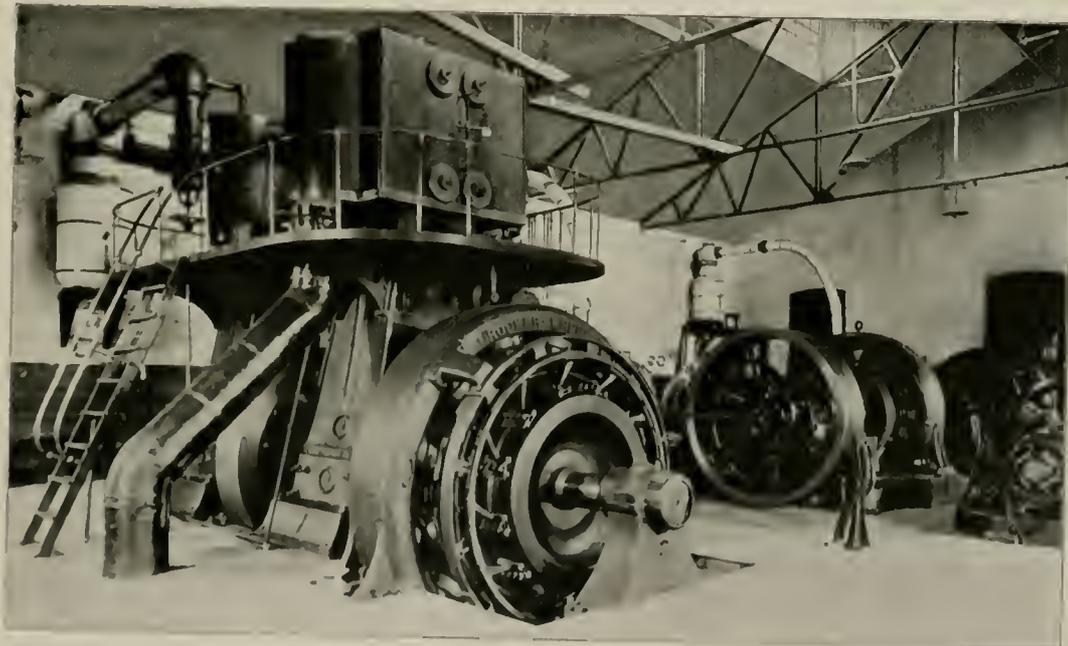

SWITCHBOARD FOR BATTERY STATION "C."

SWITCHBOARD FOR BATTERY NO. 3, STATION "L."

ing erected. The Filer & Stowell engine differs somewhat from previous standards of that company. The shaft is Bethlehem hollow forged steel, 20-in. in diameter at wheel fit, with bearings 26 x 48 in., and 26 ft. long; axial hole, 10 in. square; weight of shaft alone 41,574 lb.; weight of shaft with crank disks, pins and hub, 102,200 lb.; fly-wheel, 23 ft. in diameter; weight of fly-wheel, 160,000 lb. Cross heads are fitted with an extension, so that slippers are fastened by means of studs to cross head proper, insuring that slippers

Three Reynolds-corriss engines, 26 x 48 in., direct coupled to 400-kw. Siemens & Halske outside field generators. Eight Aultman & Taylor boilers, 250 h. p. each, set in batteries of two, and fitted with Murphy stokers. All pumps are Davidson make. Two General electric 100-kw. boosters, one for Detroit end of line and one for Orchard Lake end. These boosters are only run on increased loads, the regular schedule not receiving their use. One air compressor for Magann storage air brakes used on cars.

STATION G, ROCHESTER, MICH. BALL & WOOD ENGINE CROCKER-WHEELER GENERATOR.

will be retained in case the adjusting screw breaks. Valve gear is connected straight through, no wrist plates being used on either admission or exhaust. Both high and low pressure piston junk rings are babbitted. Connecting rod is babbitted at both ends. Low pressure cylinder head is fitted with manhole, so that access

Station "E" is situated at Birmingham, on the Pontiac Division, 18 miles from City Hall. The equipment is: Two Westinghouse compound condensing engines, 16 and 30 by 18 in., belted to 250-kw. Westinghouse D. C. 650-volt generators.

One Babcock & Wilcox 250-h. p. boiler, fitted with Roney stoker,

and three fire-tube boilers of 125 h. p. each, which are fired by hand. The pumps are all Worthington. One air compressor, 8 x 7 x 4 x 12 in., for supplying Magam storage air brakes used on cars.

The Weingo system of water purification and softening is used with success at this plant.

Station "F" is situated at Pontiac, the terminus of the Pontiac Division, and is used only in emergency cases, when all help required for operation is sent from the shops of the company. The equip-

1,500-KW. CHLORIDE BATTERY, STATION C.

ment is: One Dick & Church engine, 16 x 15 in., and one Ball engine, 15 x 16 in., each belted to 100-kw. Westinghouse generators. Two Phoenix Iron Works 100-h. p. boilers. One Worthington boiler feed pump, 6 x 4 x 6 in.

Station "G" is at Rochester, on the Flint Division, 28 miles from the City Hall. The machinery is contained in a building 72 x 104 ft., and is as follows:

Two 325-h. p. Ball & Wood horizontal tandem compound condensing engines, 15 and 30 x 16 in., direct connected to Crocker-Wheeler 200-kw. generators. The engines are of the single valve type, having the high pressure valve under control of the inertia shaft governor, and are operated at 200 r. p. m.

One 600-h. p. Ball & Wood vertical cross compound condensing engine, 21½ and 45 by 20 in., direct connected to Crocker-Wheeler

One 60 kw. direct current booster for feeding the Detroit end of line.

One 250-kw. S. K. C. inverted rotary built by the Stanley Electric Manufacturing Co., of Pittsfield, Mass. The method of utilizing this machine is explained later in this article.

One 90-kw. alternating current single-phase lighting generator direct driven by a 600-volt direct current motor, taking current from the station bus.

The boiler equipment consists of four 450-h. p. Aultman & Taylor boilers.

The pumps were all furnished by Dean, of Holyoke, and comprise: One 14 x 20 x 24-in. jet condenser; two 8 x 14 x 18-in. jet condensers, and two 7½ x 5 x 10-in., for boiler feed.

There is an air compressor for supplying air to Magam storage air brakes used on cars.

This station furnishes commercial lighting for the city of Rochester, Mich.

The use of the inverted rotary is somewhat unusual. Part of the direct current generated is fed directly to the line and a part is put through the S. K. C. inverted rotary, converted therein to three-phase, 300-volt, alternating current, and then stepped up by Stanley type T transformers to 15,000 volts and transmitted to rotary sub-stations at Oxford and Atlas, distant 13 miles and 30 miles respectively, from Rochester power house.

Each of these sub-stations is equipped with three 100-kw. type T Stanley 15,000-300-volt transformers; one 250-kw. S. K. C. rotary converter, and complete high and low tension alternating and direct current switchboards, switches, breakers, etc. An extra 250-kw. rotary is also located at Atlas sub-station for use as a reserve.

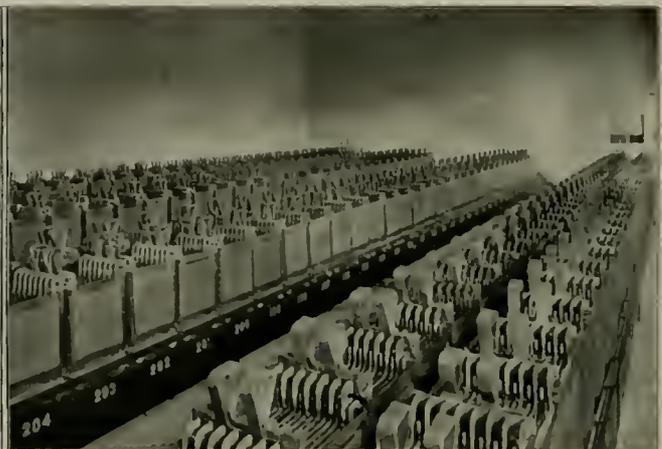

At Station "G" there will be installed, about September of this year, one 750-h. p. Ball & Wood vertical cross compound engine, 22 and 45 by 24 in., to which will be direct connected one 500-kw. Bullock 300-volt, three-phase revolving field alternator. The building will be extended for this equipment, and there will also be provided additional boilers, pumps, condensers, etc., of the same capacity as this unit.

When this alternating current unit has been installed it is proposed at all times of heavy load to operate from this unit the two sub-stations at Oxford and Atlas on the Flint Division, and from the direct current generators located in the same power house to operate the sections between Royal Oak and Rochester, Rochester and Orion and Rochester and Romeo.

If, however, it is noted that either the direct or the alternating current machinery is not loaded up to its economical capacity, the

1,000-KW. CHLORIDE BATTERY—STATION H.

150-KW. CHLORIDE BATTERY—STATION I.

400-kw. generators. This engine is of the corliss valve type. All admission valves are under control of inertia shaft governor and exhaust valves driven by separate fixed eccentric so that each may be adjusted independently of the other or of the admission. The frames are entirely enclosed with large manholes and hand holes, covered by closely fitting metal casings, so that no oil or spray can escape to governor or generators. The shaft, bearings and all working parts are of ample proportions. The engine runs at 180 r. p. m. at 150-lb. initial steam pressure.

S. K. C. rotary now used as an inverted rotary, will then be used to convert some of the output of the lightly loaded portion of the station to the other kind of current, so that at all times all units in operation will be operated economically. On very light loads the sections between Royal Oak, Romeo and Flint, it is expected, will be operated from either the 500-kw. alternator or the 400-kw. direct current generator, by utilizing in combination with either of these units the S. K. C. rotary, using it as an inverted rotary, if the greater portion of the current required is direct, and consequently

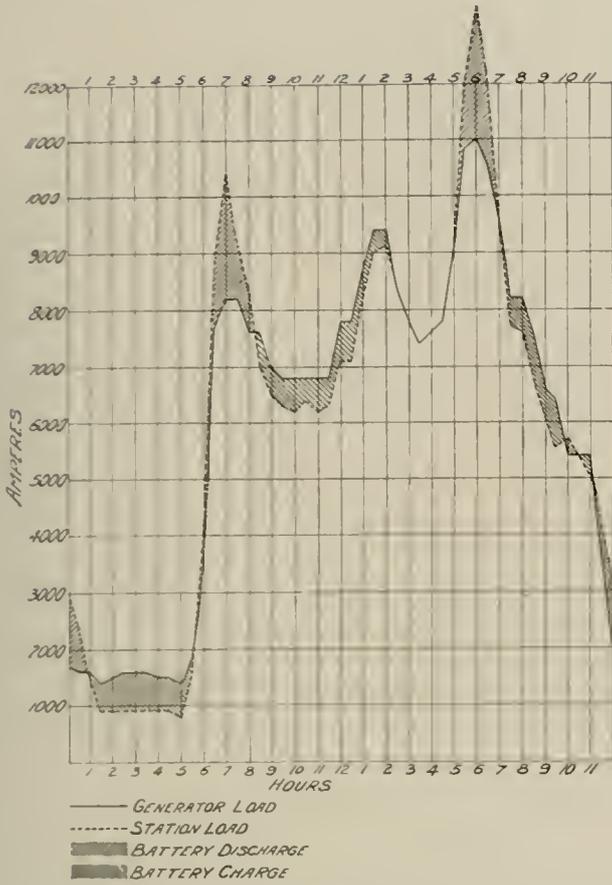

FIG. 1 BATTERY LOAD OCT. 10, 1901—BATTERY NO. 1—STATION C.

the direct current engine unit is operated; or, if the major portion of the current required is alternating, and the alternator unit is operated, then using the rotary in the ordinary direct manner to convert from alternating to direct current.

It is also proposed at times when momentarily first the alternating current and then the direct current units are likely to be overloaded, to keep this rotary in operation as a floating medium of conversion between the alternating current and the direct current sides of the station, so that neither may be overloaded unless the entire station is similarly affected. This regulating action will be accomplished automatically by the rotary.

Storage Battery Installations.

As stated, there are three storage batteries in use, all being "chloride" accumulators, furnished by the Electric Storage Battery Co., of Philadelphia, through the Michigan Electric Co., of Detroit. A description of each battery follows:

Battery No. 1, known as Battery Station "C."

FIG. 2 DIAGRAM FOR ONE MINUTE—BATTERY OUT OF SERVICE.

This battery, which was installed during August, 1900, is of 1,500-kw. capacity, and consists of 276 cells of "Chloride" accumulators, each cell being a lead-lined tank containing 67 type G plates, each of which is 15 5-16-in. square. A 250-kw. Western Electric

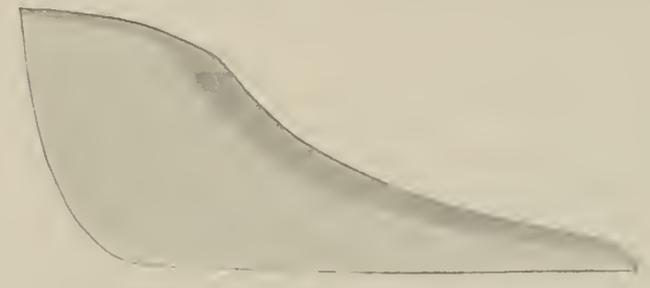

FIG. 3 DIAGRAM FOR ONE MINUTE—BATTERY IN SERVICE.

motor-driven booster was also furnished with this battery, and by this means the charging and discharging can be regulated either by hand or automatically.

The discharge capacity of the battery installation is 2,500 amperes at 575 volts for one hour, 1,250 amperes for three hours, or 625 amperes for eight hours.

This battery was installed to help carry peak loads, which on this railway system are excessive, owing to the fact that the number of cars operated during certain hours of the morning and evening is nearly double the number operated at any other time. The load curve, Fig. 1, illustrates the main power house load of this com

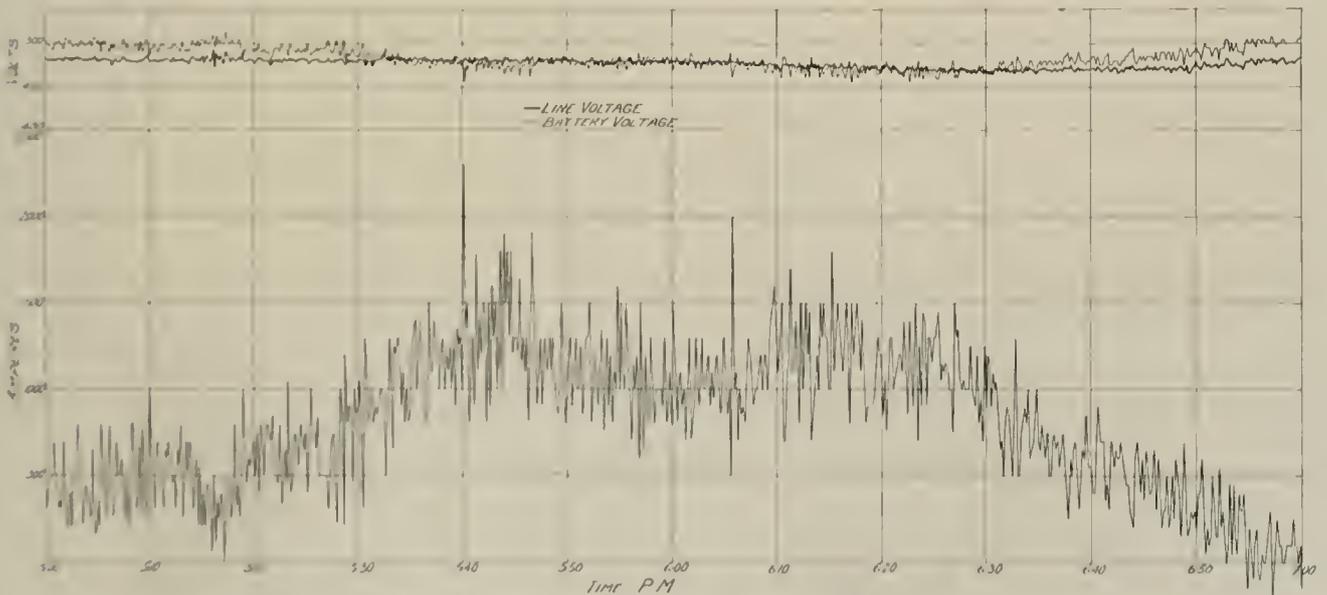

FIG. 4 LOAD ON BATTERY NO. 2, STATION B, MAR. 26, 1902.

FIG. 5 LOAD ON BATTERY NO. 3, STATION 1, JULY 22, 1902.

pany, and the portion which is carried by the battery, as well as the period for charging.

This battery also serves another purpose, that of reducing the fluctuations on the main station. The reduction of the fluctuations on the generators and engines is very neatly shown by the indicator diagrams shown in Figs. 2 and 3; Fig. 2 shows an indicator card taken with the battery off the system, the pencil of the indicator

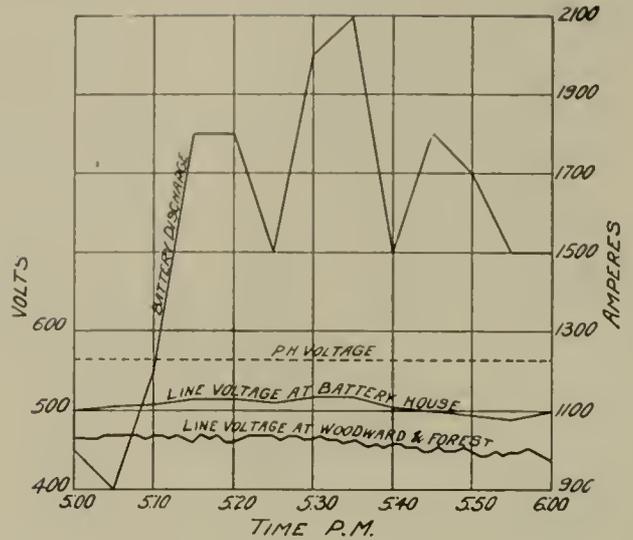

FIG. 6 SITUATION AT EQUALIZER WIRE.

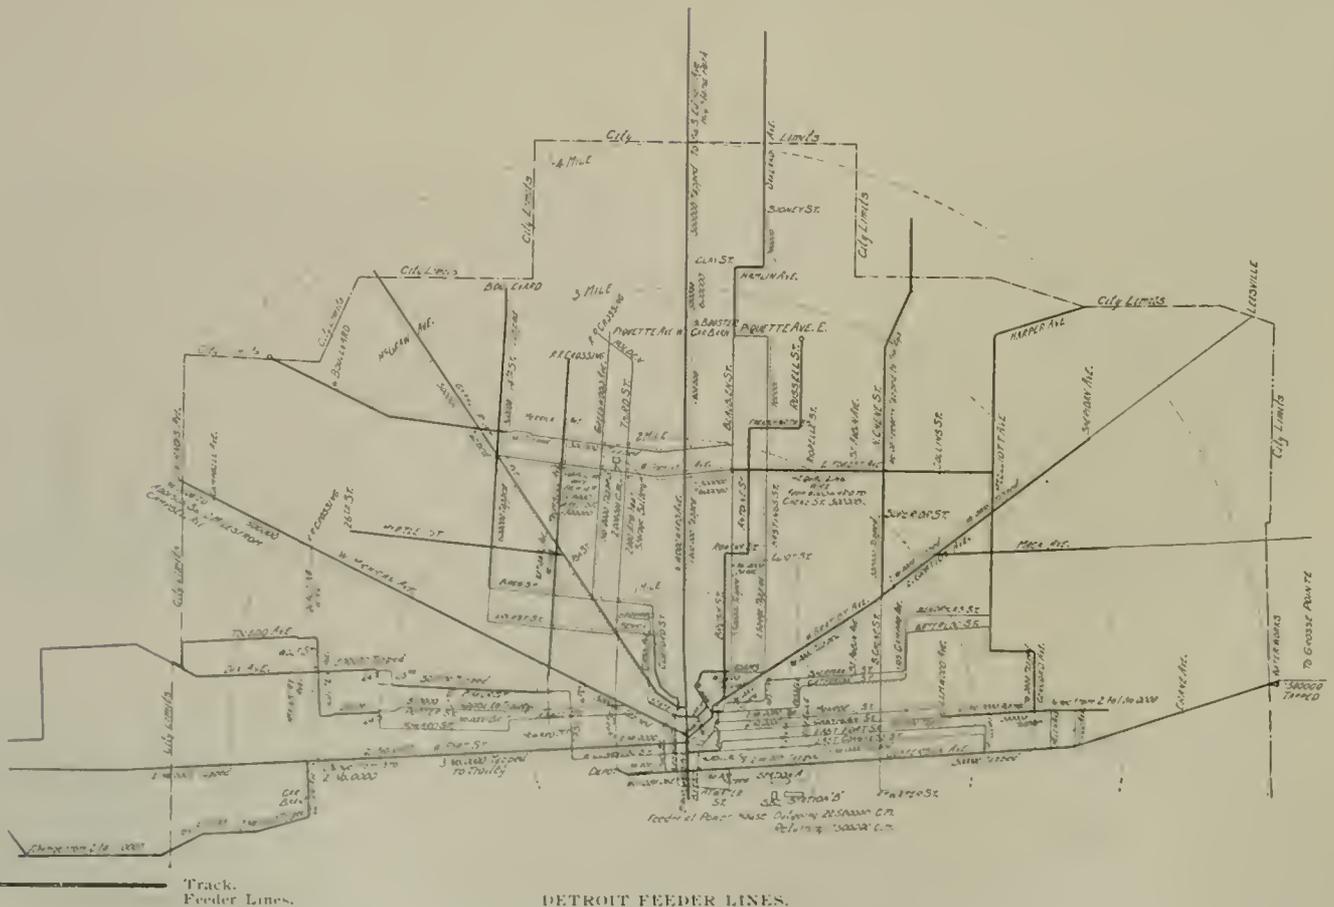

being left on the card for one full minute. The card shown in Fig. 3 was obtained in a similar manner with the battery on the system.

The battery has been in constant service of the most severe character ever since it was first installed, and has probably had, in doing so, as exacting a service as any railway battery in the country.

This battery is located across the street from Station "A;" the booster and switchboard being located in said power house and connected with the battery by means of cables which pass through a tunnel under the street.

Battery No. 2, known as Battery Station "H."

This battery is of 1,000-kw. capacity and consists of 250 "chloride" accumulators, each cell consisting of 52 type G plates in a G-76 lead-lined tank. There was also furnished with this battery a 150-kw. Western Electric motor-driven booster for regulating the charge and discharge. The discharge capacity is 2,000 amperes at

DETROIT FEEDER LINES.

500 volts for one hour, 1,000 amperes for three hours, or 500 amperes for eight hours.

This battery is located about three miles from the power house, and about two miles beyond the center of the railway company's city lines; it is used to help carry the morning and evening peaks, relieving in so doing the power house from a portion of the load, and also maintaining a better voltage throughout the portion of the city where it is located than could be maintained from the power house, without materially increasing the power house voltage. It feeds into the equalizing wire previously mentioned.

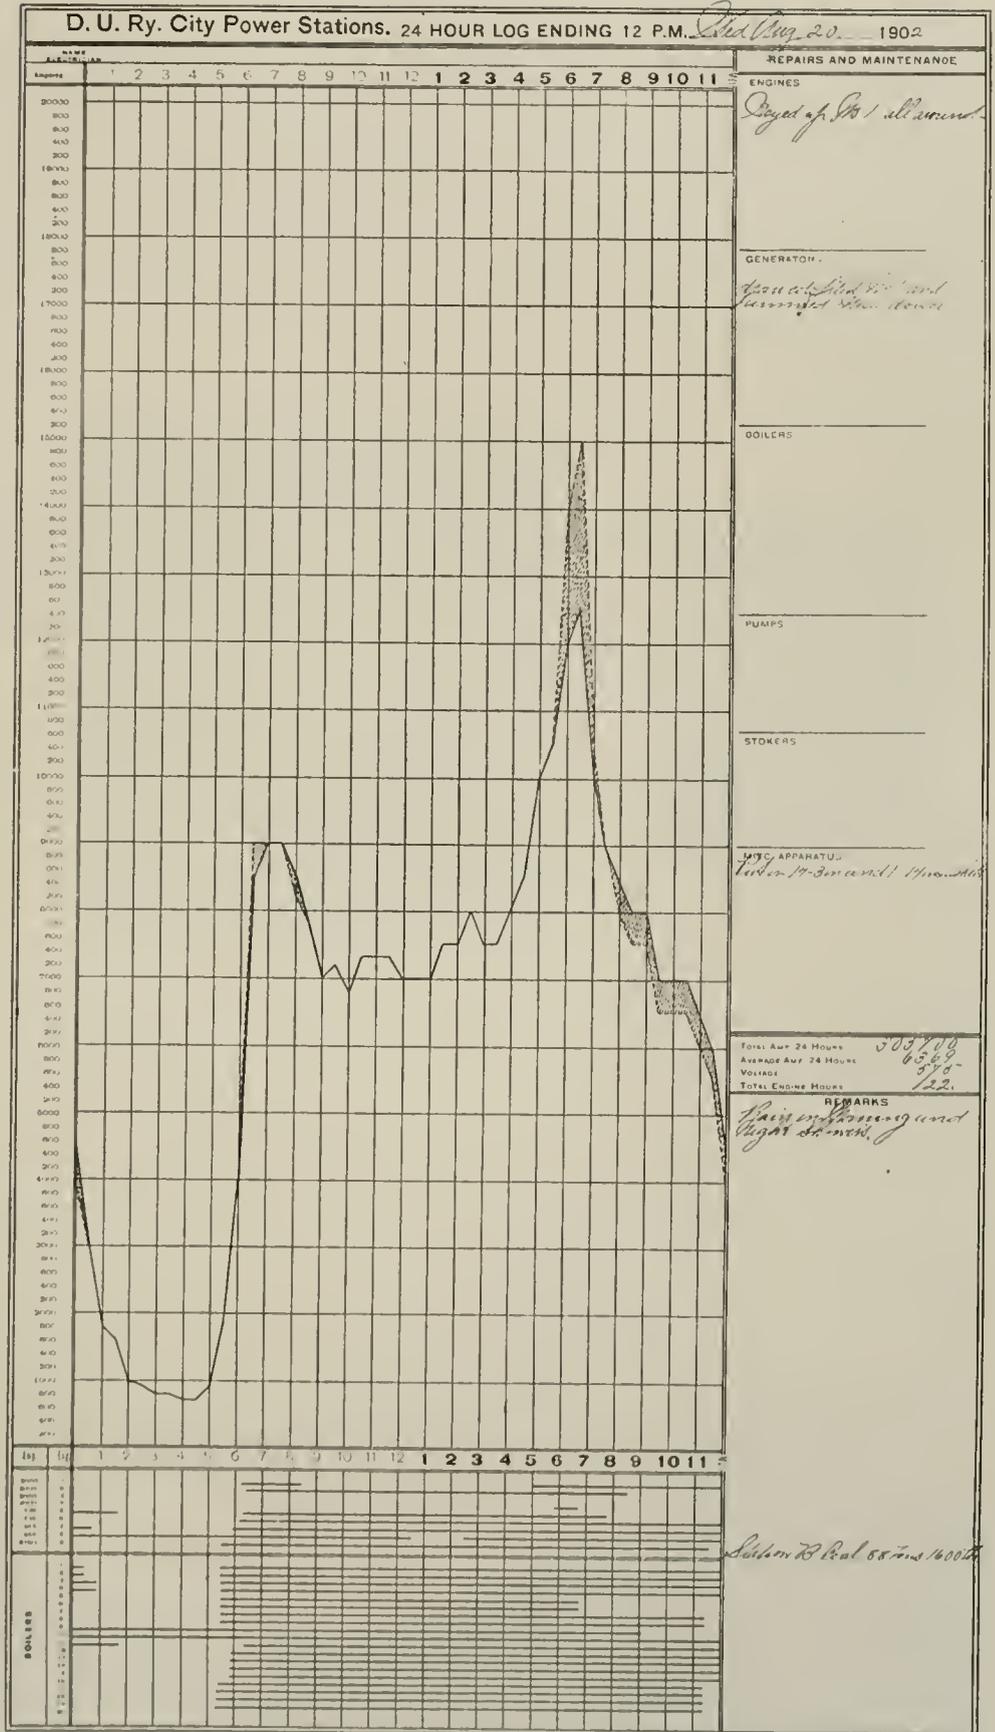

This battery was installed in January, 1901, since when it has been in daily use. Fig. 4 illustrates a typical day's load on this battery.

Battery No. 3, known as Battery Station "L."

This battery is of 150-kw. capacity, and is located at Ecorse, on the Wyandotte Division, the battery building being about 10½ miles from the power house. The battery installation consists of 276 "chloride" accumulators, type F-15; the plates being 11 by 10½ in., contained in glass jars mounted upon suitable stringers, which are in turn supported on brick piers. This battery is used for regulating purposes; the average voltage being 575, and the battery having 300-ampere capacity for regulating fluctuations. It can be used for operating the line without the aid of current from the power house to the extent of 280 amperes for one hour.

Previous to the installation of Battery No. 3 on this division a 30-minute service was operated, and the trip from the city limits to Trenton and return (a distance of 20¾ miles) required 90 minutes. Current was obtained for that service from the power house through a booster located therein. The voltage at the city limits end of the line under these conditions varied from 425 minimum to 800 maximum, and the amperage from 160 minimum to 600 maximum, the result being that electrical repairs on the cars used for this service were naturally excessive and the service not at all satisfactory as was desired. The lighting in cars was also exceedingly poor.

Since Battery No. 3 has been installed on this division the service has been increased to a 20-minute headway, and the run from the city limits and return, cut down from 90 minutes to 80 minutes, yet not with tarding the increase of car service and improved running time the voltage at the battery station, located about the center of the division, only varies from 520 minimum to 610 maximum, and the amperage required from the city power house from 160 minimum to 270 maximum, car repairs having also been re-

TYPICAL DAILY LOAD CURVE SHOWING COMBINED LOAD ON CITY POWER HOUSES IN CONNECTION WITH BATTERY CHARGE AND DISCHARGE.

duced to normal, and lighting and general car service being now of the most satisfactory character. A typical load curve of this battery is given in Fig. 5.

# The Rapid Railway System.

BY F. W. BROOKS, GENERAL MANAGER, ASSISTED BY W. O. WOOD, GENERAL SUPERINTENDENT, AND A. C. MARSHALL, CHIEF ENGINEER.

The Detroit & Port Huron Shore Line Railway, generally known as the "Rapid Railway System," extends from the northerly city limits of Detroit to Keewahdin Beach, on the shores of Lake Huron, passing along the shore of Lake St. Clair and the St. Clair River and through the following towns and villages: Roseville, Grosse Pointe, Mt. Clemens, Chesterfield, New Baltimore, Anchorville, Fair Haven, Pearl Beach, Algonac, Roberts' Landing, Cherry

overhead line work and track bonding; general freight and passenger agent, reporting to the general manager; general claim agent, reporting to the general manager; auditor, reporting to the general manager; attorney, reporting to the general manager.

The Rapid Railway System is in a strict sense an interurban rather than a suburban road. The first step toward the construction of this line was the completion of the Rapid Railway from

W. O. WOOD.

F. W. BROOKS.

A. C. MARSHALL.

Beach, Marine City, St. Clair, Maryville and Port Huron. The various steps in the formation of the system, with the names of all the constituent companies, are shown graphically in one of the accompanying tables. The system comprises a total of 113 miles in operation and 10 miles under construction. A close relationship exists between the Rapid Railway System and the Detroit United Ry., and the two properties are operated in entire harmony.

The operating organization is as follows: General manager, who reports direct to the president; general superintendent, who reports to the general manager; two division superintendents, one roadmaster, one chief and two assistant train dispatchers, reporting to the general superintendent; one chief engineer, reporting to the general manager, he having charge of the power plants, car shops,

Detroit to Mt. Clemens. After this line had been operated for several years, an extension from Mt. Clemens to Port Huron was completed and operation commenced in the summer of 1900. The City Electric Railway Co., embracing all of the city lines in Port Huron, was taken into the System July 1, 1901.

The line is practically level, there being no grades of any consequence. The standards of construction which have been followed are those which are most approved by the steam railroads. The organization of the force in the road department is based upon steam railway practice, dividing the line into sections, each under the charge of a section foreman, these foremen reporting to the roadmaster, who is in charge of the road department of the entire line.

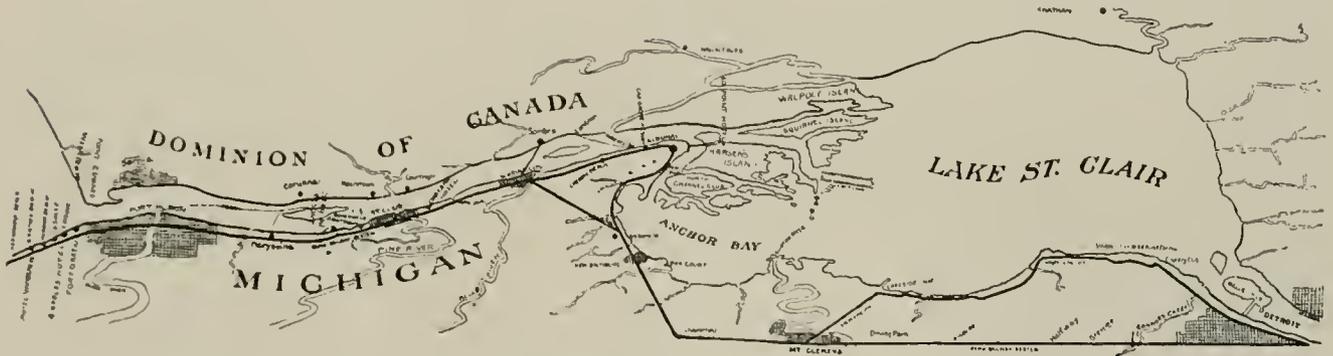

TYPICAL SCENE ON THE BEACHES SERVED BY THE RAPID RAILWAY.

The track outside the cities is laid with rails of A. S. C. E. standard 70 and 60-lb. section, according to the requirements of the traffic. The ties are 6 x 8 in. x 8 ft. cedar for the tangents, and the curves are laid on white oak ties of the same size. Switches are standard railway split switches, with spring rail frogs of standard construction. Gravel from deposits found along the line is used for ballasting.

The few places where bridging is required are provided with pile trestle, none of them consisting of more than one bent, excepting in the case of a viaduct over the Michigan Central R. R. at St. Clair, where a trestle supporting the elevated track provides against the possibility of crossing accidents. This is the only place where the line crosses another railroad at grade.

Its route follows the shores of the St. Clair Flats, one of Detroit's famous fishing, hunting and outing regions.

The movement of cars is under a system which is a modification of the standard code of train rules of the American Railway Association. South bound regular trains are given right of track, which continues until a train is three minutes late. The movement of extra trains and of regular trains which for any reason are not running on time, is looked after through a regular dispatching system. The dispatching is done by telephone from the dispatcher's office at Mt. Clemens. The orders are received at telephones in booths provided at each switch and at other places where it is convenient to receive orders. The orders are given by the dispatcher to the motorman, are repeated by the motorman to the

BIRDSEYE VIEW OF RAPID RAILWAY SYSTEM.

In the cities the standard of construction is a 7-in. T rail of the Lorain Steel Co., section No. 264, placed upon a 10-in. stringer of concrete and fastened with bar iron ties.

Car barns are provided at terminals of runs, namely, Port Huron, Marine City, and Mt. Clemens, and are well equipped for purposes of the machinery department.

Transportation Department.

The Rapid Railway serves the travel between Detroit, Mt. Clemens, New Baltimore, Pearl Beach, Algonac, Marine City and Port Huron, and provides a city service in Mt. Clemens and in Port Huron. An hourly service between 6 a. m. and midnight is main-

dispatcher, and likewise repeated by the conductor. A train sheet kept by the dispatcher and also a complete copy of each order retained in the dispatcher's order book provide against any question as to what movement is ordered. Motormen and conductors receive their orders relative to the movement of trains from the dispatcher, but report to their respective division superintendents, who are in authority over all train men.

In the employment of men an application in detail, giving the previous history of the applicant and certificates from persons to whom he refers and certificates of his physical qualifications are required.

The company requires from both conductors and motormen re-

CAR HOUSE IN PORT HURON RAPID RAILWAY.

tained over the length of the interurban line between Detroit and Port Huron, and a half hourly service over that portion of the line between Detroit and Mt. Clemens, the cars reaching the Detroit City Hall over the direct Gratiot Ave. line of the Detroit United Ry. In addition to this line hourly service is maintained over the Shore Line Division from Detroit, via Grosse Pointe farms and the Lake Shore to Mt. Clemens, carrying passengers to the Country Club and various club houses and resorts along the shore. In addition to its regular all year round traffic, the system enjoys an exceptionally heavy summer business, its territory between cities and towns being practically one great summer resort.

ports of every mishap or unusual occurrence. The questions which they are required to answer are such as will give as intelligent and comprehensive an idea of the circumstances as can be given in concise form. This report is followed by an investigation and a detailed signed statement from the employe, giving every particular, setting forth the circumstances in minute detail. These reports are filed for reference in the claim department, after they have served the purpose of the operating department. All claims resulting from personal injury or damage to property are looked after by the general claim agent.

All material and supplies are obtained upon requisition bearing

the signature of the head of the department and the approval of the general manager, through the purchasing department. Bills for material are approved by the head of the department for which the purchase is made and are vouchered and put through the accounting department in the usual course.

The City of Port Huron is well laid out for street railway purpose. To the extreme north are the beaches on Lake Huron, with heavy summer travel to the hotels, cottages and parks. The extensive repair shops of the Grand Trunk Railway System are in the northern end of the city, while at the extreme southern end are a number of factories. In the extreme western end of the city is the Union Depot, which is reached only by the street car service.

In Mt. Clemens the city cars connect with all interurban cars,

The building is a handsome brick structure, 110 ft. long by 80-ft. wide, taken up entirely by the engine room and boiler room, with a commodious basement under the engine room. The building rests on 40 ft. pile, capped by an extremely heavy stratum of concrete, so that under the entire building is practically a huge monolith.

The boiler room, 100 ft. by 38 ft., contains four Babcock & Wilcox 350-h. p. boilers, with Roney mechanical stokers; two Worthington boiler feed pumps; Green economizer; the circulating pump and dry air pump for the condenser and two 10-ft. direct connected fans for draft. These fans are depended upon for the draft, as the stack extends but 7 ft. above the roof.

A side track for coal is just outside the boiler room wall and about 8 ft. from the boilers. Coal cars are placed here every night

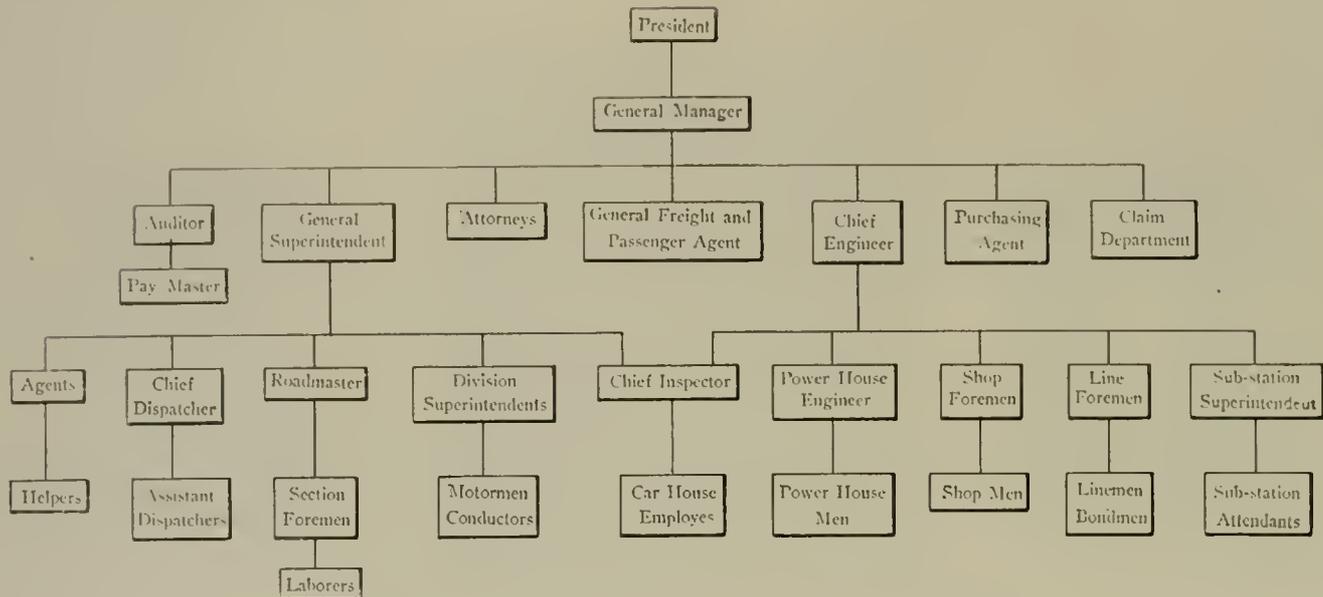

DIAGRAM OF THE ORGANIZATION OF THE RAPID RAILWAY SYSTEM.

serving the depots and hotels and in addition run frequent service to Lakeside, a fashionable resort on the shore of Lake St. Clair, about two and one-half miles distant from the city.

Power Equipment.

The general scheme of power equipment is to generate all the power at one large central power house, transmit it by means of high tension circuits to sub-stations located along the line, and there convert it to direct current. The main power house is located at New Baltimore, on Lake St. Clair. Here is generated all the power for the entire system, including the main line, the Lake Shore Division, and the Port Huron city system. The daily output at this station averages about 16,000 kilowatt-hours, this being generated in a 20-hour run.

by the freight locomotive, and during the run the coal is shoveled directly from these cars into the hoppers through large iron chutes. One man on a watch can in this way keep four boilers going. Although in normal running coal is thus used directly from the cars, there is always kept unloaded a reserve supply of coal of about 500 or 600 tons. Ohio and West Virginia slack coal is used and the coal consumption averages about 5.75 to 6 lb. per kilowatt-hour.

The water for boilers comes from Lake St. Clair, through a pipe which extends about 1,400 ft. into the lake, to avoid the mud nearer the shore. The water is quite soft, and is, in fact, remarkably free from lime and other undesirable ingredients. It undergoes no purifying process whatever, neither is any compound used in the boiler.

Epitome of the History of the Rapid Railway System.

(For relation existing between this system and the Detroit United Railway see text.)

The system was formed in the spring of 1900 by the merger of the following companies:

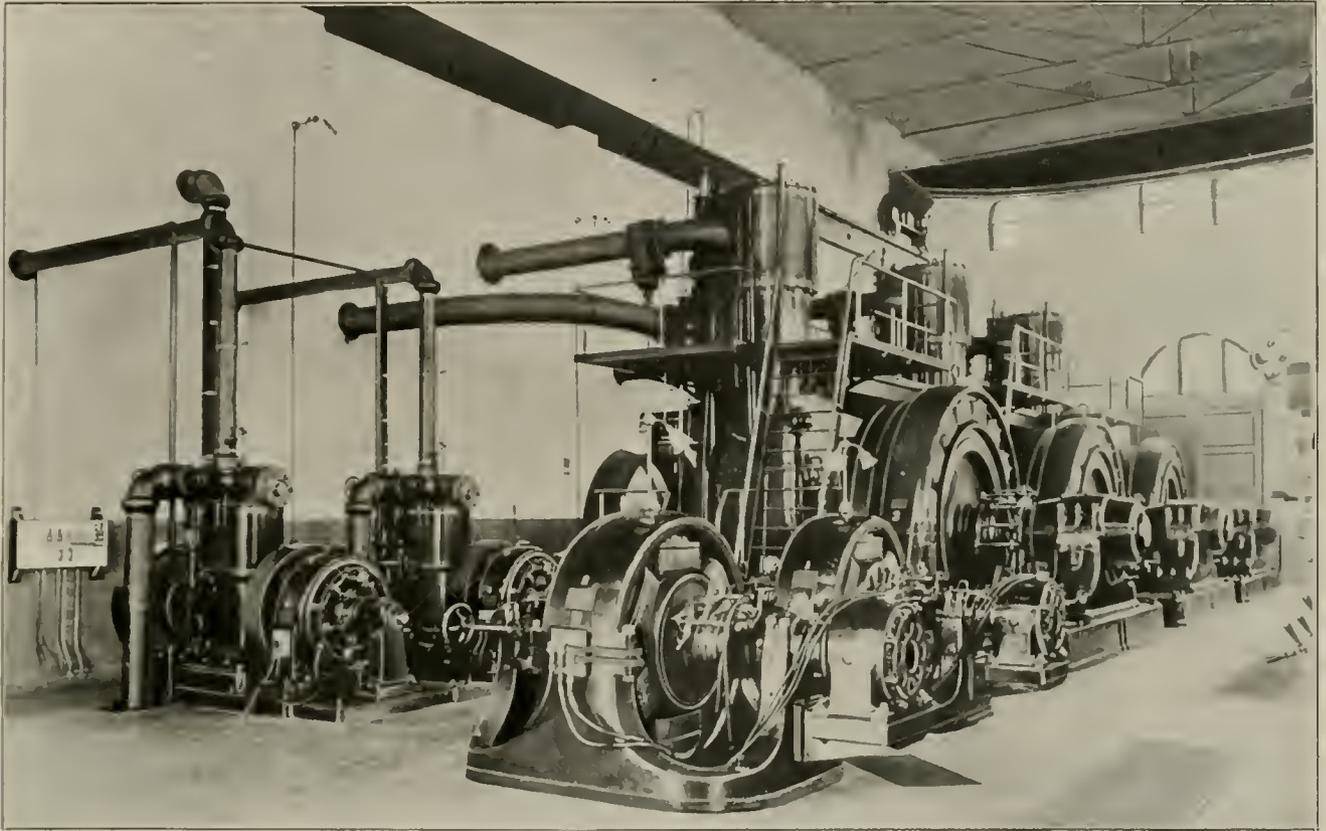

- THE RAPID RY.—Chartered March 1, 1894.
- THE DETROIT, MT. CLEMENS & MARINE CITY RY.—Chartered March 22, 1899, under the laws of Michigan. On Dec. 30, 1899, the company purchased all the properties of the following two companies:
  - MT. CLEMENS & LAKE SIDE TRACTION CO.—This company was organized June 30, 1895, as a consolidation of the Mt. Clemens Street Railway Co., Ltd., and the Mt. Clemens Lakeside Electric Street Railway & Dock Co., which two companies owned franchises in the city of Mt. Clemens, granted at various dates between 1890 and 1895.
  - THE DETROIT & RIVER ST. CLAIR RY. This company was organized Aug. 17, 1895. A receiver was appointed Jan. 9, 1897, and was discharged Dec. 31, 1899, at which time the property was purchased by The Detroit River & St. Clair Ry.
- THE PORT HURON, ST. CLAIR & MARINE CITY RAILWAY CO.—This company was organized Apr. 12, 1899.

- CITY ELECTRIC RAILWAY CO. OF PORT HURON.—This company was organized May 19, 1892.
- THE RAPID RAILROAD CO.—Organized Jan. 6, 1898, to build a connection between the Rapid Ry. and the Grand Trunk R. R. (For additional particulars see text.)
- THE CONNOR'S CREEK & CLINTON RIVER PLANK ROAD CO.—Organized Dec. 17, 1895. On Mar. 24, 1897, the company purchased all the rights and property of the DETROIT & ERIN PLANK ROAD CO., which had been organized on Feb. 7, 1857, as a consolidation of the Detroit & Erin Plank Road Co. (organized Apr. 3, 1848) and the Erin & Mt. Clemens Plank Road Co. (Organized Mar. 20, 1859.)
- DETROIT & LAKE ST. CLAIR RY.—Organized on Mar. 23, 1900, and on Mar. 24, 1900, purchased all the rights and property of the Detroit, Lake Shore & Mt. Clemens Ry., which had been organized in 1897, and built what is now the Shore Line Division of the Rapid Railway System.

The water for condensing purposes is taken directly from the end of the slip near the boiler room, through a 14-in pipe.

The engine room is 100 ft. by 42 ft., and contains three Westinghouse tandem compound engines 21½-in. and 37 in. x 22 in., sometimes designated as the World's Fair type. These are direct connected to three Westinghouse three-phase alternating current

For this purpose there are seven 400-kw. static transformers located in the basement of the engine room. These are connected in star connection. Three are used for the north line, three for the south line, and one is held in reserve. The generators, transformers, rotary converters, and lightning arresters are all of standard Westinghouse type. The engine room is provided with a

INTERIOR OF RAPID RAILWAY CENTRAL STATION—NEW BALTIMORE.

generators, rated at 500-kw. capacity, but capable of standing all the load that the 1,000-h. p. engine can carry. There are two exciter sets, each consisting of a 40-kw., 110-volt direct current generator direct connected to a Westinghouse compound engine. Each exciter is large enough to excite all three main generators and also light the entire building and grounds.

steam air compressor, and also with a traveling crane of 40,000-lb. capacity.

There are six sub-stations, counting the sub-station machinery in the main power house. These are located at Roseville, Mt. Clemens, New Baltimore, Algonac, Marine City and St. Clair. These stations are all substantial brick buildings, built for this

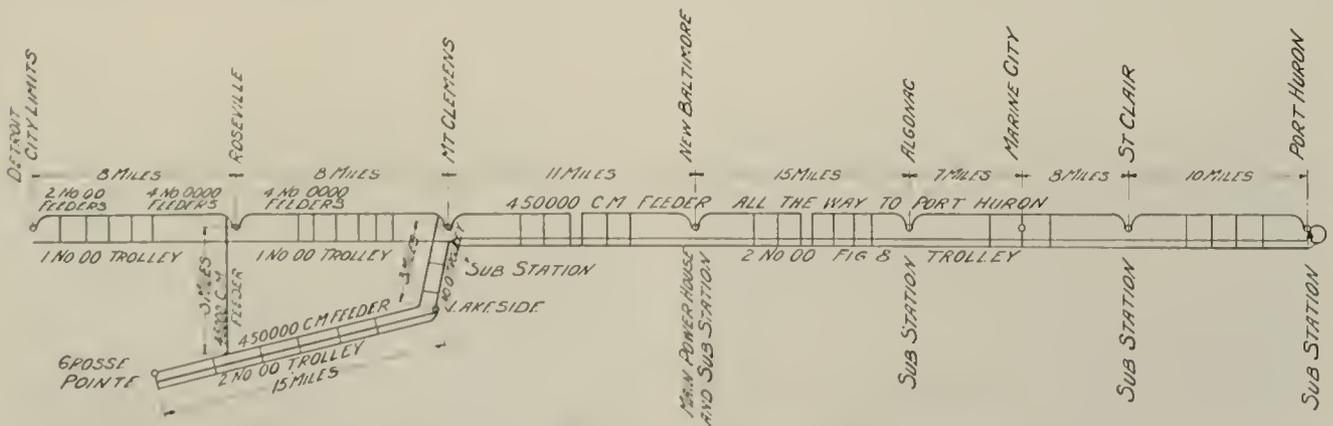

DIAGRAM OF LOW TENSION COPPER RAPID RAILWAY SYSTEM.

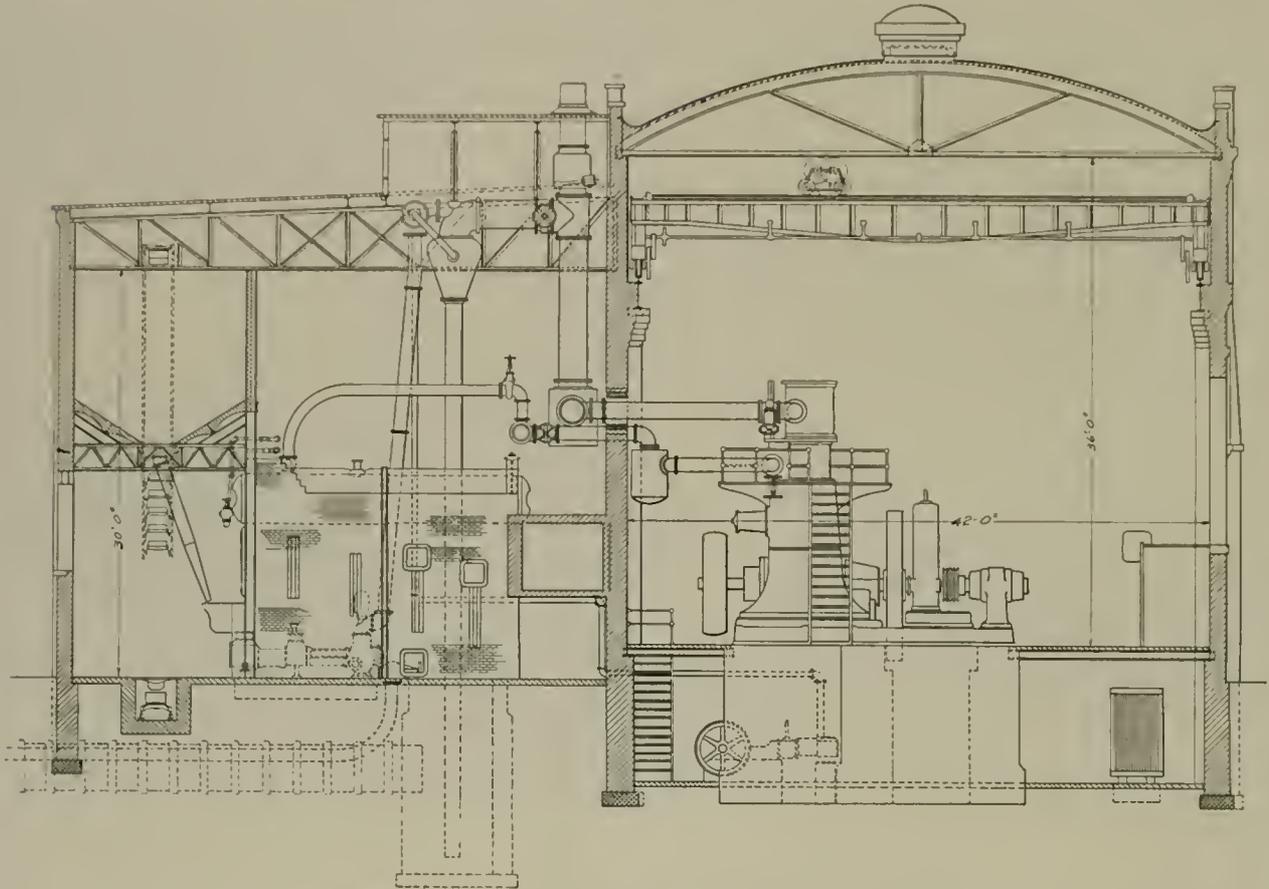

In the engine room there are also two 200-kw. rotary converters for supplying direct current to the trolley near the power house. These take alternating current directly from the bus-bars of the main switchboard. The alternators generate three phase current at 300 volts, and thus, after passing through the main switchboard, is stepped up to 10,000 volt for transmission to the sub-stations.

purpose, and most of them contain, in addition to the machinery room, a freight ware room, passenger waiting room and ticket office. The station at Roseville contains three 200-kw. rotary converters and six 150 kw. static transformers and the necessary switchboard. The high tension wires entering the building pass first through the choke coils and lightning arresters and then

through six high tension fused pole switches to the six transformers.

These transformers are connected in star connection and are grouped in two banks of three each and by means of the high tension switches and corresponding knife switches on the secondary side, either bank alone or both can be put into service. The transformers are of the oil cooled type, the coils being im-

sometimes it is hard to tell that any machinery is in operation. The floor in this station, and, in fact, in all the sub-stations, is hard maple, kept well oiled. This is considered much better, both in appearance and cleanliness, than concrete, for this type of station. Two men are required to run each sub-station, one on each watch. In addition to caring for the machinery these men act as station agents, selling tickets and attending to the general freight business.

CROSS SECTION NEW BALTIMORE STATION - RAPID RAILWAY.

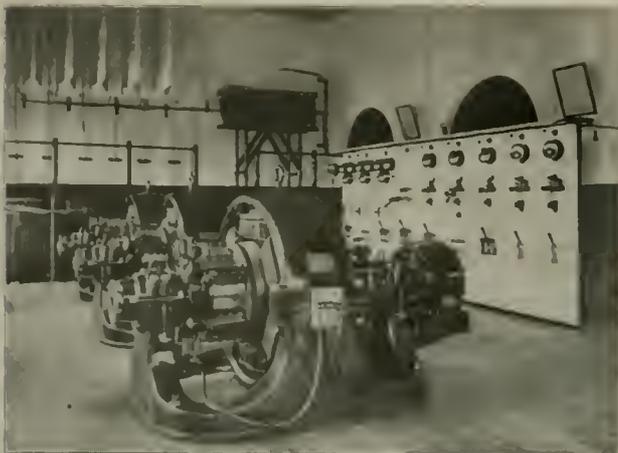

mersed in special transformer oil, contained in a corrugated iron case which radiates the heat rapidly. The temperature of these transformers rarely rises above 125° F., even on hot summer days.

The rotaries receive the three-phase alternating current at 390 volts and deliver direct current at about 600 volts. The pressure on the direct current side can be varied slightly by means of the field rheostat. All the rotaries are bolted to solid brick foundations, resting on a concrete sub-base, and they run so quietly that

The sub-station at Mt. Clemens is in the same building with the dispatcher's office, and the dispatchers look after the machinery. There are two 200-kw. rotaries and three 150-kw. transformers in this station; otherwise it is the same as Roseville.

The rotaries at New Baltimore are in the main power house and have been described.

Algonac is the next station, going north along the line. This is in the same building with the passenger and freight rooms, and

ROSEVILLE SUB-STATION - RAPID RAILWAY.

INTERIOR OF ALGONAC SUB STATION - RAPID RAILWAY.

is looked after by the station agents. Here there are two 200-kw. rotary converters and three 150-kw. transformers. Part of the time it is necessary to run both of these machines, but for the greater portion of the day one is sufficient.

St. Clair is the next going north, and is similar to Algonac in regard to operation by station agents, but it contains three 200-kw. rotaries and six 150-kw. transformers. Two of these rotaries are run all the time and one is held in reserve.

The last station is in Port Huron, at the extreme north end of the line. This station has just been installed, and it is the intention to furnish power from here for the Port Huron city system as well as the interurban cars. There are two 200-kw. rotaries and three 150-kw. transformers here, but there are foundations in for two more rotaries and three more transformers which may be installed later. This station is in the same building with the city ticket office and freight ware room, and the offices of the general superintendent and division superintendent are also here.

Line.

There is a carefully constructed high tension line about 60 miles long connecting these various stations with the main power house. This is divided into two entirely independent sections, north and south of the main power house respectively, and these are independent, even including the step-up transformers at this point.

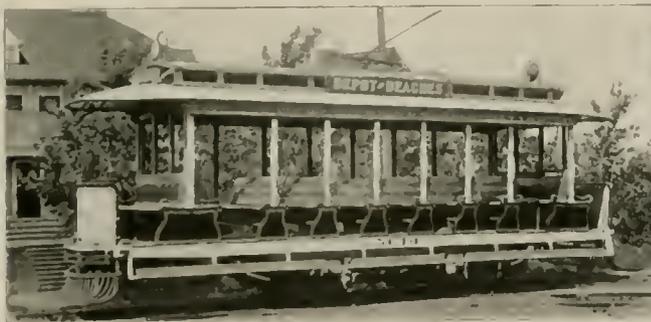

In addition to this, the high tension line can be opened at any sub-station, cutting out the line beyond that point, so that in case of trouble on the line one or two stations can still be operated, and at the same time the trouble is in this way very quickly located. The high tension wires are for the most part, on the same poles carrying the trolley and feeders.

The standard construction is a 35-ft. pole, with a 7-in. top. There is a 7-ft. cross arm at the top for the high tension wires, and a 5-ft. cross arm for the direct current feeders, placed 4 ft. below the top arm. Two of the high tension wires are carried on the arms

150-FT. MASTS CARRYING HIGH TENSION LINES OVER PINE RIVER RAPID RY.

Through Mt. Clemens and Marine City, the high tension line leaves the main line and is carried around the city on an independent pole line, in order to avoid the high trees, buildings, etc., in the central part of the town.

CARS FOR CITY SERVICE IN PORT HURON LACLEDE CAR CO.

and the middle wire is mounted directly on top of the pole. Locke porcelain insulators are used, some being No. 3 and some No. 4, the latter being considered the better. These insulators are carried on iron pins with a wooden thread and a porcelain base or sleeve surrounding the iron bolt. The wires are not arranged in an exact equilateral triangle, but they are transposed about every three

In St. Clair it was necessary to cross Pine River, a navigable stream, up which large vessels pass, having masts sometimes more than 120 ft. high. Rather than put submarine cable under this river for the high tension current, two poles were erected, one on each side of the river, each 150 ft. high and about 220 ft. apart, and the wires are carried on these.

The distribution of the direct current from sub-stations to cars is effected by a system of trolley and feeder wires. From Mt. Clemens to Port Huron on the main line there are two No. 00 trolley wires of Figure 8 section, and one bare-stranded copper feeder of 450,000 c. m. The trolley wires are carried on 9-ft. iron brackets, except through towns, where span wire construction is followed.

The feeder is carried on a cross arm placed 4 ft. below the high tension arm, and is tied to glass insulators on oak and locust pins. This feeder runs practically the entire length of the line, and is brought into the switchboard at each sub-station through two feeder panels. There are no taps between feeder and trolley within a mile of each sub station. This not only gives a very uniform distribution of power, but is much easier on the rotaries than would be the case were there a short connection made between the trolley and rotary. It is practically impossible to get an absolutely dead short circuit on the machines. There is a circuit breaker in the trolley in front of each sub station shunted by a heavy switch mounted on the pole. In normal running this switch

RAPID RAILWAY PASSENGER CAR—G. C. KUILMAN CAR CO.

miles. No. 1 bare copper wire is used for the entire distance for the high tension line, and the loss, at 10,000 volts, is practically negligible.

is closed, so that the trolley is solid from one end of the line to the other, but in case of trouble it can be cut up into sections.

From Mt. Clemens to Detroit, on the main line, there is but one trolley, and there are from one to four No. 0000 feeders instead of the one large one, but the general construction is the same as north of Mt. Clemens. The trolley wire is about 10 ft. from the ground, and is attached to the hangers by clunch ears almost entirely. Mechanical clips were used at first, but these are being replaced with the clunch ears as fast as possible. In the Figure 8 trolley the joints are made with a riveted splice.

#### Car Equipment.

The passenger car equipment consists of 12 cars 55-ft. long over all and 9-ft. wide, and 18 smaller cars about 40 ft. long over all.

LINE CAR RAPID RAILWAY SYSTEM.

The large cars are used for through service on the main line, and the smaller ones for intermediate service, more local in character. Besides these there are in Port Huron City service 16 single truck open cars and 13 single truck closed cars, and in Mt. Clemens city service 2 single truck closed cars and one single truck open car. These single truck cars are from 25 to 29 ft. long over all. Of the long cars part were built by the G. C. Kuhlman Car Co. and part by the Barney & Smith Car Co.

All the interurban cars are equipped with air brakes, each car having an independent motor compressor. There are 10 Westinghouse air brake equipments, consisting of Westinghouse rotary

follows: Four No. 76 Westinghouse motors, with L-4 controller; four No. 38B Westinghouse motors with K-14 controller; two No. 76 Westinghouse motors with K-13 controller, and two 75-h. p. Walker motors with Walker controller.

The two No. 76 motors are mounted both on the rear truck while the two 75-h. p. Walker motors are mounted one on each truck. The four No. 76 motors are given the most severe service.

An accurate record is kept of the mileage of each car, and it has been found that a car will make 15,000 miles on one set of armature bearings before getting dangerously low. A medium weight grease is used in these bearings and grease is applied about every 50 miles while the car is running.

There are three different kinds of trucks in use under the large cars, i. e., Du Pont, Barney & Smith and Brill No. 27. A standard wheel has been adopted for all future use. This has a 3-in. tread with a small bevel on the edge, a 5 $\frac{1}{8}$ -in. flange, and weighs 580 lb. for a 36-in. wheel.

In addition to the passenger equipment there is an extensive freight and construction car equipment. There are four baggage and express cars. These resemble as nearly as possible in external appearance the regular passenger cars. They are equipped with four 50-h. p. motors each.

There are about 24 flat cars which are used in general construction work and in the fall these are fitted with sides 5-ft. high and are used to haul sugar beets, there being two beet sugar factories along the line, one at Marine City and one at Mt. Clemens, and the handling of the beets is an extensive undertaking.

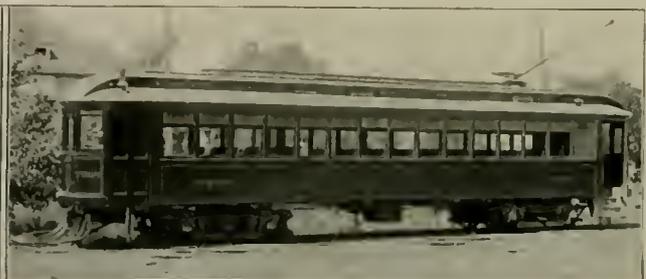

There are two single truck construction cars with motor equipment which are used for general hauling, and two line construction cars. All the line work on the 100 miles and more of line is done with these two cars, each manned by two men. In addition to this car equipment, the road owns two locomotives, ten freight and a way car, used in the steam freight business.

The repair shops are located at Roseville, and embrace a machine shop, carpenter shop, armature room, black-smith shop, storage room, etc. The machine shop contains two good lathes, two drill presses, a shaper, emery wheels, etc., etc.

The armature room contains two coil winding machines, a press for shaping field coils, several hand presses for armature coils, a special machine for bending flat ribbon used in Walker armatures and the usual bench tools and banding reels.

There are five car houses along the line, located as follows: One brick barn at Roseville, capacity about 10 large 55-ft cars; one brick barn in Mt. Clemens, capacity four large cars; one iron shed near Mt. Clemens, capacity 12 to 16 large cars; one frame barn at Marine City, capacity six large cars; one large brick and iron barn in Port Huron, capacity about 30 large cars.

The officers of the company are as follows: President, J. C.

MAIL AND PASSENGER CARS RAPID RAILWAY SYSTEM BARNEY & SMITH COMPANY.

motor-driven air compressors, and the rest are those of the Christensen Engineering Co., of Milwaukee. Each car is provided with a traveling trolley carriage and stand, by means of which the trolley stand can be moved from one end of the car to the other on an angle-iron track. This device is handled by H. L. Walker Co., Detroit, and is described elsewhere in this issue. All the cars are heated with the Peter Smith hot water heater, which has proved to be a very satisfactory and a very cheap method of heating. A self-oiling trolley harp and wheel is used which has given very good service, the life of some wheels being over 10,000 miles.

There are four different styles of motor equipment in use, as

Hutchins; vice-president, F. W. Brooks; treasurer, Geo. H. Russell; general manager, F. W. Brooks; general superintendent, W. O. Wood; chief engineer, A. C. Marshall; division superintendents, F. C. Hill, C. A. Culver; road master, A. N. Paisley; general foreman motive power and car department, Chas. Mear.

#### PERSONAL.

Mr. F. W. BROOKS began his railroad experience immediately after leaving college, in 1882. In that year he entered the engineering department of the New Orleans & Pacific Division of the Texas & Pacific R. R., and remained with this road during its construction. He left this service to take up a similar position

with the V. S. & P. Division of the Queen & Crescent Route, during its construction. He was then appointed to a responsible position with the Yazoo & Mississippi Valley R. R., which was afterward acquired by the Illinois Central R. R., and remained in this service for some time, afterward entering the operating department. He remained in this connection some eleven years, resigning in 1895 to take charge of the Rapid Railway property. He now holds the office of vice-president and general manager of the entire Rapid Railway System.

Mr. W. O. WOOD, general superintendent, began his railway career in 1885, with the Louisville & Nashville R. R., and was employed in various positions in the operating and engineering

mechanical equipment on the entire property. Mr. Marshall is a graduate from the electrical engineering course of the University of Michigan, class of 1893, and during the past ten years has had extensive experience in electric lighting and railway work, in both constructing and operating departments.

MR. CHARLES MEAR is general shop foreman and has charge of all shop employes and all repair work.

MR. F. C. HILL, division superintendent, entered the service of the Port Huron, St. Clair & Marine City Ry. in September, 1898, in charge of construction forces. After this road was completed he was appointed assistant superintendent, and on Jan. 1, 1902, was promoted to the office of division superintendent.

CHARLES MEAR,  
General Foreman.

F. C. HILL,  
Division Superintendent.

A. N. PAISLEY,  
Roadmaster.

C. A. CULVER,  
Division Superintendent.

departments until July, 1889. He then became chief clerk in the general manager's office of the J. T. & K. W. system, at Jacksonville, Florida, remaining until April, 1890. He then served as secretary to the general manager of the L. N. O. & T. R. R. until October, 1890. From October, 1890, until July, 1897, he was engaged in the service of the Illinois Central R. R. as secretary to the second vice-president, J. T. Harahan, and as chief clerk in various offices of the operating department. In July, 1900, he resigned the position of trammaster on the Illinois Central, which he had filled for three years, to enter the service of the Rapid Railway System.

Mr. A. C. MARSHALL, chief engineer, has full charge of the

MR. CHARLES A. CULVER, division superintendent, became connected with the Rapid Ry. in 1896, as conductor. He was promoted to the office of assistant superintendent in March, 1900, and was made division superintendent July 1, 1901.

MR. A. N. PAISLEY, roadmaster on the Rapid Railway System, entered the railway service in 1885 as brakeman on the F. & P. M. R. R. He was employed in this capacity and as a laborer on track for two years, and as section foreman and as foreman of construction until 1899, when he entered the service of the Rapid Railway System as foreman of construction. He was appointed roadmaster in 1900.

EXPRESS SERVICE IN DETROIT.

Extract from article written for the "Street Railway Review" by George W. Parker, General Passenger and Freight Agent, and published in the "Review" for Jan. 15, 1902, page 25.

There are now 15 electric express cars, each from 35 to 40 ft. long, on the electric railways which center in Detroit, and serve the territory within a radius of 60 miles, giving all the various towns in that territory from one to three deliveries per day.

The business is all handled from a central depot near the heart of the city. For convenience a separate company known as the Electric Depot Co., was organized to erect and operate this depot, the various interurban companies doing business with the Electric Depot Co. in about the same way as steam roads now secure terminal facilities in all the leading cities through a Union Terminal company. The expense of the electric express depot are pro-rated to the various parties to the contract on a strict tonnage basis

G. W. PARKER

(irrespective of mileage), the parties using the depot being the interurban line controlled by the Detroit United Ry. (including the Rapid Railway System), and the Detroit, Ypsilanti, Ann Arbor & Jackson Ry. Each company furnishes its own cars and crews.

On the several divisions of the Detroit properties, agents have

been placed at principal points. Some are on a salary and others on commission, this depending in a measure on the size of the town and the prospective business. Experience has demonstrated that better results can be obtained on the salary basis. Where it has been found necessary to establish agents, they have been started on commissions, the change to salary being made when the agency has been developed to a certain standard. Where no agents are located, such as prepaid stations, small combination express and waiting room shelters have been erected, where the express and freight can be placed under cover until such time as owners call for it. All shipments for these prepaid stations are accepted entirely at owner's risk of delivery, and are so receipted for. The idea is to relieve the electric road of all responsibility for delivery after freight has reached its destination.

The milk business has also grown rapidly, and in order to properly handle it, it has been found necessary to operate special milk cars on the several divisions, which cars leave the outer terminal of the line the first thing in the morning, and pick up milk all the way into Detroit. The milk traffic is handled on regular milk tickets, which are all consecutively numbered and taken into account through the cashier's office. These tickets resemble an ordinary shipping-tag; they are perforated in the middle, the lower portion being detached by the conductor carrying the cans when filled, and the other portion being left on to pass the empty cans on return trip. This ticket is printed, showing the point of shipment, destination, shipper and to whom consigned, this information being on both portions of

INTERIOR ELECTRIC EXPRESS DEPOT, DETROIT.

ticket, eliminating the possibility of errors in delivery of cans when either filled or empty. These tickets are charged for at so much per ticket, according to the distance the milk is to be hauled.

The company's baggage business is increasing rapidly. Trunks are carried in the regular express cars at a flat rate of 25 cents, irrespective of distance. Arrangements have lately been made with a local transfer company in Detroit whereby baggage is transferred to any depot or steamboat landing or to any house address upon payment of 25 cents additional, the railway company and the transfer company issuing a joint check for this purpose. This ticket is 6½ in. long by 2 in. wide, and is divided by perforated lines into three divisions. One division is detached by the conductor of the express car; the second is detached by the driver of the transfer company, and the third, or "strap check," remains attached to the baggage until claimed. The railway company collects the whole amount of 50 cents for each piece of baggage carried, and at the end of each month redeems from the transfer company all checks in the latter's possession at 25 cents each.

A description of all the blanks used in the express department,

STANDARD FREIGHT AND EXPRESS CAR.

with reproductions of the various forms, will be found in the article referred to, published in the "Review" for Jan. 15, 1902.

The express department, except for the Detroit, Ypsilanti, Ann Arbor & Jackson Railway Co., is under charge of Mr. George W. Parker, lately connected with the Grand Trunk Railway system at Pittsburg, who is general express and passenger agent, and Mr. Albert Eastman, who has had considerable experience with the Grand Trunk and Michigan Central roads and who has recently

LOADING PLATFORM, EXPRESS DEPOT, DETROIT.

been appointed traveling express agent. The electric express depot at Detroit has been placed under the supervision of Mr. A. R. Patterson, as joint express agent. Mr. Patterson has had years of experience in local office work with the Michigan Central and consequently he is well fitted for the management of this depot.

### SPEED, POWER AND EFFICIENCY CURVES.

BY E. J. BURDICK, ASSISTANT SUPERINTENDENT OF MOTIVE POWER, DETROIT UNITED RY., IN CHARGE OF OVERHEAD DEPARTMENT.

When the Detroit United Ry. took over the several interurban roads there was a continual demand from the operating and mechanical departments for information bearing upon the speed, power consumption and efficiency of the different car equipments. It was found upon investigation that there were but little practical data obtainable upon this subject, and there was but one thing to do. Consequently we started in to test out our different apparatus, and after several cut-and-try methods we adopted as a standard the curves reproduced herewith, as obtained from car No. 12 on the Flint Division. These are fair samples of the different tests we have made. Our tests are made upon cars in regular service, and give us data of great value, not only in car, power house, and line operation, but also in determining to a certain extent the size of equipment necessary, and the advisability of making cuts and fills upon our right of way to overcome objectionable power-consuming grades. Hence, we claim that a practical car test made over every division, is the keynote to the whole interurban railway proposition from an operating standpoint.

Our tests are all made with instruments of standard manufacture which are frequently checked for accuracy. It will be noticed upon the curves of car No. 12 that the power comes from three different sources. From the City Hall to the six-mile road, the line is fed by the main power house, located in the city; the length of the feeders is practically 7¼ miles. From the Six-mile road to Royal Oak, about 5½ miles, the line is fed from the power house at Birmingham, upon the Detroit & Pontiac Division. From Royal Oak to Rochester, 14.6 miles, current is fed from the power house located in Rochester, this section being handled by the help of a series booster. At Rochester is also located an inverted rotary which feeds into the high tension alternating current lines which run north to sub-stations located at Oxford and Atlas, a distance of 13½ and 31 miles respectively. The Oxford sub-station rotary

E. J. BURDICK,  
Assistant Superintendent Overhead  
Construction.

feeds directly into the line at 600 volts, and equalizes upon the line running south with the direct current from the Rochester power house at a point intermediate, depending upon the relative position of the load. The Atlas sub-station is also equalized upon the line with the Oxford sub-station.

The curve immediately below the feeder distribution plan shows the deviation from uniform schedule, and also the average speed in miles per hour. Both curves are laid in by space averages taken at every mile post.

The integrating wattmeter curve is taken in practically the same manner, but owing to the inability to read small variations, does not show the irregularity in power consumption that actually exists. The volt and ampere readings were taken every 10 seconds, and plotted in the curves on minute averages.

COMPARATIVE CAR TESTS—FLINT DIVISION.

Date	Car	Time, hours	Stops	Stops per mile	Total Kw. h.	Kw. h. per mile	Watt-hours per ton mile
Feb. 25, 1902	No. 10	3.57	43	.65	111	1.64	49.6
July 24, 1902	No. 12	3.25	41	.60	113	1.68	50.9

The cars were each 51 ft. long over all, 8 ft. 9 in. wide, equipped with four Westinghouse No. 56 motors and K-14 controllers, mounted on Brill No. 27 trucks and weighed 33 tons.

Full data regarding the car tested will be found beneath the curves. In the small table will be found the results of two tests taken at different times.

It is found that there is a great deal of detail work preparatory to these tests, such as checking of all instruments and thoroughly instructing all assistants who take readings and make observations, as to just what their duties are, and impressing upon them the necessity of each one doing his duty—nothing more and nothing less. Upon these instructions depends the entire success of the test, as during the progress of the test there is no time for explanations or extra readings.

In closing I wish to state that I hope in the near future this subject will receive a greater amount of consideration than it has in the past. I am firmly convinced that actual running tests upon apparatus in regular service is what the average general manager and electrical engineer is after.

## THE ELECTRIC RAILWAY TRAVELING EXPRESS AGENT.

BY A. EASTMAN, TRAVELING EXPRESS AGENT, DETROIT UNITED RY.

To properly represent his company, and to be able to deal intelligently with all matters pertaining to the handling of express traffic by electric car, a knowledge of the general rules of transportation is the first and most important requirement of a traveling express agent.

He is the connecting link between the company and the patrons of that department, incidentally receiving complaints from patrons of all imaginary wrongs, and making an effort to adjust to the satisfaction of both company and patron all actual grievances or existing wrongs.

It is also very essential that the traveling express agent shall have as extensive and favorable an acquaintance, as possible, with the business men and shippers at all points reached. The day of obtaining traffic for your company through the medium of a "jolly" is past, and in order to obtain your proportion of the business you must be able to show the prospective patrons some good reason why they should patronize your line. This is particularly hard to do in towns where the service of other transportation companies has already been established, and continues satisfactory. Unless you are in a position to give a better service than your competitors you cannot expect a business house or shipper to route shipments your way.

Even should your line offer no inducements by way of reduced rates, or a more frequent service, one point still remains that will recommend itself to your prospective patron; namely, that the Electric Express Co., being exclusively a local institution, the combined efforts of all persons employed in that department, from

general express agent down to messenger, are being exerted towards perfecting as complete a local transportation company as possible. Giving all their time and attention to the local traffic the result should be a very satisfactory service to the shippers and merchants in the smaller suburban towns, and a service that should be highly appreciated by all dealers in the larger towns and cities reached; also from the fact that the head of the department can be reached and arrangements entered into much more readily than can be done with the larger transportation companies.

After becoming acquainted with the prospective patron and making it clear, for the reasons just outlined, and as many others as can be mentioned, why your company should receive the preference over your competitors, and taking it for granted this prospective patron is willing to have his future shipments come via your line, a signed routing order, such as shown in the accompanying illustration, should be obtained. This is simply a signed order on shipper by consignee asking that all future shipments be forwarded via your line, and is very important, as shippers will always respect the request of a buyer as to the route goods are to be forwarded, and will decline to change routing, unless requested to do so by the buyer.

A. EASTMAN.

Having obtained a routing order from the consignee, and placed it with the consigner, you should make an effort to see that such shipments are properly handled, and continue to move over the road you represent. The latter information should be obtained from the local agent, as he is in a position to know the moment any of your business is being diverted to some other line, and should keep you well informed on this point.

The closest possible relations should exist between the traveling express agent and local agents, as it requires their co-operation to obtain new business and retain same after it has been acquired.

As the business transacted on electric lines is exclusively local, the company cannot afford to engage an experienced local express agent at all points, or, in other words, cannot afford to pay a salary large enough to permit the local agent to devote his entire time and attention to the Electric Express Co.'s interest. This makes it necessary that the traveling express agent shall call on local agents as often as possible, and give whatever information and assistance are required to keep both business and station accounts in as good shape as possible.

The traveling express agent should also do everything possible to keep posted, and in turn advise the head of his department, of all prospective shipments, and make an effort to obtain such shipments for his company. This can be done in various ways. The first and best way is to see the party controlling the routing of such shipments, and explain why his company should receive the preference.

One of the most worthy points to bring forward is the fact that electric express cars are so built and equipped as to make it much safer to ship goods liable to damage by breaking, etc., via the electric line.

If possible to do so, call on farmers and local dealers, and place before them the advantages of shipping their produce to the cities via electric cars, as compared with the usual manner of hauling by wagon, or sending by regular express companies.

The traveling express agent can also call on dairymen, and if a milk service is given, show them the advantages of shipping on an electric car passing, in many cases, in front of their farms, and putting the milk in the city in from one to two hours, thereby saving time and money ordinarily spent in taking the milk to regular depots.

Last, but not least, the traveling express agent should keep before patrons that as the traffic carried is exclusively local, and the Electric Express Co., being a strictly local institution, and having no through traffic to fall back on, it is very necessary that in order to maintain a satisfactory service, or, in fact, any service at all, the Electric Express Co. must receive the patronage of the local mer-

chant and shipper, and there are few business men, local dealers, or farmers, who do not realize that competition is the life of trade, and that the electric express has solved for them a question that has long been a perplexing one, namely, furnishing the farmer a means of delivering his produce into the heart of the city, and in the markets with the least possible delay and in first-class condition, and afford-

ing the wholesale houses the same means of placing the daily necessities of life in the small suburban towns, and at the country cross-roads and farmers' homes, making it possible for the farmers to sell their produce at a better margin than heretofore, and buy in turn their daily necessities and luxuries at a greatly reduced price, owing to the avoidance of the usual long haul from the railroad station.

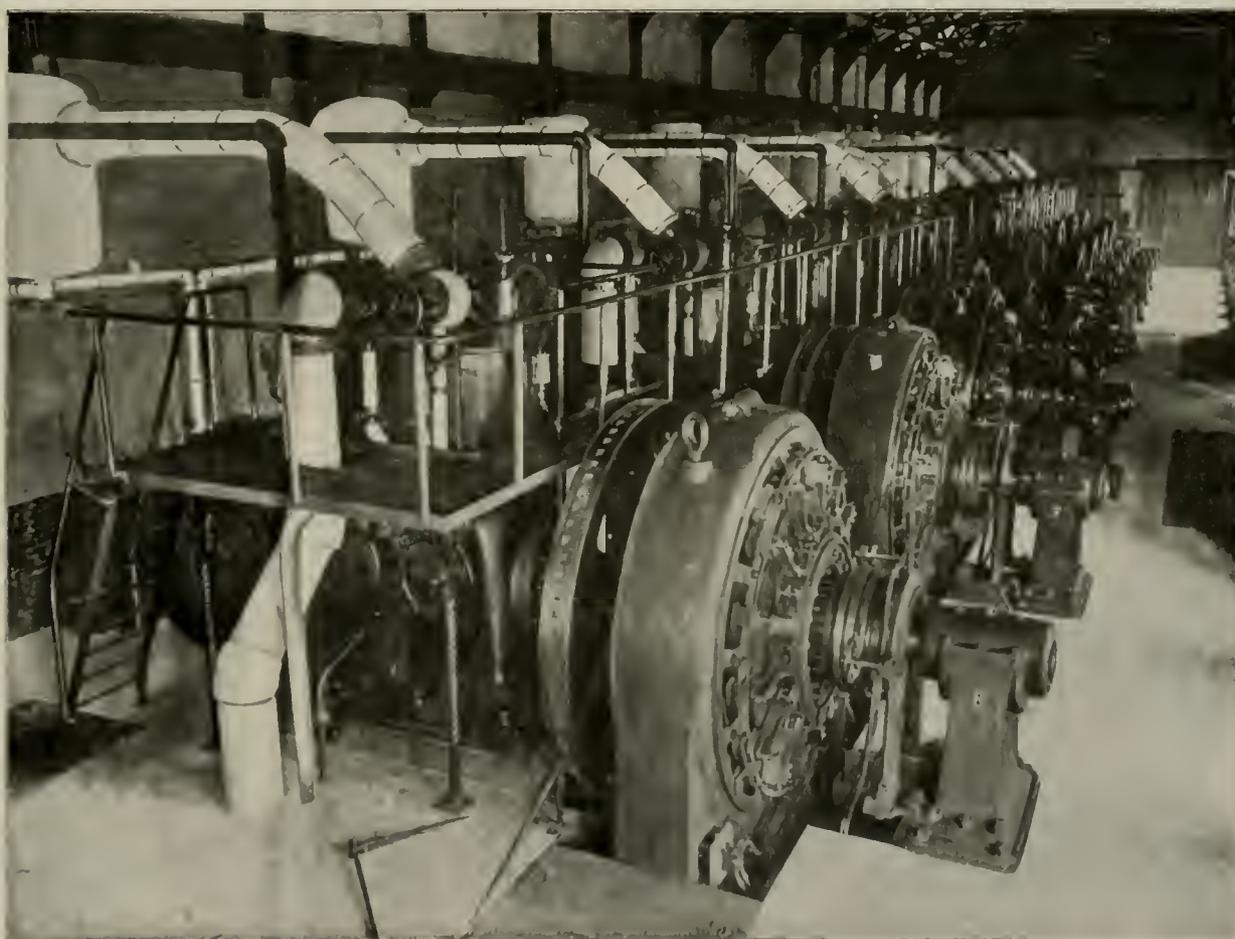

## The System of the Detroit, Ypsilanti, Ann Arbor & Jackson Railway.

BY F. E. MERRILL, MANAGER.

The Detroit, Ypsilanti & Ann Arbor Ry. was probably the pioneer long distance electric railway in this country, it being the first inter-urban road to construct 40 miles of track. The company was organized in 1897, and on December 24th of that year the first 10 miles of road was in operation from Detroit to Dearborn. During the summer of 1898 the line was extended to Ann Arbor, an addition of 30 miles. During the season of 1899 the Ypsilanti and

being one of the oldest towns in the state, having been settled in 1705. Located within its borders is a large sanitarium known as St. Joseph's Retreat, which accommodates 500 patients; the beautiful grounds and buildings make it one of the distinctive features of the village.

Eloise (the seat of the Wayne County House), is a pretty little station located on a miniature lake 15 miles from Detroit. The

INTERIOR DETROIT, YPSILANTI, ANN ARBOR & JACKSON POWER STATION WESTINGHOUSE ENGINES AND GENERATORS.

Saline line was built; this extension of 10 miles combined with the City Ry. in Ann Arbor, which had been purchased, made up a system of 60 miles of road.

In January, 1901, the Detroit, Ypsilanti, Ann Arbor & Jackson Ry. was incorporated and acquired the property of the Detroit, Ypsilanti & Ann Arbor Ry. An extension to Jackson, about 40 miles, was built during the summer and fall of 1901.

The road from Detroit to Ann Arbor is constructed in the highway along what is known as Michigan Ave. West of Ann Arbor the construction is on private right of way.

Many interesting features along the route are well worthy of attention. The village of Dearborn is a picturesque town 10 miles from Detroit, with a population of 1,000, and has the distinction of

surrounding country and the public buildings make this a particularly attractive spot, which is visited daily by excursionists.

Wayne, 18 miles from Detroit, is an enterprising town of 2,000 inhabitants; large manufacturing interests are located here, including a carriage works employing about 300 men. The town has a number of brick business blocks, several churches, fine schools, parks, etc. It is also on the line of the Pere Marquette railroad, and through connections for the North and South are made with the electric cars.

Ypsilanti, the next place of note, is 30 miles from Detroit. The large and modern power house and car barns of the company are located here. This city has a population of 8,000, and is situated on the banks of the picturesque Huron River. Its manufacturing in-

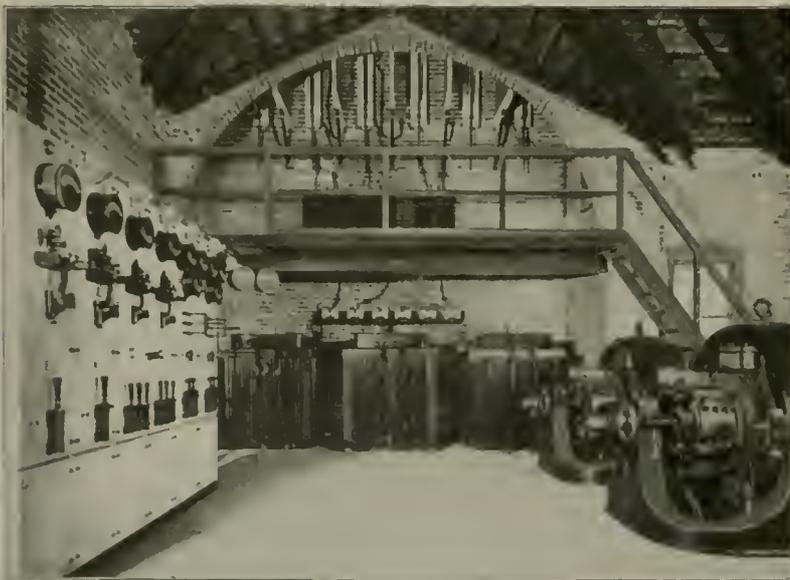

terests are many and varied. The fine buildings of the State Normal College occupy a commanding site overlooking the city, the attendance at this popular school averaging 1,200. The Cleary Business College, with an attendance of 300, is another educational institution attracting students from all parts of the state.

OFFICE BUILDING YPSILANTI LINE.

Ann Arbor, 40 miles west from Detroit, is first of all a university town. The University of Michigan, with its 4,000 students, ranks with the leading universities of the country, its beautiful art gallery and fine library; its museum and modern gymnasium being some of its attractions. Nature and art have combined to make Ann Arbor an unusually beautiful city. There are also many manufacturing industries.

Chelsea is a pretty village of 2,000, 54 miles west of Detroit, embracing a number of manufacturing plants, and is noted for its beautiful homes. The people are very enterprising and have succeeded in making their town a modern one, with electric lights, etc.

INTERIOR OF SUB-STATION.

The visitor is impressed by the up-to-date business blocks and general appearance of prosperity.

Grass Lake is located 59 miles west of Detroit. It is a very pretty town, and its population of 1,000 is made up largely of retired farmers and general business men. It has two factories which em-

ploy about 100 men. The town derives its name from the lake near which it is situated.

Jackson, the western terminus of the line, has a population of 25,000, not including those temporarily disfranchised and involuntarily confined within the walls of the State Penitentiary, located here. Jackson is a railway center for several of the great trunk lines of the west; it has large manufacturing interests and is a modern city.

The territory traversed by the lines of the Detroit, Ypsilanti, Ann Arbor & Jackson Ry. is one of the richest and best agricultural sections in the state, and all of the adjacent property is under a high

SUB-STATION, SHOWING TOWER FOR HIGH TENSION WIRE.

state of cultivation, and the fruit shipments add materially to the revenues of the railway.

#### Track Construction.

The total mileage is about 100 miles of single track of standard steam railroad construction. The track is laid with 75-lb A. S. C. E. standard T-rails, with 42-in. angle bars on 8-ft. cedar ties, 2 ft. c. to c., gravel ballasted. There are two substantial steel bridges at crossings over the main line of the Michigan Central R. R., one over the Rouge River, and one over the Huron River.

#### Rolling Stock.

The rolling stock consists of 33 closed cars and four open cars built by the Barney & Smith Manufacturing Co., of Dayton, O. The length of these cars is 52 ft. over all. The closed cars are similar to the standard type of steam railroad coach made by the Barney & Smith company, with a seating capacity for 56 people. There are two compartments, a smoking room 12 ft. long, and a passenger compartment, 32 ft. long, finished in oak. The seats have rigid backs and are upholstered in plush. Trucks are the Barney & Smith pattern, equipped with four Westinghouse motors to each car. Some of the coaches are fitted with 50-h. p. motors, and some with 75-h. p., giving from 200 to 300 h. p. to each car. Pinions and gears are made of steel, and are furnished by the Ohio Brass Co., and the Westinghouse company.

The company is using in its high speed work a special roller-bearing, self-lubricating trolley wheel with marked success. The wheels are made by an Ypsilanti brass foundry from specifications supplied by the railway company.

One of the half-tone engravings shows the wheel and bearings. The greatest diameter of this wheel is 6 in. from flange to flange, and the bearing drum is 17½ in. in diameter. Within the drum are six steel roller pins, ½ in. in diameter and 1½ in. long. The spindle (shown in the engraving) upon which the

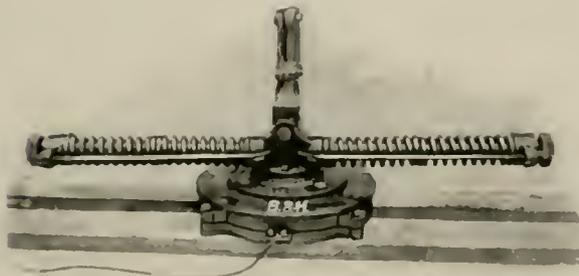

steel rolls turn is a case-hardened steel pin 1/2 in. in diameter. When the rollers and the spindle are in place, the entire bearing drum is filled with grease of special make and the bearing cap is screwed into place, as shown in the assembled wheel. The groove for the trolley wire is U-shape instead of V-shape, and the harp used in connection with the wheel has all its corners rounded so there are no projections to catch in the overhead work.

The trolley base is also a special design, made by the United States Electric Railway Supply Co., for which the Henry L. Walker Co., 40 to 44 East Larned St., Detroit, is sole agent. This base is in reality a small turn table, on which any form of trolley stand may be mounted. It consists of two circular plates, the upper one rotating

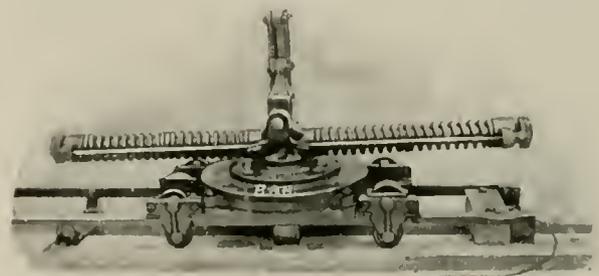

axles, it having been found that the more usual 4 and 4 1/2-in. axles are too light for this rigorous interurban service.

Babbitt bearings are used for both armatures and axles. The brake shoes are also made at Ypsilanti, and the management has found that a good gray-iron gives best results. Just as the iron is ready to be poured into the shoe molds, a handful of steel chippings taken from the refuse under one of the shop lathes is thrown into the mixture, and this has been found to add 100 per cent to the life of the shoes. All cars are equipped with Westinghouse air brakes.

For fighting snow a heavy plate nose is bolted to the front of the regular passenger cars and these have been found to be as effective as separately propelled snow plows. With cars so equipped drifts reaching half way to the roof have been cut through without trouble,

STATIONARY TROLLEY BASE.

TRAVELING TROLLEY BASE.

upon the lower one through the medium of small roller casters. It is said to effect a considerable saving in trolley wheels, poles and overhead construction by reducing the chance of the wheel leaving the wire and by reducing the likelihood of damage to the overhead work when the wheel does leave the wire, inasmuch as the pole is free to swing or rotate, and therefore does not deliver a hard blow upon any part of the overhead work. In the new forms the base is entirely self-oiling. In some cases the base is mounted directly upon the roof of the car, and in others is mounted upon a narrow track of angle irons, attached to the roof and permitting the trolley pole and base to slide from one end of the car to the other, depending upon the direction of travel. The base may be moved to and fro on the small track by merely pulling on the trolley cord, and is held at either end by catches which can be unlocked by tugging on the cord. It will be evident, therefore, that all the movements of the base can be controlled from the ground.

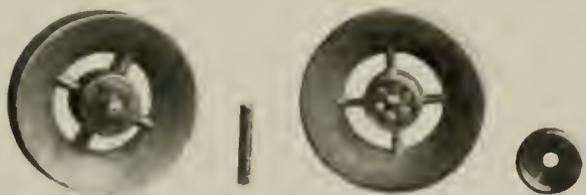

and no great difficulty has ever been experienced in keeping the entire line open.

Car Houses and Shops.

The car houses and their capacities are as follows: At Dearborn, brick and steel, 6 cars; at Ypsilanti, brick and steel, 18 cars; at Ann Arbor City, corrugated iron, 6 cars; at Jackson, corrugated iron, 4 cars.

The general repair shops are in Ypsilanti. The construction is brick and steel, 102 ft. long and 67 ft. wide; the armature room, 48 ft. long and 27 ft. wide. The shop is thoroughly equipped for all kinds of repair work, a partial list of the tools comprising lathes, shapers,

On the heavy coaches the trucks have 36-in. spoke wheels weighing 575 lb. and having 2 1/2-in. treads and 11-16-in. flanges. On the inner side away from the flange, the tread has a 1/2-in. offset. This form of wheel has been adopted after extended experiment, and has been found to fully meet the requirements. It might be remarked that the tread is somewhat narrow, and the flange somewhat shallow for high-speed work, but these dimensions are made

TROLLEY WHEEL WITH AND WITHOUT BEARING IN PLACE

necessary owing to the grooved rail over which the cars enter the city, and also to fit the special work. The management believes it is better to run with whole 11-16-in. flanges than to operate with deeper flange that are constantly becoming chipped by running through special work. As a matter of fact the company has never had a wheel leave the rail as the result of flange or tread. On the contrary in one instance, when a car entered a curve at too high speed the car was lifted from the track and thrown to one side of the track without derauling one of the wheels. The spoke wheel was selected as being less noisy. Wheels are supplied by the Griffin Wheel Works.

In the line of greater safety the company is using 5 1/4-in. steel

boring mill, wheel press, wheel grinders, winding and taping machines. The paint shop is also located in Ypsilanti.

#### Passenger Service

Through cars are operated between Detroit and Jackson every hour from 6 o'clock a. m. to 9 o'clock p. m., and between Detroit and Ann Arbor every half hour from 6:15 a. m. to 11 p. m. On Saturdays and Sundays 15 minute cars are operated between Detroit and

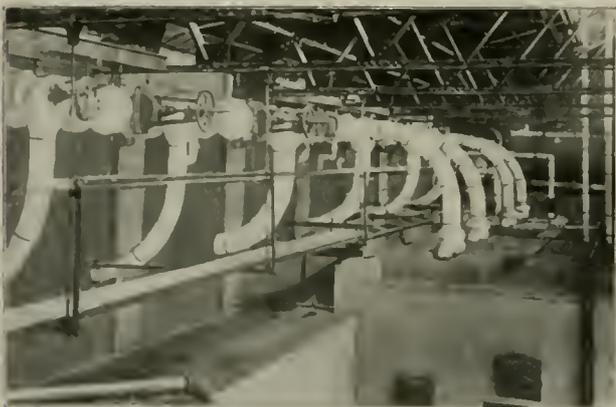

CAR HOUSE YPSILANTI LINE.

Wayne, as travel may demand. Special cars are chartered to private parties, and on special occasions. Regular cars stop at permanent stations and at street crossings in cities and towns and anywhere in the country where passengers may wish to take or leave the car.

Single and round-trip tickets are sold at regular stations, and a number of special forms are also kept on sale to suit various classes of riders. One hundred mile books are sold at the rate of 1½ cents per mile, and 1,000 mile books, good between Detroit and Ann Arbor, at the rate of 1 cent per mile. Formerly these books were made up of coupons, placed in page form, but these have now been abandoned in favor of coupons attached in one continuous strip and inserted between stiff cardboard covers. With the strips the conductor can more readily detach any number of coupons than can be done when the coupons are in leaves or pages.

For use when passengers pay fare on the cars the company employs the duplex ticket now commonly used for this work. A somewhat

HIGH PRESSURE STEAM PIPING.

new feature has been introduced, however, in that "mile posts" take the place of station names on the ticket. The conductor, in addition to the amount of fare collected, also punches the numbers of the two mile posts between which the passenger is traveling. The cash fare when paid on the cars is at the rate of 1½ cents per mile, but a somewhat cheaper rate is made on tickets purchased at the regular stations.

A special time table is printed for the government of employes and another one for public circulation. The movement of cars is directed by a central dispatcher over a private telephone system. Cars run according to time table until they become late, when their movement is governed by special orders from the dispatcher. As a special precaution against a motorman forgetting his orders, a small iron plate is laid on top of the controller, just under the controller handle. On one side of the plate are the words "No Orders," and on the other the words "Orders." The motorman before leaving a switch turns one or the other side up, as the case may be, and the words remain before him as a constant reminder of his instructions.

An extensive express and freight business is conducted by the company in addition to the passenger service. Express matter is carried under the official classification of the steam railways and the department is modeled largely after steam railroad practice. Three express cars are run each way daily between Detroit and Ann Arbor, and two between Ann Arbor and Jackson. The company uses the central electric depot in the City of Detroit, in conjunction with the several interurban lines of the Detroit United Ry. The management is inaugurating a small packet carrying business whereby packages

WAITING STATION YPSILANTI LINE.

will be picked up and left at any point on the line, instead of only at regular stations, as has been previously done.

The officers of the company are: President, J. D. Hawks; vice-president and treasurer, S. F. Angus; secretary, F. A. Hinchman; manager, F. E. Merrill; superintendent, S. J. Dill; master mechanic, J. M. Miller.

#### Power.

Power for the original railway from Detroit to Ann Arbor was furnished by two power houses, one at Dearborn, and one at Ypsilanti. These plants were described and illustrated in the "Review" for January, 1900. Each power house contained three 225-h. p. Babcock & Wilcox boilers, equipped with Roney mechanical stokers, three Westinghouse automatic compound engines, and three Westinghouse direct current 575-volt generators, connected to the engines by means of spring couplings. Boosters were provided in each station for raising the voltage on long feeders. Draft for the boiler plants was obtained by means of a mechanical draft plant, consisting of duplicate fans and engines, and each plant was provided with a fuel economizer.

To provide power for the extension of the line from Ann Arbor to Jackson and to obtain a more uniform and economical distribution of the power on the existing road, an alternating current system, with a main power house at Ypsilanti and six sub-stations was adopted. The Ypsilanti power house building was extended and all apparatus from the Dearborn power house, except the direct current generators, was removed to Ypsilanti. The old direct current generators at Ypsilanti were replaced by alternating current generators, and two additional units, including boilers, engines, and generators, were installed.

The power house at Ypsilanti is constructed of brick and steel and is located on the bank of the Huron River, water from which is used for condensers and boiler feed. The boiler room is 156 ft. long

by 36 ft. wide. The engine room is 156 ft. long by 31 ft. wide, and has an extension on one side 60 ft. by 18 ft., in which are located the static transformers, and the high tension wiring and apparatus for switching and protecting the same.

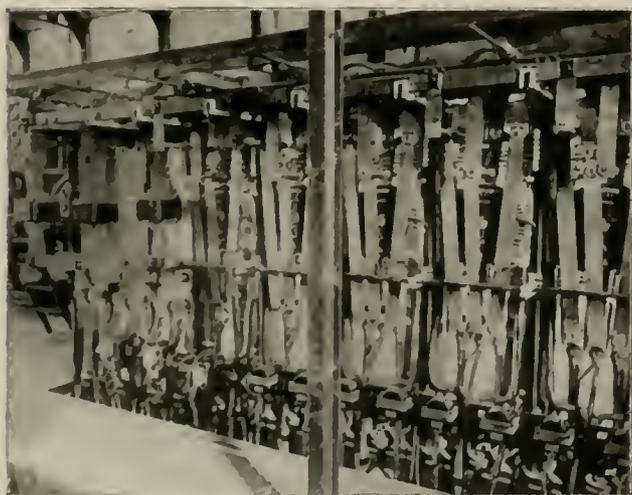

There is a basement under the entire engine room in which are the condensers and all exhaust piping.

The equipment consists of five 250-kw. 300-volt three-phase Westinghouse generators and three 250-kw. Westinghouse double-current generators, designed to furnish three-phase alternating current at 300 volts, and direct current at 650 volts, from each machine. All generators are direct connected to Westinghouse vertical single acting compound engines, having cylinders 18 in. and 30 in. by 16 in. stroke, and are operated at 250 revolutions per minute. The engines are operated condensing, and each engine is connected to an independent Worthington jet condenser.

The steam piping consists of one main steam header 10-in. in diameter, the ends of which are connected by an auxiliary header 3 in. in diameter, which serves to equalize the pressure on the header and to furnish steam to condensers, pumps, and auxiliary apparatus. The header is provided with valves between each boiler so that sections can be cut off without interfering with the operation of the plant. All pipe connections from boilers to header and from header to engines are made by long sweep pipe bends. All fittings on high pressure are extra heavy of cast iron, and all valves are extra heavy Chapman make. The water of condensation from the engine separators and steam piping is returned automatically to the boilers by means of a Holly gravity return system.

Exciting current for the generators, and also current for lighting offices, shops, and power house is furnished by two 50-kw. Westinghouse 125-volt direct current generators. Each generator is direct connected to a Westinghouse automatic compound engine having cylinders 9 in. and 15 in. in diameter by 9 in. stroke.

The boiler plant is arranged in two sections, each provided with its economizer and mechanical draft plant, engine for operating stoker, boiler feed pumps and exhaust steam feed water heater. The smoke flue, which is located back of the boilers, extends the entire length of the boiler room and is provided with necessary dampers so that either or both of the mechanical draft plants can furnish draft for the entire boiler plant. There are eight 225-h. p. Babcock & Wilcox boilers set in four batteries. The boilers are equipped with Roney mechanical stokers, operated by two 8-h. p. Westinghouse standard engines, which are also belted to a line shaft for operating the economizer scrapers. Mechanical draft plants are located at either end of the boiler room and consist of two fans and

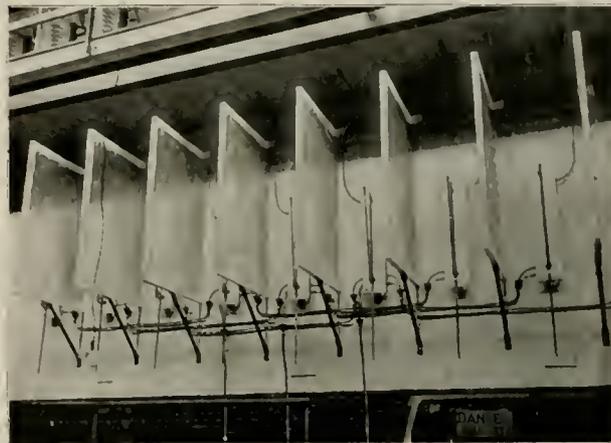

REAR OF DIRECT CURRENT SWITCHBOARD.

engine, and are provided with damper, so that either or both fans can be operated.

The boiler feed water is furnished by four outside packed pressure pattern Worthington pumps, two of which are operated at one time. The exhaust from the feed pump, condensers, and fan and stoker engine passes through exhaust steam feed water heaters, and the feed water, after going through these heaters, passes through the economizer.

Slack coal is used for fuel, about 40 tons being consumed daily. Coal is delivered on siding by the steam railroad and hauled to the power house by an electric motor car, where it is transferred to bins or coal pockets adjacent to the boiler room.

There are two switchboards which are of the Westinghouse standard type and are of white Italian marble supported by angle-iron frame. One of these boards is for the control of the alternating current system, and is made up of eleven panels, eight of which are

HIGH TENSION SWITCHBOARD WITH GLASS BARRIERS.

generator panels and three are feeder or transformer panels. On each generator panel is mounted one three-pole quick-break machine switch, one double-pole quick-break field switch, three alternating current ammeters, and one indicating wattmeter. The transformer panels control all the current from the eight generators to the transformers, and on each panel is mounted two 3,000-ampere switches, one time-limit circuit breaker, and one 6,000-ampere ammeter. A polyphase wattmeter is connected to the system and records the total alternating current output. This switchboard is also provided with two alternating current voltmeters and a synchroscope. One of the voltmeters is connected to the bus bar, and the second voltmeter to a system of receptacles so that the voltage of any generator can be obtained before it is thrown in. The synchroscope has been found to be a very valuable piece of apparatus, as it enables the station attendant to synchronize and throw the generator in without loss of time and with absolute certainty that the generator about to be connected is in phase.

The second switchboard is for the direct current system and consists of seven panels, three of which are generator panels and are for the control of the direct current end of the double-current generators. On each panel is mounted three single pole quick-break generator switches, one single-pole circuit breaker, and one ammeter. Three of the panels are for line feeders, and are mounted with one single-pole switch, one single-pole circuit breaker, and one ammeter. One panel contains necessary switching apparatus for two exciters. Two voltmeters are provided and are supported on a swinging bracket at one end of the switchboard. The switchboard also contains one recording wattmeter.

The alternating current is generated at 300 volts, three phase, at 3,500 alternations. Three 500-kw. Westinghouse self-cooling and oil insulated transformers, which are connected in delta, raise the voltage to 22,000 volts. At this voltage the current is transmitted to the several sub-stations by three circuits; one circuit of three No. 4 wires feeds east a distance of twenty miles, to Wayne and Dearborn sub-stations; one circuit of three No. 4 wires feeds west a distance of 30 miles, and supplies Ann Arbor, Lima Center, and Francisco sub-stations; the third feeder, consisting of three No. 3 wires, runs direct to Michigan Center sub-station, a distance of 41 miles. The circuits which feed the several sub-stations are looped into the sub-stations, and are connected through with fuse switches so that the line can be opened at any sub-station. All high tension wires at the power house and sub-stations are provided with high tension fuse switches. Westinghouse static interrupters and low-equivalent lightning arresters are connected to all high tension wires at the power house and at the various sub-stations. At the sub-stations the high tension current is reduced to 300 volts alternating, and con-

verted into direct current at 650 volts, which is fed direct to the line and direct current feeders. Each sub-station contains three 200-kw. oil cooled transformers, two 250 kw. rotary converters, and a switch-board of six panels—two alternating current machine panels, two direct current machine panels, and two feeder panels. All electrical apparatus at sub-stations is Westinghouse make. The machines at all stations are protected with Westinghouse tank lightning arresters and Wurtz non-arcing lightning arresters.

The sub-stations are of brick, iron and tile throughout, and are combined with the waiting room and freight room, except at Ann Arbor, where the freight business is so large that it requires a separate building, and at Dearborn, where it was not convenient to have them located in the same building.

The overhead line consists of two Figure 8, No. 000 trolley wires the entire length of the road, with a No. 3 D. C. feeder between Ypsilanti and Wayne tapped in parallel with the trolley, a 300,000 c. m. feeder from Michigan Center to Jackson, and a 400,000 c. m. feeder from Dearborn station east four miles to Detroit city limits. (Wayne station was located 12 miles from Ypsilanti for convenience of having the waiting room, freight room and sub-station combined, hence the necessity of the No. 3 feeder.)

Between Detroit and Ypsilanti the trolley wires are supported from span wires, from Ypsilanti to Jackson they are carried on Ohio Brass flexible brackets. The wires are strung 6 m. apart. On the span work, 30-ft. cedar poles were used, and on new bracket work poles from 40 to 70 ft. long have been selected.

The trolley is cut at each station by means of a line circuit breaker, but with the line switch in at all stations, the circuit is completed through the switchboard, and the trolley wires are tapped together every 500 ft. for the entire length of the line. At all regularly used turnouts the two trolley wires separate, one wire following each track, thus avoiding overhead switches. At turnouts used at infrequent intervals, both wires follow the main track and an auxiliary wire is led round over the siding. This permits a through run in either direction over the main track, but if a car is to take the siding the conductor must change the trolley wheel to the auxiliary wire.

All feeder and transmission lines are copper, with the exception of the direct current feeder from Michigan Center west to end of line. Over this section aluminum wire is being tried as an experiment.

## Track Department of the Detroit United Railway.

The Detroit United Ry. is now operating about 300 miles of track, including all city and interurban lines, but excluding the Rapid Railway System. Most of the city mileage is laid with 7-in., 85-lb., or 9-in., 90-lb. grooved girder rails, on 6 in. of concrete with metal ties. Detroit was one of the first cities in the United States to use concrete construction in track work, and the results of the experiments here are interesting. The company is thoroughly satisfied

with concrete construction, but has found that in the early work the concrete foundation was not made deep enough nor heavy enough. Most of the early work was laid with 6 m. of Louisville cement, mixed with 2-4-8, laid the entire width of the road bed, and brought up on top of the ties a sufficient distance to form the foundation for the brick paving between the rails. Track so built has been in place about six years, but is now beginning to show serious cracks,

CROSSINGS ON THE DETROIT UNITED RAILWAY.

Overhead crossing over Grand Trunk,  
Crossing under P. O. & N. Oxford.

Trestle near Rochester,  
Trestle over Michigan Central near Orion.

extending clear through the concrete bed. In all new work, and in repairing old work, it is the practice to put in at least 1 ft. of concrete under the ties. It has also been decided to use a good quality of Portland cement in place of the Louisville mixture. No ties are used, but the track is held to gage by iron bars, which are

TEMPORARY TURNSTABLE.

attached to the rails by special clips and hook bolts, as shown by the plan of track reproduced herewith.

The interurban lines have been built at various times by different companies, and are laid with various weights of T rail, ranging from 60 to 120 lb., but in the main follow steam railroad practice.

Continuous and Weber joints are in use and there is considerable track electrically welded by the Lorain Steel Co's. method.

Mr. John Kerwin, superintendent of tracks, has designed a number of special features in connection with his department that are a little out of the ordinary.

One of his latest experiments is with concrete ties. The tie is 6x8 in. by 8 ft. long, made of concrete mixed in equal quantities of stone, sand and portland cement. Embedded in the tie are two iron bars  $1\frac{1}{2}$ x2 $\frac{1}{4}$  in., and 6 ft. 4 in. long. For the purposes of spiking the rails to the ties, two pieces of 2-in. pipe are sunk into the tie on the line where the base of the rail rests. These iron pipes are filled with wooden plugs into which the rail spikes are driven. After the ties are molded they are permitted to stand three months in order to allow the cement to thoroughly set. This form of concrete tie has not been in use for a sufficiently long period to justify

NEW SAFETY SWITCH BAR HITCHED TO SWITCH POINT.

a definite statement as to its strength and satisfactory qualities, but if it is found to fill the requirements, it will probably supersede to some extent the practice of laying a bed of concrete underneath the entire road bed.

The railway company has developed several new designs in special work. For instance, in double winged frogs, the central member

is one continuous rail to which the wings are bolted. This permits the renewing of the center rail when the head becomes unduly worn. Another departure is the method of attaching the cross bars at switch points. Ordinarily these bars are rigidly fastened to the inside of the points. This rigid fastening permits no play of the point, and if the point is thrown out of alignment by wheels of a passing car, it never again fits snugly to the head of the rail. By the new method of fastening the cross bars are hinged to the point so that if the point is pried over by a wheel or a stone, it will rock slightly on the hinge, and will immediately return to perfect alignment when the obstruction is removed.

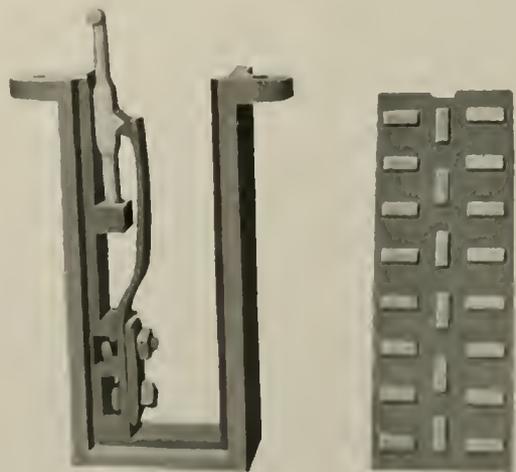

For spring switches a special mechanism has been designed to always insure positive action, and prevent the point from moving in either direction, except when movement is actually desired. The mechanism is housed in a metal box under the track. The interior of the box is illustrated in one of the half-tone engravings. As will be seen, the switch point when thrown moves a plunger having on

CAR ON TURNTABLE.

one side a projection or shoulder which engages the end of a flat plate spring. In the illustration the plunger is shown covered with white chalk in order to distinguish it. From the construction it will be evident that in order to fix the switch point in either open or closed position, it is necessary that the point be thrown the entire distance, and after it has been so thrown, it cannot be changed until sufficient force has been applied to overcome the tension of the plate spring.

To lessen the risk of motormen running into open switches on the interurban lines, Mr. Kerwin has designed a simple but novel system of levers with telltale semaphore attachment by which a semaphore positively indicates the position of the point. It some-

BOX AND MECHANISM FOR SPRING SWITCH CONTROLLER.

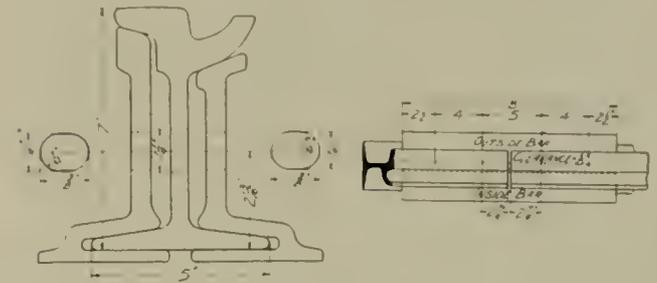

times happens that a small stone or other obstruction becomes lodged between the point and the rail, and although the levers may be thrown to close the switch, the stone will prevent the point from fitting closely against the rail. This may very easily occur without the employe noticing that the switch has not absolutely closed, and the conditions are, therefore, very favorable for a bad accident

caused by the next car over the track running into the open switch. In the new design of signal stand this danger is positively eliminated by attaching the semaphore independently to the extreme point of the switch, and not to the operating levers. Inasmuch as the rod that actuates the semaphore is attached to the extreme end of the switch point, the point must bear hard against the rail before the semaphore will return to its safe position, and there is absolutely no danger of running into an open switch, unless the motorman deliberately disregards the semaphore. The adjustment is such that the signal returns to danger if the switch is open even so small a distance as one quarter of an inch.

The company secures a good quality of sand from sand pits at the side of its tracks, near Farmington Junction. For loading sand into cars there has been designed a sand elevator or conveyor, which is well shown in two of the accompanying engravings. The elevator is mounted on a low truck and consists of a double line of bucket conveyors, fastened to a sprocket chain. Each bucket is about 1 ft. long x 5 in. wide x 4 in. deep with a capacity of about 2½ cu. ft. The conveyors are operated by a 25-h. p. motor. The method of procedure is to build temporary tracks into the pit. The conveyor is then pushed onto the track in such a way that the buckets will lift the sand and gravel and deposit the material in flat cars placed on a second track at one side. This machine requires but one man to operate it, and does work that formerly required 20 men in the gravel pit. In addition to sand and gravel to supply all of its own needs, the company screens the sand for roofing and paving gravel, and sell the material to contractors in the city. The sand is dried in a large dryer by passing it through a revolving metal cylinder under which a fire is kept burning. The cylinder is slightly inclined, the sand entering at the higher end, and leaving at the lower, there being rows of angle irons on the inside of the drum which catch the sand and carry it part way up the sides of the cylinder as it slowly revolves. The drum has a capacity of 60 cu. yd. of dry sand. The dryer is so located that the dry sand can be passed into cars down a long chute without extra handling.

The company has been able to save considerable money by the use of temporary turntables designed by the track department. One of these tables is illustrated. It is used in various emergencies, par-

upon heavy plank, a pin in the center serving to center the two plates. A ¾-in. iron washer is placed between the plates. The outside end of the two rails move upon a circular track made of light T rail. The rails on the turn-table are locked in alignment with the track rails by means of an ordinary switch throw by which lugs are thrown in and out of engagement with the ends of the turn-table rails. The car to be turned is first run upon the table and centered so that the turn-table is well balanced. It is then pushed around by hand. This turn-table can be built for \$15, and in tem-

"CONTINUOUS" RAIL JOINT, AS USED BY DETROIT UNITED RY.

porary work saves the construction of crossings which would probably cost \$300. The particular advantage will be understood when it is remembered that all cars in Detroit are run the same end on at all times.

For smoothing off the top of rail joints, and also for grinding down special work when necessary, the track department has rigged up a portable emery wheel shown in one of the illustrations. The wheel is mounted on a frame supported on three wheels as shown. The emery wheel is 11 in. in diameter, and is fitted with screw adjustments and can be raised or lowered at will. When being used the device is accompanied by a small truck upon which is mounted a

JOHN KERWIN,  
Superintendent Track Construction.

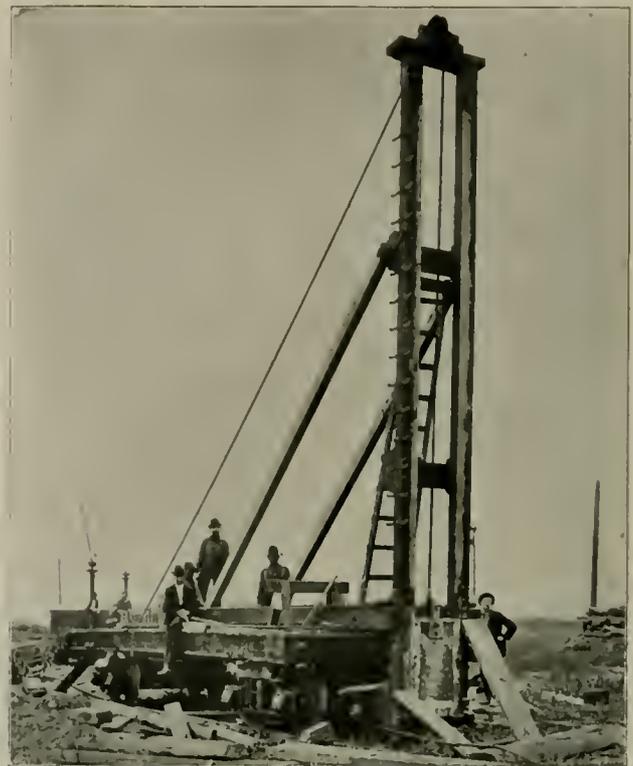

cars placed on a second track at one side. This machine requires but one man to operate it, and does work that formerly required 20 men in the gravel pit. In addition to sand and gravel to supply all of its own needs, the company screens the sand for roofing and paving gravel, and sell the material to contractors in the city. The sand is dried in a large dryer by passing it through a revolving metal cylinder under which a fire is kept burning. The cylinder is slightly inclined, the sand entering at the higher end, and leaving at the lower, there being rows of angle irons on the inside of the drum which catch the sand and carry it part way up the sides of the cylinder as it slowly revolves. The drum has a capacity of 60 cu. yd. of dry sand. The dryer is so located that the dry sand can be passed into cars down a long chute without extra handling.

The company has been able to save considerable money by the use of temporary turntables designed by the track department. One of these tables is illustrated. It is used in various emergencies, par-

SAND DRIER.

ticularly where it is desired to turn cars back without installing a loop, crossing or Y. This table consists of two rails upon which the car rests, these rails being thoroughly braced with cross bars, and mounted upon a ring plate 18 in. in diameter. The plate moves upon another plate permanently set between the rails and mounted

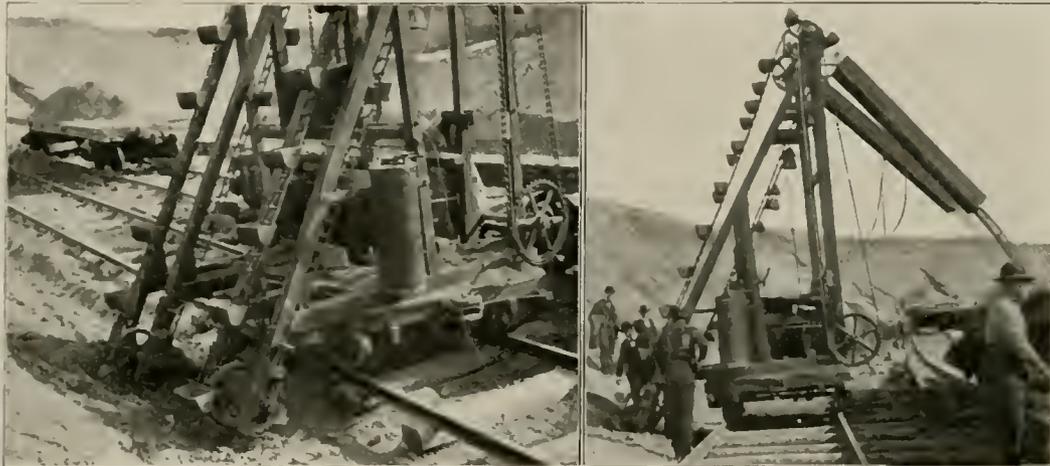

PORTABLE PILE DRIVER.

motor taking current by fish pole connection from the overhead trolley. The emery wheel is driven from this motor by means of a flexible shaft.

Another novelty in this department is a pile driver mounted upon a flat car, and designed to be used in repairing washouts, building

trestles and bridges, or anywhere where piles are to be driven in or near the track. As will be seen from one of the illustrations the driver comprises two uprights made of heavy timber 6<sup>1</sup>/<sub>2</sub>x8 in. x 25 ft. high. The base timbers, which are fastened to the car platform, are 6<sup>1</sup>/<sub>2</sub>x8 in. and 22 ft. long. The uprights are held in place by two 5x5-in. braces, which engage notches in the uprights. These braces can be disengaged at their lower ends, permitting the two uprights to swing back upon the platform of the car, the uprights being

up from the steam railroad car and deposited on the ground or in a trolley car on the adjoining track. The lifting is done by attaching the end of the hoisting rope to a motor car and pulling away from the derrick. The distance from the ground to the under side of the I-beam is 22 ft. 8 in. The width of the derrick at top is 20 ft., and at bottom 26 ft. The two uprights rest in a bed of concrete 3 ft. square and 5 ft. deep. Rails are handled in the manner shown by means of chain train sling and two heavy tongs. With

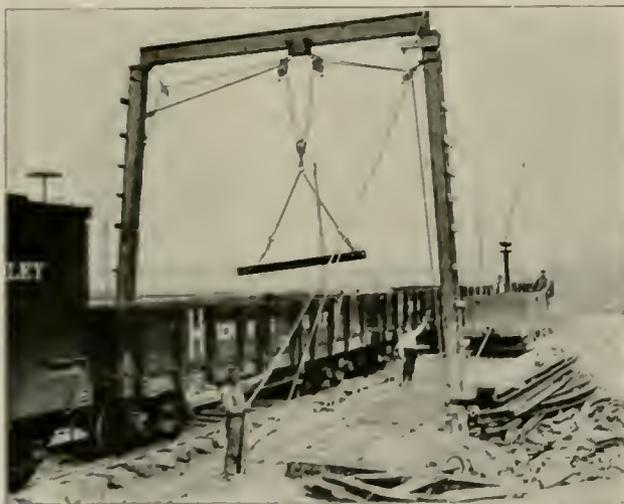

SAND ELEVATOR.

hinged to the base-pieces for this purpose. The hammer weighs about 2,200 lb., and will drive a pile 20 ft. long. Although the illustration does not show it, there is to be mounted upon the rear of the car platform a small steam-hoisting engine for operating the hammer, steam being used in place of electric motor so that the pile driver can be used along the track at night when the power is shut down. The flat car on which the pile-driver is mounted is designed to be pushed or pulled by a motor car. The framing constituting the base of the pile-driver is pivoted in the center of the car platform, permitting the driver to be swung clear around to the side, allowing it to drive a pile 2 ft. to one side of the track. The base framing moves upon a circular track made of light T rail when the driver is being swung around to the side position.

At the company's storage yards there has been rigged up a convenient derrick for unloading special work rails, and other heavy

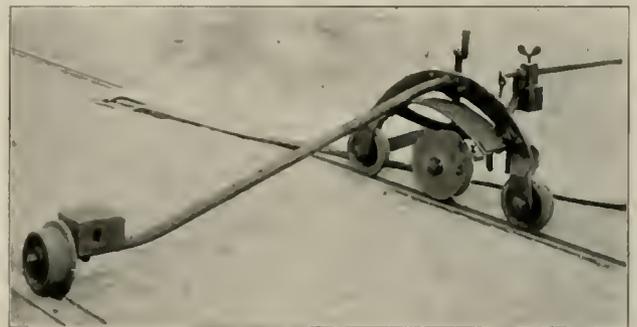

one motor car and this derrick 60-ft. rails can be unloaded without difficulty.

Two very useful construction cars used by this company were described and illustrated in the "Street Railway Review" for March, 1901, page 160. One of these is a derrick car, which is said to have given the greatest satisfaction of any machine employed in the track department. The derrick is rigged on one end of a flat car and the boom is arranged to swing all the way around, so that the car may be run up alongside a steam railroad car and unload the heaviest special work or girder rails and place them on the

DERRIK FOR HANDLING RAILS.

shipments from car. This derrick is also shown in one of the illustrations. It consists of two uprights 12x12 in. carrying at the top a 16 in. I beam having a 5 in. web. On the web of this I beam runs a small trolley which carries the tackle used in lifting the heavy piece. It will be seen that this permits a piece of rail to be picked

PORTABLE EMORY WHEEL.

derrick car itself or on a car standing at the end of or at the opposite side of the derrick car. The cable for hoisting is run down the post of the derrick and comes out under the draw head of the car, so that any motor car on the same track can be attached to this cable to do the hoisting.

The other construction car mentioned is a track spiker by means of which the tracks are spiked to the ties without the use of hand labor. The pairs of tongs on opposite sides of the car pick up the tie and hold it firmly against the rail with a pressure of four tons, and the car is provided with a boiler and steam hammers, each of the latter driving two spikes at the same time. It is estimated that with this machine two men can spike 1,200 ties per day, which means a saving of \$15.00 per day over hand labor.

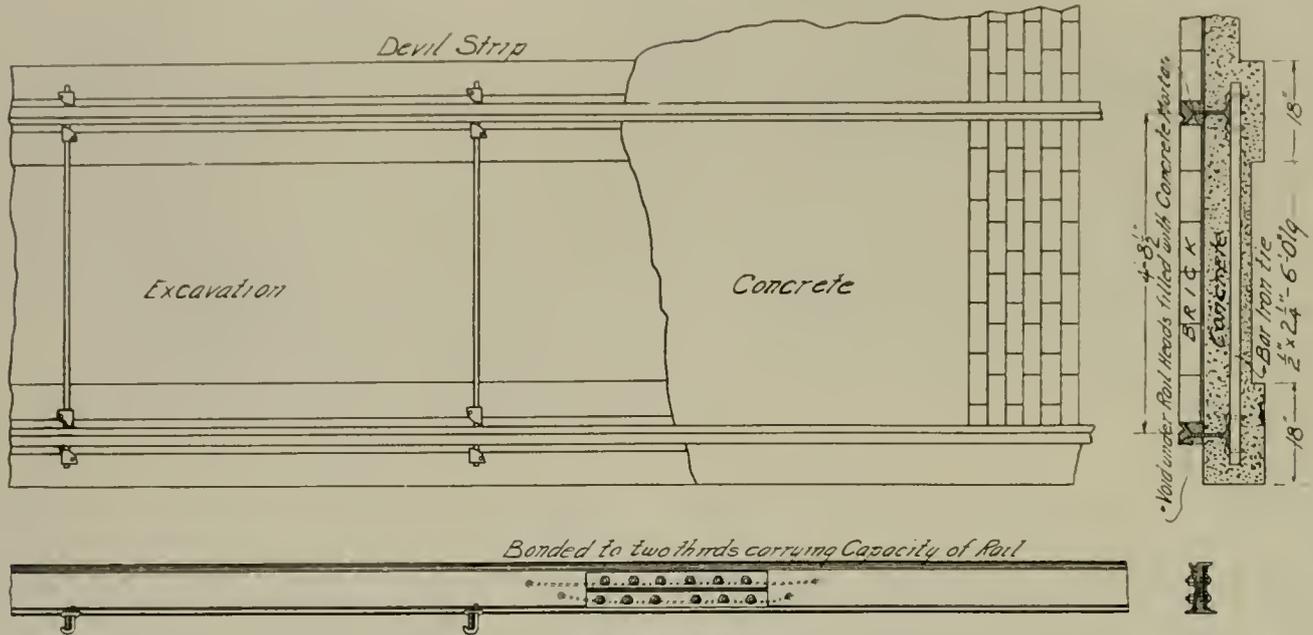

During the past season the company has been bothered a great deal by the exceedingly heavy rains which caused troublesome wash-outs on many of the interurban lines, requiring very energetic work

on the part of the track department to keep the line in repair. In this connection the manner in which a washed-out bridge was renewed is worthy of mention.

The bridge was about 60 ft. long, and was entirely washed away by a sudden rise in the river. As soon as word was received that the bridge had gone out a force of men was hurried to the scene, and the cars were again running within a few hours. In the work of repair bags were first thrown into the beds of the stream, and these were protected by building around them a hollow square of old ties laid log cabin fashion. These ties formed the abutments for the temporary bridge, and were brought up to nearly the floor level of the old bridge. A number of 60 ft. sections of 6-in. girder rail

than to adze down ties which have heaved. They are directed to be very particular to secure a uniform bearing on all shims used both on rail and on tie. White oak shims 8 in. long and 4 in. wide, are to be used, and they are to be driven under the rail from the outside. Shim  $\frac{3}{4}$  in. thick and over on straight track, and 1 in. thick and over, on either rail of curve, must be accompanied by wooden rail brace, extending at least 1 ft. from the neck of the rail and securely held by spike.

Mr. Kerwin is preparing to try an experiment that is believed will greatly aid in making inspection and repairs on the interurban lines. He has nearly 300 miles of interurban track under his supervision, some of the lines being 70 miles in length, and it is often

STANDARD PAVING AND TRACK CONSTRUCTION IN DETROIT.

were then suspended over the stream, these rails resting on the tie abutments in the center, and on the old approaches at each end. The track ties were bolted to these rails. The bridge thus built has proven to be satisfactory in every way, and will be retained until a new, permanent structure can be put in place.

It is the policy of the company when necessary to resurface track not to disturb the ties by retamping, but to bring the track to surface by putting oak shims between the ties and the rails. Foremen are directed to use shims up to 1 in. in thickness if necessary, rather

necessary to go out over these lines when the power is off. He is therefore, having built a gasoline hand car which will accommodate four people and 150 lb. of tools, etc. The car is to be driven by a small gasoline engine direct coupled to the axles. It will be furnished by Fairbanks & Morris, Chicago agents for the Sheffield Car Co.

For preventing delays in case of fires the company keeps on hand 24 hose jumpers. These are simple in construction, and are made of wood with strap iron for the car to run upon.

**DISTRIBUTION SYSTEM AND OVERHEAD CONSTRUCTION OF THE DETROIT UNITED RY.**

The city feeder distribution system comprises about 23,000,000 c. m., capacity in overhead feeders, ranging from No. 0000 to to 500,000 c. m. The distribution scheme provides for an equalizing wire running through the center of the city, about three miles from the city power houses. All feeders crossing this section tap, through an automatic circuit breaker, into this equalizing wire, which acts as a balancing wire, and to which is also connected a storage battery, to assist in carrying the peak load.

Careful attention has been paid to the return system, the return comprising about 17,500,000 c. m., capacity in underground feeders. The district around the power house is particularly well protected, and the company is just at present putting in nearly two miles of return feeders, comprising two 1,000,000 c. m. cables, covered with asphaltum, and laid in a concrete trench with connections to track wherever the cables pass under intersecting tracks. The bonding is extra heavy "Crown" bonds, put in with drift pins. Particular attention is paid to the return circuit at special work and complicated crossings. It is the practice to run heavy bond wires underneath the entire special work itself. For this purpose the company uses old trolley wire annealed, and after the wire has been put in it is painted with a carbon paint, which is a product of gas manu-

facture. This by-product of the gas house is also used for painting poles. After the bond is placed the head of the bond and pin are also given a coat of paint. This serves to keep out moisture and brackets and overhead material; also connectors made by the Kisinger Iron Co., Cincinnati.

There is one under-grade crossing on Woodward Ave., where the street railway tracks pass under the steam road, where considerable trouble was had in keeping the trolley wheel on the wire, on account of the height of the suburban cars. This difficulty has been overcome by installing an overhead pan under the viaduct. The pan consists of a 6-in. channel iron with pan approaches, mounted on a thoroughly insulated board with tin roofing over the top of the board to keep the seepage and drainage water from working down to the face of the pan. The pan is insulated by a layer of asbestos between the tin and the board. The bolts for joining the parts together are also insulated.

In interurban work no overhead pans are used at turnouts or crossings. At turnouts the two overhead trolley wires follow the straight track, and a supplementary wire is led off around the turnout. This requires the conductor on any car that is taking a siding to change his trolley pole, but all cars that are not to take

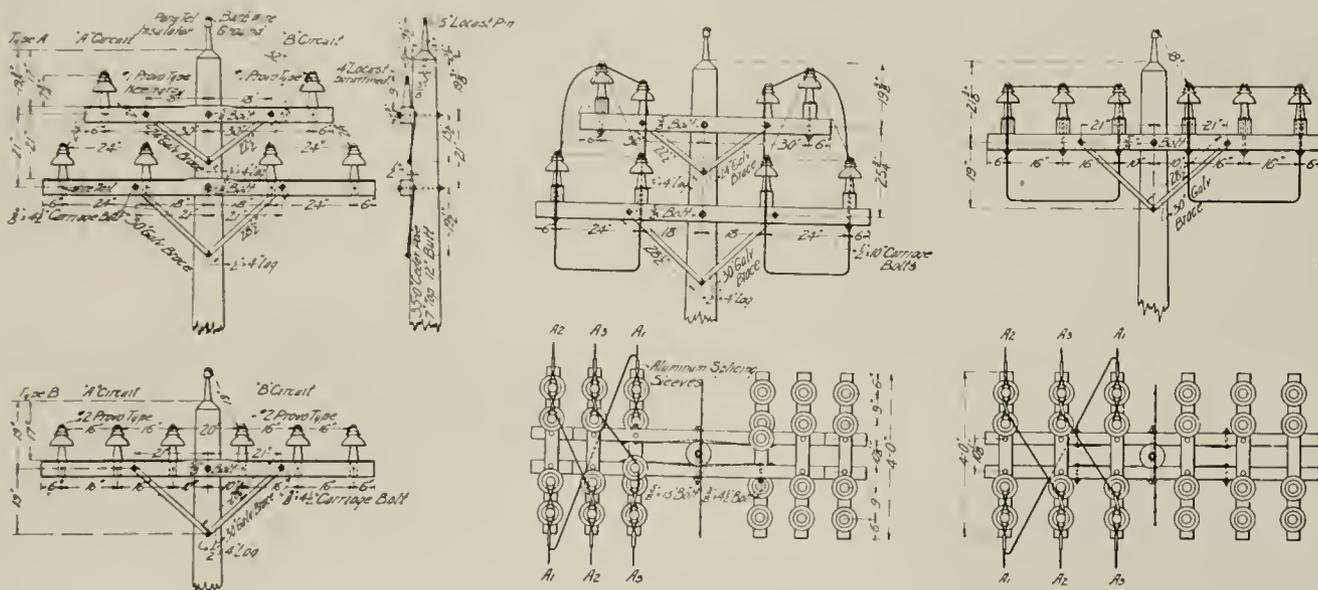

the siding can run straight through without bothering with overhead crossings or switches.

The type of construction adopted as standard in interurban work is illustrated in one of the drawings, which shows all details, including method of suspending feeders, telephone wires, the double Fig. 8 trolley wire, and also sets forth the scheme of coloring and numbering poles.

The high tension system which is operated from the Rochester power house, described in Mr. Farmer's article, comprises two circuits of No. 4 aluminium wire, furnished by the Pittsburg Reduction Co. The method of suspension and transposition is set forth in the various positions in the drawings shown herewith. For

minutes. This is done to prevent sub-station rotaries from becoming inverted, and charging back on line with high-tension current

In case of trouble upon but one high-tension circuit linemen are instructed, after having become satisfied that the circuit is clear from power house and sub-stations, to immediately locate break or breaks, and make them as safe as possible by clearing wires from track, telephone or direct-current system, and in the event of wires being in a dangerous position, are instructed to leave a man to watch them, or in case this cannot be done, are to place a danger signal at this point. You are not to try to repair while the other circuit is in operation, but wait until night time, after the shutting down of the alternating current machinery, and you are positively sure that lines are not charged.

POLE TOPS.

part of the distance the three wires for each of the circuits are carried in the same plane, but in the newer work the more modern practice of arranging the wires at the angles of an equilateral triangle has been followed. The high tension wires are suspended on Hemingway No. 1 and No. 2 "provo" glass insulators, with a 14-in. pin. In joining the aluminum wires the MacIntosh sleeve joint has been used.

In view of the general desire for information concerning the care of high-tension circuits in electric railway work, we give the following "Instructions on High-Tension Operation and Repair," as formulated by Mr. E. J. Burdick, who has charge of this department in connection with his other duties:

**INSTRUCTION ON HIGH-TENSION OPERATION AND REPAIR.**

In case of circuit breaker opening or fuses blowing on alternating current system, it is the duty of the engineer in charge to throw the machine back upon the line to be perfectly assured that the circuit opening was not caused by overload other than short circuit. After satisfying himself that it is not overload, he is to separately test each high-tension circuit to find if he has one good circuit remaining, and if he has, he is to continue to operate upon it.

Immediately after the test, he is to notify both sub-stations with reference to condition of circuits, etc., instructing them to clear the switchboard of all switches upon the circuit or circuits in trouble.

It will then be his duty to notify linemen, who are available at all times, of the trouble, who immediately thereafter are in full control of all alternating circuit wires until such time as they may report them clear.

Linemen are to thoroughly satisfy themselves with reference to just what conditions are, and are perfectly justified in demanding any precautionary tests or measures to insure safety, etc.

In case the power house engineer cannot reach sub-stations by telephone, he is instructed to pull open the direct current feeder switch, which feeds Oxford and Flint end, leaving it open for five

minutes. In case of both line cars being out on the trouble, it is the duty of each lineman in charge of them to call up the dispatcher or power house, stating, "I have my trouble cleared, have you heard from the other line crew?" This is very important and should always be done.

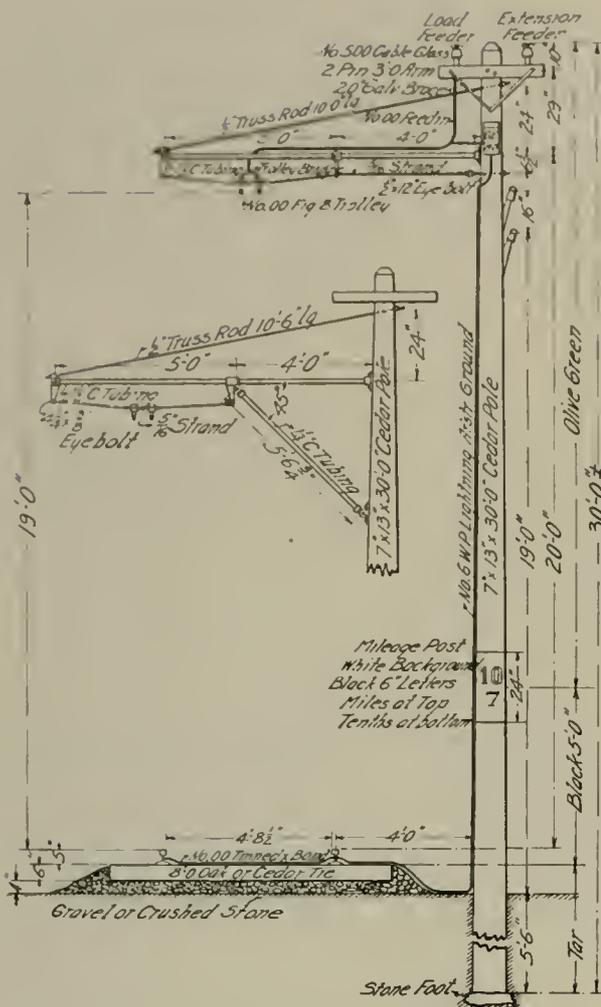

Great caution should be exercised by linemen in handling alternating current or high-tension wires, and at all times treat them as

VIEW ON FLINT DIVISION—UNITED RY.

being alive until they have been tested by the short-circuiting or grounding method. You may be positively certain that both sub-stations and power house are all cleared, but wires might be in contact at other points with the live circuit.

Linemen and all employees should use great care in working on or handling telephones, or direct current lines, in case of trouble

These cars are mounted on various types of trucks, including du Pont and Brill single trucks and du Pont, Brill, Peckham and Jackson & Sharp double trucks. They are equipped with Westinghouse

THE DETROIT SIGN.

and General Electric motors of various sizes. Gears and pinions are made by Van Dorn & Dutton. Sterling-Mecker registers are used in city cars and Ohmer registers on several of the suburban lines. In the city the cars are heated with stoves, but all the interurban cars have hot water heaters, made by the Peter Smith Heating Co. of Detroit. Car wheels are Griffin make, 33 in. in diameter, and

THE DETROIT PLATFORM.

weigh 475 lb. All the interurban cars are fitted with Magann storage air brakes, as made by the Magann Air Brake Co., of Detroit; also with the Wilson trolley catcher.

The trolley wheel used is a special design originated by Mr. Farmer. The wheel is used with a malleable iron harp, which is fit-

on the alternating-current system. Sub-station men are cautioned to use the greatest care in their operations, following these instructions explicitly. Keep in touch with the power house and linemen, and if telephones are not working, watch the high-tension circuits for static discharges, and also govern yourself by power house signals.

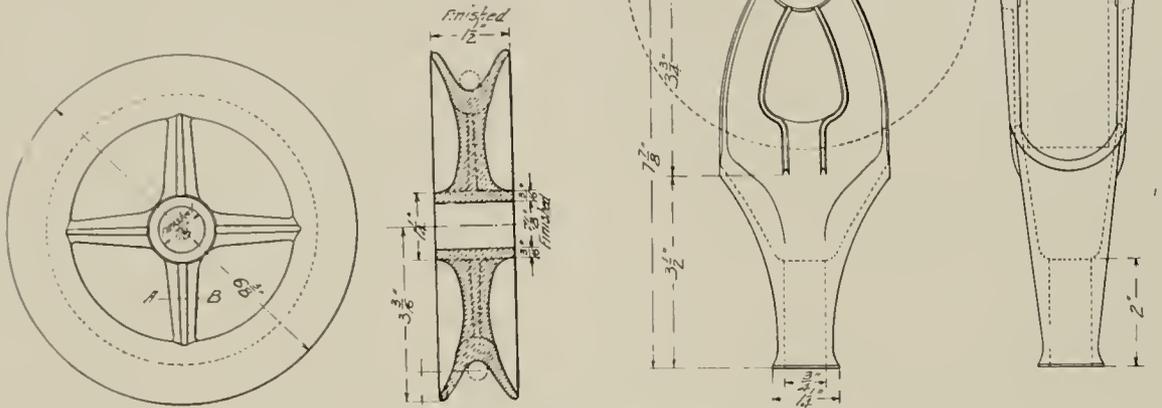

If possible, always keep direct current upon the trolley or direct-current system to facilitate the handling of line cars, etc.

All cars, both city and interurban, run the same end on at all times, and most of them are equipped with controllers at one end only. On most of the city cars the back platform is extended, thus giving increased standing room. The extended platform is 6 ft. 8 in. long, and 6 ft. 9 in. wide. The platform is permanently enclosed on one side, with a wide opening on the side of egress and exit. The timbers supporting the platform run forward under the car about 5 ft., or as close to the wheels as is possible. These platform timbers are 2<sup>1</sup>/<sub>4</sub> by 8 in., reinforced by a 3<sup>1</sup>/<sub>8</sub>x6 in. iron plate on the inside. They are bolted through to each cross timber, and at the end cross sills are supported by two bolts with bearing plates underneath. The novel feature about the platform is an iron railing, which divides it into two portions, and is designed to prevent passengers when standing on the platform from interfering with passengers entering or leaving the car. The railing is shown in one of the engravings, and is made of 1-in. iron pipe put together with malleable iron elbows at each end. The railing is 38 in. high, and has an extreme width of 4 ft. 10 in. From the top of the rail to the step is 17 in.; from the step to the platform is 12 in.; and there is a 7-in. rise from the car platform to the car proper.

As might be expected where so many different companies have been consolidated under one management the rolling stock varies greatly. The following is a list showing the number, maker and length of body of the cars of different types:

ted with two copper contact pieces for carrying the current. The working drawings for the wheel and the harp are reproduced herewith. The bushing is seamless steel tubing, slotted, and filled with wicking to hold the lubricant.

The sign used in Detroit for designating routes is a very effective one. This sign consists of a 1½-in. board 8¼ in. wide, and long enough to accommodate the longest street name. The board is

DETROIT TROLLEY WHEEL AND HARP.

painted black, and the letters are cut out with a jig saw, the standard letter being 5 in. high. Over the back of the letters are tacked pieces of white celluloid, and the letters are also edged with white paint. The signs are hung in front of the deck lights by special malleable iron hangers, both over the hood and at the side of the car. The signs are all made the same size, and are, therefore, interchangeable on all cars. This sign is very easily read in daytime,

storms there are eight levelers and six nose plows, which were built in the company's own shops.

**NO POWER TO REDUCE FARE.**

The City Attorney of St. Paul has rendered an opinion that the Common Council of the city does not possess the power to order the

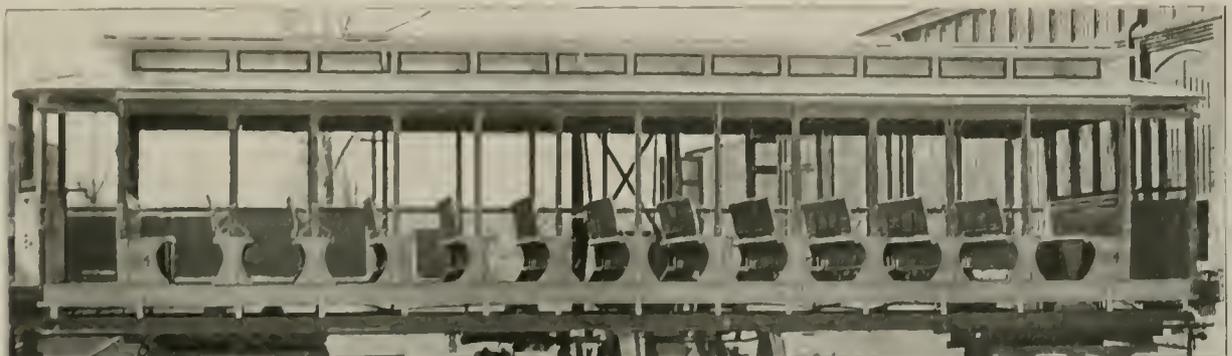

INTERURBAN PARLOR CAR FOR DETROIT UNITED RY. JEWETT CAR CO.

and at night the light from the interior of the car shining through the celluloid makes the individual letters distinguishable for a distance of several hundred feet.

In addition to the rolling stock mentioned, the company owns three line wagons, one fire hose wagon, three trolley wagons, a 7-ton truck fitted with windlass for hauling heavy pieces and material, and other wagons and vehicles. In the shops, and in emergency work, Pearson and Norton jacks are utilized. For use in snow

reduction of street car fares from 5 cents to 3 cents. The city attorney found that the enabling act passed in 1899 gives municipalities the right to provide for regulating and controlling any public franchise, but it exercises no power to fix maximum rates. A long line of decisions which have been rendered also give the City Council the right to enter into contracts with corporations, but when the contracts have been once made the powers granted to the municipality cease and the contracts must stand.

NEW OPEN CAR FOR DETROIT UNITED RY. JOHN STEPHENSON CO.

# Real Estate Department of the Detroit United Railway.

BY ROBERT OAKMAN, REAL ESTATE COMMISSIONER.

The real estate and tax agent has come to be a necessary adjunct to almost every great steam railroad system in the country, but so far as the writer knows the necessity for such an officer had never made itself felt with sufficient force to bring about the establishment by a street railway company of a separate department for this work until the Detroit United Railway, after acquiring the properties of the various suburban roads centering in Detroit, created the office of Real Estate and Tax Commissioner of the Detroit United Railway.

The duties of this officer are manifold and complex because the commissioner must have an acquaintance with all the departments of the railway and must be in close touch with all of them. He must also have a thorough knowledge of the tax laws of the state and the municipalities.

The Detroit United Railway owns two million dollars worth of real estate, within the city limits of Detroit, and the assessable

on a stone, running thence northerly about 200 feet to a point opposite a hedge, thence southeasterly to a stick drove by a spotted willow tree and westerly to the place of beginning." After the road is in operation a year or so you are informed that your track and poles are not located on your own property and you are referred to the deed with the foregoing description to substantiate the claim.

After the purchase of the suburban roads one of the first steps taken by the commissioner was to secure an accurate survey of the route of the lines as now located and established, this survey showing all the property lines, lengths and widths of right of way, and former owners, fencing, kinds and dimensions of buildings near track, farm crossings, highway crossings, location of poles, stations, etc., and other special points primarily affecting the physical property of the company. On a copy of this map, we are drawing plats of all the parcels of land for which deeds have been se-

valuation of the real estate and personal property of the entire system is over \$20,000,000. The real estate of the company is situated in every ward of the city, so that almost every regulation as to paving, sewerage, street opening, tearing up of streets by municipal or other corporations, is felt by the railway company, and for this reason the real estate and tax commissioner must keep himself informed as to the workings of the various city departments having these matters in charge.

It is the opinion of the real estate commissioner that a street railway company can purchase as cheaply as any other corporation, for the real estate commissioner should be thoroughly acquainted

with the workings of the various city departments having these matters in charge. By this means we are enabled to tell at a glance on what properties we are encroaching and how much, and what properties we are losing by reason of inaccurate fencing. We are also enabled to tell whether the conditions of the deeds have been complied with as to cattle guards, cattle passes, farm crossings, gates, etc., and this often becomes important for us to know.

These maps or surveys will also serve as the basis for our filing system. Each parcel of land is given a distinguishing number and the contracts, deeds, mortgages, abstracts, etc., are numbered to correspond. The originals being permanently filed, copies are

## Detroit United Railway.

### TAX LIST FOR TOWNSHIP, STATE AND COUNTY TAXES.

Please fill out this blank in detail and return to Robert Oakman, Real Estate Commissioner, Detroit United Railway, 12 Woodward Ave., Detroit, Mich.

A full description on this blank of each real estate and personal property will prove advantageous both to the officers of the township and of the company, and will enable the company's officers to compare such descriptions with the original deeds and papers and thus avoid errors that might invalidate the assessment.

Please separate the school tax by school districts and the road tax by road districts, and put the number of each school district in column 15 and the number of each road district in column 17.

If convenient, please state the number of miles of track assessed in the township and the number of miles of track in each village of the township, under the heading "Description" in the third column of the blank.

with land values in the districts through which the roads run, so that he can not only save his company from the sand-bagging tactics of the prospective sellers, but can also so select his purchase that real estate investments will at least approximate in earnings the earnings of the rest of the system in proportion to the money invested.

In straightening the tangles in rights of way over several hundreds of miles of suburban railways through country districts, he comes upon many queer complications, caused by the haste of the builders of the road to get the tracks down. Descriptions for rights of way are as follows: "Begin at a point marked by a brick

used for general reference. In addition there is prepared a short form record or abstract of all the deeds, contracts, mortgages, etc. of the company, which record will be published in book form.

We have classified the written records not only according to the name of "the opposite party" by a card index system, but also have arranged the documents according to the location of the property on each of the respective lines. Thus deeds numbered from 100 to 200 will describe a continuous right of way made up of one hundred separate but adjoining parcels. Our letter files are also arranged on the same system, viz., according to the location of the property concerned. Each letter as received and answered is filed

with a carbon copy of the reply under a number corresponding with the number given the parcel of land to which the letter relates, so that at any moment all the correspondence relating to any particular parcel of land is easily obtainable.

Under the Michigan statutes a street railway company must secure a franchise from each and every city, village and township through which it passes. The result is that the franchise records of any line of considerable length are very cumbersome. The Detroit United Railway files its franchises like its deeds with a safety deposit company and for general reference has duplicates neatly printed and bound in compact book form.

For real estate situated in the city of Detroit we keep an assessment and tax roll which is a duplicate of the official roll of the city and county, and besides this we have a land book in which is recorded the information called for in the blank form published herewith. All properties are set down according to the ward in which they are located and are described according to the description under which they are assessed. This land book is our working record in which changes are made from time to time.

For real estate outside of the city of Detroit a record is kept in

August and January. Water taxes are payable quarterly, while special taxes for pavement, sewers and street openings are payable at different specified times. There is also a burdensome tax of fifty cents charged for every electric freight car entering or leaving the city. Failure to pay any one of these taxes promptly results in the imposition of fines and penalties.

The good will of the officers and people along the line of a suburban railway is a valuable asset of the company and the real estate commissioner in his daily intercourse with these officers must bear in mind that the village council has the power to grant franchises, levy taxes and regulate the speed of cars, etc.; that it is the duty of the township supervisor to assess the railway property for the purpose of taxation and that the township board of which he is the chairman controls the highways, bridges, grades, franchises, taxes, etc., for the township; that the highway commissioner, the two justices of the peace and township clerk are all members of that important body known as the township board; that the treasurer and surveyor of the township have much to do with a suburban railway and that the three hundred overseers of highways or pathmasters are ever on the alert to see that the tracks are neither

IN THE CITY OF DETROIT, MICHIGAN.

WHEN PURCHASED	USED FOR	RENTED OR LEASED	FOR SALE	TITLE AND ABSTRACT	CITY TAXES WHEN PAID	COUNTY TAXES WHEN PAID	STATE TAXES WHEN PAID	SPECIAL TAXES	REMARKS
									1
									2

LAND REGISTER—RIGHT HAND PAGE [SIZE OF ORIGINAL 16 X 18 1/4 IN.; 50 LINES PER PAGE.]

a register conforming in every particular to the township assessment roll, the form for which is prescribed by law. The taxes and tax rates are also set down in this record, so that the new assessment and the new tax may be easily compared with the old. When paying the taxes the rolls of the city or county must check with the company's rolls and the tax receipts must check with both. The record of the payment of the tax is the same for the company's roll as for the city and county rolls; thus giving a perfect check system which can be easily and economically executed. After payment of the taxes the original tax receipts are filed with the deeds in the safety vault. The importance of a complete assess-

ment and tax record cannot easily be overestimated by a large railway system in Michigan, for the system of assessment and collection of taxes is not uniform. For example, the ad valorem taxes for Detroit are payable to the receiver of taxes in July and the taxes on gross earnings are payable to the city treasurer in January and July, while state and county taxes for the city of Detroit are payable to the county treasurer in November. Again, the city and village taxes outside of Wayne County are payable at various and sundry times and the township and county taxes outside of Wayne County are payable in December and January. The immovable road district taxes may be called for at any time between

above nor below the grade and that the fences, crossings and cattle guards are in a safe condition and finally that the road district tax is promptly paid. The commissioner must know the register of deeds and the county treasurer, the heads of the counties through which the road runs and he must be on speaking terms with the sheriff and the marshal of the village, who can, if he will, protect the property of the company from thieves and vandals. Besides this, he must remember that there are tax reviewing boards in every city, village and township who can "soak" the railway for high taxes if they choose to do so.

It goes without saying that if the operating department desires

to run a steam train at night over an electric railway whose franchise prohibits the use of steam, the commissioner is asked to obtain a franchise from the village councils and the township boards as well as to secure releases from damages from the abutting property holders. If a crossing at grade is desired over a steam railroad, the commissioner must go to the state commissioner of railroads, or to the state crossing board, who, by the way, are uniformly opposed to such crossings, and obtain a permit. These are a few of the duties imposed upon the real estate commissioner of the Detroit United Railway.

Under the constitution of Michigan all property, real and per-

sonal, not expressly exempted by law, is assessed at cash value and the statute defines cash value as the usual selling price, being the price which could be obtained therefor at private sale and not at forced or auction sale. The assessor must consider the advantages or disadvantages of location, quality of soil, franchises and other privileges. A street railway franchise is assessed with the track which is held to be personal property under our law.

The Board of State Tax Commissioners, which has supervisory control over the assessing officers of the state and which has power

ROBERT OAKMAN.

to review the assessments of the local assessing officers, estimates the value of the road as a unit taking into consideration the value of the franchises as well as the value of the physical property. It also investigates the gross earnings, the net earnings of the road and the stock and bond values. Sometimes it uses one method, sometimes another, and frequently a method of its own. It attempts to get at the value of each road as an entirety and then deduct from this sum the value of the real estate which is assessable

condition of the road at the time of the assessment. For the preparation of this blank elaborate reports are required by the real estate and tax commissioner from the various departments of the company and much time and labor is required on the part of the commissioner in order to so systematize and set forth these details as to present a comprehensive statement of values.

After the assessments have been made by the supervisors and passed upon by the local boards of review, but previous to the date set for collection of the taxes, the real estate of the company is listed according to the township it is situated, on blank "B" and the sheet sent to the local treasurer who reports to the company the exact assessment and tax against both the real estate and personal property of the company. For our preparation of this blank we refer to the land register previously mentioned. This blank serves the purpose of receiving reports as to city and village taxes as well as township taxes as the city and village officers can use the blanks columns.

[Mr. Robert Oakman was for ten years engaged in the real estate business in the City of Detroit previous to his appointment as City Assessor in that city. He served for four years as Assessor and resigned his position in order to accept an appointment under Governor Pingree as a member of the first Board of State Tax Commissioners of Michigan. While a member of that board he calculated the values of the steam roads of the state for the benefit of the State Legislature on the earning power basis, while Professors Cooley and Adams of the University of Michigan were estimating the physical property values and the franchise values on stock and bond and other bases. Mr. Oakman has held many positions of trust from city, county and state and is an authority on the Michigan Tax Law.]

CLAIM DEPARTMENT DETROIT UNITED RY.

The company's instructions to employes regarding accidents read as follows: "You will use the utmost care and vigilance to prevent accidents. Should any accident or collision, however slight, occur, or should any accident happen to a person who has just left the car before reaching the sidewalk, or should you have any trouble with passengers with reference to fares or otherwise, you must immediately fill out an accident blank in duplicate, giving the date, line, place, time, direction, car number, number of passengers on the car at the time of accident, your name, the names and addresses (business address preferred) of as many witnesses as possible, and those of the party or parties injured or with whom controversy took place, with a brief description of the accident, collision or trouble. These you must sign—one to be left at the car house for your

CITY TAX LIST  
DETROIT UNITED RAILWAY

Real Estate in the City of Detroit,  
For City Purposes.

YEAR 190

Make Receipt in the name of DETROIT UNITED RAILWAY and notify Robert Oakman, Real Estate Commissioner, 12 Woodward Avenue.

where situated, the remainder is apportioned to the various townships in proportion to the track mileage in the township.

In order to assist the Tax Commission and the local assessing officers in arriving at the cash value of properties a statute provides that every assessing officer shall require from every person a full and correct written statement under oath of all the property he owns liable to assessment in each assessment district. The State Tax Commission provides a blank form on which to make this statement. This blank requires full and detailed information as to all classes of physical property, the original cost of each piece of property, its present condition, etc., and also a detailed statement of the financial

division superintendent, and the other to be enclosed in the proper envelope and forwarded to the claim department immediately. After 6:00 o'clock p. m. both reports will be left with the car house foreman. In case of serious accident notify telephone 2238, who in turn will immediately advise the proper persons.

"Too much emphasis cannot be laid on the necessity of getting the names and addresses of the party or parties injured and as many witnesses as possible, and getting the report to the claim department at once.

"You are absolutely prohibited from talking about any accident to any person, except the proper officers of the company.

"If any person is injured, however slight, you must render all assistance in your power, and if the services of an outsider are required, state in your report just what action was taken.

"You will send to the claim department, whenever possible, the names and addresses of anybody whom you may see indulging in reckless driving."

As soon as the report of an accident is received at the claim department, it is entered in what is known as the "Accident Record Book." The book is ruled in columns, the columns heads across the page being as follows: "Year," "Month," "Day," "Number," "Line," "Car Number," "Names of Motorman and Conductor," "Name of Injured Party," "Nature of Case," and "Remarks." All accident reports as they are received are numbered consecutively, this number being placed after each case in the column headed "Number." Just as soon as the report reaches the office, and if the passenger is badly injured, a special report is immediately sent to the company's surgeon, who, as soon thereafter as possible, calls on the injured party, secures the statement of the victim, and all the witnesses possible, and of course does everything in his power to relieve suffering and pain. It is found the employment of a special doctor in this way is productive of excellent results, inasmuch as he is able to protect the company's interests to a greater degree than would an outside physician who might be called to treat the case. It is also believed that this procedure is in the interests of the injured party, as the company's doctor is able to give expert treatment and advice without charge to the patient, whereas if the first doctor within reach was called, it might result in the patient receiving improper treatment, and in any event, the expense would be considerable.

If a claim arises out of an accident, the case is immediately entered in a book known as the "Claim Register." Each claim has a separate page, at the top of which are the headings: "File Number," "Name" and "Nature of Claim." On this page is kept a complete history of the case, including records of all papers made out, dates when papers are received and delivered out, references to witnesses' statements, etc. When the case is entered in the claim register, it is given a number known as the "Claim Number." All papers pertaining to each case are kept in a file together, and are given a number corresponding to the claim number. A force of investigators is employed for the purpose of looking up accidents, securing witnesses' statements, etc., etc. The company seldom settles a case to avoid law suits; in other words, if the company is clearly responsible it makes the best settlement possible, but if, in the opinion of its legal advisers, it is not responsible, the case is always fought out in the courts. Judge Walter Ross is the company's claim agent. In a recent interview, Judge Ross pointed out a few of the difficulties arising in the claim department of a street railway that are not encountered in steam railroad practice. For instance, the Detroit United Ry. is operating cars every half minute on the principal streets for 16 hours a day, and these cars make more stops on a single line from the river to the city limits, than the Michigan Central Railroad makes from Detroit to Chicago. The street railway company operates in the crowded public streets with teams, bicycles, pedestrians and children occupying its tracks to about the same extent as do the company's cars. In addition there is the transfer question with all the misunderstandings and disagreements arising from the same. In view of these conditions, the wonder would seem to be, not that accidents occur on street railroads, but that the number of serious accidents is as small as it is.

#### DISPATCHING CARS AND SAFETY PRECAUTIONS IN DETROIT.

Cars on practically all the interurban lines owned by the Detroit United Ry. are dispatched by telephone from one central office located at Royal Oak. A time table especially prepared for the guidance of employes is issued and heads of operating departments are required to see that all their subordinates are furnished with each issue of the time table and each employe must sign a receipt for his copy of the schedule. Due notice of the issue of a new schedule is given by special notice posted upon the bulletin boards. On the time table scheduled meeting or passing points are indicated by figures in full faced type. As long as these meeting times are complied with no special orders are necessary, but whenever

cars fail to make regular meeting points they immediately become subject to orders from the dispatcher and must not move without such orders.

The chief dispatcher keeps a train sheet on which he enters all orders given, leaving and arriving times, and other information for his own guidance relative to the moving of cars. The sheet is similar to several that have been reproduced in recent issues of the "Review." Mr. A. E. Rosso is chief dispatcher. The company has a private telephone line equipped with instruments made by Stromberg & Carlston, of Chicago. On its dispatching telephone line the company has adopted instruments having 60,000-ohm generators, and 1,600-ohm ringers.

#### HOTELS IN DETROIT.

Detroit has long been known as the "Convention City," and the hotel accommodations are second to none in any city of equal size. The A. S. R. A. headquarters will be at the Hotel Cadillac, on Michigan Ave. not far from the City Hall.

The oldest hotel in the city and a most popular one is the Russell House, directly opposite the City Hall; this hotel is first class in all appointments, having a particularly good restaurant. Accommodations may be had on either the American or European plan.

The Hotel Normandie is a handsome five-story structure at 11 to 23 Congress St., in the heart of the city, and is equipped in the most modern manner throughout; this is an American plan house and the table and service are first class.

The Griswold House, which is conveniently located for Convention attendants, is conducted on both European and American plans, the rates being \$2 to \$3 per day American, and \$1 to \$2 European; Postal & Morey are the proprietors. The same firm also conducts the Oriental-Griswold Annex, which is entirely on the European plan.

The Hotel Metropole is on Woodward Ave., near the Russell House, and conducted on the European plan, the house having an excellent restaurant.

Other down-town hotels are the Hotel Sainte Claire and the Hotel du Nord, on the American plan, and the Hotel Wayne, American and European.

#### KANSAS CITY NOTES.

On the night of September 1st the Troost Ave. cable of the Metropolitan Street St. was stopped for the last time, and taken out, and the following day electric cars began operating on one track while the opposite track was being relaid with 106-lb. rails.

The park season has been an exceptionally successfully one with the Metropolitan Street Railway Co. An Italian band at Troost park attracted the largest crowds that the park has ever held and at Electric Park there were 50 per cent more admissions than at any previous season, about 571,000 persons being admitted to the park during the season. A loop the loop railway proved one of the principal attractions. During the month of August while the large band was at Troost Park the local band and moving pictures were removed to Budd Park, a handsome park owned by the city, and although the attractions were free at this park, they did not prove much of a success, people evidently preferring to pay admission to the other parks.

The ducts for operating the high tension alternating current cables from the new power stations to the sub-stations are being put in place very rapidly. They are being laid with a view to future extensions and several times as many ducts are being put in place as are required for present use. The ducts are of glazed tile set in Portland cement mortar forming a very substantial construction. They all contain No. 6 lead covered cables.

Early on the morning of September 2d two men overpowered the night watchman at the Carbondale Division car barn and commanded him to open the safe that contained all the receipts of Labor Day. As the night man did not have the combination of the safe the men proceeded to blow it open with dynamite. While they were engaged in this work an officer happened to come into the barn and in the fight which ensued the officer was killed and the night man was shot twice and probably fatally wounded. The robbers left without securing anything. The company at once offered \$500 reward for the capture of the men, and they were taken into custody before the following night.

LIGHT GUARD ARMORY - THE CONVENTION HALL.

**OFFICERS A. S. R. A.**

President—H. H. Vreland, president Metropolitan Street Railway Co., New York, N. Y.

First Vice-President—Charles W. Wason, president Cleveland, Painesville Eastern Railway Co., Cleveland, O.

Second Vice-President—Edwin C. Foster, vice-president Boston & Northern Railroad Co., Boston, Mass.

Third Vice-President—H. M. Sloan, general manager Calumet Electric Street Railway Co., Chicago, Ill.

Secretary and Treasurer—T. C. Pennington, treasurer Chicago City Railway Co., Chicago, Ill.

Executive Committee—The president, the vice-presidents and Walton H. Holmes, Kansas City, Mo.; John A. Rigg, president Union Traction Co., Reading, Pa.; Daniel B. Dyer, president Augusta Railway & Electric Co., Augusta, Ga.; T. J. Nicholl, vice-president Rochester Railway Co., Rochester, N. Y.; George W. Dickinson, vice-president Seattle Electric Co., Seattle, Wash.

A complete list of the cities where the conventions have been held and the presiding officer is as follows:

Boston	Moody Merrill	1882
Chicago	H. H. Littell	1883
New York	William H. Hazzard	1884
St. Louis	*Calvin S. Richards	1885
Cincinnati	Julius S. Walsh	1886

Washington	Charles B. Holmes	1888
Minneapolis	George B. Kerper	1889
Buffalo	Thomas Lowry	1890
Pittsburg	Henry M. Watson	1891
Cleveland	John G. Holmes	1892
Milwaukee	D. F. Longstreet	1893
Atlanta	Henry C. Payne	1894
Montreal	Joel Hurt	1895
St. Louis	H. M. Littell	1896
Niagara Falls	Robert McCulloch	1897
Boston	Albion E. Lang	1898
Chicago	C. S. Sergeant	1899
Kansas City	J. M. Roach	1900
New York	Walton H. Holmes	1901
Detroit	H. H. Vreland	1902

\*Deceased.

The Light Guard Armory, of Detroit, which has been selected for the Convention Hall, is a well-built brick building in the business center of the city, and is conveniently located to hotels and street railway lines. Ample provisions have been made for heat, light and power, and both alternating and direct current will be at the disposal of exhibitors. A heavy wooden flooring will be put in place so that exhibits can be bolted or nailed down if desired.

Curt Hoffman, Abend Post.  
Adolph Niederprum, Michigan Volksblatt.  
PRESS AGENT G. Walter Meade.

The headquarters of the "Daily Street Railway Review" during the Convention will be Space No. 28 at the Convention Hall, where

representatives of the "Review" will be on hand to welcome all visitors. Both the members of the Associations and the supply men attending the Convention are cordially invited to visit the headquarters of the "Review," where conveniences for correspondence, etc., will be at their disposal. The "Daily Review" will be issued on the morning of October 8, 9, 10 and 11, and will contain complete proceedings of the sessions of the Associations.

**A. S. R. A. PROGRAM.**

Papers will be presented at the American Street Railway Association convention on the following subjects:

"Registration of Transfers"—Brooklyn Heights Railroad Co., by C. D. Meenly, secretary and treasurer.

"Benefit Associations"—Metropolitan Street Railway Co., of New York, by Oren W. Root, assistant general manager.

"Discipline of Employes by the Merit System"—Metropolitan Street Railway Co., of Kansas City, by W. A. Satterlee, general superintendent.

"Transportation of Light Express and Parcel Delivery"—Detroit United Railway, by George W. Parker, general express agent.

"The Steam Turbine: Its Commercial Aspect"—E. H. Sniffen, of Westinghouse, Church, Kerr & Co., New York.

"Signals for Urban and Interurban Railways"—Old Colony Railway Co., Boston, by G. W. Palmer, jr., electrical engineer.

"The Adjustment of Damage Claims"—Chicago City Railway Co., by M. B. Starring, assistant general council.

Report of Committee on Standards: N. H. Heft, president Meriden (Conn.) Electric R. R., chairman; E. G. Connette, vice-president and general manager, Syracuse (N. Y.) Rapid Transit Co.; C. F. Holmes, Kansas City; John I. Beggs, president and general manager Milwaukee Electrical Railway & Light Co.; E. A. Newman, general manager, Portland (Me.) Railroad Co.; R. T. Laffin, general manager, Worcester (Mass.) Consolidated Street Railway Co.; Will Christy, vice-president Northern Ohio Traction Co., Akron, O.

Report of committee on Rules for the Government of Employes: J. C. Brackenridge, general manager Brooklyn Heights R. R., chairman; E. C. Foster, general manager Old Colony Street Railway Co.; W. E. Harrington, general manager Camden (N. J.) & Suburban Railway Co.

The annual banquet will be at the Hotel Cadillac, the association headquarters, Friday evening, October 10th.

Thursday, October 9th, has been set apart as "Exhibitors' Day," and no meetings of the association will be held on that day.

The papers have not yet been assigned to the different sessions, but other details of the program are as follows:

**WEDNESDAY.**

Address of welcome by Mayor W. C. Maybury, of Detroit.

Roll call.

Invitations extended to join the association.

Address of President.

Report of Executive Committee.

Report of Secretary and Treasurer.

Appointment of committee on nomination of officers and selection of next place of meeting.

**THURSDAY.**

No business session will be held on Thursday.

**FRIDAY.**

Report of committee on standard rules for government of employes.

Report of committee on standards.

Election of officers.

**ENTERTAINMENTS.****WEDNESDAY,**

An informal reception will be tendered the ladies in attendance at the convention from 10 a. m. to 4 p. m. at Hotel Cadillac.

A general reception will be held at Hotel Cadillac at 8 o'clock in the evening.

**THURSDAY,**

The entire day will be devoted to the examination of exhibits at Convention Hall.

Thursday evening there will be a theater party at the Detroit Opera House to see "When Johnnie Comes Marching Home."

**FRIDAY,**

A trolley ride will be given for the ladies on Friday morning, leaving Hotel Cadillac at 10 a. m. for Mount Clemens, via the Rapid Ry. and Gratiot Ave., returning via the Shore Line to the Country Club, Grosse Pointe, where luncheon will be served at 1 o'clock. The return to the city will be made at 4 p. m.

The banquet will be held at Hotel Cadillac at 8 o'clock, at which the installation of the officers elect will be held.

**ANNOUNCEMENTS.**

Badges of the association will be honored on all city and interurban lines.

Information bureaus will be established at Hotel Cadillac and at Exhibition Hall.

The Western Union and Postal Telegraph companies will establish offices in the Exhibition Hall and the Michigan Bell Telephone Co. has installed telephone instruments for the use of the delegates at the hall.

The American District Telegraph Co. will also install its service at Exhibition Hall.

The power houses and storage battery stations at Riopelle St. and Hancock and Third Aves., in Detroit, and at Farmington Junction, Birmingham, Rochester, Ecorse, New Baltimore, Ypsilanti, on the interurban lines, will be open for inspection of delegates at the convention.

**PROGRAM OF ACCOUNTANTS' ASSOCIATION.**

Tuesday, Oct. 7, 1902.

Meeting of the Executive Committee, Hotel Cadillac.

Wednesday, Oct. 8, 1902, 10 a. m.

Address of Welcome by Hon. F. A. Blades, Comptroller of the City of Detroit.

Annual Address of President.

Annual Report of Executive Committee.

Annual Report of Secretary and Treasurer.

Paper: "The Collection and Reporting of Fares on City and Interurban Lines," by Wm. C. Sampson, treasurer, Union Traction Co. of Indiana.

Appointment of Convention Committees on Nominations and Resolutions.

Afternoon, 2 o'clock.

Annual Report of Committee on Standard Material and Supply Accounting.

Paper: "The Stationery Store-room," by J. R. Shurtz, auditor South Jersey Gas, Electric & Traction Co., Camden, N. J.

No Session on Thursday, Oct. 9, 1902.

Friday, Oct. 10, 1902, 10 a. m.

Chart of Street Railway Blanks, suggested by G. E. Tripp, general auditor, Stone & Webster's Co's., Boston, Mass.

Annual Report of Standardization Committee.

Afternoon, 2 o'clock.

Report of Committee on Standard Form of Report for Electric Railways.

Report of Committee on Nominations.

Election of Officers.

Report of Committee on Resolutions.

Installation of Officers.

Adjournment.

**OFFICERS ACCOUNTANTS' ASSOCIATION.**

President, H. C. Mackay, comptroller Milwaukee Electric Railway & Light Co., Milwaukee, Wis.

First Vice-President, C. L. S. Tingley, secretary American Railways Co., Philadelphia, Pa.

Second Vice-President, W. B. Longyear, auditor Brooklyn Rapid Transit Co., Brooklyn, N. Y.

Third Vice-President, S. C. Cooper, secretary Cincinnati Traction Co., Cincinnati, O.

Secretary and Treasurer, W. B. Brockway.

Executive Committee, the officers and—

W. F. Ham, comptroller Washington Traction & Electric Co., Washington, D. C.

*Address all Communications and Remittances to Windsor & Kenfield Publishing Co  
Chicago, Ill.*

**CORRESPONDENCE.**

We cordially invite correspondence on all subjects of interest to those engaged in any branch of street railway work, and will gratefully appreciate any marked copies of papers or news items our street railway friends may send us, pertaining either to companies or officers.

**DOES THE MANAGER WANT ANYTHING?**

If you contemplate the purchase of any supplies or material, we can save you much time and trouble. Drop a line to THE REVIEW, stating what you are in the market for, and you will promptly receive bids and estimates from all the best dealers in that line. We make no charge for publishing such notices in our Bulletin of Advance News, which is sent to all manufacturers.

This paper is a member of the Chicago Trade Press Association.

Entered at the Post Office at Chicago as Second Class Matter.

VOL. XII.

SEPTEMBER 20, 1902.

NO. 9

The "Daily Street Railway Review" will be published at Detroit October 8th, 9th, 10th and 11th, and each number should be preserved and filed for binding. The "Daily" supplements the regular monthly issues of the "Review" and its pages will be numbered consecutively, following this issue. The "Daily Street Railway Review" will be mailed to all subscribers and give them the first complete reports of the two conventions.

As the date for the conventions approaches it becomes more certain that the Detroit meetings will justify the use of the well-worn phrase "better than any preceding convention." Secretary Pennington, of the A. S. R. A., had printed copies of all the convention papers and reports in the hands of members over three weeks before the date of the meeting, and his successful efforts in this direction will make it possible for the convention sessions to be devoted more exclusively to discussions than has been customary. Secretary Brockway, of the Accountants' Association, also arranged to have the reports and papers on subjects requiring special preparation for discussion, sent to the members well in advance of the meeting. We doubtless appreciate better than do members of the associations the difficulties to be met in thus securing the papers in advance, and we extend our congratulations to the secretaries.

Occasionally city street railway companies are asked to change the practice, which is now practically universal in this country, of stopping at the far side of street crossings. Stopping cars on the near side of crossings may at times be a convenience to a small minority of patrons, but it has two serious disadvantages. By far the greater number of passengers board and leave cars by the rear platform (many companies in fact prohibit passengers using the front platform) and when the car is halted on the near side of the street, the rear end is some distance from the crosswalk, the passenger having to step into a too-often muddy street and walk several yards through mud or, in winter, slush to the curb. The principal objection is the increase in the number of collisions with

vehicles and pedestrians resulting from attempts to pass in front of street cars in the belief that the car will stop before crossing the street, when such a stop is unnecessary and consequently is not made. Experience in several of the larger cities, and especially in Chicago, has shown that accidents from the cause mentioned can only be prevented by having a uniform rule; thus at boulevards and railroad crossings cars are always halted on the near side, stopping on the far side also if there are persons wishing to board the car at that point.

It is now practically certain that the organization of an association of street railway manufacturers and suppliers will be one of the important features of the Detroit convention. At a meeting of exhibitors at New York last year a committee was appointed to discuss plans for a "Street Railway Manufacturers' Association," and this committee has issued a call for a meeting to be held at Detroit on October 8th, the first day of the convention, for the purpose of organization.

It will be remembered that at the meeting of the executive committee of the American Street Railway Association held in Detroit last February, it voted "to make no change in the manner of handling exhibits." This action of the committee was, we understand, intended as a rejection of a plan submitted at that time which was in substance as follows: That the entire matter of the exhibits and convention entertainments, aside from the banquet, be placed in charge of an association or committee representing the suppliers, who would provide an exhibit hall at their own expense and also bear the cost of the various excursions and entertainments.

We believe that all parties in interest heartily approve of the A. S. R. A. executive committee in rejecting this proposition which was volunteered by some person, whom we do not know, not a member of the committee appointed by the suppliers at New York. The plan outlined by those representing the Street Railway Manufacturers' Association contemplates no changes in the relations heretofore and now existing between the A. S. R. A. and exhibitors at conventions, but is designed to relieve the street railway officials in the convention city of many of the responsibilities and annoyances now imposed upon them, and to enable the exhibitors themselves to handle matters relating to the transportation, installation and removal of exhibits in a more systematic and economical manner.

The call for the organization meeting of the Street Railway Manufacturers' Association will be published in the first number of the "Daily Review."

The change of name of the Union Internationale Permanente de Tramways, of Europe, to include both street railways and light railways, which is noted elsewhere in this issue, suggests the propriety of a change of the name of the American Street Railway Association to one which would be more characteristic of the present scope of the organization. Twenty-one years ago when the Association was organized its name was admirably chosen and it then represented exactly the province to which its business was limited. At that time street railways were comparatively short lines built with strap rails laid on stringers and the cars were exceedingly small, compared with present standards, and were universally propelled by horses or mules. The most important subjects before the Association then were the proper care of the live stock and of the stables, but during the last few years all this has changed and the street railway of olden times has practically ceased to exist. It is of course true that there are some companies operating cable and horse railways, which are members of the association, but it is now, we believe, ten years since a paper on cable railways has been read at one of the annual meetings; horse railway subjects have not been discussed for eleven years.

The definition of a street railway as given by Booth in his work on the "Law of Street Railways" was a road "constructed in streets, whether on, below, or above the surface, along and over which cars are propelled by animal or other power on fixed tracks as common carriers of passengers for the convenience and accommodation of the people living upon or near such highways, and to facilitate the transportation of travelers thereon." Street railways have always been distinguished in law from other railways by reason of the fact that they might, in common with the general

public, use the public highways, while steam railroads had the exclusive use of their roadbeds. Even so late as 1898, the special committee on the "Relations between Cities and Towns and Street Railway Companies," appointed by the Massachusetts Legislature, said of the street railway: "This is all the street railway was fifty years ago, when first laid; it is all it is now,—an improved line of omnibuses, running over a special pavement."

Obviously these definitions fail to define the membership of the American Street Railway Association today and the reason is that since the introduction of electricity there has come into existence a new class of roads which was formerly unknown; these are the suburban, interurban and what are known in Europe as light railways, on all of which electricity is the motive power. The Association is now concerned solely with electric railways, of which the strictly urban lines are by no means the most prominent.

So long as electric suburban and interurban railways confined themselves to the highways there was some propriety in calling them "street" railways, but now that these companies organize under the general railroad laws and build over private rights of way they certainly can not be called street railways. In fact at the time the Massachusetts Committee thus characterized street railways, emphasizing the use of the streets, there were 18 electric railways in that state which in the aggregate had 33 miles of road on private rights of way; four years later there were 51 roads built partly on private rights of way, in the aggregate 118 miles.

Yet the natural affiliations of the electric railway are with the American Street Railway Association, and they have but little in common with the members of steam railroad associations. Within ten years the name Street Railway Association has been outgrown because of the development of the business.

The "American Electric Railway Association" suggests itself as a name which would be eminently in keeping with the present scope of the organization and one which exactly defines its field today. Many of its most prominent representatives are able electrical engineers, in fact, even if not by title, and a perusal of the programs of the annual meetings for several years back will show the proceedings to have consisted largely of papers and discussions on electrical engineering subjects of a highly technical character.

We are convinced that what has been said concerning the name of the American Street Railway Association applies with equal, and possibly greater, force to the name of the "Street Railway Review," and we therefore make the announcement that beginning with our 13th volume in January, 1903, this paper will be known as the "Electric Railway Review."

At this time among the most important problems confronting the men charged with operating high-speed electric railways are the selection and perfecting of train-dispatching and signal systems, and the institution of a satisfactory discipline among the operating force. At the meeting of the New York State Street Railway Association there were several papers dealing with one or more of these subjects—Mr. C. B. Fairchild discussed discipline, Mr. T. E. Mitten presented a paper on car dispatching, Mr. C. R. Barnes, the electrical expert of the New York Railroad Commission, in an extended review of "Accidents on Electric Railroads" touched upon signals, dispatching and discipline, as well as accidents, and in addition a "Standard Code of Rules" for street railway men was submitted. On examination of the program for the Detroit convention of the American Street Railway Association it will be found that the merit system of discipline and signals for urban and interurban railway will be treated in papers, and that a committee will report a set of "Standard Rules." It is quite evident that the electric railway men of the country appreciate the importance of these questions and have them under consideration.

After reviewing the statistics on electric railway accidents in New York and discussing the causes Mr. Barnes recommended two subjects to the action of the association:

First—Every company should adopt a book of rules based on the standard rules. When the companies ask the commission for a copy of the standard rules they are unable to furnish them, as there are no official standard rules. There should be a standard set of rules adopted by the convention immediately.

Second—In nearly every head-on or rear-end collision which occurs, one of the cars telescopes the other. This is caused by difference in height of buffer and difference in construction of cars. This association should adopt a standard set of specifications for the con-

struction of the various sizes of cars, all to be of uniform height of buffer and uniform construction for each size of car.

Mr. Barnes states that "the ideal method of operation on any suburban or interurban railroad is the running of cars under a telegraphic train dispatching system," although he says in the next sentence that on most roads in New York this is impracticable. The relative merits of the telegraph and the telephone for car dispatching have been much discussed of late and there is by no means general acquiescence in regard to the telegraph system being the ideal one or even the best one. While the Hudson Valley Railway Co. has recently abandoned the telephone in favor of the telegraph, it is, we believe, the only electric railway that has done so; on the other hand, the present tendency of steam railroad companies is towards adopting telephones, the Illinois Central being one of the companies that considers the telephone more desirable for dispatching.

Apropos of discipline and accidents reference should be made to the strike with which the Hudson Valley Railway Co. is now contending. Two motormen were discharged because in the opinion of the superintendent, who had carefully investigated the matter, they had been guilty of negligence that caused collisions. The union to which the employes belonged demanded that the two men be reinstated, and on this demand being refused declared a strike that tied up the road for weeks by which its operation is still seriously crippled. It must be apparent that good discipline, such as is absolutely necessary to insure the safety of patrons, cannot co-exist with an organization of employes so unreasonable in its demands.

This number of the "Review" being our annual "Convention Souvenir," it is quite appropriate that a considerable portion of the paper should be devoted to the railways in and about the convention city. The history of the Detroit United Railway, which includes not only an extensive urban system, but also all but one of the seven electric interurban lines entering the city, is identified with more of the controverted questions connected with the development of electric railways than is the case with any other city system. As a result of the attempt to provide competing street railways which should charge a fare of but 3 cents the Detroit railway has had to confront some peculiar conditions. We believe that although the fare on some of the Detroit city lines is today but 3 cents (and it must be remembered in this connection that the city imposes certain burdens in matter of paving and repairs) it is recognized by the public that a 3-cent fare will not enable a railway company to operate its lines and by extensions into unremunerative territory assist in developing the suburbs of the city, which has everywhere been so important a function of street railways.

Some of the interesting features of operation in Detroit have been discussed by Mr. Stanley in his article on page 512. Among these are the conditions resulting from a reduced fare at certain hours; the congestion of traffic during a few hours morning and evening is phenomenal even when compared with the "rush hours" in other cities, the conditions in Detroit being aggravated, because all institutions employing large numbers of men arrange their working hours so that employes may avail themselves of the lower fare on the railways.

Mr. Stanley also refers to the transfer question and the arrangements made to dispense with transfer points in the down-town district, thus avoiding conditions favorable to the abuse of the transfer privilege. The experience at Detroit in the matter of track construction and rolling stock will doubtless prove instructive. The concrete sub-construction for tracks is pronounced highly satisfactory, provided the foundation be made deep enough. In the matter of rolling stock it is considered that a 12-bench open car 33 ft. long is as large as is desirable, while the present standard closed car (22-ft. body) could be enlarged with satisfactory results; the objections to larger open cars are that too much time is required for passengers to enter or leave the car and the difficulty the conductor has in collecting all the fares.

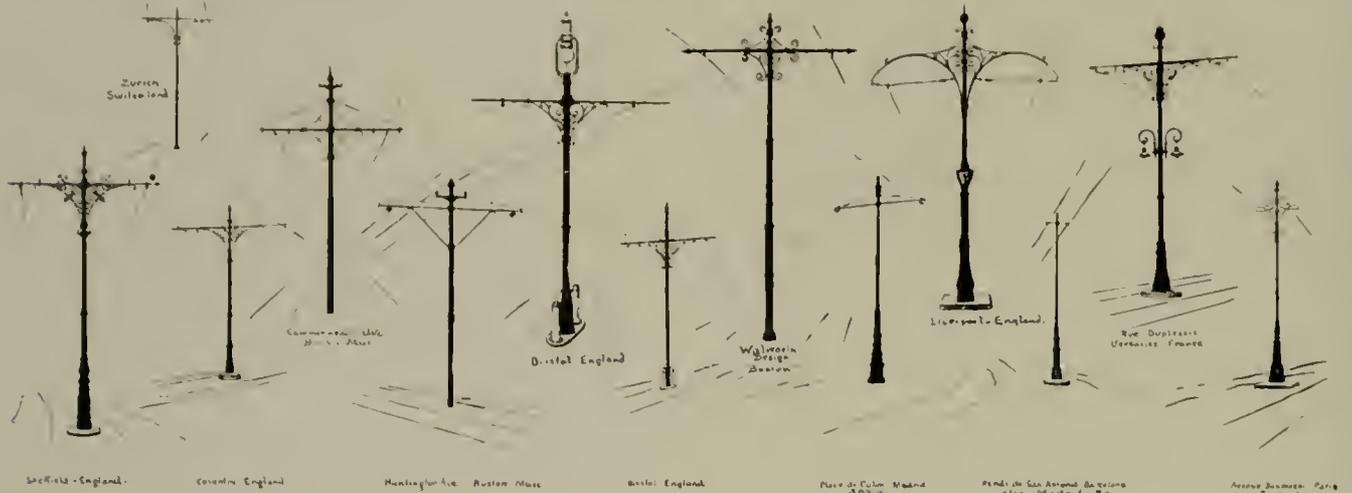

The numerous interurban lines centering in Detroit, some 300 miles of which are a part of the United Railway system, have favored the development of special services; pleasure riding has been promoted by the existence of favorably located parks and a special car which is designed for the use of visitors desiring to see the city has proved a paying venture, and the freight and express business of the city has required the organization of a special department which is fully described elsewhere.

# The Artistic Treatment of Electric Railway Line Construction.

BY H. P. QUICK.

In the United States at least, the earliest street railways using the overhead trolley wires were not situated where an attempt at artistic design in the matter of supports for these wires was thought necessary, or desirable, on account of the extra expense. The double wooden pole span wire construction was used in most suburban and cross country work, and even in the small towns and

have been more successful in the older countries, and there the long established artistic standards for public works have brought about the development of ornamental street railway poles, to a high degree. So much so that municipalities which spurned the American idea of two-pole span wire construction have allowed the introduction of electric railways, long delayed, using the center and side

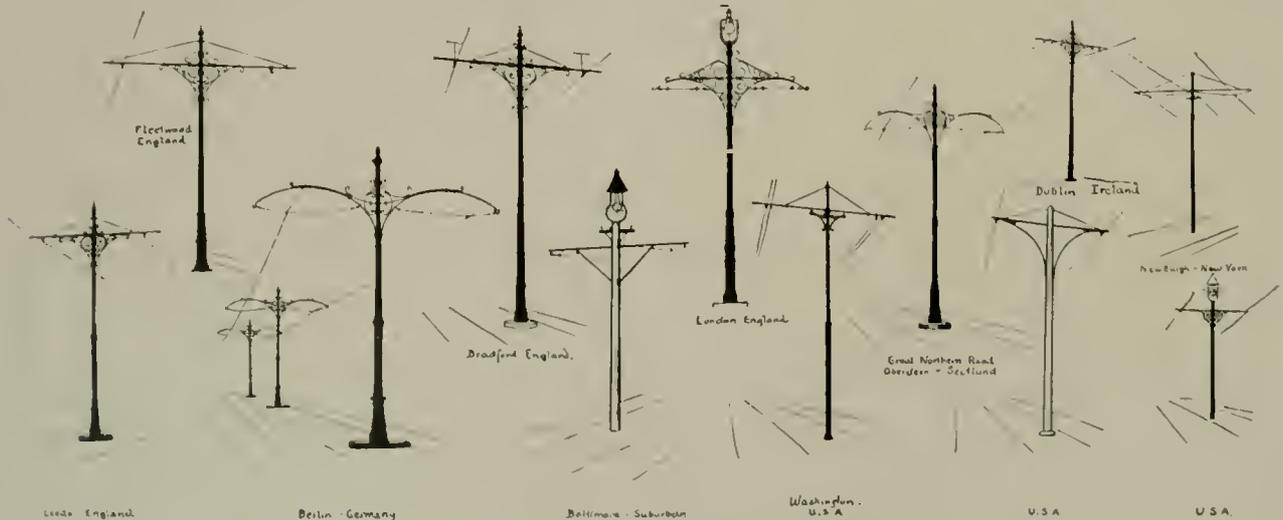

cities these poles were considered no worse than the existing telegraph poles. Municipal authorities in the thickly settled places soon demanded a more durable type, however, and the telescopic iron or steel pole was brought out and continues today most universally used.

It was soon discovered that old world street railways were using a more elaborate pole design, ornamenting it in various ways, and various influences were brought to bear upon railway companies in this country to follow in the old world's footsteps. Certain city developments coincident with the electrification of street railways favored this and so on boulevards and street reservations today

poles with bracket arms of an artistic pattern, and frequently electric light fixtures attached.

This difference in the treatment of such things is with us, I take it, not due to lack of skill or talent, but to lack of appreciation of the finer influences of such designs, and to greater haste in construction for a short lived usefulness, rather than for everlasting endurance. In the older countries centuries of existence seem to have brought the matter of the architectural adornment of streets to the point where nothing has been allowed to interfere with the standards set generations ago, for the beautifying of all the principal show places of the various cities, and this inherited artistic sense

may be seen many attempts at improvement in the character of pole design. Some of these are allowed to suffer from weather wear, or lack of paint and repair, and are burdened with various inelegant crossarms, braces, guard wires and poor looking wire connections until their faults have become so conspicuous that a return to two-pole span wires is considered more desirable in those cases. This is not so everywhere.

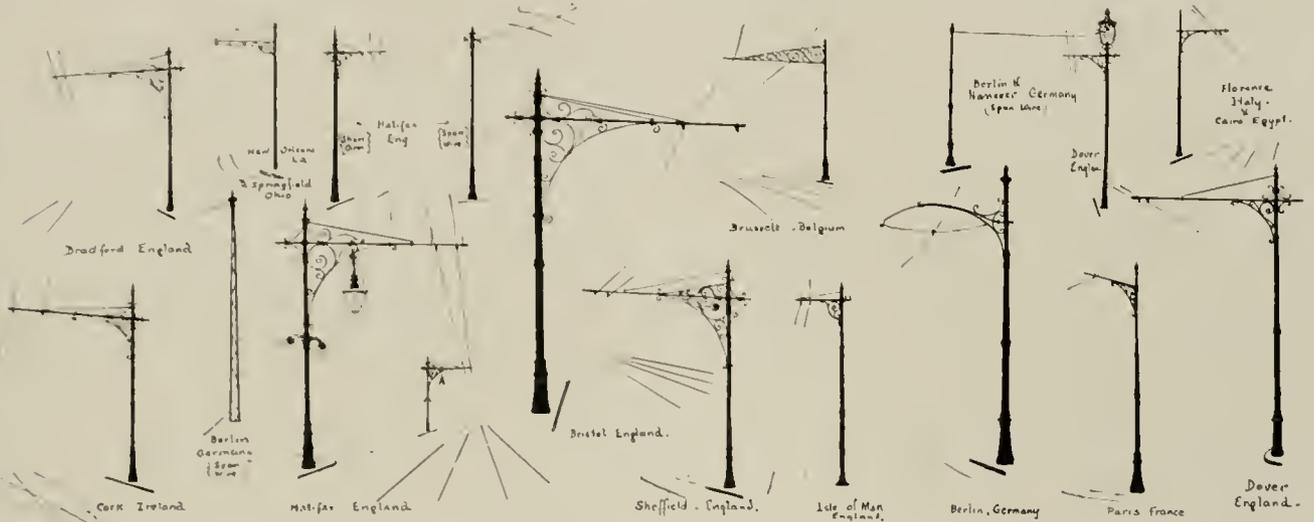

It must be confessed that the efforts to do this sort of work well

is ever observable in the finest works of the past and present generations, not only in buildings, walls, bridges, and architectural adornments, but in various other features of a city's outdoor embellishment. To this of course there are exceptions, but on the whole the statement is true, and we are constantly being reminded by people of the older countries of our defects in these lines. Nevertheless, with us the artistic sense is being developed and already there are signs that the germs of ideas which our architects and artists have

long had stored up from observation and study of the old world's work, are taking on forms that will ultimately influence public opinion to the extent of demanding greater attention to the artistic lines possible, even in commonplace things such as street signs, lanterns, gates, lights, and railway poles.

The influence of our great expositions is being felt, especially in public buildings, and when some one shall exhibit at such a place in connection with the general scheme, and in the most conspicuous

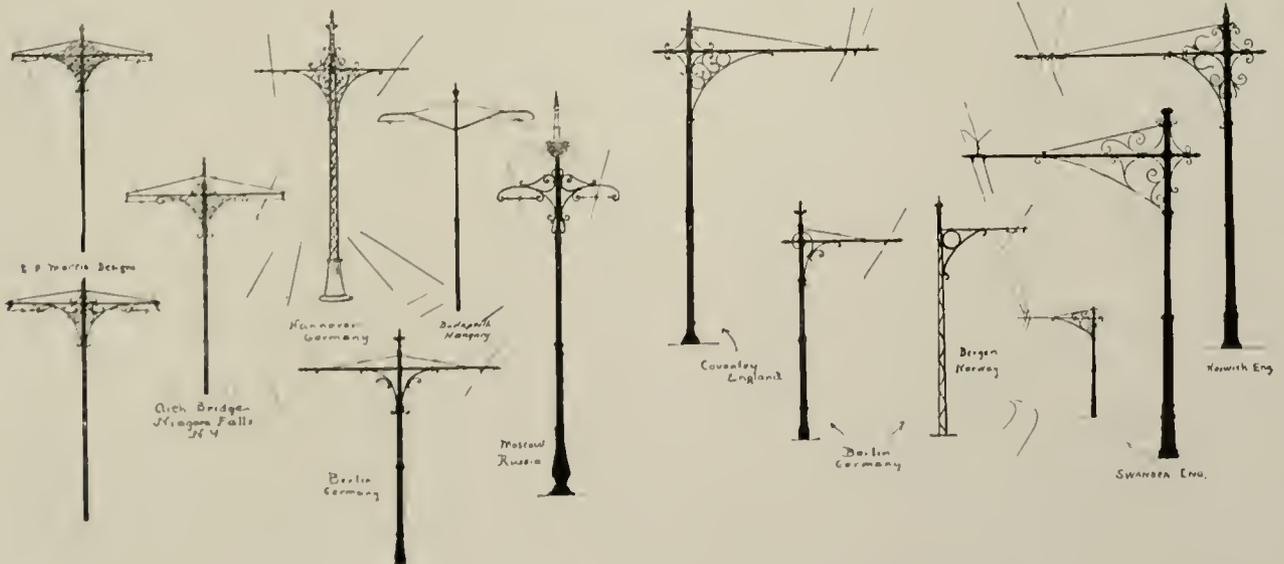

must be said that the latter is away ahead of the former, but the features of some foreign types of railway are so advantageous to the working out of ornamental line construction that they will be referred to here. The usual type of trolley pole or contact device used on top of the cars there, for example, is quite different from that in the United States because of the extensive use of double decked cars having roof seats requiring the pole to be placed on one side of the car roof. Further than that, the use of a horizontal

part of it, an example of the highest development possible, in street railway construction, together with all other street features, then will there be an influence at work in the matter of our street construction which no amount of other illustration will bring about.

All this is from the standpoint of the artist, engineer, or philanthropic citizen who looks at it with the eyes of a benefactor. It will usually be argued that the railway managers are not of this way of thinking, unless they see ultimate profit in that course. That there is a profit cannot be definitely proved, but it is generally noticed that attention to the appearance of lines and equipment, tends to draw people out and increase traffic, to make resi-

dwelling trolley contact is general and these features allow the wire to be placed so far to one side of the center of the track that when two tracks are close together with center or side pole bracket arms, these arms can be very short as some of the designs show, and hence the artistic treatment becomes easier and simpler. Where there is one track, the problem is still simpler, and the side pole becomes more decorative. Abroad there is frequently greater space allowed between tracks and this permits the use of center poles with islands about them which is more attractive and protects the poles better. The civil authorities too are more zealous for the public weal and taste, and require the carrying out of a great deal of

dence along the lines attractive. That such means are being used in the pole line is evident from a glance at the illustrations here with given, which are taken direct from photograph of actual construction in various parts of the world. They illustrate the variety possible, yet not all can be said to be worth reproducing. Some are more or less overladen with ornamentation, and others show a partial absence of it.

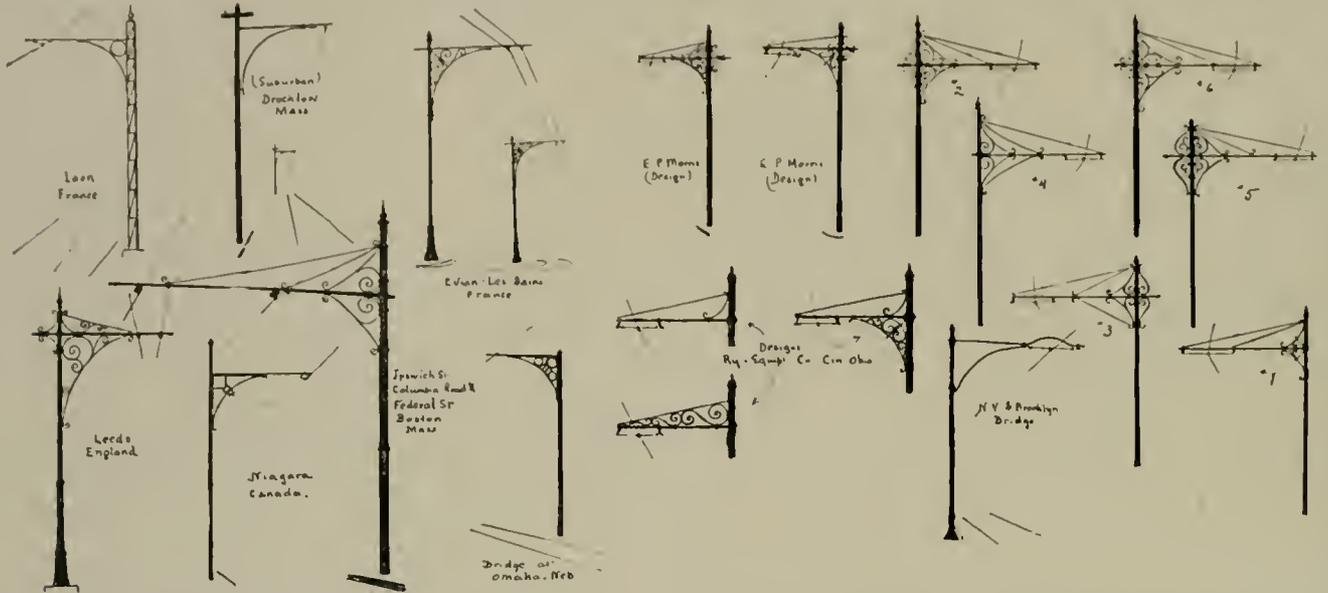

In comparing American with foreign practice in this regard it

ornamentation and as before stated, often require the combination of electric lights with the railway poles, adding much to the attractiveness of the streets.

In this country, however, the civil authorities are not to any extent influenced by the sensitive artistic natures of individual cities, but seem rather to advocate anything that will be financially profitable to them, or their constituents, while the interests of the railway company of course are those of erecting the most economical and

servicable pole considered consistent with its financial ability. If authorities do require a little ornamentation, it is left to the railway company to suit its convenience in getting that design and it will probably either be done by its mechanical foreman or some stock design of a manufacturer will be chosen, which may not have the merit of being hand wrought or artistic. On the other hand an architect if employed will most always overload a plain shaft with unnecessary ornamentation. The best results should come

moisture, inaccessibility to painting, and as with ordinary poles the use of concrete foundations extending above surface of ground far enough to prevent moisture working in to the joint; covering all pipe ends with caps, using short span wires under arms for hangers rather than long rigid bare arms, with no flexibility in connection. With these points looked after, there will be no more trouble with broken wires than on any ordinary span construction. Examples of most satisfactory and artistic center poles with short

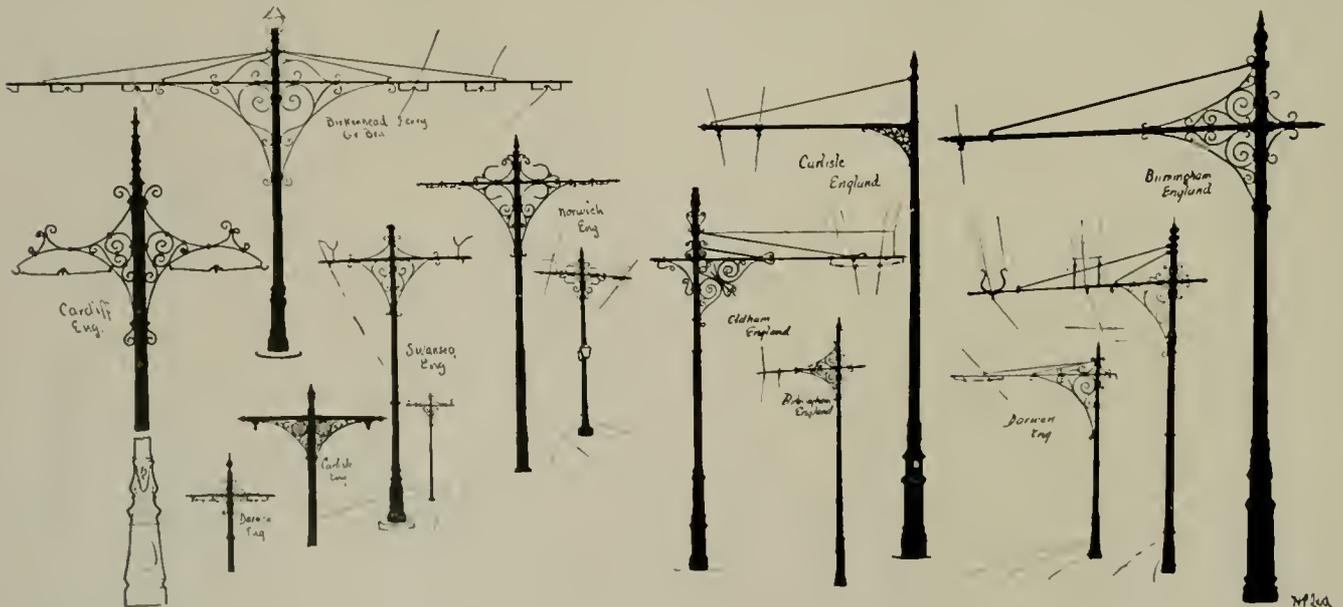

from the artistic mechanical engineer who knows how to come down to the level of the pole and invade the territory of the ornamental without making too great contrasts or injuring its practical value from the standpoint of construction, or operation, or exceeding the limit set upon decoration by the management.

A segmental or telescopic pole is not a beautiful form by itself, and requires some treatment in keeping with even the simplest

arms are those at Moscow, Russia, and Avenue Daumesnil, Paris, and for a wide span those at Berlin, Germany, or Norwich, England, could not be excelled. For a simple ornamentation with braces adapted to the line of strain, that on Commonwealth Avenue, Boston, is satisfactory from a practical point of view.

For side poles an artistic short arm construction is that at Paris, and Evian les Bains, France, and at Berlin, while for a long arm

bracket arms ornamentation. The joints, base, top and junctions of arms are usually ugly points needing attention and concealment.

If this be done the simpler and more massive the arm bracings are, the better. The main points to look after are flexibility in the span wire which carries the insulating ear or wire hanger, rigidity under both the upward pressure of the trolley pole and the downward pull of the wire with the vibrations in both instances, and provision for shocks due to flying poles, avoidance of pockets for

type those at Berlin, at Norwich, England, or at Boston and Birmingham are well balanced designs.

In this country it will be admitted it is generally impracticable and often dangerous to attempt to use either center or side bracket arm poles. The space between passing cars will not admit their use, nor are the widths of streets or location of tracks with relation to curbs suitable. But for parks, bridges, boulevards and reservations they are eminently suitable and desirable.

## RECENT STREET RAILWAY DECISIONS.

EDITED BY J. L. ROSENBERGER, ATTORNEY AT LAW, CHICAGO.

### DUTY TO REGULATE SPEED APPROACHING CROSSINGS.

West Chicago Street Railroad Co. v. Petters (Ill.), 63 N. E. Rep. 662. Apr. 16, 1902.

It was the duty of the company and its servants, in approaching crossings, the supreme court of Illinois holds, to so regulate the speed of its cars that collisions with other persons having the right to cross such streets could, by the exercise of ordinary care, be avoided.

### INJURY TO PASSENGER BY SUDDEN STOPPING OF CAR BY AND TO AVOID COLLISION—CULPABILITY ESSENTIAL TO LIABILITY.

Cleveland City Railway Co. v. Osborn (Ohio), 63 N. E. Rep. 664. Feb. 25, 1902.

Where a passenger on a street railway car was thrown from the car and injured by the sudden stopping of the car in an effort to avoid a collision, and by the shock of a collision which was not brought about by the negligence of the company, the supreme court of Ohio holds that it was *dammum absque injuria*, a loss without a wrong, or that kind of damage for which an action will not lie. It says that in an action to recover for personal injury occasioned by negligence of the defendant, the plaintiff cannot recover by merely proving an act of the defendant which was the proximate cause of the injury; but, to authorize a recovery, the plaintiff must also show that such act resulted from culpable negligence by the defendant.

### CONSTRUCTION AND OPERATION OF ROAD UNDER AUTHORIZED ORDINANCE WILL NOT PREVENT GRANT TO ANOTHER COMPANY—"EXTENSION" DEFINED—CONSTRUCTION OF INDEPENDENT RAILWAY AS EXTENSION.

Pennsylvania Railroad Co. v. Inhabitants of Hamilton Township and Mercer County Traction Co. (N. J. Sup.), 51 Atl. Rep. 926. Feb. 24, 1902.

A street railway company, the supreme court of New Jersey holds, obtains no such rights in a public road or street by the construction and operation of a railway therein under an ordinance passed ultra vires or beyond the lawful capacity or powers, say of a township, as will prevent the township committee from granting permission to another railway company to construct and operate its railways in the same public roads or streets. An "extension" of a railway, as the word signifies, it says, is a prolongation of it from one of its termini to some other designated point. And it holds that a grant of permission to construct as an extension what is rather an independent railway is beyond the powers of a township committee, and altogether nugatory, and that the mere construction, maintenance, and operation of such an extension can give no rights to the company.

### MUST PROTECT PASSENGERS AGAINST INJURY FROM WILLFUL MISCONDUCT OF EMPLOYEES.

Johnson v. Detroit Ypsilanti & Ann Arbor Railway (Mich.), 60 N. W. Rep. 274. May 8, 1902.

A passenger who paid his fare to a certain place and received a check or ticket in receipt for it was informed, after a change of conductors, that the ticket was not good, and, on his refusing to pay his fare, was ejected from the car. He again boarded the car, paid his fare again, and, it was testified, demanded the return of the ticket which was refused. A few minutes later, he went to the rear platform, where the conductor was, and again demanded the return of the ticket. In an altercation which ensued the conductor struck him and inflicted the injuries sued for. The principal contention of the company was that it was not liable for this act of the conductor, because not within the scope of his authority. The supreme court of Michigan, however, affirms a judgment

in the passenger's favor. It says that it thinks the rule relieving the master from liability for a malicious injury inflicted by his servant when not acting within the scope of his employment does not apply between a common carrier of passengers and a passenger, and that it is the duty of the carrier to protect its passengers against injury from the willful misconduct of its servants while performing the contract to carry.

### FRANCHISE CONDITIONS ENFORCEABLE BY MANDAMUS AGAINST PURCHASING COMPANY.

Township of Grosse Pointe v. Detroit & Lake St. Clair Railway (Mich.), 90 N. W. Rep. 42. Apr. 22, 1902.

In this case a peremptory writ of mandamus was issued by the circuit court, on petition of the township, requiring the Detroit, Lake Shore & Mt. Clemens Railway and the Detroit & Lake St. Clair Railway to comply with certain conditions of a franchise granted by the township to the first company, its successors and assigns, and accepted by such company, which afterwards sold its railroad, franchise rights, and other property to the second company. The writ commanded both companies to maintain certain electric lights during the hours of darkness, while actually engaged in running cars, and to run a car over said line daily, except Sundays, at such an hour that passengers thereon might make convenient connection at the terminus of said railway in Grosse Pointe Farms, with a car on the Citizens' line, reaching Woodward avenue, in Detroit, at 7 o'clock a. m., local time. The purchasing company contended that the writ of mandamus should not have issued against it—First, upon the ground that the franchise or license of a town board was a mere contract, and did not rise to the dignity of a statute, and therefore that the duty to perform the acts required by the writ was not a duty imposed by law, but a mere contractual obligation; and, second, upon the ground that it was not shown to have accepted the conditions of the franchise. With neither contention, however, does the supreme court of Michigan agree. It says that authority to occupy the highway was derived from the statute. The only limitation was that the consent of the local authorities be first obtained, and when that was obtained, the conditions were as binding as though imposed in the statute. As to the contention that the purchasing company was not liable to be proceeded against in the same manner as its grantor was, the court thinks it, unsound. It says that the only rights derived were by purchase, it was true, but it seems clear that such a purchasing company takes the road subject to all the obligations resting upon its grantor. Hence, the court holds that the writ of mandamus was properly directed to the purchasing company. But the other company having sold out to it, and not being in position to comply with the requirements of the writ, the order as to it was reversed.

### BACKING DELIVERY WAGON UP TO CURB WITH TEAM ON TRACK—DUTY OF EMPLOYEES TO NOTICE CONDITIONS PREVAILING ALONG TRACK—DUTY OF MOTORMAN APPROACHING WAGON.

Fenner v. Wilkesbarre & Wyoming Valley Traction Co. (Pa.), 51 Atl. Rep. 1034. May 12, 1902.

When a delivery wagon which was so constructed that the front wheels would not turn under the bed was backed up and stood against the curb, which was 12 feet 8 inches from the street railway track, at a place where a delivery was to be made, the horses were necessarily standing on the track. This was the position in which the driver was required to place his team to make the delivery. The supreme court of Pennsylvania says that it was upon the public highway, where the driver had the right to be, and where, in the performance of his duty, he was required to be. It was not a place of known danger, and the presence of the railway tracks upon the street did not make it so. The right of the company to use the track was superior to his right to occupy it, but this well-established rule did not prohibit him from using it temporarily for a

legal purpose, nor authorize the company's employes in charge of the car to endanger his life, when, by the observance of their duty, it could have been avoided. The place of the accident was in the public street, where both parties had a right to be, and where each, therefore, was bound to be on the lookout for the other. The position of the driver of the wagon became perilous not by reason of an illegal act in placing his team on the street car track, but by the subsequent recklessness and negligent conduct of the conductor and motorman on the car, which he could not, and was not required to anticipate. It was not in evidence that he saw an approaching car when he placed his wagon against the curb, nor that he had reason to apprehend the presence of one before he could deliver his goods and depart. The inference from the facts disclosed by the testimony was directly to the contrary. Whether he used ordinary and reasonable care under the circumstances disclosed by the evidence was a question for the jury.

Again, the court says that the street was narrow, and the community was thickly populated. Certain obstructions in front of the property where the delivery was to be made which necessitated the backing in of the wagon to unload it on the premises had been there for five or six months prior to the accident, and the company's employes in charge of the car knew this fact. It was their duty to take notice of the conditions prevailing along the track at the time of the accident, and which, according to their own testimony, they knew, and to run their car at a rate of speed which would not endanger the safety of those who might lawfully be on the track. A failure to observe these precautions was negligence. The undisputed fact here was that the motorman had a clear, unobstructed view of the team for a distance of more than 200 yards, and therefore his duty required him not only to run his car at a reasonably safe speed, but also to give warning of its approach to the wagon, regardless of the fact that it was on the track, not at a crossing. It was a place of danger,—where a collision might occur,—and hence it was his duty to take the necessary precautions to avoid an accident.

#### EJECTION OF PASSENGER HOLDING WRONG COUPONS THROUGH MISTAKE OF PRIOR CONDUCTOR—MEASURE OF DAMAGES.

*Brown v. Rapid Railway Co.* (Mich.), 90 N. W. Rep. 290. May 8, 1902.

A round-trip ticket consisted of eight coupons. Four of these coupons, colored respectively white, pink, yellow, and blue, were the "going portions of the ticket," and four coupons, colored respectively blue, yellow, pink, and white were for the return in inverse order. Each coupon contained the names of the stations between which it was good, and the words, "Detroit to Marine City, and Return," and "Void if Detached from Signature Coupon." The third conductor on the going trip discovered, and notified the passenger, that the previous conductors had made a mistake, and had taken coupons from the wrong end of the ticket; tore off and handed him the first two going coupons, and himself took the third one. The passenger asked if he could use the detached portions, and was told that they would be accepted by succeeding conductors. On the return trip, however, the conductor in charge of the car refused to honor these coupons, notwithstanding the passenger's explanation and offer to corroborate his statement by other passengers, and, on his refusal to pay another fare, expelled him from the car, after which he took the next car an hour later and paid his fare, on the conductor's refusal to accept the coupons after learning of the other conductor's action. Testimony was offered to show that the passenger had been sick, and suffered a relapse, being confined to his bed four or five weeks thereafter. In justice court he recovered a judgment for \$500, and the company appealed to the circuit court, where a verdict was directed in its favor. But the judgment of the latter court is reversed by the supreme court of Michigan, and a new trial ordered, though without costs to either party.

The supreme court says, in further explanation, that the most serious inconvenience that the passenger need have suffered was to pay 40 cents for his return fare, present his tickets, with proof of the circumstances, and get his money refunded. He was not content to do this. Rather than lose 40 cents, or be to the trouble of asking that it be refunded, he preferred to refuse to recognize the reasonable rule of the company. He refused to leave the car, notwithstanding the suggestion of the conductor that he pay his fare, and have it refunded later, and allowed the conductor to drag

him through the car, and actually made him lift him off. The supreme court says that it has several cases which hold that under such circumstances as these the conductor does not commit a wrong by ejecting from his train one who has no ticket, and refuses to pay, and that it would be absurd to hold that the conductor must take his passenger's word regarding his failure to have an appropriate ticket, or take the evidence of fellow passengers, and determine the matter at his peril, or that of the company. These two coupons which the passenger had were the first that should have been detached. Had he succeeded in riding over the first two sections without detection by the conductor, and detached them himself, he could have made the same claim, or sold them to another for second use. The law permits these companies to make reasonable rules for their protection, and this passenger had no cause of action arising out of his ejection from the car, as the circuit judge properly held. But, under the proofs, he paid 40 cents by reason of the inadvertence of the conductor, and, under his declaration, which alleged the contract and its breach, as well as the expulsion in aggravation of it, he had a right to recover that amount, though he had no right to expect a verdict of \$500.

#### ABUTTER MAY ENJOIN UNAUTHORIZED LAYING OF TRACK—RIGHT TO QUESTION POWER—CONSTRUCTION OF DELEGATIONS OF POWER—INDIVIDUALS NOT ENTITLED TO CONSTRUCT STREET RAILWAYS—WHAT STATUTE MEANS BY STREET RAILWAY.

*Allen v. Clausen* (Wis.), 90 N. W. Rep. 181. Apr. 22, 1902.

An abutting lot owner, the supreme court of Wisconsin holds, must submit without remedy or compensation to the injury caused by the construction of a street railway, when the acts are done within the street by authority of law, but may enjoin the laying of a railway track which is about to be laid without authority of law on the street in front of his premises.

A number of cases, the court says, have established the law in Wisconsin that the vacating of a franchise granted by the state can be accomplished only by proceeding in the nature of quo warranto in the name of the state, and that it is not within the province of a court of equity, at the suit of a private plaintiff, to question the regularity of the proceedings by which a municipality has, under duly delegated authority, granted a franchise on behalf of the state, of which the grantee is in de facto or actual exercise and enjoyment. It has, however, never been held that, where one attempts to justify acts by a pretended license or franchise which the grantor had no power whatever to confer, a court, whether of law or equity, cannot discover that fact and deny the claim of justification. It matters not whether such defect of power rests upon the state itself or upon any of its subordinate agencies attempting its exercise. The readiness of courts so to do has been evinced in many cases in this state and elsewhere.

As a corollary of the doctrine that the highways of the state are under the control of the general state government, and that the right to use the same for street railways, etc., is by franchise emanating from the state, the court says that it results that the municipal corporations have power to make such grants only by delegation from the state. It is a general proposition that a municipal corporation possesses and can exercise only powers granted by express words, or those necessarily implied in or incident thereto, or those essential to the declared purposes; not merely convenient, but indispensable. Any ambiguity or doubt as to existence of a power is to be resolved against the corporation, and the power denied. Another cardinal rule of construction is that the grant of a power under specified circumstances, or accompanied by defined conditions or limitations, excludes that power otherwise. The maxim, "Expressio unius, exclusio alterius," that is, "the expression of one thing is the exclusion of another," is especially controlling upon such legislation. The application of such rules of construction to section 1862 of the Revised Statutes of Wisconsin of 1898 must, of course, result in denial of power in any city to grant franchise to use streets for a street railway, except to a corporation organized for the purpose of operating such establishment under the Wisconsin statutes, or to persons "who have a right to construct, maintain, and operate a street railway," the section providing that any municipal corporation or county may grant to any such corporation, or to any

such person, the use of any streets or bridges within its limits. The last class obviously does not contemplate persons who have merely the common right to do business, for to that end the quoted words would be meaningless. The legislature must have intended to limit such franchises to persons distinguished from the great mass of mankind by the qualifying description. The descriptive words used with reference to the permitted grantees are well adapted to segregate those who have already had franchises from the rest of mankind. Those who have not received such franchise cannot, in any fair sense, be said to have the "right to construct, maintain, and operate a street railway." Men generally may have the natural right to build and use a railway on their own land or on that of others by their license; but a street railway, as mentioned in the statutes, means one laid in a street, and no man has a right to either construct or operate a railway there without permission so to do from the state. That an authorization to grant such franchises only to corporations excludes any power to confer one on individuals, and renders void any attempt so to do, has been often decided by other courts. The reasons for such holdings are obvious. The legislature having created corporations for the public purpose of operating street railways, having hedged them about with a code of statutory regulations for the safety and convenience of the public, and having the reserved right to change and control them, even to destroy them, may well adopt a policy of conferring extraordinary rights in its highways only upon the corporate bodies so within its control. The court cannot doubt that such legislative policy and purpose is apparent in the Wisconsin statutes, and that from the municipal corporations has been withheld any power to grant to individuals, except of a specified class, franchises to construct or operate street railways in or over the public streets.

### BUFFALO RAILWAY EMPLOYES' OUTING.

The International Railway Co., of Buffalo, gave each of its employes a day's outing this summer. This annual outing commenced on July 14th, and continued for eleven days, until every employe of the company had been afforded a pleasant day's excursion at Olcott Beach, the company's summer resort. The men were divided into eleven different sections, or groups, each group comprising the employes of one station, and it was planned to give each station force one day of freedom from railway cares and an opportunity for recreation at one of the finest resorts on Lake Ontario. Every man in the company's employ was afforded a pleasant day at the beach with his wife and children and friends. The company furnished free transportation for all, and its records show that 7,649 persons took advantage of the trip.

The entire beach and all of its amusement features were at the

A FEW OF THE BOYS.

service of the men and their friends, and everything was free, the company standing all the expense. No tickets were collected at the theater, and refreshments consisting of ice cream, lemonade, coffee, etc., were served free. Each section of excursionists arranged a program of games and sports for the day, all of which were carried out with much enthusiasm. A good band was in

attendance to furnish music for the occasion, and when the games and sports were over the Casino was thrown open for dancing, while the children crowded the merry-go-rounds and other amusement features.

One of the accompanying illustrations gives a view of a train carrying a station force to the beach. This train left the station

BUFFALO RAILWAY EMPLOYES' TRAIN TO OLCOTT BEACH.

at 8:30 a. m., accompanied by a band of music and with decorations flying. On some days the trains were 17 cars in length, and they attracted much attention from the stores and windows as they passed out Main St. on their way to Olcott Beach. The men all wore white outing caps and badges, and presented a fine appearance. Each day was voted a complete success by the excursionists, and all returned to their homes at night fully appreciating the favor which the company had bestowed upon them.

On the day following the last excursion to the beach the premiums which the company gives to its employes every six months for good conduct and for avoiding accidents were distributed among the men. The sum of \$15,000 was distributed at this time, and many of the fortunate ones were made glad hearted by reason of full pockets.

The premium plan inaugurated by this company, which was described in detail in the "Review" for February, 1902, has proved to be very successful, and the number of accidents has been reduced during the present year by a large percentage over that of former years.

### KIOTO ELECTRIC TRACTION CO.

A new electric railroad is in course of construction in Kioto, Japan, which is expected to be completed and in operation during the present month. The road consists of 8½ miles of city line and four miles of suburban line. The company was chartered in May, 1895, and has an authorized capital stock of \$600,000, of which \$362,500 is paid up. The officers of the company are: Bumpei Takagi, president; Z. Ozawa, vice-president; G. Iwahashi, secretary; H. Furuya, treasurer; T. Ido, general manager; Y. Kawarabayashi, superintendent, and Ichiro Goto, electrical and mechanical engineer. The power house contains one 14 x 28 x 36-in. cross compound condensing engine, built by the Allis-Chalmers Co., and two 200-h. p. Heine safety boilers. The generating unit consists of one 225-kw. Westinghouse machine. In addition to this equipment there has been ordered this year one 16 x 32 x 36-in. Reynolds-Corliss engine, one 30-kw. General Electric generating set, one 250-h. p. Heine boiler, and one 166-tube Green economizer. The company has 46 closed motor cars 20-ft. long by 6-ft. wide. No trailers are used, as they are forbidden by law. The company builds its own cars and 12 additional cars will be added this year to the company's rolling stock.

The cars are mounted on Brill 21 E trucks, and are equipped with G. E. 800 motors.

The Saginaw Valley Traction Co., of Saginaw, Mich., has sued the city for damages as the result of closing the Genesee Ave. bridge to the cars of the company's lines.

### RAILWAY PARK AT OIL CITY, PA.

Situated just midway between Franklin and Oil City, Pa., being about five miles from each of these places, is an extremely attractive railway park, owned and operated by the Citizen's Traction Co., of Oil City, Pa. The park might indeed be called a summer resort, for its beautiful scenery and delightful location have led a number of persons from the two cities to build cottages on its grounds and make their homes there during part of the summer.

The park covers 60 acres, half of which is open and diligently cared for by an expert landscape gardener.

The most striking feature of the park is the number of mineral springs upon its grounds, there being seven in all, and each sending forth a different mineral water. The most remarkable of these springs is that known as the "Boiling" water; this spring comes up through black quicksand, is 20 ft. in circumference, and it is very interesting to watch the water boiling up and turning the sand over and over. A distance of only 500 ft. from this spring is another boiling out of white quicksand, with a 6-in. stream. The waters from the different springs meet and make a beautiful brook, winding its way through the park. Well-kept flower beds and electric fountains adorn the grounds, and rustic seats, hammocks and

MERRY-GO-ROUND AT OIL CITY RAILWAY PARK.

swings with an abundance of shade add to the pleasure of all visitors.

A great deal of money has been spent to make the park both comfortable and handsome. A large theater is fitted with modern furniture and scenes, and performances are given every evening, or the hall devoted to parties and dances. A large double-deck restaurant, 59 x 90 ft., supplies all those who do not bring their baskets to the park, and here one may be as well served as in any modern hotel in the state. Besides this accommodation there is a public hall provided for those who bring their lunch, and a kitchen is also provided where patrons may make themselves coffee and cook short-order dishes.

Another striking feature is the electric tower, a miniature of the Pan-American electric tower. It has a 20-ft. base, is 112 ft. high, covered with 3,000 lights of different colors, making a very brilliant display.

There are amusement parlors fitted with all the modern slot machine amusements; a band pagoda, where a good band plays every afternoon and evening; a merry-go-round and a miniature railway. The merry-go-round is nicely located under its own house, and the miniature railway, which makes a circuit around the park just inside a fine bicycle track, furnishes a grand amusement for the children. The merry-go-round and miniature railway were built by the Armitage-Herschell Co., of North Tonawanda, N. Y. Much care has been taken with these two features and they have been a source of great revenue to the company. Contrary to the usual plan of covering the merry-go-round with a tent, this company has seen fit to give it a real house, as shown in accompanying illustration, and from the enthusiasm of the managers of the Citizen's Traction Co. it would seem that the managers of other railways have made a great mistake by not owning their own merry-go-

rounds for their parks. During 20 days in July this merry-go-round and miniature railway took in \$1,256, which is certainly a fine return on the investment.

In handling the crowd to and from the park the railway company experiences very little difficulty, because the work is done with system. A nicely finished depot 30 x 150 ft. is equipped with turnstiles, where all fares are collected as people pass out from the park. Passengers are unloaded at one place and taken on at another, so that there is no rushing over each other. A check room is provided for all who desire the convenience, and a charge of 5 cents is made for checking.

The police regulation of this park is of the best, each guard being a deputy sheriff. No intoxicated persons and no spirituous liquors are permitted on the ground.

The buildings are neatly constructed and nicely painted; the water works, which are complete in every way, are owned by the railway company, and the sanitary arrangements are perfect in every detail.

During the past season the superintendent, Mr. J. H. Forebush, has given much of his time to the park, and his efforts have been quite successful in making it a popular resort.

### CONTEST FOR RIGHT OF WAY IN INDIANA.

An interesting legal controversy has arisen between two electric interurban railway companies in Indiana, the course of which will be closely followed by electric railway men in that state, as the decision will give an interpretation of recent Indiana electric railway legislation. The Indiana legislature, at its 1901 session, amended the electric railway law, giving electric interurban companies practically the same rights of condemnation as steam railroads had previously enjoyed. The act provides that the railway companies may enter upon lands to make its surveys and if it cannot agree with land owners for the purchase of the route desired, it may file articles of appropriation and thus secure the exclusive use of the land for the purpose named, whereupon the circuit court appoints appraisers to determine the value of the land appropriated.

The facts of the controversy are as follows: In November, 1901, the Lafayette & Indianapolis Rapid Railway Co. was incorporated to build an electric railway between the cities named in the title, and after a favorable report on the project had been made by Mr. Damon of the Arnold Electric Power Station Co., of Chicago, the railway company surveyed and established its route between Lafayette and Indianapolis, closely following that of the Big Four railroad. About the same time the Indianapolis, Lebanon & Frankfort Traction Co. was incorporated to build an electric road from Indianapolis to Lebanon and thence to Frankfort, and located its line for fifteen miles (about half) of the distance between Indianapolis and Lebanon on the route chosen by the Lafayette & Indianapolis company, and began to get optional contracts from the owners of lands embraced in the right of way established by the Lafayette & Indianapolis company. The Lafayette & Indianapolis company endeavored to make agreement with the landowners, and failing to do so filed articles of appropriation as provided in the statute referred to (See St. Ry. Rev., July, 1901, p. 422) and appraisers were appointed by the Boone Circuit Court. In the meantime, Townsend, Reed & Co., the contractors for the Indianapolis, Lebanon & Frankfort company, began grading over the disputed right of way, completing the work for some ten miles. The Lafayette & Indianapolis company thereupon brought suit against the Indianapolis, Lebanon & Frankfort company, asking for a permanent injunction restraining the latter not only from constructing its road but from operating it if completed.

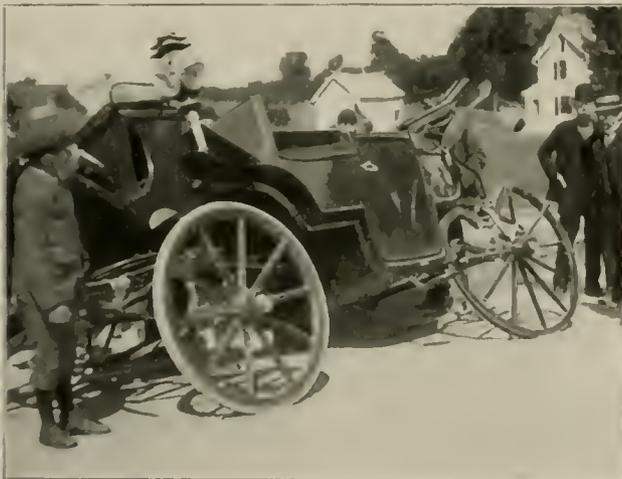

The question involved, that is whether the company first surveying and locating its route has the prior right, has not been decided in Indiana where railroads are involved, but the Lafayette & Indianapolis company relies upon the decisions on similar statements of fact in other jurisdictions and particularly upon that rendered in the case of the Indiana Power Co. v. St. Joseph & Elkhart Power Co. (63 N. E. 304). In this case it was held that a hydraulic company organized under the act (Burns Revised Statutes, 1901, paragraph 4827) authorizing the incorporation of such companies, and which files an instrument for the appropriation of real estate with the clerk of the court, as required by the act, may include

therein and condemn lands purchased by another company, incorporated prior to the incorporation of the company condemning the land, for the purpose of constructing similar works, but which has failed to file an instrument of appropriation, even though the water power in question is capable of being utilized by one company only. The eminent domain act under which this case was decided is substantially the same as the railroad act, and in fact was copied from the railroad act.

### PRESIDENT'S ACCIDENT AT PITTSFIELD, MASS.

President Roosevelt's recent New England trip was marred by a very sad accident on the morning of September 3d, while the President's party was en route from Pittsfield, Mass., to the Country Club at Lenox. As the result of collision with a trolley car one of the President's attendants, William Craig, of the Secret Service, was killed outright, Mr. Roosevelt and Secretary Cortelyou were badly shaken up and more or less injured, while the driver of their carriage, David J. Pratt, was so severely hurt that for some time his life was despaired of, but he is convalescing. In the carriage with President Roosevelt, and at his side, was Governor Crane of Massachusetts, who, fortunately, escaped practically unhurt.

The accident occurred about 3½ miles out of Pittsfield and about 200 yards from the Country Club, where were gathered many members and friends to greet the presidential party. The President

THE PRESIDENT'S CARRIAGE AFTER THE ACCIDENT NEAR PITTSFIELD, MASS.

and Governor Crane occupied the rear seat of the barouche and Secretary Cortelyou sat opposite. Detective Craig was on the box with the driver. Following the President's carriage were five others, containing men of prominence, including Dr. Lung, the surgeon assigned by the navy department to accompany the President. The carriages were going at a good rate of speed along North street, a broad macadam turnpike with a trolley line on it. About 200 yards from the Country Club, on the Pittsfield side, the track shifts from the middle of the road to the left hand side. The carriages were on the left side of the track as they started down the incline approaching the rise on which the Country Club stands. The driver swung the leaders a little as he approached the turn of the track, so the wheels of the barouche would not slide along the rails. The leaders had barely crossed the track when the car struck them, but as Craig turned with extended arm to warn the President.

Mr. Roosevelt and Governor Crane were thrown to the right, while Craig fell directly in front of the car and was terribly mangled by the wheels. Secretary Cortelyou was thrown backward and suffered a contusion on the back of his head. The driver was rendered unconscious. One of the horses was so badly injured that it was shot. Three of the carriage wheels were smashed. The only thing that saved the President and Governor Crane was their being thrown to the right, instead of the left.

Dr. Lung ran to the President's assistance, but it is character-

istic of the man that he thought of others first. Mr. Roosevelt's injuries were such that if received by a less sturdy man they would have been pretty serious. A blow on the right side of his face caused it to swell and the right eye was blackened, as in fact, was all the upper part of his face. Blood was drawn from a slight scratch on his cheek. The President said to a friend that he had received worse injuries in foot ball and polo, and if it were not for poor Craig's death he wouldn't give a snap of his finger for what happened.

After the accident the management of the Pittsfield Electric Street Railway Co. was severely criticised for permitting cars to operate on the road while the President's party was en route. Superintendent P. H. Dolan of the company, in an interview denies the published reports that the company was ordered or requested to stop running cars while the presidential party was in the city, but as a matter of fact operation was suspended while the carriages were passing through the city proper. The management, however, saw no good reason why cars should not run along the highway to the Country Club, as there were many officials and invited guests who had no other way of reaching the club grounds. The car that figured in the accident was a special car chartered by members of the Country Club to make the run to the clubhouse, and Mr. Dolan states it otherwise would not have been sent out, although he saw no reason at the time for suspending operation of cars on that line.

### NEW ALTERNATING CURRENT TRACTION SYSTEM.

The Washington, Baltimore & Annapolis Electric Railway Co., which is now building from Washington to Baltimore, a distance of 31 miles, is preparing to install a new electric system using alternating current apparatus throughout.

The current will be generated by three 1,500-kw. single-phase generators in the main power station, located at Hyattsville, and will be distributed at 15,000 volts to transformer stations located along the line. These sub-stations will contain only stationary transformers and the necessary switches and fuses, and will not require the presence of an attendant. From the sub-stations the current will be fed to a single overhead trolley wire at a pressure of 1,000 volts.

The cars, which will be about 60 ft. in length, will be equipped with four motors, each of 100 h. p. capacity, which it is expected will permit of a speed of from 45 to 60 miles per hour. The motor, which is the novel feature of the system, is a variable speed alternating current motor, which has been developed by the Westinghouse Electric & Manufacturing Co., under the supervision of Mr. B. G. Lamme, assistant chief engineer, and it is claimed to have characteristics specially adapted to railway service.

The company is to take over a small direct-current road running from Washington to Laurel, Md., and current for this road will be supplied by two 200-kw. single-phase rotary converters located at the main power house; this apparatus is also novel. The building of the road is being done by the Cleveland Construction Co. The officers of the Washington, Baltimore & Annapolis Electric Railway Co. are: W. H. Lamprecht, president, and Otto Miller, secretary, both of Cleveland, O.

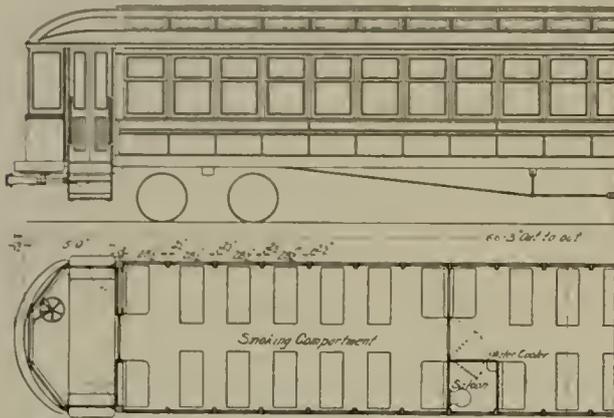

### NO 3-CENT FARES FOR CLEVELAND.

The 3-cent fare railway proposed for Cleveland seems to be practically dead. John B. Hoelgen, who obtained a franchise some time ago for an extensive system of 3-cent fare roads in Cleveland, which was afterwards declared invalid by the courts, states that he did not bid for a franchise for the 3-cent-fare lines which were offered last month. The old 3-cent fare franchises were declared illegal, and the case is now before the state supreme court. Pending the final decision on this point the city council planned to get proposals for new 3-cent fare franchises, which were supposedly legal.

August 17th the cylinder head was blown out of the engine in the power house of the Logansport, Rochester & Northern Traction Co., and no cars were run for two days and a half following until the damage was repaired.

**THE LARGEST INTERURBAN CAR.**

Fig. 1 shows an excursion car for the Columbus, Delaware & Marion Ry., several of which are in course of construction at the shops of the Jewett Car Co. These cars are 66 ft. 3 in. long over the buffers and are, we believe, the longest interurban cars by 5 ft. ever attempted by any car builder for electric interurban service. Fig. 2 shows the floor framing. The side sill consists of one piece  $4\frac{5}{8}$  x  $7\frac{1}{2}$  in. and one piece  $14\frac{1}{2}$  x  $5\frac{1}{2}$  in. long leaf yellow pine in one continuous piece without splicing, with a 6 x  $\frac{1}{2}$  in. steel plate between the sills and a

FLOOR PLAN AND ELEVATION.

7 x  $\frac{1}{2}$  in. steel plate on the outside, these being thoroughly bolted together.

The center and intermediate sills are  $3\frac{5}{8}$  x  $5\frac{1}{2}$  in. long leaf yellow pine in one continuous piece without splicing. The over-truss is a truss plank 9 x 2 in. yellow pine in a continuous piece, securely bolted to the side sills. The under-truss consists of four  $1\frac{1}{4}$ -in. rods going the full length of the car, over bolsters and through the end sills. The end sill is also plated with 6 x  $\frac{1}{2}$ -in. steel. The bolster is made of two steel plates, 8 x  $\frac{3}{4}$  and 8 x 1-in. M. C. B. type of construction.

The platform construction of these cars is exceptionally strong to prevent any possibility of sagging. The outside platform knees are made of 5 x  $\frac{5}{8}$ -in. steel plates with suitable oak filling, and the center

These cars have all modern conveniences, such as toilet room, drinking fountain, etc., and also have a smoking room.

A special feature of the cars is that the glass is only  $28\frac{1}{2}$  in. from the floor, which gives quite an unobstructed view from the inside and gives the effect of riding in an observation car.

Each end of the car is provided with "Providence" fenders, and Van Dorn automatic draw bars. The steps are of the Stanwood type and the step openings are closed with the Jewett automatic trap door. The cars are mounted on Peckham No. 32 M. C. B. trucks and equipped with GE No. 73-A motors. The weight of the car complete, ready for service, is about 35,000 lb.

**CANADIAN NOTES.**

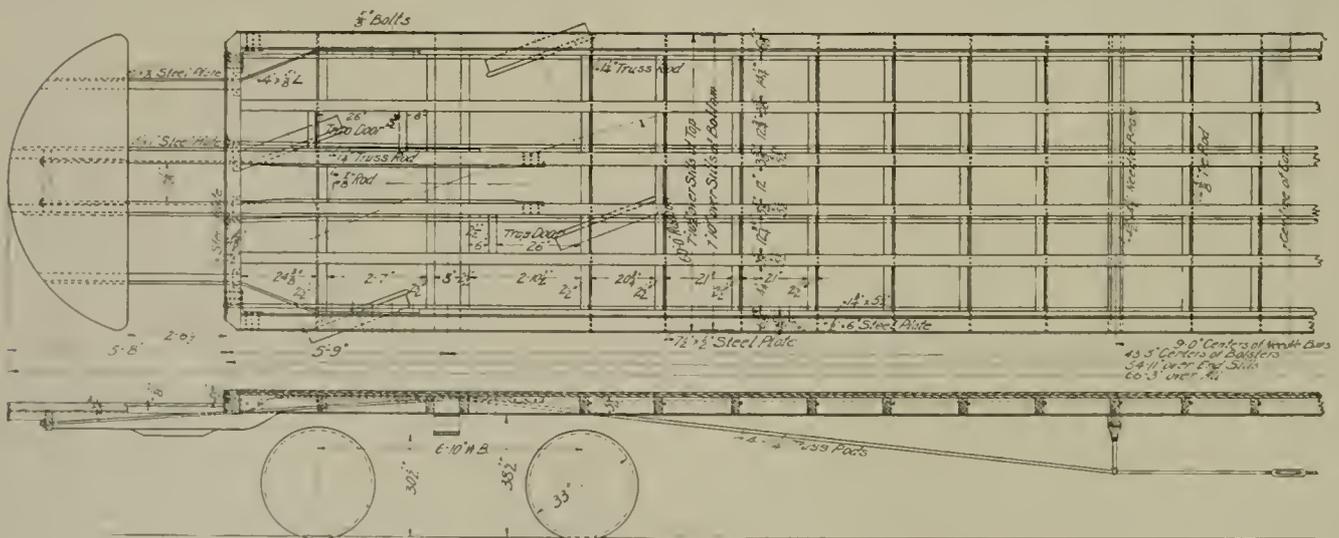

The Southwestern Traction Co., incorporated by special act of the legislature, has applied for a franchise in London. The company's charter covers a main trunk line from Hamilton through to Glencoe and Strathroy, a distance of 105 miles, passing through Brantford, Paris, Woodstock, Ingersoll and London, besides thriving villages every few miles. It is the intention of the company to build during the first year some 29 miles of road between Ingersoll, London and Delaware. The whole of the proposed route is through a rich and fertile farming country with a population of between 90,000 and 100,000. The municipalities of Ekfrid, Caradoc, Westminster and Delaware (covering all the line between London and Strathroy) have granted 50-year franchises, with free right of way over the public highways and exemption from taxes for 20 years. The capital of the company has been almost entirely subscribed by local capitalists. The officers are: F. G. Rumball, of London, president; F. B. Leys, London, first vice-president; Robt. McEwan, of Byron, second vice-president, and A. E. Welch, of London, managing director.

It is stated that Cleveland capitalists are anxious to secure the charter for the proposed electric road between Toronto and Hamilton, a distance of about 44 miles. This route is considered one of the most desirable in Canada.

There is considerable discussion at Phoenix, B. C., regarding the construction of an electric line to Greenwood.

The Hamilton, Grimsby & Beamsville Electric Ry. has been granted free right of way through the township of Clinton for its 12-mile extension from Vineland to St. Catharines, where it will connect with the Niagara, St. Catharines & Toronto Ry.

A franchise has been granted for the construction of a line of

FLOOR FRAMING PLAN OF 66-FT. INTERURBAN CAR—JEWETT CAR CO.

knees are made of 5 x 1-in. steel plates extending back through the bolster, and have filling for bolting the buffer. For further strengthening the platform, two rods are put in the center of the car, which act also as draft rods. The seating capacity of this car is 123.

The construction of the side of the car is such as to allow an exceptionally long seat, which will accommodate three passengers. They are of the "Walkover type," made by the Hale & Kilburn Manufacturing Co. and upholstered with rattan.

electric railway between Picton, Ont., and Wellington. Mr. M. R. Allison, of Picton, is one of those principally interested.

The Halifax Tramway Co. has secured the contract for lighting the dockyard.

The Canadian Pacific Railway Co. has purchased the Hull & Alymer electric road. The purchase price is said to be between \$700,000 and \$800,000.

The Ottawa & Hull Power Co. expects to complete its works in

about three months, when it will have developed 12,500 h. p. The construction of the power house is well advanced; five dynamo of 2,500 h. p. each will be installed.

Mr. E. S. Harrison, of Winnipeg, states that tenders for preliminary construction work on the proposed electric railway between Winnipeg and Headingly, Man., will be called for immediately. There will be four divisions of 2 $\frac{1}{4}$  miles each.

The town council of Cookshire, Que., has decided to purchase the water power on the St. Francis River, situated a few miles above Angus. It is proposed to develop the power electrically and transmit it to Cookshire, a distance of 20 miles.

An agreement has been reached between the town council of Sault Ste. Marie, Ont., and the Intercolonial Transit Co. by which the latter agrees to have electric cars running in the town by October next.

The Montreal Street Ry. Co. has now completed the survey for the extension of its line to Longue Pointe, a 10-year franchise having been obtained from the municipal council. The new line will be about three miles in length, two miles of which will be double tracked and will run from the present terminus at Viauville eastward along the river bank to about one mile east of Longue Pointe.

The Montreal Terminal Railway Co. are making rapid progress on its new line into the city and expects to have it completed in a short time. This company has just placed a contract for 16 new cars of a special pattern, and contemplates double tracking the line between Montreal and Bout de l'Île.

Arrangements are being made to utilize the water power available at Kingston mills for the purpose of supplying power to the Kingston Street Ry.

The St. Lawrence River Electric Power Co. has been incorporated with a capital stock of \$250,000 by M. W. Beach and W. J. Redmond, of Iroquois; Erwin Halliard, of Morrisburg; W. H. Meldrum, of Peterborough, and D. A. King, of Winchester. The company intends to build and operate an electric railway from Ottawa to Lachine, where it will connect with the city lines.

It is the purpose of the Canadian Pacific Railway Co. to build an electric power house at Fort William, Ont., although the plans are not yet complete.

The municipalities interested in the proposed Huron, Bruce & Grey Electric Ry. are holding meetings for the purpose of discussing the situation. At the last session of the legislature a charter was granted for this road, to run from Wiarton to Owen Sound, with branches to Seaforth and Blyth.

An offer has been made the Sherbrooke Gas & Electric Co. by a syndicate representing local and foreign capitalists to purchase the company's stock at \$78.00 per share. The capital stock of the electric company is placed at \$200,000, and the new company proposes to take over also the floating debt of the company, which is \$60,000. It is stated that the new syndicate is also after the Sherbrooke Street Ry. and the Peoples Telephone Co., and if the offer of the syndicate is accepted the three companies will be merged.

The Galt, Preston & Hespeler Electric Ry. has been granted permission to extend its lines to Puslinch Lake, a popular summer resort near that town, and work is to be commenced at once.

The Schomberg & Aurora Electric Ry. is now in operation. The road extends from Aurora, an Ontario town some 30 miles north of Toronto, to Schomberg, at the head of the water outlet of Lake Simcoe, where it connects with the Metropolitan Electric Ry., thus securing an entrance to Toronto. Freight sheds and yards are to be erected at the terminal near Bond Lake.

The following figures showing the gross receipts of the Toronto Railway Co. for the month of July during the past five years, will be of interest as showing the remarkable increase during that period: 1898, \$103,679; 1899, \$117,689; 1900, \$125,723; 1901, \$150,620; 1902, \$160,043.

The Atlanta (Ga.) summer resort, Ponce de Leon springs, is to undergo great alterations and improvements at the hands of the Georgia Railway, Gas & Electric Co. The company has engaged a landscape gardener from New England, who will lay out entirely new plans for the springs. Immense flower beds, winding walks and ornamental shrubbery are to be introduced, and a casino capable of accommodating 1,000 guests will be erected. A large electric fountain is to be operated in front of the Ponce de Leon spring which is the central point of attraction of the park.

## MODERN CAR WIRING.

There are many places in car barns, power shops, and on both surface and elevated trains, where it is necessary to employ a conduit for wiring which is not only flexible but also very durable, being weather proof and proof against mechanical injury, and the flexible products manufactured under the Greenfield patents by the Sprague Electric Co. are designed to meet every requirement of this class of work.

The "Flexible Metallic Conduit" has been on the market a number of years, and has been used in many of the most prominent public and private buildings in this country. The design of the conduit is such that while affording the greatest ease in bending to a curved formation, it absolutely prevents the possibility of flattening. The interior is thus of uniform diameter and symmetrical proportions, at whatever angle the conduit may be bent. The amount of energy required to bend this conduit is no more than is required

FLEXIBLE STEEL ARMORED CONDUCTORS LEAD COVERED.

to bend a piece of new manila rope of the same size. The conduit is composed of convex and concave metal strips wound spirally upon each other in such a manner as to provide thorough ventilation and also to afford complete protection from mechanical and other injuries.

The "Flexible" steel armored conductors are a more recent invention, and consist of twin wires surrounded with the best high-grade insulation and covered with a flexible steel armor, thus giving the wires both electrical and mechanical protection and eliminating the necessity of fishing or drawing in wires. Both these products represent the latest advance in the art of electric wiring, and reduce installation to great simplicity. The "Flexible" steel armored conductors are also made with an additional cover of lead, which makes them desirable for use in wet or damp locations. The steel armored "Flexible" cord for lamp pendants and portables are very desirable for use in such places as engine and boiler rooms, machine shops, mills, factories, show-windows and other places where the ordinary cord is impractical or positively prohibited. The use of these flexible armored products is very highly recommended by first-class engineers, contractors, architects and others who have to do with electric wiring. The tools required for working these flexible products are simple, few and inexpensive.

Delegates to the convention in Detroit will be interested to know that over 60,000 ft. of "Flexible" metallic conduit is installed in the Wayne County Building.

This conduit is also installed in the Cadillac Hotel and the late Senator McMillan's residence, Detroit.

## OBSERVATION CAR IN CLEVELAND.

An observation car will be put in commission in the city of Cleveland, O., next spring, which will make regular trips through the city at scheduled times, for the purpose of giving visitors an opportunity to see the city. The fare will be 25 cents for the trip and an attendant will point out the principal places of interest along the route. The car which is to be used for this purpose is now being built. It is to be luxuriously furnished and handsomely appointed in every respect.

There has always been a great demand for positions on the cars of the Union Traction Co. of Indiana, and at the present time there are more than 500 applications on file for positions of motormen or conductors.

### LONDON LETTER.

The present condition of steam railways gives very little more satisfaction to the public whom they serve than to that other more limited public to whom they pay—or undertake to pay dividends. As regards long journeys this dissatisfaction at present finds vent in nothing very practical or effective—the established lines must of necessity be patronized at any cost, and the traveller puts up more or less thankfully with whatever minimum of dirt, discomfort and delay the companies can see their way to providing. But in the matter of short distances, of local and suburban traffic, a change has made itself very distinctly felt of late, the monopoly of the steam railway companies has not only been threatened but quite effectually encroached upon, and the question of a change to more up to date methods can no longer be ignored or postponed. Wherever electric tramways have been opened between city and suburb, they have played incredible havoc with the receipts of the local steam railway lines, and that obviously not because tramways are in themselves more popular or more suited to the public taste and needs than railways, but because they are worked by electricity and possess all the advantages thereby implied. Traffic is not a matter of fashion or caprice, and with methods of locomotion above all things it is a case of the survival of the fittest. The electric tramways have not only invariably tempted away a public that until then had patronized the local railways, they have in many places created an entirely new pleasure traffic and have greatly helped to develop new neighborhoods. What has been achieved by electric surface tramways has been done with even more conspicuous success by short lines of electric railway. Where there is any question of long tunnels or underground routes, electric traction is essential to ensure even the reasonable comfort of the passengers. In the St. Gothard tunnel it is on record that trains have on more than one occasion had to be stopped to prevent the men in charge from being asphyxiated, and though the passengers were not exposed to the same dangers, the pleasure trip is attended with very considerable discomfort. There is indeed no longer any question that electricity is the best motive power for underground and overhead railways. It is interesting to remember that Great Britain was after all the pioneer even in electric railway enterprise, and that the first electric railway in the world was that built in 1883 between Portrush and the Giants' Causeway in Ireland. The first underground electric railway was the City & South London, built in 1890, and the first overhead electric line that which runs along the docks at Liverpool. After this we proceeded as usual to do nothing, while the rest of the world went ahead, thriving on our discoveries and learning by our mishaps.

The cause of this slackness, if all circumstances be taken into account, was probably very largely a financial one. The outburst of speculation between 1879 and 1881 led to a great commercial crisis and a consequent distrust of all undertakings of the kind. We have always had a tendency, too, in this country, either to invest in consols or to bestow our favor on undertakings of a distinctly problematical character, to the detriment of useful and legitimate industrial enterprise, which in many cases had had to go abroad for capital. Now, however, the distrust in electrical engineering undertakings is fast becoming a thing of the past, and we have lately done much to make up the leeway we had lost. In 1896 six millions were invested in this country in electric railways and tramways, in 1900 this total had increased to twenty-six millions, without counting nearly four millions similarly invested by various municipalities. In fact, the boom that was to be expected to make up for past inaction, has come. The Waterloo & City Railway was opened in 1898, the Central London in 1900. The forthcoming electrification of the Metropolitan marks the beginning of an even more important era, since we have here not the building of a new line, but the successful adaptation of already existing resources, and in this direction much of the future of electric traction must necessarily lie. The journey round the Inner Circle, we are told, will for the future be performed in 50 minutes instead of 70; the expenses of working the line with the new equipment will be reduced 30 per cent, while the carrying capacity will be increased 35 per cent.

From the North we hear the news of the electric line on the mono-rail system between Liverpool and Manchester, which will of course get most of the passenger traffic at present divided between three railways, in addition to a great deal that does not yet exist, but will assuredly come into being when the distance between the two cities

can be covered in 20 minutes. The working expenses are estimated at 7½d. per traction car mile, and the company expects to get a dividend of 5 per cent on the capital invested. The Mersey Railway has contracted with the British Westinghouse Co. to convert the line to electric traction on the unit control system. A line between London and Brighton is planned and others will rapidly follow. Of the existing main lines not a few are reported to be considering the question of adopting electric traction. The steam railways have reached a very critical turning-point in their career. On every side companies are springing into existence to establish electric traction either on tramways or on short lines of railway between busy centers of commerce and manufacture. Several bills have lately been passed to sanction the erection of large central power stations at convenient industrial centers on the Tyne, the Clyde, in South Lancashire, South Yorkshire and South Wales. Very soon electrical energy will be available at various points throughout the country for traction and industrial purposes. The railway companies possess a monopoly, but one of a precarious nature. Will they avail themselves now of their unique opportunity, and make the monopoly a lasting asset, or will they fall victims to the fatal mistake made once before in our industrial history—and that by their own opponents? The towns which in the early days of railway enterprise refused to countenance the building of the new lines through their territory, cut themselves off from the main line of traffic and business, and in spite of all subsequent efforts to recover lost ground, impaired their prosperity forever. The railways which insist on closing their eyes to the possibilities that lie before them, are very likely to suffer the same fate.

D. N. D.

### RIVALS FOR MARYLAND FRANCHISE.

An interesting trolley war is being carried on between the Elkton & Chesapeake City Electric Railway Co. and the Cecil & Kent Electric Railway Co., for a franchise to use the county roads from the Delaware state line to Chesapeake City, a distance of nine miles. Two years ago the Elkton & Chesapeake company obtained a franchise for this road from the County Commissioners of Cecil County, but no attempt has since been made to build a road between these points. Recently the Cecil & Kent Electric Co. petitioned the commissioners for a franchise for the same route and offered a cash deposit as a guarantee that the road would be completed within eight months. The counsel for the former company contend that a franchise already given cannot be revoked, as no time was fixed in it for the completion of the road. The new company states, however, that if the commissioners grant it the right of way it would give the people of Cecil County a direct trolley line from Philadelphia to Galena, passing through Wilmington, Newark and Elkton. The commissioners have taken the matter under consideration and action on the franchises has been deferred for a time.

### LEVIS COUNTY RAILWAY.

A new electric railway is in course of construction in Levis County, Can., which will connect Levis, St. Joseph, Bienville and St. Romuald, which is on the St. Lawrence River, directly opposite Quebec. The company's car barn, located at St. Romuald, is nearly completed. It is a substantial brick structure having two towers on the front, facing the river. The sub-station of the road has been completed for some time, and the machinery for this building, which is made by the Bullock Electric Manufacturing Co., of Cincinnati, is already on the ground. The power for operating the road has been contracted for with the Canadian Electric Light Co. This will be transmitted at a pressure of 10,000 volts. The pole line has been completed for the greater part of the route, and all the overhead material is on hand and will be put in place as soon as the roadbed is completed, which is expected to be ready during the present month. The company has completed a private telephone system on its line which is already in operation.

The Birmingham (Ala.) Railway, Light & Power Co. has built a new car barn and is busy connecting the new building with its tracks and overhead system. The new tracks which are being laid down may also be used by some of the interurban cars to reach the center of the city.

## NEW YORK STATE STREET RAILWAY ASSOCIATION MEETING.

The twentieth annual meeting of the Street Railway Association of the State of New York was held at the Fort William Henry Hotel, Caldwell, N. Y., on Lake George, Tuesday and Wednesday, Sept. 9-10, 1902. About 200 delegates and supply men were in attendance, and the character of the papers and the discussions, the ideal location on Lake George at the gateway of the Adirondacks, and the cordial hospitality extended by the officers of the Hudson Valley Railway Co., all combined to make this one of the most valuable and enjoyable conventions ever held by the New York State Association.

The opening session was called to order at 11 a. m. Tuesday morning with President G. Tracy Rogers in the chair. After the preliminary order of business, a paper was presented on "Accidents on Electric Railroads," by C. R. Barnes, electrical engineer to the New York Board of Railroad Commissioners.

The paper was fully discussed, and was followed by a paper prepared by Judge J. H. Daly of New York, general counsel for the Metropolitan Street Railway system, and dealing with the legal aspects of accidents. The afternoon session convened about 3 o'clock, the first order of business being the reading of President Roger's annual address. In his paper President Rogers as usual gave an elaborate and exceedingly valuable review of street railway matters and development in New York state.

This was followed by the presentation of the Executive Committee's annual report, and the treasurer's report which showed the New York Association to be in excellent condition, both as regards membership and financial affairs.

The following papers were read and thoroughly discussed: "Supply House Methods," by A. C. Tully, purchasing agent and general store keeper of the Metropolitan Street Railway System; "Power House Accounting," by R. E. Danforth of Rochester; "Discipline," by C. B. Fairchild of New York; Report of Committee on Rules.

Owing to the lateness of the hour, discussion of the report of the Committee on Rules was postponed until the Wednesday morning session.

The Wednesday morning session was called to order in good time, and the standard code of rules suggested by the committee was made the first order of business. After considerable discussion, it was decided to merely discuss these rules, and a resolution was passed to the effect that all the members of the association be requested to make written suggestions to the committee, within 30 days, each member company to have the privilege of suggesting new rules or modifications of the code presented by the committee. The Committee on Rules was instructed to consider all these suggestions and report to the Executive Committee within 30 days after the expiration of the first 30 days a code of rules embodying as far as possible the suggestions received. The Executive Committee was also given authority to promulgate and distribute the committee's report with the official sanction of the association.

Papers were then read on the following subjects: "Dispatching," by T. E. Mitten of Buffalo; "Removal of Snow and Ice," by W. B. Reed, engineer maintenance of way of the Metropolitan system of New York; "Methods for Removing Snow and Ice," by R. E. Danforth, assistant manager of the Rochester Railway Co.; "Signal System," by J. A. Powers, general manager of the Hudson Valley Ry.

President Rogers then read letters and telegrams of regret from many street railway and supply men who were unable to be present.

The committee on nominations consisting of Messrs. Fasset, Allen and Mitten, presented the following list of officers for the ensuing year, their report being unanimously adopted. President, G. Tracy Rogers; first vice president, E. G. Connette of Syracuse; second vice president, A. B. Colvin of Glens Falls; secretary and treasurer, H. A. Robinson of New York. Executive Committee: G. T. Rogers; H. H. Vreeland; W. Caryl Ely; T. J. Nicholl, of Rochester; and J. L. Greatinger of Brooklyn.

By invitation of Mr. Connette, Syracuse was selected as the place of meeting next year.

After a few general remarks by Messrs. Vreeland, Ely and others, and the adoption of a vote of thanks to the officers of the Hudson Valley Ry. for the cordial reception extended, the convention adjourned to meet in Syracuse next September.

## ENTERTAINMENTS.

Several pleasant trips and outings were arranged by the Hudson Valley company, these including a drive for the ladies, trip up Prospect Mountain, and a steamboat ride on Lake George. The usual banquet was held at Fort William Henry Hotel, and was attended by about 150 guests. For the first time at any banquet of the New York State Association, the ladies were invited to partake of the dinner, and this feature was pronounced by all to be a very capital idea. Mr. Colvin made a very witty toastmaster, and kept the diners in happy mood by his unique introductions when presenting the various speakers. Among those who responded to toasts were Messrs. Vreeland, O'Connor, Cole, Dale, Stedman, Powers and Ely.

Music was furnished by an excellent orchestra, and to add to the informality of the occasion cards were passed around bearing the words of the various popular airs rendered by the orchestra, and between courses the guests joined in singing the popular songs.

## PRESIDENT ROGERS' ANNUAL ADDRESS BEFORE THE NEW YORK STREET RAILWAY ASSOCIATION.

In behalf of the Association and the Hudson Valley Railway Co., whose guests we are, it gives me great pleasure to extend a hearty welcome and cordial greeting to you all. We assemble upon this occasion, following a year of general thrift and prosperity. This is, indeed, fortunate, as without this condition of affairs disastrous results to the business interests we represent might have ensued, inasmuch as the summer months just passed (the harvest season of street railways, particularly those of smaller cities and interurban lines) have proved the most unseasonable, stormy and disagreeable the country has ever experienced, a fact probably so plainly manifest to you all that even a casual allusion to the unfortunate condition of affairs is not necessary. I consider it proper to congratulate the street railroads of the state upon the excellent showing made under the adverse conditions that have existed.

When this year in the life of this Association is completed, two decades will have passed since its birth and one has but to review the published proceedings of the twenty annual conventions to comprehend the wonderful changes which have taken place in the street railroad world during that time. What the next two decades will unfold to us is difficult to predict. During the first ten years of the Association's existence the principal topic of discussion at these meetings was that of the care of horses and mules. During the last decade each succeeding meeting has proved a series of important and instructive surprises in the new and advanced ideas presented affecting street railways, their development, advancement and betterment. Instead of a few hours devoted to the business proceedings of the meeting, now the greater portion of two days is insufficient to give proper consideration to the many subjects of practical interest that could be profitably considered. In the early days of the Association the number of different operating companies in New York City alone was almost equal to the present number of roads throughout the state, and the number of organizations in each city was in the same relative proportion, each charging a five-cent fare over their respective lines, requiring a day's travel and a pocketful of nickels to reach a distant point in a large city. Truly, what a wonderful change. To-day there is hardly a city which has more than one company and in many cases the one company serves not only to its own city, but many of the surrounding cities, towns and villages. Cars are no longer moved by horse or mule power, and in place of the bolttail cars running over tracks composed of a stringer and a strap rail, we have at present palatial cars, lighted, heated and propelled by electricity, operated over an almost perfect track. Now, in nearly every city one may travel from one point to another and over different lines for one five-cent fare, due entirely to the general transfer system adopted within the last ten years, and to consolidation or lease.

Were we to review in detail the evolution of the street railroad methods during the past twenty years and consider what has been accomplished in the interest of both street railroad properties and the public during that period, the time of this meeting would be more than fully occupied. We are now, without doubt, the best and most highly organized industrial body in the business world.

Years ago street railroad properties were small; served limited sections only and each respective road operated exclusively over its own lines within the confines of the city or village in which it was constructed, interurban street railway intercourse and the transfer system being practically unknown. These properties were owned by a few local men, who were usually officers of the company. To-day the public owns the street railroads, the stock and bonds are held for investment by all classes of men and financial institutions. The men in charge of the practical operation of street railroads are employed on account of their fitness and ability to manage the properties in the interest of the stock and bond holders and to serve the public as the ostensible owners of the property.

The perplexities and cares of a successful management cannot be understood by the people at large. They are, unfortunately, too ready and willing to denounce the management of a road, when the cause of the criticism is often entirely outside of the company's control.

Does the public appreciate the efforts made by a street railroad company in its behalf? Apparently not, when compared with the horse and mule car days when the captious public and press had little or nothing to say in the way of criticism or fault finding, and public franchises were dealt out by municipal officials for the asking. On the contrary, with the broad development and increased transportation facilities provided by the up-to-date street railway systems, and notwithstanding the company is striving to serve their best interests, often at a loss financially, the people generally are too ready to denounce them as grasping, greedy, dishonest and anxious for its own interests alone. This spirit is shown in a more pronounced way when the company seeks any courtesy or extension of franchises at the hands of the public authorities. It is then that our requests are viewed with suspicion and criticised; we are subject to all forms of abuse, inconvenience and loss of time and money. This should not be, as railroads to-day do not ask for franchises or grants unless they are needed to better subserve the comfort and accommodation of the people, as is clearly shown when these advanced ideas are put into practice; it is then that the public realizes more fully the benefit it derives as a result of the company's efforts in its behalf. Franchises are only valuable to the extent that they may be made to serve the people. It is the high state of development of street railroading of to-day that has given life and value to these franchises—that has, so to speak, created them. There is no public serving corporation more important to a community than a street railroad; the people are dependent upon it in all walks of life. There should be more sympathy, than now exists, between the street railroad and the public and this must come from the people. In nearly all cases the street railroad is striving to meet the public requirements, and the situation is not benefited by the adoption of drastic laws and ordinances, ostensibly for the welfare of the public, but which are, in their ultimate effects, antagonistic to both railroad and public.

The electric road is so important, not only to the cities, but to the development of the country at large, that its growth should be assisted and not impeded or retarded, either through adverse public criticism, by curtailing of franchises, by the imposing of burdensome taxation or by the press, which too often caters to public clamor, inviting and exciting public hostilities for sensational purposes. The science of transportation is the greatest study of the day.

It is unnecessary for me to attempt to call public attention or the attention of the delegates here assembled to the enormous work that is being done by the electric railroads in the improvement of social conditions and the augmentation of values and populations. The civilized world has already recognized its value—for the electric railway has taken its place as one of the economic factors in all of the countries of the globe. Where communities have been isolated by topographical conditions, electric roads have made it possible, so to speak, to give freedom and expansion to the people by making other areas of land accessible for both residential and commercial uses and occupation—by, in fact, annexing the adjacent territory. Factories, extensive manufacturing plants and villages have grown up in waste places as well as outlying cities and these have been made tributary to commercial and shipping centers. While farmers and cultivators of market gardens have found readier access for marketing their products.

A phase of the usefulness of the electric street railway, of its

power for good in the direction of building up the moral, as well as the physical health of the people, is the opportunity that is afforded for outings and entertainment to the tired worker and his family whether he be a worker of the office or factory, or the farm. For him the interurban railway especially affords the ever present opportunity for a cheap and health giving ride amid fields, woods and pleasant scenes; and still more is this noticeable where the company maintains a pleasure park, a casino, or perhaps a vaudeville entertainment as an adjunct to the railway system. In nearly all these cases that I know of, where such an additional attraction, of a strictly moral nature, is maintained, the investment has been more than satisfactory and in many cases self-sustaining. Many of these resorts have been built upon a decidedly elaborate scale. But even if there be no pleasure resort, the outing itself is an invigorating ride and a means of entertainment as well as a promoter to the health of the minds as well as the bodies of the people. I may indeed suggest that in this regard the trolley ride proves a moral factor also, by drawing people away from baser resorts within the closely built and summer-heated cities.

It is my belief that in the near future the steam roads will seek ownership or a closer alliance with electric lines which will serve as feeders to them, as is illustrated by the acquisition and extensive construction of roads by the New York, New Haven and Hartford, and other steam railways. The advantages of such an alliance to both parties are numerous and cannot help but be a benefit to the public and property. The recent decision by the Court of Appeals in the suit brought by the Hudson Valley Ry. to compel the Boston & Maine railroad to make a physical connection of their tracks and to interchange freight, in which the court held that the legislature of the state has recognized electric railways as a part of the transportation system of the state, and that travelers and shippers of freight are entitled to the benefit of all the facilities provided for in the articles of incorporation of transportation companies as well as the duties imposed by the railroad law of the state. The court after stating that the steam railroads have become great arteries over which the greater part of the commerce of our country is carried, says: "It has not been considered profitable or practicable for steam roads to be constructed to every village, hamlet or productive district in the country. This, however, is being rapidly accomplished by the numerous electric roads that are in process of construction or are contemplated. By their means the farmer and mill owner and the merchandise vendor in distant places may be able to reach the steam roads, and through them the great markets of our cities, with their merchandise and products and in this way one road may become the feeder and distributor for the other."

It can readily be seen that the court does not consider the two classes of roads antagonistic, but the electric road is rendering a service that both the steam road and the people alike require. In many cases the steam roads have recognized our usefulness and have welcomed a connection with our tracks, realizing that transportation begets transportation, and that development produces freight and through passenger travel. This fact is illustrated by the development of the Hudson Valley Ry., which company has adopted largely steam railroad methods of construction and operation.

In my opinion, the progressive interurban electric road must adopt the best methods of both the steam and electric railroads. In our construction of roads, outside of cities and villages, we are now building, to a great extent, on our own right of way, with double tracks, and in many instances in conformity to steam railroad principles of construction. In a number of cases, steam and electric service is now carried on over the same rails and road-bed.

The great activity in electric railroad building, which surpasses the most sanguine expectations of a few years ago, is in a large measure accountable for the falling off of the increase of new mileage by the steam railroads of over fifty per cent between 1890 and 1900 as compared with the interim between 1880 and 1890. When a steam road is requested to give additional train service by the public, the public is often met with the reply, "another train won't pay." By this policy they do not stimulate travel. The electric road doesn't wait for business but goes after it, and the result is that when it taps a territory of an existing steam railroad, it increases the rides

per capita per annum many fold over what they were with the steam roads. This is largely due to lower fares and more frequent service. The cordial relation existing between the steam railroads and street railways of this state is a matter of favorable comment and congratulation, and makes possible a great deal in the way of development and interchange of business from which the general public inherit an untold benefit that would not be available if this friendly relation did not exist.

I may here be permitted to call attention to the prevalence of harassing and expensive litigation through damage claims.

Many bills are introduced each year in the legislature in the interest of the Negligence Lawyer, more commonly known as the "Ambulance Chaser." Each year they become bolder in their legislative demands and to such an extent that they have fallen by their own weight and accomplished little or nothing. In the large cities their methods are no better than the highwayman who uses more violent means to accomplish his purpose. The legal profession has been seriously compromised by this class of lawyers. Equally prominent in fomenting litigation is the doctor who recommends his particular friend as a lawyer and not infrequently is a sharer in the unfair percentage wrongfully collected out of the company's treasury. In this connection I might state that, in my opinion, no better claim agent, especially for the smaller road, can be secured than the honest, upright company surgeon, who at all times works in the interest of the company. Juries are often biased and easily prejudiced by unfair counsel. They do not hear the insidious entreaties of the shark lawyer or his agent to be allowed to bring the case upon a basis of 50 per cent and often larger. Some very good work has been done of late in exposing their methods and it is to be hoped with good results. As the law now stands, a suit can be brought for ten dollars; the company must either settle or stand an expensive litigation and take its chances on the fairness of the jury. In my opinion, a large percentage of this speculative litigation of the "hold-up" class can be overcome by proper and just legislation. I am aware that the Court of Appeals of our state has approved in general language of agreements between lawyers and their clients whereby the former should receive a percentage of the recovery for their professional services. However fair this may seem to be in those cases where the amount is fixed in the contract or promissory note, I am unalterably of the opinion that this course of dealing should not be allowed in suits for personal injuries, but that on the contrary, the fee should be one fixed by statute or by a competent authority to pass equitably on cases of this nature. The sharing in the recovery whereby the counsel becomes as much interested financially as the client in the recovery is a condition to be deprecated by all right minded persons. This is exactly what congress has found it necessary to do and has done by legislation in the cases of the compensation which attorneys are allowed to collect for services in pension claims against the government.

I will also call your attention to the injustice of the present law whereby an action can be brought against us in an accident case any time within three years without giving notice. We and the individual or other corporations are entitled to the same consideration in this respect that is now given to the municipalities, whereby notice is required of the accident. This question has been before the legislature for a number of years and I believe it is the duty of every member of the association to strenuously urge that some law be passed to remedy this evil. In my opinion the association should make a determined effort to have a law passed, to the end suggested, thereby in a degree stemming the tide of unjust, speculative litigation which is so rapidly increasing.

The mutual benefit association so generally inaugurated on our roads still continues to be of untold value to all. The plan of furnishing pleasant club rooms for our men is another step in the right direction; too much interest cannot be taken in endeavoring to raise the standard of our men and looking after their comforts, by elevating them to a higher degree of efficiency and improved discipline.

The sentiment and enthusiasm of the employe toward his work has more to do with the success of the street railroad than most any other business, as the dealings are more direct with the public than any other industry, and the success of the operation depends largely upon the policy of the company towards its employes. The discipline and handling of men is one of the most important of a street road. Each year finds a marked improvement in the class of men

on our roads. This improvement has been brought about, not only through care in selecting the men, but largely by the conditions we have surrounded them with, and this class of men must have just and fair treatment.

A number of street railroads are refusing to continue carrying the mails at a loss. I have referred to the fact in my previous report that the rate paid per car mile for the transportation of the mails is insufficient to meet the expense; at the present rate we are simply paying for the privilege; some step should be taken to have this injustice corrected.

The unfortunate recurrence of some half dozen severe and fatal accidents within the present summer brings to the members of the association, in the most forcible manner, the ever present obligation of ceaseless care and vigilance in the management and operation of their respective roads. It is a simple matter to lay down a formula for the "prevention" of such accidents, but so long as human nature is fallible, railway accidents can never be wholly prevented. The most that can be done is to minimize the risk or possibility of accidents. You all know what elements of care, of prudence, enter into this consideration—substantial construction, complete equipment, good discipline, and last of all, but of the highest importance, constant inspection and accountability. When due attention is given to these four elements, accidents will be very rare, and then will only occur through the failure of the human elements,—the forgetful inspector, the careless motorman, the confused car dispatcher, or the incidents of storms or other unavoidable occurrences. We owe it to the public, as well as to ourselves, and to the reputation of industrial and mechanical intelligence, that every safeguard which experience, caution and liberal expenditure of money affords shall be applied to the carrying on of our several enterprises.

The standardization of equipment for electric railways is a subject which is year by year engrossing more closely the attention of both operating officers and manufacturers, and it is only necessary for me to say here that it is a matter worthy of fullest consideration. Its effect will be to facilitate, as well as cheapen maintenance, to improve practical operation, and to a large degree add to the safety of our patrons.

I should consider myself derelict if I did not make a brief allusion to the excellent work performed by the committee appointed to prepare a standard code of rules. We all appreciate that this is a difficult proposition to handle to the entire satisfaction of all parties but I feel confident that the vast amount of time and thought devoted to the report that will undoubtedly be submitted at this meeting will be productive of beneficial results.

I am also gratified by the large number of supply men that are always in attendance at our annual meetings, as they not only add to the numbers but to the interest of the occasion, and the pleasant interchange of social intercourse between the street railway officials and the men with whom they deal cannot help but prove beneficial in many ways.

I take pleasure in stating that the predictions made in my last year's report regarding the street railway development of greater New York and the continued advance in reconstruction of horse lines in the older city of New York have been fully carried out and the general interests of the citizens thereof greatly subserved. That very noteworthy improvement, the construction of the subway in the city of New York, is progressing and has now reached a stage where 70 per cent of the construction work is completed, and upon reliable official information I am prepared to state that the work is progressing quite up to expectations and that the contract for equipment, buildings, etc., are all made predicated upon beginning operation of a portion of the road to at least 145th street on the West Side and to 145th street and Lenox avenue on the East Side by January 1st, 1904. The rapid transit proposition seems still to be in an embryonic state, as far as furnishing a complete system of transportation is concerned, for the chief engineer of the subway frankly concedes that the present construction will not be adequate to satisfy the requirements of the city.

The elevated roads in old New York still continue to carry on the work of improvement, and the introduction of a third rail system on its various lines is well advanced, while the facilities furnished the public by the improvement are plainly noticeable.

I have often called your attention to the unjust discriminations in the State Franchise Tax Law, whereby we are taxed one per cent of our gross earnings and other public serving corporations pay but

one-half of one per cent. This subject is one that merits your thoughtful consideration and action.

In this connection I desire also to mention the unjust burden imposed upon the street railways of the state by the enactment of the Ford Franchise Tax Law. I shall not attempt a detailed argument of the situation, which remains practically unchanged since the presentation of certain figures and statistics submitted by me as President of this Association at the hearing before the Governor of this State on May 11, 1899; suffice it to say that one hundred and one street surface railroads operated by mechanical traction submitted reports to the state for the year ending June 30, 1901; sixty-one showing a surplus for the year, forty showing a deficit. Of the total surplus 58 per cent is shown by the companies of greater New York; of the one hundred and one companies but sixteen declared dividends, three of which showed a deficit after so doing and which are included in the sixty-one roads mentioned as showing a surplus.

An enormous amount of money is invested in the street railways of this state, a large percentage of which was sunk in the depreciation of values and in demonstrating the practicability of electrical traction, the benefit of which the public at large has inherited and for which the state under the Ford Franchise Law now assesses as real estate. That public corporations should pay their full and just measure of taxation none will deny, but that any discrimination should be made against them simply because they are public corporations is unjust and unfair.

The most serious annoyance and handicap the street railroads of the state have suffered since the introduction of mechanical traction is the burdensome and perplexing question of pavements. The general state law regarding the proportion of expense to be borne by street railway companies is one of the old methods of horse street railroading handed down of which we are unable to rid ourselves. The exorbitant demands made upon us in this respect are a constant menace not only to the financial interest of the smaller roads of the state but the larger ones as well. Fortunately the legislature of the state recently modified the law slightly whereby the smaller municipalities and street railroad companies can now fix by contract the amount to be paid by the company. This is only a step in the right direction and the modification should apply to all cities. That we are entitled to still further legislative consideration in the pavement matter no street railroad company which has suffered the burdensome taxation under the law as it now exists will gainsay.

In closing I esteem it a pleasure to briefly allude to the general usefulness of our association, which has been so clearly and frequently demonstrated in the past, especially from an operating standpoint. The annual meetings have proved fruitful and profitable and I firmly believe that the properties we represent and public interest as well, have been greatly subserved by the presentation and discussion of the many subjects of practical interest. Notwithstanding the past enviable record of the association there is a still broader field of usefulness to be developed which can only be completely accomplished by every street railway company of this state becoming identified with the association and its work.

#### CAR DISPATCHING ON INTERURBAN LINES.\*

BY THOMAS E. MITTEN, GENERAL MANAGER INTERNATIONAL RAILWAY COMPANY, BUFFALO, N. Y.

Since the introduction of high speed electric service between cities, there has been a great demand for a satisfactory method of car dispatching on interurban lines. So many lines of this description have been constructed within the past few years, either independently or in connection with existing city systems, that the subject has become one of common interest; there has, however, up to the present time, been apparently little, if any, concerted action, the management of each road having adopted some method designed with a view of meeting the particular requirements of the line to which applied. Theoretically, the ideal system would be that controlled by an automatic block, operated independent of trolley circuit and absolute in its action, which would permit of but a single car or train upon a section of track at one time. Up to the present time, such a system has not, to my knowledge, been satisfactorily worked out as applied to electric lines. Experiments with electric signals, operated in con-

\*Read at the annual convention of the New York State Street Railway Association, Sept. 9-10, 1902.

nection with the trolley circuit, have been made from time to time, and some lines are now being operated relying almost entirely upon the protection afforded by such signals. This practice, however, seems to be confined to the shorter lines where but few cars are operated, the results obtained not seeming to have been such as to warrant its general adoption.

In the operation of the longer and more important lines, where high speeds are attained and cars run with greater frequency, the disposition is rather in the direction of following steam railway practice, and it would seem that much might be gained by a careful study of the system in general use by steam railways representing, as it does, the result of much thought and many years' experience. The accidents occurring on interurban lines have shown that as we more nearly approach the speed of steam railway trains, we become correspondingly subject to the same class of accidents. It would, therefore, appear that we should make our rules looking to their prevention conform as nearly as may be practicable to those which the steam roads, by long use, have found most effective.

Believing that the solution lies in this direction, the writer has, for some years past, been endeavoring to perfect a system which, while closely patterned after steam railway practice, has greater flexibility and can be simplified to conform to the requirements of the line and service to which applied. Under the system referred to, a printed time table, containing the running schedule, meeting points, and all rules necessary to a proper understanding, is provided, a copy being supplied to each motorman, conductor and such other employes as are interested therein.

Trains are of two classes: regular and extras.

Regular trains are given a number and shown on time table, and are designated by a corresponding red figure displayed, in a conspicuous place, on front and rear of train by day, and, in addition, a red light at either end of train at night.

Extra trains can occupy main track only upon written order from the dispatcher, and are designated by a green letter "X" by day and green light at night.

Regular trains, having a second section following, carry in addition to their red number or red light signal, a white sign worded "Car following" by day and a white light at night.

Trains, running in sections, are required to keep 3,000 ft. apart by day or 5,000 ft. at night or during foggy weather when running at speed, distance and speed being correspondingly reduced when approaching meeting points.

Extra trains are required to be in on siding to clear at least five minutes before a regular train is due.

A red flag and a red lantern are carried on front platform at all times, lanterns to be kept lighted at night and during foggy weather, ready for immediate use.

Trains which are disabled in the vicinity of curves where vision is obstructed, are required to be immediately protected by conductor (using red flag by day and red lantern at night) proceeding at least 1,000 ft. in the direction from which danger may be expected.

Under ordinary conditions, where no unusual delays are encountered, this time table is found to be all that is necessary.

A dispatcher is located at a central point, who by telegraph or telephone issues the necessary orders under prescribed form, when, owing to the operation of extra cars, or unusual delay, such are found to be necessary.

Operators, or receiving agents, are maintained at certain stations on the line for the purpose of copying and delivering train orders to passing cars.

When receiving an order, the operator or receiving agent, makes three copies on manifold paper, the original is retained by him, the duplicate and triplicate being passed to the motorman and conductor to whom addressed.

As soon as the operator or receiving agent receives an order, by telephone or telegraph, he at once repeats it back to the dispatcher, who, at that time, copies it into a book of permanent record, the orders being numbered by him consecutively, commencing with No. 1 at 12 a. m. each day.

The plan described affords protection to both the front and rear of trains, the complete time table representing, in a concrete form, the method which has been satisfactorily used for nearly two years upon a single track line over thirty miles in length, where at times, the patronage requires the operation of the largest number of cars possible at a maximum speed of 45 miles per hour.

## ECONOMICAL METHODS FOR REMOVING SNOW AND ICE.\*

BY R. E. DANFORTH, ASSISTANT GENERAL MANAGER ROCHESTER RAILWAY COMPANY.

Those of us who are connected with railways in northern and western New York, find our "great problem" in handling snow; that of removing it from our tracks to allow for the passage of cars, and often in keeping open cuts between small mountains of hard wind-packed snow, rather than that of caring for it after we have heaped it up along our lines. We congratulate our more fortunate brethren, who not only live where a milder winter climate prevails, but who are furnished with so ample an equipment of snow-handling machinery, and we regret our inability to adopt their methods and obtain their results.

On roads having an average passenger car headway of 7½ to 10 minutes, are not often found the number of plows or sweepers required to maintain over the system, a headway of even 60 minutes. This fact, together with climatic conditions, renders the problem of snow removal, in our smaller cities and towns, and also, in all cities and towns of northern and western New York one of serious importance.

With us, it is a question of ways and means; a question of number and types of plows, of capacity of rotaries, of strength of sweeper brooms, of means of throwing the snow over banks, from five to

this little better than our sweepers, we placed the board ahead and shoved it along. The board soon changed its form from a vertical plank, placed diagonally across the track, to a warped surface shear, tending to cut, lift and then roll a mass of snow along its length.

Finding this snow-plow ineffective in banks over five or six feet high, an ingenious friend produced an electrically-driven boring machine and called it a rotary track cleaner. With this machine we are able to cut our way slowly but surely through banks of snow of almost any depth and of any condition, short of hard ice.

We have, also, placed upon all our passenger cars, track-cleaners or scrapers, which will, without difficulty, remove snow from the rails to the depth of 4 in., unless the snow has been packed to this depth by the street traffic; and it may be well to say that scrapers, which will remove even hard packed snow, are in use in Toronto and elsewhere.

Each type of plow has its place and cannot economically be used in service for which it is not adapted. It is as improper to attempt to remove 6 in. of snow with a rotary, as to attempt to cut through 2 ft. of snow with a rattan sweeper. In either case the feat may be accomplished, but in neither case with greatest economy.

Considering, first, the removal of snow in cities, it may be said that experience in western New York has shown that, with the equipment at hand the work should be performed about as follows: On the appearance of a snow storm, when the streets are free from snow, light plows and sweepers should commence work, when about two inches have fallen. If the storm continues and the snow falls

WINTER SCENES ON THE ROCHESTER & SODUS BAY RY.

fifteen feet high, and of providing electric power to operate both plows and cars.

In our towns, we cannot haul all the snow off the streets, because there is too much to possibly handle; we therefore confine our efforts in this respect to the business centers, cross-walks and junction points. Along the remainder of the lines the snow is piled up between curb and walk, or spread between track and curb, as the locations warrant. The snow we do remove is hauled away in sleighs, and sometimes on flat cars. In considering our snow fighting equipment, we find that all types of machines for removing snow are useful. We even require horse plows or walkaways for leveling back banks of snow, thrown out by the plows, and for cutting down drifts and opening gutter work which cannot always be readily done by a track plow.

In localities where winter commences early in December and lasts until April, and where storm follows storm, and where a "thaw" means a rise in temperature slightly above 32 degrees, and closely followed by more snow storms, severe cold and unusually high winds, the accumulation of snow from one storm almost never disappears before it is buried beneath another. In the outskirts of the cities, and on the suburban line, the high winds, continuing for days, are the cause of most of the trouble, as huge drifts of hard sandy snow are formed as rapidly as removed, which defy ordinary snow-plow apparatus successfully.

To combat our local conditions we have drifted away from rattan broom and followed, more or less intelligently, modern steam road practice. First we dragged a board along the track; and, finding

so rapidly that there is a probability that the accumulation between trips of the plows and sweepers, will exceed three inches, the heavy shear-plows are sent out. When the ridge formed by the plows and levellers approaches 24 in. in depth, walkaways are used to level off the same, and shovelers sent out to clean all cross-walks.

At the commencement of a storm a force of trackmen are sent out to clean switches.

In storms of recent years, when snow has fallen to depths of over thirty inches it has been found impossible to depend upon the light plows and sweepers to do more than follow after the heavy plows, to clean the street to the pavement. The work of the rotary commences when the banks of snow on either side of the tracks become so high that the plows can no longer shove them back.

The rotary is a slow moving machine, because of the power limitations of the ordinary street car motor, but its work is positive and effective. As our storms are usually accompanied, or followed by high winds, the new fallen snow is soon piled in drifts in the thinly settled portions of the city. The snow thrown out by the rotary is spread over a large surface and does not materially add to the height of the bank, until the snow has become wind packed and sandy, and then, for the reason stated, the height of the bank is only slightly increased. Teams and shovelers commence the removal of snow at junction points, as soon as it accumulates. When the storm is over, the work of removing the banks of snow in the business section, thrown up by the plows, and from the sidewalks, is undertaken by the railway and city forces jointly.

When the storm ceases our work has just fairly begun, while there remains little to be done in the centers of the city, drifts are being rapidly formed in the outskirts, and plows and rotaries must remain in constant operation for days to keep the lines open.

\*Read at the annual convention of the New York State Street Railway Association, Sept. 9-10, 1902.

Suburban lines which cross the line of prevailing winds and those which are run along the highways, require constant, and at times, heroic effort to keep them open. When snow fences are liberally used and properly placed along the exposed portions of the line, the saving in snow expense is marked.

The Rochester snow plow equipment consists of eight antiquated sprocket driven mold-board plows, equipped with Westinghouse No. 3 motors, three combined rattan sweepers, one double truck four-motor Wason nose plow, one double-end tin fan rotary, two single truck heavy shear plows and six walkaway or horse plows. With this equipment, was kept open, throughout the severe storms of last winter, 100 miles of track, including 25 miles of side or boulevard track, placed between rows of trees on one side and hydrants, stepping stones and hitching posts on the other, with less than ten feet between the two. This peculiar location of tracks renders the use of wings or levelers impossible, and the snow is therefore, soon piled up close to the tracks and the cars are operated in a cut, the width of the car body. Under these conditions the removal of snow is made difficult and expensive, and, because of the narrow space between rails and sidewalk, the number of shovelers and the expense of snow removal is greatly increased. The cost of removal of snow and ice for the winter of 1901-2 in Rochester was \$90 per mile, a large percentage of which may be attributed to the 25 miles of boulevard tracks. A double track line 5½ miles long between Ontario Beach, Charlotte and Rochester City line, and running north and south, lies on the west side of the highway, between the curb and fence lines. The hedges and line fences form a snow fence, which stops the drifting snow and heaps it up to great depths on the tracks. This line has been kept in continuous operation for eight years by two to four men, with a rotary plow. During the most severe weather cars are obliged to closely follow the rotary over the line, but are never stalled. Although this plow is equipped with small motors (four G. E. 800) it has been operated for three seasons without a burnout. A section gang of four men has been used to clean switches and crossings on the 11 miles of track.

The Rochester & Sodus Bay Ry., operating about 40 miles of line, mostly along a highway, is kept open by two rotaries and ten shovelers, but with considerable difficulty. The location of this line is peculiarly favorable for its obstruction by snow drifts, which form along almost the entire line, often higher than the roofs of the cars. The plows on this line are overtaxed and require a considerable expenditure for their maintenance. Under the conditions existing on this line, each car should be provided with a pilot plow—a heavy nose-plow with long side wings or levelers, should be provided, for use through the villages—and the rotaries should be the single, instead of the double blade pattern, so as to be able to lift the snow higher.

The cost of removal of snow and ice during the winter 1901-2, along this line, was \$2,300 or \$57.50 per mile.

When the average life of a rattan-filled broom is considered, as with its extreme flexibility, the additional cost of a steel broom, properly re-enforced by steel plates, is more than made up. Those who have operated steel brooms driven by 50 h. p. motors, know that they will cut through drifts of moderate depth, and sweep the track clean, with no apparent injury to the brooms. For comparison, it may be well to state, that the steel brushes cost \$42 per set and last from two to five years with ordinary care. A sweeper thus equipped will readily go through two feet of loose snow and at good speed, and will cut all packed snow to the pavement when properly operated.

### IMPROVEMENTS BY THE UNION TRACTION CO., OF INDIANA.

The Union Traction Co. of Indiana is contemplating some improvements in its line which will eliminate several dangerous points and enable it to shorten the schedule time between Marion and Indianapolis. All the short curves on the line between Marion, Jonesboro and Fairmount will be done away with and a double track will be laid over part of this route. It is believed that after the changes the company will be able to run cars from Marion to Indianapolis in 2 hours and 45 minutes, which is the running time of the steam railroad. On the fast trains chair cars are to take the place of those now in use.

### DISCIPLINE.\*

BY C. B. FAIRCILD.

Some time since, the writer was riding on the front seat of an open car, on a country road, where it was not against the rules to talk to the motorman, and in conversation with a thoughtful man, he remarked: "The repair men give, and are required to give, special attention to the controller and motor equipment of our cars, but they frequently neglect, or only give a passing thought, to the brakes." "Now," said he, "if I cannot make a car go I certainly can do no harm or have an accident, but if I can make my car go, and am not able to stop or control it, I can do untold damage." Now, the subject of this paper is not brakes, but discipline, and I quote the foregoing only for the philosophy that is in it.

Managers and others, in operating street railway systems, strain every nerve, advertise, and make their cars attractive, to induce patronage, or to get nickels into the hands of their conductors, but what are they doing to insure that all these nickels get into the treasury, or, after getting them into the treasury, what are they doing to prevent their escaping or being paid out to meet excessive accident and repair claims, due to the ignorance and carelessness of the conductors and motormen? In other words, managers select their motors and other appliances with great care and then watch, shield, nurse, protect and repair them assiduously, to prevent their burning out, bucking or kicking, but what are they doing to improve, protect, shield and enlighten the two human machines that operate on the two platforms of the cars? Do they never buck or kick? And those others, who have charge of the track and car house repairs, as well as the clerical force?

What if a motor or controller does go wrong? You do not usually discharge it or lay it off without pay, nor take a crow bar and jam it into it and tell it what a — fool it is, that it ought to know better, had been told often enough. Isn't it in your book of rules? You are not a profitable machine for this company. You do none of these things, but you put an expert on it and have it repaired.

It is to the human machines that our subject, "Discipline," relates.

The word "discipline" is from the Latin *disco*, meaning to learn. The word "disciple" is from the same root, and has reference to a learner, or one who receives instruction from another. "Discipline" used as a noun means education, instruction, and usually comprehends instruction in arts, sciences, manners and due subordination to authority. "Discipline" as a verb means to instruct or educate, to inform the mind, or to prepare one by instruction in correct principles for a profession or any useful work.

Originally these words applied only to instruction, but in ecclesiastical affairs, in the early church, when heresy hunting began, the word had reference as well to the execution of the laws by which the church was governed, and the inflicting of penalties enjoined against offenders. So in later times the word means not only to instruct, but to correct, to chastise, to punish, with a view to bringing the offender to repentance and reformation, and more attention is usually given to the latter meaning than to instruction, whereas the reverse should be the rule. For our present purpose, the word "discipline" will mean the rules and regulations by which a body of men are kept in a state of efficiency and order, and under complete command.

At once, it appears, that there are two related parties—the instructor and the learner, or the disciplinarian and the disciples, both human beings and of the same common stock, involving the principle of brotherhood with a common object in view, viz: The efficiency of the service. The first recognition is this relation. The second, how best to impart the instruction, and enforce its observance.

It was well remarked by a member of this association at the last annual meeting, to the effect "that inasmuch as the machinery for propelling cars is decidedly in advance over the old type of machine (meaning horses), so the men who stand on the platforms of your cars must also be a decided improvement over the old street car men." This is true, and it is also true that applicants for such positions, and, in fact, nearly all working men, are a different kind of men from those employed a decade ago, and they will not submit

\*Read at the annual convention of the New York State Street Railway Association, Sept. 9-10, 1902.

to the bossy and abusive treatment that was formerly supposed to be necessary, in order to make men know their places, or to get work out of them, which was probably the outcome of the spirit of slavery then existing. For this reason a manager or superintendent must know the basic principles upon which the relation of man to man exists, and must base his action on these principles in order to insure satisfactory results.

Among these principles are the following: The brotherhood of man is fundamental from the very nature and constitution of man, hence one cannot do a wrong to another or speak unkindly, without doing a greater wrong to himself. For the thought of wrong is first generated in one's own mind, where it will do its corrosive work before reaching its intended victim. Again, mankind are indissolubly related by ties of common nature and origin too deep for anything to put asunder; and, being so related, self-preservation demands that one should act kindly and do justice to all, including the meanest and weakest and most defenseless of his fellow men. Again, since man's constitution is based on the principles of charity and good will to all, slavery of any kind is not the natural birthright of any one, and when a master puts a chain about the neck of a slave, the other end must of necessity fasten itself around his own neck.

These principles were recognized and well illustrated by one of the speakers at your Rochester convention. He said: "I do not believe that any workman was ever made a better man by harsh or cross rebuke administered to him by his superior in the presence of his fellows. He feels that he is an inferior, if he is subject to such treatment, and whenever I have occasion to speak to a man, for any infraction of duty or violation of rules, or the neglect of his duty, I take occasion to take him alone and appeal to the better side of his nature. My experience has been that more than ninety-nine per cent of mankind are subject to the better influence. There is a great deal of man in every man, and all that you have to do is to develop it, give him a chance, bring him close to you, for there is scarcely a man so dense but what he is open to an appeal to the better side of his nature."

Employees in whatever situation reflect the color of the mind which directs them, so courtesy will be found to be one of the greatest factors in success. The writer is aware that most of the managers and superintendents who are members of this association recognize and practice these principles, but the duties of a manager or superintendent in this matter of treatment of men does not end in his personal treatment of his associates and employees, but should be followed up by careful inspection to learn if the heads of departments and foremen are co-operating with him. He should know that every man down to the lowest grade receives fair and just treatment from his immediate superiors. It is a patent fact that a gang of workmen will not be better than their foreman, and if he is overbearing, cross and profane, the men and their work will partake of the same low character. If a foreman gets angry and quarrels with his men, he puts himself on their lowest level and loses his power of discipline, and by getting angry wastes his own physical strength that might better be spent in the service of the company. Let your men all understand that they are free to complain, or report any ill treatment on the part of subordinates without fear of being persecuted. Let your men understand that they are not to be serfs, and are not expected to submit to petty tyranny, but that they are to be independent and have the right to resent, in a proper manner, any unjust or ungentlemanly treatment. Let your foreman and subordinates understand that each man sets an estimate upon himself, and if he uses the language of a blackguard he must expect his men to do the same. Let him understand that one must first learn to govern himself, and that anger is a confession of weakness.

In the enforcing of discipline one should remember that no matter how stupid, ignorant or vicious a man may appear, he still knows some thing that the superintendent would be the better or wiser for knowing. Even though you have decided to discharge a man, by keeping cool and winning his confidence you may, by adroit questioning, be able to get from him admissions or confessions that will prove exceedingly valuable in rooting out discordant elements among the men or draw out some hint that will be of value to the service. In reproving or cautioning men keep on their good side and regard all your men as so many feeders or avenues for seeking and transmitting to headquarters knowledge that will add

to the efficiency of the service, and all your men should be encouraged to plan and suggest.

In the matter of shielding employees, special attention should be given to the night men, whether car men or night repair men. The late night men are apt to be influenced unfavorably or debauched by the people who patronize the late night cars, and unless carefully watched will pick up careless habits or shady practices that will in time spread to the entire force. Men should never be required to remain too long on late night runs, or at night work of any kind. In the business of street railway management there are three classes of parties to which a superintendent finds himself related; first, the employees; second, the public, and, third, the stockholders, and in proportion to the attention given to the first class does he benefit the other two classes. When the employees please the public the public becomes liberal patrons and the stockholders get the benefit of the extra nickels.

So much for the relation; now for the instruction and its enforcing.

We often hear it remarked by the heads of departments in street railway matters: "If you knew the calibre of the men we employ you would know they would never think of using such or such an appliance if we should adopt it; or, our men can never be brought to such a state of efficiency." One who says such things only confesses his own inefficiency as an instructor, for men will do, and all men will do well, whatever they are properly instructed to do. It is in them as a possibility; the question is how to bring it out, and make it actual. It is not enough to dismiss the subject and say that it has been tried and failed, for so far as the writer is informed men working in the street railway field are not generally fully instructed, or rightly informed. Note the difference between instructed and informed. They may be well instructed in mechanical details, and as to their particular duties in particular situations, but have never received instruction along the higher lines, as how to develop and employ their own native powers, their own power to think, and act promptly and correctly, under any and all circumstances that may arise. A man may be familiar with all the rules, and yet not know them, and it is a mark of a good instructor to so teach that his pupils know the subject, can digest it and make it a part of their own immediate knowledge, always ready for use without taking time to fish about in their minds to recall the rule that applies to any particular case. Every mind is so constituted that it can acquire, if properly taught, and instruction is the only thing that will, or can, do away with the limitations that hamper street railway practice. Mere instruction, however, is only half, and the smaller half, of the requirements. Every teacher knows that no matter how lucidly a subject is presented to a class of pupils, the learning is solely a mental act on the part of the individual pupil. The object of the teacher and pupil is the same, but the relation to the work to be done is different, and as said above, the object can only be attained by the mental act of the learner, by his observing, remembering, etc. It is clear, then, that what he does, and not what the teacher does, is the essential part of the process, that is, the appropriation and assimilation of knowledge, by the mind, and can be performed by no one but the learner. The teacher can no more think for his men than he can walk, sleep, or digest for them. The process of thinking, then, by which a pupil learns being essentially his own, the teacher's part is that of a guide director, or superintendent of the operation by which the pupil teaches himself. The instructor can stimulate and direct, but he cannot do the thinking necessary to give the desired results for his pupil. The teacher's problem is how to get his pupils to learn, how to get all his pupils to learn, the so-called stupid ones, as well as the bright ones, and how to adapt his teaching to the calibre of the individuals and see that they make the mental effort to learn. And he should remember that there is no need for haste, the only thing needful is accurate knowledge, to have something thoroughly, perfectly, immovably known, the same as is required of a machine, that it will work perfectly under all conditions. Even then the teacher's work is only just begun, instruction must be followed up by continuous, persistent and careful inspection of the men when on or off duty, not with the view, merely, of finding if rules are being violated, or for the purpose of administering reproofs and reprimands, but for the purpose of keeping acquainted, of watching their general conduct, and for the purpose of impressing upon the man the rightness and advantage of honesty, sobriety,

and politeness. Let the reprimands and reproofs, if necessary, come afterwards, when the individual offender can be called aside and warned or instructed by himself. Indiscriminate censure when anything has gone wrong, or is going wrong, only defeats good discipline. In the matter of inspection remember that if everything is found working smoothly one day it is not an evidence or guarantee that it will be so running the next day, unless you make it so by your presence. Never take it for granted that your men, or assistants, are doing what you have told them, but watch and see—come upon them at odd spells day and night. Let them feel that you are omnipresent. In preparing a code of rules for the government of street railway employes it will be more expedient to so word them that they will all be constructive rather than prohibitive laws and penalties. It is much pleasanter and more effective to have laws that will tell men what they ought to do, rather than what they must not do. For instance, rules that read "It shall be lawful and proper, etc.," rather than it shall be "unlawful, etc." "Said crime or misdemeanor or infraction of rules shall be punished by fine, suspension or discharge." Rules that read "thou shalt not" often serve as a challenge or suggestion, to certain minds, to do the forbidden thing, for the purpose of showing their independence, and that they can do it without being detected. It weakens the force of a rule to state it arbitrarily with must or forbid when its violation cannot be enforced. For instance, "Indulgence to excess in intoxicating liquors when off duty is positively prohibited." "Spitting in this car is positively forbidden." A man might be discharged for intoxication, but there is no way that the company can prohibit a man from becoming intoxicated. The rule about spitting cannot be enforced, for the passenger might spit out of the window or the door, or might use the coal box, or, if he should spit on the floor, the chances are that the conductor would not see him. A better notice would be, "Gentlemen, please do not spit on the floor of this car." Or, "The Board of Health has made it a misdemeanor to spit on the floor of a car."

A book of rules should have no reference to specific rewards or punishment. These matters should be left to the individual judgment of the one who is responsible for their enforcement. Incentives are better than penalties, in the matter of securing obedience to the rules, but as there are always employes with whom incentives have no weight, penalties are sometimes necessary. They need not be severe, however, but reproof or punishment must be certain, following any offense, whether injury has resulted or not, and must tend to instruct or train the offender so that he will want to obey the rule. In no case should a disciplinarian threaten a man, or impose a penalty, and then let him beg off. Investigate carefully, and be sure of your ground before imposing a penalty. The offender should be made to realize that reproof or penalty is imposed for neglect or disobedience, not simply because the manager is displeased and seeks revenge. Penalties except in rare cases should not affect the man's pay, for if it does his family or friends may be made to suffer, and the women of his household, not knowing the circumstances, are apt to blame the manager and gossip and circulate reports injurious to the interests of the company, and the man himself, thinking he is unjustly fined, will be apt to seek, or try some means by which he may get even with the company. It is gratifying to know that this matter of affecting a man's pay has already been settled by a number of companies in this state, as shown by the reports and discussions of your previous meetings. Merit and demerit marks may be used, but a record of these necessitates an endless amount of bookkeeping, and often leads to no end of misunderstanding and jealousy among the men, and is often attended by annoyances that defeat the end sought to be gained. (The bookkeeping mentioned does not refer to the man's record.) It is better to leave it to the manager or superintendent to devise some original method of reward to suit meritorious cases, without any previous promise made in the matter. In the whole matter, however, it is better to remember that formation is better than reformation, and that more attention being paid to instruction, and drill, will save time and worry in the matter of punishment. It is conceded by prison authorities and others that punishment as ordinarily administered is not reformatory. In enforcing discipline let not authority be the impelling motive. Temper your attitude by imagining yourself in his place. Think that if you had had his hereditary, his conditions and environment you would be just like him, and this will furnish a good lesson in toleration. Interpret the

man from his own point of view, and remember, that until he sees the justice and truth of your action, it is not truth to him. To convince him, find other points of agreement, and he will be led towards recognition and at length exclaim "I see it." If you seek common ground you can always find it, and when found its area naturally increases. Hold the other man's view in respect, and that will bring him towards yours. Your toleration will outlaw his law.

In the matter of correction a distinction should be made between offences from ignorance, indifference, recklessness, carelessness and those where willfulness or guilt are involved. So far as the company is concerned, a loss from carelessness or forgetfulness is just as bad as a loss where guilt is a factor, but the penalties cannot be the same. The fact, however, should be impressed on the minds of all the men that loss from any cause is a serious matter, especially when it is accompanied with injury to life or limb, and that accidents are not measured by the money value only, but have an important influence on the general reputation and patronage of the road. Accidents do not happen, nothing happens; there is a cause for every effect. There are no unavoidable accidents. According to psychological laws the cause can usually be found, in the mental make-up of the man responsible for the accident. The mental attitude of some men invites accidents and all sorts of so-called ill luck. The man who has one accident will have another and another and will continue to have them unless his mentality is changed. The best men never have any accidents, and all the accidents can usually be traced to a certain few men who, when known, had better be discharged or transferred to some situation where they cannot do much injury, either to themselves, to others, or to property. It is a mistake to suppose that men must necessarily have accidents, violate rules, or be a little reckless, or careless at times, in order to learn street railroading. People learn to walk by walking and not by falling down. Mistakes or accidents are not instructive or reformatory, and a man is never better for them. The writer was surprised to hear the statement made at your last convention by a superintendent, that he would have no objection to employing a man who had been discharged from another road for having an accident, upon the ground that such a man would realize the seriousness of his error and make a better man than before. Such reasoning is contrary to mental laws, and contrary to all the information the writer has been able to gather on the subject in his fifteen years' continuous association with street railway men.

All the triumphs of skill which we observe are merely the shaping of things by the subtle power of thought. The grander the achievement, the grander and more masterly the thought that has embodied itself. The scientific work which calls for the praise and admiration of men is the result of the scientific thought of the worker. Man then, being a master of thought, and of all things through it, any desired object or condition becomes possible of realization. Once master of the principles of thinking one can become a specialist in any particular line of invention or discovery that may be demanded by the necessities of the service. Once master of that kind of thinking, which builds men, bringing into expression the ideal qualities that are essential to profitable street railroading, a manager can advance his service to an earning capacity beyond anything he has ever imagined. The question is often asked, "What is your experience in such a matter?" or "In my experience I have found so and so to be of advantage." Now experience is merely what has been found out in practice, but it should be remembered that there is much beyond what has yet been so found out. A turn may come in street railway affairs and sometime a wiser method of discipline may be suggested, productive of unheard of results. So it is never safe to reason on the basis of experience, or on a basis that one knows all that is to be known on any subject and so declare a new idea impossible or silly. It is not always experience, custom or practice that is to be followed, but some higher, advanced or better way. Those who are the great masters of commercial matters today are those who have dared to try something new that has come to their thought. An example is found in the matter of welding the joints of street railway rails. Engineers who were skilled in all such knowledge when told of the idea pronounced it impossible and silly, declaring that in the summer's heat the rails would hump up, pull the spikes and ruin the road, or in winter time, the rails would pull apart by contraction.

Their reasoning was conclusive, according to experience up to that time, but when the actual trial was made the results were surprising. There was little or no trouble from expansion or contraction, and it has become an almost universal practice. Those who declared such ideas absurd have in this day their companions but prompt action is the secret of success in the line of new suggestions, but it should be action, that is right in line with one's regular work.

We must not limit the possibilities of today by the attainments of yesterday: if we should do so, we would bring to an end all progress, and in the matter of discipline no advancement could be made towards the time when there shall be fewer accidents, less expense for repairs and when employes shall be more considerate of the rights and comfort of passengers.

In the matter of instruction, it is a commendable practice to provide schools or lectures for instruction and practice as has already been done by some of the largest systems in our state. In these schools, oral instruction should be given in addition to printed rules, and when rules are provided, it is best not to put them into the hands of green men to study, at first. Not until they have had some opportunity to become familiar with the names of the parts of a car, and road equipment. Even then it is better that the rules be first read and explained to the men, as some men, although they can read, find it difficult to comprehend written instructions. It was well remarked at the last convention that, "So far as the question of training is concerned it should continue so long as the man is in the employ of the company. The training of every employe should be continuous, as new questions and conditions are constantly coming up." This training can best be given by having schools for this purpose, as is already the practice with some companies, and through the business and social meetings, in connection with the benefit associations or other organizations. Schools of some kind are especially desirable for small companies, as it is usually found to be more difficult to give thorough instruction to employes on a small system than on large roads, for the reason that the superintendent is so burdened with details that he finds little time to devote to instruction. Thus it frequently happens that a motorman, for instance, receives his entire teaching from another motorman, who receives all his instructions from a previous motorman. So that the rules that the last man receives are only copies of copies, and are likely to be very much distorted from the original. Again, when frequent changes are made among the men, a new man may be put on to learn from a man who himself was new only a short time before.

It should be borne in mind that in the present state of society it is of advantage to a company to provide instruction in schools or by lectures for their men, along lines, other than those relating to their mechanical duty. In other words some means to counteract the philosophy of the "bar rooms" and make the men conscious of their own mental and moral powers. Not only the philosophy of the "bar rooms" is to be counteracted, but that given at public halls where the men listen to bitter harangues on society in general, attacks on property, on the church and the institutions of our social fabric, when men blame everybody and everything except themselves and fire the souls of their hearers, as bad whiskey fires the body, and for the same reason. Labor troubles arise from ignorance, and can only be avoided by bringing all the men to the same general knowledge of all the local conditions, that the chiefs in the service themselves enjoy. Men can be taught to feel that their interests and those of the company are identical. Individual opinions are founded upon, and colored by, an innumerable variety of factors which have preceded, and if you expect men to think as you do and be actuated by high and lofty motives and loyalty to the company, they must be taught the same things which have made you what you are. As was said last year, there are bound to be seeds of passion, seeds of discontent and disloyalty planted in the minds of the employes somehow, hence a matter of self-defence, from a selfish or commercial standpoint, without any reference to ethics, morals or religion, street railway companies should undertake to fill the minds of their employes with seeds of truth for truth's own sake. Men are tired of make-shift, they do not wish to be bribed by gifts or abused by penalties, but they do want food for their minds, and when teachers are provided, who will proclaim the brotherhood of man, and the law of mind, as founded on the very nature and constitution of man, men will crowd and throng the classes. Men must be shown

that they have a higher nature which is ever leading them on. That this nature has a tendency to evolve until they outwardly manifest, in full, their relations and possibilities, being filled with the hope and expectation of bettering their condition in life. When men are taught how to think, how to recognize and use their power to think, they will have the key to all problems, for thought is creative and all creation and all progress of the race, as manifest in means for transportation, in printing, etc., has been through thought.

The principles enumerated are not one-sided, are not for one class only, but are to be observed by the employes as well as the employer, but it must be remembered that these principles cannot be forced upon any class of people, nor upon the public, for this reason, these truths cannot be put into practice until your employes are educated up to them, but the responsibility of teaching principles to what are known as the laboring classes rest with the higher or more advanced and enlightened, usually the employer. From the fact that street railways are closely allied to most every other industry they have the opportunity, and it will be for their credit to take the initiative in this matter. It is often said by street railway men that they are not in the missionary business, but it is now known that any enterprise or industry is prosperous in proportion to its missionary work.

Some of the larger companies have formed schools for instruction. It would be doubtless to the advantage of the smaller companies if they would club together and organize schools in different parts of the state, or subsidize and encourage private schools where instructions can be given in all matters relating to street railway affairs, to which young men can go and fit themselves for the business or profession of street railroading. We have numerous commercial colleges, schools of dramatic art, of music, etc., why not have schools for the science and art of street railroading and street railway management—schools equipped with cars, motors, trucks and all the mechanical appliances, with a course of instruction in all the duties required of a street railway employe, embracing his relation to the public which he is expected to serve?

### ACCIDENTS ON ELECTRIC ROADS.\*

BY C. R. BARNES, ELECTRICAL ENGINEER FOR THE NEW YORK RAILROAD COMMISSION.

As a representative of the Railroad Commission I have officially come in contact with nearly every manager of electric railroads in the state. My relations with them, I think, without exception, are cordial and friendly, and I hope that condition to continue.

The subject of this paper is at the present time a very important one. The author has had eight years' experience in the investigation of accidents in this state, and this experience has taught him the importance of the subject, and also how incompetent he is to present a paper on it before a convention of representative railroad men such as this. But to treat the subject in even my humble way, facts must be stated, and in doing this it is desired that every member of the association should know that there is no criticism on the management of any one particular road intended; but the general information in reference to the operation of all roads which has been obtained in my official position will be used in the hope that it may in a small measure aid in what you are all interested in accomplishing, namely, reducing the number of accidents to those which are incidental to the operation of an electric railroad and which experience shows to be practically unpreventable, even with reasonable care and foresight.

In the year 1898 there were 1,174.38 miles of electric railroads in this state; 4,002 box, 3,498 open, 10 mail and 208 freight, express and service cars operated. In that year there were 74 persons killed and 541 injured. In 1899 there were 1,225.16 miles of road; 4,743 box, 3,681 open, 139 mail and 631 freight, express and service cars operated. There were 126 persons killed and 580 injured. In 1900 there were 1,413.26 miles of road; 5,098 box, 3,666 open, 22 mail and 666 freight, express and service cars operated. There were 148 persons killed and 650 injured. In 1901 there were 1,548.66 miles of road; 5,199 box, 3,945 open, 10 mail and 558 freight, express and service cars operated, and 160 persons were killed and 807 injured. The complete reports of mileage and the number of

\*Read at the annual convention of the New York State Street Railway Association, Sept. 9-10, 1902.

cars operated for the year ending June 30, 1902, have not yet been received in the railroad commission office. In this year to June 30th there were 127 people killed and 823 injured. You are all familiar with the serious accidents which have occurred since June 30th, one of which resulted in 14 deaths and the injury of 60 persons, another in 4 deaths and 20 or 30 injured; one where three were killed and several injured; two where one was killed, and several others where a number were injured.

These figures show that the death rate caused by accidents in reference to miles of road operated was .003 in 1898, .102 in 1899, .104 in 1900 and .103 in 1901. As stated above, these figures cannot be given for 1902. But with the exception of the year 1901, in which year the death rate in proportion to miles of road was less than the year previous, there has been a continuous increase in the death rate as compared to the mileage. This increase between the years 1898 and 1901 was .040, an increase of about 63 per cent. The percentage of passengers injured in reference to miles of road operated in 1898 was .462; in 1899, .480; in 1900, .450, and in 1901, .559. This shows a steady increase in the percentage of passengers injured in reference to mileage of road except in the year 1900, when the percentage was less than in the year previous. There has been an increase between the years 1898 and 1901 of .097, an increase of about 21 per cent.

These figures include the accidents on all of the electric railroads in the state, including city and other roads, and are compiled from the annual reports of the companies made to the railroad commission. It was the intention to have classified these accidents, and also to have made a percentage comparison based on car mileage, but the investigation of the number of serious accidents which have occurred recently has occupied so much time that I was unable to make as detailed a statement of accidents and as clear a comparison of them with the growth of the electric railroads as would be desirable in a paper of this kind.

While these figures include the killed and injured resulting from all classes of accidents, a large majority of them are the result of head-on collisions, tail-end collisions, collisions at grade crossings of steam railroads, collisions at grade crossings of electric railroads, derailments and failures of bridges and trestles. The future consideration of this subject will be confined to this class of accidents. The accidents incidental to city operation, such as striking persons and vehicles on the street, passengers injured boarding and leaving cars, passengers thrown from cars, etc., will not be discussed in the following portions of this paper.

The greatest loss of life and injury to passengers on electric railroads in the last five years has been caused by rear-end collisions; the next largest loss of life and injury to passengers has been caused by head-on collisions, and in this comparative line of the causes of death and injury to passengers are the collisions at grade crossings of steam and electric railroads, the derailment of cars and the collapse of bridges and trestles. The causes for the above class of accidents are numerous, and to state only a small portion of them would be beyond the limits of a paper of this character. The more important ones will be briefly mentioned.

Head-on and rear-end collisions can be dealt with under one head, as the causes which produce them are in most cases similar. In the investigation of this class of accidents, it is found that motormen have two stereotyped excuses for their occurrence: First, "When I saw the car ahead of me I applied the brake, but it would not work;" second, "I then put on the reverse, but it would not take." The testimony of all persons directly interested in the operation of the cars in collision is taken in the investigation of accidents, and in nine cases out of ten this evidence goes to show that the motorman's statement was not true. When a motorman has been running a car the larger part of the day, making his usual stops without trouble, and in such a manner that the conductor's attention has not been attracted to them, this being the case on the run on which the accident occurred, it is safe to infer that the motorman is mistaken when he says the brakes would not work. Of course, there is always the possibility of the brake giving out on the stop just before the accident; but in the investigation of this class of accidents, the inquiry must extend further than the crew of the car; it must be carried to a thorough examination of the methods of operation, the physical conditions of the road, the kind of brakes used on the cars, and the equipment of cars, including sand boxes. In the investigation of the methods of operation of rail-

roads in reference to accidents, the statement can safely be made that in a large majority of them the primary cause of the accident can be traced to inefficient management of the road, and while the motorman may be the immediate cause of the accident, it in all probability would have been prevented had the management been more systematic.

There has been a large number of tail-end and head-on collisions. The larger portion of these have been caused by motormen running past switches where they were due to meet a car. Several have been caused by misunderstanding of train orders, transmitted over a telephone system; several by conflicting orders being given by different officers of the company; some by crews attempting to "steal" a switch; several by crews taking it for granted that a car which was due at a junction of two lines had passed that point; others by the failure of block signal systems; a few by cars getting beyond the control of the motorman on heavy grades and not stopping at a switch where they should have stopped; a number by facing-point switches on cross-overs on double tracks, and there have been two cases where motormen have seen cars approaching them on the same track, and have continued at full speed, with the intention of making the other car back up to the switch, the speed continued on both cars for the same purpose until it was impossible to stop either; two were caused by the running of special and work cars over a road without proper notice being given to the regular cars; one head-on collision was caused by an ordinary passenger car being used as a work car and not being placarded as such; a regular car met it on a switch where another car was due, supposing it was the regular car the crew ran out on to the main track, and the two regulars met in head-on collision. Among the causes of tail-end collisions may be mentioned the 500-foot distance rule in use on a large number of the suburban and interurban railroads; cars coming to a stop at points on the road where the view of an approaching car is limited; cars "running away" on grades and on wet and slippery tracks; regular cars running into work cars, standing upon the main track without protection; broken trolley wheels leaving a car standing on the track without lights; trains being run in sections without the rear end of the first section being properly protected, and a number of other causes.

The accidents at grade crossings of steam and electric railroads and at grade crossings of electric railroads, are invariably caused by violation of the running rules of the company, for I do not know of a crossing of steam and electric tracks in this state, where there is any considerable volume of traffic on the steam road, but what the company's rules require the electric car to come to a stop and the conductor to go ahead and flag his car over the crossing. But some collisions have been caused by the power giving out while the electric car was going over the steam tracks, or by the trolley leaving the wire while this was being done, in this manner stalling the electric car in front of the steam train or engine. At nearly every crossing of two electric tracks the cars on one of them are required by the rules to come to a full stop before proceeding over the crossing.

The causes of derailment of cars are so varied that it would be almost impossible in the limited space of this paper to enumerate them. The principal causes, however, are: Cars going around sharp curves at too high a rate of speed; the spreading of tracks on curves; the irregularity and poor alignment of curves and lack of proper elevation on them; where the grooved rail is used, the groove being filled with stone, sand or other substances; frogs and switches not being properly placed; open switches; poor alignment and surface of track; broken flanges on wheels; axles out of line; loose wheels; wheels not properly gaged, etc.

There have been several accidents resulting from bridge and trestle failures. These in most cases have been caused by leaving old structures in the road and increasing the weight of cars operated over them without increasing the strength of the structure. There have been two derailments on bridges, resulting in serious injury to passengers, brought about by the custom of planking highway and street bridges flush with the top of the rail, without proper guards to prevent a car from going off the rails and over the side of the bridge. This planking flush-with-the-top-of-the-rail is almost the universal custom and is a very dangerous one.

These are the most frequent accidents occurring on suburban and interurban railroads and the principal causes of them. The question now to be considered is how to prevent their occurrence.

The solution of this problem, to some minds, appears to be an easy one. Read any of the papers of the daily press after an accident has occurred, and the editor volunteers a ready solution of the question of preventing accidents on electric railroads. In some of these papers you will see that double tracking a road would prevent all accidents on it in the future; in others equipping the cars with John Smith's automatic brake would prevent accidents of all characters; in another, the adoption by the company of Bill Smith's block signal device would be a guarantee against accidents, and so on through a long list of suggestions, the writers being confident of their ability to judge of the merits of the different devices mentioned and their positive knowledge that the adoption of that device or plan would be the solution of the question under consideration. But you, gentlemen, who are more experienced and far more interested than the editors in preventing accidents, know that accidents on electric railroads have multiplied in variety and number with the advances made in electric railroading. It is not a case of a sick child where a dose of paregoric can be administered and the disease will disappear. The present conditions result largely from the tireless efforts of manufacturers and inventors of electrical machinery to increase the efficiency, power and speed of their apparatus, and from the failure of electric railroad managers to keep pace with them in track construction, safety devices and methods of operation. This condition has been a growth of years, and the remedy for it must be found in the free use of safety appliances, in more perfect and complete construction and equipment, and more careful and systematized methods of operation.

It is taken for granted that every member of this association realizes that the electric railroad business is face to face with grave problems; that the numerous serious accidents, not only in this state, but throughout the country, are injuring the standing of the electric railroad before the public, and that if they continue, the revenues must be impaired for the reason that people will lose confidence in electric railroads and will prefer to patronize steam roads. Up to this time the electric car has met with favor by the public, preference being given to it for suburban and interurban rides, even when a destination could be reached quicker by the steam roads. The comforts of the electric service, including fresh air, free from smoke and cinders, the unobstructed view which can be had from the open car, and especially the combined pleasures of a ride on them through a country district have caused the public to patronize them liberally; but these frequent accidents are creating alarm and distrust. The confidence of the public must be restored, or you will not only drive people from the electric cars, but you will drive capital from investment in electric railways. These statements are intended to apply only to roads other than the distinctively city roads in the state. The city railroads are operated in a manner which reflects credit upon the management of them as well as upon the electric railroad business generally.

This condition of safe operation does not exist on all of the suburban and interurban roads, and upon most of them the railroad commission have had to investigate serious accidents. Still, there are several of these roads which are operated under rules and regulations which compare favorably with steam railroad methods. On one of them there is a complete telegraph train dispatching system in use; on another, a tram dispatching system, in which the orders are transmitted by telegraph and telephone; on several others there are tram dispatching systems, the orders being transmitted by telephone only.

Of course, it is expected in a paper of this nature, after describing the character of accidents occurring on electric railroads, that suggestions should be made to prevent their occurrence, and this is the point where I realize my inability to fully meet the requirements of the situation. However, I will mention a few points in which my experience and observation have led me to believe that improvement could be made. As stated above, the investigation of accidents, in a large majority of the cases shows a defect in the organization of the operating force and in the methods of operation. A well organized operating force on an electric railroad can be compared to the motor, pinion and gear wheel of an electric car, the president being the motive force of the organization compared to the motor, the superintendent or general manager, through whom the president's policies are carried out, compared to the pinion, and the heads of the different departments, including motormen and conductors, to whom the superintendent issues his orders,

represented by the different cogs on the gear wheel. The whole forms an unbroken line in the case of the organization from the president down to the motormen, conductors and other employes, as in the combination the pinion and gear transmit the power of the motor to the traction wheel. In the latter case each member must be in perfect working order, each one must be fully equipped and efficient in itself; any defect in one shows a defect in the whole. This is also true of the organization. If the president lacks in ability, sound judgment and common sense, he will interfere with the operation of the organization, and above all he must not reach over beyond the pinion, the superintendent, in carrying out his ideas and policies as illustrated in the case of the motor, pinion and gear; if the leads of the motor extend beyond the pinion and come in contact with the gear wheel, a damage is caused which results in the breaking down of the whole combination. It is not meant by this statement that the president must not come in contact with the employes of the road, but that he must not interfere with the operation of the road when it is in operation except through the proper channel, the general manager or superintendent. When the machinery is at rest after the day's work is done, or when employes are off duty, the more he comes in contact with them, the better it is for everyone interested in the welfare of the road; but in the regular routine of business the president's duties consist in outlining policies and plans for the benefit of the road; the details of the execution of these plans and policies devolve upon the superintendent. The superintendent of a railroad should be a man of ample experience and capacity, qualified to take charge of the operation of the road in all its branches, carrying out the views and ideas of the president, but to all intents and purposes he should be the czar of everything pertaining to the direct operation of the system. The heads of the different departments, motormen and conductors, as represented by the gear of the combination, must mesh into the different apertures between the cogs of the pinion, and if one of the cogs of the gear becomes rusted and will not readily absorb the lubrication, which in the case of organization is represented by the book of rules and special instructions, it weakens the whole structure, and if not removed will cause a break-down. When a cog becomes worn out it must be removed from the system. In the case of the organization, when a motorman becomes too old for service, he must be removed from that position, and usually there are places on an electric road into which an old, faithful motorman can be put, where he will not be a detriment to the service. If a motorman becomes too large for his position, as in the case of the cog, he will not mesh into the aperture assigned to him, but interferes with the smooth running, and must also be removed. This illustration might be carried further, showing that perfect organization is an essential thing to the welfare of an electric railroad. But the illustration clearly sets forth one point which to my mind is essential to the safe operation of any road, that is: the duties of the superintendent or general manager should be confined to carrying out the instructions received from the president in reference to the operation—and nothing but the operation—of the railroad. He should not be burdened with any additional duties, such as the supervision of construction of extensions, nor the negotiation of extensions, nor the negotiation of stock or bonds; his whole duty should be trying to earn dividends, not to negotiate the securities of the road.

From personal observation it is known that every one of the managers of railroads in this state is interested in reducing accidents to a minimum. The Board of Railroad Commissioners is doing all in its power to bring about this condition. Their expert has inspected nearly every foot of track in the state of New York; also the equipment of cars; examined into the methods of operation, and the board has investigated nearly every serious accident that has occurred in the past five years, and on all of these inspections and investigations recommendations have been made with a view of preventing accidents. These recommendations have in most cases been received by the companies in a proper spirit. A large number of them have been complied with, but there are some instances where the managers have thought that, while the recommendation if carried out would be a benefit to the road, the possibility of accident involved was so remote that they have delayed compliance with the recommendation from time to time in order to keep down the operating expenses for this year and intending to comply next year or in the near future. A large number of these recommenda-

tions apply to the protection of crossings of steam and electric railroads at grade. It has often been said to me when a suggestion for protection at a crossing of this character is made: "We have operated that crossing for ten years and never had an accident on it. Our men are all instructed to flag their cars over it, and it is impossible for an accident to occur at that point. These are all old men, all live here in the town, and most of them own their homes; they are a good steady, industrious lot of men, and I know each of them personally." Now that manager was sincere and honest in the statement. He could not be led to believe that there was any danger at that crossing for the reasons which he stated. The fact is, no matter what class of motormen are employed or what wages paid, an accident is likely to occur at a crossing of that kind unless it is so protected that the car crew is obliged to come to a stop, the conductor going ahead on to the steam track before the motorman can proceed over the crossing. As an illustration of what motormen and conductors may do: On an inspection tour I visited a certain town in this state, arriving there about noon. I called up the road superintendent by telephone, told him my business and arranged to call on him at his office after lunch. At that time I boarded a car, and on the way to his office we met another car on a switch. The conductor of that car entered the one in which I was the only passenger, and looking at me and seeing no other person in the car, called out to the crew of the car: "Boys, be sure and flag the crossing, as there is a railroad commissioner in town this afternoon." From that remark I drew two conclusions; one, that it was not customary to flag the crossing; the other, that I did not look like a railroad commissioner. No matter how long motormen and conductors have been in the employ of the company, or how reliable they may be, accidents will occur at crossings which are not properly protected. The commission's efforts to prevent accidents on electric railroads cannot be effective without the willing and ready co-operation of every person interested in the operation of these roads, and while a large majority of the managers of roads are in hearty co-operation with them we find that there is not a proper realization of the danger connected with the operation on the part of some of the officials.

In stating the number of accidents which have occurred on electric roads in the past five years, a partial classification of them was made. In suggesting means of preventing their occurrences it is not necessary to consider each class of accidents by itself. The remedy which will prevent the occurrence of a head-on collision would be a remedy for almost all of the other kinds of accidents; this remedy is, a proper organization of the operating force of the road, proper discipline of employes, proper track construction, proper equipment of cars and proper methods of operation, and this statement is applicable to all roads, no matter what the extent of them. For proper organization and discipline of the operating force, so as to prevent head-on collisions, only competent and properly qualified men should be motormen and conductors. It is not meant by this statement that none but experienced motormen and conductors should be employed, but it is intended that a better class of men would be secured if more care was taken in investigating their past records and physical condition before employment. In order to do this, proper printed blanks, furnished by the company, should be filled out by the applicant, these giving all of the necessary information in regard to their previous employment, reasons for leaving it, references as to character, etc., and in addition a thorough physical examination, especially as to eyesight and hearing, by a doctor employed for that purpose by the company; more care should be exercised, and a more thorough system of "breaking in" or instructing motormen than is the custom at present on most roads. It is found that the general custom on a majority of the interurban roads is to take a man, no matter what his previous occupation was, put him on a car with an old motorman and let him run ten days, then make one or two trips with the superintendent, inspector or master mechanic, after which he is reported qualified and is given charge of the front end of a car. This easy method of making motormen was all right in the early days of electric railroading, with the 16-foot, 6-ton car, but is all wrong with the heavy equipment of interurban roads of the present time. It is inviting accident to place such a man in charge of an 18 or 20 ton car, loaded with fifty or sixty passengers, descending 5 per cent grades with sharp curves, such as exist on almost all of this class of railroads. The motormen should not be compelled to serve the apprenticeship which is

required of the steam railroad engineer, but should receive a training by which he would have some general knowledge of the construction and operation of the apparatus under his control.

Another matter of importance which devolves upon the management of a railroad is the matter of discipline. The first step in this direction is the compiling and furnishing to employes of a complete set of rules. It is the usual custom to require motormen and conductors to learn the rules before they are given permanent employment, but very few companies require these men to remember them. In investigations of accidents, the question is asked a motorman: "Are you familiar with the rules contained in the company's book of rules?" The usual answer is: "I knew them when I went to work for the company, but don't know as I could repeat them now." The discipline and efficiency of employes in the United States mail service is as near perfection as possible. In that service employes are required to pass an examination at stated intervals, based on their knowledge of the business and the rules governing it. Motormen and conductors should be obliged to do likewise. These rules should be made as explicit and clear as possible, covering every emergency which can arise, leaving as little to the judgment of the motorman or conductor as possible. The importance of proper rules cannot be overestimated in behalf of safe operation of a railroad. As an illustration of this: An accident recently occurred on one of the roads in this state where fourteen persons were killed and sixty injured. This accident might have been prevented had the conductor of the car used proper judgment and set the rear brake after the front one had become disabled by the breaking of a brake rod. When asked why he did not do this, he answered, "Because I did not receive four bells from the motorman," and he considered it would be a violation of the rules for him to do it without that signal even in an emergency. The rules, among other things, should especially provide for the safety of trains when operated in more than one section. Usually the book of rules prescribes a 500 or 1,000-foot spacing distance. Experience has shown that this rule alone is not sufficient to insure safety of operation where one car is following another, as the construction of country roads is such that in many cases the view is limited to less than this distance. There should be a rule compelling the conductor of the head car to protect the rear end by means of fuseses or in some other way while in motion and by a flag or lantern while standing still.

Next in importance to rules and discipline is the question of train dispatching, block signal or telephone system. The ideal method of operation on any suburban or interurban railroad is the running of cars under a telegraphic train dispatching system. On most of the roads in this state this is impracticable, and the telephone is in a number of cases substituted for the telegraph, the motormen or conductors acting as operators. A reliable block signal system, the cost of which would place it within reach of electric railroads, is something which is much needed, and it would be an important factor in reducing accidents. There is no such system in extensive use on any of the railroads in this state. Improvements have been made within a short time on several of the roads in the method of handling train orders by telephone. Formerly either the motorman or conductor would call up a train dispatcher, receive from him an order to run to a certain point, he would repeat this back, and receive "O. K." from the dispatcher. Several serious accidents occurred through a misunderstanding of orders, and this system has been changed on some of these roads. Now a motorman receives the order from the dispatcher and writes the body of the order on a printed blank; this is manifolded, a copy given to the conductor, who then repeats it back to the train dispatcher, giving the name of the motorman and conductor, he receiving "complete" and time from the dispatcher. Another important matter in connection with the safe operation of an electric road is a proper time table. The management of every road, no matter how many cars are operated on it, should prepare and have printed a proper time table, showing the time of each car at the terminus and at every turnout switch or station on the line of the road, the meeting points shown in prominent type, with rules governing the movement of cars, based on steam railroad time tables, shown on it. This matter of telephone equipment and time tables is one to which the managers of some of the smaller roads object. In replying to a suggestion of this kind, some have said: "I consider that unnecessary, as in our regular operation we only run two cars." This is not a valid excuse for not equipping a road with a telephone system and running

cars under the authority of a time table, for it takes only two cars to cause a collision, and the results of a collision on a road of this character may be as serious as on a road where a larger number of cars are operated. This is illustrated in a collision which recently occurred on a road four miles in length, where in regular service only three cars were operated. This collision resulted in the death of fourteen persons and the injury of sixty.

The question of derailment of cars is one on which it is not necessary to occupy a great deal of the time of the convention. Derailments are caused by defects in track or equipment, or by carelessness in the operation of cars. Defects in track are so apparent that the manager of a road is aware of their existence and knows the poor spots in his road better than anyone else. These are often not repaired, not because he does not know that they add to the possibility of derailment, but in a number of cases on account of the financial condition of the company. It has been stated to the representative of the railroad commission after an inspection of a railroad:

"I know that that, derailing switch should be put in; I know that that track should be raised up; I know that this section should be ballasted, and I know that that curve is in bad condition, and I have asked our folks for the money to do this work. I am glad you have made the recommendation for it, as they think that we can get along without it for another year." This is poor policy, as the putting in of a derail switch at the foot of a grade might prevent a runaway car from going around the curve below it and tipping over. The raising and ballasting of the track, the alignment of a curve; any one of these might prevent a derailment which would place the road in the hands of a receiver.

On the question of failure of bridges and trestles, the board of railroad commissioners have made an examination of nearly every bridge and trestle in the state over which electric cars pass, and in case of apparent weakness, have made recommendations for the strengthening of the structure, or its replacement by a modern one. In cases where there was any question as to the strength of the structure, it has recommended that it be examined by a bridge expert. These recommendations have been generally complied with.

Another important matter relating to accidents on electric railroads is the brake equipment of cars. This matter has been so thoroughly discussed and everyone is so familiar with the subject that it is not necessary to do more than to say that, on country roads, and by country roads I mean the suburban and interurban roads in this state, it is almost criminal carelessness on the part of the management to operate the class of cars which are usually operated on these roads with only a single chain hand-brake on them. There are very few of these roads on which there are no heavy grades; most of them have grades running from two to ten per cent, and in some cases more than that, and there are sharp curves on nearly all of them, these frequently occurring at the foot of the grades. Cars on these roads should be equipped with the best braking appliance obtainable in addition to the ordinary hand-brake, and in cases of extreme heavy grades and sharp curves, they should be equipped with additional emergency brakes, and all cars both open and closed should be equipped with a sand box on each end.

Accidents are less likely to occur on a double-track road than on a single-track one. The number of accidents would be reduced if all suburban and interurban roads in this state were double track. The financial condition of the majority of these roads will not permit the construction of a second track, but where physical and financial conditions are such that this can be accomplished it should be done. All extensions of old roads and the construction of new ones over which cars are to be operated at high speeds should, as far as possible, be on private right of way. The reduction in the accident account will more than pay the interest on the investment required for this purpose.

In addition to the above suggestion in reference to improvements in method of operation, discipline of employes and equipment of track and cars, to reduce the number of accidents occurring it is necessary that managers of railroads make a study of the business in which they are engaged. There are some roads in this state on which the railroad commission is seldom or ever called upon to investigate an accident. When we visit the manager's office of these roads we invariably find a business office, everything indicating that the man in charge is attending to his business and is thoroughly

posted in it. One of the indications of this is that, somewhere in the office, you will see on file one or more of the different periodicals devoted to electric railway interests. On the other hand, the manager's office of railways on which a large portion of the time of the Railroad Commission is spent in the investigation of accidents is devoid of anything in the shape of literature pertaining to electric railway operation. The successful managers of electric railroads have been found in attendance at the street railway conventions for a number of years past; the managers of the roads on which most of the accidents are occurring are rarely or ever met at these conventions unless the convention happens to be held in a city near which they are located. This is justification for the advice to managers to be in touch with the business in which they are engaged, by keeping posted through the electric railway publications and by attending the conventions of this association and entering into the discussion of the different subjects presented. And on this line, this association owes a duty to the public, which as the representative of the railroad interests of the state of New York it should fulfill.

First—The Railroad Commission recommends to every railroad company the adoption of a book of rules based on the standard rules. When the companies ask the commission for a copy of the standard rules they are unable to furnish them, as there are no official standard rules. There should be a standard set of rules adopted by this convention immediately.

Second—In nearly every head-on or rear-end collision which occurs, one of the cars telescopes the other. This is caused by difference in heights of buffer and difference in construction of cars. This association should adopt a standard set of specifications for the construction of the various sizes of cars, all to be of uniform height of buffer and uniform construction for each size of car.

The recommendation has been made to railroad managers to keep posted on the current literature affecting their interests. One word to the editors of journals devoted to the interests of electric railroads; they have a duty to perform as well as others interested in the safe operation of roads and to some extent are responsible for the conditions which exist today that make possible the number of serious accidents occurring. While they have been the means of educating a large number of the managers of our railroads, and are today keeping them posted on the improvements in appliances and methods of operation which are being introduced in different sections not only of this, but of the old countries, once in awhile they allow an article to creep in which adds to the fancied security of electric railroad managers whose roads are operated without sufficient safety devices or proper precautions in methods. As an illustration of this, a short time ago there appeared in one of the most influential electric railroad publications of the day, an article describing a train dispatching system for interurban work. This was a telephone system. The article set out by discarding the telegraph system as being too cumbersome to meet the requirements of an electric road, and, continuing, the writer said: "It has been urged against the use of the telephone in train dispatching that there is more chance for error in receipt of messages than by telegraph. It is hard to see that this objection has much weight. If desired, messages can be written down and repeated back for approval to guard against errors as in telegraph messages. However, these points are hardly worth arguing, because the telephone has now become generally used and recognized as the proper instrument for dispatching on electric interurban roads. This article, therefore, resolves itself into a review of the methods of using the telephone in train dispatching." Then follows a description of the system, occupying three columns of the paper, all of which demonstrate the merit of the system, which is summed up in the fact that a train order can be handled in ten seconds. Articles of this kind appearing in a publication of the standing of the one in which it was printed are likely to result in the adoption, by electric railroad managers, of a system of train dispatching such as is described. This would be a step in increasing, rather than diminishing, the number of accidents. The ideal method of train dispatching for electric railroads is that which after years of experience has been adopted by the steam railroads of this country. The expense of maintenance of operators at different points along the road prevents its general adoption by electric railroads. The closer this principle of train dispatching is followed the smaller the number of accidents which will be caused by errors in handling train orders, and

any method of handling such orders where only ten seconds is consumed in transmission is a dangerous one, and should not be employed by any railroad in this state.

The disagreeable portion of this paper has been written. Let us now turn with satisfaction and pride to the operation of the city roads of this state. These are managed and operated in a manner to challenge the operation of steam railroads. During the year 1907 there were 1,162,139,614 passengers carried on electric railroads in this state, and 81,000,000 on steam roads. The record of fatalities and injuries shows that passengers are relatively safer on these electric roads than on the steam railroads. The everyday transactions of the Metropolitan Street Railway Co., carrying the immense number of people which it daily does, with the small number killed and injured, is one illustration of the safety of operation of electric railroads. The comfort, convenience and safety with which the large crowds at the Pan-American Exposition were handled by the Buffalo Traction Co. last year is another illustration of the careful operation of an electric railroad. That the managements of city roads realize the importance of reducing accidents to a minimum is shown in the case of the Brooklyn Heights railroad. For some years past a large portion of the time of the railroad commission was occupied in investigating accidents on this system. At present the large crowds going to and from the summer re-

### ELECTRIC FREIGHT LOCOMOTIVE.

An interesting electric locomotive has recently been built for the Inter Urban Railway Co., of Des Moines, Ia., by the Des Moines Street Railway Co., after the design of Mr. James Weleh, its master mechanic. We are indebted to Mr. H. H. Polk, president of the Inter-Urban Railway Co., for the accompanying illustration.

This locomotive is used for hauling standard cars to and from points on the Inter-Urban company's Colfax line running from Des Moines to Colfax, Ia., a distance of 25 miles. The line passes through a large coal field and a rich farming district. The dimensions of the locomotive are as follows: Height from rail to top of body, 12 ft. 10 in., height over trolley stand 13 ft. 5 in., length over end sills 26 ft., extreme width 8 ft. 3 in. The frame is constructed entirely of steel, the sills consisting of two 8-in., 25-lb. channels. The bolsters are made of two 10 in., 35-lb. I beams bolted together with pieces of hard pine between them well fitted to the beams. The ends of the bolster are planed to fit the channels and are held in place by strong angle plates of  $\frac{1}{2}$  in. x 6 in. steel. All the corners of the frame are fastened by similar angle plates. The posts are all 6 x 6 in. oak fitted between the channels and the space between the posts is filled with hard pine, to which the floor is nailed. This filling also protects the posts from any

ELECTRIC LOCOMOTIVE FOR INTER-URBAN CO., DES MOINES, IA.

sorts on Long Island are handled in comparative safety and very few persons are killed or injured, as compared with the number riding. There are summer resorts located near all of the smaller cities in the state, such as Rochester, Syracuse, Utica, Albany, Binghamton, Elmira, Jamestown and Auburn, to and from which there is unusually heavy traffic during the summer season. These crowds are carried and managed in such a manner that it is very seldom that a person is killed through any defect in the method of operation or the equipment on these railroads.

In conclusion, I may express the hope that, through the combined efforts of all interested, next year's convention will find your lines throughout this state equipped and operated in such a manner that the confidence of the public will be restored in the safest and most comfortable of all methods of transportation, the electric railroad.

The Seattle Electric Co., owing to the growth of the city and the increasing patronage of its cars, has recently ordered 25 new cars, which will be added to its equipment at an early date.

The Sunday traffic on the Amhurst & Sunderland Street Ry. has recently increased to such an extent that the company has been obliged to run trains of two cars from ten o'clock in the morning throughout the remainder of the day.

sheering tendency to which they may be liable. The body is mounted on Taylor trucks and the total weight of the locomotive on the rails is 44,550 lb. At each end of the locomotive there are two boxes each capable of holding one cubic yard of sand and between the two sand boxes are other boxes for carrying jacks, camel backs and blocks. The locomotive is equipped with four 50-h. p. General Electric motors, Westinghouse air brakes and Janney standard couplers. It also contains a device for sanding the track on curves which consists of a hopper fastened on the truck frame. The sand is dropped into this hopper by means of which it is distributed on the shortest curves in the city; the latter device was also designed by Mr. Weleh.

### ELECTRICITY ON THE EVANSVILLE & TERRE HAUTE.

It is reported that the Evansville & Terre Haute Railroad will adopt electric car service on its line between Indianapolis and Princeton in order to meet the competition that is expected with the completion of the Evansville & Princeton Traction Co., which is now under course of construction. The new trolley road almost parallels the Evansville & Terre Haute R. R., and passes through one of the richest stretches of country in Indiana, and is the first electric line to be built in that part of the state.

## THE GROWTH OF A WELL-KNOWN SUPPLY HOUSE.

From a single room to an eight-story building in less than a dozen years is the story, in a few words, of the growth in the street railway supply business of the Mayer & Englund Co., of Philadelphia. In 1893 Mr. C. J. Mayer started in business as commission agent for several makers of street railway supplies. On Dec. 1, 1895, Mr. A. H. Englund was taken into the concern and the firm name became Mayer & Englund. At that time the business was all transacted in one office in the Betz building, Philadelphia, and the firm employed one stenographer who was also bookkeeper, and one clerk who looked after the orders and shipments. Mr. Mayer and Mr. Englund constituted the sole selling force. Jan. 1, 1897, the business was moved to the building at 10 South 10th St., and occupied the first floor and basement which was also the storeroom. March 1, 1899, the business was incorporated as The Mayer & Englund Co., and the second floor of the same building was engaged in order to meet the demands for more room. In 1900 the demand for greater space was still growing and in that year the company engaged the

the W. T. C. Macallen Co., of Boston. To this line have been added from time to time various specialties and street railway material, and at the present time the company is furnishing a complete line of electrical and mechanical supplies required for street railway construction, maintenance and operation, as well as supplies required by large industrial plants, as steel plants, foundries, etc.

One of the most important additions to the firm's assets during the past two or three years has been the acquisition of a large number of patents, covering "Protected" rail bonds, and tools and machines for installing bonds in railway tracks. Many of these patents were handled by the Protected Rail Bond Co., which is controlled by Mr. C. J. Mayer, and for which the Mayer & Englund Co. acts as general selling agent. The growth of the company's bond business has been phenomenal. "Protected" bonds have been installed on 515 electric railways or a total of 10,000 miles of track, which is more than one-half of all the street railway mileage in the United States.

The overhead material handled by the firm is known as one of the best in the markets, on account of the heavy, substantial nature of all the designs, the company considering this a very essential requirement in modern overhead work. Nearly all the designs are

Office of C. J. Mayer.  
Storeroom.

General Office.

Office of A. H. Englund.  
Basement Storeroom.

building at 10 South 10th St., including five floors and basement. The building had gradually become almost a landmark to many whose names are prominently identified with the street railway industry, including street railway men as well as supply representatives.

In the spring of the present year, the company once more found itself cramped for room, by reason of the demand for its specialties, and in July, 1902, it moved into the new modern eight story fire-proof building occupying Nos. 1020, 1022, 1024 Filbert St., in the business heart of Philadelphia. Here the company has fitted up a suite of offices and storeroom as fine as any to be found in this country. The first, second and seventh floors, together with the entire basement, have been reserved to accommodate the several departments, i. e., the storeroom for heavy goods in the basement; the general shipping and storeroom on the first floor; the accounting, executive and general offices on the second floor; and an overflow storeroom on the seventh floor. Each of these floors is 60 ft. front by 80 ft. deep, giving a total of nearly 20,000 sq. ft. of floor space or nearly three times the room occupied by the company in the old building on South 10th St.

At first the line of goods handled by Mayer & Englund consisted almost entirely of the gear, and pinion and trolley made by the R. D. Nuttall Co.; the fare registers and fixture made by the International Register Co.; a complete line of overhead insulation by

original with the company and differ in many respects from other lines on the market.

The company carries a large stock of all its specialties and is thereby enabled to ship goods at short notice. The new headquarters are conveniently situated near all of the depots, and the shipping facilities are of the best.

The company's annual catalog is one of the largest and finest issued by any company in any trade. It contains 580 pages and over 500 separate and distinct articles are listed. The work contains a complete code formulated by the company for the purpose of saving its customers unnecessary expense when ordering goods by cable or telegram.

As before mentioned the new building on Filbert St. is modern and up-to-date in every respect, and the company's methods of doing business are also strictly modern and up-to-date. Its general and other office departments are provided with the latest labor-saving office devices and appliances.

All the company's correspondence is kept by the vertical file and index system, under which each particular subject is given an index number, and all papers relating to the same subject are filed under the same number. All letters are written in carbon, and the original is filed with the answer. The clerical department uses the loose leaf system in all bookkeeping with the exception of the general ledger. All orders, invoices, bills, etc., are written on book

typewriters. A system of columnated bookkeeping is used in which separate accounts are kept with each general line of specialties for the purpose of ascertaining the relative profit on different lines at the end of the year. The entire cost of conducting the business is charged pro rata to each of the different lines according to the volume of gross sales.

The company's employes now number 24, including 9 employes in the sales department, 11 in the selling, accounting, order and general office department, and 12 in the shipping and storeroom. The company maintains branch offices in charge of the following agents:

At 35 Liberty St., New York City, in charge of W. A. Cockey; Park Building, Pittsburg, in charge of George W. Provost; 135 Adams St., Chicago, in charge of J. M. Gallagher; Equitable Building, Atlanta, Ga., in charge of H. M. Loftin, who also maintains a branch office in the Heinen Building, New Orleans, La., which is under his direct care. The company is also planning to establish an office in Cleveland, O. No regular foreign agencies have been established, but the company has enjoyed an enormous foreign business, it being no unusual occurrence to ship goods in one day to all four points of the compass.

The following is a list of the principal manufacturers represented by The Mayer & England Co.; R. D. Nuttall Co., Pittsburg, Pa.; The International Register Co., Chicago, Ill.; The Protected Rail Bond Co., Philadelphia; W. T. C. Macallen Co., Boston; Speer Carbon Co., St. Mary's; American Electric Heating Corporation, Boston; Garton-Daniels Co., Keokuk, Ia.; Strieby & Foote Co., Newark; Sterling Varnish Co., Pittsburg; Pittsburg Insulating Co., Pittsburg; Universal Safety Tread Co., Providence, R. I.; Trolley Vestibule Shade Co., Bridgeport, Conn.; William Hall & Co., Boston, Mass.

### AMERICAN STEEL & WIRE CO. IN THE SPRING BUSINESS.

The American Steel & Wire Co. has just issued a new catalog on springs in which it calls attention to many new features. As makers of all grades of steel, from the raw material, this company is in an excellent position to meet all requirements and to insure satisfactory results. The company has enlarged the equipment of its factories in Worcester, Mass., Waukegan, Ill., and San Francisco, Cal., and can supply its patrons promptly. Its products in the line of springs covers the entire range of extension, compression, torsion and flat springs. In addition to the descriptions and illustrations of all kinds of springs the catalog contains a number of useful wire tables with comparisons of different gages, etc., and it also includes a list of products of the American Steel & Wire Co.

### THE STERLING NO. 5 REGISTER.

The Sterling-Meaker Co. is receiving many flattering reports from its new Sterling No. 5 register; several master mechanics have expressed themselves with considerable freedom, and one says that "this register will last as long as the car." Such strong approval was, of course, not without foundation. Fare registers get a good deal of hard usage, and if so complex a machine will keep a true record for a reasonable period, no one can complain of it, even if it has not life everlasting. Increased durability is, however, equivalent to a lower first cost, and the Sterling No. 5 machines have been highly commended for this feature. The register involves a number of new ideas in construction that would appear to make a falsification of the record utterly impossible. The back, or ringing device, also contains some new features of importance. The company is much gratified to learn from the companies using the machine that it has been doing perfect work for all.

### ONTARIO TRACTION CO'S. EXTENSION.

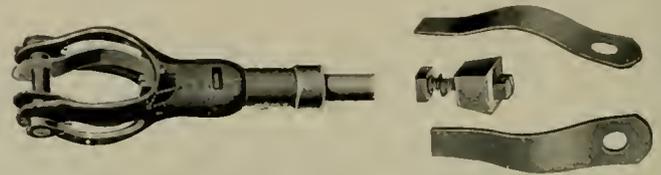

The Ontario (N. Y.) Light & Traction Co. is projecting an extension of its lines east from Canandaigua to Geneva and west to Rochester. Certificates of extension have been filed in Ontario County and preparation for the surveys are being made. The eastern extension will run through the towns of Hopewell and Seneca and the western extension through Victor and Fairport to

Rochester. The new line will parallel both the Auburn branch of the New York Central Ry. and the line of the Geneva and Western Rapid Ry.

### IMPROVED TROLLEY HARP.

Mr. A. Johnson, electrician for the Quincy (Ill.) Horse Railway & Carrying Co., has recently designed an improvement in trolley harps with the idea of providing a simple structure in which the contact springs can be conveniently replaced when worn out and which at the same time will hold sufficiently rigid to insure good electrical contact. The device has been named the "Reliable."

The harp has a tapering recess in the base for holding the contact springs, and for clamping them a tapered plug is used. In forcing the plug down, to clamp the contact springs firmly a 5-16-in. bolt is provided, the bolt passing down through the plug and an opening in the body of the harp where a nut is located. The head of the bolt is slotted for the reception of a screw driver by means of which a few turns will either tighten or loosen the plug as may

THE "RELIABLE" TROLLEY HARP.

be desired. For forcing the plug back to release the contacts a small coil spring is placed around the bolt between the plug and body of the harp.

The contact springs can be renewed in a very few minutes and the change does not necessitate the removal of the pole from the car, an important saving in time and labor.

As is well known the contact springs are the life of the bushings, and the bushings of the pins, hence with a reliable harp a good bushing with proper contact springs will outwear the wheel. The contact springs are easily made and have but one hole.

The body of the harp is made of malleable iron with a 3/4-in. cold rolled shaft to connect with the pole. The wheel pins are case hardened and the contact springs made of heavy copper bronze. The completed harp is made strong and in a first-class manner, and will receive the standard make of wheels. It has been in use on the Quincy street railway for a number of months and has proved entirely satisfactory in all particulars, especially for heavy travel and large motors.

### LOUISVILLE-CINCINNATI INTERURBAN.

A new interurban road is being promoted in Kentucky which will run from Sanfordtown through Florence, Carrollton, Milton and Louisville. The line will enter Covington via Latonia, and cross the Chesapeake & Ohio bridge to Cincinnati. The estimated cost is \$500,000, and Mr. C. T. Tennis, of the Tennis Construction Co., in company with other promoters, recently made a trip over the proposed route. It is believed that some difficulty will be experienced by the new road in entering Louisville for the reason that the new road will be built to standard gage, while the roads in and about Louisville are broad gage.

### INDIANAPOLIS, LEBANON & FRANKFORT ROAD.

Townsend, Reed & Co., 1208 Stephenson Building, Indianapolis, Ind., advise us that they have closed a contract with the General Electric Co. for three 800-kw. generators, four sub-station equipments and 24 motor car equipments which are intended for the Indianapolis, Lebanon & Frankfort Traction Co. Three 1,500-h. p. cross-compound engines for the main station have been ordered of the Hamilton-Corliss Engine Works, Hamilton, O., and the contract for 10,000 tons of 70-lb. T rails has been let to the Carnegie Steel Co. The grading between Lebanon and Indianapolis is approaching completion and rail laying commenced last week.

## PENNSYLVANIA STREET RAILWAY ASSOCIATION ANNUAL CONVENTION.

The tenth annual convention of the Pennsylvania Street Railway Association was held at the Country Club, York, Pa., September 10th, and was one of the most interesting in the history of the association.

The success of the meeting was largely due to Capt. W. H. Lanus, president of the York County Traction Co., who lent every effort to make the convention a memorable one.

The convention was called to order by Captain Lanus, treasurer of the association, who announced that John A. Rigg, of Reading, the president, was unable to attend, and that Henry C. Moore, of the United Traction Company, of Trenton, N. J., would act as chairman of the convention. Upon taking the chair Mr. Moore introduced Mayor M. B. Gibson, of York, who welcomed the delegates to the city. The address of Mayor Gibson was responded to by Mr. Moore, after which a call of the roll was taken, showing the following companies represented:

Harrisburg Traction Co., B. F. Meyers, F. B. Musser; Lebanon Valley Street Railway Co., C. H. Smith; Conestoga Traction Co., O. M. Hoffman, J. H. Cramer, Charles W. Witmer, Frank S. Given; Schuylkill Valley Traction Co., George Hoeger; United Traction Co. (Reading), Henry C. Moore, Samuel A. Rigg, S. S. Hoff, Charles S. Banghart; Wilkesbarre & Wyoming Valley Traction Co., John Clifford; Williamsport Passenger Street Railway Co., C. T. Herrick, S. W. Rhen; York Street Railway Co., W. H. Lanus, Grier Hersh, George S. Schmidt, Charles H. Mayer, J. H. Mellinger; Chester Traction Co., John MacFayden; Philadelphia & Delaware Electric Street Railway Co., A. G. Jack; Holmesburg, Tacony & Frankford Electric Railway Co., H. Glazier; Wilmington City Electric Co., C. E. Vantrump; Trenton Street Railway Co., P. E. Hurley; Continuous Rail Joint Co. of America, Mr. Barr; Heil Railjoint Welding Co., C. J. Harrington; J. G. Brill Co., W. H. Huehlings, J. Elwood Brill; General Electric Co., R. E. Moore; John A. Roebling's Sons Co., Charles Cushing, Foster Ivins; Lobdell Car Wheel Co., F. A. Lex; Westinghouse Electric & Manufacturing Co., T. Cooper, C. A. Bragg; Street Railway Journal, W. K. Beard; Lehigh Car Wheel & Axle Co., B. F. Swartz; Columbia Machine Works, W. R. Kerschner; C. J. Harrington, C. J. Harrington; H. C. Roberts Electric Supply Co., C. M. Maxwell, John Mustard; Western Electric Co., Fred C. Jeeger; The Electric Storage Battery Co., Edward L. Reynolds; Street Railway Review, E. H. Bowen; The Mayer & Englund Co., J. F. McCarthy, W. A. Armstrong; Sawyer-Mann Electric Co., Geo. W. Simpson.

Following the roll call a committee on nomination of officers was appointed, after which papers were read on "The Most Economical Management of the Repair Shop," by C. S. Banghart, and "Track Construction of Suburban and Interurban Railways," by S. S. Hoff.

Captain W. H. Lanus, treasurer of the association, made his report, which showed a balance in the treasury of \$1,873.93. The nominating committee then presented its report which was ratified by the convention. The officers for the ensuing year are as follows: President, E. H. Davis, general manager of the Williamsport Traction Co., Williamsport; first vice-president, Edward C. Bailey, Harrisburg Traction Co., Harrisburg; second vice-president, W. W. Grieb, Conestoga Traction Co., Lancaster; secretary, Charles H. Smith, Lebanon Valley Street Railway Co., Lebanon; treasurer, W. H. Lanus, York County Traction Co., York; executive committee, B. F. Myers, Harrisburg; John A. Rigg, Reading; W. H. Lanus, York; E. H. Davis, Williamsport; C. H. Smith, Lebanon.

After the adjournment of the convention the members were taken for a ride over the York County Traction lines. A visit was made to the Lafayette Club and on the next morning a trip to Gettysburg was made, where the management of the Gettysburg Street Railway Co. extended the use of its cars to the visitors. At the Lafayette Club one of York's popular orchestras furnished the music for the occasion and the Hon. W. F. Bay Stewart gave an interesting address on the York Haven Water & Power Co., which is now constructing the largest electric plant on the Susquehanna River.

August 23d a new street railway line, running from St. Louis, a northern suburb of Montreal, Canada, to the latter city, was opened for traffic.

## THE MOST ECONOMICAL MANAGEMENT OF THE REPAIR SHOP.\*

BY CHARLES S. BANGHART, SUPERINTENDENT OF REPAIR SHOP UNITED TRACTION CO., READING, PA.

The repair work of an electric road operating twelve or fifteen cars, is, generally speaking, as varied in character as that of a much larger road. But, since it would be impossible for small roads to maintain a repair equipment equal to that of a larger road, much of their repair work must be done outside. Therefore, I will speak of the large road, one which operates from 75 to several hundred cars.

In the list of machinery and tools which I have prepared, I have aimed to give those which are most generally useful in a repair shop. Many small conveniences for the quick and easy handling of work will suggest themselves and can be added to the equipment. The machine shop, with its auxiliaries, the blacksmith shop, truck shop and armature and coil room, naturally take first place in repair work.

The value of a convenient arrangement of these departments and the proper location of work benches and machinery to give ample working space cannot be overestimated. In a repair shop you never know "what a day may bring forth." A good rule to observe in this connection is to take as much room as you think you may need and double it.

A lathe equipment, consisting of one 24-inch, one 20-inch and one 10-inch speed lathe, will meet ordinary requirements for that class of work. The large lathe should be provided with crane fitted with chain blocks, for the safe handling of heavy work. One large drill press, 26 inch, and one speed drill press will answer for that class of work. The other machinery necessary may be listed about as follows:

- A good milling machine.
- A shaper.
- Hydraulic wheel press.
- Vertical wheel boring machine.
- Power shearing machine.
- Power hack saw.
- Power thread cutter (right and left.)

The grinding work can be done with an emery wheel and ordinary grind stone. There should also be a set of buffing wheels for finishing car and electric fittings and a good habbiting outfit. The latter is essential.

A good arrangement regarding tools is to have a special tool room in charge of a competent man, and a check system for the purpose of holding workmen responsible for tools drawn.

In the armature room, besides the necessary work benches and armature stands, a binding machine, field winding machine and bake oven, are required. At this point I would state that it is an unnecessary precaution to bake armatures after rewinding, as in motors of modern type the cells are wound and painted with insulating compound and then dried before being inserted in the core. But the oven is essential for baking armature and field coils.

An overhead trolley with chain blocks is necessary for the proper handling of armatures. Also a full outfit for testing work; such as instruments for testing open circuits and for short circuited coils on completed armatures. Armatures when completed should be given an insulation brake down test of not more than 2,000 or less than 1,500 volts, alternating current. All armatures should, after being completed, be given the generator test. The system is very simple, and the entire process can be carried on by one man and a helper.

The coil department, besides having work benches and form holders, should be fitted with taping machine, pair of rollers for flattening leads, a press for pressing completed coils, and tanks for insulating compound for dipping armature and field coils.

The truck shop, besides assembling tools, should have an overhead hand power crane with sufficient capacity for the safe handling of motors and truck frames.

The following outfit will do for all ordinary carpenter work: One planer, one resurfacing machine, one jointer, one mortiser, one boring machine, one shaper, one wood turning machine, one hand saw, one circular saw, one emery wheel, one grind stone.

\*Read at the annual meeting of the Pennsylvania Street Railway Association Sept. 10, 1902.

In the space devoted to work on car bodies see that there is plenty of room for necessary trestle benches and convenient handling of work. Pit room in this department for half a dozen cars is a necessity.

The paint shop should be constructed so that it will have good roof light, and the space between the tracks should be such as to allow the work to be done on cars standing parallel and not to crowd the workmen. The floor should be concrete, with smooth surface, so as to be easily kept free from dirt, and graded to be readily drained.

In the maintenance of motor equipments to-day, where almost continuous service is demanded and high mileage made, only those equipments fitted with both oil and grease boxes will safely run over thirty to forty days without a thorough overhauling. With a large road it is necessary to do this work at several different points, but a smaller road can concentrate it.

To overhaul a motor car thoroughly, it is advisable to have, at each overhauling shop, trucks with motors mounted, and in first-class order, ready to run under a car body whose trucks and motors need overhauling. For the purpose of lifting the body from the trucks, four chain hoists, conveniently located, together with two cross-timbers and four stirrup irons, form a good combination, and will do the work with the least possible injury to the car body.

When the car is lifted the truck to be overhauled is run out, the good truck substituted, car lowered, connected up and turned over to the operating department; the whole operation taking just about one hour, and for that length of time only is the use of the car lost. A suitable crane equipped with a carriage and chain block will be found a great convenience in overhauling. This department should be fitted with a wheel pit, with necessary jacks, to be able quickly to renew broken and worn-out wheels without removing car from the trucks.

Motor shells should be thoroughly cleaned out, either by compressed air or kerosene. The grease in grease boxes should be taken out and put in the gear case, and grease box thoroughly cleaned. Brush holders should be taken out, thoroughly inspected and cleaned. At this time you have the best opportunity for truck inspection. To prolong the life of an equipment and to reduce the number of crippled cars, new fields and newly wound armatures should be put in motors by themselves.

I have found that overhauling done with a car standing over the pits, with the bottom half of motor dropped, does not allow as thorough an overhauling as is necessary to keep the motor equipment in perfect shape, besides tying up the car body while the work is being done.

In the matter of general inspection, a car started out in perfect order can run safely for several days without it being necessary to inspect it, with the exception of cars run at high speed on suburban and interurban lines. These should be thoroughly inspected after each day's run.

In this connection, to inspect from twenty-five to thirty cars per day, one man can be responsible for the proper inspection of all trolleys, including the taking out and replacing of any defective poles, wheels or springs, and the straightening of all bent poles.

Another man should be responsible for the proper inspection of all circuits, together with hood switches, fuse boxes, circuit breakers and lightning arresters.

Another should give his whole attention to controllers; while the brakeman and his assistant should be able to keep all brakes in good shape and replace all worn out shoes.

This arrangement of inspection and overhauling should keep the truck and motor equipment in good shape if the night inspection of carbons, grease and oil boxes be done after an equally thorough system.

At a car house operating seventy-five to one hundred cars, three or four men should be able to grease motors, inspect brushes and make small trolley repairs. I recommend doing as little work as possible at night. The night car cleaning should be limited to sweeping and dusting cars and cleaning windows, while all washing should be done during the day. If cars are of the closed type, with drop sash, the space under the seat should be cleaned once a week.

My experience has been that the "Car Report" system, by which the conductor on housing his car reports it in good shape or designates some portion of the equipment in bad order, is a great as-

sistance to both day and night inspection and to the shop work in general. All cars should be taken to the general repair shop once a year and the body thoroughly repaired, and the car varnished or burnt off and painted anew, as the case may demand.

While the car body is in the carpenter's hands, the truck should be run out and gone over thoroughly. In case it is a built up truck, all rivets and bolts should be carefully inspected and renewed where necessary. The brake rigging at this time should be taken apart and if it is a truck with brake beams working in slides, the beams should have what we call "Dutchmen" jumped into the ends, to bring the wearing parts back to their original thickness, as the beams will probably have worn wedge shaped.

If the brake beams are hung by links, these should be renewed if they show any sign of wear.

At this shop should be concentrated all classes of repair work. It pays all railway companies operating fifty or more cars to make their own repairs on electrical apparatus, including the making of armature coils and renewing of commutators. Regarding the latter, we find that the dropped forged bars make the best commutators. Most roads will find it cheaper to buy the ordinary repair parts to controllers, hood switches, etc., and assemble them themselves.

I would advise that car body repairs,—painting, rewinding armatures, making commutators, armature and field coils,—be made by piece work. If good inspection is provided and the prices honestly matched, both the company and its employes are gainers by this method.

There are two more things which I think very essential to the economical maintenance of car equipment; first, that all material of any consequence be bought by specification subjected to a rigid chemical and physical test; second, that the employe who operates the equipments be properly instructed and schooled in handling them.

Managers, do not be afraid to keep in touch with the repair shop, for though it works in dirt, it performs the vital work of renovating that which is a clog to the entire system.

## TRACK CONSTRUCTION OF SUBURBAN AND INTERURBAN ELECTRIC RAILWAYS.\*

BY S. S. HOFF.

The above subject, which I presume also includes the construction of a roadbed upon which to put the track, is one of deep interest to the investor, the manager, the manufacturer, the local civic authority, and the urban as well as the sub-urban populace, and in this opening decade of the twentieth century will most likely tend to develop more territory and civilize, in the higher sense, more people than any three decades of the past life of the steam railway; hence, the importance of the development of the electric railway on true and correct lines cannot be overestimated.

As this is a state organization, the laws and practices of our own commonwealth bearing upon this subject must be used and conditions as we find them must be accepted in our discussion; experience alone can suggest wherein such laws, practices and conditions are wrong in principle and tend to retard rather than to promote true progress.

We have two systems of suburban and interurban electric railways now in operation, by virtue of our street railway laws, the one constructed upon the public highway and the other, generally under a steam railway charter, through private property; each has its advantages and disadvantages, the adoption of either depending largely upon local conditions.

In locating and building a railroad, be it steam or electric, it is not only the engineer's province to give the investor the best for the least money, but he must also think of the manager and consider fully the safety and economy of operation and maintenance.

In the public highway system, the engineer starts out to build a railway under the supervision of not only his own employer and the local civic authorities, but also of every resident along its route, and in a short time he runs up against a mass of grievances in number almost as great as the number of residents.

Under the beneficent rights vouchsafed us by the charity of the

\*Read at the annual meeting of the Pennsylvania Street Railway Association, Sept. 10, 1902.

steam railway managers, if your engineer is not a successful diplomat he finds himself trying to build a sectional railway, differing radically in many parts from his original well thought out plans, or else he encounters the broken link in his system with exasperating delays in the courts or in attempts to effect a compromise before he secures a completed roadway; but we had better start to build our road and leave these generalities to the manager.

A preliminary survey of the highway is necessary to get a proper conception of the grades and alignment, and in projecting a location on this information it is frequently advisable to make many minor changes in the original roadway in order to avoid many small "kinks" in surface and line and by judicious management with the local authorities this can be frequently accomplished; these changes may slightly increase the first cost of construction but are justifiable.

In the construction of a railway through private property much more judgment is required of an engineer than is necessary in building one upon the fixed line of a public highway, and more time should be accorded him in making a location than is generally given, principally for the reason that after the rights of way have been secured it is very difficult to make such revisions as subsequent developments may require or make desirable.

In securing rights of way, care should be taken that a width is adopted which will not only protect your roadbed but also afford sufficient material for future repairs.

In the selection of a general route by the projectors of a road is where the engineer often encounters his greatest drawback to making a good location. The practice of the investor, as a rule, is to seek the poorest land on a farm for his railroad, at the sacrifice of his roadbed, under the impression that it cheapens the cost of the right-of-way, whereas my experience has been that the land occupied by a railroad is, in the eyes of the average farmer, "the best on the farm," his price being fixed on this basis, and very often where money may be saved on land damages it entails much additional cost in the construction and future operation and maintenance of the road.

In making a location, it is advisable to keep away from bottom lands in the vicinity of long tortuous water-courses and territory of rapid water sheds, as in such localities you find that it is necessary to erect many bridges, that material for embankments is very scarce, and that the roadbed, especially light embankments, will be in constant danger of wash from high water and sudden downpours of rain forming rapid and uncontrollable floods.

Another thing to be avoided, wherever practicable, is a sharp curve in or at the foot of a heavy descending grade. This combination is the fruitful source of many accidents, as is so frequently attested by newspaper accounts of accidents caused by runaway cars.

Long straight lines or tangents are with many the great desideratum and frequently to gain this end sharp curves are resorted to whereas by the introduction of some additional lighter ones those with very short radii might often be avoided, and when the factor of safety together with the wear and tear of roadbed and rolling stock are considered relative economy results. The same rule applies to heavy grades which should be avoided wherever practicable. It is much better to spend a little more money once to make the cuts a few feet deeper and the banks a few feet higher, than to be constantly spending it for additional power to climb excessive grades. Simply because electric cars can be operated around sharper curves and over heavier grades than steam cars can does not imply that these are desirable things to have in an electric railway.

In constructing the roadbed, the cuts should be made wide enough—a minimum of 15 ft.—to admit of a ditch along either side of the track to keep water from the ends of the ties.

The embankments should be of sufficient width to support the full load under the ties and leave room beyond, on either side, for "cutting" or "jacking up" a car, should the running gear or machinery become disabled while running on the same; a minimum width of 13 ft. should be maintained upon all embankments. The slope of both cut and embankment should be made sufficiently flat to resist the erosive effects of the elements.

Should it be necessary to construct an embankment through marshy ground that cannot be drained it will pay to make it of stone, if available, but, if this cannot be had, the next best plan is to cover the ground to the full width of the embankment, including the slope, with a thick mattress of brush and build the embankment

upon it; this will force the water out of the ground and secure a firm foundation.

In bridge work the masonry should be put up in a substantial manner, not necessarily of expensive cut work but with an eye to solidity. Especial care should be taken to make the foundations broad enough to sustain the load to be carried, and deep enough to resist the action of frost and of abrasion or undermining by the periodical visitations of continuous high water and sudden floods. Should quicksand be encountered in foundations, it is best to bridge the same with a cement concrete floor, in fact I prefer making all foundations of concrete, giving ample time for the cement to set and harden before building upon it. In the point of durability stone or concrete arches, steel or iron superstructure, and wooden construction rank in the order named, the use of either depending largely upon local conditions and the amount of available funds.

Cast iron pipe drains can often be used to advantage and with economy, but when you have decided upon the size of pipe to use at any point, don't fail to put one in of double its capacity, and under no circumstances use any of less than 12 in. diameter.

A thorough system of drainage should be adopted for all roadbeds, not one which will concentrate the water upon your right of way and carry it along for an indefinite distance, as is often done in borrowing material for embankments out of ditches along and against its sides, but such a system as will provide ample openings at frequent intervals to carry across, if necessary, and away from the roadbed, all water wherever intercepted before it accumulates into large destructive volumes. All roadbeds should be so constructed as to admit of placing 6 in. of clean gravel or broken stone ballast under the ties for the promotion of sub-drainage and for tamping the ties to a firm and elastic bearing, from the ends to about 10 or 12 in. inside the rail bearings, the middle of the tie remaining untamped.

The ties should be placed two ft. apart between centers; they should have a top and bottom face of eight in., a depth or thickness of six in., and be not less than seven, preferably eight ft. long. They should be made of sound white or rock oak timber, if it is available, on account of its wearing qualities and its tenacity in holding spikes, but other woods such as white chestnut or spruce pine, if seasoned, must be substituted when the white oak cannot be obtained.

The rails should be of a weight corresponding to the weight of rolling stock and service required, but no mistake has ever been made in using a too heavy rail. The weight of new rolling stock, according to present practice, never lessens after a road has been put in operation and it is very difficult to keep a track in even fair surface or line when the rails begin to depress between the tie bearings.

The joints of rails should be made as strong as possible, the splice called the "Continuous Rail Joint," giving the most rigid construction. The joints proper, or the ends of the rails, should come between ties with good tie bearings under the ends of the splice plates.

The rails should be laid with broken and not even or opposite joints to prevent the double hammer on the joint ties which the latter method produces and which, in time, gives a slight downward bend to the end of each rail that can never be removed; hence, rough riding.

I know engineers and managers frequently disagree upon the policy of even or broken joints, but I am willing to take my own experience with steam road work and that of old track repairmen to back up my position on this point whether a T or girder rail is used. Special work should be the best obtainable, long radii being always used on the switch ends in preference to the quick, jerky, short leads and points one often sees, and the best efforts should be put forth in securing dry and uniformly firm beds throughout the full length of the frog and switch pieces to eliminate as much as possible the tendency to wear out in spots.

In order to maintain the proper gage with girder rail construction, the rails should be braced at about every fourth tie with outside pressed steel braces, the reason for my preferring this kind being that the weight of the car on the rail assists the brace in doing its work, there is no obstruction in the track to interfere with paving and there are no screw threads to rust out or nuts to become loosened as with the tie-rod.

Concealed joint bonding I consider the best for a track and the least liable to be loosened by vibration or careless interference by trackmen at their ordinary repair work as well as affording protection against robbery, yet the utmost care should be exercised to

secure a clean and full contact in the barrel of the hole in the rail and such bond should be selected as would best produce this result. Riveting or bolting against the face of the web will retain contact about as long as it takes to attach the bond, for vibration will very soon cause the harder metal to compress the softer and thereby destroy the contact. Cross bonding and bonding around special work should be as carefully done as the joint bonding, using well tinned copper for the purpose, and the lines of wire should be carried down and buried in the sub-grade to protect them against the midnight prowler and careless repairmen; but this work belongs rather to the electrical than the civil engineer.

At road crossings, excepting those with long skewers, I would dispense with the use of wood or plank, substituting a length of rail on the inside of each running rail to form a groove for the wheel flange and packing the space inside and outside the track with broken stone covered with screenings or, if this cannot be obtained, with gravel and sand.

On all curves of less than 500 ft. radius, I would recommend for safety the use in T-rail work of a guard rail along the inner running rail and bolted to it in like manner to the guard rail of a spring frog; this will give the assistance of the weight of the car on the running rail to hold the guard in place instead of depending entirely on spikes for that purpose; grooved rails should be used in girder work under similar conditions.

The outer rail of curves should be given sufficient elevation to overcome the centrifugal force generated by the highest rate of speed which the cars are capable of developing in order to protect the passengers as well as the company against the careless or indifferent motorman who tries to make up lost time without consideration for possible consequences, yet there may be unavoidable parts of the roadbed where "slowing-up" is essential to good running and managers should never be lenient in dealing with a motorman who disregards instructions covering such points.

After the track is laid, tamped and surfaced, the space between the ties, to the top of the same, should be filled with broken stone, gravel or sand, materials which retain the least moisture, to hold the track in rigid position and prevent the shifting about which always results when this space is left open.

For safety, all private rights of way through pasture lands should be fenced, and cattle guards should be placed at all road crossings, even though they are not absolutely effective, in order to reduce to a minimum the danger from roving cattle, particularly on high speed roads.

The proper section of rail to use where no paving is to be done is unquestionably the T, but in cities and towns where much wagon travel parallel to the track is encountered and where special work is necessary in a wagon road, it is essential to use the girder, and this should be deep enough to dispense with the use of chairs wherever possible.

All tracks in cities should be paved inside and outside the rails to the limits of the ties, and this paving should consist of a material and be so shaped as to shed water as rapidly as possible to prevent it seeping through to the ties.

To insure this result it is best to cover the bed and ties with a cement concrete base, tamped in well against the web of the rails, which will not only keep moisture from the ties but also, by giving a uniform and firm foundation to the paving surface, materially prolong the life of the whole roadway. If good material and workmanship have been put into the track and it has been properly ballasted, the most improved and lasting pavement is, with time consideration, the most economical to lay.

With the right of eminent domain accorded the steam road charter, which should also be extended at least to the interurban electric road, it is possible to build an electric road capable of being operated safely and successfully at any rate of speed to which the electric system of the future may be developed.

## ELECTRIC WIRE CONDUITS IN CINCINNATI.

The contractor who installed the wire conduits for the Cincinnati Gas & Electric Co. has been highly complimented on the manner in which this work, involving 1,250,000 ft. of conduits in 40 miles of streets, has been carried out. General Hickenlooper, of the Cincinnati Gas & Electric Co., said of the work: "G. M. Gest, the

contractor, has handled the business very well, and he has done the work with the minimum of inconvenience to the public. His arrangements for covering the excavations at most frequented crossings, and his use of bridges over the trenches at street crossings, have been productive of the best results, and Mr. Gest deserves a great deal of credit for the way in which he has carried out the enterprise, which is one of the largest undertakings in the way of making conduits that has been done in any of the large cities." The undertaking was more than usually exacting because of the short time allowed by the city in which to complete it.

## PROPOSED AUSTRALIAN RAILROAD.

The North Australian League of Melbourne, Australia, which has for one of its principal objects the promotion of the Trans-Australian railway, running north and south between Adelaide and Port Darwin, has issued a prospectus in regard to the proposed road. This league was formed for the purpose of centering public opinion on this matter, and in pursuance of this object offers to bona fide capitalists in any part of the world its services free of charge in investigating local technical conditions and in preparing statistics. No pecuniary benefit is sought by the members of the league, but it will do everything possible to accomplish the realization of the railway to Port Darwin and will assist in formulating and carrying out the preliminary measures. The prospectus is issued to induce the financial railway interests of all countries to investigate the opportunities offered for such a road, and to write for further information on the subject. The premier of South Australia has agreed to submit to Parliament, during the present session, a motion confirming the desirability of this road. Capitalists and railway directors interested in the project are invited to watch the progress of the measure through the South Australian Parliament.

## INFORMATION ABOUT EMPLOYEES.

The Brooklyn Rapid Transit Co. has decided to keep a more complete record of information relative to employes, and has called for answers to the following questions:

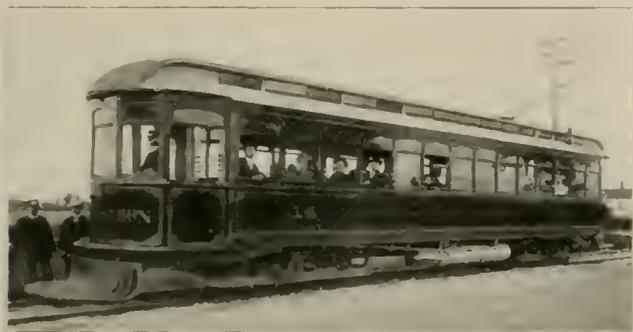

1. (a) In what department are you employed? (b) In what capacity. (c) Under what foreman or head of the department?
- (d) What weekly (monthly) salary are you paid?
2. (a) How long have you been in this company's service? (b) In what positions, and where located? (c) How long have you held your present position?
3. What is your age (year of birth)?
4. Where were you born?
5. Are you married or single, or widower?
6. (a) What family have you dependent upon you for support? (b) Are others than your family dependent upon you for support; if so, state particulars?
7. Name of father? Name of mother?
8. Nearest living relative? Residing at? Relation?
9. In case of serious accident, please notify \_\_\_\_\_, Address \_\_\_\_\_.
10. Are you healthy and able-bodied?
11. Do you use any kind of liquors (either wines, spirits or malt) as a beverage?
12. Are there any unsatisfied judgments against you?
13. Are you in the habit of engaging in games of chance or in speculating in any way?
14. Have you ever been arrested or accused in a civil or criminal court of any infraction of the law?
15. Are you engaged in outside business, producing income other than your salary; if so, state particulars as to time devoted to such business, and income derived?
16. Have you ever been discharged or suspended from the service of this company, or of any of the companies which now form a part of the Brooklyn Heights Railroad system; if so, state particulars?
17. Do you belong to any fraternal or labor organizations; if so, give name?

August 1st the Dallas & Oak Cliff Electric Railway Co. was absorbed by the Northern Texas Traction Co., and will hereafter be known as the Dallas division of the system.

**G. P. MAGANN STORAGE AIR BRAKE.**

The G. P. Magann Air-Brake Co., Ltd., which has its principal offices at Detroit, advises us that its brakes are used on all inter-urban lines out of Detroit, except one, and is also used on the city cars of the Detroit United Ry. The company has just closed a large order for brakes to go on the new Toledo & Monroe Ry. As is well known the Magann air brake is a storage system and as such received a very gratifying endorsement from the New York Railroad Commissioners.

In its storage air brake system the company claims to have met every condition of street railway operation. Stored air is used, confined in reservoirs fixed to the car and filled in a few seconds by

KUHLMAN CAR EQUIPPED WITH MAGANN STORAGE AIR BRAKE.

charging from a stationary air compressor, at the power station, or at any convenient point on the line, and at sufficient pressure to allow a car to make an average of 300 stops or more, according to the requirements. The care and expense incident to air-brake machinery is reduced to a minimum, for there is very little mechanism on the car. In fact, it is stated, that during five years' operation of this brake system not one dollar was spent on maintenance, this being due, it is claimed, to there being no machinery upon the car for compressing the air. The equipment is not subject to the occurrence of "jammed" brakes.

**NEW PIPE THREADING AND CUTTING-OFF MACHINES.**

The accompanying illustration shows a No. 0 pipe-threading and cutting-off machine which is a fair type of the machines made for this purpose by the Armstrong Manufacturing Co., of Bridgeport, Conn. The Armstrong machines thread pipe from 1/4 in. to 6 in. in

size; with a competent workman in charge the time required is from two and one-half to four minutes according to the size of the pipe. They are so arranged that when cutting off pipe the dies are opened for the pipe to pass through without being removed from the machine, this being effected by a simple motion of the hand-wheel or lever. All gearings and bearings are enclosed in an oil chamber, so that lubrication is perfect and working parts are protected from dust and

chip. The die head has no gear teeth where it comes into contact with the bell; the head has a large wearing surface and does not wear loose, and the vice may be fastened to a post or bench, or to the side of a house.

On the No. 0 machine the operator can cut pipe from 1/4 in. to 1 in. very quickly, and by changing the handle from one spindle to another he can cut from 1 1/4 to 2 in. more slowly but still easily. There is no need of a large number of turns on small pipes, an advantage which it is claimed is found in no hand machine except the Armstrong. Nos. 0 and 00 may be quickly changed from hand to power.

The company also manufacture the "Genuine Armstrong's" tools and dies, nipple holders, vices, pipe cutters, wrenches, etc.,

and will send complete catalogue No. 22 on request. The company's New York office is at 139 Center St.

**NEW ENGLAND STREET RAILWAY CLUB OUTING.**

The New England Street Railway Club held its annual outing on Thursday, Sept. 4, 1902. About 150 members and guests left Boston by special train for Hampton, Mass., arriving there about 11 o'clock in the morning. At this place electric cars were taken to Hampton Beach, where a ball game and various athletic events were indulged in until dinner time. After an excellent fish dinner, the guests congregated at the athletic grounds, where a 100-yard dash, high jumping and potato racing and various other athletic events were hotly contested. Entry was open to all, and four silver cups were offered as prizes to those scoring the most points in the games. The 100-yard dash was won by F. W. Whittemore; the high jump, by R. W. Conant; the potato race by Mr. White, and F. O. Nourse, who was third in high jumping and potato race, also received a cup.

E. D. Miller, of Boston, had charge of the events, assisted by F. S. B. Sias, with J. E. Johnston, recorder. The judges were D. L. Prendergast, of Boston; F. G. Henderson, of Newton, and E. W. Goss, of Milford. C. H. Hill, of Boston, was starter, and P. W. Davis, of Boston, was timekeeper.

**SHARON-NEW CASTLE INTERURBAN OPENED.**

On August 18th there was a formal opening of the new inter-urban railway between Sharon, O., and New Castle. The company entertained a number of newspaper men of the Youngstown Press Club, who made the trip over the road accompanied by Mr. R. Montgomery, president, Mr. Godfrey Morgan, general superintendent, and a number of Youngstown city officials. The roadbed was in excellent condition, and at times a high speed was attained, one mile being made in 59 seconds. A stop was made at the sub-station, where the guests inspected the machinery, and after completing the line to Sharon the return trip was made to Youngstown where the party, which had by this time reached considerable size, was given a dinner by the company.

**THE NEW YORK CENTRAL AND PAN-AMERICAN STAMPS.**

After mentioning a number of most ingenious methods of "American Railway Advertising" Mr. John T. Bramhall, advertising agent for the Monon Route, writing on that subject for Transport, of London, says:

"But these are all as nothing compared to the brilliant coup of Mr. George H. Daniels, of the New York Central, who is admitted to be the prince of railway advertisers, in suggesting, or causing it to be suggested (for Mr. Daniels modestly disclaims the personal honor) to the postmaster general the proposition of illustrating the idea of transportation in the new series of Pan-American stamps. The plan being adopted, what more natural than to picture the New York Central lake steamers on the one cent, and the Empire State express on the two cent stamps? I do not know how many millions of these stamps were sent out all over the world, but Mr. Daniels was shrewd enough at the close of the year to buy up all the remaining stock of the issue for the exclusive use of the New York Central road."

**FRANCHISE EXTENSION VOID.**

The Rogers law, which granted the Cincinnati Street Railway Co. an extension of its franchises for 50 years, expiring in 1946, was declared unconstitutional last month by the Superior Court. If the Supreme Court sustains the Superior Court a number of franchises granted elsewhere under the same law may be void. The law gave a 50-year extension of franchises only for such street railways as complied with various conditions on the date it went into operation. Attorneys for street railways state that they will file exception and new petitions at once.

## DISCIPLINE FOR STREET RAILWAY EMPLOYEES.

BY W. F. HARRINGTON, VICE-PRESIDENT AND GENERAL MANAGER  
CAMDEN & SUBURBAN RY. CO., CAMDEN, N. J.

There are various systems of discipline in practice, of which the Brown System is the best known. They all have for their purpose the advancement of those employes who by good work and steady service show their worth, to the most desirable positions.

In some systems employes are discharged for failing to comply with rules and regulations. The men remaining in employ being advanced to the position previously held by the discharged men. The disadvantage in such a system is that frequently employes who should be disciplined in some way or other do not lose their position on the seniority list. The result of this is that men who by faithful service should receive some consideration for such service remain for a long time in a position which does not properly reward them for their good service.

In other systems where the promotion plan is followed, men are frequently advanced for good service rendered in such a way that a feeling of bitterness is engendered in the breasts of other men who have not been advanced, as it is a well known fact that employes are very jealous of their position and standing. To follow the promotion plan, great care has to be observed in awarding promotions and it is very easy owing to the multitudinous cases that arise in street railway practice to unjustly advance men over the heads of their fellow employes.

In the system where merits and demerits are employed, the same objections apply as is shown in the promotion system, as it is exceedingly difficult to properly apply merits and whatever practice be followed for crediting a man with a given number of merits, difficulty is experienced in deciding the number of merits to be given for each case of good service. In the strict application of this system as long as a man's standing on the seniority list is not affected, he does not seem to care whether he has 60 or 200 merits or demerits. It has been noticed among street railway managers and, in fact, in all industrial operations where large numbers of men are employed, that great jealousy exists on the part of the men as to their standing.

It suggested itself to the writer, after trying various methods of discipline, to take advantage of this later feature, and on April 1, 1901, the "demotion" system was put into effect and after 18 months' operation, the following interesting results have been obtained: Prior to the adoption of the system great trouble was occasioned on the part of employes missing roll calls. Repeated cases where men would miss from 9 to 17 times during a month may be picked at random from our files. After the change the greatest number of times any one employe missed in a month has not exceeded 6.

It is proper here to describe the essential features of the demotion system. The general rules of the dispatching of conductors and motormen are outlined below in the appendix. Part first relates to regular men, and part second relates to extra men. In addition to that shown in the appendix, conductors and motormen are demoted by the general manager one or more points on the seniority list as may be deemed advisable. In cases of petty irregularities and violations of rules, for instance, a conductor may be demoted 5 points for permitting smoking on his car. The motorman may be demoted 5 points for starting car without receiving signal from conductor.

It has been noticed since the adoption of this system that men who have been in the employ of the company for years, who have been careless and negligent of their duties, have been demoted gradually until they have reached points well down on the seniority list. In looking over the files, in the 18 months there are men who have been demoted as high as 43 points and one 37 points and several respectively 27 points, 26 points, and 22 points. This as can be readily seen throws these men who have been rendering faithful services correspondingly by the inverse process advanced or promoted on the list.

It is an interesting fact to note in looking over the files, as an instance, a conductor who entered the employ of the company in 1891 is on the straight day runs and is below men on the seniority list who entered the employ of the company in 1896. This is the

best class of runs at the disposal of the company. In the straight from noon runs it is interesting to note that men entering the employ of the company in 1901 are ahead of men who had entered in 1900. In the evening runs, men who entered in 1902 are ahead of men entering in 1901. On the extra list, men who were employed in June, 1902, are ahead of men entering in May. This also applies to conductors.

The motorman list shows quite a fluctuation, but does not work as rapidly as the conductor list.

We find cases of men who are above other men who have been in the employ of the company for two or three years under the operation of this system.

It took the first year for the employes to realize the full significance of the demotion system. The last six months it has been found that the men exercise the greatest care in order not to come under the ruling of the demotion system and wherever they can, by explanation, they will endeavor to have the points removed.

It has been found that by posting on the bulletin board in the car house the names of those men who have been reported for irregularities that they will be demoted one or more points if the irregularity be not explained on or before a set date, that they take special pains to meet the general manager to clear their record, giving the general manager an opportunity to get in better touch with his men and enabling him to exercise judgment in enforcing the discipline.

The writer has noticed in many instances that men who have reached a point in their demotions where the exercise of discipline would throw them, for instance, from the straight from noon runs to the swing run, that even though the fault under which the discipline is acknowledged the employe would request that he be given one or more weeks' suspension or one or more weeks at the bottom of the extra list, rather than be demoted.

Under this system any employe by good conscientious service can advance to the better runs at the sacrifice of less capable men, and it has been found that the men approve the plan and appreciate the reward for faithful service.

This system permits the gradual weeding out of such men who are undesirable by a natural process of the "survival of the fittest."

The following facts are noticeable in the operation of this method of discipline:

Men have a general knowledge of how the list stands and when some one ahead of them misses they will look at the rack and see if their name has been advanced. They do not talk much about it, or seem glad that some one else has been set back, but regard it as a reward for good service. The man missing says very little about it, usually being a person who does not seem to care much for discipline. The majority of men missing roll calls seem to consist of young single men, who do not take the necessary rest when they should.

It is noteworthy that in many cases when an employe realizes that he is gradually going down on the list, he wakens up and from that time on becomes more efficient.

In conclusion, prior to the adoption of the demotion system the number of men missing roll calls to the total number of men employed averaged monthly 42 per cent. After the adoption of the demotion system and for the last six months the average has been 26 per cent.

### RULES FOR THE GOVERNMENT OF CONDUCTORS AND MOTOR- MEN, CAMDEN & SUBURBAN RY.

#### REGULAR MEN.

1. In case a regular man wishes to be excused from duty he should ask the day before, and, if excused such runs will be marked up from top of extra list (as it stands on the next day) in the order of the reporting time of the runs to be filled.

2. A regular man must report ten minutes before it is time for his car to leave the car house. For failing to report, either in person or by message for car, the first time in a month he will be demoted one point and given one day for each hour or fraction of an hour missed and he will have to report at each succeeding roll call and in that time to receive work only after all men on extra list have been assigned.

Any employe having a clear record for the previous two months will be relieved from demotion for the first failure to report in a month.

The second time in a month a run is missed he will be demoted two points and given one day for each hour or fraction of an hour missed and he will have to report at each succeeding roll call and in that time to receive work only after all men on the extra list have been assigned.

The third time in a month a run is missed he will be demoted three points and given one day for each hour or fraction of hour missed and will have to report at each succeeding roll call and in that time to receive work only after all men on extra list have been assigned.

## THE HOLLAND TROLLEY BASE.

The United States Electric Railway Supply Co., of 40 and 42 Larned St., Detroit, invites attention to its patented self-oiling trolley base, which is in general use throughout the country, and for which it is claimed that it prevents trolley trouble and saves the wheels, poles and overhead equipment. It is pointed out that the base requires but 1 qt. of oil per year and any stand can be mounted on this base in 15 minutes. Stands in which the base has worn an oval hole can be plugged, mounted on this base and used as long as there is any tension left in the springs. Another feature of this invention, and an admirable one, is that it keeps the trolley wheel on the wire and prevents injury to the overhead construction.

Among the many users of the device are the Detroit United Ry., Rapid Railway System, Detroit, Ypsilanti, Ann Arbor & Jackson Ry., Hamilton Electric Light & Cataract Power Co., Limited, Bay Cities Consolidated Railway Co., Brockton & Plymouth Street Railway Co., Boston & Worcester Street Railway Co., Dayton & Western Traction Co., Dayton & Troy Electric Railway Co., General Electric Co., Lorain Steel Co., Mahoning Valley Railroad Co., St. Louis Transit Co., and others.

## IDEAL STEAMBOAT SERVICE.

Eastern visitors to the A. S. R. A. Convention will find it pleasant and profitable to utilize the new daily service of the Detroit & Buffalo Steamboat Co. Two new mammoth steel sidewheel passenger steamers have been constructed to be operated daily between Detroit and Buffalo and are christened the Eastern and Western States. They are the largest and fastest steamers ever built on the Great Lakes for passenger service and cost \$650,000 each. Each has 5,000 horse-power engines, with an average speed of 21 miles an hour, or 23 miles at their highest mark. The boats are licensed to carry 3,500 people; each has sleeping accommodations for 750 passengers, 242 state rooms and 12 parlors, with bath. The dining-room seats 150 people. The main cabin decorations are French renaissance, with velvet carpets and mahogany furniture.

The steamers leave Detroit and Buffalo almost simultaneously at an early hour every evening and reach their destination before breakfast. It is a most desirable change from the hot ride by rail and in addition there is a saving in the cost that is not to be despised. Connections are easily made with all points East and West and stop-over privileges are allowed with round trip tickets, which are good until October 31st. For comfort, speed, safety and service this line is recommended.

Tickets at excursion rates are for sale at all principal railway and steamship ticket offices. By the company's advanced system meals and berths are not included in the price of a ticket and patrons are at liberty to provide for themselves if they so desire. Berths between Detroit and Buffalo are \$1.00 and \$1.50, and state-rooms are \$2.50. Transportation one way is \$3.50; round trip, \$6.50.

## BRIDGE REPAIRS ENJOINED AT DAYTON.

The Board of City Affairs of Dayton, O., has enjoined the Peoples Railway Co. from making repairs to its Washington St. bridge. The railroad company has built 48 bents under the bridge requiring a large amount of piling, and it is alleged that these piles dam up the river to such an extent that danger of flooding the city would follow in case of high water in the river. The board claims that no permission has been granted the company to repair the bridge in this manner. The request of the company to build a temporary trestle on one side of the bridge was refused, and it is claimed that the company does not intend to ultimately remove its bents which menace the city.

The assessment of the Metropolitan Street Railway, of Kansas City, has been raised about half a million dollars, under the agreement made between the company and the city, whereby the city received 8 per cent of the company's gross receipts in lieu of the old rate of taxation.

The fourth time in a month a run is missed he will have to report to general manager.

All these rulings are subject to appeal to the general manager.

3. No extras are carried to relieve men who may miss their second car, as at dinner, supper or swing time; in such cases the early men will be demoted to the bottom of late runs, the late man will be demoted to the bottom of swing runs, and the swing man to night car. The night car man will be demoted to tripper runs and the tripper man demoted to extra list. In case of an extra, he will be demoted from his position on the extra list, three points.

4. The slate will be put out daily at regular time suitable to the requirements of the depot, after which no one will be excused without reporting.

5. A regular man asking off sick must lose two days' work and must report at depot the day before he takes his car.

Telephonic or telegraphic messages or letters sent by mail or by employees will not be accepted, as requests for leave of absence due to sickness or other causes.

The only recognized forms of request will be by letter brought to car house by some person not an employe or made personally at the car house, not later than ten minutes before the allotted reporting time.

Requests will be accepted only at car house.

Employees not complying with the above will be placed at bottom of extra list one day for each hour or fraction thereof for failing to report as above provided.

6. No regular man is excused from work after taking his car, without he is sick or disabled. He must work run out.

7. Changes on account of vacancies will be made from first to tenth day of each month, unless in case of a run being vacant three (3) days or more. In that event it will be filled by the oldest extra not otherwise engaged, until such time as he may be called for regular position, or the man to whom it belongs returns.

8. Promotions on account of discharge, etc., are made from extra list to tripper runs, from tripper runs to night car, from night car to swing runs, from swing runs to straight from noon runs, from straight from noon runs to straight day runs.

## EXTRA MEN.

On and after Monday, April 1, 1901, extra men will report as follows: (at car house for morning work).

1. After the noon roll call at the ferry the list is telephoned to the car house and dispatcher books off the regular men for the next day, the first extra men booked up for regular runs are those working the tripper runs, then come those who did not get work at noon. In event a man who did not get work at noon should get a six-hour run at night roll call he will be expected to take run he is booked up for the next morning. In event he is not booked up he will not have to report until 10:59 next day.

2. Instead of extra men reporting at 4:50 a. m. a limited number of men will be delegated to report at 4:30, 5, 5:20 and 5:35 a. m.

On arrival at car house each man will report to dispatcher, giving name and time of report.

3. For failing to report as scheduled, the following rules will be strictly enforced:

a. The first report missed in a month will be demoted one point on the extra list and must stand on bottom of extra list one day for each hour or fraction of an hour late.

b. The second report missed in a month will be demoted two points on the extra list and must stand on the bottom of extra list one day for each hour or fraction of an hour late.

c. The third report missed in a month will be demoted three points on the extra list and must stand on bottom of extra list for each hour or fraction of an hour late.

d. The fourth roll call missed in a month will have to report to general manager.

All these rulings are subject to appeal to the general manager.

Any employe having a clear record for the previous two months will be relieved from demotion for the first failure to report in a month.

4. Extra men not otherwise excused from morning work will report as above.

Extra men not reporting and sending note that they are sick must take two days on bottom of extra list and must report at car barn the day before taking place on list.

5. Extra men taking straight from noon runs are not required to report until 10:59 report next day. If extra man has a noon run for more than one day, he must report ten minutes before it is time for the car to go out. Subject to Rule 3, Sections a, b, c and d.

Telephonic or telegraphic messages or letters sent by mail or by employees will not be accepted, as requests for leave of absence due to sickness or other causes.

The only recognized forms of request will be by letter brought to car house by some person not an employe or made personally at the car house, not later than ten minutes before the allotted reporting time.

Requests will be accepted only at car house.

Employees not complying with the above will be placed at bottom of extra list one day for each hour or fraction thereof for failing to report as above provided.

6. Extra man taking six-hour run at night is not required to report at early report next day, except he is booked up for a run; then he must report ten minutes before car is due to leave car house, subject to Rule 3.

7. Extra men will take runs as booked and hold until regular man returns. Subject to provision, Rule 7, regular men.

8. Early morning roll call at car house, see Rule 2, Extra Men. Noon roll call is made at the ferry 10:59 a. m. daily; 10:50 a. m. Sunday.

Night roll call is made at the ferry 5 p. m. daily; 4:50 p. m. Sunday.

9. After the noon runs are given out all men not excused will report at car house, subject to Rule 2, Extra Men. Dispatcher will appoint five or more men, as may be required, on extra list not working to report at Federal St. ferry 5 o'clock p. m. roll call.

10. An extra man relieving a sick man for part of a run will be entitled to such run until regular man returns, subject to Rule 7, Regular Men.

11. Extra men who have been excused from work will be turned down on list same as if they had been called for a car.

12. Men appointed for roll calls or reports will not be excused for failing to report.

13. Extra men holding straight day runs, not scheduled for Sunday work must report at depot Sunday morning, (as per Rule 21, Extra Men).

The Hamilton, Glendale & Cincinnati Traction Co. has brought suit against Peter Schwab for \$1,700 damages. The action is based on two injunction suits brought by Mr. Schwab against the company, causing considerable delay in its work of construction.

## POWER HOUSES AT DETROIT.

The direct current portion of station G of the Detroit United Railway, described in the article by Mr. Farmer, on page 522, was furnished and installed by J. G. White & Co., engineers and contractors, of New York. The extension of this power house, including the 500-kw. unit to be installed this fall, will be furnished and installed by J. J. Kennedy, contracting engineer, of New York. The Stanley rotary converters, transformers, switchboards, etc., were furnished by the Stanley Electric Manufacturing Co., Pittsfield, Mass. All of these contracts were given through Jos. E. Lockwood, president of the Michigan Electric Co., of Detroit, agent for all of these concerns.

## AUTOMATIC LOW WATER ALARM.

The Jones Automatic Low Water Alarm Co., of Detroit, makes a low water alarm that can be easily adjusted to the water column of any boiler and is intended to give immediate warning when the feed water becomes low in the boiler. The device is simple and has been endorsed by the chief factory inspectors of Ohio and Michigan, as well as by many engineers.

The action of this unique alarm is based upon the expansion and contraction of metals. The alarm is put on a water column by removing the lower and upper gage cocks and placing a tee and close nipple and screw in where the water gage cocks were, and screwing the water gage cocks in the end of the tees, the side outlook of the tee being used to attach the alarm. If it is not desirable to remove cocks, holes may be tapped above the crown sheet or flues. When the water gets below the bottom connection (J), water flows out of the copper pipe (C) attached to the alarm back into the water column and steam rushes up and takes its place. The steam heating the copper pipe expands it and by an arrangement of connecting rod and lever the alarm whistle blows until the water in the boiler gets up to the original point. It also blows if the water column gets stopped up.

The low water alarm does away with the undesirable high water alarm that blows so frequently for high or low water as to become a nuisance. The low water alarm, too, tends to make engineers more careful, it is stated, because an engineer is apt to become indifferent when none but he knows that the water is low. This alarm has no floats to collapse and fill with water, there is no mechanism in the boiler to get out of order and it is not a fusible plug or electric contrivance for batteries to exhaust. It can be tested at any time without running the water low.

The Jones Alarm Co. also makes a smaller alarm intended for steam vehicles of all kinds, especially automobiles, which may be used on small boilers. It is entirely of brass and is made for 400 lb. pressure.

## PETER SMITH HEATERS.

The Peter Smith Heating Co., of Detroit, has installed its system of hot water heating on practically all the interurban lines controlled by the Detroit United Ry. A statement of the number of heaters sold, by divisions, is as follows: Detroit Shore Line, 12; Rapid Ry., 40; Detroit, Rochester & Romeo, 14; Detroit & Flint, 10; Detroit & Pontiac, 14; Detroit & Northwestern, 12; Detroit & Wyandotte, 15; special car Yolande, 1. The Peter Smith company has met with unqualified success in introducing its system of heating long interurban cars and the list of companies now using it is a long one. The list includes the following: Grand Rapids, Holland & Lake Michigan Ry.; Toledo & Western; Toledo & Bowling Green; Toledo & Maumee Valley; Cleveland & Eastern; Cleveland & Chagrin Falls; Cleveland, Elvia & Western; Sandusky & Interurban; Mahoning Valley Ry.; Fort Wayne & Southwestern; Indianapolis Street Ry.; Cleveland & Painesville; Chicago & South Shore; Indianapolis & Shelbyville; Milwaukee Interurban Ry.; Fond du Lac & Oshkosh Ry.; Columbus & New Albany Ry.; Lansing Traction Co.; Saginaw Interurban Ry.; Kansas & Leavenworth Ry.; Louisville & Pewee Valley Ry.; Alliance Interurban Ry.; Cincinnati Traction Co., and others.

## WILLANS ENGINE IN AMERICA.

The Bradley Manufacturing Co., of Pittsburg, Pa., has recently purchased the American rights for the Willans engine, and has erected a new plant at Pittsburg, Pa., where this engine will be built in sizes of from 25 to 3,000 h. p. The company has issued a preliminary catalog illustrating and describing its engines, and has a large and complete catalog now in course of preparation. The Willans engine, which is one of the most prominent English types, is a single acting engine, designed so that the upper brasses of its bearings are always in compression, which enables the engine to run at high speed without knocking. The piston speed, however, is comparatively low, and the wear in the cylinders and piston rings is consequently small. The valves are of the piston type, and work inside the piston rods. These engines are built according to size, with from one to six cranks. Each piston is connected to its corresponding crank by two exactly similar connecting rods, between which is an eccentric forged upon the crank pin. As the piston valves move inside the hollow piston rods the valve face is the inside surface of the hollow rod, and as the valve face moves with the piston the relative motion of the valve and the valve face is obtained by mounting the eccentrics on the crank pins. The eccentric rods, in the same way as the connecting rods, are designed to work always in compression. The Bradley Manufacturing Co. will maintain in the manufacture of these engines a quality of workmanship fully equal to that of the English standard, and special tools will be employed in making those parts which require extreme accuracy.

## ROSS PARK, BINGHAMPTON, IN LITIGATION.

Erastus Ross, the donor of Ross Park, Binghamton, N. Y., has brought suit against the city seeking the reversion of the property on the ground that the conditions of the gift have been violated. He also sues G. Tracy Rogers and other officers of the Binghamton Railway Co., asking a judgment of ouster from the premises and \$50,000 damages for the use of the park. Mr. Ross alleges that the park was deeded to the city of Binghamton upon the express conditions that the premises be held by the city as a public park for the benefit and enjoyment of the inhabitants of that city and on the further condition that the property, nor any part of it, should not be sold, leased, or in any way disposed of by the city. Mr. Ross charges that the conditions have been violated in the case of a lease of certain parts of the park to the Levavan Switchback Co. made by the park commissioners in 1892 for the period of five years and for a consideration of \$200. He also alleges that the city has violated the conditions of the gift by entering into a lease for a period of three years with officers of the street railway company whereby special privileges were secured to it to the exclusion of all others for maintaining upon the park grounds cafes, merry-go-rounds, platforms, buildings, and other places of amusement. The city, it is claimed, has also granted the Binghamton Railroad Co. permission to occupy part of the park grounds to the exclusion of the public for its tracks, gates, platforms and other structures.

## WORLD'S LARGEST SIDEWHEELERS.

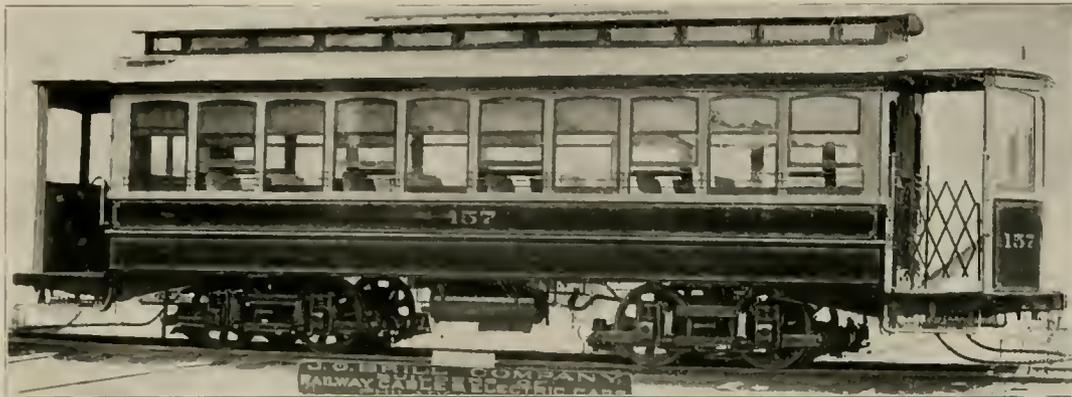

The Detroit & Cleveland Navigation Co. has contracted for two new steamers for the Cleveland route, which will be the largest sidewheel steamers in the world. They will be 25 per cent larger than the Eastern States and the Western States, owned by the same interests, and will have 30 per cent more power. The hulls will be built at the Wyandotte yards of the Detroit Shipbuilding Co. during next winter, although only one boat will be in commission by 1903.

General Manager McMillan of the Detroit & Cleveland company states that the new boats will be larger than the famed Fall River Line steamers. Each will cost about \$850,000. They will be four-deckers and each will have sleeping accommodations for between 1,100 and 1,200 passengers.

General Passenger Agent A. A. Schantz states that with one more boat on the line next season each will have one-third more time in port, and with two more boats an express service will be established between Detroit and Mackinac on an 18-hour schedule and 25 hours from Cleveland.

### BRILL SEMI-CONVERTIBLE CARS FOR ATLANTA.

The Georgia Railway & Electric Company, of Atlanta, Ga., has recently received ten handsome semi-convertible cars from the J. G. Brill Co., of Philadelphia. The interior of these cars is wider than usual by reason of there being no wall pockets, which are also frequently objectionable because of their use as receptacles for rubbish. The windows become clogged and in attempting to raise them the glass is often broken. The floors of the cars are double and the inter-space filled with mineral wool. This excellent preventive against cold floors will doubtless be appreciated by the passengers. The interior finish is natural cherry with handsomely decorated birch ceilings. The length over the vestibules is 37 ft.

37-FT. SEMI-CONVERTIBLE CAR FOR ATLANTA J. G. BRILL CO.

5 m., width over sills, 7 ft. 10½ in., and over posts at belt, 8 ft. 2 in. Angle iron bumpers, "Dedenda" gongs and folding gates, are among the Brill patented specialties with which the cars are equipped. The trucks are Brill 27-F.

### THE R. D. NUTTALL CO.

Doubtless few persons realize the magnitude of the gear, pinion and trolley business of the R. D. Nuttall Co. A dozen years ago, when this company first began the manufacture of gears and pinions for street railway service, the demand for this class of material required the use of but one gear-cutting machine; soon it was found necessary to add another machine, and later to increase the equipment by two additional machines. Since then new and improved machinery has been added from time to time, until now upwards of 70 gear-cutting machines (believed to be the largest gear-cutting equipment in the world) are taxed to their utmost to supply the demand for the well-known "Nuttall make" gears and pinions.

Within the past few years foreign agencies have been established in the larger European cities, and the number and size of orders received through this source has exceeded all expectations. The almost universal adoption of heavy cars and powerful motors for high speed and interurban service has made it necessary to correspondingly increase the weight and improve the design of motor gearing, and this company, fully alive to these requirements, has placed in the market a very complete line of heavy design gearing for this particular service. A complete motor bearing department has recently been added by the company, and a full line of all standard bearing will be carried in stock.

Last, but by no means least, is the trolley department of the plant, in which are manufactured trolleys and trolley repair parts for every conceivable trolley service.

Under the able management of Mr. F. A. Estep this company has attained an enviable position in the street railway supply business, and the reputable business methods to which past success may be accredited are sure to be adhered to in the future.

The traffic of the South Side Elevated for August is estimated to be about 10 per cent above that of the corresponding month last year.

### INTERNATIONAL TRAMWAY AND LIGHT RAILWAY UNION.

At the Twelfth Annual Congress of the Union Internationale Permanente de Tramways, a change was made in the name of the association to include suburban and interurban railways, as well as tramways, as for a long time questions relating to interurban railways have been considered by the Union as well as matters strictly concerning tramways. The name International Tramway and Light Railway Union (Union internationale de tramways et de chemins de fer d'interet local) was adopted by the London Congress.

Accompanying the notice of this change of name the Union also calls attention to the new office of general secretary. As in every

important country of Europe close relations exist between the members of the national association and their standing committees, it is desired that the International Union shall become the center of information for its members of all nationalities, to which they may all have recourse in all cases for complete and precise information in regard to everything pertaining to the tramway industry. It is for this reason that the office of general secretary has been established, and it is desired that the members will furnish the union with data of all description in regard to technical matters, methods of operation, railway materials and devices, and mechanical questions.

The general secretary of the International Union has issued a circular letter to the various members in regard to the speed of street cars in different localities. This question is brought up by the fact that the English government is preparing some new legislation in regard to the tramways and light railways, and the question of regulating the speed of cars is under discussion. The questions are as follows:

"Does your franchise contain a special clause relating to the speed of cars on your road? If so, state by whom this regulation has been made, and enclose copy of same.

"It is desirable that you send a copy of the map of the route and state the speed usually employed as well as indicate the time used in making stops. This information should be given both in the case of city lines running from one extremity of the city to the other, and passing through the center of the city, and for short local roads.

"It is desired that the commercial speed be indicated, that is to say, the average speed used in running from one extremity of the route to the other, including the time taken for stops; also the average speed of the divisions of the line, the speed on the latter being presumed to vary with the density of the traffic and different local circumstances.

"Have you fixed stopping places? If so, indicate the average distance apart at which they are located.

"What is the maximum speed attained by cars on any point of your line?"

The Berkshire (Mass.) Street Railway Co. opened its new street railway park to the public on August 18th. The park is under the management of Mr. P. J. Casey, of Springfield.

### ACCIDENTS OF THE MONTH.

A directors' car on the Lancaster, Mechanicsburg & New Holland Ry., which is operated by the Conestoga Traction Co., of Lancaster, Pa., collided with a regular passenger car near Mechanicsburg, at 8.40 a. m., August 11th. The conductor on the directors' car was injured.

A serious accident on the Jersey City, Hoboken & Paterson Street Ry., in Jersey City, August 18th, resulted in injuries to 20 persons. The car was going at a high rate of speed when the front wheels struck a locked switch, causing the car to jump the track and plunge for a considerable distance along a rough stone road until it collided with a stone wall and overturned. The wall at this place is protection from a precipice about 100 ft. deep.

A flat car, loaded with crossties, on the lines of the Charleston (S. C.) Consolidated Ry., was thrown from the track August 18th, and one of the five negro laborers in charge of the freight was killed. The crossties projected on either side of the platform. In rounding a curve the projecting edges struck a telephone pole, with the result that the car was thrown from the track.

An electric car on the Union Ry., New York, on its way to Yonkers, jumped the track and was overturned at 11:30 p. m., August 10th, causing injuries to 20 persons. The car was running at the rate of 35 miles an hour, when, for no cause that can be ascertained, it left the tracks and dashed into a pole beside the road, landing on its side with several of the 40 passengers pinned beneath it.

A collision between a construction car and a passenger car on the lines of the Toledo, Bowling Green & Southern Traction Co., at Bowling Green, O., August 21st, resulted in the death of one of the motormen and injuries to several passengers.

August 22d, at 6:10 p. m., the Independence Ave. cable train on the lines of the Metropolitan Street Railway Co., Kansas City, Mo., crashed into and telescoped a Ninth St. train at the foot of the incline from the elevated structure. Some 15 passengers on the cable train were reported more or less injured, and the gripman, W. D. Taylor, subsequently died from his injuries. Both trains were going down the incline at a high rate of speed when the one in the rear became unmanageable, and despite the efforts of the gripman to check its speed, began gaining on the other. The force of the collision was sufficient to lift the forward car, trucks and all, clear of the tracks. Had it not struck a heavy iron pillar it must inevitably have dropped into the street, several feet below.

A car on the lines of the Union Traction Co. of Indiana met with an uncommon accident August 22d, in making the last run for the night into North Marion. A pole but a short distance behind the car broke off near the ground and fell into the street, carrying with it all the overhead wires. The result rivaled the most ambitious fireworks display, and badly frightened the few passengers on board. No one was injured, however, and the damage was quickly repaired by the wrecking crew.

A head-on collision occurred August 24th on the lines of the Bay Shore Terminal Co., near Norfolk, Va., resulting in the death of three persons and injuries to several others.

A car loaded with passengers on the interurban lines between Carbondale and Scranton, Pa., jumped the track while crossing the bridge near the power house at Scranton, August 26th, and plunged into a creek eight ft. below. Only one of the passengers was seriously injured.

An excursion car on the electric interurban lines between Terre Haute, Ind., and Brazil, collided with a freight car on the Chicago & Eastern Illinois R. R., at 6:30 p. m., August 27th. There were 110 passengers aboard the electric car, but none was injured.

An accident on the Youngstown (O.)-Sharon Ry. occurred August 27th, near Youngstown, when two cars, bound in opposite directions, collided in a dense fog, with the result that several passengers were injured and one man killed. The motorman of one of the cars, it is stated, misunderstood his orders, and failed to wait at a switch, as he should have done, for the other car to pass. The fog was so dense that he could not see the approaching car until it was within six ft., when it was too late to avoid a collision.

Eight passengers were slightly injured in a rear-end collision on the Mahoning Valley Ry. at 11 p. m., August 30th, near Niles, O. A limited train from Youngstown was closely following a regular car, when the latter stopped unexpectedly. The limited was traveling at a high rate of speed, and the motorman was unable to

check it in time to prevent its crashing into the rear platform of the car ahead.

Twenty passengers were badly shaken up but not seriously injured in a collision which occurred on the Clayton division of the St. Louis Transit Co.'s lines, at midnight, August 31st. The motorman of one of the cars is blamed for not having waited at the proper switch for the passing of the other car.

On the morning of September 4th a car on the San Francisco & San Mateo Electric Ry. was struck by a train on the lines of the Southern Pacific Co. at the crossing near Sunnyside Ave., San Francisco, and seven passengers on the electric car were injured. The gateman in the tower at the crossing is believed to be responsible for the accident, since the gates were not closed to warn the motorman of the approach of the steam train. The train was invisible by reason of a fog, and it is claimed, neither bell nor whistle warned the crew of the motor car that the train was coming.

A cable train on the Milwaukee Ave. line, in Chicago, was partially wrecked in an accident which occurred on the morning of September 4th, resulting in injuries more or less serious to some 12 passengers. Near Evergreen Ave. the train, which was composed of a grip car and two trailers, struck either some impediment in the cable slot or a protruding man-hole cover with such force that the first trailer telescoped the grip car and the second trailer dashed into the two, hurling passengers from their seats and sending splinters of wood and shattered glass flying into the roadway. Several of the injured persons were removed to hospitals.

A rear-end collision occurred on the Snelling line of the Twin City Rapid Transit Co., in St. Paul, on the evening of September 7th, 10 passengers being seriously injured. The trolley of the forward car slipped from the wire, causing the car to come to a standstill and all its lights to go out. The motorman of the car following was unable to see what had happened on account of the darkness and therefore made no effort to slow up until it was too late to avoid a collision. It is feared that some of the injured will not recover.

### BRILL COMPANY BUYS PLANT OF AMERICAN CAR CO.

Concerning the newspaper reports from St. Louis which have appeared recently regarding the J. G. Brill Co. having purchased the works of the American Car Co. in St. Louis, the following are the facts, as furnished by officials of the Brill company:

The Brill company has been considerably hampered in its output during the two months and more of strike among its employes and during all this time new work has been coming in rapidly so that its facilities for handling orders have proved inadequate at the present time. Finding a well-equipped car works in St. Louis, the owners of which have been endeavoring to make sale of it to the Brill Co., beginning with March of the present year, the Brill company decided after examination to purchase the works. The plant is, of course, very much smaller than that of the J. G. Brill Co., but it is capable of turning out about one-half of the number of cars annually that the Brill works can make. The facilities for providing for the additional amount of work could not have been made ready at the Brill works in less than six months' time. The property of the American Car Co. had been held by trustees for a St. Louis bank, who represented the creditors. The trustees were ordered to sell the property, which they did on September 12th, and it was bought for the J. G. Brill Co.

The Erie Rapid Transit Street Ry., of Erie, Pa., has fitted up a special car for express and baggage, and is calling for and delivering express from all points on its lines. The company calls for baggage on telephone calls, and the goods are carried at once to any part of the city on the company's lines, which insures a very quick delivery of merchandise.

The Aurora, Elgin & Chicago Ry. is attracting a great deal of attention and on September 7th there were 3,000 persons, who had gone out to the 52d Ave. terminus with the intention of taking a ride over the electric line, who were obliged to return because the equipment was not sufficient to take care of them. The receipts of the road on that day were stated to have been about \$400.00 per car. The curb quotations on the stock of this company are 98 to 102 for preferred and 39 to 42 for the common.

**CONVERTIBLE BALLAST CARS.**

In view of the rapid development of interurban electric railways which are being built in great numbers, upon a scale very much more extended than was usual a few years ago, and the fact that the importance of a well built and thoroughly ballasted track is now better realized than ever before, the ballast cars shown in section in the accompanying engravings will be of interest at this time. These are known as the Hart convertible type, as built by the Rodger Ballast Car Co., of Chicago. This company has had a great deal of experience in the design and construction of ballast cars, its earlier designs having been placed on the market some twelve years ago, and 15,000 or more of the Rodger ballast cars

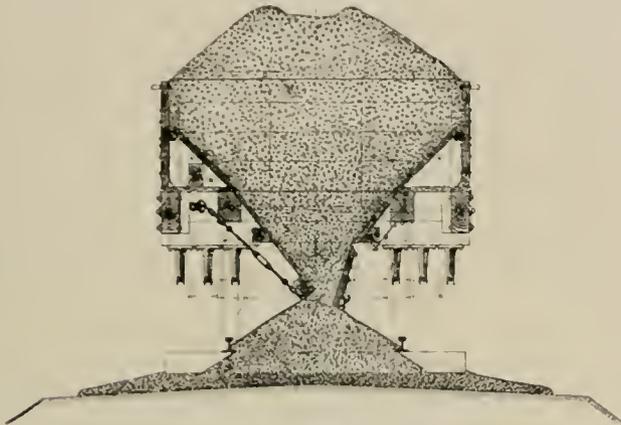

FIG. 1 CLASS CC AS HOPPER CAR.

are now in use by leading steam railroads. Since their introduction a few month ago, several thousand of the convertible cars have been purchased by such roads as the Wabash, the Michigan Central, the Rock Island and the Santa Fe. We are advised by the company that these cars are standard on 90 per cent of the roads and 60 per cent of the mileage of the country.

The convertible cars here shown are the class C C and the class C S. The class C C may be used as a hopper-bottom car when it appears as in Fig. 1, and may be converted into a flat bottom gondola for merchandise or other general freight service. The con-

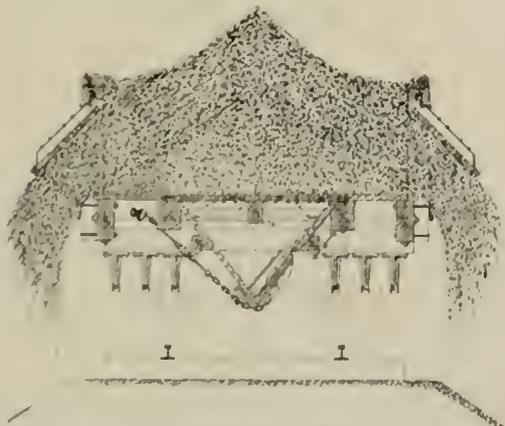

FIG. 3 CLASS CS AS SIDE DUMP CAR.

dition is effected by first putting in place at the center of the car the temporary center sill which in Fig. 1 is shown resting on the floor of the car under the movable section of the hopper bottom at the left hand side. Then the two upper sections of the hopper bottom are folded toward the center, the edges resting on the temporary sill mentioned, making the car in section as shown in Fig. 2. Used as a ballast car with 3-ft. sides, the class C C car holds 32 cu. yd., with 4 ft. sides, the capacity is 39 cu. yd.; converted for a gondola car the capacity is 32 cu. yd. with 3-ft. sides, and 52 cu. yd. with 4 ft. sides, the difference being due to the fact that when converted the piece forming the end of the hopper is moved from

its position over the truck back to the extreme end of the platform.

The class C S car is provided with side doors, so that if desired it may be operated as a side dump ballast car, as shown in Fig. 3, or as a hopper bottom center dump car, as shown in Fig. 4. This car also, it is apparent, may be converted to a flat bottom gondola for general freight service. The company also makes a hopper bottom ballast car which may be converted to a flat car for general service (this is known as the F. H. type), and a box car which may be converted to a hopper bottom dump car.

The general dimensions of the C C and C S cars mentioned are: length over end sills, 34 ft.; width over side sills, 8 ft. 9 in.; height inside, 4 ft. They are made with wooden outside stakes or steel inside stakes, the former being shown in Fig. 2 and the latter in Fig. 1. The hopper-flat cars, class F. H., are 40 ft. long. Each of

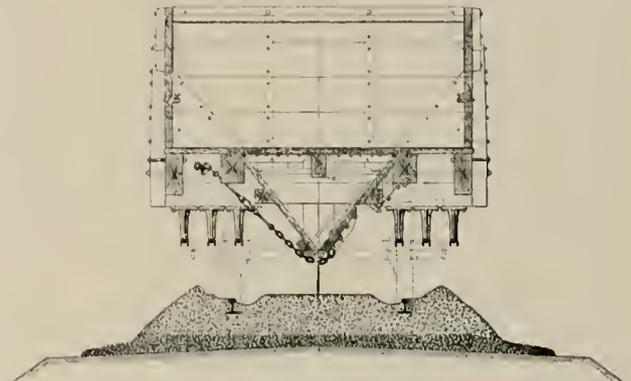

FIG. 2 CLASS CC AS GONDOLA CAR.

the classes are of 80,000-lb. capacity, though they are in service frequently considerably overloaded.

In designing these cars the company has made use of the most common of the standard sizes of rolled shapes, and all complexity in castings has been avoided, the idea being to use materials and parts that in event of accident can be replaced with the least loss of time. M. C. B. standards are generally used throughout.

The rapidity with which ballast can be unloaded and distributed by the use of cars of this type is surprising to one who has not had experience in such work; thus, with a train of 20 cars of the class C C from 600 to 700 cu. yd. can be unloaded and distributed in 20 minutes, and spread by means of the double-plow distributing car, so that the track is left flanged and clear for fast traffic, only three men being needed to operate the train. In converting one of

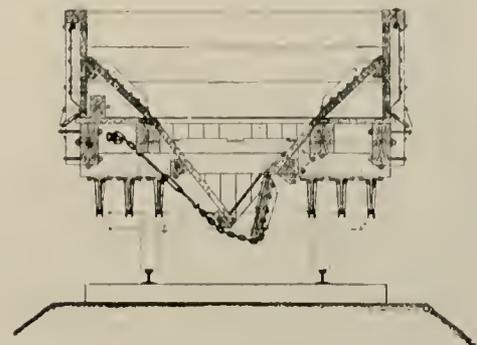

FIG. 4 CLASS CS AS HOPPER CAR.

these cars to the gondola type the work of four men for about 20 minutes is required, no tools except a monkey wrench being necessary.

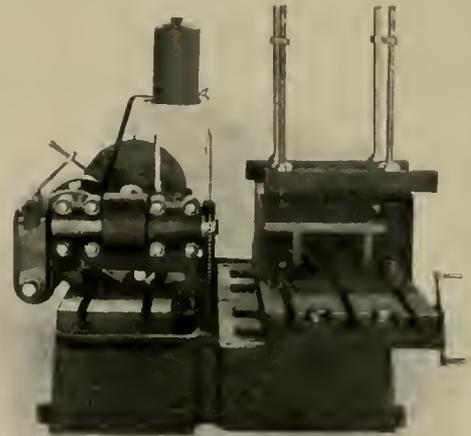

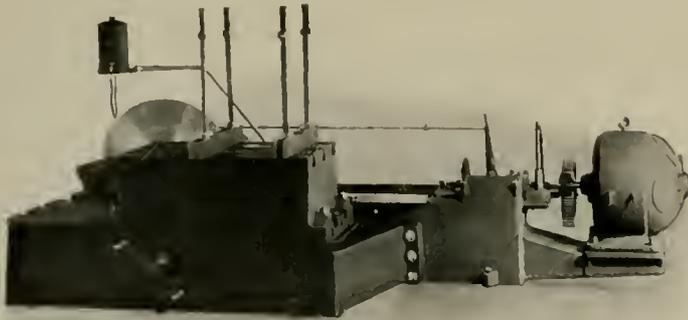

The Canonsburg Street Railway Co. and the borough council of Canonsburg have come to an understanding after considerable controversy in regard to the kind of rails to be used in the town. The company is to be allowed to use T rails, and the time for the completion of the road through the town has been extended to November, 1903. In consideration of the extension of time the company will pay the borough \$3,000.

### ELECTRIC ROAD FOR CUBA.

The project to build an electric street railway in Havana and across the island of Cuba has been under consideration for some time and the plans have now been matured to a degree which makes the project appear certain. Demson, Prior & Co., of Cleveland, are the principal promoters of the new road and have had engineers investigating the route for some time. The engineers have reported favorably on the plans and at a meeting of the promoters held early this month it was decided to begin the work of construction at once. The projectors have formed a corporation capitalized at \$1,000,000 and will build, in addition to a trolley system in the city of Havana, a number of interurban lines. Grants of rights of way across the entire island of Cuba have been secured. The principal interurban line will be from Havana to Baraboa, an important seaport on the south coast. The length of this line is 30 miles and the road will pass through several intermediate towns. Another line will extend from Havana to Sand Beach, and the company claims that this line will be in operation by spring. The parties who investigated the situation report that conditions are ripe in Cuba for transportation facilities such as trolley roads will provide. The carrying of the products of that country from the interior to the coast is an important problem which it is believed would be solved more readily with electric traction than with steam roads, as the distances are comparatively short owing to the limitations of the island.

### METAL SAWING MACHINES.

The accompanying illustrations show one of the latest type of metal sawing machines made by the Q & C Co., and are a part of

Q & C METAL SAWING MACHINE.

the new line of saws that have recently been brought out by the company. Machines of the type shown here have been installed in the new shops of the Lake Shore & Michigan Southern railroad at Collingwood, Ohio, and by the Chicago City Railway Co., Chicago, to be used principally for frog and switch work, but also when required are suitable for a wide range of work on structural shapes, plates, bars, etc.

The machine comprises a heavy bed saw carriage, feeding and driving mechanism, and two work tables that are fitted to the bed. The work is bolted to either of these tables and is cut off by the motion of the saw and carriage being fed into it. The saw blade is 27-in. in diameter, fine tooth, of the arbor-driven type, and has a longitudinal travel of 30 in., giving it a capacity for cutting I beams up to 15 in. in a vertical position, and 8-in. round sections. The arbor is of crucible steel, with the pinion formed solid with it, thus doing away with all possibility of weakness due to a construction where these parts are keyed together. The worm wheel shaft on which the driving pinion is also formed solid, is of hardened crucible steel; the worm is of hardened steel and the worm wheel of phosphor bronze.

The machine has the Q & C Co's. latest type of friction feed, giving an automatic feed variable from 3-16 to 13-16 in. per minute. Motion is given to the feed screw through a crown clutch, which in one position engages with the automatic feed and in another position by friction engages the feed screw with a train of gears giving

a quick return movement to the carriage by power. The lever shown in the engraving actuates this clutch, and by means of a rod passing through a lug on the carriage forms an automatic stop to the saw in both directions. When this clutch is out of gear the carriage can be moved in either direction.

A desirable feature, and one of considerable interest in this saw, is the manner by which the entire travel of the saw blade is made available for cutting off work on the top side table, while at the same time round or square pieces up to 8 in. can be cut off in a V-block, provided for this purpose, at the front end of the table. The side table is in two parts; the lower portion is movable longitudinally upon the base, and the upper portion is movable transversely upon the lower portion of it. This transverse movement is for the purpose of adjusting the work with relation to the saw blades after it has been clamped into position, so as to enable it to be cut off at exactly the desired point without undue time being taken in clamping it.

When the lower table is in its extreme forward position the saw blade can cut off work on the upper side table through the entire range of its travel. By moving this table backwards the V-block is brought within range of the saw blade so that by this method a greater capacity is obtained for a given length of saw travel than is possible in the ordinary construction.

There is 8½ in. of the blade available for cutting above the upper side table, and with its 30-in. travel the machine is very desirable for splitting rails or other material where it is desirable to make long cuts.

### WAGES ADVANCED IN CANADA.

The British Columbia Electric Railway Co., which operates in Vancouver, B. C., Westminster and Victoria, made a general increase in the wages of its employes last month, in addition to which it is introducing a co-operative system, with the object of giving the men a better return for their work and to enlist their interest in the welfare of the company's business. Hereafter all the employes of this company will receive a share of the profits when the latter exceed the amount necessary to pay a 4 per cent dividend on the stock. The amount of profits available for dividends after the payment of the 4 per cent will be divided into three parts, two of which go to the share holders and the remaining third to the employes. The old rate of pay for conductors and motormen was 20 cents an hour for the first year, 21 cents for the second and third years, and 22 cents thereafter. The company now pays 20 cents for the first year, 23 cents for the second and third years, 24 cents for the fourth year and 25 cents for the fifth year and thereafter.

The Indianapolis Street Railway Co. has four pieces of property under consideration for its new terminal station, but unreasonable values have been placed on this property by its owners. None of this property will be purchased at the high prices demanded, and the company may begin condemnatory proceedings to secure a site.

## News of the Month.

Barring unforeseen delays, work will be begun within 30 days on the tunnel extension of the rapid transit system to Brooklyn, N. Y., the bid of the Belmont-McDonald syndicate for this work having been accepted on July 24th. When completed, the tunnel will enable people to ride from the proposed terminal at Flatbush and Atlantic Aves. through to the end of the Belmont system in the Bronx for five cents. President Orr, of the Rapid Transit Commission, is quoted as declaring that the Brooklyn extension will be only the second link in a great tunnel system which will eventually connect all parts of the boroughs of Manhattan, Brooklyn, Queens and the Bronx, with perhaps, in the future, an extension to Richmond.

Residents along the route of the subway in New York are held largely responsible for the unsanitary condition of the excavation. There has been a general disposition on the part of the public to regard the big cut as a convenient dumping ground for rubbish, and the watchfulness of the contractors of each particular section has not sufficed to prevent such use being made of it. This is the statement made by Mr. William Barclay Parsons, engineer to the Rapid Transit Commission, in answer to the complaint of the president of the Board of Health that the conditions existing in the excavations are in some places a menace to the public health. Mr. Parsons, in an interview, contends that "in such an undertaking as the construction of the underground the disturbance of sewers and gas-pipes is bound in a measure to be detrimental to health, yet not more so than the work of repairing mains which is constantly being done by the city authorities. The absence of an epidemic as a result of torn up streets indicates the exercise of uniform care by those having the work in charge."

Two cars for use in the rapid transit subway have been delivered in Long Island City and experimental runs will be made on the Long Island R. R. These cars are appropriately named, No. 1 being the "August Belmont" and No. 2 the "John B. McDonald." No. 1 is painted white, with gold trimmings, and No. 2 is a bright yellow. The cars are 42 ft. long, and have a novel feature in their sloping sides which are designed to conform to the walls of the subway. The sides are vertical to a height of 30 inches, and then slant inward to the roof. The seating arrangements are similar to those on elevated trains, and each is equipped with double folding doors and a device for shutting all the doors of the car simultaneously. The interior is resplendent with polished wood, mirrors and brass work, and illuminated with incandescent lamps. The cars may be run either separately or as trailers. Each is equipped with a searchlight. Both have the word "Interborough" painted at the top. These cars were built by the Wason Manufacturing Co., Springfield, Mass.

The stockholders of the Interborough Rapid Transit Co., at a special meeting in the offices of August Belmont, 23 Nassau St., August 26th, voted to increase the company's capital stock from \$25,000,000 to \$35,000,000, for the purpose of providing funds to defray the expense of building the proposed tunnel from Manhattan to Brooklyn, connecting with the Manhattan underground system. One hundred thousand shares of stock will be issued at \$100 par value.

The Buffalo (N. Y.) Railway Co. has begun tracklaying for its extension to the steel manufactories. Other improvements will be effected which will give a quicker service through the downtown district.

The Rochester, Syracuse & Eastern Railroad Co. has received a certificate from the railroad commission authorizing the construction of its proposed line between Rochester and Syracuse over a private right of way except through cities and villages. Except for a few miles of grading and tracklaying which will be done this fall no construction work will be undertaken until all engineering work has been completed and right of way secured.

The Rochester Railway Co. gave its employes two picnics, on Wednesday and Friday, September 3d and 5th, at Windor Beach. A ball game between men chosen from the employes of the Sudus and Rochester lines was a feature of the entertainment. The picknickers were conveyed to the beach in a chartered car, and were accompanied by a regimental band disposing music.

The Mountain Lake Electric Railroad Co. of Glaver ville, N. Y.,

on whose lines 12 persons were killed and 20 injured in a collision on July 4th, contemplates settling claims for damages by paying the claimants in securities of the company, if these shall be considered acceptable. The company has an issue of 5 per cent bonds on which interest has been paid regularly. These it is proposed to turn over to the heirs of those persons who were killed in the collision of July 4th.

A miniature battle between two gangs of workmen resulted August 26th from the attempt of the Olean (N. Y.) Street Railway Co. to cross the tracks of the Shawmut R. R. in the construction of its extension from Portville to Ceres and Bolivar. After some controversy the Olean company had been granted an order to cross the steam tracks at Ceres, and Mr. T. W. Miller, superintendent, repaired to that place with 20 men to begin the work. The construction crew was met by an equal number of employes of the steam road, who chopped down trolley poles as fast as they were erected and in other ways interfered. A fight resulted in which pickaxes, pick-handles and stones were used, and a number of men, including Superintendent Miller, were injured. Local sentiment favors the street railway company and the desired crossing will undoubtedly be effected.

The suit brought by Abraham L. Graham to recover damages from the North Jersey Street Railway Co. for the death of his son, who was killed by the company's cars, was settled August 23d, after having been tried six times. This was the case in which Justice Gummere of the Supreme Court decided that \$1.00 was sufficient damages for the death of a child. Verdicts ranging from \$3,000 to \$5,000 had been awarded by the juries of the lower courts but were each time set aside by the Supreme Court as excessive. By the settlement the company will pay Mr. Graham \$1,000 and all the costs, amounting to about \$3,000.

The Elizabeth, Plainfield & Central Jersey Railway Co. ran its first car over the bridge at Pieton on its railway branch, August 25th. Three cars were run onto the bridge at once, and this test of its firmness resulted satisfactorily. When the connecting link shall be completed, alternate cars will run through to Plainfield without change, thus traversing a loop from Westfield Junction westward, including Plainfield, Bound Brook, New Brunswick, the Amboys, Rahway and Pieton.

The Jersey City, Hoboken & Paterson Railway Co., of Hoboken, N. J., has awarded the contract for the erection of a new car house in Paterson. The building will cost approximately \$100,000.

The Philadelphia & Lehigh Valley Traction Co., of Allentown, Pa., ran its first car under the "Trenton cut off" bridges on the Bethlehem pike, September 10th, the injunction obtained by the Pennsylvania R. R. restraining the company from running its cars under the bridges having been dissolved the preceding day. Passengers are now carried from North Wales to Flourtown without change of cars.

The new interurban between Meadville, Pa., and Saegertown was opened September 8th, and an extension to Cambridge Springs, 15 miles east of Meadville, will soon be completed. Connections will be made with the line running from Cambridge Springs to Erie, thus making a continuous route of 41 miles.

The Wilkesbarre (Pa.) & Hazleton Railway Co. proposes to establish a summer resort at Triangular Lake, which is a hard some sheet of water on the new electric line between Wilkesbarre and Hazleton. The site is an exceptionally good one, and is accessible by half-an-hour's ride from either city. In addition to a hotel and the usual resort attractions, cottages may be erected and every means will be availed of to draw a summer population.

The annual outing of the Pittsburg Railways Co. was notable this year for several novel amusement features. As it was impossible to care for the 4,000 employes on one occasion, two picnics were arranged, each of two days' duration. The first, on August 28th and 29th, was especially for the employes of the Consolidated and Monongahela systems; the second, on September 10th and 11th, for the United Southern and Birmingham employes. These rules, however, were not stringent, and the employes of any division might, if desiring, share in either event. Many sports and amusements were arranged, perhaps the principal of them being

a ball game which was umpired by President James D. Callery who personally gave a prize of \$50 in gold to the winning team. Prizes awarded the winners of other contests amounted to \$300 in cash. One share of stock was offered to the employe having the largest family at the picnic, certificates of birth or other proof being required to authenticate the statements of the contestants, and this plan not only proved a fortunate one as affording entertainment, but served the purpose of the entertainers in greatly increasing the attendance. On the days devoted to picnicing car schedules were shortened on all the company's lines so that no employe might lack an opportunity to spend a few hours at least at Calhoun Park, which was the scene of the festivities.

The Pittsburg Express Co., which was organized some years ago under the direction of the late C. L. Magee to operate trolley express cars over the railways in Pittsburg, has decided to discontinue business and shipments will not be received for transportation after September 30th. The company was originally organized with a capital of \$100,000, and several of the larger express concerns of Pittsburg were absorbed by it. For the first year the business did not meet the expectations of the promoters, but after Mr. C. V. Wood, of Beaver, was made general manager of the system, several innovations in the service were introduced and the street railway express became a profitable business. Stations were established in East Liberty, Homestead, Braddock, Turtle Creek, McKeesport and Carnegie in addition to the central office in Seventh St., Pittsburg. Ten cars and 10 wagons have been operated, but owing to the discrimination of some of the boroughs in favor of less expensive service the business has lately resulted unprofitably and will be abolished at the end of the month.

The Philadelphia Rapid Transit Co. has completed plans for two emergency houses and a motormen and conductors' building. The emergency houses will be two and a half stories high and will be located one on the southeast corner of 41st and Walnut Sts. and the other at 915-17 Walnut St. It is the intention of the company to convert the old car house at Allegheny Ave. and Richmond St. into comfortable quarters for its conductors and motormen. It will contain a library and other facilities of the club-house. The Philadelphia Rapid Transit Co. has frustrated another extraordinary attempt on the part of professional swindlers to mulct it for damages. One William Doran, reported to be an accomplished acrobat and contortionist, has been arrested in New York on the charge of instituting bogus damage suits against Philadelphia street railways. Doran is alleged to have made a practice of permitting himself to be struck by street cars going at the rate of 30 miles an hour, his proficiency as an acrobat preventing his being run over or seriously injured.

It is stated that the Philadelphia Rapid Transit Co. contemplates taking over the property of the Fairmount Park Transportation Co. The officials of the former however are quoted as denying the report.

The West Chester (Pa.) Street Railway Co. has recently increased its capital stock from \$300,000 to \$1,000,000, and has franchises for proposed lines to cross Chester County in several directions. This company opened its new extension of the West Chester & Lenape branch, which was recently purchased from the Wilmington & Northern R. R., August 31st. The extension runs from Lenape to Downingtown, a distance of 14 miles. The road was built by the Tennis Construction Co., which has all the contracts for the West Chester company's contemplated construction work. A franchise has been secured in Parkersburg for the proposed line of the West Chester company from Downingtown to Coatesville and Parkersburg, which is to be opened for traffic early in October. The line to Kennett Square will probably be in operation by October 15th.

Surveys are being made for the York County Traction Co.'s proposed extension from York, Pa., to Wrightsville, a distance of 11 miles, and from York to Hanover along the York and Gettysburg pike, passing through Spring Grove and Thomasville. The extensions when completed, one in an easterly and the other in a westerly direction, will be the connecting link in the two traction systems which will eventually reach Washington by way of Gettysburg and Philadelphia by way of Columbia. Construction work will be under way in the early spring and will be pushed to completion as rapidly as possible. An auxiliary of the York County Traction Co. was recently organized and has been incorporated

with a capital stock of \$25,000 under the title of the Wellsville Street Railway Co. to build an electric line from Dover to Wellsville.

The perpetual charter recently granted to the Princess Anne (Md.) & Deal's Island Light, Power & Railroad Co. gives the company the right to use the county roads in Somerset County and the streets of Princess Anne and intermediate towns for the construction of a 25-mile electric line to Deal's Island, with lateral lines, and to furnish electricity for lighting, heating and industrial purposes. The proposed road runs over a level country through a prosperous farming and village section. It should receive a large business at Deal's Island from all the products of the country bordering on Chesapeake Bay. Connections will be made by steamers to points north and west. Local interests have largely subscribed to the stock of the Princess Anne & Deal's Island company, and outsiders will be invited to do so. The company has an authorized capital stock of \$200,000, and an authorized bond issue of \$150,000. The officers of the company are: Hampden P. Dashfield, president, and William F. Lankford, secretary; and H. P. Dashfield, O. T. Beauchamp, Roger Woodward and S. F. Dashfield, executive committee.

The Natchez (Miss.) Electric Street Railway & Power Co. has purchased the entire property of the Natchez Electric Light & Transit Co., proposing to enlarge that company's old power house to handle both the street railway traffic and the electric lighting business. A part of the present track system will be rebuilt, a new car house will be erected and additional equipment will be installed.

Natchez parties are believed to be interested in a proposed electric railway from Biloxi to Pass Christian, about 25 miles in length, passing through Beauvoir, Mississippi City, Gulfport and Long Beach. Nothing definite has been done as yet toward advancing this project.

The Rapid Transit Company of Chattanooga has ordered six large passenger cars of the John Stephenson Company which will soon be delivered and put in commission on the city and suburban lines in Chattanooga. The track system is to be extended and improved and a large sum will be expended on the mountain line. It is announced that the company will soon begin issuing universal transfers. Formerly, transfers were issued only to purchasers of books of tickets.

The Birmingham (Ala.) Railway, Light & Power Co. will, after September 20th, issue transfers to any point on its system within the five-cent fare limit.

Mr. Percival Moore, vice-president and general manager of the Louisville (Ky.), Anchorage & Pewee Valley Railway Co., recently invited the municipal officers and leading business men of Louisville to make a trip of inspection over that company's completed lines to Lyndon and Beard. The power house and offices of the road are located at Lyndon, and these were made the subject of special attention. Seven cars have been ordered for the Louisville, Anchorage & Pewee Valley Ry. They will be 47 ft. long, with a capacity of running 45 miles an hour. The trucks will be equipped with four motors of 57-h. p. each. The fenders will be of the regulation locomotive "cow-catcher" pattern, a novelty in this part of the South; the interior will be finished in mahogany and illuminated with 15 incandescent lights. Rattan seats, water coolers, chemical fire extinguishers, lavatories and parcel-racks will complete the appointments of the cars, which will cost approximately \$8,500 each.

The electric interurban between Hagerstown, Md., and Boonsboro has been opened for traffic, and nine cars are run in each direction daily. Though the passenger traffic has been all that might be expected since the opening of the line, the transportation of freight has been the chief feature of the business, especially the transportation of peaches. A fare of 50 cents is charged for the round trip between Hagerstown and Boonsboro.

Press reports state that the passenger business of the Kentucky & Indiana Bridge & Railroad Co., of Louisville, will be taken over by the New Albany (Ind.) Railway Co. if pending negotiations are consummated. The New Albany company is building a line to Jeffersonville, and preparing to extend its facilities in New Albany. The Kentucky & Indiana Bridge & Railroad Co., operating what is popularly known as the Daisy Line between New Albany and Louisville, contemplates making the freight traffic on

this road its exclusive business, and may turn the passenger traffic over to the New Albany company under lease.

Rumors are still in circulation concerning a merger of the interurban interests at Columbus, O. The plans under advisement contemplate practically a consolidation of the Appleyard, Webb-Fisher and Mandelbaum-Pomeroy syndicates, and the completion of direct systems from Columbus to Cincinnati, Cleveland and Indianapolis. At present, the Columbus, Buckeye Lake & Newark Traction Co. has not been included in the negotiations. The Central Market line at Columbus, which is to control the loop, will soon be opened for traffic. It is expected that the universal transfer system will be established with the opening of this route.

Eight new passenger cars for the Central Market line have arrived in Columbus and will be used on the loop until the Central market is put in operation.

The Columbus, Delaware & Marion Railroad Co. recently inaugurated its service from Delaware to the Franklin County line, a distance of 14 miles, and a two-hour schedule has since been maintained. The company fired the boilers at the Stratford power house for the first preliminary trial September 11th. Rapid progress is being made on the line between Delaware and Columbus which is soon to be open for traffic, and the company has just completed stringing its private telephone line from Columbus to Stratford.

The Columbus, London & Springfield Railway Co. will within two months put several 60-ft. freight and express cars in commission of its lines, the freight traffic having increased to such an extent that special equipment for the accommodation of the service is considered indispensable. This company ran its first through cars on a regular schedule, August 24th, accommodating an especially heavy passenger traffic without accident or delay. The running time is at present two hours and fifty minutes, but this will be reduced so soon as arrangements can be perfected for increasing power-house facilities at the Columbus end of the route.

The Columbus, New Albany & Johnstown Traction Co. is rapidly completing its street improvements in Columbus. The company did a heavy business in carrying crowds to the New Albany camp meeting during the last week of August.

It is now proposed to erect at Columbus a union freight and passenger depot for the interurbans entering that city. Options have been secured on a desirable site on the north side of West Broad St. at the corner of Park St.

The municipal code affecting electric railways prepared under the direction of Governor Nash to be presented to the special session of the Ohio Legislature contains provisions limiting franchises to a term of 25 years, and making them subject to revision every 10 years by the councils of municipalities, which are given the right, in changing franchises, to regulate the price, the rate of fare or other conditions of travel. Senator Hanna, in consultation with members of the Legislature August 27th, is alleged to have favored perpetual franchises but to have endorsed the provision reserving to municipal councils the right to revise grants every 10 years. He is further quoted as opposing the constitutional amendment proposed by Senator Foraker allowing the enactment of special laws for municipalities, and the provision of the Nash code which propose a tax of 5 per cent on the gross earnings of public service corporations.

The Miami & Erie Canal Transportation Co. on August 17th opened its new route, propelling four canal boats from Hamilton to Lockland by electricity. The run was made in three hours, which is much longer than will be required ultimately, and as an experimental trip it was entirely a success. It is locally rumored that the company will add a passenger service to the freight service over this route, between Dayton and Cincinnati and eventually between Cincinnati and Toledo, but no announcements to this effect have as yet been authorized. The Miami & Erie company is making rapid progress in construction work between Lockland and Cincinnati. Tracklaying and ballasting have been completed for a greater part of the distance to be covered.

The Cleveland, Elyria & Western Railway Co. has completed its bridge over the Vermillion River at Birmingham and is now competing with the Lake Shore Electric Ry. for the traffic between Cleveland and Norwalk. The Cleveland, Elyria & Western and the Lake Shore have effected a traffic agreement whereby the

former enters Norwalk over the Lake Shore tracks. The distance between Cleveland and Norwalk is 57 miles, and is made by the Cleveland, Elyria & Western in three hours.

The Toledo, Bowling Green & Southern Traction Co. has nearly completed its new power house at Cygnet, which will be put in operation so soon as the dynamos shall be installed and the stack erected.

The Jackson (Mich.) & Suburban Traction Co. opened its new casino at Wolf Lake, August 20th, conveying some 2,000 passengers to and from the lake on the opening day, and operating seven of the large summer cars for their accommodation. The casino is a spacious and modern building. The ground floor is used as a restaurant; the second is furnished for dancing, and on the roof is an attractive summer garden. Heating facilities have been installed and the casino will be kept open until November 1st.

The Detroit United Ry. has issued the second edition of its recent publication entitled "Detroit, 1902." The book, which contains cuts of the principal buildings and parks of the city, and full information concerning street railway routes to points of interest, is designed as a souvenir, and a guide to excursionists. The photographic views include the island and the many summer resorts along the Detroit River, and a "bird's-eye" view of the city and its environs.

The electric line between Oshkosh, Wis., and Omro, 10 miles distant, was put in operation September 10th.

Two interurban railways, from Manitowac, Wis., to Green Bay, 39 miles, and from Green Bay to Kaukauna, 10 miles, are projected by the Construction & Equipment Co., which also has under consideration several other routes in Wisconsin. Cleveland, Pittsburg and New York parties are interested, and the entire charge of the proposed construction work will be given to Mr. J. H. Martin, whose headquarters will be in Green Bay.

The Indianapolis, Shelbyville & Southeastern Traction Co. has opened its new line between Shelbyville and Indianapolis, a distance of 28 miles, and cars are operated at intervals of 30 minutes. The run between the termini is made in an hour and 18 minutes, 18 minutes being required for the run within the corporate limits of Indianapolis. The contract for the construction of this road was awarded to Townsend, Reed & Co. on September 26, 1901, and actual work was begun on the grading on October 21st. The road is thoroughly ballasted, and there are 28 bridges en route, 11 of which are of steel construction, one a stone arch bridge and one a concrete arch. The longest bridge is at Shelbyville and is 200 ft. in length. The steepest grade is only 4 per cent. The officers of the company are: E. K. Adams, president; Albert de Prez, vice president; T. E. Goodrich, secretary, and John R. Messick, treasurer. The general offices and power house are located at Shelbyville.

The Union Traction Company of Indiana is eliminating curves and otherwise improving its system between Marion and Indianapolis with a view to making the run between these cities in the same time as the steam roads, which is two hours and 45 minutes.

The Indianapolis & Martinsville Traction Co. began running cars through to Brooklyn, August 31st. The line between Brooklyn and Martinsville is to be opened for traffic by November 1st.

The Fort Wayne & Southwestern Traction Co. has applied to the postal authorities for permission to carry mails between Fort Wayne and Wabash, Ind.

The County Attorney of Cook County, Illinois, in an opinion given August 20th, declares the board of assessors and the board of review to have no jurisdiction to assess the franchises granted to street railway, telephone, electric light and gas companies, the jurisdiction to make such assessment, according to the county attorney's opinion, being vested in the state board of equalization. The opinion further states: "It is clear from the express provision of the statute that the state board of equalization has exclusive jurisdiction to value the capital stock of these corporations and to assess the same, including the franchise, over and above the assessment of the tangible property as made and returned by the local assessors. The term 'capital stock' means all the property and rights of the corporation of every kind and nature. The general assembly has, however, by particular description, placed certain properties of these corporations within the jurisdiction of the local assessing tribunals for valuation and assessment. The properties under discussion, consisting of the rights of user and

occupancy of the public streets, have not been so placed, but have by the terms and express provisions of our revenue law been placed within the jurisdiction of the state board of equalization."

An uncommon accident happened to the Lake St bridge of the Lake Street Elevated Railroad Co., Chicago, September 7th. The electric wires beneath the flooring of the bridge became crossed, causing a fire which damaged the motors employed to raise and turn the bridge. The only remedy of the difficulty was to lower the bridge for two inches, an action which the company was reluctant to take as it would throw the track proportionately out of alignment and it was feared that an accident to passing trains might result. Pending a decision, tugs and steamboats bound up the river were blockaded, and an appeal was made to the harbor authorities to require the mending of the bridge at once in order that it might be opened for the boats to pass. After six hours' delay the bridge was lowered and repairs begun. It was found that by running slowly and with caution the cars could cross with entire safety.

The Gage Hotel Co. has brought suit for \$300,000 damages in the Circuit Court against the Union Elevated Railroad Co., of Chicago, alleging that its property, the Wellington Hotel, at Jackson Boulevard and Wabash Ave., has diminished in value owing to the contiguity of the elevated loop, and that the patronage of the hotel has decreased because of the noise of the trains.

The Aurora, Elgin & Chicago Ry., a complete description of which recently completed system was given in the Street Railway Review last month, pages 441-459, began its passenger service August 25th. The first train carried no passengers or guests except the officers of the company, but subsequent trains were crowded and the service has been eminently satisfactory from the beginning. For the present trains are run at intervals of half an hour, the running time from the Garfield Park terminus of the Metropolitan elevated to Aurora being an hour and a quarter. Trains will be composed of four cars and will be run more frequently so soon as the road is in full running order, and the time will be reduced to one hour for local trains and 45 minutes for express trains.

The Chicago City Railway Co. will soon put in service 80 additional cars of the same type as the 125 double truck cars built for it by the St. Louis Car Co.; the order for the 80 new cars was given to the same company.

The Rockford (Ill.) Railway, Light & Power Co. during the recent Chautauqua assembly, adopted the plan of employing small boys on its cars, whose duties were to keep the trolley on the wire in rounding curves, to ring the bell for the motorman to stop or start, to tighten brakes when stops were made and otherwise to relieve the busy conductors. The boys gave satisfactory service and were paid 10 cents an hour. One 13-year-old boy made a record by working 16 consecutive hours in a day.

Two new companies have been organized to build electric inter-urban railways in Illinois. The Springfield & Central Illinois Railway Co., capitalized at \$200,000, projects a system connecting Springfield and Bloomington, and Bloomington, Decatur and Jacksonville. Its principal promoters are St. John Boyle, vice-president of the Louisville (Ky.) Railway Co., and C. K. Minary, treasurer and manager of the Springfield Consolidated Ry. The Danville, Paxton & Wilmington Electric Railway Co., of which J. P. Middlecoff, of Paxton, Ill., is president, has been incorporated to build a line between the cities named in the title.

The Chicago & Milwaukee Electric Railway Co. expects to complete its extension from Lake Bluff to Libertyville this month. Six miles of double track have been completed, as well as a brick power house and depot at Libertyville. The road will later be extended to Fox Lake.

The Alton (Ill.) & East Alton Railway & Power Co. has begun the construction of a four-mile line from the terminus of the Alton Railway, Gas & Electric Co.'s lines in Alton to East Alton. The extension, when completed, will be leased by the Alton Railway, Gas & Electric Co.

The Kansas City & Olathe Electric Railway Co. has nearly completed the grading of its line from Kansas City, Mo., to Olathe, Kan., and will receive bids on 50,000 ties, 1,824 tons of 60-lb. steel rails, and relays, new or in good repair. Fred C. Goodwin, of Kansas City, Mo., is president of the company.

Rumors are in circulation to the effect that all the street railway

systems in Portland, Ore., may eventually be consolidated by the Baltimore interests which organized the United Railways & Electric Co. of Baltimore in 1899, and recently effected the consolidation of the lines in San Francisco. The plan, as reported, contemplates the merger of the Portland Railway Co., operating a 35-mile system; the City & Suburban Railway Co., a 70-mile system, and probably the Oregon Water Power & Railway Co., a 25-mile system, under the title of the United Railroad & Electric Co.

The City & Suburban Railway Co., of Portland, is now building 12 closed cars for fall traffic, which will be 36 ft. long and vestibuled at both ends. The Oregon Water Power & Railway Co. has awarded contracts for the construction of a 5½-mile electric line between Lentz and Gresham. Contracts for the construction of 25 miles additional will later be awarded.

The Everett (Wash.) Street Railway Co. has awarded contracts for the construction of extensions of its lines at an estimated cost of \$100,000. It is stated that the Everett company will purchase new rolling stock.

On August 26th the first car was run over the new lines of the Seattle-Tacoma Interurban Ry. The car carried the officers of the road and the mayor and other city officers of Tacoma to Seattle to attend the Elks' carnival in the latter city.

The Northwestern Development Syndicate of Nelson, B. C., will apply to the Provincial Parliament at its next session for a franchise to construct a 10-mile electric railway for the transportation of passengers and freight through the mining district near Nelson. Power for the operation of the proposed road will be supplied from the syndicate's present plant on Menhemick Creek, the capacity of which will be greatly increased for this purpose.

The United Railroads of San Francisco will soon place a new transfer system in operation which will give additional privileges to passengers. The company's new power house is nearing completion, and contracts for about half the steam and electrical machinery required have been awarded. This plant will have a capacity of 16,000 h. p.

A. J. Babcock, chief engineer of the North Shore Railroad Co., has returned from the East and is perfecting plans for the conversion of the narrow gage steam road formerly known as the North Pacific Coast R. R. into an electric line. The third-rail system is being favorably considered, and the change to electric traction is to be effected not later than March 1, 1903.

The Pacific Electric Railway Co., of Los Angeles, Cal., is erecting a new power house at Los Angeles in addition to the Pasadena plant. The new station will contain one 1,050-kw. direct current generator; two 1,500-kw. three-phase generators, and three 600-kw. and five 200-kw. motor generator sets. One 650-h. p. Ball & Wood cross-compound condensing engine; one 450-h. p., and one 250-h. p. machine of the same type as is now used in the Pasadena plant, and an additional equipment of one 200-h. p., and two 2,500-h. p. McIntosh & Seymour cross-compound condensing engines will be installed. Steam is to be furnished by four 250-h. p. Stirling boilers, and later an addition of eight 400-h. p. Babcock & Wilcox boilers will be made. The officers of the company are: H. E. Huntington, of San Francisco, president; Epes Randolph, of Los Angeles, vice president and general manager; E. E. Bacon, of Los Angeles, secretary, and I. W. Hellman, of San Francisco, treasurer. F. Van Vranken is superintendent of the Los Angeles plant and W. H. Smith of the Pasadena plant.

The proposed electric railway from Santa Cruz, Cal., to Capitola and other resorts and suburban towns will be completed in the early spring if the bonuses asked by the promoters shall be conceded. The road will border the Bay of Monterey for a distance of three miles, serving the city of Santa Cruz and the resorts and villages of East Santa Cruz, Seabright, Twin Lakes, Del Mar and Capitola. Santa Cruz has an average population of 7,000 except in the summer when it is twice as great, and the other places en route have at present an aggregate population of 6,000 and are growing rapidly. The promoters have purchased the Monterey & Pacific Grove Street R. R. and are converting it into an electric railway which will serve as a feeder to the Santa Cruz-Capitola resort line. Mr. F. W. Swanton, of Santa Cruz, has been principally identified with the work of building up the resorts on the Bay of Monterey and is largely interested in the present project for the construction of an electric line connecting them. The route lies through one of the most beautiful sections of California.

**GEORGE W. KNOX.**

George W. Knox, the president of the Knox Engineering Co., has had an extended and varied experience in electric railway practice, which in his present work cannot but prove to be of the greatest value to him. After graduation from the Northern Illinois College in 1885 he was with the Chicago, Burlington & Northern Railway Co., in the mechanical department for two years, and in 1887 went with the Pullman Palace Car Co., street car department, where he was engaged till he took up electrical work with the Thompson-

Houston Co., in equipping the first cars that went west of the Mississippi River, these cars being for Omaha. In 1888 he joined the old Sprague company with headquarters at Chicago. While with the Sprague company Mr. Knox was employed as assistant engineer on the installation of the West Side line at Milwaukee, and in 1890 he was sent to Minneapolis and St. Paul as assistant to the chief engineer, in charge of the equipment of these roads, which comprised over 200 miles of track, one of the largest contracts ever let for electrical equipment of a road; here he had charge of the

G. W. KNOX.

equipment of the interurban road between Minneapolis and St. Paul, with what was then considered high-speed motors, 25 miles per hour. In May, 1891, having finished the Minneapolis and St. Paul installation, Mr. Knox was sent by the Edison General Electric Co., which had purchased the interests of the Sprague company, to Milwaukee, as assistant to the chief engineer in charge, to equip the remaining horse railway lines of that city. He remained in Milwaukee until the fall of 1891, when he was put on special installations throughout the country, going to Cincinnati, Columbus, Newark, Lincoln and Springfield, Ill., St. Joseph, Mo., and other places. In the spring of 1892 he changed over the storage battery system of the Dubuque Street Railway to the overhead system, being still in the employ of the Edison General Electric Co. In the fall of the same year he was sent by the General Electric Co. to Kansas City, Mo., to install the motors and generators on the Kansas City Elevated Ry.

While at Kansas City Mr. Knox was offered a position, through the late M. K. Bowen, with the Chicago City Railway Co., and the 160 miles of this road was equipped throughout under his charge. He was later made, in addition to electrical engineer, engineer of the construction for the company, having charge of the construction of all track and special work for the company. Mr. Knox remained with the Chicago City Railway Co. until 1900, when he resigned to take up general railway construction and engaged with Kohler Bros., as manager of the railway department. Early in the spring of 1901 he severed his connection with Kohler Bros., and opened an office as electrical engineer and builder.

The class of work with which Mr. Knox has been identified during the last sixteen years would naturally insure the immediate success which has come with this venture and which is attested by the line of interurban roads under construction during the past eighteen months.

Mr. Knox has had associated with him, during the last year and a half, Mr. R. M. Heskett, a graduate from the Armour Institute of Technology, with a number of years' railway experience to his credit. Mr. Heskett will be closely identified with Mr. Knox in his future work.

**TOLEDO RAILWAY MEN BANQUET.**

September 11th the members of the operating department of the Toledo Railway & Light Co., assembled at the railway company's Casino, where a banquet was served. Those in attendance were John F. Collins, superintendent; J. S. Young, assistant superintendent; P. Boyle and Harro Harrsen, division superintendents; A. Sherman, Earl Coffin, James Hallett, Edward Hagerty, E. Mc Gangan, M. E. Johnson, dispatcher; J. Anglan, F. H. Sterns,

Thomas Eslinger, C. Caldwell and Ben Walker, inspectors. An ornamental desk clock was presented to Mr. Collins, the presentation speech being made by Mr. Harrsen. On the clock was engraved "To John F. Collins, Superintendent the Toledo Railway & Light Co., from his Helpmates of the Operating Department."

After the banquet the afternoon was spent in seeing the play at the Casino, riding on the scenic and miniature railways and a shooting contest in which Mr. Collins took first honors. The party returned to the city on a special car after being photographed in a group.

**WASHINGTON (PA.) & CANNONSBURG INTERURBAN.**

An electric railway between Washington, Pa., and Cannonsburg, a distance of about nine miles, is being constructed by the Cannonsburg & Washington Street Railway Co., and the road will constitute an extension of the present line in Washington, Pa. The company is doing its own construction work, and owing to several bridges which must be built, material for which cannot be obtained under eight months, the road cannot be ready for operation before spring.

**AUGUSTA-AIKEN INTERURBAN OPENED.**

The new interurban road between Augusta, Ga., and Aiken, N. C., was opened for traffic August 28th; the cars making the initial trip carried several officers of the company and a large number of invited guests. Special cars took the party from Augusta to Aiken and the appearance of the handsome new cars of the company was greeted with great enthusiasm by the dwellers along the route. The excursion was accompanied by a band of music and after its return to Augusta a barbecue was served by the railroad company accompanied by speeches, music and general rejoicing. The length of the new road is 23½ miles and it parallels the South Carolina & Georgia Ry. for a large part of its route.

**WIRE THIEVES IN NEW JERSEY.**

Six times within a few weeks the Valley Road line of the North Jersey Street Railway Co. has been crippled by wire thieves. The last attempt was made August 18th, when about 1,000 ft. of copper wire was taken down from the poles. At the time of this theft detectives were watching the south end of the town, where the thieves operated the night before, and the loss was only discovered when the first car in the morning reached Mount Clair. The service was suspended for several hours before new wire could be procured and put into place.

**NEW CARS FOR PITTSBURG.**

In connection with the description of the open cars, illustrated on page 491 of our issue for August, which the St. Louis Car Co. is building for the Pittsburg Railways Co., it was stated that six of the cars had just been completed. The number should have been sixty.

**THE WABASH SPECIAL.**

The Wabash Railroad has issued an announcement that for the meeting of the American Street Railway Association it will make a rate of \$9.00 for the round trip from Chicago to Detroit on the certificate plan. A special train of parlor cars (one of which is reserved for ladies) and dining car will leave Chicago Tuesday afternoon, October 7th, at 1:00 p. m., from the station at Dearborn and Polk Sts., and will run through to Detroit, arriving at 7:00 p. m. Dinner will be served on the train until the arrival at Detroit. For those not able to take the A. S. R. A. Special the Wabash has trains leaving Chicago at 11:00 a. m., at 3:03 p. m. and at 11:00 p. m. The special will be personally conducted by Mr. N. C. Keeran, who has had charge of the A. S. R. A. Special trains to the Conventions for the last five years. Applications for space, which should be reserved as early as convenient, should be made to N. C. Keeran, No. 97 Adams St., Chicago, or to T. F. Harrington, 8th and Olive Sts., St. Louis.

## PERSONAL.

MR. D. W. DOZIER has resigned as chief mechanical engineer of the Metropolitan Street Railway Co., of Kansas City.

MR. J. Z. GEORGE has resigned as manager and purchasing agent of the Vicksburg (Wis.) Railroad, Power & Manufacturing Co.

MR. A. B. CORYELL, formerly of Waverly, Tenn., has been appointed superintendent and manager of the new electric railway at Huntsville, Ala.

MR. D. W. GORDON has resigned as superintendent of the Lake Cities Electric Railway Co. of Michigan City, Ind., and will remove to Chicago.

MR. J. M. LOFTUS, formerly superintendent of the Newark & Granville lines of Newark, O., has been appointed general manager of the Indianapolis-Martinsville Rapid Transit Co.

MR. M. A. HAYS, formerly with the Southern Railway, has severed his connection with that company to become secretary of the Chamber of Commerce, of Sault Ste. Marie, Mich.

MR. NICHOLAS HAMILTON has resigned as assistant superintendent of the Youngstown (O.) & Sharon Street Railway Co. Mr. Hamilton has not announced his plans for the future.

MR. THOMAS ADDISON, president of the Sacramento Electric, Gas & Railway Co., resigned that position at the annual meeting of the board of directors and Mr. Albert Gallatin was elected his successor.

MR. THOMAS B. WHITTED, manager of the sales department of the General Electric Co., at Denver, has resigned that position to become manager of the gas and electric enterprises owned by Joseph J. Henry.

MR. B. H. RANNELS has resigned as general manager of the Dayton & Kenton Railway Co. and is devoting all of his time to the Cincinnati, Milford & Goshen Street Ry., with which he is prominently identified.

MR. J. W. PERRY has been appointed chief of the electrical department of the H. W. Johns-Manville Company with headquarters in New York City. He was formerly the company's representative in Philadelphia.

MR. F. W. EMERY, formerly of Knoxville, Tenn., has been appointed general manager of the proposed electric interurban between Galesburg and Kewanee, Ill. Mr. Emery will establish his permanent home in Kewanee next month.

MR. A. HALL BERRY, who for many years has been associated with the H. W. Johns Co., as manager of the electrical department, has resigned to become general manager for F. H. Lovell & Co., with headquarters at 100 William St., New York.

MR. B. J. LAMBERT has resigned as chief engineer of the Waterloo (Ia.) & Cedar Falls Rapid Transit Co. to become instructor in civil engineering in the state university at Iowa City. Mr. Lambert graduated from this university in 1900.

MR. WILLIAM LINTERN, formerly master mechanic of the Cleveland, Elyria & Western Ry., has resigned that position and is now giving all his time to the interests of the Nichols-Lintern Co. His headquarters are at No. 312 Electric Bldg., Cleveland.

MR. NICHOLAS RIVIERE, who resigned a year ago from the position he had long held as secretary and treasurer of the St. Charles Street Railroad Co., New Orleans, La., has been appointed to again fill this position by the new management of the road.

MR. FRANK MILLER will act as salesman throughout the New England territory for C. J. Harrington, of New York, manufacturer of electric railroad supplies. Mr. Miller was formerly superintendent and passenger agent of the Worcester (Mass.) & Webster Street Railway Co.

MR. EDWARD B. GRIMES, who for 18 years has been connected with the Dayton Herald and since 1885 has been its editor, has resigned that position to become superintendent of the Ohmer Car Register Co., of Dayton. Mr. Grimes retains his financial interest in the Herald.

MR. F. W. EDMUNDS, who was for several years secretary of the Q. & C. Co., and had charge of the steel department when that company represented the Pennsylvania Steel Co., is now with Wornham & Major, of 29 Broadway, N. Y., engineers and manufacturers' representatives.

MR. WILLIAM WAMPLER, formerly a representative of the Stuart-Howland Company, Boston, Mass., has resigned his position

to accept one as sales agent for the Peckham Manufacturing Co., and he is now looking after the interests of this company during an extended trip through the far West and the Pacific Coast.

MR. GEORGE C. EWING has resigned as president of the Morris Electric Co. and the American Union Electric Co., of New York, and has taken offices in the Board of Trade Bldg., Boston, for the general agency of street railway material. He also represents the Nernst Lamp Co., of Pittsburg, in New England.

MR. F. L. MOWRY has resigned as clerk of the Hartford (Conn.) & Springfield Street Railway Co., and, it is understood, will superintend the construction of new lines in Ohio for the National Construction Co. The employees of the Hartford & Springfield company presented Mr. Mowry on his departure with a smoking set in gold and silver.

MR. J. W. DUGGAN, formerly superintendent of rolling stock of the Youngstown (O.) & Sharon Street Railway Co., has been appointed to a similar position with the Worcester (Mass.) & Webster Street Railway Co.; the Webster & Dudley Street Railway Co.; the Worcester & Connecticut Eastern Street Railway Co. and the People's Tramway Co. of Putnam, Conn.

MR. B. S. JOSSELYN, on August 30th, resigned as general manager of the Kentucky & Indiana Bridge & Railroad Co., to become general manager of the Hudson Valley Railway Co., Waterford, N. Y. Mr. Josselyn has had an extended experience in steam railroad work, and has occupied the position of general manager of the Kentucky & Indiana company for the last three years.

MR. C. F. GLADFELTER severed his connection with the Chicago Electric Traction Co., on June 30th, to become auditor for the Miami & Erie Canal Transportation Co., of Cincinnati. Mr. Gladfelter will be remembered as having been identified with Chicago street railways since 1897 when he was connected with the Englewood & Chicago Electric Street Railway Co.

MR. C. D. PORTERFIELD, engineer and salesman for the Atlas Railway Supply Co., Chicago, has just returned from a very successful business trip in Europe. Mr. Porterfield had charge of the exhibit of his company at the Light Railway and Tramway Exhibition in London during the first two weeks in July. Since that time he has been traveling over England and the continent.

MR. W. O. HANDS has resigned as superintendent of the Northeastern Division of the Metropolitan Street Railway Co., of Kansas City, Mo., and taken a position on the engineering staff of the company. His long experience in railway construction will make his service specially valuable to the company in the large amount of new work which is now under way in the department.

PROFESSOR GEORGE F. SEVER, of Columbia University, who was last year superintendent of electrical exhibits at the Pan-American Exposition, has been appointed electrical engineer of the Department of Water Supply, Gas & Electricity of New York City. Professor Sever, who is consulting engineer for Wendell & McDuffie, of New York, has supervised the plans of the proposed electric railway between Oneonta, Cooperstown & Richfield Springs, N. Y.

MR. JAMES P. POTTER has been appointed general superintendent of the Oakland Transit Co., San Francisco, and has assumed the duties of that position. Mr. A. H. Smith has been appointed general superintendent of all the lines of this company, Mr. E. E. Thornton, superintendent of the Haywards division, and C. P. Piper, superintendent of the eastern and western divisions.

MR. CHARLES G. WINGATE, son of the late Gen. W. Wingate who was formerly vice-president of the Brooklyn Elevated Railroad Co., is now in the New York office of the Crocker-Wheeler Company. Mr. Wingate was formerly superintendent of the Ridgewood Ave. division of the Brooklyn Rapid Transit Co. and has had charge of the construction of several electric lines in Connecticut and New York.

MR. L. E. GOULD, who for the last year has been assistant electrical engineer of the Aurora, Elgin & Chicago Ry., has been appointed electrical engineer for the Sterling, Dixon & Eastern Electric Railway Co., with headquarters at Sterling, Ill. Mr. Gould has had an extended experience with third-rail electric lines, having been with the Albany & Hudson Railway & Power Co. during construction and the first year of operation.

MR. F. J. GREEN, of Springfield, O., has resigned as general manager of the Dayton, Springfield & Urbana Electric Railway Co.,

and, it is stated, will engage in the construction of new electric lines. He will be succeeded by Mr. Richard Emory, general manager of the Columbus, London & Springfield Ry., who will retain his office in the latter company while discharging his duties as general manager of the Dayton, Springfield & Urbana road.

MR. O. E. OLESON, who for the past six years has been chief engineer of the Toledo Railway & Light Co. and its predecessor, has resigned to become the chief of the engineering department of the Twin City Rapid Transit Co., at Minneapolis. On leaving Toledo, Mr. Oleson was presented with an Elks' ring inlaid with diamonds by the employees of the power house. Mr. Oleson will be succeeded as chief engineer of the Toledo Railway & Light Co. by Mr. W. L. Long, who was formerly his first assistant.

MR. GEORGE C. FISK, president of the Wason Manufacturing Co., of Springfield, Mass., recently completed 50 years of continuous service with this concern. During this time he has risen from clerk in a comparatively small shop to president of one of the most important car building establishments in the country. In commemoration of the event the employees of the company presented Mr. Fisk with a handsome black leather album, containing photographs of all the officials of the company and also with a series of photographs showing the places and houses in which Mr. Fisk has lived or carried on business, these forming a pictorial outline of Mr. Fisk's life. The establishment, of which Mr. Fisk is the head, has grown from a small beginning. Started in 1845 by Thomas W. Wason and his brother, Charles, in a shed on the bank of the Connecticut just south of the railway bridge, its first year's work was six single and two double-truck freight cars for the Connecticut River railway company, amounting to less than \$5,000. Work was begun in a shed not large enough to house an entire freight car. Now the company has an output of about 400 cars a year, and has a pay-roll, the largest in the history of the concern, of 575. The output for last year amounted to about \$1,000,000. The magnitude of its undertakings is shown in the contract it has on its hands to equip the Manhattan elevated road with the rolling stock for an electric system, or the making of 250 new cars and the remodeling of hundreds of old.

---

### OBITUARY.

MR. MATTHEW M. ROBY, superintendent of the Electric Railway & Power Co. of Tiffin, O., died in that city August 20th from heart disease. Mr. Roby was 41 years of age.

MR. THOMAS NEVINS, of East Orange, N. J., a large stockholder in several electric traction companies in the eastern part of the United States, and largely connected with railroad and gas enterprises in New Jersey, died at his residence, Mount Shannon, Castle Connell, County Limerick, Ireland, on August 21st. Mr. Nevins and his son, T. A. Nevins of Newark, N. J., had been sojourning in Europe for some months prior to the death of the elder man, for the purpose of investigating the prospects for an electric line between Manchester and Liverpool.

---

### RECENT STRIKES.

The street railway strike and boycott which were in effect for several weeks at Lafayette, Ind., were declared off August 28th. This controversy was rather peculiar inasmuch as but eight men of the 35 or more employed by the company quit work and their attempts to injure the company's traffic were principally through boycott. The settlement was effected by submitting the matter to arbitration at the hands of a committee representing the Merchants' Association of the city, both the street railway company and the Central Labor Union which was promoting the boycott agreeing to abide by the decision of the arbitrators. This committee reported that the five men whose discharge led to the declaration of the strike were properly discharged for cause, that the charges of coercion brought against the railway company were without ground and that the eight strikers should be given employment with the railroad company, being placed on the extra list and in line for promotion in the future. The Central Labor Union, while accepting the decision of the arbitrators, took occasion in a very offensively worded resolution, to denounce them for showing prejudice and "not basing their decision upon the testimony of the strikers."

Two hundred employes of the Hudson Valley Railway Co., whose interurban system comprises 100 miles of railways between Warrenburg, Saratoga, Ballston, Troy and Schuylerville, N. Y., went out on strike on the morning of August 30th, and from that date until 2 p. m., September 12th, no cars were operated on the company's lines. The cause was the company's refusal to reinstate two motormen whom it held responsible for the recent accident, who were discharged for this reason. On September 2d the announcement was made that all persons who had left their employment with the company, and who should apply for positions on or before Wednesday, September 3d, at 6 p. m., would be taken back individually and positions assigned to them in the order in which their applications were made. Few of the former employes availing themselves of this offer, the company secured substitutes, and a number of deputy sheriffs were sworn in. The Stillwater town board passed resolutions forbidding the company to run cars through that town on its lines between Mechanicsville and Schuylerville with motormen and conductors who had not been in its employ for 21 days prior to September 1st. A conference between the company and the strike leaders failed to accomplish an agreement, and other than this the strike was uneventful until September 12th, when the 14-mile line between Stillwater and Schuylerville was opened for passenger traffic. The first car carried several deputy sheriffs. Its departure from the barns was watched by a crowd of 200 strikers and their sympathizers, but no attempt at violence or obstruction was made. At Glens Falls the company's wires were cut on the morning of September 15th. On the same day the village board of Sandy Hill held a special meeting and annulled the company's franchise because of its failure to operate through the village for two weeks. Subsequently, a conference was held with the governor of New York, who said that the question of the right of motormen to run cars without having had previous experience on the road was one for the courts to decide in the event of arrests of such motormen, and that he would not order troops out unless their presence should be necessary to preserve life and property. The sheriffs of the counties through which the lines run were called upon, and three military companies were notified to be in readiness for duty when the company should resume passenger traffic on its Glens Falls division. On September 18th a car left Glens Falls manned with non-union men and in charge of militia and deputy sheriffs. A crowd gathered and the conductor was struck by a stone. The car stopped and the military guard dispersed the crowd. At Fort Edward an attempt was made to stop a car, but the riot act was read and the crowd dispersed. Mr. B. S. Josselyn, formerly of Louisville, Ky., had been appointed general manager of the road and assumed his duties September 15th. On the 16th he announced that all former employes who applied personally for reinstatement would be taken back. Two cars were run from Saratoga to Ballston and back on that day without incident.

All motormen and conductors in the employ of the Ottumwa (Ia.) Traction & Light Co. quit work on the morning of September 12th out of sympathy with the linemen of the company, who had struck for higher wages and the recognition of the union. Operations were entirely suspended on the line after a day of riot, during which trolley wires had been cut and car windows broken. On the following day the blacksmiths joined the strikers and it was feared that the lighting system as well as the street railway service would be affected. The company offered to concede the increase in wages, but at latest reports still refused to recognize the union, and a settlement has not been effected.

A strike was declared on all the tramway lines in the city of Geneva, Switzerland. The cause was the action of the manager of the electric workshops, an American, who had dismissed 42 men employed in the shops, offering them positions as conductors, instead.

---

The St. Louis, St. Charles & Western Railroad Co. was recently made plaintiff in three damage suits aggregating \$15,000. The plaintiffs claim that they were unlawfully assaulted by the conductor on one of the company's cars. The three plaintiffs, in company with thirteen other persons, became involved in an altercation with the conductor which led to a general fight, and the conductor as well as the plaintiffs were considerably bruised. A counter suit has been filed by the manager of the railroad company for damages against the three plaintiffs.

### LARGEST ORDER FOR AIR BRAKES.
